This form sets the compression method for a column, determining how values inserted in future will be compressed (if the storage mode permits compression at all). This does not cause the table to be rewritten, so existing data may still be compressed with other compression methods. If the table is restored with \texttt{pg_restore}, then all values are rewritten with the configured compression method. However, when data is inserted from another relation (for example, by \texttt{INSERT \ldots SELECT}), values from the source table are not necessarily detoasted, so any previously compressed data may retain its existing compression method, rather than being recompressed with the compression method of the target column. The supported compression methods are \texttt{pglz} and \texttt{lz4}. (\texttt{lz4} is available only if \texttt{--with-lz4} was used when building PostgreSQL.) In addition, \texttt{compression_method} can be \texttt{default}, which selects the default behavior of consulting the \texttt{default_toast_compression} setting at the time of data insertion to determine the method to use.

\textbf{ADD \texttt{table_constraint} \{ NOT VALID \}}

This form adds a new constraint to a table using the same constraint syntax as \texttt{CREATE TABLE}, plus the option \texttt{NOT VALID}, which is currently only allowed for foreign key and CHECK constraints.

Normally, this form will cause a scan of the table to verify that all existing rows in the table satisfy the new constraint. But if the \texttt{NOT VALID} option is used, this potentially-lengthy scan is skipped. The constraint will still be enforced against subsequent inserts or updates (that is, they'll fail unless there is a matching row in the referenced table, in the case of foreign keys, or they'll fail unless the new row matches the specified check condition). But the database will not assume that the constraint holds for all rows in the table, until it is validated by using the \texttt{VALIDATE CONSTRAINT} option. See Notes below for more information about using the \texttt{NOT VALID} option.

Although most forms of \texttt{ADD \texttt{table_constraint}} require an \texttt{ACCESS EXCLUSIVE} lock, \texttt{ADD FOREIGN KEY} requires only a \texttt{SHARE ROW EXCLUSIVE} lock. Note that \texttt{ADD FOREIGN KEY} also acquires a \texttt{SHARE ROW EXCLUSIVE} lock on the referenced table, in addition to the lock on the table on which the constraint is declared.

Additional restrictions apply when unique or primary key constraints are added to partitioned tables; see \texttt{CREATE TABLE}. Also, foreign key constraints on partitioned tables may not be declared \texttt{NOT VALID} at present.

\textbf{ADD \texttt{table_constraint_using_index}}

This form adds a new \texttt{PRIMARY KEY} or \texttt{UNIQUE} constraint to a table based on an existing unique index. All the columns of the index will be included in the constraint.

The index cannot have expression columns nor be a partial index. Also, it must be a b-tree index with default sort ordering. These restrictions ensure that the index is equivalent to one that would be built by a regular \texttt{ADD PRIMARY KEY} or \texttt{ADD UNIQUE} command.

If \texttt{PRIMARY KEY} is specified, and the index's columns are not already marked \texttt{NOT NULL}, then this command will attempt to do \texttt{ALTER COLUMN SET NOT NULL} against each such column. That requires a full table scan to verify the column(s) contain no nulls. In all other cases, this is a fast operation.

If a constraint name is provided then the index will be renamed to match the constraint name. Otherwise the constraint will be named the same as the index.
ALTER TABLE

After this command is executed, the index is “owned” by the constraint, in the same way as if the index had been built by a regular ADD PRIMARY KEY or ADD UNIQUE command. In particular, dropping the constraint will make the index disappear too.

This form is not currently supported on partitioned tables.

Note

Adding a constraint using an existing index can be helpful in situations where a new constraint needs to be added without blocking table updates for a long time. To do that, create the index using CREATE INDEX CONCURRENTLY, and then install it as an official constraint using this syntax. See the example below.

ALTER CONSTRAINT

This form alters the attributes of a constraint that was previously created. Currently only foreign key constraints may be altered.

VALIDATE CONSTRAINT

This form validates a foreign key or check constraint that was previously created as NOT VALID, by scanning the table to ensure there are no rows for which the constraint is not satisfied. Nothing happens if the constraint is already marked valid. (See Notes below for an explanation of the usefulness of this command.)

This command acquires a SHARE UPDATE EXCLUSIVE lock.

DROP CONSTRAINT [ IF EXISTS ]

This form drops the specified constraint on a table, along with any index underlying the constraint. If IF EXISTS is specified and the constraint does not exist, no error is thrown. In this case a notice is issued instead.

DISABLE/ENABLE [ REPLICA | ALWAYS ] TRIGGER

These forms configure the firing of trigger(s) belonging to the table. A disabled trigger is still known to the system, but is not executed when its triggering event occurs. For a deferred trigger, the enable status is checked when the event occurs, not when the trigger function is actually executed. One can disable or enable a single trigger specified by name, or all triggers on the table, or only user triggers (this option excludes internally generated constraint triggers such as those that are used to implement foreign key constraints or deferrable uniqueness and exclusion constraints). Disabling or enabling internally generated constraint triggers requires superuser privileges; it should be done with caution since of course the integrity of the constraint cannot be guaranteed if the triggers are not executed.

The trigger firing mechanism is also affected by the configuration variable session_replication_role. Simply enabled triggers (the default) will fire when the replication role is “origin” (the default) or “local”. Triggers configured as ENABLE REPLICA will only fire if the session is in “replica” mode, and triggers configured as ENABLE ALWAYS will fire regardless of the current replication role.

The effect of this mechanism is that in the default configuration, triggers do not fire on replicas. This is useful because if a trigger is used on the origin to propagate data between tables, then the replication system will also replicate the propagated data, and the trigger should not fire a second time on the replica, because that would lead to duplication. However, if a trigger is used for another purpose such as creating external alerts, then it might be appropriate to set it to ENABLE ALWAYS so that it is also fired on replicas.
This command acquires a SHARE ROW EXCLUSIVE lock.

DISABLE/ENABLE [ REPLICA | ALWAYS ] RULE

These forms configure the firing of rewrite rules belonging to the table. A disabled rule is still known to the system, but is not applied during query rewriting. The semantics are as for disabled/enabled triggers. This configuration is ignored for ON SELECT rules, which are always applied in order to keep views working even if the current session is in a non-default replication role.

The rule firing mechanism is also affected by the configuration variable session_replication_role, analogous to triggers as described above.

DISABLE/ENABLE ROW LEVEL SECURITY

These forms control the application of row security policies belonging to the table. If enabled and no policies exist for the table, then a default-deny policy is applied. Note that policies can exist for a table even if row-level security is disabled. In this case, the policies will not be applied and the policies will be ignored. See also CREATE POLICY.

NO FORCE/FORCE ROW LEVEL SECURITY

These forms control the application of row security policies belonging to the table when the user is the table owner. If enabled, row-level security policies will be applied when the user is the table owner. If disabled (the default) then row-level security will not be applied when the user is the table owner. See also CREATE POLICY.

CLUSTER ON

This form selects the default index for future CLUSTER operations. It does not actually re-cluster the table.

Changing cluster options acquires a SHARE UPDATE EXCLUSIVE lock.

SET WITHOUT CLUSTER

This form removes the most recently used CLUSTER index specification from the table. This affects future cluster operations that don't specify an index.

Changing cluster options acquires a SHARE UPDATE EXCLUSIVE lock.

SET WITHOUT OIDS

Backward-compatible syntax for removing the oid system column. As oid system columns cannot be added anymore, this never has an effect.

SET ACCESS METHOD

This form changes the access method of the table by rewriting it. See Chapter 62 for more information.

SET TABLESPACE

This form changes the table's tablespace to the specified tablespace and moves the data file(s) associated with the table to the new tablespace. Indexes on the table, if any, are not moved; but they can be moved separately with additional SET TABLESPACE commands. When applied to a partitioned table, nothing is moved, but any partitions created afterwards with CREATE TABLE PARTITION OF will use that tablespace, unless overridden by a TABLESPACE clause.
ALTER TABLE

All tables in the current database in a tablespace can be moved by using the ALL IN TABLESPACE form, which will lock all tables to be moved first and then move each one. This form also supports OWNED BY, which will only move tables owned by the roles specified. If the NOWAIT option is specified then the command will fail if it is unable to acquire all of the locks required immediately. Note that system catalogs are not moved by this command; use ALTER DATABASE or explicit ALTER TABLE invocations instead if desired. The information_schema relations are not considered part of the system catalogs and will be moved. See also CREATE TABLESPACE.

SET { LOGGED | UNLOGGED }

This form changes the table from unlogged to logged or vice-versa (see UNLOGGED). It cannot be applied to a temporary table.

This also changes the persistence of any sequences linked to the table (for identity or serial columns). However, it is also possible to change the persistence of such sequences separately.

SET ( storage_parameter [= value] [, ... ] )

This form changes one or more storage parameters for the table. See Storage Parameters in the CREATE TABLE documentation for details on the available parameters. Note that the table contents will not be modified immediately by this command; depending on the parameter you might need to rewrite the table to get the desired effects. That can be done with VACUUM FULL, CLUSTER or one of the forms of ALTER TABLE that forces a table rewrite. For planner related parameters, changes will take effect from the next time the table is locked so currently executing queries will not be affected.

SHARE UPDATE EXCLUSIVE lock will be taken for fillfactor, toast and autovacuum storage parameters, as well as the planner parameter parallel_workers.

RESET ( storage_parameter [, ... ] )

This form resets one or more storage parameters to their defaults. As with SET, a table rewrite might be needed to update the table entirely.

INHERIT parent_table

This form adds the target table as a new child of the specified parent table. Subsequently, queries against the parent will include records of the target table. To be added as a child, the target table must already contain all the same columns as the parent (it could have additional columns, too). The columns must have matching data types, and if they have NOT NULL constraints in the parent then they must also have NOT NULL constraints in the child.

There must also be matching child-table constraints for all CHECK constraints of the parent, except those marked non-inheritable (that is, created with ALTER TABLE ... ADD CONSTRAINT ... NO INHERIT) in the parent, which are ignored; all child-table constraints matched must not be marked non-inheritable. Currently UNIQUE, PRIMARY KEY, and FOREIGN KEY constraints are not considered, but this might change in the future.

NO INHERIT parent_table

This form removes the target table from the list of children of the specified parent table. Queries against the parent table will no longer include records drawn from the target table.

OF type_name

This form links the table to a composite type as though CREATE TABLE OF had formed it. The table's list of column names and types must precisely match that of the composite type. The table must
ALTER TABLE

not inherit from any other table. These restrictions ensure that CREATE TABLE OF would permit
an equivalent table definition.

NOT OF

This form dissociates a typed table from its type.

OWNER TO

This form changes the owner of the table, sequence, view, materialized view, or foreign table to the
specified user.

REPLICA IDENTITY

This form changes the information which is written to the write-ahead log to identify rows which are
updated or deleted. In most cases, the old value of each column is only logged if it differs from the
new value; however, if the old value is stored externally, it is always logged regardless of whether it
changed. This option has no effect except when logical replication is in use.

DEFAULT

Records the old values of the columns of the primary key, if any. This is the default for non-
system tables.

USING INDEX index_name

Records the old values of the columns covered by the named index, that must be unique, not
partial, not deferrable, and include only columns marked NOT NULL. If this index is dropped,
the behavior is the same as NOTHING.

FULL

Records the old values of all columns in the row.

NOTHING

Records no information about the old row. This is the default for system tables.

RENAME

The RENAME forms change the name of a table (or an index, sequence, view, materialized view, or
foreign table), the name of an individual column in a table, or the name of a constraint of the table.
When renaming a constraint that has an underlying index, the index is renamed as well. There is no
effect on the stored data.

SET SCHEMA

This form moves the table into another schema. Associated indexes, constraints, and sequences owned
by table columns are moved as well.

ATTACH PARTITION partition_name { FOR VALUES partition_bound_spec | DEFAULT }

This form attaches an existing table (which might itself be partitioned) as a partition of the target table.
The table can be attached as a partition for specific values using FOR VALUES or as a default partition
by using DEFAULT. For each index in the target table, a corresponding one will be created in the
attached table; or, if an equivalent index already exists, it will be attached to the target table's index,
ALTER TABLE

as if ALTER INDEX ATTACH PARTITION had been executed. Note that if the existing table is a foreign table, it is currently not allowed to attach the table as a partition of the target table if there are UNIQUE indexes on the target table. (See also CREATE FOREIGN TABLE.) For each user-defined row-level trigger that exists in the target table, a corresponding one is created in the attached table.

A partition using FOR VALUES uses same syntax for partition_bound_spec as CREATE TABLE. The partition bound specification must correspond to the partitioning strategy and partition key of the target table. The table to be attached must have all the same columns as the target table and no more; moreover, the column types must also match. Also, it must have all the NOT NULL and CHECK constraints of the target table. Currently FOREIGN KEY constraints are not considered. UNIQUE and PRIMARY KEY constraints from the parent table will be created in the partition, if they don’t already exist. If any of the CHECK constraints of the table being attached are marked NO INHERIT, the command will fail; such constraints must be recreated without the NO INHERIT clause.

If the new partition is a regular table, a full table scan is performed to check that existing rows in the table do not violate the partition constraint. It is possible to avoid this scan by adding a valid CHECK constraint to the table that allows only rows satisfying the desired partition constraint before running this command. The CHECK constraint will be used to determine that the table need not be scanned to validate the partition constraint. This does not work, however, if any of the partition keys is an expression and the partition does not accept NULL values. If attaching a list partition that will not accept NULL values, also add NOT NULL constraint to the partition key column, unless it’s an expression.

If the new partition is a foreign table, nothing is done to verify that all the rows in the foreign table obey the partition constraint. (See the discussion in CREATE FOREIGN TABLE about constraints on the foreign table.)

When a table has a default partition, defining a new partition changes the partition constraint for the default partition. The default partition can’t contain any rows that would need to be moved to the new partition, and will be scanned to verify that none are present. This scan, like the scan of the new partition, can be avoided if an appropriate CHECK constraint is present. Also like the scan of the new partition, it is always skipped when the default partition is a foreign table.

Attaching a partition acquires a SHARE UPDATE EXCLUSIVE lock on the parent table, in addition to the ACCESS EXCLUSIVE locks on the table being attached and on the default partition (if any).

Further locks must also be held on all sub-partitions if the table being attached is itself a partitioned table. Likewise if the default partition is itself a partitioned table. The locking of the sub-partitions can be avoided by adding a CHECK constraint as described in Section 5.11.2.2.

DETACH PARTITION partition_name [ CONCURRENTLY | FINALIZE ]

This form detaches the specified partition of the target table. The detached partition continues to exist as a standalone table, but no longer has any ties to the table from which it was detached. Any indexes that were attached to the target table’s indexes are detached. Any triggers that were created as clones of those in the target table are removed. SHARE lock is obtained on any tables that reference this partitioned table in foreign key constraints.

If CONCURRENTLY is specified, it runs using a reduced lock level to avoid blocking other sessions that might be accessing the partitioned table. In this mode, two transactions are used internally. During the first transaction, a SHARE UPDATE EXCLUSIVE lock is taken on both parent table and partition, and the partition is marked as undergoing detach; at that point, the transaction is committed and all other transactions using the partitioned table are waited for. Once all those transactions have completed, the second transaction acquires SHARE UPDATE EXCLUSIVE on the partitioned table and ACCESS EXCLUSIVE on the partition, and the detach process completes. A CHECK constraint that duplicates
the partition constraint is added to the partition. **CONCURRENTLY** cannot be run in a transaction block and is not allowed if the partitioned table contains a default partition.

If **FINALIZE** is specified, a previous **DETACH CONCURRENTLY** invocation that was canceled or interrupted is completed. At most one partition in a partitioned table can be pending detach at a time.

All the forms of **ALTER TABLE** that act on a single table, except **RENAME**, **SET SCHEMA**, **ATTACH PARTITION**, and **DETACH PARTITION** can be combined into a list of multiple alterations to be applied together. For example, it is possible to add several columns and/or alter the type of several columns in a single command. This is particularly useful with large tables, since only one pass over the table need be made.

You must own the table to use **ALTER TABLE**. To change the schema or tablespace of a table, you must also have **CREATE** privilege on the new schema or tablespace. To add the table as a new child of a parent table, you must own the parent table as well. Also, to attach a table as a new partition of the table, you must own the table being attached. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have **CREATE** privilege on the table's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the table. However, a superuser can alter ownership of any table anyway.) To add a column or alter a column type or use the **OF** clause, you must also have **USAGE** privilege on the data type.

**Parameters**

**IF EXISTS**

Do not throw an error if the table does not exist. A notice is issued in this case.

**name**

The name (optionally schema-qualified) of an existing table to alter. If **ONLY** is specified before the table name, only that table is altered. If **ONLY** is not specified, the table and all its descendant tables (if any) are altered. Optionally, ***** can be specified after the table name to explicitly indicate that descendant tables are included.

**column_name**

Name of a new or existing column.

**new_column_name**

New name for an existing column.

**new_name**

New name for the table.

**data_type**

Data type of the new column, or new data type for an existing column.

**table_constraint**

New table constraint for the table.

**constraint_name**

Name of a new or existing constraint.
ALTER TABLE

CASCADE

Automatically drop objects that depend on the dropped column or constraint (for example, views referencing the column), and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the column or constraint if there are any dependent objects. This is the default behavior.

trigger_name

Name of a single trigger to disable or enable.

ALL

Disable or enable all triggers belonging to the table. (This requires superuser privilege if any of the triggers are internally generated constraint triggers such as those that are used to implement foreign key constraints or deferrable uniqueness and exclusion constraints.)

USER

Disable or enable all triggers belonging to the table except for internally generated constraint triggers such as those that are used to implement foreign key constraints or deferrable uniqueness and exclusion constraints.

index_name

The name of an existing index.

storage_parameter

The name of a table storage parameter.

value

The new value for a table storage parameter. This might be a number or a word depending on the parameter.

parent_table

A parent table to associate or de-associate with this table.

new_owner

The user name of the new owner of the table.

new_access_method

The name of the access method to which the table will be converted.

new_tablespace

The name of the tablespace to which the table will be moved.

new_schema

The name of the schema to which the table will be moved.
ALTER TABLE

partition_name

The name of the table to attach as a new partition or to detach from this table.

partition_bound_spec

The partition bound specification for a new partition. Refer to CREATE TABLE for more details on the syntax of the same.

Notes

The key word COLUMN is noise and can be omitted.

When a column is added with ADD COLUMN and a non-volatile DEFAULT is specified, the default is evaluated at the time of the statement and the result stored in the table's metadata. That value will be used for the column for all existing rows. If no DEFAULT is specified, NULL is used. In neither case is a rewrite of the table required.

Adding a column with a volatile DEFAULT or changing the type of an existing column will require the entire table and its indexes to be rewritten. As an exception, when changing the type of an existing column, if the USING clause does not change the column contents and the old type is either binary coercible to the new type or an unconstrained domain over the new type, a table rewrite is not needed. However, indexes must always be rebuilt unless the system can verify that the new index would be logically equivalent to the existing one. For example, if the collation for a column has been changed an index rebuild is always required because the new sort order might be different. However, in the absence of a collation change, a column can be changed from text to varchar (or vice versa) without rebuilding the indexes because these data types sort identically. Table and/or index rebuilds may take a significant amount of time for a large table; and will temporarily require as much as double the disk space.

Adding a CHECK or NOT NULL constraint requires scanning the table to verify that existing rows meet the constraint, but does not require a table rewrite.

Similarly, when attaching a new partition it may be scanned to verify that existing rows meet the partition constraint.

The main reason for providing the option to specify multiple changes in a single ALTER TABLE is that multiple table scans or rewrites can thereby be combined into a single pass over the table.

Scanning a large table to verify a new foreign key or check constraint can take a long time, and other updates to the table are locked out until the ALTER TABLE ADD CONSTRAINT command is committed. The main purpose of the NOT VALID constraint option is to reduce the impact of adding a constraint on concurrent updates. With NOT VALID, the ADD CONSTRAINT command does not scan the table and can be committed immediately. After that, a VALIDATE CONSTRAINT command can be issued to verify that existing rows satisfy the constraint. The validation step does not need to lock out concurrent updates, since it knows that other transactions will be enforcing the constraint for rows that they insert or update; only pre-existing rows need to be checked. Hence, validation acquires only a SHARE UPDATE EXCLUSIVE lock on the table being altered. (If the constraint is a foreign key then a ROW SHARE lock is also required on the table referenced by the constraint.) In addition to improving concurrency, it can be useful to use NOT VALID and VALIDATE CONSTRAINT in cases where the table is known to contain pre-existing violations. Once the constraint is in place, no new violations can be inserted, and the existing problems can be corrected at leisure until VALIDATE CONSTRAINT finally succeeds.

The DROP COLUMN form does not physically remove the column, but simply makes it invisible to SQL operations. Subsequent insert and update operations in the table will store a null value for the column. Thus, dropping a column is quick but it will not immediately reduce the on-disk size of your table, as the
ALTER TABLE

space occupied by the dropped column is not reclaimed. The space will be reclaimed over time as existing rows are updated.

To force immediate reclamation of space occupied by a dropped column, you can execute one of the forms of ALTER TABLE that performs a rewrite of the whole table. This results in reconstructing each row with the dropped column replaced by a null value.

The rewriting forms of ALTER TABLE are not MVCC-safe. After a table rewrite, the table will appear empty to concurrent transactions, if they are using a snapshot taken before the rewrite occurred. See Section 13.6 for more details.

The USING option of SET DATA TYPE can actually specify any expression involving the old values of the row; that is, it can refer to other columns as well as the one being converted. This allows very general conversions to be done with the SET DATA TYPE syntax. Because of this flexibility, the USING expression is not applied to the column's default value (if any); the result might not be a constant expression as required for a default. This means that when there is no implicit or assignment cast from old to new type, SET DATA TYPE might fail to convert the default even though a USING clause is supplied. In such cases, drop the default with DROP DEFAULT, perform the ALTER TYPE, and then use SET DEFAULT to add a suitable new default. Similar considerations apply to indexes and constraints involving the column.

If a table has any descendant tables, it is not permitted to add, rename, or change the type of a column in the parent table without doing the same to the descendants. This ensures that the descendants always have columns matching the parent. Similarly, a CHECK constraint cannot be renamed in the parent without also renaming it in all descendants, so that CHECK constraints also match between the parent and its descendants. (That restriction does not apply to index-based constraints, however.) Also, because selecting from the parent also selects from its descendants, a constraint on the parent cannot be marked valid unless it is also marked valid for those descendants. In all of these cases, ALTER TABLE ONLY will be rejected.

A recursive DROP COLUMN operation will remove a descendant table's column only if the descendant does not inherit that column from any other parents and never had an independent definition of the column. A nonrecursive DROP COLUMN (i.e., ALTER TABLE ONLY ...) DROP COLUMN never removes any descendant columns, but instead marks them as independently defined rather than inherited. A nonrecursive DROP COLUMN command will fail for a partitioned table, because all partitions of a table must have the same columns as the partitioning root.

The actions for identity columns (ADD GENERATED, SET etc., DROP IDENTITY), as well as the actions TRIGGER, CLUSTER, OWNER, and TABLESPACE never recurse to descendant tables; that is, they always act as though ONLY were specified. Adding a constraint recurses only for CHECK constraints that are not marked NO INHERIT.

Changing any part of a system catalog table is not permitted.

Refer to CREATE TABLE for a further description of valid parameters. Chapter 5 has further information on inheritance.

Examples

To add a column of type varchar to a table:

```
ALTER TABLE distributors ADD COLUMN address varchar(30);
```

That will cause all existing rows in the table to be filled with null values for the new column.

To add a column with a non-null default:
ALTER TABLE measurements
  ADD COLUMN mtime timestamp with time zone DEFAULT now();

Existing rows will be filled with the current time as the value of the new column, and then new rows will receive the time of their insertion.

To add a column and fill it with a value different from the default to be used later:

ALTER TABLE transactions
  ADD COLUMN status varchar(30) DEFAULT 'old',
  ALTER COLUMN status SET default 'current';

Existing rows will be filled with old, but then the default for subsequent commands will be current. The effects are the same as if the two sub-commands had been issued in separate ALTER TABLE commands.

To drop a column from a table:

ALTER TABLE distributors DROP COLUMN address RESTRICT;

To change the types of two existing columns in one operation:

ALTER TABLE distributors
  ALTER COLUMN address TYPE varchar(80),
  ALTER COLUMN name TYPE varchar(100);

To change an integer column containing Unix timestamps to timestamp with time zone via a USING clause:

ALTER TABLE foo
  ALTER COLUMN foo_timestamp SET DATA TYPE timestamp with time zone
  USING
    timestamp with time zone 'epoch' + foo_timestamp * interval '1 second';

The same, when the column has a default expression that won't automatically cast to the new data type:

ALTER TABLE foo
  ALTER COLUMN foo_timestamp DROP DEFAULT,
  ALTER COLUMN foo_timestamp TYPE timestamp with time zone
  USING
    timestamp with time zone 'epoch' + foo_timestamp * interval '1 second',
  ALTER COLUMN foo_timestamp SET DEFAULT now();

To rename an existing column:

ALTER TABLE distributors RENAME COLUMN address TO city;

To rename an existing table:
ALTER TABLE distributors RENAME TO suppliers;

To rename an existing constraint:

ALTER TABLE distributors RENAME CONSTRAINT zipchk TO zip_check;

To add a not-null constraint to a column:

ALTER TABLE distributors ALTER COLUMN street SET NOT NULL;

To remove a not-null constraint from a column:

ALTER TABLE distributors ALTER COLUMN street DROP NOT NULL;

To add a check constraint to a table and all its children:

ALTER TABLE distributors ADD CONSTRAINT zipchk CHECK
(char_length(zipcode) = 5);

To add a check constraint only to a table and not to its children:

ALTER TABLE distributors ADD CONSTRAINT zipchk CHECK
(char_length(zipcode) = 5) NO INHERIT;

(The check constraint will not be inherited by future children, either.)

To remove a check constraint from a table and all its children:

ALTER TABLE distributors DROP CONSTRAINT zipchk;

To remove a check constraint from one table only:

ALTER TABLE ONLY distributors DROP CONSTRAINT zipchk;

(The check constraint remains in place for any child tables.)

To add a foreign key constraint to a table:

ALTER TABLE distributors ADD CONSTRAINT distfk FOREIGN KEY (address)
REFERENCES addresses (address);

To add a foreign key constraint to a table with the least impact on other work:

ALTER TABLE distributors ADD CONSTRAINT distfk FOREIGN KEY (address)
REFERENCES addresses (address) NOT VALID;
ALTER TABLE distributors VALIDATE CONSTRAINT distfk;

To add a (multicolumn) unique constraint to a table:
ALTER TABLE distributors ADD CONSTRAINT dist_id_zipcode_key UNIQUE (dist_id, zipcode);

To add an automatically named primary key constraint to a table, noting that a table can only ever have one primary key:

ALTER TABLE distributors ADD PRIMARY KEY (dist_id);

To move a table to a different tablespace:

ALTER TABLE distributors SET TABLESPACE fasttables;pace;

To move a table to a different schema:

ALTER TABLE myschema.distributors SET SCHEMA yourschema;

To recreate a primary key constraint, without blocking updates while the index is rebuilt:

CREATE UNIQUE INDEX CONCURRENTLY dist_id_temp_idx ON distributors (dist_id);
ALTER TABLE distributors DROP CONSTRAINT distributors_pkey,
ADD CONSTRAINT distributors_pkey PRIMARY KEY USING INDEX dist_id_temp_idx;

To attach a partition to a range-partitioned table:

ALTER TABLE measurement
  ATTACH PARTITION measurement_y2016m07 FOR VALUES FROM ('2016-07-01') TO ('2016-08-01');

To attach a partition to a list-partitioned table:

ALTER TABLE cities
  ATTACH PARTITION cities_ab FOR VALUES IN ('a', 'b');

To attach a partition to a hash-partitioned table:

ALTER TABLE orders
  ATTACH PARTITION orders_p4 FOR VALUES WITH (MODULUS 4, REMAINDER 3);

To attach a default partition to a partitioned table:

ALTER TABLE cities
  ATTACH PARTITION cities_partdef DEFAULT;

To detach a partition from a partitioned table:
ALTER TABLE measurement
   DETACH PARTITION measurement_y2015m12;

Compatibility

The forms ADD (without USING INDEX), DROP [COLUMN], DROP IDENTITY, RESTART, SET DEFAULT, SET DATA TYPE (without USING), SET GENERATED, and SET sequence_option conform with the SQL standard. The other forms are PostgreSQL extensions of the SQL standard. Also, the ability to specify more than one manipulation in a single ALTER TABLE command is an extension.

ALTER TABLE DROP COLUMN can be used to drop the only column of a table, leaving a zero-column table. This is an extension of SQL, which disallows zero-column tables.

See Also

CREATE TABLE
ALTER TABLESPACE

ALTER TABLESPACE — change the definition of a tablespace

Synopsis

ALTER TABLESPACE name RENAME TO new_name
ALTER TABLESPACE name OWNER TO { new_owner | CURRENT_ROLE |
CURRENT_USER | SESSION_USER }
ALTER TABLESPACE name SET ( tablespace_option = value [, ... ] )
ALTER TABLESPACE name RESET ( tablespace_option [, ... ] )

Description

ALTER TABLESPACE can be used to change the definition of a tablespace.

You must own the tablespace to change the definition of a tablespace. To alter the owner, you must also be a direct or indirect member of the new owning role. (Note that superusers have these privileges automatically.)

Parameters

name

The name of an existing tablespace.

new_name

The new name of the tablespace. The new name cannot begin with pg_, as such names are reserved for system tablespaces.

new_owner

The new owner of the tablespace.

tablespace_option

A tablespace parameter to be set or reset. Currently, the only available parameters are seq_page_cost, random_page_cost, effective_io_concurrency and maintenance_io_concurrency. Setting these values for a particular tablespace will override the planner's usual estimate of the cost of reading pages from tables in that tablespace, and the executor's prefetching behavior, as established by the configuration parameters of the same name (see seq_page_cost, random_page_cost, effective_io_concurrency, maintenance_io_concurrency). This may be useful if one tablespace is located on a disk which is faster or slower than the remainder of the I/O subsystem.

Examples

Rename tablespace index_space to fast_raid:
ALTER TABLESPACE index_space RENAME TO fast_raid;

Change the owner of tablespace index_space:

ALTER TABLESPACE index_space OWNER TO mary;

Compatibility

There is no ALTER TABLESPACE statement in the SQL standard.

See Also

CREATE TABLESPACE, DROP TABLESPACE
ALTER TEXT SEARCH CONFIGURATION

ALTER TEXT SEARCH CONFIGURATION — change the definition of a text search configuration

Synopsis

ALTER TEXT SEARCH CONFIGURATION name
   ADD MAPPING FOR token_type [, ... ] WITH dictionary_name [, ... ]
ALTER TEXT SEARCH CONFIGURATION name
   ALTER MAPPING FOR token_type [, ... ] WITH dictionary_name [, ... ]
ALTER TEXT SEARCH CONFIGURATION name
   ALTER MAPPING REPLACE old_dictionary WITH new_dictionary
ALTER TEXT SEARCH CONFIGURATION name
   ALTER MAPPING FOR token_type [, ... ] REPLACE old_dictionary WITH new_dictionary
ALTER TEXT SEARCH CONFIGURATION name
   DROP MAPPING [ IF EXISTS ] FOR token_type [, ... ]
ALTER TEXT SEARCH CONFIGURATION name RENAME TO new_name
ALTER TEXT SEARCH CONFIGURATION name OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER | SESSION_USER }
ALTER TEXT SEARCH CONFIGURATION name SET SCHEMA new_schema

Description

ALTER TEXT SEARCH CONFIGURATION changes the definition of a text search configuration. You can modify its mappings from token types to dictionaries, or change the configuration's name or owner.

You must be the owner of the configuration to use ALTER TEXT SEARCH CONFIGURATION.

Parameters

name

The name (optionally schema-qualified) of an existing text search configuration.

token_type

The name of a token type that is emitted by the configuration's parser.

dictionary_name

The name of a text search dictionary to be consulted for the specified token type(s). If multiple dictionaries are listed, they are consulted in the specified order.

old_dictionary

The name of a text search dictionary to be replaced in the mapping.

new_dictionary

The name of a text search dictionary to be substituted for old_dictionary.
ALTER TEXT SEARCH CONFIGURATION

new_name

The new name of the text search configuration.

new_owner

The new owner of the text search configuration.

new_schema

The new schema for the text search configuration.

The ADD MAPPING FOR form installs a list of dictionaries to be consulted for the specified token type(s); it is an error if there is already a mapping for any of the token types. The ALTER MAPPING FOR form does the same, but first removing any existing mapping for those token types. The ALTER MAPPING REPLACE forms substitute new_dictionary for old_dictionary anywhere the latter appears. This is done for only the specified token types when FOR appears, or for all mappings of the configuration when it doesn't. The DROP MAPPING form removes all dictionaries for the specified token type(s), causing tokens of those types to be ignored by the text search configuration. It is an error if there is no mapping for the token types, unless IF EXISTS appears.

Examples

The following example replaces the english dictionary with the swedish dictionary anywhere that english is used within my_config.

```
ALTER TEXT SEARCH CONFIGURATION my_config
  ALTER MAPPING REPLACE english WITH swedish;
```

Compatibility

There is no ALTER TEXT SEARCH CONFIGURATION statement in the SQL standard.

See Also

CREATE TEXT SEARCH CONFIGURATION, DROP TEXT SEARCH CONFIGURATION
ALTER TEXT SEARCH DICTIONARY

ALTER TEXT SEARCH DICTIONARY — change the definition of a text search dictionary

Synopsis

```
ALTER TEXT SEARCH DICTIONARY name {
    option [ = value ] [, ... ]
}
ALTER TEXT SEARCH DICTIONARY name RENAME TO new_name
ALTER TEXT SEARCH DICTIONARY name OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER | SESSION_USER }
ALTER TEXT SEARCH DICTIONARY name SET SCHEMA new_schema
```

Description

ALTER TEXT SEARCH DICTIONARY changes the definition of a text search dictionary. You can change the dictionary's template-specific options, or change the dictionary's name or owner.

You must be the owner of the dictionary to use ALTER TEXT SEARCH DICTIONARY.

Parameters

- **name**
  - The name (optionally schema-qualified) of an existing text search dictionary.

- **option**
  - The name of a template-specific option to be set for this dictionary.

- **value**
  - The new value to use for a template-specific option. If the equal sign and value are omitted, then any previous setting for the option is removed from the dictionary, allowing the default to be used.

- **new_name**
  - The new name of the text search dictionary.

- **new_owner**
  - The new owner of the text search dictionary.

- **new_schema**
  - The new schema for the text search dictionary.

Template-specific options can appear in any order.

Examples

The following example command changes the stopword list for a Snowball-based dictionary. Other parameters remain unchanged.
ALTER TEXT SEARCH DICTIONARY my_dict ( StopWords = newrussian );

The following example command changes the language option to *dutch*, and removes the stopword option entirely.

ALTER TEXT SEARCH DICTIONARY my_dict ( language = dutch, StopWords );

The following example command “updates” the dictionary's definition without actually changing anything.

ALTER TEXT SEARCH DICTIONARY my_dict ( dummy );

(The reason this works is that the option removal code doesn't complain if there is no such option.) This trick is useful when changing configuration files for the dictionary: the *ALTER* will force existing database sessions to re-read the configuration files, which otherwise they would never do if they had read them earlier.

**Compatibility**

There is no *ALTER TEXT SEARCH DICTIONARY* statement in the SQL standard.

**See Also**

CREATE TEXT SEARCH DICTIONARY, DROP TEXT SEARCH DICTIONARY
ALTER TEXT SEARCH PARSER

ALTER TEXT SEARCH PARSER — change the definition of a text search parser

Synopsis

ALTER TEXT SEARCH PARSER name RENAME TO new_name
ALTER TEXT SEARCH PARSER name SET SCHEMA new_schema

Description

ALTER TEXT SEARCH PARSER changes the definition of a text search parser. Currently, the only supported functionality is to change the parser's name.

You must be a superuser to use ALTER TEXT SEARCH PARSER.

Parameters

name

The name (optionally schema-qualified) of an existing text search parser.

ew_name

The new name of the text search parser.

new_schema

The new schema for the text search parser.

Compatibility

There is no ALTER TEXT SEARCH PARSER statement in the SQL standard.

See Also

CREATE TEXT SEARCH PARSER, DROP TEXT SEARCH PARSER
ALTER TEXT SEARCH TEMPLATE

ALTER TEXT SEARCH TEMPLATE — change the definition of a text search template

Synopsis

```
ALTER TEXT SEARCH TEMPLATE name RENAME TO new_name
ALTER TEXT SEARCH TEMPLATE name SET SCHEMA new_schema
```

Description

ALTER TEXT SEARCH TEMPLATE changes the definition of a text search template. Currently, the only supported functionality is to change the template's name.

You must be a superuser to use `ALTER TEXT SEARCH TEMPLATE`.

Parameters

- **name**
  
  The name (optionally schema-qualified) of an existing text search template.

- **new_name**
  
  The new name of the text search template.

- **new_schema**
  
  The new schema for the text search template.

Compatibility

There is no `ALTER TEXT SEARCH TEMPLATE` statement in the SQL standard.

See Also

CREATE TEXT SEARCH TEMPLATE, DROP TEXT SEARCH TEMPLATE
ALTER TRIGGER

ALTER TRIGGER — change the definition of a trigger

Synopsis

ALTER TRIGGER name ON table_name RENAME TO new_name
ALTER TRIGGER name ON table_name [ NO ] DEPENDS ON
    EXTENSION extension_name

Description

ALTER TRIGGER changes properties of an existing trigger.

The RENAME clause changes the name of the given trigger without otherwise changing the trigger definition. If the table that the trigger is on is a partitioned table, then corresponding clone triggers in the partitions are renamed too.

The DEPENDS ON EXTENSION clause marks the trigger as dependent on an extension, such that if the extension is dropped, the trigger will automatically be dropped as well.

You must own the table on which the trigger acts to be allowed to change its properties.

Parameters

name
    The name of an existing trigger to alter.

table_name
    The name of the table on which this trigger acts.

new_name
    The new name for the trigger.

extension_name
    The name of the extension that the trigger is to depend on (or no longer dependent on, if NO is specified). A trigger that's marked as dependent on an extension is automatically dropped when the extension is dropped.

Notes

The ability to temporarily enable or disable a trigger is provided by ALTER TABLE, not by ALTER TRIGGER, because ALTER TRIGGER has no convenient way to express the option of enabling or disabling all of a table's triggers at once.

Examples

To rename an existing trigger:
ALTER TRIGGER emp_stamp ON emp RENAME TO emp_track_chgs;

To mark a trigger as being dependent on an extension:

ALTER TRIGGER emp_stamp ON emp DEPENDS ON EXTENSION emplib;

**Compatibility**

ALTER TRIGGER is a PostgreSQL extension of the SQL standard.

**See Also**

ALTER TABLE
ALTER TYPE

ALTER TYPE — change the definition of a type

Synopsis

```
ALTER TYPE name OWNER TO { new_owner | CURRENT_ROLE | CURRENT_USER | SESSION_USER }
ALTER TYPE name RENAME TO new_name
ALTER TYPE name SET SCHEMA new_schema
ALTER TYPE name RENAME ATTRIBUTE attribute_name TO new_attribute_name
   [ CASCADE | RESTRICT ]
ALTER TYPE name action [, ... ]
ALTER TYPE name ADD VALUE [ IF NOT EXISTS ] new_enum_value [ { BEFORE
   | AFTER } neighbor_enum_value ]
ALTER TYPE name RENAME VALUE existing_enum_value TO new_enum_value
ALTER TYPE name SET ( property = value [, ... ] )
```

where action is one of:

```
ADD ATTRIBUTE attribute_name data_type [ COLLATE collation ]
   [ CASCADE | RESTRICT ]
DROP ATTRIBUTE [ IF EXISTS ] attribute_name [ CASCADE | RESTRICT ]
ALTER ATTRIBUTE attribute_name [ SET DATA ] TYPE data_type
   [ COLLATE collation ] [ CASCADE | RESTRICT ]
```

Description

ALTER TYPE changes the definition of an existing type. There are several subforms:

OWNER

This form changes the owner of the type.

RENAME

This form changes the name of the type.

SET SCHEMA

This form moves the type into another schema.

RENAME ATTRIBUTE

This form is only usable with composite types. It changes the name of an individual attribute of the type.

ADD ATTRIBUTE

This form adds a new attribute to a composite type, using the same syntax as CREATE TYPE.
ALTER TYPE

DROP ATTRIBUTE [ IF EXISTS ]

This form drops an attribute from a composite type. If IF EXISTS is specified and the attribute does not exist, no error is thrown. In this case a notice is issued instead.

ALTER ATTRIBUTE ... SET DATA TYPE

This form changes the type of an attribute of a composite type.

ADD VALUE [ IF NOT EXISTS ] [ BEFORE | AFTER ]

This form adds a new value to an enum type. The new value's place in the enum's ordering can be specified as being BEFORE or AFTER one of the existing values. Otherwise, the new item is added at the end of the list of values.

If IF NOT EXISTS is specified, it is not an error if the type already contains the new value: a notice is issued but no other action is taken. Otherwise, an error will occur if the new value is already present.

RENAME VALUE

This form renames a value of an enum type. The value's place in the enum's ordering is not affected. An error will occur if the specified value is not present or the new name is already present.

SET ( property = value [, ... ] )

This form is only applicable to base types. It allows adjustment of a subset of the base-type properties that can be set in CREATE TYPE. Specifically, these properties can be changed:

- RECEIVE can be set to the name of a binary input function, or NONE to remove the type's binary input function. Using this option requires superuser privilege.

- SEND can be set to the name of a binary output function, or NONE to remove the type's binary output function. Using this option requires superuser privilege.

- TYPMOD_IN can be set to the name of a type modifier input function, or NONE to remove the type's type modifier input function. Using this option requires superuser privilege.

- TYPMOD_OUT can be set to the name of a type modifier output function, or NONE to remove the type's type modifier output function. Using this option requires superuser privilege.

- ANALYZE can be set to the name of a type-specific statistics collection function, or NONE to remove the type's statistics collection function. Using this option requires superuser privilege.

- SUBSCRIPT can be set to the name of a type-specific subscripting handler function, or NONE to remove the type's subscripting handler function. Using this option requires superuser privilege.

- STORAGE can be set to plain, extended, external, or main (see Section 72.2 for more information about what these mean). However, changing from plain to another setting requires superuser privilege (because it requires that the type's C functions all be TOAST-ready), and changing to plain from another setting is not allowed at all (since the type may already have TOASTed values present in the database). Note that changing this option doesn't by itself change any stored data, it just sets the default TOAST strategy to be used for table columns created in the future. See ALTER TABLE to change the TOAST strategy for existing table columns.

See CREATE TYPE for more details about these type properties. Note that where appropriate, a change in these properties for a base type will be propagated automatically to domains based on that type.
The `ADD ATTRIBUTE`, `DROP ATTRIBUTE`, and `ALTER ATTRIBUTE` actions can be combined into a list of multiple alterations to apply in parallel. For example, it is possible to add several attributes and/or alter the type of several attributes in a single command.

You must own the type to use `ALTER TYPE`. To change the schema of a type, you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the type's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the type. However, a superuser can alter ownership of any type anyway.) To add an attribute or alter an attribute type, you must also have `USAGE` privilege on the attribute's data type.

**Parameters**

**name**

The name (possibly schema-qualified) of an existing type to alter.

**new_name**

The new name for the type.

**new_owner**

The user name of the new owner of the type.

**new_schema**

The new schema for the type.

**attribute_name**

The name of the attribute to add, alter, or drop.

**new_attribute_name**

The new name of the attribute to be renamed.

**data_type**

The data type of the attribute to add, or the new type of the attribute to alter.

**new_enum_value**

The new value to be added to an enum type's list of values, or the new name to be given to an existing value. Like all enum literals, it needs to be quoted.

**neighbor_enum_value**

The existing enum value that the new value should be added immediately before or after in the enum type's sort ordering. Like all enum literals, it needs to be quoted.

**existing_enum_value**

The existing enum value that should be renamed. Like all enum literals, it needs to be quoted.

**property**

The name of a base-type property to be modified; see above for possible values.
ALTER TYPE

CASCADE

Automatically propagate the operation to typed tables of the type being altered, and their descendants.

RESTRICT

Refuse the operation if the type being altered is the type of a typed table. This is the default.

Notes

If ALTER TYPE ... ADD VALUE (the form that adds a new value to an enum type) is executed inside a transaction block, the new value cannot be used until after the transaction has been committed.

Comparisons involving an added enum value will sometimes be slower than comparisons involving only original members of the enum type. This will usually only occur if BEFORE or AFTER is used to set the new value's sort position somewhere other than at the end of the list. However, sometimes it will happen even though the new value is added at the end (this occurs if the OID counter “wrapped around” since the original creation of the enum type). The slowdown is usually insignificant; but if it matters, optimal performance can be regained by dropping and recreating the enum type, or by dumping and reloading the database.

Examples

To rename a data type:

ALTER TYPE electronic_mail RENAME TO email;

To change the owner of the type email to joe:

ALTER TYPE email OWNER TO joe;

To change the schema of the type email to customers:

ALTER TYPE email SET SCHEMA customers;

To add a new attribute to a composite type:

ALTER TYPE compfoo ADD ATTRIBUTE f3 int;

To add a new value to an enum type in a particular sort position:

ALTER TYPE colors ADD VALUE 'orange' AFTER 'red';

To rename an enum value:

ALTER TYPE colors RENAME VALUE 'purple' TO 'mauve';

To create binary I/O functions for an existing base type:
CREATE FUNCTION mytypesend(mytype) RETURNS bytea ...;
CREATE FUNCTION mytyperecv(internal, oid, integer) RETURNS mytype ...;
ALTER TYPE mytype SET (
    SEND = mytypesend,
    RECEIVE = mytyperecv
);

Compatibility

The variants to add and drop attributes are part of the SQL standard; the other variants are PostgreSQL extensions.

See Also

CREATE TYPE, DROP TYPE
ALTER USER

ALTER USER — change a database role

Synopsis

ALTER USER role_specification [ WITH ] option [ ... ]

where option can be:

- SUPERUSER | NOSUPERUSER
- CREATEDB | NOCREATEDB
- CREATEROLE | NOCREATEROLE
- INHERIT | NOINHERIT
- LOGIN | NOLOGIN
- REPLICATION | NOREPLICATION
- BYPASSRLS | NOBYPASSRLS
- CONNECTION LIMIT connlimit
- [ ENCRYPTED ] PASSWORD 'password' | PASSWORD NULL
- VALID UNTIL 'timestamp'

ALTER USER name RENAME TO new_name

ALTER USER { role_specification | ALL } [ IN DATABASE database_name ]
  SET configuration_parameter { TO | = } { value | DEFAULT }
ALTER USER { role_specification | ALL } [ IN DATABASE database_name ]
  SET configuration_parameter FROM CURRENT
ALTER USER { role_specification | ALL } [ IN DATABASE database_name ]
  RESET configuration_parameter
ALTER USER { role_specification | ALL } [ IN DATABASE database_name ]
  RESET ALL

where role_specification can be:

- role_name
- CURRENT_ROLE
- CURRENT_USER
- SESSION_USER

Description

ALTER USER is now an alias for ALTER ROLE.

Compatibility

The ALTER USER statement is a PostgreSQL extension. The SQL standard leaves the definition of users to the implementation.

See Also

ALTER ROLE
ALTER USER MAPPING

ALTER USER MAPPING — change the definition of a user mapping

Synopsis

ALTER USER MAPPING FOR { user_name | USER | CURRENT_ROLE | CURRENT_USER | SESSION_USER | PUBLIC } 
SERVER server_name
OPTIONS ( [ ADD | SET | DROP ] option ['value'] [, ... ] )

Description

ALTER USER MAPPING changes the definition of a user mapping.

The owner of a foreign server can alter user mappings for that server for any user. Also, a user can alter a user mapping for their own user name if USAGE privilege on the server has been granted to the user.

Parameters

user_name

User name of the mapping. CURRENT_ROLE, CURRENT_USER, and USER match the name of the current user. PUBLIC is used to match all present and future user names in the system.

server_name

Server name of the user mapping.

OPTIONS ( [ ADD | SET | DROP ] option ['value'] [, ... ] )

Change options for the user mapping. The new options override any previously specified options. ADD, SET, and DROP specify the action to be performed. ADD is assumed if no operation is explicitly specified. Option names must be unique; options are also validated by the server’s foreign-data wrapper.

Examples

Change the password for user mapping bob, server foo:

ALTER USER MAPPING FOR bob SERVER foo OPTIONS (SET password 'public');

Compatibility

ALTER USER MAPPING conforms to ISO/IEC 9075-9 (SQL/MED). There is a subtle syntax issue: The standard omits the FOR key word. Since both CREATE USER MAPPING and DROP USER MAPPING use FOR in analogous positions, and IBM DB2 (being the other major SQL/MED implementation) also requires it for ALTER USER MAPPING, PostgreSQL diverges from the standard here in the interest of consistency and interoperability.

CREATE USER MAPPING, DROP USER MAPPING
ALTER VIEW

ALTER VIEW — change the definition of a view

Synopsis

```
ALTER VIEW [ IF EXISTS ] name ALTER [ COLUMN ] column_name SET
   DEFAULT expression
ALTER VIEW [ IF EXISTS ] name ALTER [ COLUMN ] column_name DROP
   DEFAULT
ALTER VIEW [ IF EXISTS ] name OWNER TO { new_owner | CURRENT_ROLE |
   CURRENT_USER | SESSION_USER }
ALTER VIEW [ IF EXISTS ] name RENAME [ COLUMN ] column_name
   TO new_column_name
ALTER VIEW [ IF EXISTS ] name RENAME TO new_name
ALTER VIEW [ IF EXISTS ] name SET SCHEMA new_schema
ALTER VIEW [ IF EXISTS ] name SET ( view_option_name
   [= view_option_value] [, ... ] )
ALTER VIEW [ IF EXISTS ] name RESET ( view_option_name [, ... ] )
```

Description

ALTER VIEW changes various auxiliary properties of a view. (If you want to modify the view's defining
query, use CREATE OR REPLACE VIEW.)

You must own the view to use ALTER VIEW. To change a view's schema, you must also have CREATE
privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new
owning role, and that role must have CREATE privilege on the view's schema. (These restrictions enforce
that altering the owner doesn't do anything you couldn't do by dropping and recreating the view. However,
a superuser can alter ownership of any view anyway.)

Parameters

name

The name (optionally schema-qualified) of an existing view.

column_name

Name of an existing column.

new_column_name

New name for an existing column.

IF EXISTS

Do not throw an error if the view does not exist. A notice is issued in this case.

SET/DROP DEFAULT

These forms set or remove the default value for a column. A view column's default value is substituted
into any INSERT or UPDATE command whose target is the view, before applying any rules or triggers.
for the view. The view’s default will therefore take precedence over any default values from underlying relations.

new_owner

The user name of the new owner of the view.

new_name

The new name for the view.

new_schema

The new schema for the view.

SET (view_option_name [= view_option_value] [, ... ])
RESET (view_option_name [, ... ])

Sets or resets a view option. Currently supported options are:

check_option(enum)

Changes the check option of the view. The value must be local or cascaded.

security_barrier(boolean)

Changes the security-barrier property of the view. The value must be a Boolean value, such as true or false.

security_invoker(boolean)

Changes the security-invoker property of the view. The value must be a Boolean value, such as true or false.

Notes

For historical reasons, ALTER TABLE can be used with views too; but the only variants of ALTER TABLE that are allowed with views are equivalent to the ones shown above.

Examples

To rename the view foo to bar:

ALTER VIEW foo RENAME TO bar;

To attach a default column value to an updatable view:

CREATE TABLE base_table (id int, ts timestamptz);
CREATE VIEW a_view AS SELECT * FROM base_table;
ALTER VIEW a_view ALTER COLUMN ts SET DEFAULT now();
INSERT INTO base_table(id) VALUES(1); -- ts will receive a NULL
INSERT INTO a_view(id) VALUES(2); -- ts will receive the current time
Compatibility

`ALTER VIEW` is a PostgreSQL extension of the SQL standard.

`CREATE VIEW`, `DROP VIEW`
ANALYZE

ANALYZE — collect statistics about a database

Synopsis

ANALYZE [ ( option [, ...] ) ] [ table_and_columns [, ...] ]
ANALYZE [ VERBOSE ] [ table_and_columns [, ...] ]

where option can be one of:

   VERBOSE [ boolean ]
   SKIP_LOCKED [ boolean ]

and table_and_columns is:

   table_name [ ( column_name [, ...] ) ]

Description

ANALYZE collects statistics about the contents of tables in the database, and stores the results in the pg_statistic system catalog. Subsequently, the query planner uses these statistics to help determine the most efficient execution plans for queries.

Without a table_and_columns list, ANALYZE processes every table and materialized view in the current database that the current user has permission to analyze. With a list, ANALYZE processes only those table(s). It is further possible to give a list of column names for a table, in which case only the statistics for those columns are collected.

When the option list is surrounded by parentheses, the options can be written in any order. The parenthesized syntax was added in PostgreSQL 11; the unparenthesized syntax is deprecated.

Parameters

VERBOSE

   Enables display of progress messages.

SKIP_LOCKED

   Specifies that ANALYZE should not wait for any conflicting locks to be released when beginning work on a relation: if a relation cannot be locked immediately without waiting, the relation is skipped. Note that even with this option, ANALYZE may still block when opening the relation's indexes or when acquiring sample rows from partitions, table inheritance children, and some types of foreign tables. Also, while ANALYZE ordinarily processes all partitions of specified partitioned tables, this option will cause ANALYZE to skip all partitions if there is a conflicting lock on the partitioned table.

   boolean

   Specifies whether the selected option should be turned on or off. You can write TRUE, ON, or 1 to enable the option, and FALSE, OFF, or 0 to disable it. The boolean value can also be omitted, in which case TRUE is assumed.
**ANALYZE**

`table_name`

The name (possibly schema-qualified) of a specific table to analyze. If omitted, all regular tables, partitioned tables, and materialized views in the current database are analyzed (but not foreign tables). If the specified table is a partitioned table, both the inheritance statistics of the partitioned table as a whole and statistics of the individual partitions are updated.

`column_name`

The name of a specific column to analyze. Defaults to all columns.

**Outputs**

When `VERBOSE` is specified, `ANALYZE` emits progress messages to indicate which table is currently being processed. Various statistics about the tables are printed as well.

**Notes**

To analyze a table, one must ordinarily be the table's owner or a superuser. However, database owners are allowed to analyze all tables in their databases, except shared catalogs. (The restriction for shared catalogs means that a true database-wide `ANALYZE` can only be performed by a superuser.) `ANALYZE` will skip over any tables that the calling user does not have permission to analyze.

Foreign tables are analyzed only when explicitly selected. Not all foreign data wrappers support `ANALYZE`. If the table's wrapper does not support `ANALYZE`, the command prints a warning and does nothing.

In the default PostgreSQL configuration, the autovacuum daemon (see Section 25.1.6) takes care of automatic analyzing of tables when they are first loaded with data, and as they change throughout regular operation. When autovacuum is disabled, it is a good idea to run `ANALYZE` periodically, or just after making major changes in the contents of a table. Accurate statistics will help the planner to choose the most appropriate query plan, and thereby improve the speed of query processing. A common strategy for read-mostly databases is to run `VACUUM` and `ANALYZE` once a day during a low-usage time of day. (This will not be sufficient if there is heavy update activity.)

`ANALYZE` requires only a read lock on the target table, so it can run in parallel with other activity on the table.

The statistics collected by `ANALYZE` usually include a list of some of the most common values in each column and a histogram showing the approximate data distribution in each column. One or both of these can be omitted if `ANALYZE` deems them uninteresting (for example, in a unique-key column, there are no common values) or if the column data type does not support the appropriate operators. There is more information about the statistics in Chapter 25.

For large tables, `ANALYZE` takes a random sample of the table contents, rather than examining every row. This allows even very large tables to be analyzed in a small amount of time. Note, however, that the statistics are only approximate, and will change slightly each time `ANALYZE` is run, even if the actual table contents did not change. This might result in small changes in the planner's estimated costs shown by `EXPLAIN`. In rare situations, this non-determinism will cause the planner's choices of query plans to change after `ANALYZE` is run. To avoid this, raise the amount of statistics collected by `ANALYZE`, as described below.

The extent of analysis can be controlled by adjusting the `default_statistics_target` configuration variable, or on a column-by-column basis by setting the per-column statistics target with `ALTER TABLE ... ALTER COLUMN ... SET STATISTICS`. The target value sets the maximum number of entries in the most-common-value list and the maximum number of bins in the histogram. The default target value is 1689.
100, but this can be adjusted up or down to trade off accuracy of planner estimates against the time taken for `ANALYZE` and the amount of space occupied in `pg_statistic`. In particular, setting the statistics target to zero disables collection of statistics for that column. It might be useful to do that for columns that are never used as part of the `WHERE`, `GROUP BY`, or `ORDER BY` clauses of queries, since the planner will have no use for statistics on such columns.

The largest statistics target among the columns being analyzed determines the number of table rows sampled to prepare the statistics. Increasing the target causes a proportional increase in the time and space needed to do `ANALYZE`.

One of the values estimated by `ANALYZE` is the number of distinct values that appear in each column. Because only a subset of the rows are examined, this estimate can sometimes be quite inaccurate, even with the largest possible statistics target. If this inaccuracy leads to bad query plans, a more accurate value can be determined manually and then installed with `ALTER TABLE ... ALTER COLUMN ... SET (n_distinct = ...)`. If the table being analyzed has one or more children, `ANALYZE` will gather statistics twice: once on the rows of the parent table only, and a second time on the rows of the parent table with all of its children. This second set of statistics is needed when planning queries that traverse the entire inheritance tree. The autovacuum daemon, however, will only consider inserts or updates on the parent table itself when deciding whether to trigger an automatic analyze for that table. If that table is rarely inserted into or updated, the inheritance statistics will not be up to date unless you run `ANALYZE` manually.

For partitioned tables, `ANALYZE` gathers statistics by sampling rows from all partitions; in addition, it will recurse into each partition and update its statistics. Each leaf partition is analyzed only once, even with multi-level partitioning. No statistics are collected for only the parent table (without data from its partitions), because with partitioning it's guaranteed to be empty.

By contrast, if the table being analyzed has inheritance children, `ANALYZE` gathers two sets of statistics: one on the rows of the parent table only, and a second including rows of both the parent table and all of its children. This second set of statistics is needed when planning queries that process the inheritance tree as a whole. The child tables themselves are not individually analyzed in this case.

The autovacuum daemon does not process partitioned tables, nor does it process inheritance parents if only the children are ever modified. It is usually necessary to periodically run a manual `ANALYZE` to keep the statistics of the table hierarchy up to date.

If any child tables or partitions are foreign tables whose foreign data wrappers do not support `ANALYZE`, those tables are ignored while gathering inheritance statistics.

If the table being analyzed is completely empty, `ANALYZE` will not record new statistics for that table. Any existing statistics will be retained.

Each backend running `ANALYZE` will report its progress in the `pg_stat_progress_analyze` view. See Section 28.4.1 for details.

**Compatibility**

There is no `ANALYZE` statement in the SQL standard.

BEGIN

BEGIN — start a transaction block

Synopsis

BEGIN [ WORK | TRANSACTION ] [ transaction_mode [, ...] ]

where transaction_mode is one of:

   ISOLATION LEVEL { SERIALIZABLE | REPEATABLE READ | READ COMMITTED
   | READ UNCOMMITTED }
   READ WRITE | READ ONLY
   [ NOT ] DEFERRABLE

Description

BEGIN initiates a transaction block, that is, all statements after a BEGIN command will be executed in a single transaction until an explicit COMMIT or ROLLBACK is given. By default (without BEGIN), PostgreSQL executes transactions in “autocommit” mode, that is, each statement is executed in its own transaction and a commit is implicitly performed at the end of the statement (if execution was successful, otherwise a rollback is done).

Statements are executed more quickly in a transaction block, because transaction start/commit requires significant CPU and disk activity. Execution of multiple statements inside a transaction is also useful to ensure consistency when making several related changes: other sessions will be unable to see the intermediate states wherein not all the related updates have been done.

If the isolation level, read/write mode, or deferrable mode is specified, the new transaction has those characteristics, as if SET TRANSACTION was executed.

Parameters

WORK
TRANSACTION

Optional key words. They have no effect.

Refer to SET TRANSACTION for information on the meaning of the other parameters to this statement.

Notes

START TRANSACTION has the same functionality as BEGIN.

Use COMMIT or ROLLBACK to terminate a transaction block.

Issuing BEGIN when already inside a transaction block will provoke a warning message. The state of the transaction is not affected. To nest transactions within a transaction block, use savepoints (see SAVE-POINT).
For reasons of backwards compatibility, the commas between successive `transaction_modes` can be omitted.

**Examples**

To begin a transaction block:

```
BEGIN;
```

**Compatibility**

`BEGIN` is a PostgreSQL language extension. It is equivalent to the SQL-standard command `START TRANSACTION`, whose reference page contains additional compatibility information.

The `DEFERRABLE transaction_mode` is a PostgreSQL language extension.

Incidentally, the `BEGIN` key word is used for a different purpose in embedded SQL. You are advised to be careful about the transaction semantics when porting database applications.

**See Also**

`COMMIT`, `ROLLBACK`, `START TRANSACTION`, `SAVEPOINT`
CALL

CALL — invoke a procedure

Synopsis

CALL name ( [ argument ] [, ... ] )

Description

CALL executes a procedure.

If the procedure has any output parameters, then a result row will be returned, containing the values of those parameters.

Parameters

name

The name (optionally schema-qualified) of the procedure.

argument

An argument expression for the procedure call.

Arguments can include parameter names, using the syntax name => value. This works the same as in ordinary function calls; see Section 4.3 for details.

Arguments must be supplied for all procedure parameters that lack defaults, including OUT parameters. However, arguments matching OUT parameters are not evaluated, so it's customary to just write NULL for them. (Writing something else for an OUT parameter might cause compatibility problems with future PostgreSQL versions.)

Notes

The user must have EXECUTE privilege on the procedure in order to be allowed to invoke it.

To call a function (not a procedure), use SELECT instead.

If CALL is executed in a transaction block, then the called procedure cannot execute transaction control statements. Transaction control statements are only allowed if CALL is executed in its own transaction.

PL/pgSQL handles output parameters in CALL commands differently; see Section 43.6.3.

Examples

CALL do_db_maintenance();
CALL

Compatibility

CALL conforms to the SQL standard, except for the handling of output parameters. The standard says that users should write variables to receive the values of output parameters.

CREATE PROCEDURE
CHECKPOINT

CHECKPOINT — force a write-ahead log checkpoint

Synopsis

CHECKPOINT

Description

A checkpoint is a point in the write-ahead log sequence at which all data files have been updated to reflect the information in the log. All data files will be flushed to disk. Refer to Section 30.5 for more details about what happens during a checkpoint.

The CHECKPOINT command forces an immediate checkpoint when the command is issued, without waiting for a regular checkpoint scheduled by the system (controlled by the settings in Section 20.5.2). CHECKPOINT is not intended for use during normal operation.

If executed during recovery, the CHECKPOINT command will force a restartpoint (see Section 30.5) rather than writing a new checkpoint.

Only superusers or users with the privileges of the pg_checkpointer role can call CHECKPOINT.

Compatibility

The CHECKPOINT command is a PostgreSQL language extension.
**CLOSE**

CLOSE — close a cursor

**Synopsis**

CLOSE { name | ALL }

**Description**

CLOSE frees the resources associated with an open cursor. After the cursor is closed, no subsequent operations are allowed on it. A cursor should be closed when it is no longer needed.

Every non-holdable open cursor is implicitly closed when a transaction is terminated by COMMIT or ROLLBACK. A holdable cursor is implicitly closed if the transaction that created it aborts via ROLLBACK. If the creating transaction successfully commits, the holdable cursor remains open until an explicit CLOSE is executed, or the client disconnects.

**Parameters**

*name*

The name of an open cursor to close.

*ALL*

Close all open cursors.

**Notes**

PostgreSQL does not have an explicit OPEN cursor statement; a cursor is considered open when it is declared. Use the DECLARE statement to declare a cursor.

You can see all available cursors by querying the pg_cursors system view.

If a cursor is closed after a savepoint which is later rolled back, the CLOSE is not rolled back; that is, the cursor remains closed.

**Examples**

Close the cursor liahona:

```sql
CLOSE liahona;
```

**Compatibility**

CLOSE is fully conforming with the SQL standard. CLOSE ALL is a PostgreSQL extension.

DECLARE, FETCH, MOVE
CLUSTER

CLUSTER — cluster a table according to an index

Synopsis

CLUSTER [VERBOSE] table_name [ USING index_name ]
CLUSTER ( option [, ...] ) table_name [ USING index_name ]
CLUSTER [VERBOSE]

where option can be one of:

   VERBOSE [ boolean ]

Description

CLUSTER instructs PostgreSQL to cluster the table specified by table_name based on the index specified by index_name. The index must already have been defined on table_name.

When a table is clustered, it is physically reordered based on the index information. Clustering is a one-time operation: when the table is subsequently updated, the changes are not clustered. That is, no attempt is made to store new or updated rows according to their index order. (If one wishes, one can periodically recluster by issuing the command again. Also, setting the table's fillfactor storage parameter to less than 100% can aid in preserving cluster ordering during updates, since updated rows are kept on the same page if enough space is available there.)

When a table is clustered, PostgreSQL remembers which index it was clustered by. The form CLUSTER table_name reclusters the table using the same index as before. You can also use the CLUSTER or SET WITHOUT CLUSTER forms of ALTER TABLE to set the index to be used for future cluster operations, or to clear any previous setting.

CLUSTER without any parameter reclusters all the previously-clustered tables in the current database that the calling user owns, or all such tables if called by a superuser. This form of CLUSTER cannot be executed inside a transaction block.

When a table is being clustered, an ACCESS EXCLUSIVE lock is acquired on it. This prevents any other database operations (both reads and writes) from operating on the table until the CLUSTER is finished.

Parameters

   table_name

      The name (possibly schema-qualified) of a table.

   index_name

      The name of an index.

   VERBOSE

      Prints a progress report as each table is clustered.
**boolean**

Specifies whether the selected option should be turned on or off. You can write TRUE, ON, or 1 to enable the option, and FALSE, OFF, or 0 to disable it. The boolean value can also be omitted, in which case TRUE is assumed.

**Notes**

In cases where you are accessing single rows randomly within a table, the actual order of the data in the table is unimportant. However, if you tend to access some data more than others, and there is an index that groups them together, you will benefit from using CLUSTER. If you are requesting a range of indexed values from a table, or a single indexed value that has multiple rows that match, CLUSTER will help because once the index identifies the table page for the first row that matches, all other rows that match are probably already on the same table page, and so you save disk accesses and speed up the query.

CLUSTER can re-sort the table using either an index scan on the specified index, or (if the index is a b-tree) a sequential scan followed by sorting. It will attempt to choose the method that will be faster, based on planner cost parameters and available statistical information.

When an index scan is used, a temporary copy of the table is created that contains the table data in the index order. Temporary copies of each index on the table are created as well. Therefore, you need free space on disk at least equal to the sum of the table size and the index sizes.

When a sequential scan and sort is used, a temporary sort file is also created, so that the peak temporary space requirement is as much as double the table size, plus the index sizes. This method is often faster than the index scan method, but if the disk space requirement is intolerable, you can disable this choice by temporarily setting enable_sort to off.

It is advisable to set maintenance_work_mem to a reasonably large value (but not more than the amount of RAM you can dedicate to the CLUSTER operation) before clustering.

Because the planner records statistics about the ordering of tables, it is advisable to run ANALYZE on the newly clustered table. Otherwise, the planner might make poor choices of query plans.

Because CLUSTER remembers which indexes are clustered, one can cluster the tables one wants clustered manually the first time, then set up a periodic maintenance script that executes CLUSTER without any parameters, so that the desired tables are periodically reclustered.

Each backend running CLUSTER will report its progress in the pg_stat_progress_cluster view. See Section 28.4.4 for details.

Clustering a partitioned table clusters each of its partitions using the partition of the specified partitioned index. When clustering a partitioned table, the index may not be omitted.

**Examples**

Cluster the table employees on the basis of its index employees_ind:

```
CLUSTER employees USING employees_ind;
```

Cluster the employees table using the same index that was used before:

```
CLUSTER employees;
```
Cluster all tables in the database that have previously been clustered:

```
CLUSTER;
```

**Compatibility**

There is no `CLUSTER` statement in the SQL standard.

The syntax

```
CLUSTER index_name ON table_name
```

is also supported for compatibility with pre-8.3 PostgreSQL versions.

`clusterdb`, Section 28.4.4
COMMENT

COMMENT — define or change the comment of an object

Synopsis

COMMENT ON

{ ACCESS_METHOD object_name | AGGREGATE aggregate_name ( aggregate_signature ) | CAST (source_type AS target_type) | COLLATION object_name | COLUMN relation_name.column_name | CONSTRAINT constraint_name ON table_name | CONSTRAINT constraint_name ON DOMAIN domain_name | CONVERSION object_name | DATABASE object_name | DOMAIN object_name | EXTENSION object_name | EVENT TRIGGER object_name | FOREIGN DATA WRAPPER object_name | FOREIGN TABLE object_name | FUNCTION function_name [ ( [ argmode ] [ argname ] argtype [, ...] ] ) ] | INDEX object_name | LARGE OBJECT large_object_oid | MATERIALIZED VIEW object_name | OPERATOR operator_name (left_type, right_type) | OPERATOR CLASS object_name USING index_method | OPERATOR FAMILY object_name USING index_method | POLICY policy_name ON table_name | [ PROCEDURAL ] LANGUAGE object_name | PROCEDURE procedure_name [ ( [ argmode ] [ argname ] argtype [, ...] ] ) ] | PUBLICATION object_name | ROLE object_name | ROUTINE routine_name [ ( [ argmode ] [ argname ] argtype [, ...] ] ) ] | RULE rule_name ON table_name | SCHEMA object_name | SEQUENCE object_name | SERVER object_name | STATISTICS object_name | SUBSCRIPTION object_name | TABLE object_name | TABLESPACE object_name | TEXT SEARCH CONFIGURATION object_name | TEXT SEARCH DICTIONARY object_name | TEXT SEARCH PARSER object_name | TEXT SEARCH TEMPLATE object_name |
COMMENT stores a comment about a database object.

Only one comment string is stored for each object, so to modify a comment, issue a new COMMENT command for the same object. To remove a comment, write NULL in place of the text string. Comments are automatically dropped when their object is dropped.

A SHARE UPDATE EXCLUSIVE lock is acquired on the object to be commented.

For most kinds of object, only the object's owner can set the comment. Roles don't have owners, so the rule for COMMENT ON ROLE is that you must be superuser to comment on a superuser role, or have the CREATEROLE privilege to comment on non-superuser roles. Likewise, access methods don't have owners either; you must be superuser to comment on an access method. Of course, a superuser can comment on anything.

Comments can be viewed using psq1's \d family of commands. Other user interfaces to retrieve comments can be built atop the same built-in functions that psq1 uses, namely obj_description, col_description, and shobj_description (see Table 9.79).

Parameters

object_name
relation_name.column_name
aggregate_name
constraint_name
function_name
operator_name
policy_name
procedure_name
routine_name
rule_name
trigger_name

The name of the object to be commented. Names of objects that reside in schemas (tables, functions, etc.) can be schema-qualified. When commenting on a column, relation_name must refer to a table, view, composite type, or foreign table.

table_name
domain_name

When creating a comment on a constraint, a trigger, a rule or a policy these parameters specify the name of the table or domain on which that object is defined.
source_type

The name of the source data type of the cast.

target_type

The name of the target data type of the cast.

argmode

The mode of a function, procedure, or aggregate argument: IN, OUT, INOUT, or VARIADIC. If omitted, the default is IN. Note that COMMENT does not actually pay any attention to OUT arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the IN, INOUT, and VARIADIC arguments.

argname

The name of a function, procedure, or aggregate argument. Note that COMMENT does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

argtype

The data type of a function, procedure, or aggregate argument.

large_object_oid

The OID of the large object.

left_type

right_type

The data type(s) of the operator's arguments (optionally schema-qualified). Write NONE for the missing argument of a prefix operator.

PROCEDURAL

This is a noise word.

type_name

The name of the data type of the transform.

lang_name

The name of the language of the transform.

text

The new comment, written as a string literal; or NULL to drop the comment.

Notes

There is presently no security mechanism for viewing comments: any user connected to a database can see all the comments for objects in that database. For shared objects such as databases, roles, and tablespaces, comments are stored globally so any user connected to any database in the cluster can see all the comments for shared objects. Therefore, don't put security-critical information in comments.
Examples

Attach a comment to the table mytable:

COMMENT ON TABLE mytable IS 'This is my table';

Remove it again:

COMMENT ON TABLE mytable IS NULL;

Some more examples:

COMMENT ON ACCESS METHOD gin IS 'GIN index access method';
COMMENT ON AGGREGATE my_aggregate (double precision) IS 'Computes sample variance';
COMMENT ON CAST (text AS int4) IS 'Allow casts from text to int4';
COMMENT ON COLLATION "fr_CA" IS 'Canadian French';
COMMENT ON COLUMN my_table.my_column IS 'Employee ID number';
COMMENT ON CONVERSION my_conv IS 'Conversion to UTF8';
COMMENT ON CONSTRAINT bar_col_cons ON bar IS 'Constrains column col';
COMMENT ON CONSTRAINT dom_col_constr ON DOMAIN dom IS 'Constrains column of domain';
COMMENT ON DATABASE my_database IS 'Development Database';
COMMENT ON DOMAIN my_domain IS 'Email Address Domain';
COMMENT ON EVENT TRIGGER abort_ddl IS 'Aborts all DDL commands';
COMMENT ON EXTENSION hstore IS 'implements the hstore data type';
COMMENT ON FOREIGN DATA WRAPPER mywrapper IS 'my foreign data wrapper';
COMMENT ON FOREIGN TABLE my_foreign_table IS 'Employee Information in other database';
COMMENT ON FUNCTION my_function (timestamp) IS 'Returns Roman Numeral';
COMMENT ON INDEX my_index IS 'Enforces uniqueness on employee ID';
COMMENT ON LANGUAGE plpython IS 'Python support for stored procedures';
COMMENT ON LARGE OBJECT 346344 IS 'Planning document';
COMMENT ON MATERIALIZED VIEW my_matview IS 'Summary of order history';
COMMENT ON OPERATOR ^ (text, text) IS 'Performs intersection of two texts';
COMMENT ON OPERATOR - (NONE, integer) IS 'Unary minus';
COMMENT ON OPERATOR CLASS int4ops USING btree IS '4 byte integer operators for btrees';
COMMENT ON OPERATOR FAMILY integer_ops USING btree IS 'all integer operators for btrees';
COMMENT ON POLICY my_policy ON mytable IS 'Filter rows by users';
COMMENT ON PROEDURE my_proc (integer, integer) IS 'Runs a report';
COMMENT ON PUBLICATION alltables IS 'Publishes all operations on all tables';
COMMENT ON ROLE my_role IS 'Administration group for finance tables';
COMMENT ON ROUTINE my_routine (integer, integer) IS 'Runs a routine (which is a function or procedure)';
COMMENT ON RULE my_rule ON my_table IS 'Logs updates of employee records';
COMMENT ON SCHEMA my_schema IS 'Departmental data';
COMMENT ON SEQUENCE my_sequence IS 'Used to generate primary keys';
COMMENT ON SERVER myserver IS 'my foreign server';
COMMENT ON STATISTICS my_statistics IS 'Improves planner row estimations';
COMMENT ON SUBSCRIPTION alltables IS 'Subscription for all operations on all tables';
COMMENT ON TABLE my_schema.my_table IS 'Employee Information';
COMMENT ON TABLESPACE my_tablespace IS 'Tablespace for indexes';
COMMENT ON TEXT SEARCH CONFIGURATION my_config IS 'Special word filtering';
COMMENT ON TEXT SEARCH DICTIONARY swedish IS 'Snowball stemmer for Swedish language';
COMMENT ON TEXT SEARCH PARSER my_parser IS 'Splits text into words';
COMMENT ON TEXT SEARCH TEMPLATE snowball IS 'Snowball stemmer';
COMMENT ON TRANSFORM FOR hstore LANGUAGE plpython3u IS 'Transform between hstore and Python dict';
COMMENT ON TRIGGER my_trigger ON my_table IS 'Used for RI';
COMMENT ON TYPE complex IS 'Complex number data type';
COMMENT ON VIEW my_view IS 'View of departmental costs';

**Compatibility**

There is no COMMENT command in the SQL standard.
COMMIT

COMMIT — commit the current transaction

Synopsis

COMMIT [ WORK | TRANSACTION ] [ AND [ NO ] CHAIN ]

Description

COMMIT commits the current transaction. All changes made by the transaction become visible to others and are guaranteed to be durable if a crash occurs.

Parameters

WORK
TRANSACTION

Optional key words. They have no effect.

AND CHAIN

If AND CHAIN is specified, a new transaction is immediately started with the same transaction characteristics (see SET TRANSACTION) as the just finished one. Otherwise, no new transaction is started.

Notes

Use ROLLBACK to abort a transaction.

Issuing COMMIT when not inside a transaction does no harm, but it will provoke a warning message. COMMIT AND CHAIN when not inside a transaction is an error.

Examples

To commit the current transaction and make all changes permanent:

COMMIT;

Compatibility

The command COMMIT conforms to the SQL standard. The form COMMIT TRANSACTION is a PostgreSQL extension.

See Also

BEGIN, ROLLBACK
COMMIT PREPARED

COMMIT PREPARED — commit a transaction that was earlier prepared for two-phase commit

Synopsis

COMMIT PREPARED transaction_id

Description

COMMIT PREPARED commits a transaction that is in prepared state.

Parameters

transaction_id

The transaction identifier of the transaction that is to be committed.

Notes

To commit a prepared transaction, you must be either the same user that executed the transaction originally, or a superuser. But you do not have to be in the same session that executed the transaction.

This command cannot be executed inside a transaction block. The prepared transaction is committed immediately.

All currently available prepared transactions are listed in the pg_prepared_xacts system view.

Examples

Commit the transaction identified by the transaction identifier foobar:

COMMIT PREPARED 'foobar';

Compatibility

COMMIT PREPARED is a PostgreSQL extension. It is intended for use by external transaction management systems, some of which are covered by standards (such as X/Open XA), but the SQL side of those systems is not standardized.

See Also

PREPARE TRANSACTION, ROLLBACK PREPARED
COPY

COPY — copy data between a file and a table

Synopsis

COPY table_name [ ( column_name [, ...] ) ]
FROM { 'filename' | PROGRAM 'command' | STDIN }
[ [ WITH ] ( option [, ...] ) ]
[ WHERE condition ]
COPY { table_name [ ( column_name [, ...] ) ] | ( query ) }
TO { 'filename' | PROGRAM 'command' | STDOUT }
[ [ WITH ] ( option [, ...] ) ]

where option can be one of:

- FORMAT format_name
- FREEZE [ boolean ]
- DELIMITER 'delimiter_character'
- NULL 'null_string'
- HEADER [ boolean | MATCH ]
- QUOTE 'quote_character'
- ESCAPE 'escape_character'
- FORCE_QUOTE { ( column_name [, ...] ) | * }
- FORCE_NOT_NULL ( column_name [, ...] )
- FORCE_NULL ( column_name [, ...] )
- ENCODING 'encoding_name'

Description

COPY moves data between PostgreSQL tables and standard file-system files. COPY TO copies the contents of a table to a file, while COPY FROM copies data from a file to a table (appending the data to whatever is in the table already). COPY TO can also copy the results of a SELECT query.

If a column list is specified, COPY TO copies only the data in the specified columns to the file. For COPY FROM, each field in the file is inserted, in order, into the specified column. Table columns not specified in the COPY FROM column list will receive their default values.

COPY with a file name instructs the PostgreSQL server to directly read from or write to a file. The file must be accessible by the PostgreSQL user (the user ID the server runs as) and the name must be specified from the viewpoint of the server. When PROGRAM is specified, the server executes the given command and reads from the standard output of the program, or writes to the standard input of the program. The command must be specified from the viewpoint of the server, and be executable by the PostgreSQL user. When STDIN or STDOUT is specified, data is transmitted via the connection between the client and the server.

Each backend running COPY will report its progress in the pg_stat_progress_copy view. See Section 28.4.6 for details.
Parameters

**table_name**

The name (optionally schema-qualified) of an existing table.

**column_name**

An optional list of columns to be copied. If no column list is specified, all columns of the table except generated columns will be copied.

**query**

A `SELECT`, `VALUES`, `INSERT`, `UPDATE`, or `DELETE` command whose results are to be copied. Note that parentheses are required around the query.

For `INSERT`, `UPDATE` and `DELETE` queries a `RETURNING` clause must be provided, and the target relation must not have a conditional rule, nor an `ALSO` rule, nor an `INSTEAD` rule that expands to multiple statements.

**filename**

The path name of the input or output file. An input file name can be an absolute or relative path, but an output file name must be an absolute path. Windows users might need to use an `E''` string and double any backslashes used in the path name.

**PROGRAM**

A command to execute. In `COPY FROM`, the input is read from standard output of the command, and in `COPY TO`, the output is written to the standard input of the command.

Note that the command is invoked by the shell, so if you need to pass any arguments to shell command that come from an untrusted source, you must be careful to strip or escape any special characters that might have a special meaning for the shell. For security reasons, it is best to use a fixed command string, or at least avoid passing any user input in it.

**STDIN**

Specifies that input comes from the client application.

**STDOUT**

Specifies that output goes to the client application.

**boolean**

Specifies whether the selected option should be turned on or off. You can write `TRUE`, `ON`, or `1` to enable the option, and `FALSE`, `OFF`, or `0` to disable it. The `boolean` value can also be omitted, in which case `TRUE` is assumed.

**FORMAT**

Selects the data format to be read or written: `text`, `csv` (Comma Separated Values), or `binary`. The default is `text`.

**FREEZE**

Requests copying the data with rows already frozen, just as they would be after running the `VACUUM FREEZE` command. This is intended as a performance option for initial data loading. Rows will be
COPY

frozen only if the table being loaded has been created or truncated in the current subtransaction, there are no cursors open and there are no older snapshots held by this transaction. It is currently not possible to perform a COPY FREEZE on a partitioned table.

Note that all other sessions will immediately be able to see the data once it has been successfully loaded. This violates the normal rules of MVCC visibility and users specifying should be aware of the potential problems this might cause.

DELIMITER

Specifies the character that separates columns within each row (line) of the file. The default is a tab character in text format, a comma in CSV format. This must be a single one-byte character. This option is not allowed when using binary format.

NULL

Specifies the string that represents a null value. The default is \N (backslash-N) in text format, and an unquoted empty string in CSV format. You might prefer an empty string even in text format for cases where you don’t want to distinguish nulls from empty strings. This option is not allowed when using binary format.

Note

When using COPY FROM, any data item that matches this string will be stored as a null value, so you should make sure that you use the same string as you used with COPY TO.

HEADER

Specifies that the file contains a header line with the names of each column in the file. On output, the first line contains the column names from the table. On input, the first line is discarded when this option is set to true (or equivalent Boolean value). If this option is set to MATCH, the number and names of the columns in the header line must match the actual column names of the table, otherwise an error is raised. This option is not allowed when using binary format. The MATCH option is only valid for COPY FROM commands.

QUOTE

Specifies the quoting character to be used when a data value is quoted. The default is double-quote. This must be a single one-byte character. This option is allowed only when using CSV format.

ESCAPE

Specifies the character that should appear before a data character that matches the QUOTE value. The default is the same as the QUOTE value (so that the quoting character is doubled if it appears in the data). This must be a single one-byte character. This option is allowed only when using CSV format.

FORCE_QUOTE

Forces quoting to be used for all non-NULL values in each specified column. NULL output is never quoted. If * is specified, non-NULL values will be quoted in all columns. This option is allowed only in COPY TO, and only when using CSV format.

FORCE_NOT_NULL

Do not match the specified columns’ values against the null string. In the default case where the null string is empty, this means that empty values will be read as zero-length strings rather than nulls,
even when they are not quoted. This option is allowed only in COPY FROM, and only when using CSV format.

FORCE_NULL

Match the specified columns' values against the null string, even if it has been quoted, and if a match is found set the value to NULL. In the default case where the null string is empty, this converts a quoted empty string into NULL. This option is allowed only in COPY FROM, and only when using CSV format.

ENCODING

Specifies that the file is encoded in the encoding_name. If this option is omitted, the current client encoding is used. See the Notes below for more details.

WHERE

The optional WHERE clause has the general form

WHERE condition

where condition is any expression that evaluates to a result of type boolean. Any row that does not satisfy this condition will not be inserted to the table. A row satisfies the condition if it returns true when the actual row values are substituted for any variable references.

Currently, subqueries are not allowed in WHERE expressions, and the evaluation does not see any changes made by the COPY itself (this matters when the expression contains calls to VOLATILE functions).

Outputs

On successful completion, a COPY command returns a command tag of the form

COPY count

The count is the number of rows copied.

Note

psql will print this command tag only if the command was not COPY ... TO STDOUT, or the equivalent psql meta-command \copy ... to stdout. This is to prevent confusing the command tag with the data that was just printed.

Notes

COPY TO can be used only with plain tables, not views, and does not copy rows from child tables or child partitions. For example, COPY table TO copies the same rows as SELECT * FROM ONLY table. The syntax COPY (SELECT * FROM table) TO ... can be used to dump all of the rows in an inheritance hierarchy, partitioned table, or view.
COPY FROM can be used with plain, foreign, or partitioned tables or with views that have INSTEAD OF INSERT triggers.

You must have select privilege on the table whose values are read by COPY TO, and insert privilege on the table into which values are inserted by COPY FROM. It is sufficient to have column privileges on the column(s) listed in the command.

If row-level security is enabled for the table, the relevant SELECT policies will apply to COPY table TO statements. Currently, COPY FROM is not supported for tables with row-level security. Use equivalent INSERT statements instead.

Files named in a COPY command are read or written directly by the server, not by the client application. Therefore, they must reside on or be accessible to the database server machine, not the client. They must be accessible to and readable or writable by the PostgreSQL user (the user ID the server runs as), not the client. Similarly, the command specified with PROGRAM is executed directly by the server, not by the client application, must be executable by the PostgreSQL user. COPY naming a file or command is only allowed to database superusers or users who are granted one of the roles pg_read_server_files, pg_write_server_files, or pg_execute_server_program, since it allows reading or writing any file or running a program that the server has privileges to access.

Do not confuse COPY with the psql instruction \\copy. \\copy invokes COPY FROM STDIN or COPY TO STDOUT, and then fetches/stores the data in a file accessible to the psql client. Thus, file accessibility and access rights depend on the client rather than the server when \\copy is used.

It is recommended that the file name used in COPY always be specified as an absolute path. This is enforced by the server in the case of COPY TO, but for COPY FROM you do have the option of reading from a file specified by a relative path. The path will be interpreted relative to the working directory of the server process (normally the cluster's data directory), not the client's working directory.

Executing a command with PROGRAM might be restricted by the operating system's access control mechanisms, such as SELinux.

COPY FROM will invoke any triggers and check constraints on the destination table. However, it will not invoke rules.

For identity columns, the COPY FROM command will always write the column values provided in the input data, like the INSERT option OVERRIDING SYSTEM VALUE.

COPY input and output is affected by DateStyle. To ensure portability to other PostgreSQL installations that might use non-default DateStyle settings, DateStyle should be set to ISO before using COPY TO. It is also a good idea to avoid dumping data with IntervalStyle set to sql_standard, because negative interval values might be misinterpreted by a server that has a different setting for IntervalStyle.

Input data is interpreted according to ENCODING option or the current client encoding, and output data is encoded in ENCODING or the current client encoding, even if the data does not pass through the client but is read from or written to a file directly by the server.

COPY stops operation at the first error. This should not lead to problems in the event of a COPY TO, but the target table will already have received earlier rows in a COPY FROM. These rows will not be visible or accessible, but they still occupy disk space. This might amount to a considerable amount of wasted disk space if the failure happened well into a large copy operation. You might wish to invoke VACUUM to recover the wasted space.

FORCE_NULL and FORCE_NOT_NULL can be used simultaneously on the same column. This results in converting quoted null strings to null values and unquoted null strings to empty strings.
File Formats

Text Format

When the text format is used, the data read or written is a text file with one line per table row. Columns in a row are separated by the delimiter character. The column values themselves are strings generated by the output function, or acceptable to the input function, of each attribute's data type. The specified null string is used in place of columns that are null. COPY FROM will raise an error if any line of the input file contains more or fewer columns than are expected.

End of data can be represented by a single line containing just backslash-period (\.). An end-of-data marker is not necessary when reading from a file, since the end of file serves perfectly well; it is needed only when copying data to or from client applications using pre-3.0 client protocol.

Backslash characters (\) can be used in the COPY data to quote data characters that might otherwise be taken as row or column delimiters. In particular, the following characters must be preceded by a backslash if they appear as part of a column value: backslash itself, newline, carriage return, and the current delimiter character.

The specified null string is sent by COPY TO without adding any backslashes; conversely, COPY FROM matches the input against the null string before removing backslashes. Therefore, a null string such as \N cannot be confused with the actual data value \N (which would be represented as \\N).

The following special backslash sequences are recognized by COPY FROM:

<table>
<thead>
<tr>
<th>Sequence</th>
<th>Represents</th>
</tr>
</thead>
<tbody>
<tr>
<td>\b</td>
<td>Backspace (ASCII 8)</td>
</tr>
<tr>
<td>\f</td>
<td>Form feed (ASCII 12)</td>
</tr>
<tr>
<td>\n</td>
<td>Newline (ASCII 10)</td>
</tr>
<tr>
<td>\r</td>
<td>Carriage return (ASCII 13)</td>
</tr>
<tr>
<td>\t</td>
<td>Tab (ASCII 9)</td>
</tr>
<tr>
<td>\v</td>
<td>Vertical tab (ASCII 11)</td>
</tr>
<tr>
<td>\digits</td>
<td>Backslash followed by one to three octal digits specifies the byte with that numeric code</td>
</tr>
<tr>
<td>\xdigits</td>
<td>Backslash x followed by one or two hex digits specifies the byte with that numeric code</td>
</tr>
</tbody>
</table>

Presently, COPY TO will never emit an octal or hex-digits backslash sequence, but it does use the other sequences listed above for those control characters.

Any other backslashed character that is not mentioned in the above table will be taken to represent itself. However, beware of adding backslashes unnecessarily, since that might accidentally produce a string matching the end-of-data marker (\. ) or the null string (\N by default). These strings will be recognized before any other backslash processing is done.

It is strongly recommended that applications generating COPY data convert data newlines and carriage returns to the \n and \r sequences respectively. At present it is possible to represent a data carriage return by a backslash and carriage return, and to represent a data newline by a backslash and newline. However, these representations might not be accepted in future releases. They are also highly vulnerable to corruption if the COPY file is transferred across different machines (for example, from Unix to Windows or vice versa).
COPY

All backslash sequences are interpreted after encoding conversion. The bytes specified with the octal and hex-digit backslash sequences must form valid characters in the database encoding.

COPY TO will terminate each row with a Unix-style newline ("\n"). Servers running on Microsoft Windows instead output carriage return/newline ("\r\n"), but only for COPY to a server file; for consistency across platforms, COPY TO STDOUT always sends "\n" regardless of server platform. COPY FROM can handle lines ending with newlines, carriage returns, or carriage return/newlines. To reduce the risk of error due to un-backslashed newlines or carriage returns that were meant as data, COPY FROM will complain if the line endings in the input are not all alike.

CSV Format

This format option is used for importing and exporting the Comma Separated Value (CSV) file format used by many other programs, such as spreadsheets. Instead of the escaping rules used by PostgreSQL’s standard text format, it produces and recognizes the common CSV escaping mechanism.

The values in each record are separated by the DELIMITER character. If the value contains the delimiter character, the QUOTE character, the NULL string, a carriage return, or line feed character, then the whole value is prefixed and suffixed by the QUOTE character, and any occurrence within the value of a QUOTE character or the ESCAPE character is preceded by the escape character. You can also use FORCE_QUOTE to force quotes when outputting non-NULL values in specific columns.

The CSV format has no standard way to distinguish a NULL value from an empty string. PostgreSQL’s COPY handles this by quoting. A NULL is output as the NULL parameter string and is not quoted, while a non-NULL value matching the NULL parameter string is quoted. For example, with the default settings, a NULL is written as an unquoted empty string, while an empty string data value is written with double quotes (" "). Reading values follows similar rules. You can use FORCE_NOT_NULL to prevent NULL input comparisons for specific columns. You can also use FORCE_NULL to convert quoted null string data values to NULL.

Because backslash is not a special character in the CSV format, \., the end-of-data marker, could also appear as a data value. To avoid any misinterpretation, a \., data value appearing as a lone entry on a line is automatically quoted on output, and on input, if quoted, is not interpreted as the end-of-data marker. If you are loading a file created by another application that has a single unquoted column and might have a value of \., you might need to quote that value in the input file.

Note

In CSV format, all characters are significant. A quoted value surrounded by white space, or any characters other than DELIMITER, will include those characters. This can cause errors if you import data from a system that pads CSV lines with white space out to some fixed width. If such a situation arises you might need to preprocess the CSV file to remove the trailing white space, before importing the data into PostgreSQL.

Note

CSV format will both recognize and produce CSV files with quoted values containing embedded carriage returns and line feeds. Thus the files are not strictly one line per table row like text-format files.
Note

Many programs produce strange and occasionally perverse CSV files, so the file format is more a convention than a standard. Thus you might encounter some files that cannot be imported using this mechanism, and COPY might produce files that other programs cannot process.

Binary Format

The binary format option causes all data to be stored/read as binary format rather than as text. It is somewhat faster than the text and CSV formats, but a binary-format file is less portable across machine architectures and PostgreSQL versions. Also, the binary format is very data type specific; for example it will not work to output binary data from a smallint column and read it into an integer column, even though that would work fine in text format.

The binary file format consists of a file header, zero or more tuples containing the row data, and a file trailer. Headers and data are in network byte order.

Note

PostgreSQL releases before 7.4 used a different binary file format.

File Header

The file header consists of 15 bytes of fixed fields, followed by a variable-length header extension area. The fixed fields are:

Signature

11-byte sequence PGCOPY\n\377\r\n\0 — note that the zero byte is a required part of the signature. (The signature is designed to allow easy identification of files that have been munged by a non-8-bit-clean transfer. This signature will be changed by end-of-line-translation filters, dropped zero bytes, dropped high bits, or parity changes.)

Flags field

32-bit integer bit mask to denote important aspects of the file format. Bits are numbered from 0 (LSB) to 31 (MSB). Note that this field is stored in network byte order (most significant byte first), as are all the integer fields used in the file format. Bits 16–31 are reserved to denote critical file format issues; a reader should abort if it finds an unexpected bit set in this range. Bits 0–15 are reserved to signal backwards-compatible format issues; a reader should simply ignore any unexpected bits set in this range. Currently only one flag bit is defined, and the rest must be zero:

Bit 16

If 1, OIDs are included in the data; if 0, not. Oid system columns are not supported in PostgreSQL anymore, but the format still contains the indicator.

Header extension area length

32-bit integer, length in bytes of remainder of header, not including self. Currently, this is zero, and the first tuple follows immediately. Future changes to the format might allow additional data to be
present in the header. A reader should silently skip over any header extension data it does not know what to do with.

The header extension area is envisioned to contain a sequence of self-identifying chunks. The flags field is not intended to tell readers what is in the extension area. Specific design of header extension contents is left for a later release.

This design allows for both backwards-compatible header additions (add header extension chunks, or set low-order flag bits) and non-backwards-compatible changes (set high-order flag bits to signal such changes, and add supporting data to the extension area if needed).

Tuples

Each tuple begins with a 16-bit integer count of the number of fields in the tuple. (Presently, all tuples in a table will have the same count, but that might not always be true.) Then, repeated for each field in the tuple, there is a 32-bit length word followed by that many bytes of field data. (The length word does not include itself, and can be zero.) As a special case, -1 indicates a NULL field value. No value bytes follow in the NULL case.

There is no alignment padding or any other extra data between fields.

Presently, all data values in a binary-format file are assumed to be in binary format (format code one). It is anticipated that a future extension might add a header field that allows per-column format codes to be specified.

To determine the appropriate binary format for the actual tuple data you should consult the PostgreSQL source, in particular the *send and *recv functions for each column's data type (typically these functions are found in the src/backend/utils/adt/ directory of the source distribution).

If OIDs are included in the file, the OID field immediately follows the field-count word. It is a normal field except that it's not included in the field-count. Note that oid system columns are not supported in current versions of PostgreSQL.

File Trailer

The file trailer consists of a 16-bit integer word containing -1. This is easily distinguished from a tuple's field-count word.

A reader should report an error if a field-count word is neither -1 nor the expected number of columns. This provides an extra check against somehow getting out of sync with the data.

Examples

The following example copies a table to the client using the vertical bar (|) as the field delimiter:

COPY country TO STDOUT (DELIMITER ' | ');

To copy data from a file into the country table:

COPY country FROM '/usr1/proj/bray/sql/country_data';

To copy into a file just the countries whose names start with 'A':

1716
COPY (SELECT * FROM country WHERE country_name LIKE 'A%') TO '/usr1/proj/bray/sql/a_list_countries.copy';

To copy into a compressed file, you can pipe the output through an external compression program:

COPY country TO PROGRAM 'gzip > /usr1/proj/bray/sql/country_data.gz';

Here is a sample of data suitable for copying into a table from STDIN:

AF      AFGHANISTAN
AL      ALBANIA
DZ      ALGERIA
ZM      ZAMBIA
ZW      ZIMBABWE

Note that the white space on each line is actually a tab character.

The following is the same data, output in binary format. The data is shown after filtering through the Unix utility `od -c`. The table has three columns; the first has type `char(2)`, the second has type `text`, and the third has type `integer`. All the rows have a null value in the third column.

```
0000000   P   G   C   O   P   Y  
377  

0000020  
0000040   A
A
0000060  
0000100  
0000120  
A
0000140  
0000160  
0000200  
```

**Compatibility**

There is no `COPY` statement in the SQL standard.

The following syntax was used before PostgreSQL version 9.0 and is still supported:

```
COPY table_name [ ( column_name [, ...] ) ]
FROM ( 'filename' | STDIN )
[ [ WITH ]
  [ BINARY ]
  [ DELIMITER [ AS ] 'delimiter_character' ]
  [ NULL [ AS ] 'null_string' ]
```
COPY

[ CSV [ HEADER ]
  [ QUOTE [ AS ] 'quote_character' ]
  [ ESCAPE [ AS ] 'escape_character' ]
  [ FORCE NOT NULL column_name [, ...] ] ] ]

COPY { table_name [ ( column_name [, ...] ) ] | ( query ) } TO { 'filename' | STDOUT }
  [ [ WITH ]
    [ BINARY ]
    [ DELIMITER [ AS ] 'delimiter_character' ]
    [ NULL [ AS ] 'null_string' ]
    [ CSV [ HEADER ]
      [ QUOTE [ AS ] 'quote_character' ]
      [ ESCAPE [ AS ] 'escape_character' ]
      [ FORCE QUOTE { column_name [, ...] | * } ] ] ] ]

Note that in this syntax, BINARY and CSV are treated as independent keywords, not as arguments of a FORMAT option.

The following syntax was used before PostgreSQL version 7.3 and is still supported:

COPY [ BINARY ] table_name FROM { 'filename' | STDIN }
  [ [USING] DELIMITERS 'delimiter_character' ]
  [ WITH NULL AS 'null_string' ]

COPY [ BINARY ] table_name TO { 'filename' | STDOUT }
  [ [USING] DELIMITERS 'delimiter_character' ]
  [ WITH NULL AS 'null_string' ]

Section 28.4.6
CREATE ACCESS METHOD

CREATE ACCESS METHOD — define a new access method

Synopsis

CREATE ACCESS METHOD name
    TYPE access_method_type
    HANDLER handler_function

Description

CREATE ACCESS METHOD creates a new access method.

The access method name must be unique within the database.

Only superusers can define new access methods.

Parameters

name

The name of the access method to be created.

access_method_type

This clause specifies the type of access method to define. Only TABLE and INDEX are supported at present.

handler_function

handler_function is the name (possibly schema-qualified) of a previously registered function that represents the access method. The handler function must be declared to take a single argument of type internal, and its return type depends on the type of access method; for TABLE access methods, it must be table_am_handler and for INDEX access methods, it must be index_am_handler. The C-level API that the handler function must implement varies depending on the type of access method. The table access method API is described in Chapter 62 and the index access method API is described in Chapter 63.

Examples

Create an index access method heptree with handler function heptree_handler:

CREATE ACCESS METHOD heptree TYPE INDEX HANDLER heptree_handler;

Compatibility

CREATE ACCESS METHOD is a PostgreSQL extension.

CREATE AGGREGATE

CREATE AGGREGATE — define a new aggregate function

Synopsis

```sql
CREATE [ OR REPLACE ] AGGREGATE name ( [ argmode ] [ argname ]
  arg_data_type [ , ... ] )
  SFUNC = sfunc,
  STYPE = state_data_type
  [ , SSPACE = state_data_size ]
  [ , FINALFUNC = ffunc ]
  [ , FINALFUNC_EXTRA ]
  [ , FINALFUNC_MODIFY = { READ_ONLY | SHAREABLE | READ_WRITE } ]
  [ , COMBINEFUNC = combinefunc ]
  [ , SERIALFUNC = serialfunc ]
  [ , DESEIALFUNC = deserialfunc ]
  [ , INITCOND = initial_condition ]
  [ , MSFUNC = msfunc ]
  [ , MINVFUNC = minvfunc ]
  [ , MSTYPE = mstate_data_type ]
  [ , MSSPACE = mstate_data_size ]
  [ , MFINALFUNC = mfunc ]
  [ , MFINALFUNC_EXTRA ]
  [ , MFINALFUNC_MODIFY = { READ_ONLY | SHAREABLE | READ_WRITE } ]
  [ , MINITCOND = minitial_condition ]
  [ , SORTOP = sort_operator ]
  [ , PARALLEL = { SAFE | RESTRICTED | UNSAFE } ]
)
```

or the old syntax

```sql
CREATE [ OR REPLACE ] AGGREGATE name ( [
  argmode ]
  arg_data_type [ , ... ] )
  ORDER BY [ argmode ]
  arg_data_type [ , ... ]
  SFUNC = sfunc,
  STYPE = state_data_type
  [ , SSPACE = state_data_size ]
  [ , FINALFUNC = ffunc ]
  [ , FINALFUNC_EXTRA ]
  [ , FINALFUNC_MODIFY = { READ_ONLY | SHAREABLE | READ_WRITE } ]
  [ , INITCOND = initial_condition ]
  [ , PARALLEL = { SAFE | RESTRICTED | UNSAFE } ]
  [ , HYPOTHETICAL ]
)
```

or the old syntax

```sql
CREATE [ OR REPLACE ] AGGREGATE name ( BASETYPE = base_type,
  SFUNC = sfunc,
```
CREATE AGGREGATE defines a new aggregate function. CREATE OR REPLACE AGGREGATE will either define a new aggregate function or replace an existing definition. Some basic and commonly-used aggregate functions are included with the distribution; they are documented in Section 9.21. If one defines new types or needs an aggregate function not already provided, then CREATE AGGREGATE can be used to provide the desired features.

When replacing an existing definition, the argument types, result type, and number of direct arguments may not be changed. Also, the new definition must be of the same kind (ordinary aggregate, ordered-set aggregate, or hypothetical-set aggregate) as the old one.

If a schema name is given (for example, CREATE AGGREGATE myschema.myagg ...) then the aggregate function is created in the specified schema. Otherwise it is created in the current schema.

An aggregate function is identified by its name and input data type(s). Two aggregates in the same schema can have the same name if they operate on different input types. The name and input data type(s) of an aggregate must also be distinct from the name and input data type(s) of every ordinary function in the same schema. This behavior is identical to overloading of ordinary function names (see CREATE FUNCTION).

A simple aggregate function is made from one or two ordinary functions: a state transition function \( sfunc \), and an optional final calculation function \( ffunc \). These are used as follows:

\[
\text{sf}\text{unc}(\text{internal-state, next-data-values}) \rightarrow \text{next-internal-state} \\
\text{fffunc}(\text{internal-state}) \rightarrow \text{aggregate-value}
\]

PostgreSQL creates a temporary variable of data type \( \text{stype} \) to hold the current internal state of the aggregate. At each input row, the aggregate argument value(s) are calculated and the state transition function is invoked with the current state value and the new argument value(s) to calculate a new internal state value. After all the rows have been processed, the final function is invoked once to calculate the aggregate's return value. If there is no final function then the ending state value is returned as-is.

An aggregate function can provide an initial condition, that is, an initial value for the internal state value. This is specified and stored in the database as a value of type \text{text}, but it must be a valid external representation of a constant of the state value data type. If it is not supplied then the state value starts out null.
CREATE AGGREGATE

If the state transition function is declared "strict", then it cannot be called with null inputs. With such a transition function, aggregate execution behaves as follows. Rows with any null input values are ignored (the function is not called and the previous state value is retained). If the initial state value is null, then at the first row with all-nonnull input values, the first argument value replaces the state value, and the transition function is invoked at each subsequent row with all-nonnul input values. This is handy for implementing aggregates like \texttt{max}. Note that this behavior is only available when \texttt{state\_data\_type} is the same as the first \texttt{arg\_data\_type}. When these types are different, you must supply a nonnull initial condition or use a nonstrict transition function.

If the state transition function is not strict, then it will be called unconditionally at each input row, and must deal with null inputs and null state values for itself. This allows the aggregate author to have full control over the aggregate's handling of null values.

If the final function is declared "strict", then it will not be called when the ending state value is null; instead a null result will be returned automatically. (Of course this is just the normal behavior of strict functions.) In any case the final function has the option of returning a null value. For example, the final function for \texttt{avg} returns null when it sees there were zero input rows.

Sometimes it is useful to declare the final function as taking not just the state value, but extra parameters corresponding to the aggregate's input values. The main reason for doing this is if the final function is polymorphic and the state value's data type would be inadequate to pin down the result type. These extra parameters are always passed as NULL (and so the final function must not be strict when the \texttt{FINAL\_FUNC\_EXTRA} option is used), but nonetheless they are valid parameters. The final function could for example make use of \texttt{get\_fn\_expr\_argtype} to identify the actual argument type in the current call.

An aggregate can optionally support \textit{moving-aggregate mode}, as described in Section 38.12.1. This requires specifying the \texttt{MSFUNC}, \texttt{MINVFUNC}, and \texttt{MSTYPE} parameters, and optionally the \texttt{MSPACE}, \texttt{MFINALFUNC\_EXTRA}, \texttt{MFINALFUNC\_MODIFY}, and \texttt{MINITCOND} parameters. Except for \texttt{MINVFUNC}, these parameters work like the corresponding simple-aggregate parameters without \texttt{M}; they define a separate implementation of the aggregate that includes an inverse transition function.

The syntax with \texttt{ORDER BY} in the parameter list creates a special type of aggregate called an \textit{ordered-set aggregate}; or if \texttt{HYPOTHETICAL} is specified, then a \textit{hypothetical-set aggregate} is created. These aggregates operate over groups of sorted values in order-dependent ways, so that specification of an input sort order is an essential part of a call. Also, they can have \textit{direct} arguments, which are arguments that are evaluated only once per aggregation rather than once per input row. Hypothetical-set aggregates are a subclass of ordered-set aggregates in which some of the direct arguments are required to match, in number and data types, the aggregated argument columns. This allows the values of those direct arguments to be added to the collection of aggregate-input rows as an additional "hypothetical" row.

An aggregate can optionally support \textit{partial aggregation}, as described in Section 38.12.4. This requires specifying the \texttt{COMBINEFUNC} parameter. If the \texttt{state\_data\_type} is \texttt{internal}, it's usually also appropriate to provide the \texttt{SERIALFUNC} and \texttt{DESERIALFUNC} parameters so that parallel aggregation is possible. Note that the aggregate must also be marked \texttt{PARALLEL SAFE} to enable parallel aggregation.

Aggregates that behave like \texttt{MIN} or \texttt{MAX} can sometimes be optimized by looking into an index instead of scanning every input row. If this aggregate can be so optimized, indicate it by specifying a \textit{sort operator}. The basic requirement is that the aggregate must yield the first element in the sort ordering induced by the operator; in other words:

\begin{verbatim}
SELECT agg(col) FROM tab;
\end{verbatim}

must be equivalent to:

\begin{verbatim}

1723
SELECT col FROM tab ORDER BY col USING sortop LIMIT 1;

Further assumptions are that the aggregate ignores null inputs, and that it delivers a null result if and only if there were no non-null inputs. Ordinarily, a data type's < operator is the proper sort operator for MIN, and > is the proper sort operator for MAX. Note that the optimization will never actually take effect unless the specified operator is the “less than” or “greater than” strategy member of a B-tree index operator class.

To be able to create an aggregate function, you must have USAGE privilege on the argument types, the state type(s), and the return type, as well as EXECUTE privilege on the supporting functions.

**Parameters**

*name*

The name (optionally schema-qualified) of the aggregate function to create.

*argmode*

The mode of an argument: IN or VARIADIC. (Aggregate functions do not support OUT arguments.) If omitted, the default is IN. Only the last argument can be marked VARIADIC.

*argname*

The name of an argument. This is currently only useful for documentation purposes. If omitted, the argument has no name.

*arg_data_type*

An input data type on which this aggregate function operates. To create a zero-argument aggregate function, write * in place of the list of argument specifications. (An example of such an aggregate is count(*)).

*base_type*

In the old syntax for CREATE AGGREGATE, the input data type is specified by a basetype parameter rather than being written next to the aggregate name. Note that this syntax allows only one input parameter. To define a zero-argument aggregate function with this syntax, specify the basetype as "ANY" (not *). Ordered-set aggregates cannot be defined with the old syntax.

*sfunc*

The name of the state transition function to be called for each input row. For a normal N-argument aggregate function, the sfunc must take N+1 arguments, the first being of type state_data_type and the rest matching the declared input data type(s) of the aggregate. The function must return a value of type state_data_type. This function takes the current state value and the current input data value(s), and returns the next state value.

For ordered-set (including hypothetical-set) aggregates, the state transition function receives only the current state value and the aggregated arguments, not the direct arguments. Otherwise it is the same.

*state_data_type*

The data type for the aggregate’s state value.

*state_data_size*

The approximate average size (in bytes) of the aggregate's state value. If this parameter is omitted or is zero, a default estimate is used based on the state_data_type. The planner uses this value to estimate the memory required for a grouped aggregate query.
CREATE AGGREGATE

ffunc

The name of the final function called to compute the aggregate's result after all input rows have been traversed. For a normal aggregate, this function must take a single argument of type state_data_type. The return data type of the aggregate is defined as the return type of this function. If ffunc is not specified, then the ending state value is used as the aggregate's result, and the return type is state_data_type.

For ordered-set (including hypothetical-set) aggregates, the final function receives not only the final state value, but also the values of all the direct arguments.

If FINALFUNC_EXTRA is specified, then in addition to the final state value and any direct arguments, the final function receives extra NULL values corresponding to the aggregate's regular (aggregated) arguments. This is mainly useful to allow correct resolution of the aggregate result type when a polymorphic aggregate is being defined.

FINALFUNC_MODIFY = { READ_ONLY | SHAREABLE | READ_WRITE }  

This option specifies whether the final function is a pure function that does not modify its arguments. READ_ONLY indicates it does not; the other two values indicate that it may change the transition state value. See Notes below for more detail. The default is READ_ONLY, except for ordered-set aggregates, for which the default is READ_WRITE.

combinefunc

The combinefunc function may optionally be specified to allow the aggregate function to support partial aggregation. If provided, the combinefunc must combine two state_data_type values, each containing the result of aggregation over some subset of the input values, to produce a new state_data_type that represents the result of aggregating over both sets of inputs. This function can be thought of as an sfunc, where instead of acting upon an individual input row and adding it to the running aggregate state, it adds another aggregate state to the running state.

The combinefunc must be declared as taking two arguments of the state_data_type and returning a value of the state_data_type. Optionally this function may be “strict”. In this case the function will not be called when either of the input states are null; the other state will be taken as the correct result.

For aggregate functions whose state_data_type is internal, the combinefunc must not be strict. In this case the combinefunc must ensure that null states are handled correctly and that the state being returned is properly stored in the aggregate memory context.

serialfunc

An aggregate function whose state_data_type is internal can participate in parallel aggregation only if it has a serialfunc function, which must serialize the aggregate state into a bytea value for transmission to another process. This function must take a single argument of type internal and return type bytea. A corresponding deserialfunc is also required.

deserialfunc

Deserialize a previously serialized aggregate state back into state_data_type. This function must take two arguments of types bytea and internal, and produce a result of type internal. (Note: the second, internal argument is unused, but is required for type safety reasons.)

initial_condition

The initial setting for the state value. This must be a string constant in the form accepted for the data type state_data_type. If not specified, the state value starts out null.
CREATE AGGREGATE

msfunc

The name of the forward state transition function to be called for each input row in moving-aggregate mode. This is exactly like the regular transition function, except that its first argument and result are of type mstate_data_type, which might be different from state_data_type.

minvfunc

The name of the inverse state transition function to be used in moving-aggregate mode. This function has the same argument and result types as msfunc, but it is used to remove a value from the current aggregate state, rather than add a value to it. The inverse transition function must have the same strictness attribute as the forward state transition function.

mstate_data_type

The data type for the aggregate's state value, when using moving-aggregate mode.

mstate_data_size

The approximate average size (in bytes) of the aggregate's state value, when using moving-aggregate mode. This works the same as state_data_size.

mfunc

The name of the final function called to compute the aggregate's result after all input rows have been traversed, when using moving-aggregate mode. This works the same as ffunc, except that its first argument's type is mstate_data_type and extra dummy arguments are specified by writing MFINALFUNC_EXTRA. The aggregate result type determined by mfunc or mstate_data_type must match that determined by the aggregate's regular implementation.

MFINALFUNC_MODIFY = { READ_ONLY | SHAREABLE | READ_WRITE }

This option is like FINALFUNC_MODIFY, but it describes the behavior of the moving-aggregate final function.

minitial_condition

The initial setting for the state value, when using moving-aggregate mode. This works the same as initial_condition.

sort_operator

The associated sort operator for a MIN- or MAX-like aggregate. This is just an operator name (possibly schema-qualified). The operator is assumed to have the same input data types as the aggregate (which must be a single-argument normal aggregate).

PARALLEL = { SAFE | RESTRICTED | UNSAFE }

The meanings of PARALLEL SAFE, PARALLEL RESTRICTED, and PARALLEL UNSAFE are the same as in CREATE FUNCTION. An aggregate will not be considered for parallelization if it is marked PARALLEL UNSAFE (which is the default!) or PARALLEL RESTRICTED. Note that the parallel-safety markings of the aggregate's support functions are not consulted by the planner, only the marking of the aggregate itself.

HYPOTHETICAL

For ordered-set aggregates only, this flag specifies that the aggregate arguments are to be processed according to the requirements for hypothetical-set aggregates: that is, the last few direct arguments
CREATE AGGREGATE

must match the data types of the aggregated (WITHIN GROUP) arguments. The HYPOTHETICAL
flag has no effect on run-time behavior, only on parse-time resolution of the data types and collations
of the aggregate's arguments.

The parameters of CREATE AGGREGATE can be written in any order, not just the order illustrated above.

Notes

In parameters that specify support function names, you can write a schema name if needed, for example
SFUNC = public.sum. Do not write argument types there, however — the argument types of the
support functions are determined from other parameters.

Ordinarily, PostgreSQL functions are expected to be true functions that do not modify their input values.
However, an aggregate transition function, when used in the context of an aggregate, is allowed to cheat
and modify its transition-state argument in place. This can provide substantial performance benefits com-
pared to making a fresh copy of the transition state each time.

Likewise, while an aggregate final function is normally expected not to modify its input values, sometimes
it is impractical to avoid modifying the transition-state argument. Such behavior must be declared using
the FINALFUNC_MODIFY parameter. The READ_WRITE value indicates that the final function modifies
the transition state in unspecified ways. This value prevents use of the aggregate as a window function,
and it also prevents merging of transition states for aggregate calls that share the same input values and
transition functions. The SHAREABLE value indicates that the transition function cannot be applied after
the final function, but multiple final-function calls can be performed on the ending transition state value.
This value prevents use of the aggregate as a window function, but it allows merging of transition states.
(That is, the optimization of interest here is not applying the same final function repeatedly, but applying
different final functions to the same ending transition state value. This is allowed as long as none of the
final functions are marked READ_WRITE.)

If an aggregate supports moving-aggregate mode, it will improve calculation efficiency when the aggregate
is used as a window function for a window with moving frame start (that is, a frame start mode other
than UNBOUNDED PRECEDING). Conceptually, the forward transition function adds input values to the
aggregate's state when they enter the window frame from the bottom, and the inverse transition function
removes them again when they leave the frame at the top. So, when values are removed, they are always
removed in the same order they were added. Whenever the inverse transition function is invoked, it will
thus receive the earliest added but not yet removed argument value(s). The inverse transition function can
assume that at least one row will remain in the current state after it removes the oldest row. (When this
would not be the case, the window function mechanism simply starts a fresh aggregation, rather than using
the inverse transition function.)

The forward transition function for moving-aggregate mode is not allowed to return NULL as the new
state value. If the inverse transition function returns NULL, this is taken as an indication that the inverse
function cannot reverse the state calculation for this particular input, and so the aggregate calculation will
be redone from scratch for the current frame starting position. This convention allows moving-aggregate
mode to be used in situations where there are some infrequent cases that are impractical to reverse out
of the running state value.

If no moving-aggregate implementation is supplied, the aggregate can still be used with moving frames,
but PostgreSQL will recompute the whole aggregation whenever the start of the frame moves. Note that
whether or not the aggregate supports moving-aggregate mode, PostgreSQL can handle a moving frame
end without recalculation; this is done by continuing to add new values to the aggregate's state. This is
why use of an aggregate as a window function requires that the final function be read-only: it must not
damage the aggregate's state value, so that the aggregation can be continued even after an aggregate result
value has been obtained for one set of frame boundaries.
The syntax for ordered-set aggregates allows VARIADIC to be specified for both the last direct parameter and the last aggregated (WITHIN GROUP) parameter. However, the current implementation restricts use of VARIADIC in two ways. First, ordered-set aggregates can only use VARIADIC "any", not other variadic array types. Second, if the last direct parameter is VARIADIC "any", then there can be only one aggregated parameter and it must also be VARIADIC "any". (In the representation used in the system catalogs, these two parameters are merged into a single VARIADIC "any" item, since pg_proc cannot represent functions with more than one VARIADIC parameter.) If the aggregate is a hypothetical-set aggregate, the direct arguments that match the VARIADIC "any" parameter are the hypothetical ones; any preceding parameters represent additional direct arguments that are not constrained to match the aggregated arguments.

Currently, ordered-set aggregates do not need to support moving-aggregate mode, since they cannot be used as window functions.

Partial (including parallel) aggregation is currently not supported for ordered-set aggregates. Also, it will never be used for aggregate calls that include DISTINCT or ORDER BY clauses, since those semantics cannot be supported during partial aggregation.

Examples
See Section 38.12.

Compatibility
CREATE AGGREGATE is a PostgreSQL language extension. The SQL standard does not provide for user-defined aggregate functions.

ALTER AGGREGATE, DROP AGGREGATE
CREATE CAST

CREATE CAST — define a new cast

Synopsis

CREATE CAST (source_type AS target_type)
    WITH FUNCTION function_name [ (argument_type [, ...]) ]
    [ AS ASSIGNMENT | AS IMPLICIT ]

CREATE CAST (source_type AS target_type)
    WITHOUT FUNCTION
    [ AS ASSIGNMENT | AS IMPLICIT ]

CREATE CAST (source_type AS target_type)
    WITH INOUT
    [ AS ASSIGNMENT | AS IMPLICIT ]

Description

CREATE CAST defines a new cast. A cast specifies how to perform a conversion between two data types.

For example,

    SELECT CAST(42 AS float8);

converts the integer constant 42 to type float8 by invoking a previously specified function, in this case float8(int4). (If no suitable cast has been defined, the conversion fails.)

Two types can be binary coercible, which means that the conversion can be performed “for free” without invoking any function. This requires that corresponding values use the same internal representation. For instance, the types text and varchar are binary coercible both ways. Binary coercibility is not necessarily a symmetric relationship. For example, the cast from xml to text can be performed for free in the present implementation, but the reverse direction requires a function that performs at least a syntax check. (Two types that are binary coercible both ways are also referred to as binary compatible.)

You can define a cast as an I/O conversion cast by using the WITH INOUT syntax. An I/O conversion cast is performed by invoking the output function of the source data type, and passing the resulting string to the input function of the target data type. In many common cases, this feature avoids the need to write a separate cast function for conversion. An I/O conversion cast acts the same as a regular function-based cast; only the implementation is different.

By default, a cast can be invoked only by an explicit cast request, that is an explicit CAST(x AS typename) or x::typename construct.

If the cast is marked AS ASSIGNMENT then it can be invoked implicitly when assigning a value to a column of the target data type. For example, supposing that foo.f1 is a column of type text, then:

    INSERT INTO foo (f1) VALUES (42);
CREATE CAST

will be allowed if the cast from type integer to type text is marked AS ASSIGNMENT, otherwise not. (We generally use the term assignment cast to describe this kind of cast.)

If the cast is marked AS IMPLICIT then it can be invoked implicitly in any context, whether assignment or internally in an expression. (We generally use the term implicit cast to describe this kind of cast.) For example, consider this query:

```
SELECT 2 + 4.0;
```

The parser initially marks the constants as being of type integer and numeric respectively. There is no integer + numeric operator in the system catalogs, but there is a numeric + numeric operator. The query will therefore succeed if a cast from integer to numeric is available and is marked AS IMPLICIT — which in fact it is. The parser will apply the implicit cast and resolve the query as if it had been written

```
SELECT CAST ( 2 AS numeric ) + 4.0;
```

Now, the catalogs also provide a cast from numeric to integer. If that cast were marked AS IMPLICIT — which it is not — then the parser would be faced with choosing between the above interpretation and the alternative of casting the numeric constant to integer and applying the integer + integer operator. Lacking any knowledge of which choice to prefer, it would give up and declare the query ambiguous. The fact that only one of the two casts is implicit is the way in which we teach the parser to prefer resolution of a mixed numeric-and-integer expression as numeric: there is no built-in knowledge about that.

It is wise to be conservative about marking casts as implicit. An overabundance of implicit casting paths can cause PostgreSQL to choose surprising interpretations of commands, or to be unable to resolve commands at all because there are multiple possible interpretations. A good rule of thumb is to make a cast implicitly invokable only for information-preserving transformations between types in the same general type category. For example, the cast from int2 to int4 can reasonably be implicit, but the cast from float8 to int4 should probably be assignment-only. Cross-type-category casts, such as text to int4, are best made explicit-only.

```
Note
```

Sometimes it is necessary for usability or standards-compliance reasons to provide multiple implicit casts among a set of types, resulting in ambiguity that cannot be avoided as above. The parser has a fallback heuristic based on type categories and preferred types that can help to provide desired behavior in such cases. See CREATE TYPE for more information.

To be able to create a cast, you must own the source or the target data type and have USAGE privilege on the other type. To create a binary-coercible cast, you must be superuser. (This restriction is made because an erroneous binary-coercible cast conversion can easily crash the server.)

**Parameters**

`source_type`

The name of the source data type of the cast.

`target_type`

The name of the target data type of the cast.
create cast

function_name((argument_type [, ...]))

The function used to perform the cast. The function name can be schema-qualified. If it is not, the
function will be looked up in the schema search path. The function's result data type must match the
target type of the cast. Its arguments are discussed below. If no argument list is specified, the function
name must be unique in its schema.

without function

Indicates that the source type is binary-coercible to the target type, so no function is required to perform
the cast.

with inout

Indicates that the cast is an I/O conversion cast, performed by invoking the output function of the
source data type, and passing the resulting string to the input function of the target data type.

as assignment

Indicates that the cast can be invoked implicitly in assignment contexts.

as implicit

Indicates that the cast can be invoked implicitly in any context.

Cast implementation functions can have one to three arguments. The first argument type must be identical
to or binary-coercible from the cast's source type. The second argument, if present, must be type integer;
it receives the type modifier associated with the destination type, or −1 if there is none. The third argument,
if present, must be type boolean; it receives true if the cast is an explicit cast, false otherwise.
(Bizarrely, the SQL standard demands different behaviors for explicit and implicit casts in some cases.
This argument is supplied for functions that must implement such casts. It is not recommended that you
design your own data types so that this matters.)

The return type of a cast function must be identical to or binary-coercible to the cast's target type.

Ordinarily a cast must have different source and target data types. However, it is allowed to declare a cast
with identical source and target types if it has a cast implementation function with more than one argument.
This is used to represent type-specific length coercion functions in the system catalogs. The named function
is used to coerce a value of the type to the type modifier value given by its second argument.

When a cast has different source and target types and a function that takes more than one argument, it
supports converting from one type to another and applying a length coercion in a single step. When no
such entry is available, coercion to a type that uses a type modifier involves two cast steps, one to convert
between data types and a second to apply the modifier.

A cast to or from a domain type currently has no effect. Casting to or from a domain uses the casts associated
with its underlying type.

Notes

Use drop cast to remove user-defined casts.

Remember that if you want to be able to convert types both ways you need to declare casts both ways
explicitly.

It is normally not necessary to create casts between user-defined types and the standard string types (text,
varchar, and char(n), as well as user-defined types that are defined to be in the string category).
PostgreSQL provides automatic I/O conversion casts for that. The automatic casts to string types are treated as assignment casts, while the automatic casts from string types are explicit-only. You can override this behavior by declaring your own cast to replace an automatic cast, but usually the only reason to do so is if you want the conversion to be more easily invokable than the standard assignment-only or explicit-only setting. Another possible reason is that you want the conversion to behave differently from the type's I/O function; but that is sufficiently surprising that you should think twice about whether it's a good idea. (A small number of the built-in types do indeed have different behaviors for conversions, mostly because of requirements of the SQL standard.)

While not required, it is recommended that you continue to follow this old convention of naming cast implementation functions after the target data type. Many users are used to being able to cast data types using a function-style notation, that is `typename(x)`. This notation is in fact nothing more nor less than a call of the cast implementation function; it is not specially treated as a cast. If your conversion functions are not named to support this convention then you will have surprised users. Since PostgreSQL allows overloading of the same function name with different argument types, there is no difficulty in having multiple conversion functions from different types that all use the target type's name.

---

**Note**

Actually the preceding paragraph is an oversimplification: there are two cases in which a function-call construct will be treated as a cast request without having matched it to an actual function. If a function call `name(x)` does not exactly match any existing function, but `name` is the name of a data type and `pg_cast` provides a binary-coercible cast to this type from the type of `x`, then the call will be construed as a binary-coercible cast. This exception is made so that binary-coercible casts can be invoked using functional syntax, even though they lack any function. Likewise, if there is no `pg_cast` entry but the cast would be to or from a string type, the call will be construed as an I/O conversion cast. This exception allows I/O conversion casts to be invoked using functional syntax.

---

**Note**

There is also an exception to the exception: I/O conversion casts from composite types to string types cannot be invoked using functional syntax, but must be written in explicit cast syntax (either `CAST` or `::` notation). This exception was added because after the introduction of automatically-provided I/O conversion casts, it was found too easy to accidentally invoke such a cast when a function or column reference was intended.

---

**Examples**

To create an assignment cast from type `bigint` to type `int4` using the function `int4(bigint)`:  

```
CREATE CAST (bigint AS int4) WITH FUNCTION int4(bigint) AS ASSIGNMENT;
```

(This cast is already predefined in the system.)

---

**Compatibility**

The `CREATE CAST` command conforms to the SQL standard, except that SQL does not make provisions for binary-coercible types or extra arguments to implementation functions. `AS IMPLICIT` is a PostgreSQL extension, too.
See Also

CREATE FUNCTION, CREATE TYPE, DROP CAST
CREATE COLLATION

CREATE COLLATION — define a new collation

Synopsis

CREATE COLLATION [ IF NOT EXISTS ] name (  
[ LOCALE = locale, ]  
[ LC_COLLATE = lc_collate, ]  
[ LC_CTYPE = lc_ctype, ]  
[ PROVIDER = provider, ]  
[ DETERMINISTIC = boolean, ]  
[ VERSION = version ]  
)  
CREATE COLLATION [ IF NOT EXISTS ] name FROM existing_collation

Description

CREATE COLLATION defines a new collation using the specified operating system locale settings, or by copying an existing collation.

To be able to create a collation, you must have CREATE privilege on the destination schema.

Parameters

IF NOT EXISTS

Do not throw an error if a collation with the same name already exists. A notice is issued in this case. Note that there is no guarantee that the existing collation is anything like the one that would have been created.

name

The name of the collation. The collation name can be schema-qualified. If it is not, the collation is defined in the current schema. The collation name must be unique within that schema. (The system catalogs can contain collations with the same name for other encodings, but these are ignored if the database encoding does not match.)

locale

This is a shortcut for setting LC_COLLATE and LC_CTYPE at once. If you specify this, you cannot specify either of those parameters.

lc_collate

Use the specified operating system locale for the LC_COLLATE locale category.

lc_ctype

Use the specified operating system locale for the LC_CTYPE locale category.
**CREATE COLLATION**

- **provider**
  Specifies the provider to use for locale services associated with this collation. Possible values are: icu, libc. libc is the default. The available choices depend on the operating system and build options.

- **DETERMINISTIC**
  Specifies whether the collation should use deterministic comparisons. The default is true. A deterministic comparison considers strings that are not byte-wise equal to be unequal even if they are considered logically equal by the comparison. PostgreSQL breaks ties using a byte-wise comparison. Comparison that is not deterministic can make the collation be, say, case- or accent-insensitive. For that, you need to choose an appropriate LC_COLLATE setting and set the collation to not deterministic here.

  Nondeterministic collations are only supported with the ICU provider.

- **version**
  Specifies the version string to store with the collation. Normally, this should be omitted, which will cause the version to be computed from the actual version of the collation as provided by the operating system. This option is intended to be used by pg_upgrade for copying the version from an existing installation.

  See also ALTER COLLATION for how to handle collation version mismatches.

- **existing_collation**
  The name of an existing collation to copy. The new collation will have the same properties as the existing one, but it will be an independent object.

**Notes**

CREATE COLLATION takes a SHARE ROW EXCLUSIVE lock, which is self-conflicting, on the pg_collation system catalog, so only one CREATE COLLATION command can run at a time.

Use DROP COLLATION to remove user-defined collations.

See Section 24.2.2.3 for more information on how to create collations.

When using the libc collation provider, the locale must be applicable to the current database encoding. See CREATE DATABASE for the precise rules.

**Examples**

To create a collation from the operating system locale fr_FR.utf8 (assuming the current database encoding is UTF8):

```
CREATE COLLATION french (locale = 'fr_FR.utf8');
```

To create a collation using the ICU provider using German phone book sort order:

```
CREATE COLLATION german_phonebook (provider = icu, locale = 'de-u-co-phonebk');
```
To create a collation from an existing collation:

```
CREATE COLLATION german FROM "de_DE";
```

This can be convenient to be able to use operating-system-independent collation names in applications.

## Compatibility

There is a `CREATE COLLATION` statement in the SQL standard, but it is limited to copying an existing collation. The syntax to create a new collation is a PostgreSQL extension.

## See Also

`ALTER COLLATION`, `DROP COLLATION`
CREATE CONVERSION

CREATE CONVERSION — define a new encoding conversion

Synopsis

```
CREATE [ DEFAULT ] CONVERSION name
    FOR source_encoding TO dest_encoding FROM function_name
```

Description

CREATE CONVERSION defines a new conversion between two character set encodings.

Conversions that are marked DEFAULT can be used for automatic encoding conversion between client and server. To support that usage, two conversions, from encoding A to B and from encoding B to A, must be defined.

To be able to create a conversion, you must have EXECUTE privilege on the function and CREATE privilege on the destination schema.

Parameters

DEFAULT

The DEFAULT clause indicates that this conversion is the default for this particular source to destination encoding. There should be only one default encoding in a schema for the encoding pair.

name

The name of the conversion. The conversion name can be schema-qualified. If it is not, the conversion is defined in the current schema. The conversion name must be unique within a schema.

source_encoding

The source encoding name.

dest_encoding

The destination encoding name.

function_name

The function used to perform the conversion. The function name can be schema-qualified. If it is not, the function will be looked up in the path.

The function must have the following signature:

```
conv_proc(
    integer,  -- source encoding ID
    integer,  -- destination encoding ID
    cstring,  -- source string (null terminated C string)
)
CREATE CONVERSION

```c
    internal, -- destination (fill with a null terminated C string)
    integer,  -- source string length
    boolean   -- if true, don't throw an error if conversion fails
) RETURNS integer;
```

The return value is the number of source bytes that were successfully converted. If the last argument is false, the function must throw an error on invalid input, and the return value is always equal to the source string length.

Notes

Neither the source nor the destination encoding can be SQL_ASCII, as the server's behavior for cases involving the SQL_ASCII “encoding” is hard-wired.

Use DROP CONVERSION to remove user-defined conversions.

The privileges required to create a conversion might be changed in a future release.

Examples

To create a conversion from encoding UTF8 to LATIN1 using myfunc:

```
CREATE CONVERSION myconv FOR 'UTF8' TO 'LATIN1' FROM myfunc;
```

Compatibility

CREATE CONVERSION is a PostgreSQL extension. There is no CREATE CONVERSION statement in the SQL standard, but a CREATE TRANSLATION statement that is very similar in purpose and syntax.

See Also

ALTER CONVERSION, CREATE FUNCTION, DROP CONVERSION
CREATE DATABASE

CREATE DATABASE — create a new database

Synopsis

CREATE DATABASE name
   [ [ WITH ] [ OWNER [=] user_name ]
   [ TEMPLATE [=] template ]
   [ ENCODING [=] encoding ]
   [ STRATEGY [=] strategy ]
   [ LOCALE [=] locale ]
   [ LC_COLLATE [=] lc_collate ]
   [ LC_CTYPE [=] lc_ctype ]
   [ ICU_LOCALE [=] icu_locale ]
   [ LOCALE_PROVIDER [=] locale_provider ]
   [ COLLATION_VERSION = collation_version ]
   [ TABLESPACE [=] tablespace_name ]
   [ ALLOW_CONNECTIONS [=] allowconn ]
   [ CONNECTION LIMIT [=] connlimit ]
   [ IS_TEMPLATE [=] istemplate ]
   [ OID [=] oid ]

Description

CREATE DATABASE creates a new PostgreSQL database.

To create a database, you must be a superuser or have the special CREATEDB privilege. See CREATE ROLE.

By default, the new database will be created by cloning the standard system database template1. A different template can be specified by writing TEMPLATE name. In particular, by writing TEMPLATE template0, you can create a pristine database (one where no user-defined objects exist and where the system objects have not been altered) containing only the standard objects predefined by your version of PostgreSQL. This is useful if you wish to avoid copying any installation-local objects that might have been added to template1.

Parameters

name

The name of a database to create.

user_name

The role name of the user who will own the new database, or DEFAULT to use the default (namely, the user executing the command). To create a database owned by another role, you must be a direct or indirect member of that role, or be a superuser.

template

The name of the template from which to create the new database, or DEFAULT to use the default template (template1).
CREATE DATABASE

encoding

Character set encoding to use in the new database. Specify a string constant (e.g., 'SQL_ASCII'), or an integer encoding number, or DEFAULT to use the default encoding (namely, the encoding of the template database). The character sets supported by the PostgreSQL server are described in Section 24.3.1. See below for additional restrictions.

strategy

Strategy to be used in creating the new database. If the WAL_LOG strategy is used, the database will be copied block by block and each block will be separately written to the write-ahead log. This is the most efficient strategy in cases where the template database is small, and therefore it is the default. The older FILE_COPY strategy is also available. This strategy writes a small record to the write-ahead log for each tablespace used by the target database. Each such record represents copying an entire directory to a new location at the filesystem level. While this does reduce the write-ahead log volume substantially, especially if the template database is large, it also forces the system to perform a checkpoint both before and after the creation of the new database. In some situations, this may have a noticeable negative impact on overall system performance.

locale

This is a shortcut for setting LC_COLLATE and LC_CTYPE at once. If you specify this, you cannot specify either of those parameters.

Tip

The other locale settings lc_messages, lc_monetary, lc_numeric, and lc_time are not fixed per database and are not set by this command. If you want to make them the default for a specific database, you can use ALTER DATABASE ... SET.

lc_collate

Collation order (LC_COLLATE) to use in the new database. This affects the sort order applied to strings, e.g., in queries with ORDER BY, as well as the order used in indexes on text columns. The default is to use the collation order of the template database. See below for additional restrictions.

lc_ctype

Character classification (LC_CTYPE) to use in the new database. This affects the categorization of characters, e.g., lower, upper and digit. The default is to use the character classification of the template database. See below for additional restrictions.

icu_locale

Specifies the ICU locale ID if the ICU locale provider is used.

locale_provider

Specifies the provider to use for the default collation in this database. Possible values are: icu, libc. libc is the default. The available choices depend on the operating system and build options.

collation_version

Specifies the collation version string to store with the database. Normally, this should be omitted, which will cause the version to be computed from the actual version of the database collation as
CREATE DATABASE

provided by the operating system. This option is intended to be used by pg_upgrade for copying the version from an existing installation.

See also ALTER DATABASE for how to handle database collation version mismatches.

tablespace_name

The name of the tablespace that will be associated with the new database, or DEFAULT to use the template database's tablespace. This tablespace will be the default tablespace used for objects created in this database. See CREATE TABLESPACE for more information.

allowconn

If false then no one can connect to this database. The default is true, allowing connections (except as restricted by other mechanisms, such as GRANT/REVOKE CONNECT).

connlimit

How many concurrent connections can be made to this database. -1 (the default) means no limit.

istemplate

If true, then this database can be cloned by any user with CREATEDB privileges; if false (the default), then only superusers or the owner of the database can clone it.

oid

The object identifier to be used for the new database. If this parameter is not specified, PostgreSQL will choose a suitable OID automatically. This parameter is primarily intended for internal use by pg_upgrade, and only pg_upgrade can specify a value less than 16384.

Optional parameters can be written in any order, not only the order illustrated above.

Notes

CREATE DATABASE cannot be executed inside a transaction block.

Errors along the line of “could not initialize database directory” are most likely related to insufficient permissions on the data directory, a full disk, or other file system problems.

Use DROP DATABASE to remove a database.

The program createdb is a wrapper program around this command, provided for convenience.

Database-level configuration parameters (set via ALTER DATABASE) and database-level permissions (set via GRANT) are not copied from the template database.

Although it is possible to copy a database other than template1 by specifying its name as the template, this is not (yet) intended as a general-purpose “COPY DATABASE” facility. The principal limitation is that no other sessions can be connected to the template database while it is being copied. CREATE DATABASE will fail if any other connection exists when it starts; otherwise, new connections to the template database are locked out until CREATE DATABASE completes. See Section 23.3 for more information.

The character set encoding specified for the new database must be compatible with the chosen locale settings (LC_COLLATE and LC_CTYPE). If the locale is C (or equivalently POSIX), then all encodings are allowed, but for other locale settings there is only one encoding that will work properly. (On Windows, however, UTF-8 encoding can be used with any locale.) CREATE DATABASE will allow superusers to
specify SQL_ASCII encoding regardless of the locale settings, but this choice is deprecated and may result in misbehavior of character-string functions if data that is not encoding-compatible with the locale is stored in the database.

The encoding and locale settings must match those of the template database, except when template0 is used as template. This is because other databases might contain data that does not match the specified encoding, or might contain indexes whose sort ordering is affected by LC_COLLATE and LC_CTYPE. Copying such data would result in a database that is corrupt according to the new settings. template0, however, is known to not contain any data or indexes that would be affected.

There is currently no option to use a database locale with nondeterministic comparisons (see CREATE COLLATION for an explanation). If this is needed, then per-column collations would need to be used.

The CONNECTION LIMIT option is only enforced approximately; if two new sessions start at about the same time when just one connection “slot” remains for the database, it is possible that both will fail. Also, the limit is not enforced against superusers or background worker processes.

Examples

To create a new database:

CREATE DATABASE lusiadas;

To create a database sales owned by user salesapp with a default tablespace of salesspace:

CREATE DATABASE sales OWNER salesapp TABLESPACE salesspace;

To create a database music with a different locale:

CREATE DATABASE music
  LOCALE 'sv_SE.utf8'
  TEMPLATE template0;

In this example, the TEMPLATE template0 clause is required if the specified locale is different from the one in template1. (If it is not, then specifying the locale explicitly is redundant.)

To create a database music2 with a different locale and a different character set encoding:

CREATE DATABASE music2
  LOCALE 'sv_SE.iso885915'
  ENCODING LATIN9
  TEMPLATE template0;

The specified locale and encoding settings must match, or an error will be reported.

Note that locale names are specific to the operating system, so that the above commands might not work in the same way everywhere.

Compatibility

There is no CREATE DATABASE statement in the SQL standard. Databases are equivalent to catalogs, whose creation is implementation-defined.

ALTER DATABASE, DROP DATABASE
CREATE DOMAIN

CREATE DOMAIN — define a new domain

Synopsis

CREATE DOMAIN name [ AS ] data_type
[ COLLATE collation ]
[ DEFAULT expression ]
[ constraint [ ... ] ]

where constraint is:

[ CONSTRAINT constraint_name ]
{ NOT NULL | NULL | CHECK (expression) }

Description

CREATE DOMAIN creates a new domain. A domain is essentially a data type with optional constraints (restrictions on the allowed set of values). The user who defines a domain becomes its owner.

If a schema name is given (for example, CREATE DOMAIN myschema.mydomain ...) then the domain is created in the specified schema. Otherwise it is created in the current schema. The domain name must be unique among the types and domains existing in its schema.

Domains are useful for abstracting common constraints on fields into a single location for maintenance. For example, several tables might contain email address columns, all requiring the same CHECK constraint to verify the address syntax. Define a domain rather than setting up each table's constraint individually.

To be able to create a domain, you must have USAGE privilege on the underlying type.

Parameters

name

The name (optionally schema-qualified) of a domain to be created.

data_type

The underlying data type of the domain. This can include array specifiers.

collation

An optional collation for the domain. If no collation is specified, the domain has the same collation behavior as its underlying data type. The underlying type must be collatable if COLLATE is specified.

DEFAULT expression

The DEFAULT clause specifies a default value for columns of the domain data type. The value is any variable-free expression (but subqueries are not allowed). The data type of the default expression
must match the data type of the domain. If no default value is specified, then the default value is the null value.

The default expression will be used in any insert operation that does not specify a value for the column. If a default value is defined for a particular column, it overrides any default associated with the domain. In turn, the domain default overrides any default value associated with the underlying data type.

**CONSTRAINT**  

An optional name for a constraint. If not specified, the system generates a name.

**NOT NULL**  

Values of this domain are prevented from being null (but see notes below).

**NULL**  

Values of this domain are allowed to be null. This is the default.

This clause is only intended for compatibility with nonstandard SQL databases. Its use is discouraged in new applications.

**CHECK**  

**CHECK** clauses specify integrity constraints or tests which values of the domain must satisfy. Each constraint must be an expression producing a Boolean result. It should use the key word VALUE to refer to the value being tested. Expressions evaluating to TRUE or UNKNOWN succeed. If the expression produces a FALSE result, an error is reported and the value is not allowed to be converted to the domain type.

Currently, **CHECK** expressions cannot contain subqueries nor refer to variables other than VALUE.

When a domain has multiple **CHECK** constraints, they will be tested in alphabetical order by name. (PostgreSQL versions before 9.5 did not honor any particular firing order for **CHECK** constraints.)

**Notes**

Domain constraints, particularly **NOT NULL**, are checked when converting a value to the domain type. It is possible for a column that is nominally of the domain type to read as null despite there being such a constraint. For example, this can happen in an outer-join query, if the domain column is on the nullable side of the outer join. A more subtle example is

```sql
INSERT INTO tab (domcol) VALUES ((SELECT domcol FROM tab WHERE false));
```

The empty scalar sub-SELECT will produce a null value that is considered to be of the domain type, so no further constraint checking is applied to it, and the insertion will succeed.

It is very difficult to avoid such problems, because of SQL's general assumption that a null value is a valid value of every data type. Best practice therefore is to design a domain's constraints so that a null value is allowed, and then to apply column **NOT NULL** constraints to columns of the domain type as needed, rather than directly to the domain type.

PostgreSQL assumes that **CHECK** constraints' conditions are immutable, that is, they will always give the same result for the same input value. This assumption is what justifies examining **CHECK** constraints only
when a value is first converted to be of a domain type, and not at other times. (This is essentially the same
as the treatment of table CHECK constraints, as described in Section 5.4.1.)

An example of a common way to break this assumption is to reference a user-defined function in a CHECK
expression, and then change the behavior of that function. PostgreSQL does not disallow that, but it will
not notice if there are stored values of the domain type that now violate the CHECK constraint. That would
cause a subsequent database dump and reload to fail. The recommended way to handle such a change is
to drop the constraint (using ALTER DOMAIN), adjust the function definition, and re-add the constraint,
thereby rechecking it against stored data.

Examples

This example creates the us_postal_code data type and then uses the type in a table definition. A
regular expression test is used to verify that the value looks like a valid US postal code:

```sql
CREATE DOMAIN us_postal_code AS TEXT
CHECK(
    VALUE ~ '^[\d]{5}$'
    OR VALUE ~ '^[\d]{5}-[\d]{4}$'
);

CREATE TABLE us_snail_addy (
    address_id SERIAL PRIMARY KEY,
    street1 TEXT NOT NULL,
    street2 TEXT,
    street3 TEXT,
    city TEXT NOT NULL,
    postal us_postal_code NOT NULL
);
```

Compatibility

The command CREATE DOMAIN conforms to the SQL standard.

See Also

ALTER DOMAIN, DROP DOMAIN
CREATE EVENT TRIGGER

CREATE EVENT TRIGGER — define a new event trigger

Synopsis

CREATE EVENT TRIGGER name
   ON event
       [ WHEN filter_variable IN (filter_value [, ... ]) [ AND ... ] ]
       EXECUTE { FUNCTION | PROCEDURE } function_name()

Description

CREATE EVENT TRIGGER creates a new event trigger. Whenever the designated event occurs and the WHEN condition associated with the trigger, if any, is satisfied, the trigger function will be executed. For a general introduction to event triggers, see Chapter 40. The user who creates an event trigger becomes its owner.

Parameters

name

   The name to give the new trigger. This name must be unique within the database.

event

   The name of the event that triggers a call to the given function. See Section 40.1 for more information on event names.

filter_variable

   The name of a variable used to filter events. This makes it possible to restrict the firing of the trigger to a subset of the cases in which it is supported. Currently the only supported filter_variable is TAG.

filter_value

   A list of values for the associated filter_variable for which the trigger should fire. For TAG, this means a list of command tags (e.g., 'DROP FUNCTION').

function_name

   A user-supplied function that is declared as taking no argument and returning type event_trigger.

In the syntax of CREATE EVENT TRIGGER, the keywords FUNCTION and PROCEDURE are equivalent, but the referenced function must in any case be a function, not a procedure. The use of the keyword PROCEDURE here is historical and deprecated.

Notes

Only superusers can create event triggers.
Event triggers are disabled in single-user mode (see postgres). If an erroneous event trigger disables the database so much that you can't even drop the trigger, restart in single-user mode and you'll be able to do that.

Examples

Forbid the execution of any DDL command:

```sql
CREATE OR REPLACE FUNCTION abort_any_command()
    RETURNS event_trigger
    LANGUAGE plpgsql
    AS $$
BEGIN
    RAISE EXCEPTION 'command % is disabled', tg_tag;
END;
$$;

CREATE EVENT TRIGGER abort_ddl ON ddl_command_start
    EXECUTE FUNCTION abort_any_command();
```

Compatibility

There is no CREATE EVENT TRIGGER statement in the SQL standard.

See Also

ALTER EVENT TRIGGER, DROP EVENT TRIGGER, CREATE FUNCTION
CREATE EXTENSION

CREATE EXTENSION — install an extension

Synopsis

CREATE EXTENSION [ IF NOT EXISTS ] extension_name
    [ WITH ] [ SCHEMA schema_name ]
    [ VERSION version ]
    [ CASCADE ]

Description

CREATE EXTENSION loads a new extension into the current database. There must not be an extension of the same name already loaded.

Loading an extension essentially amounts to running the extension's script file. The script will typically create new SQL objects such as functions, data types, operators and index support methods. CREATE EXTENSION additionally records the identities of all the created objects, so that they can be dropped again if DROP EXTENSION is issued.

The user who runs CREATE EXTENSION becomes the owner of the extension for purposes of later privilege checks, and normally also becomes the owner of any objects created by the extension's script.

Loading an extension ordinarily requires the same privileges that would be required to create its component objects. For many extensions this means superuser privileges are needed. However, if the extension is marked trusted in its control file, then it can be installed by any user who has CREATE privilege on the current database. In this case the extension object itself will be owned by the calling user, but the contained objects will be owned by the bootstrap superuser (unless the extension's script explicitly assigns them to the calling user). This configuration gives the calling user the right to drop the extension, but not to modify individual objects within it.

Parameters

IF NOT EXISTS

Do not throw an error if an extension with the same name already exists. A notice is issued in this case. Note that there is no guarantee that the existing extension is anything like the one that would have been created from the currently-available script file.

extension_name

The name of the extension to be installed. PostgreSQL will create the extension using details from the file $SHAREDIR/extension/extension_name.control.$

schema_name

The name of the schema in which to install the extension's objects, given that the extension allows its contents to be relocated. The named schema must already exist. If not specified, and the extension's control file does not specify a schema either, the current default object creation schema is used.
CREATE EXTENSION

If the extension specifies a schema parameter in its control file, then that schema cannot be overridden with a SCHEMA clause. Normally, an error will be raised if a SCHEMA clause is given and it conflicts with the extension's schema parameter. However, if the CASCADE clause is also given, then schema_name is ignored when it conflicts. The given schema_name will be used for installation of any needed extensions that do not specify schema in their control files.

Remember that the extension itself is not considered to be within any schema: extensions have unqualified names that must be unique database-wide. But objects belonging to the extension can be within schemas.

version

The version of the extension to install. This can be written as either an identifier or a string literal. The default version is whatever is specified in the extension's control file.

CASCADE

Automatically install any extensions that this extension depends on that are not already installed. Their dependencies are likewise automatically installed, recursively. The SCHEMA clause, if given, applies to all extensions that get installed this way. Other options of the statement are not applied to automatically-installed extensions; in particular, their default versions are always selected.

Notes

Before you can use CREATE EXTENSION to load an extension into a database, the extension's supporting files must be installed. Information about installing the extensions supplied with PostgreSQL can be found in Additional Supplied Modules.

The extensions currently available for loading can be identified from the pg_available_extensions or pg_available_extension_versions system views.

Caution

Installing an extension as superuser requires trusting that the extension's author wrote the extension installation script in a secure fashion. It is not terribly difficult for a malicious user to create trojan-horse objects that will compromise later execution of a carelessly-written extension script, allowing that user to acquire superuser privileges. However, trojan-horse objects are only hazardous if they are in the search_path during script execution, meaning that they are in the extension's installation target schema or in the schema of some extension it depends on. Therefore, a good rule of thumb when dealing with extensions whose scripts have not been carefully vetted is to install them only into schemas for which CREATE privilege has not been and will not be granted to any untrusted users. Likewise for any extensions they depend on.

The extensions supplied with PostgreSQL are believed to be secure against installation-time attacks of this sort, except for a few that depend on other extensions. As stated in the documentation for those extensions, they should be installed into secure schemas, or installed into the same schemas as the extensions they depend on, or both.

For information about writing new extensions, see Section 38.17.

Examples

Install the hstore extension into the current database, placing its objects in schema addons:
CREATE EXTENSION hstore SCHEMA addons;

Another way to accomplish the same thing:

SET search_path = addons;
CREATE EXTENSION hstore;

Compatibility

CREATE EXTENSION is a PostgreSQL extension.

See Also

ALTER EXTENSION, DROP EXTENSION
CREATE FOREIGN DATA WRAPPER

CREATE FOREIGN DATA WRAPPER — define a new foreign-data wrapper

Synopsis

CREATE FOREIGN DATA WRAPPER name
[ HANDLER handler_function | NO HANDLER ]
[ VALIDATOR validator_function | NO VALIDATOR ]
[ OPTIONS ( option 'value' [, ... ] ) ]

Description

CREATE FOREIGN DATA WRAPPER creates a new foreign-data wrapper. The user who defines a foreign-data wrapper becomes its owner.

The foreign-data wrapper name must be unique within the database.

Only superusers can create foreign-data wrappers.

Parameters

name

The name of the foreign-data wrapper to be created.

HANDLER handler_function

handler_function is the name of a previously registered function that will be called to retrieve the execution functions for foreign tables. The handler function must take no arguments, and its return type must be fdw_handler.

It is possible to create a foreign-data wrapper with no handler function, but foreign tables using such a wrapper can only be declared, not accessed.

VALIDATOR validator_function

validator_function is the name of a previously registered function that will be called to check the generic options given to the foreign-data wrapper, as well as options for foreign servers, user mappings and foreign tables using the foreign-data wrapper. If no validator function or NO VALIDATOR is specified, then options will not be checked at creation time. (Foreign-data wrappers will possibly ignore or reject invalid option specifications at run time, depending on the implementation.) The validator function must take two arguments: one of type text[], which will contain the array of options as stored in the system catalogs, and one of type oid, which will be the OID of the system catalog containing the options. The return type is ignored; the function should report invalid options using the ereport (ERROR) function.

OPTIONS ( option 'value' [, ... ] )

This clause specifies options for the new foreign-data wrapper. The allowed option names and values are specific to each foreign data wrapper and are validated using the foreign-data wrapper's validator function. Option names must be unique.
Notes

PostgreSQL’s foreign-data functionality is still under active development. Optimization of queries is primitive (and mostly left to the wrapper, too). Thus, there is considerable room for future performance improvements.

Examples

Create a useless foreign-data wrapper dummy:

```
CREATE FOREIGN DATA WRAPPER dummy;
```

Create a foreign-data wrapper file with handler function file_fdw_handler:

```
CREATE FOREIGN DATA WRAPPER file HANDLER file_fdw_handler;
```

Create a foreign-data wrapper mywrapper with some options:

```
CREATE FOREIGN DATA WRAPPER mywrapper
  OPTIONS (debug 'true');
```

Compatibility

CREATE FOREIGN DATA WRAPPER conforms to ISO/IEC 9075-9 (SQL/MED), with the exception that the HANDLER and VALIDATOR clauses are extensions and the standard clauses LIBRARY and LANGUAGE are not implemented in PostgreSQL.

Note, however, that the SQL/MED functionality as a whole is not yet conforming.

[ OPTIONS ( option 'value' [, ... ] ) ]

where column_constraint is:

[ CONSTRAINT constraint_name ]
{ NOT NULL | 
  NULL | 
  CHECK ( expression ) [ NO INHERIT ] | 
  DEFAULT default_expr | 
  GENERATED ALWAYS AS ( generation_expr ) STORED } 

and table_constraint is:

[ CONSTRAINT constraint_name ]
CHECK ( expression ) [ NO INHERIT ] 

and partition_bound_spec is:

IN ( partition_bound_expr [, ... ] ) 
| 
FROM ( { partition_bound_expr | MINVALUE | MAXVALUE } [, ... ] ) 
| 
TO ( { partition_bound_expr | MINVALUE | MAXVALUE } [, ... ] ) 
| 
WITH ( MODULUS numeric_literal, REMAINDER numeric_literal )
CREATE FOREIGN TABLE

Description

CREATE FOREIGN TABLE creates a new foreign table in the current database. The table will be owned by the user issuing the command.

If a schema name is given (for example, CREATE FOREIGN TABLE myschema.mytable ...) then the table is created in the specified schema. Otherwise it is created in the current schema. The name of the foreign table must be distinct from the name of any other relation (table, sequence, index, view, materialized view, or foreign table) in the same schema.

CREATE FOREIGN TABLE also automatically creates a data type that represents the composite type corresponding to one row of the foreign table. Therefore, foreign tables cannot have the same name as any existing data type in the same schema.

If PARTITION OF clause is specified then the table is created as a partition of parent_table with specified bounds.

To be able to create a foreign table, you must have USAGE privilege on the foreign server, as well as USAGE privilege on all column types used in the table.

Parameters

IF NOT EXISTS

Do not throw an error if a relation with the same name already exists. A notice is issued in this case. Note that there is no guarantee that the existing relation is anything like the one that would have been created.

table_name

The name (optionally schema-qualified) of the table to be created.

column_name

The name of a column to be created in the new table.

data_type

The data type of the column. This can include array specifiers. For more information on the data types supported by PostgreSQL, refer to Chapter 8.

COLLATE collation

The COLLATE clause assigns a collation to the column (which must be of a collatable data type). If not specified, the column data type's default collation is used.

INHERITS ( parent_table [, ... ] )

The optional INHERITS clause specifies a list of tables from which the new foreign table automatically inherits all columns. Parent tables can be plain tables or foreign tables. See the similar form of CREATE TABLE for more details.

PARTITION OF parent_table { FOR VALUES partition_bound_spec | DEFAULT }

This form can be used to create the foreign table as partition of the given parent table with specified partition bound values. See the similar form of CREATE TABLE for more details. Note that it is currently not allowed to create the foreign table as a partition of the parent table if there are UNIQUE indexes on the parent table. (See also ALTER TABLE ATTACH PARTITION.)
CONSTRAINT constraint_name

An optional name for a column or table constraint. If the constraint is violated, the constraint name is present in error messages, so constraint names like col must be positive can be used to communicate helpful constraint information to client applications. (Double-quotes are needed to specify constraint names that contain spaces.) If a constraint name is not specified, the system generates a name.

NOT NULL

The column is not allowed to contain null values.

NULL

The column is allowed to contain null values. This is the default.

This clause is only provided for compatibility with non-standard SQL databases. Its use is discouraged in new applications.

CHECK ( expression ) [ NO INHERIT ]

The CHECK clause specifies an expression producing a Boolean result which each row in the foreign table is expected to satisfy; that is, the expression should produce TRUE or UNKNOWN, never FALSE, for all rows in the foreign table. A check constraint specified as a column constraint should reference that column's value only, while an expression appearing in a table constraint can reference multiple columns.

Currently, CHECK expressions cannot contain subqueries nor refer to variables other than columns of the current row. The system column tableoid may be referenced, but not any other system column.

A constraint marked with NO INHERIT will not propagate to child tables.

DEFAULT default_expr

The DEFAULT clause assigns a default data value for the column whose column definition it appears within. The value is any variable-free expression (subqueries and cross-references to other columns in the current table are not allowed). The data type of the default expression must match the data type of the column.

The default expression will be used in any insert operation that does not specify a value for the column. If there is no default for a column, then the default is null.

GENERATED ALWAYS AS ( generation_expr ) STORED

This clause creates the column as a generated column. The column cannot be written to, and when read the result of the specified expression will be returned.

The keyword STORED is required to signify that the column will be computed on write. (The computed value will be presented to the foreign-data wrapper for storage and must be returned on reading.)

The generation expression can refer to other columns in the table, but not other generated columns. Any functions and operators used must be immutable. References to other tables are not allowed.

server_name

The name of an existing foreign server to use for the foreign table. For details on defining a server, see CREATE SERVER.
CREATE FOREIGN TABLE

OPTIONS ( option 'value' [, ... ] )

Options to be associated with the new foreign table or one of its columns. The allowed option names and values are specific to each foreign data wrapper and are validated using the foreign-data wrapper's validator function. Duplicate option names are not allowed (although it's OK for a table option and a column option to have the same name).

Notes

Constraints on foreign tables (such as CHECK or NOT NULL clauses) are not enforced by the core PostgreSQL system, and most foreign data wrappers do not attempt to enforce them either; that is, the constraint is simply assumed to hold true. There would be little point in such enforcement since it would only apply to rows inserted or updated via the foreign table, and not to rows modified by other means, such as directly on the remote server. Instead, a constraint attached to a foreign table should represent a constraint that is being enforced by the remote server.

Some special-purpose foreign data wrappers might be the only access mechanism for the data they access, and in that case it might be appropriate for the foreign data wrapper itself to perform constraint enforcement. But you should not assume that a wrapper does that unless its documentation says so.

Although PostgreSQL does not attempt to enforce constraints on foreign tables, it does assume that they are correct for purposes of query optimization. If there are rows visible in the foreign table that do not satisfy a declared constraint, queries on the table might produce errors or incorrect answers. It is the user's responsibility to ensure that the constraint definition matches reality.

Caution

When a foreign table is used as a partition of a partitioned table, there is an implicit constraint that its contents must satisfy the partitioning rule. Again, it is the user's responsibility to ensure that that is true, which is best done by installing a matching constraint on the remote server.

Within a partitioned table containing foreign-table partitions, an UPDATE that changes the partition key value can cause a row to be moved from a local partition to a foreign-table partition, provided the foreign data wrapper supports tuple routing. However it is not currently possible to move a row from a foreign-table partition to another partition. An UPDATE that would require doing that will fail due to the partitioning constraint, assuming that that is properly enforced by the remote server.

Similar considerations apply to generated columns. Stored generated columns are computed on insert or update on the local PostgreSQL server and handed to the foreign-data wrapper for writing out to the foreign data store, but it is not enforced that a query of the foreign table returns values for stored generated columns that are consistent with the generation expression. Again, this might result in incorrect query results.

Examples

Create foreign table films, which will be accessed through the server film_server:

CREATE FOREIGN TABLE films {
    code char(5) NOT NULL,
    title varchar(40) NOT NULL,
    did integer NOT NULL,
    date_prod date,
}

1757
CREATE FOREIGN TABLE

    kind        varchar(10),
    len         interval hour to minute
)
SERVER film_server;

Create foreign table measurement_y2016m07, which will be accessed through the server server_07, as a partition of the range partitioned table measurement:

CREATE FOREIGN TABLE measurement_y2016m07
    PARTITION OF measurement FOR VALUES FROM ('2016-07-01') TO ('2016-08-01')
    SERVER server_07;

Compatibility

The CREATE FOREIGN TABLE command largely conforms to the SQL standard; however, much as with CREATE TABLE, NULL constraints and zero-column foreign tables are permitted. The ability to specify column default values is also a PostgreSQL extension. Table inheritance, in the form defined by PostgreSQL, is nonstandard.

See Also

ALTER FOREIGN TABLE, DROP FOREIGN TABLE, CREATE TABLE, CREATE SERVER, IMPORT FOREIGN SCHEMA
CREATE FUNCTION

CREATE FUNCTION — define a new function

Synopsis

CREATE [ OR REPLACE ] FUNCTION
  name ( [ [ argmode ] [ argname ] argtype [ { DEFAULT | = } default_expr ] [, ...] ] )
  [ RETURNS rettype
    | RETURNS TABLE ( column_name column_type [, ...] ) ]
  { LANGUAGE lang_name
    | TRANSFORM { FOR TYPE type_name } [, ...] }
  WINDOW
  { IMMUTABLE | STABLE | VOLATILE }
  [ NOT ] LEAKPROOF
  { CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }
  { [ EXTERNAL ] SECURITY INVOKER | [ EXTERNAL ] SECURITY DEFINER }
  PARALLEL { UNSAFE | RESTRICTED | SAFE }
  COST execution_cost
  ROWS result_rows
  SUPPORT support_function
  SET configuration_parameter { TO value | = value | FROM CURRENT }
  AS 'definition'
  AS 'obj_file', 'link_symbol'
  | sql_body
  ...
or implied in the command. You must own the function to replace it (this includes being a member of the owning role).

If you drop and then recreate a function, the new function is not the same entity as the old; you will have to drop existing rules, views, triggers, etc. that refer to the old function. Use CREATE OR REPLACE FUNCTION to change a function definition without breaking objects that refer to the function. Also, ALTER FUNCTION can be used to change most of the auxiliary properties of an existing function.

The user that creates the function becomes the owner of the function.

To be able to create a function, you must have USAGE privilege on the argument types and the return type. Refer to Section 38.3 for further information on writing functions.

Parameters

ame

The name (optionally schema-qualified) of the function to create.

argmode

The mode of an argument: IN, OUT, INOUT, or VARIADIC. If omitted, the default is IN. Only OUT arguments can follow a VARIADIC one. Also, OUT and INOUT arguments cannot be used together with the RETURNS TABLE notation.

argname

The name of an argument. Some languages (including SQL and PL/pgSQL) let you use the name in the function body. For other languages the name of an input argument is just extra documentation, so far as the function itself is concerned; but you can use input argument names when calling a function to improve readability (see Section 4.3). In any case, the name of an output argument is significant, because it defines the column name in the result row type. (If you omit the name for an output argument, the system will choose a default column name.)

argtype

The data type(s) of the function's arguments (optionally schema-qualified), if any. The argument types can be base, composite, or domain types, or can reference the type of a table column.

Depending on the implementation language it might also be allowed to specify "pseudo-types" such as cstring. Pseudo-types indicate that the actual argument type is either incompletely specified, or outside the set of ordinary SQL data types.

The type of a column is referenced by writing table_name.column_name%TYPE. Using this feature can sometimes help make a function independent of changes to the definition of a table.

default_expr

An expression to be used as default value if the parameter is not specified. The expression has to be coercible to the argument type of the parameter. Only input (including INOUT) parameters can have a default value. All input parameters following a parameter with a default value must have default values as well.

rettype

The return data type (optionally schema-qualified). The return type can be a base, composite, or domain type, or can reference the type of a table column. Depending on the implementation language it
might also be allowed to specify “pseudo-types” such as `cstring`. If the function is not supposed to return a value, specify `void` as the return type.

When there are `OUT` or `INOUT` parameters, the `RETURNS` clause can be omitted. If present, it must agree with the result type implied by the output parameters: `RECORD` if there are multiple output parameters, or the same type as the single output parameter.

The `SETOF` modifier indicates that the function will return a set of items, rather than a single item.

The type of a column is referenced by writing `table_name.column_name%TYPE`.

`column_name`:

The name of an output column in the `RETURNS TABLE` syntax. This is effectively another way of declaring a named `OUT` parameter, except that `RETURNS TABLE` also implies `RETURNS SETOF`.

`column_type`:

The data type of an output column in the `RETURNS TABLE` syntax.

`lang_name`:

The name of the language that the function is implemented in. It can be `sql`, `c`, `internal`, or the name of a user-defined procedural language, e.g., `plpgsql`. The default is `sql` if `sql_body` is specified. Enclosing the name in single quotes is deprecated and requires matching case.

`TRANSFORM { FOR TYPE type_name } [, ... ]`:

Lists which transforms a call to the function should apply. Transforms convert between SQL types and language-specific data types; see `CREATE TRANSFORM`. Procedural language implementations usually have hardcoded knowledge of the built-in types, so those don't need to be listed here. If a procedural language implementation does not know how to handle a type and no transform is supplied, it will fall back to a default behavior for converting data types, but this depends on the implementation.

`WINDOW`:

`WINDOW` indicates that the function is a `window function` rather than a plain function. This is currently only useful for functions written in C. The `WINDOW` attribute cannot be changed when replacing an existing function definition.

`IMMUTABLE`:

These attributes inform the query optimizer about the behavior of the function. At most one choice can be specified. If none of these appear, `VOLATILE` is the default assumption.

`IMMUTABLE` indicates that the function cannot modify the database and always returns the same result when given the same argument values; that is, it does not do database lookups or otherwise use information not directly present in its argument list. If this option is given, any call of the function with all-constant arguments can be immediately replaced with the function value.

`STABLE` indicates that the function cannot modify the database, and that within a single table scan it will consistently return the same result for the same argument values, but that its result could change across SQL statements. This is the appropriate selection for functions whose results depend on database lookups, parameter variables (such as the current time zone), etc. (It is inappropriate for AF–
TER triggers that wish to query rows modified by the current command.) Also note that the current_timestamp family of functions qualify as stable, since their values do not change within a transaction.

VOLATILE indicates that the function value can change even within a single table scan, so no optimizations can be made. Relatively few database functions are volatile in this sense; some examples are random(), currval(), timeofday(). But note that any function that has side-effects must be classified volatile, even if its result is quite predictable, to prevent calls from being optimized away; an example is setval().

For additional details see Section 38.7.

LEAKPROOF

LEAKPROOF indicates that the function has no side effects. It reveals no information about its arguments other than by its return value. For example, a function which throws an error message for some argument values but not others, or which includes the argument values in any error message, is not leakproof. This affects how the system executes queries against views created with the security_barrier option or tables with row level security enabled. The system will enforce conditions from security policies and security barrier views before any user-supplied conditions from the query itself that contain non-leakproof functions, in order to prevent the inadvertent exposure of data. Functions and operators marked as leakproof are assumed to be trustworthy, and may be executed before conditions from security policies and security barrier views. In addition, functions which do not take arguments or which are not passed any arguments from the security barrier view or table do not have to be marked as leakproof to be executed before security conditions. See CREATE VIEW and Section 41.5. This option can only be set by the superuser.

CALLED ON NULL INPUT
RETURNS NULL ON NULL INPUT
STRICT

CALLED ON NULL INPUT (the default) indicates that the function will be called normally when some of its arguments are null. It is then the function author's responsibility to check for null values if necessary and respond appropriately.

RETURNS NULL ON NULL INPUT or STRICT indicates that the function always returns null whenever any of its arguments are null. If this parameter is specified, the function is not executed when there are null arguments; instead a null result is assumed automatically.

[EXTERNAL] SECURITY INVOKER
[EXTERNAL] SECURITY DEFINER

SECURITY INVOKER indicates that the function is to be executed with the privileges of the user that calls it. That is the default. SECURITY DEFINER specifies that the function is to be executed with the privileges of the user that owns it.

The key word EXTERNAL is allowed for SQL conformance, but it is optional since, unlike in SQL, this feature applies to all functions not only external ones.

PARALLEL

PARALLEL UNSAFE indicates that the function can't be executed in parallel mode and the presence of such a function in an SQL statement forces a serial execution plan. This is the default. PARALLEL RESTRICTED indicates that the function can be executed in parallel mode, but the execution is restricted to parallel group leader. PARALLEL SAFE indicates that the function is safe to run in parallel mode without restriction.
CREATE FUNCTION

Functions should be labeled parallel unsafe if they modify any database state, or if they make changes to the transaction such as using sub-transactions, or if they access sequences or attempt to make persistent changes to settings (e.g., setval). They should be labeled as parallel restricted if they access temporary tables, client connection state, cursors, prepared statements, or miscellaneous backend-local state which the system cannot synchronize in parallel mode (e.g., setseed cannot be executed other than by the group leader because a change made by another process would not be reflected in the leader). In general, if a function is labeled as being safe when it is restricted or unsafe, or if it is labeled as being restricted when it is in fact unsafe, it may throw errors or produce wrong answers when used in a parallel query. C-language functions could in theory exhibit totally undefined behavior if mislabeled, since there is no way for the system to protect itself against arbitrary C code, but in most likely cases the result will be no worse than for any other function. If in doubt, functions should be labeled as UNSAFE, which is the default.

COST execution_cost

A positive number giving the estimated execution cost for the function, in units of cpu_operator_cost. If the function returns a set, this is the cost per returned row. If the cost is not specified, 1 unit is assumed for C-language and internal functions, and 100 units for functions in all other languages. Larger values cause the planner to try to avoid evaluating the function more often than necessary.

ROWS result_rows

A positive number giving the estimated number of rows that the planner should expect the function to return. This is only allowed when the function is declared to return a set. The default assumption is 1000 rows.

SUPPORT support_function

The name (optionally schema-qualified) of a planner support function to use for this function. See Section 38.11 for details. You must be superuser to use this option.

configuration_parameter value

The SET clause causes the specified configuration parameter to be set to the specified value when the function is entered, and then restored to its prior value when the function exits. SET FROM CURRENT saves the value of the parameter that is current when CREATE FUNCTION is executed as the value to be applied when the function is entered.

If a SET clause is attached to a function, then the effects of a SET LOCAL command executed inside the function for the same variable are restricted to the function: the configuration parameter's prior value is still restored at function exit. However, an ordinary SET command (without LOCAL) overrides the SET clause, much as it would do for a previous SET LOCAL command: the effects of such a command will persist after function exit, unless the current transaction is rolled back.

See SET and Chapter 20 for more information about allowed parameter names and values.

definition

A string constant defining the function; the meaning depends on the language. It can be an internal function name, the path to an object file, an SQL command, or text in a procedural language.

It is often helpful to use dollar quoting (see Section 4.1.2.4) to write the function definition string, rather than the normal single quote syntax. Without dollar quoting, any single quotes or backslashes in the function definition must be escaped by doubling them.
CREATE FUNCTION

$obj_file, link_symbol$

This form of the AS clause is used for dynamically loadable C language functions when the function name in the C language source code is not the same as the name of the SQL function. The string $obj_file$ is the name of the shared library file containing the compiled C function, and is interpreted as for the LOAD command. The string $link_symbol$ is the function's link symbol, that is, the name of the function in the C language source code. If the link symbol is omitted, it is assumed to be the same as the name of the SQL function being defined. The C names of all functions must be different, so you must give overloaded C functions different C names (for example, use the argument types as part of the C names).

When repeated CREATE FUNCTION calls refer to the same object file, the file is only loaded once per session. To unload and reload the file (perhaps during development), start a new session.

$sql_body$

The body of a LANGUAGE SQL function. This can either be a single statement

\[
\text{RETURN expression}
\]

or a block

\[
\text{BEGIN ATOMIC}
\begin{align*}
\text{statement;} \\
\text{statement;} \\
\ldots \\
\text{statement;}
\end{align*}
\text{END}
\]

This is similar to writing the text of the function body as a string constant (see definition above), but there are some differences: This form only works for LANGUAGE SQL, the string constant form works for all languages. This form is parsed at function definition time, the string constant form is parsed at execution time; therefore this form cannot support polymorphic argument types and other constructs that are not resolvable at function definition time. This form tracks dependencies between the function and objects used in the function body, so DROP ... CASCADE will work correctly, whereas the form using string literals may leave dangling functions. Finally, this form is more compatible with the SQL standard and other SQL implementations.

Overloading

PostgreSQL allows function overloading; that is, the same name can be used for several different functions so long as they have distinct input argument types. Whether or not you use it, this capability entails security precautions when calling functions in databases where some users mistrust other users; see Section 10.3.

Two functions are considered the same if they have the same names and input argument types, ignoring any OUT parameters. Thus for example these declarations conflict:

\[
\text{CREATE FUNCTION foo(int) ...} \\
\text{CREATE FUNCTION foo(int, out text) ...}
\]

Functions that have different argument type lists will not be considered to conflict at creation time, but if defaults are provided they might conflict in use. For example, consider
CREATE FUNCTION foo(int) ...
CREATE FUNCTION foo(int, int default 42) ...

A call `foo(10)` will fail due to the ambiguity about which function should be called.

**Notes**

The full SQL type syntax is allowed for declaring a function's arguments and return value. However, parenthesized type modifiers (e.g., the precision field for type `numeric`) are discarded by `CREATE FUNCTION`. Thus for example `CREATE FUNCTION foo (varchar(10)) ...` is exactly the same as `CREATE FUNCTION foo (varchar) ...`.

When replacing an existing function with `CREATE OR REPLACE FUNCTION`, there are restrictions on changing parameter names. You cannot change the name already assigned to any input parameter (although you can add names to parameters that had none before). If there is more than one output parameter, you cannot change the names of the output parameters, because that would change the column names of the anonymous composite type that describes the function's result. These restrictions are made to ensure that existing calls of the function do not stop working when it is replaced.

If a function is declared `STRICT` with a `VARIADIC` argument, the strictness check tests that the variadic array as a whole is non-null. The function will still be called if the array has null elements.

**Examples**

Add two integers using an SQL function:

```sql
CREATE FUNCTION add(integer, integer) RETURNS integer
  AS 'select $1 + $2;'
  LANGUAGE SQL
  IMMUTABLE
  RETURNS NULL ON NULL INPUT;
```

The same function written in a more SQL-conforming style, using argument names and an unquoted body:

```sql
CREATE FUNCTION add(a integer, b integer) RETURNS integer
  LANGUAGE SQL
  IMMUTABLE
  RETURNS NULL ON NULL INPUT
  RETURN a + b;
```

Increment an integer, making use of an argument name, in PL/pgSQL:

```sql
CREATE OR REPLACE FUNCTION increment(i integer) RETURNS integer AS $$
BEGIN
  RETURN i + 1;
END;
$$ LANGUAGE plpgsql;
```

Return a record containing multiple output parameters:
CREATE FUNCTION dup(in int, out f1 int, out f2 text)
    AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
    LANGUAGE SQL;

SELECT * FROM dup(42);

You can do the same thing more verbosely with an explicitly named composite type:

CREATE TYPE dup_result AS (f1 int, f2 text);

CREATE FUNCTION dup(int) RETURNS dup_result
    AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
    LANGUAGE SQL;

SELECT * FROM dup(42);

Another way to return multiple columns is to use a TABLE function:

CREATE FUNCTION dup(int) RETURNS TABLE(f1 int, f2 text)
    AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
    LANGUAGE SQL;

SELECT * FROM dup(42);

However, a TABLE function is different from the preceding examples, because it actually returns a set of
records, not just one record.

**Writing SECURITY DEFINER Functions Safely**

Because a SECURITY DEFINER function is executed with the privileges of the user that owns it, care is
needed to ensure that the function cannot be misused. For security, search_path should be set to exclude
any schemas writable by untrusted users. This prevents malicious users from creating objects (e.g., tables,
functions, and operators) that mask objects intended to be used by the function. Particularly important in
this regard is the temporary-table schema, which is searched first by default, and is normally writable by
anyone. A secure arrangement can be obtained by forcing the temporary schema to be searched last. To
do this, write pg_temp as the last entry in search_path. This function illustrates safe usage:

CREATE FUNCTION check_password(uname TEXT, pass TEXT)
RETURNS BOOLEAN AS $$
DECLARE passed BOOLEAN;
BEGIN
    SELECT (pwd = $2) INTO passed
    FROM pwds
    WHERE username = $1;

    RETURN passed;
END;
$$
LANGUAGE plpgsql
SECURITY DEFINER
-- Set a secure search_path: trusted schema(s), then 'pg_temp'.
SET search_path = admin, pg_temp;
CREATE FUNCTION
This function's intention is to access a table `admin.pwds`. But without the `SET` clause, or with a `SET` clause mentioning only `admin`, the function could be subverted by creating a temporary table named `pwds`.

Before PostgreSQL version 8.3, the `SET` clause was not available, and so older functions may contain rather complicated logic to save, set, and restore `search_path`. The `SET` clause is far easier to use for this purpose.

Another point to keep in mind is that by default, execute privilege is granted to `PUBLIC` for newly created functions (see Section 5.7 for more information). Frequently you will wish to restrict use of a security definer function to only some users. To do that, you must revoke the default `PUBLIC` privileges and then grant execute privilege selectively. To avoid having a window where the new function is accessible to all, create it and set the privileges within a single transaction. For example:

```sql
BEGIN;
CREATE FUNCTION check_password(uname TEXT, pass TEXT) ... SECURITY DEFINER;
REVOKE ALL ON FUNCTION check_password(uname TEXT, pass TEXT) FROM PUBLIC;
GRANT EXECUTE ON FUNCTION check_password(uname TEXT, pass TEXT) TO admins;
COMMIT;
```

Compatibility
A `CREATE FUNCTION` command is defined in the SQL standard. The PostgreSQL implementation can be used in a compatible way but has many extensions. Conversely, the SQL standard specifies a number of optional features that are not implemented in PostgreSQL.

The following are important compatibility issues:

- `OR REPLACE` is a PostgreSQL extension.
- For compatibility with some other database systems, `argmode` can be written either before or after `argname`. But only the first way is standard-compliant.
- For parameter defaults, the SQL standard specifies only the syntax with the `DEFAULT` keyword. The syntax with `=` is used in T-SQL and Firebird.
- The `SETOF` modifier is a PostgreSQL extension.
- Only `SQL` is standardized as a language.
- All other attributes except `CALLED ON NULL INPUT` and `RETURNS NULL ON NULL INPUT` are not standardized.
- For the body of `LANGUAGE SQL` functions, the SQL standard only specifies the `sql_body` form.

Simple `LANGUAGE SQL` functions can be written in a way that is both standard-conforming and portable to other implementations. More complex functions using advanced features, optimization attributes, or other languages will necessarily be specific to PostgreSQL in a significant way.

CREATE GROUP

CREATE GROUP — define a new database role

Synopsis

```
CREATE GROUP name [ [ WITH ] option [ ... ] ]
```

where option can be:

```
SUPERUSER | NOSUPERUSER
CREATEDB | NOCREATEDB
CREATEROLE | NOCREATEROLE
INHERIT | NOINHERIT
LOGIN | NOLOGIN
REPLICATION | NOREPLICATION
BYPASSRLS | NOBYPASSRLS
CONNECTION LIMIT connlimit
[ ENCRYPTED ] PASSWORD 'password' | PASSWORD NULL
VALID UNTIL 'timestamp'
IN ROLE role_name [, ...]
IN GROUP role_name [, ...]
ROLE role_name [, ...]
ADMIN role_name [, ...]
USER role_name [, ...]
SYSID uid
```

Description

CREATE GROUP is now an alias for CREATE ROLE.

Compatibility

There is no CREATE GROUP statement in the SQL standard.

See Also

CREATE ROLE
CREATE INDEX

CREATE INDEX — define a new index

Synopsis

```
CREATE [ UNIQUE ] INDEX [ CONCURRENTLY ] [ [ IF NOT EXISTS ] name ] ON
[ ONLY ] table_name [ USING method ]
( { column_name | ( expression ) } [ COLLATE collation ] [ opclass
[ ( opclass_parameter = value [, ... ] ) ] ] [ ASC | DESC ] [ NULLS
( FIRST | LAST ) ] [, ... ] )
[ INCLUDE ( column_name [, ... ] ) ]
[ NULLS [ NOT ] DISTINCT ]
[ WITH ( storage_parameter [= value] [, ... ] ) ]
[ TABLESPACE tablespace_name ]
[ WHERE predicate ]
```

Description

CREATE INDEX constructs an index on the specified column(s) of the specified relation, which can be a table or a materialized view. Indexes are primarily used to enhance database performance (though inappropriate use can result in slower performance).

The key field(s) for the index are specified as column names, or alternatively as expressions written in parentheses. Multiple fields can be specified if the index method supports multicolumn indexes.

An index field can be an expression computed from the values of one or more columns of the table row. This feature can be used to obtain fast access to data based on some transformation of the basic data. For example, an index computed on `upper(col)` would allow the clause `WHERE upper(col) = 'JIM'` to use an index.

PostgreSQL provides the index methods B-tree, hash, GiST, SP-GiST, GIN, and BRIN. Users can also define their own index methods, but that is fairly complicated.

When the `WHERE` clause is present, a partial index is created. A partial index is an index that contains entries for only a portion of a table, usually a portion that is more useful for indexing than the rest of the table. For example, if you have a table that contains both billed and unbilled orders where the unbilled orders take up a small fraction of the total table and yet that is an often used section, you can improve performance by creating an index on just that portion. Another possible application is to use `WHERE` with `UNIQUE` to enforce uniqueness over a subset of a table. See Section 11.8 for more discussion.

The expression used in the `WHERE` clause can refer only to columns of the underlying table, but it can use all columns, not just the ones being indexed. Presently, subqueries and aggregate expressions are also forbidden in `WHERE`. The same restrictions apply to index fields that are expressions.

All functions and operators used in an index definition must be “immutable”, that is, their results must depend only on their arguments and never on any outside influence (such as the contents of another table or the current time). This restriction ensures that the behavior of the index is well-defined. To use a user-defined function in an index expression or `WHERE` clause, remember to mark the function immutable when you create it.
CREATE INDEX

Parameters

**UNIQUE**

Causes the system to check for duplicate values in the table when the index is created (if data already exist) and each time data is added. Attempts to insert or update data which would result in duplicate entries will generate an error.

Additional restrictions apply when unique indexes are applied to partitioned tables; see CREATE TABLE.

**CONCURRENTLY**

When this option is used, PostgreSQL will build the index without taking any locks that prevent concurrent inserts, updates, or deletes on the table; whereas a standard index build locks out writes (but not reads) on the table until it's done. There are several caveats to be aware of when using this option — see Building Indexes Concurrently below.

For temporary tables, CREATE INDEX is always non-concurrent, as no other session can access them, and non-concurrent index creation is cheaper.

**IF NOT EXISTS**

Do not throw an error if a relation with the same name already exists. A notice is issued in this case. Note that there is no guarantee that the existing index is anything like the one that would have been created. Index name is required when IF NOT EXISTS is specified.

**INCLUDE**

The optional INCLUDE clause specifies a list of columns which will be included in the index as non-key columns. A non-key column cannot be used in an index scan search qualification, and it is disregarded for purposes of any uniqueness or exclusion constraint enforced by the index. However, an index-only scan can return the contents of non-key columns without having to visit the index's table, since they are available directly from the index entry. Thus, addition of non-key columns allows index-only scans to be used for queries that otherwise could not use them.

It's wise to be conservative about adding non-key columns to an index, especially wide columns. If an index tuple exceeds the maximum size allowed for the index type, data insertion will fail. In any case, non-key columns duplicate data from the index's table and bloat the size of the index, thus potentially slowing searches. Furthermore, B-tree deduplication is never used with indexes that have a non-key column.

Columns listed in the INCLUDE clause don't need appropriate operator classes; the clause can include columns whose data types don't have operator classes defined for a given access method.

Expressions are not supported as included columns since they cannot be used in index-only scans.

Currently, the B-tree, GiST and SP-GiST index access methods support this feature. In these indexes, the values of columns listed in the INCLUDE clause are included in leaf tuples which correspond to heap tuples, but are not included in upper-level index entries used for tree navigation.

**name**

The name of the index to be created. No schema name can be included here; the index is always created in the same schema as its parent table. The name of the index must be distinct from the name
CREATE INDEX

of any other relation (table, sequence, index, view, materialized view, or foreign table) in that schema. If the name is omitted, PostgreSQL chooses a suitable name based on the parent table’s name and the indexed column name(s).

ONLY

Indicates not to recurse creating indexes on partitions, if the table is partitioned. The default is to recurse.

table_name

The name (possibly schema-qualified) of the table to be indexed.

method

The name of the index method to be used. Choices are btree, hash, gist, spgist, gin, and brin. The default method is btree.

column_name

The name of a column of the table.

evaluation

An expression based on one or more columns of the table. The expression usually must be written with surrounding parentheses, as shown in the syntax. However, the parentheses can be omitted if the expression has the form of a function call.

collation

The name of the collation to use for the index. By default, the index uses the collation declared for the column to be indexed or the result collation of the expression to be indexed. Indexes with non-default collations can be useful for queries that involve expressions using non-default collations.

opclass

The name of an operator class. See below for details.

opclass_parameter

The name of an operator class parameter. See below for details.

ASC

Specifies ascending sort order (which is the default).

DESC

Specifies descending sort order.

NULLS FIRST

Specifies that nulls sort before non-nulls. This is the default when DESC is specified.

NULLS LAST

Specifies that nulls sort after non-nulls. This is the default when DESC is not specified.
CREATE INDEX

NULLS DISTINCT
NULLS NOT DISTINCT

Specifies whether for a unique index, null values should be considered distinct (not equal). The default is that they are distinct, so that a unique index could contain multiple null values in a column.

storage_parameter

The name of an index-method-specific storage parameter. See Index Storage Parameters below for details.

tablespace_name

The tablespace in which to create the index. If not specified, default_tablespace is consulted, or temp_tablespaces for indexes on temporary tables.

predicate

The constraint expression for a partial index.

Index Storage Parameters

The optional WITH clause specifies storage parameters for the index. Each index method has its own set of allowed storage parameters. The B-tree, hash, GiST and SP-GiST index methods all accept this parameter:

fillfactor(integer)

The fillfactor for an index is a percentage that determines how full the index method will try to pack index pages. For B-trees, leaf pages are filled to this percentage during initial index builds, and also when extending the index at the right (adding new largest key values). If pages subsequently become completely full, they will be split, leading to fragmentation of the on-disk index structure. B-trees use a default fillfactor of 90, but any integer value from 10 to 100 can be selected.

B-tree indexes on tables where many inserts and/or updates are anticipated can benefit from lower fillfactor settings at CREATE INDEX time (following bulk loading into the table). Values in the range of 50 - 90 can usefully “smooth out” the rate of page splits during the early life of the B-tree index (lowering fillfactor like this may even lower the absolute number of page splits, though this effect is highly workload dependent). The B-tree bottom-up index deletion technique described in Section 66.4.2 is dependent on having some “extra” space on pages to store “extra” tuple versions, and so can be affected by fillfactor (though the effect is usually not significant).

In other specific cases it might be useful to increase fillfactor to 100 at CREATE INDEX time as a way of maximizing space utilization. You should only consider this when you are completely sure that the table is static (i.e. that it will never be affected by either inserts or updates). A fillfactor setting of 100 otherwise risks harming performance: even a few updates or inserts will cause a sudden flood of page splits.

The other index methods use fillfactor in different but roughly analogous ways; the default fillfactor varies between methods.

B-tree indexes additionally accept this parameter:

deduplicate_items(boolean)

Controls usage of the B-tree deduplication technique described in Section 66.4.3. Set to ON or OFF to enable or disable the optimization. (Alternative spellings of ON and OFF are allowed as described in Section 20.1.) The default is ON.
Note

Turning `deduplicate_items` off via `ALTER INDEX` prevents future insertions from triggering deduplication, but does not in itself make existing posting list tuples use the standard tuple representation.

GiST indexes additionally accept this parameter:

`buffering (enum)`

Determines whether the buffered build technique described in Section 67.4.1 is used to build the index. With `OFF` buffering is disabled, with `ON` it is enabled, and with `AUTO` it is initially disabled, but is turned on on-the-fly once the index size reaches `effective_cache_size`. The default is `AUTO`. Note that if sorted build is possible, it will be used instead of buffered build unless `buffering=ON` is specified.

GIN indexes accept different parameters:

`fastupdate (boolean)`

This setting controls usage of the fast update technique described in Section 69.4.1. It is a Boolean parameter: `ON` enables fast update, `OFF` disables it. The default is `ON`.

Note

Turning `fastupdate` off via `ALTER INDEX` prevents future insertions from going into the list of pending index entries, but does not in itself flush previous entries. You might want to `VACUUM` the table or call `gin_clean_pending_list` function afterward to ensure the pending list is emptied.

`gin_pending_list_limit (integer)`

Custom `gin_pending_list_limit` parameter. This value is specified in kilobytes.

BRIN indexes accept different parameters:

`pages_per_range (integer)`

Defines the number of table blocks that make up one block range for each entry of a BRIN index (see Section 70.1 for more details). The default is 128.

`autosummarize (boolean)`

Defines whether a summarization run is invoked for the previous page range whenever an insertion is detected on the next one.

Building Indexes Concurrently

Creating an index can interfere with regular operation of a database. Normally PostgreSQL locks the table to be indexed against writes and performs the entire index build with a single scan of the table. Other transactions can still read the table, but if they try to insert, update, or delete rows in the table they will block until the index build is finished. This could have a severe effect if the system is a live production...
CREATE INDEX

database. Very large tables can take many hours to be indexed, and even for smaller tables, an index build can lock out writers for periods that are unacceptably long for a production system.

PostgreSQL supports building indexes without locking out writes. This method is invoked by specifying the CONCURRENTLY option of CREATE INDEX. When this option is used, PostgreSQL must perform two scans of the table, and in addition it must wait for all existing transactions that could potentially modify or use the index to terminate. Thus this method requires more total work than a standard index build and takes significantly longer to complete. However, since it allows normal operations to continue while the index is built, this method is useful for adding new indexes in a production environment. Of course, the extra CPU and I/O load imposed by the index creation might slow other operations.

In a concurrent index build, the index is actually entered as an “invalid” index into the system catalogs in one transaction, then two table scans occur in two more transactions. Before each table scan, the index build must wait for existing transactions that have modified the table to terminate. After the second scan, the index build must wait for any transactions that have a snapshot (see Chapter 13) predating the second scan to terminate, including transactions used by any phase of concurrent index builds on other tables, if the indexes involved are partial or have columns that are not simple column references. Then finally the index can be marked “valid” and ready for use, and the CREATE INDEX command terminates. Even then, however, the index may not be immediately usable for queries: in the worst case, it cannot be used as long as transactions exist that predate the start of the index build.

If a problem arises while scanning the table, such as a deadlock or a uniqueness violation in a unique index, the CREATE INDEX command will fail but leave behind an “invalid” index. This index will be ignored for querying purposes because it might be incomplete; however it will still consume update overhead. The psql \d command will report such an index as INVALID:

```
postgres=# \d tab
Table "public.tab"
   Column |   Type   | Collation | Nullable | Default
          |----------|-----------|----------|---------
    col    | integer  |           |          |
Indexes:
    "idx" btree (col) INVALID
```

The recommended recovery method in such cases is to drop the index and try again to perform CREATE INDEX CONCURRENTLY. (Another possibility is to rebuild the index with REINDEX INDEX CONCURRENTLY).

Another caveat when building a unique index concurrently is that the uniqueness constraint is already being enforced against other transactions when the second table scan begins. This means that constraint violations could be reported in other queries prior to the index becoming available for use, or even in cases where the index build eventually fails. Also, if a failure does occur in the second scan, the “invalid” index continues to enforce its uniqueness constraint afterwards.

Concurrent builds of expression indexes and partial indexes are supported. Errors occurring in the evaluation of these expressions could cause behavior similar to that described above for unique constraint violations.

Regular index builds permit other regular index builds on the same table to occur simultaneously, but only one concurrent index build can occur on a table at a time. In either case, schema modification of the table is not allowed while the index is being built. Another difference is that a regular CREATE INDEX command can be performed within a transaction block, but CREATE INDEX CONCURRENTLY cannot.

Concurrent builds for indexes on partitioned tables are currently not supported. However, you may concurrently build the index on each partition individually and then finally create the partitioned index non-
CREATE INDEX

concurrently in order to reduce the time where writes to the partitioned table will be locked out. In this case, building the partitioned index is a metadata only operation.

Notes

See Chapter 11 for information about when indexes can be used, when they are not used, and in which particular situations they can be useful.

Currently, only the B-tree, GiST, GIN, and BRIN index methods support multiple-key-column indexes. Whether there can be multiple key columns is independent of whether INCLUDE columns can be added to the index. Indexes can have up to 32 columns, including INCLUDE columns. (This limit can be altered when building PostgreSQL.) Only B-tree currently supports unique indexes.

An operator class with optional parameters can be specified for each column of an index. The operator class identifies the operators to be used by the index for that column. For example, a B-tree index on four-byte integers would use the int4_ops class; this operator class includes comparison functions for four-byte integers. In practice the default operator class for the column's data type is usually sufficient. The main point of having operator classes is that for some data types, there could be more than one meaningful ordering. For example, we might want to sort a complex-number data type either by absolute value or by real part. We could do this by defining two operator classes for the data type and then selecting the proper class when creating an index. More information about operator classes is in Section 11.10 and in Section 38.16.

When CREATE INDEX is invoked on a partitioned table, the default behavior is to recurse to all partitions to ensure they all have matching indexes. Each partition is first checked to determine whether an equivalent index already exists, and if so, that index will become attached as a partition index to the index being created, which will become its parent index. If no matching index exists, a new index will be created and automatically attached; the name of the new index in each partition will be determined as if no index name had been specified in the command. If the ONLY option is specified, no recursion is done, and the index is marked invalid. (ALTER INDEX ... ATTACH PARTITION marks the index valid, once all partitions acquire matching indexes.) Note, however, that any partition that is created in the future using CREATE TABLE ... PARTITION OF will automatically have a matching index, regardless of whether ONLY is specified.

For index methods that support ordered scans (currently, only B-tree), the optional clauses ASC, DESC, NULLS FIRST, and/or NULLS LAST can be specified to modify the sort ordering of the index. Since an ordered index can be scanned either forward or backward, it is not normally useful to create a single-column DESC index — that sort ordering is already available with a regular index. The value of these options is that multicolumn indexes can be created that match the sort ordering requested by a mixed-ordering query, such as SELECT ... ORDER BY x ASC, y DESC. The NULLS options are useful if you need to support “nulls sort low” behavior, rather than the default “nulls sort high”, in queries that depend on indexes to avoid sorting steps.

The system regularly collects statistics on all of a table's columns. Newly-created non-expression indexes can immediately use these statistics to determine an index's usefulness. For new expression indexes, it is necessary to run ANALYZE or wait for the autovacuum daemon to analyze the table to generate statistics for these indexes.

For most index methods, the speed of creating an index is dependent on the setting of maintenance_work_mem. Larger values will reduce the time needed for index creation, so long as you don't make it larger than the amount of memory really available, which would drive the machine into swapping.

PostgreSQL can build indexes while leveraging multiple CPUs in order to process the table rows faster. This feature is known as parallel index build. For index methods that support building indexes in parallel (currently, only B-tree), maintenance_work_mem specifies the maximum amount of memory that can
be used by each index build operation as a whole, regardless of how many worker processes were started. Generally, a cost model automatically determines how many worker processes should be requested, if any.

Parallel index builds may benefit from increasing maintenance_work_mem where an equivalent serial index build will see little or no benefit. Note that maintenance_work_mem may influence the number of worker processes requested, since parallel workers must have at least a 32MB share of the total maintenance_work_mem budget. There must also be a remaining 32MB share for the leader process. Increasing max_parallel_maintenance_workers may allow more workers to be used, which will reduce the time needed for index creation, so long as the index build is not already I/O bound. Of course, there should also be sufficient CPU capacity that would otherwise lie idle.

Setting a value for parallel_workers via ALTER TABLE directly controls how many parallel worker processes will be requested by a CREATE INDEX against the table. This bypasses the cost model completely, and prevents maintenance_work_mem from affecting how many parallel workers are requested. Setting parallel_workers to 0 via ALTER TABLE will disable parallel index builds on the table in all cases.

Tip
You might want to reset parallel_workers after setting it as part of tuning an index build. This avoids inadvertent changes to query plans, since parallel_workers affects all parallel table scans.

While CREATE INDEX with the CONCURRENTLY option supports parallel builds without special restrictions, only the first table scan is actually performed in parallel.

Use DROP INDEX to remove an index.

Like any long-running transaction, CREATE INDEX on a table can affect which tuples can be removed by concurrent VACUUM on any other table.

Prior releases of PostgreSQL also had an R-tree index method. This method has been removed because it had no significant advantages over the GiST method. If USING rtree is specified, CREATE INDEX will interpret it as USING gist, to simplify conversion of old databases to GiST.

Each backend running CREATE INDEX will report its progress in the pg_stat_progress_create_index view. See Section 28.4.2 for details.

Examples

To create a unique B-tree index on the column title in the table films:

```
CREATE UNIQUE INDEX title_idx ON films (title);
```

To create a unique B-tree index on the column title with included columns director and rating in the table films:

```
CREATE UNIQUE INDEX title_idx ON films (title) INCLUDE (director,
rating);
```

To create a B-Tree index with deduplication disabled:
CREATE INDEX title_idx ON films (title) WITH (deduplicate_items = off);

To create an index on the expression lower(title), allowing efficient case-insensitive searches:

CREATE INDEX ON films ((lower(title)));

(In this example we have chosen to omit the index name, so the system will choose a name, typically films_lower_idx.)

To create an index with non-default collation:

CREATE INDEX title_idx_german ON films (title COLLATE "de_DE");

To create an index with non-default sort ordering of nulls:

CREATE INDEX title_idx_nulls_low ON films (title NULLS FIRST);

To create an index with non-default fill factor:

CREATE UNIQUE INDEX title_idx ON films (title) WITH (fillfactor = 70);

To create a GIN index with fast updates disabled:

CREATE INDEX gin_idx ON documents_table USING GIN (locations) WITH (fastupdate = off);

To create an index on the column code in the table films and have the index reside in the tablespace indexspace:

CREATE INDEX code_idx ON films (code) TABLESPACE indexspace;

To create a GiST index on a point attribute so that we can efficiently use box operators on the result of the conversion function:

CREATE INDEX pointloc ON points USING gist (box(location,location));
SELECT * FROM points
     WHERE box(location,location) && '(0,0),(1,1)::box;

To create an index without locking out writes to the table:

CREATE INDEX CONCURRENTLY sales_quantity_index ON sales_table (quantity);

Compatibility

CREATE INDEX is a PostgreSQL language extension. There are no provisions for indexes in the SQL standard.

ALTER INDEX, DROP INDEX, REINDEX, Section 28.4.2
CREATE LANGUAGE

CREATE LANGUAGE — define a new procedural language

Synopsis

CREATE [ OR REPLACE ] [ TRUSTED ] [ PROCEDURAL ] LANGUAGE name
    HANDLER call_handler [ INLINE inline_handler ]
    [ VALIDATOR valfunction ]

Description

CREATE LANGUAGE registers a new procedural language with a PostgreSQL database. Subsequently, functions and procedures can be defined in this new language.

CREATE LANGUAGE effectively associates the language name with handler function(s) that are responsible for executing functions written in the language. Refer to Chapter 57 for more information about language handlers.

CREATE OR REPLACE LANGUAGE will either create a new language, or replace an existing definition. If the language already exists, its parameters are updated according to the command, but the language’s ownership and permissions settings do not change, and any existing functions written in the language are assumed to still be valid.

One must have the PostgreSQL superuser privilege to register a new language or change an existing language’s parameters. However, once the language is created it is valid to assign ownership of it to a non-superuser, who may then drop it, change its permissions, rename it, or assign it to a new owner. (Do not, however, assign ownership of the underlying C functions to a non-superuser; that would create a privilege escalation path for that user.)

The form of CREATE LANGUAGE that does not supply any handler function is obsolete. For backwards compatibility with old dump files, it is interpreted as CREATE EXTENSION. That will work if the language has been packaged into an extension of the same name, which is the conventional way to set up procedural languages.

Parameters

TRUSTED

TRUSTED specifies that the language does not grant access to data that the user would not otherwise have. If this key word is omitted when registering the language, only users with the PostgreSQL superuser privilege can use this language to create new functions.

PROCEDURAL

This is a noise word.

name

The name of the new procedural language. The name must be unique among the languages in the database.
CREATE LANGUAGE

HANDLER call_handler

call_handler is the name of a previously registered function that will be called to execute the procedural language's functions. The call handler for a procedural language must be written in a compiled language such as C with version 1 call convention and registered with PostgreSQL as a function taking no arguments and returning the language_handler type, a placeholder type that is simply used to identify the function as a call handler.

INLINE inline_handler

inline_handler is the name of a previously registered function that will be called to execute an anonymous code block (DO command) in this language. If no inline_handler function is specified, the language does not support anonymous code blocks. The handler function must take one argument of type internal, which will be the DO command's internal representation, and it will typically return void. The return value of the handler is ignored.

VALIDATOR valfunction

valfunction is the name of a previously registered function that will be called when a new function in the language is created, to validate the new function. If no validator function is specified, then a new function will not be checked when it is created. The validator function must take one argument of type oid, which will be the OID of the to-be-created function, and will typically return void.

A validator function would typically inspect the function body for syntactical correctness, but it can also look at other properties of the function, for example if the language cannot handle certain argument types. To signal an error, the validator function should use the ereport() function. The return value of the function is ignored.

Notes

Use DROP LANGUAGE to drop procedural languages.

The system catalog pg_language (see Section 53.29) records information about the currently installed languages. Also, the psql command \dL lists the installed languages.

To create functions in a procedural language, a user must have the USAGE privilege for the language. By default, USAGE is granted to PUBLIC (i.e., everyone) for trusted languages. This can be revoked if desired.

Procedural languages are local to individual databases. However, a language can be installed into the template1 database, which will cause it to be available automatically in all subsequently-created databases.

Examples

A minimal sequence for creating a new procedural language is:

```
CREATE FUNCTION plsample_call_handler() RETURNS language_handler
    AS '$libdir/plsample'
    LANGUAGE C;
CREATE LANGUAGE plsample
    HANDLER plsample_call_handler;
```

Typically that would be written in an extension's creation script, and users would do this to install the extension:
CREATE EXTENSION plsample;

Compatibility

CREATE LANGUAGE is a PostgreSQL extension.

CREATE MATERIALIZED VIEW

CREATE MATERIALIZED VIEW — define a new materialized view

Synopsis

CREATE MATERIALIZED VIEW [ IF NOT EXISTS ] table_name
    [ (column_name [, ...] ) ]
    [ USING method ]
    [ WITH ( storage_parameter [= value] [, ... ] ) ]
    [ TABLESPACE tablespace_name ]
AS query
    [ WITH [ NO ] DATA ]

Description

CREATE MATERIALIZED VIEW defines a materialized view of a query. The query is executed and
used to populate the view at the time the command is issued (unless WITH NO DATA is used) and may
be refreshed later using REFRESH MATERIALIZED VIEW.

CREATE MATERIALIZED VIEW is similar to CREATE TABLE AS, except that it also remembers the
query used to initialize the view, so that it can be refreshed later upon demand. A materialized view has
many of the same properties as a table, but there is no support for temporary materialized views.

CREATE MATERIALIZED VIEW requires CREATE privilege on the schema used for the materialized
view.

Parameters

IF NOT EXISTS

Do not throw an error if a materialized view with the same name already exists. A notice is issued
in this case. Note that there is no guarantee that the existing materialized view is anything like the
one that would have been created.

table_name

The name (optionally schema-qualified) of the materialized view to be created. The name must be
distinct from the name of any other relation (table, sequence, index, view, materialized view, or foreign
table) in the same schema.

column_name

The name of a column in the new materialized view. If column names are not provided, they are taken
from the output column names of the query.

USING method

This optional clause specifies the table access method to use to store the contents for the new materi-
alized view; the method needs be an access method of type TABLE. See Chapter 62 for more informa-
CREATE MATERIALIZED VIEW

tion. If this option is not specified, the default table access method is chosen for the new materialized view. See default_table_access_method for more information.

WITH ( storage_parameter [= value] [, ... ] )

This clause specifies optional storage parameters for the new materialized view; see Storage Parameters in the CREATE TABLE documentation for more information. All parameters supported for CREATE TABLE are also supported for CREATE MATERIALIZED VIEW. See CREATE TABLE for more information.

TABLESPACE tablespace_name

The tablespace_name is the name of the tablespace in which the new materialized view is to be created. If not specified, default_tablespace is consulted.

query

A SELECT, TABLE, or VALUES command. This query will run within a security-restricted operation; in particular, calls to functions that themselves create temporary tables will fail.

WITH [ NO ] DATA

This clause specifies whether or not the materialized view should be populated at creation time. If not, the materialized view will be flagged as unscannable and cannot be queried until REFRESH MATERIALIZED VIEW is used.

Compatibility

CREATE MATERIALIZED VIEW is a PostgreSQL extension.

ALTER MATERIALIZED VIEW, CREATE TABLE AS, CREATE VIEW, DROP MATERIALIZED VIEW, REFRESH MATERIALIZED VIEW
CREATE OPERATOR

CREATE OPERATOR — define a new operator

Synopsis

CREATE OPERATOR name (  
    (FUNCTION|PROCEDURE) = function_name  
    [, LEFTARG = left_type ] [, RIGHTARG = right_type ]  
    [, COMMUTATOR = com_op ] [, NEGATOR = neg_op ]  
    [, RESTRICT = res_proc ] [, JOIN = join_proc ]  
    [, HASHES ] [, MERGES ]  
)

Description

CREATE OPERATOR defines a new operator, name. The user who defines an operator becomes its owner. If a schema name is given then the operator is created in the specified schema. Otherwise it is created in the current schema.

The operator name is a sequence of up to NAMEDATALEN-1 (63 by default) characters from the following list:

+ - * / < > = ~ ! @ # % ^ & | ` ?

There are a few restrictions on your choice of name:

• -- and /* cannot appear anywhere in an operator name, since they will be taken as the start of a comment.

• A multicharacter operator name cannot end in + or -, unless the name also contains at least one of these characters:

   ~ ! @ # % ^ & | ` ?

   For example, @- is an allowed operator name, but *- is not. This restriction allows PostgreSQL to parse SQL-compliant commands without requiring spaces between tokens.

• The use of => as an operator name is deprecated. It may be disallowed altogether in a future release.

The operator ! = is mapped to <> on input, so these two names are always equivalent.

For binary operators, both LEFTARG and RIGHTARG must be defined. For prefix operators only RIGHTARG should be defined. The function_name function must have been previously defined using CREATE FUNCTION and must be defined to accept the correct number of arguments (either one or two) of the indicated types.

In the syntax of CREATE OPERATOR, the keywords FUNCTION and PROCEDURE are equivalent, but the referenced function must in any case be a function, not a procedure. The use of the keyword PROCEDURE here is historical and deprecated.
CREATE OPERATOR

The other clauses specify optional operator optimization clauses. Their meaning is detailed in Section 38.15.

To be able to create an operator, you must have USAGE privilege on the argument types and the return type, as well as EXECUTE privilege on the underlying function. If a commutator or negator operator is specified, you must own these operators.

Parameters

name

The name of the operator to be defined. See above for allowable characters. The name can be schema-qualified, for example CREATE OPERATOR myschema.+ (...). If not, then the operator is created in the current schema. Two operators in the same schema can have the same name if they operate on different data types. This is called overloading.

function_name

The function used to implement this operator.

left_type

The data type of the operator's left operand, if any. This option would be omitted for a prefix operator.

right_type

The data type of the operator's right operand.

com_op

The commutator of this operator.

neg_op

The negator of this operator.

res_proc

The restriction selectivity estimator function for this operator.

join_proc

The join selectivity estimator function for this operator.

HASHES

Indicates this operator can support a hash join.

MERGES

Indicates this operator can support a merge join.

To give a schema-qualified operator name in com_op or the other optional arguments, use the OPERATOR() syntax, for example:

COMMUTATOR = OPERATOR(myschema.===) ,
**CREATE OPERATOR**

**Notes**

Refer to Section 38.14 for further information.

It is not possible to specify an operator's lexical precedence in `CREATE OPERATOR`, because the parser's precedence behavior is hard-wired. See Section 4.1.6 for precedence details.

The obsolete options `SORT1`, `SORT2`, `LTCMP`, and `GTCMP` were formerly used to specify the names of sort operators associated with a merge-joinable operator. This is no longer necessary, since information about associated operators is found by looking at B-tree operator families instead. If one of these options is given, it is ignored except for implicitly setting `MERGES` true.

Use `DROP OPERATOR` to delete user-defined operators from a database. Use `ALTER OPERATOR` to modify operators in a database.

**Examples**

The following command defines a new operator, area-equality, for the data type `box`:

```sql
CREATE OPERATOR === (
    LEFTARG = box,
    RIGHTARG = box,
    FUNCTION = area_equal_function,
    COMMUTATOR = ===,
    NEGATOR = !==,
    RESTRICT = area_restriction_function,
    JOIN = area_join_function,
    HASHES, MERGES
);
```

**Compatibility**

`CREATE OPERATOR` is a PostgreSQL extension. There are no provisions for user-defined operators in the SQL standard.

**See Also**

`ALTER OPERATOR`, `CREATE OPERATOR CLASS`, `DROP OPERATOR`
CREATE OPERATOR CLASS

CREATE OPERATOR CLASS — define a new operator class

Synopsis

CREATE OPERATOR CLASS name [ DEFAULT ] FOR TYPE data_type
   USING index_method [ FAMILY family_name ] AS
   { OPERATOR strategy_number operator_name [ ( op_type, op_type ) ]
     [ FOR SEARCH | FOR ORDER BY sort_family_name ]
     [ FUNCTION support_number [ ( op_type [ , op_type ] ) ]
       function_name ( argument_type [ , ... ] )
     ]
     STORAGE storage_type
   } [, ... ]

Description

CREATE OPERATOR CLASS creates a new operator class. An operator class defines how a particular data type can be used with an index. The operator class specifies that certain operators will fill particular roles or “strategies” for this data type and this index method. The operator class also specifies the support functions to be used by the index method when the operator class is selected for an index column. All the operators and functions used by an operator class must be defined before the operator class can be created.

If a schema name is given then the operator class is created in the specified schema. Otherwise it is created in the current schema. Two operator classes in the same schema can have the same name only if they are for different index methods.

The user who defines an operator class becomes its owner. Presently, the creating user must be a superuser. (This restriction is made because an erroneous operator class definition could confuse or even crash the server.)

CREATE OPERATOR CLASS does not presently check whether the operator class definition includes all the operators and functions required by the index method, nor whether the operators and functions form a self-consistent set. It is the user’s responsibility to define a valid operator class.

Related operator classes can be grouped into operator families. To add a new operator class to an existing family, specify the FAMILY option in CREATE OPERATOR CLASS. Without this option, the new class is placed into a family named the same as the new class (creating that family if it doesn’t already exist).

Refer to Section 38.16 for further information.

Parameters

name

The name of the operator class to be created. The name can be schema-qualified.

DEFAULT

If present, the operator class will become the default operator class for its data type. At most one operator class can be the default for a specific data type and index method.
data_type
The column data type that this operator class is for.

index_method
The name of the index method this operator class is for.

case_name
The name of the existing operator family to add this operator class to. If not specified, a family named the same as the operator class is used (creating it, if it doesn't already exist).

strategy_number
The index method's strategy number for an operator associated with the operator class.

operator_name
The name (optionally schema-qualified) of an operator associated with the operator class.

op_type
In an OPERATOR clause, the operand data type(s) of the operator, or NONE to signify a prefix operator. The operand data types can be omitted in the normal case where they are the same as the operator class's data type.

In a FUNCTION clause, the operand data type(s) the function is intended to support, if different from the input data type(s) of the function (for B-tree comparison functions and hash functions) or the class's data type (for B-tree sort support functions, B-tree equal image functions, and all functions in GiST, SP-GiST, GIN and BRIN operator classes). These defaults are correct, and so op_type need not be specified in FUNCTION clauses, except for the case of a B-tree sort support function that is meant to support cross-data-type comparisons.

sort_family_name
The name (optionally schema-qualified) of an existing btree operator family that describes the sort ordering associated with an ordering operator.

If neither FOR SEARCH nor FOR ORDER BY is specified, FOR SEARCH is the default.

support_number
The index method's support function number for a function associated with the operator class.

function_name
The name (optionally schema-qualified) of a function that is an index method support function for the operator class.

argument_type
The parameter data type(s) of the function.

storage_type
The data type actually stored in the index. Normally this is the same as the column data type, but some index methods (currently GiST, GIN, SP-GiST and BRIN) allow it to be different. The

1788
CREATE OPERATOR CLASS

clause must be omitted unless the index method allows a different type to be used. If the column `data_type` is specified as `anyarray`, the `storage_type` can be declared as `anyelement` to indicate that the index entries are members of the element type belonging to the actual array type that each particular index is created for.

The `OPERATOR`, `FUNCTION`, and `STORAGE` clauses can appear in any order.

Notes

Because the index machinery does not check access permissions on functions before using them, including a function or operator in an operator class is tantamount to granting public execute permission on it. This is usually not an issue for the sorts of functions that are useful in an operator class.

The operators should not be defined by SQL functions. An SQL function is likely to be inlined into the calling query, which will prevent the optimizer from recognizing that the query matches an index.

Before PostgreSQL 8.4, the `OPERATOR` clause could include a `RECHECK` option. This is no longer supported because whether an index operator is “lossy” is now determined on-the-fly at run time. This allows efficient handling of cases where an operator might or might not be lossy.

Examples

The following example command defines a GiST index operator class for the data type `_int4` (array of `int4`). See the intarray module for the complete example.

```
CREATE OPERATOR CLASS gist__int_ops
DEFAULT FOR TYPE _int4 USING gist AS
  OPERATOR 3  &&,
  OPERATOR 6  = (anyarray, anyarray),
  OPERATOR 7  @>,
  OPERATOR 8  <@,
  OPERATOR 20 @@ (_int4, query_int),
  FUNCTION 1  g_int_consistent (internal, _int4, smallint, oid, internal),
  FUNCTION 2  g_int_union (internal, internal),
  FUNCTION 3  g_int_compress (internal),
  FUNCTION 4  g_int_decompress (internal),
  FUNCTION 5  g_int_penalty (internal, internal, internal),
  FUNCTION 6  g_int_picksplit (internal, internal),
  FUNCTION 7  g_int_same (_int4, _int4, internal);
```

Compatibility

`CREATE OPERATOR CLASS` is a PostgreSQL extension. There is no `CREATE OPERATOR CLASS` statement in the SQL standard.

See Also

`ALTER OPERATOR CLASS`, `DROP OPERATOR CLASS`, `CREATE OPERATOR FAMILY`, `ALTER OPERATOR FAMILY`
CREATE OPERATOR FAMILY

CREATE OPERATOR FAMILY — define a new operator family

Synopsis

```
CREATE OPERATOR FAMILY name USING index_method
```

Description

CREATE OPERATOR FAMILY creates a new operator family. An operator family defines a collection of related operator classes, and perhaps some additional operators and support functions that are compatible with these operator classes but not essential for the functioning of any individual index. (Operators and functions that are essential to indexes should be grouped within the relevant operator class, rather than being “loose” in the operator family. Typically, single-data-type operators are bound to operator classes, while cross-data-type operators can be loose in an operator family containing operator classes for both data types.)

The new operator family is initially empty. It should be populated by issuing subsequent CREATE OPERATOR CLASS commands to add contained operator classes, and optionally ALTER OPERATOR FAMILY commands to add “loose” operators and their corresponding support functions.

If a schema name is given then the operator family is created in the specified schema. Otherwise it is created in the current schema. Two operator families in the same schema can have the same name only if they are for different index methods.

The user who defines an operator family becomes its owner. Presently, the creating user must be a superuser. (This restriction is made because an erroneous operator family definition could confuse or even crash the server.)

Refer to Section 38.16 for further information.

Parameters

`name`

The name of the operator family to be created. The name can be schema-qualified.

`index_method`

The name of the index method this operator family is for.

Compatibility

CREATE OPERATOR FAMILY is a PostgreSQL extension. There is no CREATE OPERATOR FAMILY statement in the SQL standard.

See Also

ALTER OPERATOR FAMILY, DROP OPERATOR FAMILY, CREATE OPERATOR CLASS, ALTER OPERATOR CLASS, DROP OPERATOR CLASS
CREATE POLICY

CREATE POLICY — define a new row-level security policy for a table

Synopsis

CREATE POLICY name ON table_name
[ AS { PERMISSIVE | RESTRICTIVE } ]
[ FOR { ALL | SELECT | INSERT | UPDATE | DELETE } ]
[ TO { role_name | PUBLIC | CURRENT_ROLE | CURRENT_USER | SESSION_USER } [, ...] ]
[ USING ( using_expression ) ]
[ WITH CHECK ( check_expression ) ]

Description

The CREATE POLICY command defines a new row-level security policy for a table. Note that row-level security must be enabled on the table (using ALTER TABLE ... ENABLE ROW LEVEL SECURITY) in order for created policies to be applied.

A policy grants the permission to select, insert, update, or delete rows that match the relevant policy expression. Existing table rows are checked against the expression specified in USING, while new rows that would be created via INSERT or UPDATE are checked against the expression specified in WITH CHECK. When a USING expression returns true for a given row then that row is visible to the user, while if false or null is returned then the row is not visible. When a WITH CHECK expression returns true for a row then that row is inserted or updated, while if false or null is returned then an error occurs.

For INSERT, UPDATE, and MERGE statements, WITH CHECK expressions are enforced after BEFORE triggers are fired, and before any actual data modifications are made. Thus a BEFORE ROW trigger may modify the data to be inserted, affecting the result of the security policy check. WITH CHECK expressions are enforced before any other constraints.

Policy names are per-table. Therefore, one policy name can be used for many different tables and have a definition for each table which is appropriate to that table.

Policies can be applied for specific commands or for specific roles. The default for newly created policies is that they apply for all commands and roles, unless otherwise specified. Multiple policies may apply to a single command; see below for more details. Table 289 summarizes how the different types of policy apply to specific commands.

For policies that can have both USING and WITH CHECK expressions (ALL and UPDATE), if no WITH CHECK expression is defined, then the USING expression will be used both to determine which rows are visible (normal USING case) and which new rows will be allowed to be added (WITH CHECK case).

If row-level security is enabled for a table, but no applicable policies exist, a “default deny” policy is assumed, so that no rows will be visible or updatable.

Parameters

name

The name of the policy to be created. This must be distinct from the name of any other policy for the table.
CREATE POLICY

table_name

The name (optionally schema-qualified) of the table the policy applies to.

PERMISSIVE

Specify that the policy is to be created as a permissive policy. All permissive policies which are applicable to a given query will be combined together using the Boolean “OR” operator. By creating permissive policies, administrators can add to the set of records which can be accessed. Policies are permissive by default.

RESTRICTIVE

Specify that the policy is to be created as a restrictive policy. All restrictive policies which are applicable to a given query will be combined together using the Boolean “AND” operator. By creating restrictive policies, administrators can reduce the set of records which can be accessed as all restrictive policies must be passed for each record.

Note that there needs to be at least one permissive policy to grant access to records before restrictive policies can be usefully used to reduce that access. If only restrictive policies exist, then no records will be accessible. When a mix of permissive and restrictive policies are present, a record is only accessible if at least one of the permissive policies passes, in addition to all the restrictive policies.

command

The command to which the policy applies. Valid options are ALL, SELECT, INSERT, UPDATE, and DELETE. ALL is the default. See below for specifics regarding how these are applied.

role_name

The role(s) to which the policy is to be applied. The default is PUBLIC, which will apply the policy to all roles.

using_expression

Any SQL conditional expression (returning boolean). The conditional expression cannot contain any aggregate or window functions. This expression will be added to queries that refer to the table if row-level security is enabled. Rows for which the expression returns true will be visible. Any rows for which the expression returns false or null will not be visible to the user (in a SELECT), and will not be available for modification (in an UPDATE or DELETE). Such rows are silently suppressed; no error is reported.

check_expression

Any SQL conditional expression (returning boolean). The conditional expression cannot contain any aggregate or window functions. This expression will be used in INSERT and UPDATE queries against the table if row-level security is enabled. Only rows for which the expression evaluates to true will be allowed. An error will be thrown if the expression evaluates to false or null for any of the records inserted or any of the records that result from the update. Note that the check_expression is evaluated against the proposed new contents of the row, not the original contents.

Per-Command Policies

ALL

Using ALL for a policy means that it will apply to all commands, regardless of the type of command. If an ALL policy exists and more specific policies exist, then both the ALL policy and the more specific
CREATE POLICY

policy (or policies) will be applied. Additionally, ALL policies will be applied to both the selection side of a query and the modification side, using the USING expression for both cases if only a USING expression has been defined.

As an example, if an UPDATE is issued, then the ALL policy will be applicable both to what the UPDATE will be able to select as rows to be updated (applying the USING expression), and to the resulting updated rows, to check if they are permitted to be added to the table (applying the WITH CHECK expression, if defined, and the USING expression otherwise). If an INSERT or UPDATE command attempts to add rows to the table that do not pass the ALL policy’s WITH CHECK expression, the entire command will be aborted.

SELECT

Using SELECT for a policy means that it will apply to SELECT queries and whenever SELECT permissions are required on the relation the policy is defined for. The result is that only those records from the relation that pass the SELECT policy will be returned during a SELECT query, and that queries that require SELECT permissions, such as UPDATE, will also only see those records that are allowed by the SELECT policy. A SELECT policy cannot have a WITH CHECK expression, as it only applies in cases where records are being retrieved from the relation.

INSERT

Using INSERT for a policy means that it will apply to INSERT commands and MERGE commands that contain INSERT actions. Rows being inserted that do not pass this policy will result in a policy violation error, and the entire INSERT command will be aborted. An INSERT policy cannot have a USING expression, as it only applies in cases where records are being added to the relation.

Note that INSERT with ON CONFLICT DO UPDATE checks INSERT policies' WITH CHECK expressions only for rows appended to the relation by the INSERT path.

UPDATE

Using UPDATE for a policy means that it will apply to UPDATE, SELECT FOR UPDATE and SELECT FOR SHARE commands, as well as auxiliary ON CONFLICT DO UPDATE clauses of INSERT commands. MERGE commands containing UPDATE actions are affected as well. Since UPDATE involves pulling an existing record and replacing it with a new modified record, UPDATE policies accept both a USING expression and a WITH CHECK expression. The USING expression determines which records the UPDATE command will see to operate against, while the WITH CHECK expression defines which modified rows are allowed to be stored back into the relation.

Any rows whose updated values do not pass the WITH CHECK expression will cause an error, and the entire command will be aborted. If only a USING clause is specified, then that clause will be used for both USING and WITH CHECK cases.

Typically an UPDATE command also needs to read data from columns in the relation being updated (e.g., in a WHERE clause or a RETURNING clause, or in an expression on the right hand side of the SET clause). In this case, SELECT rights are also required on the relation being updated, and the appropriate SELECT or ALL policies will be applied in addition to the UPDATE policies. Thus the user must have access to the row(s) being updated through a SELECT or ALL policy in addition to being granted permission to update the row(s) via an UPDATE or ALL policy.

When an INSERT command has an auxiliary ON CONFLICT DO UPDATE clause, if the UPDATE path is taken, the row to be updated is first checked against the USING expressions of any UPDATE policies, and then the new updated row is checked against the WITH CHECK expressions. Note, however, that unlike a standalone UPDATE command, if the existing row does not pass the USING expressions, an error will be thrown (the UPDATE path will never be silently avoided).
CREATE POLICY

DELETE

Using DELETE for a policy means that it will apply to DELETE commands. Only rows that pass this policy will be seen by a DELETE command. There can be rows that are visible through a SELECT that are not available for deletion, if they do not pass the USING expression for the DELETE policy.

In most cases a DELETE command also needs to read data from columns in the relation that it is deleting from (e.g., in a WHERE clause or a RETURNING clause). In this case, SELECT rights are also required on the relation, and the appropriate SELECT or ALL policies will be applied in addition to the DELETE policies. Thus the user must have access to the row(s) being deleted through a SELECT or ALL policy in addition to being granted permission to delete the row(s) via a DELETE or ALL policy.

A DELETE policy cannot have a WITH CHECK expression, as it only applies in cases where records are being deleted from the relation, so that there is no new row to check.

</tr>
<tr>
<td>UPDATE/MERGE ... THEN UPDATE</td>
<td>Existing &amp; new rows a</td>
<td>Existing row</td>
<td>New row</td>
<td>—</td>
</tr>
<tr>
<td>DELETE</td>
<td>Existing row a</td>
<td>—</td>
<td>—</td>
<td>Existing row</td>
</tr>
<tr>
<td>ON CONFLICT DO UPDATE</td>
<td>Existing &amp; new rows</td>
<td>Existing row</td>
<td>New row</td>
<td>—</td>
</tr>
</tbody>
</table>

*If read access is required to the existing or new row (for example, a WHERE or RETURNING clause that refers to columns from the relation).

Application of Multiple Policies

When multiple policies of different command types apply to the same command (for example, SELECT and UPDATE policies applied to an UPDATE command), then the user must have both types of permissions (for example, permission to select rows from the relation as well as permission to update them). Thus the expressions for one type of policy are combined with the expressions for the other type of policy using the AND operator.

When multiple policies of the same command type apply to the same command, then there must be at least one PERMISSIVE policy granting access to the relation, and all of the RESTRICTIVE policies

1794
CREATE POLICY

must pass. Thus all the PERMISSIVE policy expressions are combined using OR, all the RESTRICTIVE policy expressions are combined using AND, and the results are combined using AND. If there are no PERMISSIVE policies, then access is denied.

Note that, for the purposes of combining multiple policies, ALL policies are treated as having the same type as whichever other type of policy is being applied.

For example, in an UPDATE command requiring both SELECT and UPDATE permissions, if there are multiple applicable policies of each type, they will be combined as follows:

expression from RESTRICTIVE SELECT/ALL policy 1
AND
expression from RESTRICTIVE SELECT/ALL policy 2
AND
...
AND
(
  expression from PERMISSIVE SELECT/ALL policy 1
  OR
  expression from PERMISSIVE SELECT/ALL policy 2
  OR
  ...
)
AND
expression from RESTRICTIVE UPDATE/ALL policy 1
AND
expression from RESTRICTIVE UPDATE/ALL policy 2
AND
...
AND
(
  expression from PERMISSIVE UPDATE/ALL policy 1
  OR
  expression from PERMISSIVE UPDATE/ALL policy 2
  OR
  ...
)

Notes

You must be the owner of a table to create or change policies for it.

While policies will be applied for explicit queries against tables in the database, they are not applied when the system is performing internal referential integrity checks or validating constraints. This means there are indirect ways to determine that a given value exists. An example of this is attempting to insert a duplicate value into a column that is a primary key or has a unique constraint. If the insert fails then the user can infer that the value already exists. (This example assumes that the user is permitted by policy to insert records which they are not allowed to see.) Another example is where a user is allowed to insert into a table which references another, otherwise hidden table. Existence can be determined by the user inserting values into the referencing table, where success would indicate that the value exists in the referenced table. These issues can be addressed by carefully crafting policies to prevent users from being able to insert, delete, or update records at all which might possibly indicate a value they are not otherwise able to see, or by using generated values (e.g., surrogate keys) instead of keys with external meanings.
CREATE POLICY

Generally, the system will enforce filter conditions imposed using security policies prior to qualifications that appear in user queries, in order to prevent inadvertent exposure of the protected data to user-defined functions which might not be trustworthy. However, functions and operators marked by the system (or the system administrator) as LEAKPROOF may be evaluated before policy expressions, as they are assumed to be trustworthy.

Since policy expressions are added to the user's query directly, they will be run with the rights of the user running the overall query. Therefore, users who are using a given policy must be able to access any tables or functions referenced in the expression or they will simply receive a permission denied error when attempting to query the table that has row-level security enabled. This does not change how views work, however. As with normal queries and views, permission checks and policies for the tables which are referenced by a view will use the view owner's rights and any policies which apply to the view owner, except if the view is defined using the security_invoker option (see CREATE VIEW).

No separate policy exists for MERGE. Instead, the policies defined for SELECT, INSERT, UPDATE, and DELETE are applied while executing MERGE, depending on the actions that are performed.

Additional discussion and practical examples can be found in Section 5.8.

Compatibility

CREATE POLICY is a PostgreSQL extension.

ALTER POLICY, DROP POLICY, ALTER TABLE
CREATE PROCEDURE

CREATE PROCEDURE — define a new procedure

Synopsis

```sql
CREATE [ OR REPLACE ] PROCEDURE
    name ( [ [ argmode ] ] [ argname ] argtype [ { DEFAULT | = } default_expr ] [, ... ] )
    { LANGUAGE lang_name
        | TRANSFORM { FOR TYPE type_name } [, ... ]
        | [ EXTERNAL ] SECURITY INVOKER | [ EXTERNAL ] SECURITY DEFINER
        | SET configuration_parameter { TO value | = value | FROM CURRENT }
        | AS 'definition'
        | AS 'obj_file', 'link_symbol'
        | sql_body
    } ...
```

Description

CREATE PROCEDURE defines a new procedure. CREATE OR REPLACE PROCEDURE will either create a new procedure, or replace an existing definition. To be able to define a procedure, the user must have the USAGE privilege on the language.

If a schema name is included, then the procedure is created in the specified schema. Otherwise it is created in the current schema. The name of the new procedure must not match any existing procedure or function with the same input argument types in the same schema. However, procedures and functions of different argument types can share a name (this is called overloading).

To replace the current definition of an existing procedure, use CREATE OR REPLACE PROCEDURE. It is not possible to change the name or argument types of a procedure this way (if you tried, you would actually be creating a new, distinct procedure).

When CREATE OR REPLACE PROCEDURE is used to replace an existing procedure, the ownership and permissions of the procedure do not change. All other procedure properties are assigned the values specified or implied in the command. You must own the procedure to replace it (this includes being a member of the owning role).

The user that creates the procedure becomes the owner of the procedure.

To be able to create a procedure, you must have USAGE privilege on the argument types.

Refer to Section 38.4 for further information on writing procedures.

Parameters

`name`

The name (optionally schema-qualified) of the procedure to create.
CREATE PROCEDURE

argmode

The mode of an argument: IN, OUT, INOUT, or VARIADIC. If omitted, the default is IN.

argname

The name of an argument.

argtype

The data type(s) of the procedure's arguments (optionally schema-qualified), if any. The argument types can be base, composite, or domain types, or can reference the type of a table column.

Depending on the implementation language it might also be allowed to specify "pseudo-types" such as cstring. Pseudo-types indicate that the actual argument type is either incompletely specified, or outside the set of ordinary SQL data types.

The type of a column is referenced by writing table_name.column_name%TYPE. Using this feature can sometimes help make a procedure independent of changes to the definition of a table.

default_expr

An expression to be used as default value if the parameter is not specified. The expression has to be coercible to the argument type of the parameter. All input parameters following a parameter with a default value must have default values as well.

lang_name

The name of the language that the procedure is implemented in. It can be sql, c, internal, or the name of a user-defined procedural language, e.g., plpgsql. The default is sql if sql_body is specified. Enclosing the name in single quotes is deprecated and requires matching case.

TRANSFORM { FOR TYPE type_name } [, ... ] }

Lists which transforms a call to the procedure should apply. Transforms convert between SQL types and language-specific data types; see CREATE TRANSFORM. Procedural language implementations usually have hardcoded knowledge of the built-in types, so those don't need to be listed here. If a procedural language implementation does not know how to handle a type and no transform is supplied, it will fall back to a default behavior for converting data types, but this depends on the implementation.

[EXTERNAL] SECURITY INVOKER

[EXTERNAL] SECURITY DEFINER

SECURITY INVOKER indicates that the procedure is to be executed with the privileges of the user that calls it. That is the default. SECURITY DEFINER specifies that the procedure is to be executed with the privileges of the user that owns it.

The key word EXTERNAL is allowed for SQL conformance, but it is optional since, unlike in SQL, this feature applies to all procedures not only external ones.

A SECURITY DEFINER procedure cannot execute transaction control statements (for example, COMMIT and ROLLBACK, depending on the language).

configuration_parameter

value

The SET clause causes the specified configuration parameter to be set to the specified value when the procedure is entered, and then restored to its prior value when the procedure exits. SET FROM
CREATE PROCEDURE

CURRENT saves the value of the parameter that is current when CREATE PROCEDURE is executed as the value to be applied when the procedure is entered.

If a SET clause is attached to a procedure, then the effects of a SET LOCAL command executed inside the procedure for the same variable are restricted to the procedure: the configuration parameter's prior value is still restored at procedure exit. However, an ordinary SET command (without LOCAL) overrides the SET clause, much as it would do for a previous SET LOCAL command: the effects of such a command will persist after procedure exit, unless the current transaction is rolled back.

If a SET clause is attached to a procedure, then that procedure cannot execute transaction control statements (for example, COMMIT and ROLLBACK, depending on the language).

See SET and Chapter 20 for more information about allowed parameter names and values.

definition

A string constant defining the procedure; the meaning depends on the language. It can be an internal procedure name, the path to an object file, an SQL command, or text in a procedural language.

It is often helpful to use dollar quoting (see Section 4.1.2.4) to write the procedure definition string, rather than the normal single quote syntax. Without dollar quoting, any single quotes or backslashes in the procedure definition must be escaped by doubling them.

obj_file, link_symbol

This form of the AS clause is used for dynamically loadable C language procedures when the procedure name in the C language source code is not the same as the name of the SQL procedure. The string obj_file is the name of the shared library file containing the compiled C procedure, and is interpreted as for the LOAD command. The string link_symbol is the procedure's link symbol, that is, the name of the procedure in the C language source code. If the link symbol is omitted, it is assumed to be the same as the name of the SQL procedure being defined.

When repeated CREATE PROCEDURE calls refer to the same object file, the file is only loaded once per session. To unload and reload the file (perhaps during development), start a new session.

sql_body

The body of a LANGUAGE SQL procedure. This should be a block

BEGIN ATOMIC
  statement;
  statement;
  ...
  statement;
END

This is similar to writing the text of the procedure body as a string constant (see definition above), but there are some differences: This form only works for LANGUAGE SQL, the string constant form works for all languages. This form is parsed at procedure definition time, the string constant form is parsed at execution time; therefore this form cannot support polymorphic argument types and other constructs that are not resolvable at procedure definition time. This form tracks dependencies between the procedure and objects used in the procedure body, so DROP ... CASCADE will work correctly, whereas the form using string literals may leave dangling procedures. Finally, this form is more compatible with the SQL standard and other SQL implementations.
CREATE PROCEDURE

Notes

See CREATE FUNCTION for more details on function creation that also apply to procedures.

Use CALL to execute a procedure.

Examples

CREATE PROCEDURE insert_data(a integer, b integer)
LANGUAGE SQL
AS $$
INSERT INTO tbl VALUES (a);
INSERT INTO tbl VALUES (b);
$$;

or

CREATE PROCEDURE insert_data(a integer, b integer)
LANGUAGE SQL
BEGIN ATOMIC
  INSERT INTO tbl VALUES (a);
  INSERT INTO tbl VALUES (b);
END;

and call like this:

CALL insert_data(1, 2);

Compatibility

A CREATE PROCEDURE command is defined in the SQL standard. The PostgreSQL implementation can be used in a compatible way but has many extensions. For details see also CREATE FUNCTION.

ALTER PROCEDURE, DROP PROCEDURE, CALL, CREATE FUNCTION
CREATE PUBLICATION

CREATE PUBLICATION — define a new publication

Synopsis

CREATE PUBLICATION name
    [ FOR ALL TABLES
        | FOR publication_object [, ... ] ]
    [ WITH ( publication_parameter [= value] [, ... ] ) ]

where publication_object is one of:

    TABLE [ ONLY ] table_name [ * ] [ ( column_name [, ... ] ) ]
    [ WHERE ( expression ) ] [, ... ]
    ALL TABLES IN SCHEMA ( schema_name | CURRENT_SCHEMA ) [, ... ]

Description

CREATE PUBLICATION adds a new publication into the current database. The publication name must be distinct from the name of any existing publication in the current database.

A publication is essentially a group of tables whose data changes are intended to be replicated through logical replication. See Section 31.1 for details about how publications fit into the logical replication setup.

Parameters

**name**

The name of the new publication.

**FOR TABLE**

Specifies a list of tables to add to the publication. If **ONLY** is specified before the table name, only that table is added to the publication. If **ONLY** is not specified before the table name, all its descendants are added. Optionally, ***** can be specified after the table name to explicitly indicate that descendant tables are included. This does not apply to a partitioned table, however. The partitions of a partitioned table are always implicitly considered part of the publication, so they are never explicitly added to the publication.

If the optional **WHERE** clause is specified, it defines a row filter expression. Rows for which the expression evaluates to false or null will not be published. Note that parentheses are required around the expression. It has no effect on TRUNCATE commands.

When a column list is specified, only the named columns are replicated. If no column list is specified, all columns of the table are replicated through this publication, including any columns added later. If a column list is specified, it must include the replica identity columns.

Only persistent base tables and partitioned tables can be part of a publication. Temporary tables, unlogged tables, foreign tables, materialized views, and regular views cannot be part of a publication.
CREATE PUBLICATION

When a partitioned table is added to a publication, all of its existing and future partitions are implicitly considered to be part of the publication. So, even operations that are performed directly on a partition are also published via publications that its ancestors are part of.

Specifying a table that is part of a schema specified by FOR ALL TABLES IN SCHEMA is not supported.

FOR ALL TABLES

Marks the publication as one that replicates changes for all tables in the database, including tables created in the future.

FOR ALL TABLES IN SCHEMA

Marks the publication as one that replicates changes for all tables in the specified list of schemas, including tables created in the future.

Specifying a schema along with a table which belongs to the specified schema using FOR TABLE is not supported.

Only persistent base tables and partitioned tables present in the schema will be included as part of the publication. Temporary tables, unlogged tables, foreign tables, materialized views, and regular views from the schema will not be part of the publication.

When a partitioned table is published via schema level publication, all of its existing and future partitions are implicitly considered to be part of the publication, regardless of whether they are from the publication schema or not. So, even operations that are performed directly on a partition are also published via publications that its ancestors are part of.

WITH ( publication_parameter [= value] [, ... ] )

This clause specifies optional parameters for a publication. The following parameters are supported:

publish (string)

This parameter determines which DML operations will be published by the new publication to the subscribers. The value is comma-separated list of operations. The allowed operations are insert, update, delete, and truncate. The default is to publish all actions, and so the default value for this option is 'insert, update, delete, truncate'.

This parameter only affects DML operations. In particular, the initial data synchronization (see Section 31.6.1) for logical replication does not take this parameter into account when copying existing table data.

publish_via_partition_root (boolean)

This parameter determines whether changes in a partitioned table (or on its partitions) contained in the publication will be published using the identity and schema of the partitioned table rather than that of the individual partitions that are actually changed; the latter is the default. Enabling this allows the changes to be replicated into a non-partitioned table or a partitioned table consisting of a different set of partitions.

This parameter also affects how row filters and column lists are chosen for partitions; see below for details.

If this is enabled, TRUNCATE operations performed directly on partitions are not replicated.
**Notes**

If **FOR TABLE, FOR ALL TABLES or FOR ALL TABLES IN SCHEMA** are not specified, then the publication starts out with an empty set of tables. That is useful if tables or schemas are to be added later.

The creation of a publication does not start replication. It only defines a grouping and filtering logic for future subscribers.

To create a publication, the invoking user must have the CREATE privilege for the current database. (Of course, superusers bypass this check.)

To add a table to a publication, the invoking user must have ownership rights on the table. The **FOR ALL TABLES** and **FOR ALL TABLES IN SCHEMA** clauses require the invoking user to be a superuser.

The tables added to a publication that publishes UPDATE and/or DELETE operations must have REPLICA IDENTITY defined. Otherwise those operations will be disallowed on those tables.

A row filter expression (i.e., the **WHERE** clause) must contain only columns that are covered by the REPLICA IDENTITY, in order for UPDATE and DELETE operations to be published. For publication of INSERT operations, any column may be used in the **WHERE** expression. The row filter allows simple expressions that don’t have user-defined functions, user-defined operators, user-defined types, user-defined collations, non-immutable built-in functions, or references to system columns.

For published partitioned tables, the row filter for each partition is taken from the published partitioned table if the publication parameter `publish_via_partition_root` is true, or from the partition itself if it is false (the default). See Section 31.3 for details about row filters. Similarly, for published partitioned tables, the column list for each partition is taken from the published partitioned table if the publication parameter `publish_via_partition_root` is true, or from the partition itself if it is false.

For an **INSERT ... ON CONFLICT** command, the publication will publish the operation that actually results from the command. So depending of the outcome, it may be published as either INSERT or UPDATE, or it may not be published at all.

ATTACHing a table into a partition tree whose root is published using a publication with `publish_via_partition_root` set to true does not result in the table’s existing contents being replicated.

COPY ... FROM commands are published as INSERT operations.

DDL operations are not published.

The **WHERE** clause expression is executed with the role used for the replication connection.

**Examples**

Create a publication that publishes all changes in two tables:

```sql
CREATE PUBLICATION mypublication FOR TABLE users, departments;
```

Create a publication that publishes all changes from active departments:

```sql
CREATE PUBLICATION active_departments FOR TABLE departments WHERE (active IS TRUE);
```

Create a publication that publishes all changes in all tables:
CREATE PUBLICATION alltables FOR ALL TABLES;

Create a publication that only publishes INSERT operations in one table:

CREATE PUBLICATION insert_only FOR TABLE mydata
    WITH (publish = 'insert');

Create a publication that publishes all changes for tables users, departments and all changes for all the tables present in the schema production:

CREATE PUBLICATION production_publication FOR TABLE users, departments, ALL TABLES IN SCHEMA production;

Create a publication that publishes all changes for all the tables present in the schemas marketing and sales:

CREATE PUBLICATION sales_publication FOR ALL TABLES IN SCHEMA marketing, sales;

Create a publication that publishes all changes for table users, but replicates only columns user_id and firstname:

CREATE PUBLICATION users_filtered FOR TABLE users (user_id, firstname);

**Compatibility**

CREATE PUBLICATION is a PostgreSQL extension.

ALTER PUBLICATION, DROP PUBLICATION, CREATE SUBSCRIPTION, ALTER SUBSCRIPTION
CREATE ROLE

CREATE ROLE — define a new database role

Synopsis

CREATE ROLE name [ [ WITH ] option [ ... ] ]

where option can be:

- SUPERUSER | NOSUPERUSER
- CREATEDB | NOCREATEDB
- CREATEROLE | NOCREATEROLE
- INHERIT | NOINHERIT
- LOGIN | NOLOGIN
- REPLICATION | NOREPLICATION
- BYPASSRLS | NOBYPASSRLS
- CONNECTION LIMIT connlimit
- [ ENCRYPTED ] PASSWORD 'password' | PASSWORD NULL
- VALID UNTIL 'timestamp'
- IN ROLE role_name [, ...]
- IN GROUP role_name [, ...]
- ROLE role_name [, ...]
- ADMIN role_name [, ...]
- USER role_name [, ...]
- SYSID uid

Description

CREATE ROLE adds a new role to a PostgreSQL database cluster. A role is an entity that can own database objects and have database privileges; a role can be considered a “user”, a “group”, or both depending on how it is used. Refer to Chapter 22 and Chapter 21 for information about managing users and authentication. You must have CREATEROLE privilege or be a database superuser to use this command.

Note that roles are defined at the database cluster level, and so are valid in all databases in the cluster.

Parameters

name

The name of the new role.

SUPERUSER
NOSUPERUSER

These clauses determine whether the new role is a “superuser”, who can override all access restrictions within the database. Superuser status is dangerous and should be used only when really needed. You must yourself be a superuser to create a new superuser. If not specified, NOSUPERUSER is the default.
CREATE ROLE

CREATEDB
NOCREATEDB

These clauses define a role's ability to create databases. If CREATEDB is specified, the role being defined will be allowed to create new databases. Specifying NOCREATEDB will deny a role the ability to create databases. If not specified, NOCREATEDB is the default.

CREATEROLE
NOCREATEROLE

These clauses determine whether a role will be permitted to create new roles (that is, execute CREATE ROLE). A role with CREATEROLE privilege can also alter and drop other roles. If not specified, NOCREATEROLE is the default.

INHERIT
NOINHERIT

These clauses determine whether a role “inherits” the privileges of roles it is a member of. A role with the INHERIT attribute can automatically use whatever database privileges have been granted to all roles it is directly or indirectly a member of. Without INHERIT, membership in another role only grants the ability to SET ROLE to that other role; the privileges of the other role are only available after having done so. If not specified, INHERIT is the default.

LOGIN
NOLOGIN

These clauses determine whether a role is allowed to log in; that is, whether the role can be given as the initial session authorization name during client connection. A role having the LOGIN attribute can be thought of as a user. Roles without this attribute are useful for managing database privileges, but are not users in the usual sense of the word. If not specified, NOLOGIN is the default, except when CREATE ROLE is invoked through its alternative spelling CREATE USER.

REPLICATION
NOREPLICATION

These clauses determine whether a role is a replication role. A role must have this attribute (or be a superuser) in order to be able to connect to the server in replication mode (physical or logical replication) and in order to be able to create or drop replication slots. A role having the REPLICATION attribute is a very highly privileged role, and should only be used on roles actually used for replication. If not specified, NOREPLICATION is the default. You must be a superuser to create a new role having the REPLICATION attribute.

BYPASSRLS
NOBYPASSRLS

These clauses determine whether a role bypasses every row-level security (RLS) policy. NOBYPASSRLS is the default. You must be a superuser to create a new role having the BYPASSRLS attribute.

Note that pg_dump will set row_security to OFF by default, to ensure all contents of a table are dumped out. If the user running pg_dump does not have appropriate permissions, an error will be returned. However, superusers and the owner of the table being dumped always bypass RLS.

CONNECTION LIMIT connlimit

If role can log in, this specifies how many concurrent connections the role can make. -1 (the default) means no limit. Note that only normal connections are counted towards this limit. Neither prepared transactions nor background worker connections are counted towards this limit.
CREATE ROLE

[ ENCRYPTED ] PASSWORD 'password'
PASSWORD NULL

Sets the role's password. (A password is only of use for roles having the LOGIN attribute, but you can nonetheless define one for roles without it.) If you do not plan to use password authentication you can omit this option. If no password is specified, the password will be set to null and password authentication will always fail for that user. A null password can optionally be written explicitly as PASSWORD NULL.

Note

Specifying an empty string will also set the password to null, but that was not the case before PostgreSQL version 10. In earlier versions, an empty string could be used, or not, depending on the authentication method and the exact version, and libpq would refuse to use it in any case. To avoid the ambiguity, specifying an empty string should be avoided.

The password is always stored encrypted in the system catalogs. The ENCRYPTED keyword has no effect, but is accepted for backwards compatibility. The method of encryption is determined by the configuration parameter password_encryption. If the presented password string is already in MD5-encrypted or SCRAM-encrypted format, then it is stored as-is regardless of password_encryption (since the system cannot decrypt the specified encrypted password string, to encrypt it in a different format). This allows reloading of encrypted passwords during dump/restore.

VALID UNTIL 'timestamp'

The VALID UNTIL clause sets a date and time after which the role's password is no longer valid. If this clause is omitted the password will be valid for all time.

IN ROLE role_name

The IN ROLE clause lists one or more existing roles to which the new role will be immediately added as a new member. (Note that there is no option to add the new role as an administrator; use a separate GRANT command to do that.)

IN GROUP role_name

IN GROUP is an obsolete spelling of IN ROLE.

ROLE role_name

The ROLE clause lists one or more existing roles which are automatically added as members of the new role. (This in effect makes the new role a “group”.)

ADMIN role_name

The ADMIN clause is like ROLE, but the named roles are added to the new role WITH ADMIN OPTION, giving them the right to grant membership in this role to others.

USER role_name

The USER clause is an obsolete spelling of the ROLE clause.

SYSID uid

The SYSID clause is ignored, but is accepted for backwards compatibility.
CREATE ROLE

Notes

Use ALTER ROLE to change the attributes of a role, and DROP ROLE to remove a role. All the attributes specified by CREATE ROLE can be modified by later ALTER ROLE commands.

The preferred way to add and remove members of roles that are being used as groups is to use GRANT and REVOKE.

The VALID UNTIL clause defines an expiration time for a password only, not for the role per se. In particular, the expiration time is not enforced when logging in using a non-password-based authentication method.

The INHERIT attribute governs inheritance of grantable privileges (that is, access privileges for database objects and role memberships). It does not apply to the special role attributes set by CREATE ROLE and ALTER ROLE. For example, being a member of a role with CREATEDB privilege does not immediately grant the ability to create databases, even if INHERIT is set; it would be necessary to become that role via SET ROLE before creating a database.

The INHERIT attribute is the default for reasons of backwards compatibility: in prior releases of PostgreSQL, users always had access to all privileges of groups they were members of. However, NOINHERIT provides a closer match to the semantics specified in the SQL standard.

Be careful with the CREATEROLE privilege. There is no concept of inheritance for the privileges of a CREATEROLE-role. That means that even if a role does not have a certain privilege but is allowed to create other roles, it can easily create another role with different privileges than its own (except for creating roles with superuser privileges). For example, if the role “user” has the CREATEROLE privilege but not the CREATEDB privilege, nonetheless it can create a new role with the CREATEDB privilege. Therefore, regard roles that have the CREATEROLE privilege as almost-superuser-roles.

PostgreSQL includes a program createuser that has the same functionality as CREATE ROLE (in fact, it calls this command) but can be run from the command shell.

The CONNECTION LIMIT option is only enforced approximately; if two new sessions start at about the same time when just one connection “slot” remains for the role, it is possible that both will fail. Also, the limit is never enforced for superusers.

Caution must be exercised when specifying an unencrypted password with this command. The password will be transmitted to the server in cleartext, and it might also be logged in the client's command history or the server log. The command createuser, however, transmits the password encrypted. Also, psql contains a command \password that can be used to safely change the password later.

Examples

Create a role that can log in, but don’t give it a password:

CREATE ROLE jonathan LOGIN;

Create a role with a password:

CREATE USER davide WITH PASSWORD 'jw8s0F4';

(CREATE USER is the same as CREATE ROLE except that it implies LOGIN.)
CREATE ROLE

Create a role with a password that is valid until the end of 2004. After one second has ticked in 2005, the password is no longer valid.

CREATE ROLE miriam WITH LOGIN PASSWORD 'jw8s0F4' VALID UNTIL '2005-01-01';

Create a role that can create databases and manage roles:

CREATE ROLE admin WITH CREATEDB CREATEROLE;

Compatibility

The CREATE ROLE statement is in the SQL standard, but the standard only requires the syntax

CREATE ROLE name [ WITH ADMIN role_name ]

Multiple initial administrators, and all the other options of CREATE ROLE, are PostgreSQL extensions.

The SQL standard defines the concepts of users and roles, but it regards them as distinct concepts and leaves all commands defining users to be specified by each database implementation. In PostgreSQL we have chosen to unify users and roles into a single kind of entity. Roles therefore have many more optional attributes than they do in the standard.

The behavior specified by the SQL standard is most closely approximated by giving users the NOINHERIT attribute, while roles are given the INHERIT attribute.

SET ROLE, ALTER ROLE, DROP ROLE, GRANT, REVOKE, createuser
CREATE RULE

CREATE RULE — define a new rewrite rule

Synopsis

CREATE [ OR REPLACE ] RULE name AS ON event
  TO table_name [ WHERE condition ]
  DO [ ALSO | INSTEAD ] { NOTHING | command | ( command ; command
  ... ) }

where event can be one of:

SELECT | INSERT | UPDATE | DELETE

Description

CREATE RULE defines a new rule applying to a specified table or view. CREATE OR REPLACE RULE will either create a new rule, or replace an existing rule of the same name for the same table.

The PostgreSQL rule system allows one to define an alternative action to be performed on insertions, updates, or deletions in database tables. Roughly speaking, a rule causes additional commands to be executed when a given command on a given table is executed. Alternatively, an INSTEAD rule can replace a given command by another, or cause a command not to be executed at all. Rules are used to implement SQL views as well. It is important to realize that a rule is really a command transformation mechanism, or command macro. The transformation happens before the execution of the command starts. If you actually want an operation that fires independently for each physical row, you probably want to use a trigger, not a rule. More information about the rules system is in Chapter 41.

Presently, ON SELECT rules must be unconditional INSTEAD rules and must have actions that consist of a single SELECT command. Thus, an ON SELECT rule effectively turns the table into a view, whose visible contents are the rows returned by the rule's SELECT command rather than whatever had been stored in the table (if anything). It is considered better style to write a CREATE VIEW command than to create a real table and define an ON SELECT rule for it.

You can create the illusion of an updatable view by defining ON INSERT, ON UPDATE, and ON DELETE rules (or any subset of those that's sufficient for your purposes) to replace update actions on the view with appropriate updates on other tables. If you want to support INSERT RETURNING and so on, then be sure to put a suitable RETURNING clause into each of these rules.

There is a catch if you try to use conditional rules for complex view updates: there must be an unconditional INSTEAD rule for each action you wish to allow on the view. If the rule is conditional, or is not INSTEAD, then the system will still reject attempts to perform the update action, because it thinks it might end up trying to perform the action on the dummy table of the view in some cases. If you want to handle all the useful cases in conditional rules, add an unconditional DO INSTEAD NOTHING rule to ensure that the system understands it will never be called on to update the dummy table. Then make the conditional rules non-INSTEAD; in the cases where they are applied, they add to the default INSTEAD NOTHING action. (This method does not currently work to support RETURNING queries, however.)
Create Rule

Note

A view that is simple enough to be automatically updatable (see CREATE VIEW) does not require a user-created rule in order to be updatable. While you can create an explicit rule anyway, the automatic update transformation will generally outperform an explicit rule.

Another alternative worth considering is to use INSTEAD OF triggers (see CREATE TRIGGER) in place of rules.

Parameters

name

The name of a rule to create. This must be distinct from the name of any other rule for the same table. Multiple rules on the same table and same event type are applied in alphabetical name order.

event

The event is one of SELECT, INSERT, UPDATE, or DELETE. Note that an INSERT containing an ON CONFLICT clause cannot be used on tables that have either INSERT or UPDATE rules. Consider using an updatable view instead.

table_name

The name (optionally schema-qualified) of the table or view the rule applies to.

condition

Any SQL conditional expression (returning boolean). The condition expression cannot refer to any tables except NEW and OLD, and cannot contain aggregate functions.

INSTEAD

INSTEAD indicates that the commands should be executed instead of the original command.

ALSO

ALSO indicates that the commands should be executed in addition to the original command.

If neither ALSO nor INSTEAD is specified, ALSO is the default.

command

The command or commands that make up the rule action. Valid commands are SELECT, INSERT, UPDATE, DELETE, or NOTIFY.

Within condition and command, the special table names NEW and OLD can be used to refer to values in the referenced table. NEW is valid in ON INSERT and ON UPDATE rules to refer to the new row being inserted or updated. OLD is valid in ON UPDATE and ON DELETE rules to refer to the existing row being updated or deleted.

Notes

You must be the owner of a table to create or change rules for it.
In a rule for INSERT, UPDATE, or DELETE on a view, you can add a RETURNING clause that emits the view’s columns. This clause will be used to compute the outputs if the rule is triggered by an INSERT RETURNING, UPDATE RETURNING, or DELETE RETURNING command respectively. When the rule is triggered by a command without RETURNING, the rule's RETURNING clause will be ignored. The current implementation allows only unconditional INSTEAD rules to contain RETURNING; furthermore there can be at most one RETURNING clause among all the rules for the same event. (This ensures that there is only one candidate RETURNING clause to be used to compute the results.) RETURNING queries on the view will be rejected if there is no RETURNING clause in any available rule.

It is very important to take care to avoid circular rules. For example, though each of the following two rule definitions are accepted by PostgreSQL, the SELECT command would cause PostgreSQL to report an error because of recursive expansion of a rule:

```sql
CREATE RULE "_RETURN" AS
  ON SELECT TO t1
  DO INSTEAD
    SELECT * FROM t2;

CREATE RULE "_RETURN" AS
  ON SELECT TO t2
  DO INSTEAD
    SELECT * FROM t1;
```

SELECT * FROM t1;

Presently, if a rule action contains a NOTIFY command, the NOTIFY command will be executed unconditionally, that is, the NOTIFY will be issued even if there are not any rows that the rule should apply to. For example, in:

```sql
CREATE RULE notify_me AS ON UPDATE TO mytable DO ALSO NOTIFY mytable;
UPDATE mytable SET name = 'foo' WHERE id = 42;
```

one NOTIFY event will be sent during the UPDATE, whether or not there are any rows that match the condition id = 42. This is an implementation restriction that might be fixed in future releases.

**Compatibility**

`CREATE RULE` is a PostgreSQL language extension, as is the entire query rewrite system.

**See Also**

`ALTER RULE`, `DROP RULE`
CREATE SCHEMA

CREATE SCHEMA — define a new schema

Synopsis

```
CREATE SCHEMA schema_name [ AUTHORIZATION role_specification ]
[ schema_element [ ... ] ]
CREATE SCHEMA AUTHORIZATION role_specification [ schema_element
[ ... ] ]
CREATE SCHEMA IF NOT EXISTS schema_name
[ AUTHORIZATION role_specification ]
CREATE SCHEMA IF NOT EXISTS AUTHORIZATION role_specification
```

where role_specification can be:

- `user_name`
- `CURRENT_ROLE`
- `CURRENT_USER`
- `SESSION_USER`

Description

CREATE SCHEMA enters a new schema into the current database. The schema name must be distinct from
the name of any existing schema in the current database.

A schema is essentially a namespace: it contains named objects (tables, data types, functions, and oper-
ators) whose names can duplicate those of other objects existing in other schemas. Named objects are
accessed either by “qualifying” their names with the schema name as a prefix, or by setting a search path
that includes the desired schema(s). A CREATE command specifying an unqualified object name creates
the object in the current schema (the one at the front of the search path, which can be determined with
the function `current_schema`).

Optionally, CREATE SCHEMA can include subcommands to create objects within the new schema. The
subcommands are treated essentially the same as separate commands issued after creating the schema,
except that if the AUTHORIZATION clause is used, all the created objects will be owned by that user.

Parameters

- `schema_name`

  The name of a schema to be created. If this is omitted, the `user_name` is used as the schema name.
  The name cannot begin with `pg_`, as such names are reserved for system schemas.

- `user_name`

  The role name of the user who will own the new schema. If omitted, defaults to the user executing
  the command. To create a schema owned by another role, you must be a direct or indirect member
  of that role, or be a superuser.
schema_element

An SQL statement defining an object to be created within the schema. Currently, only CREATE TABLE, CREATE VIEW, CREATE INDEX, CREATE SEQUENCE, CREATE TRIGGER and GRANT are accepted as clauses within CREATE SCHEMA. Other kinds of objects may be created in separate commands after the schema is created.

IF NOT EXISTS

Do nothing (except issuing a notice) if a schema with the same name already exists. schema_element subcommands cannot be included when this option is used.

Notes

To create a schema, the invoking user must have the CREATE privilege for the current database. (Of course, superusers bypass this check.)

Examples

Create a schema:

CREATE SCHEMA myschema;

Create a schema for user joe; the schema will also be named joe:

CREATE SCHEMA AUTHORIZATION joe;

Create a schema named test that will be owned by user joe, unless there already is a schema named test. (It does not matter whether joe owns the pre-existing schema.)

CREATE SCHEMA IF NOT EXISTS test AUTHORIZATION joe;

Create a schema and create a table and view within it:

CREATE SCHEMA hollywood
    CREATE TABLE films (title text, release date, awards text[])
    CREATE VIEW winners AS
        SELECT title, release FROM films WHERE awards IS NOT NULL;

Notice that the individual subcommands do not end with semicolons.

The following is an equivalent way of accomplishing the same result:

CREATE SCHEMA hollywood;
CREATE TABLE hollywood.films (title text, release date, awards text[]);
CREATE VIEW hollywood.winners AS
    SELECT title, release FROM hollywood.films WHERE awards IS NOT NULL;
Compatibility

The SQL standard allows a `DEFAULT CHARACTER SET` clause in `CREATE SCHEMA`, as well as more subcommand types than are presently accepted by PostgreSQL.

The SQL standard specifies that the subcommands in `CREATE SCHEMA` can appear in any order. The present PostgreSQL implementation does not handle all cases of forward references in subcommands; it might sometimes be necessary to reorder the subcommands in order to avoid forward references.

According to the SQL standard, the owner of a schema always owns all objects within it. PostgreSQL allows schemas to contain objects owned by users other than the schema owner. This can happen only if the schema owner grants the `CREATE` privilege on their schema to someone else, or a superuser chooses to create objects in it.

The `IF NOT EXISTS` option is a PostgreSQL extension.

`ALTER SCHEMA`, `DROP SCHEMA`
CREATE SEQUENCE

CREATE SEQUENCE — define a new sequence generator

Synopsis

CREATE [ { TEMPORARY | TEMP } | UNLOGGED ] SEQUENCE [ IF NOT EXISTS ] name
   [ AS data_type ]
   [ INCREMENT [ BY ] increment ]
   [ MINVALUE minvalue | NO MINVALUE ] [ MAXVALUE maxvalue | NO MAXVALUE ]
   [ START [ WITH ] start ] [ CACHE cache ] [ [ NO ] CYCLE ]
   [ OWNED BY { table_name.column_name | NONE } ]

Description

CREATE SEQUENCE creates a new sequence number generator. This involves creating and initializing a new special single-row table with the name name. The generator will be owned by the user issuing the command.

If a schema name is given then the sequence is created in the specified schema. Otherwise it is created in the current schema. Temporary sequences exist in a special schema, so a schema name cannot be given when creating a temporary sequence. The sequence name must be distinct from the name of any other relation (table, sequence, index, view, materialized view, or foreign table) in the same schema.

After a sequence is created, you use the functions nextval, currval, and setval to operate on the sequence. These functions are documented in Section 9.17.

Although you cannot update a sequence directly, you can use a query like:

SELECT * FROM name;

to examine the parameters and current state of a sequence. In particular, the last_value field of the sequence shows the last value allocated by any session. (Of course, this value might be obsolete by the time it's printed, if other sessions are actively doing nextval calls.)

Parameters

TEMPORARY or TEMP

If specified, the sequence object is created only for this session, and is automatically dropped on session exit. Existing permanent sequences with the same name are not visible (in this session) while the temporary sequence exists, unless they are referenced with schema-qualified names.

UNLOGGED

If specified, the sequence is created as an unlogged sequence. Changes to unlogged sequences are not written to the write-ahead log. They are not crash-safe: an unlogged sequence is automatically reset
CREATE SEQUENCE

to its initial state after a crash or unclean shutdown. Unlogged sequences are also not replicated to standby servers.

Unlike unlogged tables, unlogged sequences do not offer a significant performance advantage. This option is mainly intended for sequences associated with unlogged tables via identity columns or serial columns. In those cases, it usually wouldn't make sense to have the sequence WAL-logged and replicated but not its associated table.

**IF NOT EXISTS**

Do not throw an error if a relation with the same name already exists. A notice is issued in this case. Note that there is no guarantee that the existing relation is anything like the sequence that would have been created — it might not even be a sequence.

**name**

The name (optionally schema-qualified) of the sequence to be created.

**data_type**

The optional clause AS *data_type* specifies the data type of the sequence. Valid types are smallint, integer, and bigint. bigint is the default. The data type determines the default minimum and maximum values of the sequence.

**increment**

The optional clause INCREMENT BY *increment* specifies which value is added to the current sequence value to create a new value. A positive value will make an ascending sequence, a negative one a descending sequence. The default value is 1.

**minvalue**

NO MINVALUE

The optional clause MINVALUE *minvalue* determines the minimum value a sequence can generate. If this clause is not supplied or NO MINVALUE is specified, then defaults will be used. The default for an ascending sequence is 1. The default for a descending sequence is the minimum value of the data type.

**maxvalue**

NO MAXVALUE

The optional clause MAXVALUE *maxvalue* determines the maximum value for the sequence. If this clause is not supplied or NO MAXVALUE is specified, then default values will be used. The default for an ascending sequence is the maximum value of the data type. The default for a descending sequence is -1.

**start**

The optional clause START WITH *start* allows the sequence to begin anywhere. The default starting value is minvalue for ascending sequences and maxvalue for descending ones.

**cache**

The optional clause CACHE *cache* specifies how many sequence numbers are to be preallocated and stored in memory for faster access. The minimum value is 1 (only one value can be generated at a time, i.e., no cache), and this is also the default.

1817
CREATE SEQUENCE

CYCLE
NO CYCLE

The CYCLE option allows the sequence to wrap around when the maxvalue or minvalue has been reached by an ascending or descending sequence respectively. If the limit is reached, the next number generated will be the minvalue or maxvalue, respectively.

If NO CYCLE is specified, any calls to nextval after the sequence has reached its maximum value will return an error. If neither CYCLE or NO CYCLE are specified, NO CYCLE is the default.

OWNED BY table_name.column_name
OWNED BY NONE

The OWNED BY option causes the sequence to be associated with a specific table column, such that if that column (or its whole table) is dropped, the sequence will be automatically dropped as well. The specified table must have the same owner and be in the same schema as the sequence. OWNED BY NONE, the default, specifies that there is no such association.

Notes

Use DROP SEQUENCE to remove a sequence.

Sequences are based on bigint arithmetic, so the range cannot exceed the range of an eight-byte integer (-9223372036854775808 to 9223372036854775807).

Because nextval and setval calls are never rolled back, sequence objects cannot be used if “gapless” assignment of sequence numbers is needed. It is possible to build gapless assignment by using exclusive locking of a table containing a counter; but this solution is much more expensive than sequence objects, especially if many transactions need sequence numbers concurrently.

Unexpected results might be obtained if a cache setting greater than one is used for a sequence object that will be used concurrently by multiple sessions. Each session will allocate and cache successive sequence values during one access to the sequence object and increase the sequence object's last_value accordingly. Then, the next cache-1 uses of nextval within that session simply return the preallocated values without touching the sequence object. So, any numbers allocated but not used within a session will be lost when that session ends, resulting in “holes” in the sequence.

Furthermore, although multiple sessions are guaranteed to allocate distinct sequence values, the values might be generated out of sequence when all the sessions are considered. For example, with a cache setting of 10, session A might reserve values 1..10 and return nextval=1, then session B might reserve values 11..20 and return nextval=11 before session A has generated nextval=2. Thus, with a cache setting of one it is safe to assume that nextval values are generated sequentially; with a cache setting greater than one you should only assume that the nextval values are all distinct, not that they are generated purely sequentially. Also, last_value will reflect the latest value reserved by any session, whether or not it has yet been returned by nextval.

Another consideration is that a setval executed on such a sequence will not be noticed by other sessions until they have used up any preallocated values they have cached.

Examples

Create an ascending sequence called serial, starting at 101:

CREATE SEQUENCE serial START 101;
CREATE SEQUENCE

Select the next number from this sequence:

```
SELECT nextval('serial');
```

```
nextval
--------
 101
```

Select the next number from this sequence:

```
SELECT nextval('serial');
```

```
nextval
--------
 102
```

Use this sequence in an INSERT command:

```
INSERT INTO distributors VALUES (nextval('serial'), 'nothing');
```

Update the sequence value after a COPY FROM:

```
BEGIN;
COPY distributors FROM 'input_file';
SELECT setval('serial', max(id)) FROM distributors;
END;
```

**Compatibility**

CREATE SEQUENCE conforms to the SQL standard, with the following exceptions:

- Obtaining the next value is done using the `nextval()` function instead of the standard's `NEXT VALUE FOR` expression.
- The `OWNED BY` clause is a PostgreSQL extension.

**See Also**

ALTER SEQUENCE, DROP SEQUENCE
CREATE SERVER

CREATE SERVER — define a new foreign server

Synopsis

CREATE SERVER [ IF NOT EXISTS ] server_name [ TYPE 'server_type' ]
[ VERSION 'server_version' ]
FOREIGN DATA WRAPPER fdw_name
[ OPTIONS ( option 'value' [, ... ] ) ]

Description

CREATE SERVER defines a new foreign server. The user who defines the server becomes its owner.

A foreign server typically encapsulates connection information that a foreign-data wrapper uses to access an external data resource. Additional user-specific connection information may be specified by means of user mappings.

The server name must be unique within the database.

Creating a server requires USAGE privilege on the foreign-data wrapper being used.

Parameters

IF NOT EXISTS

Do not throw an error if a server with the same name already exists. A notice is issued in this case. Note that there is no guarantee that the existing server is anything like the one that would have been created.

server_name

The name of the foreign server to be created.

server_type

Optional server type, potentially useful to foreign-data wrappers.

server_version

Optional server version, potentially useful to foreign-data wrappers.

fdw_name

The name of the foreign-data wrapper that manages the server.

OPTIONS ( option 'value' [, ... ] )

This clause specifies the options for the server. The options typically define the connection details of the server, but the actual names and values are dependent on the server's foreign-data wrapper.
Notes

When using the dblink module, a foreign server's name can be used as an argument of the dblink_connect function to indicate the connection parameters. It is necessary to have the USAGE privilege on the foreign server to be able to use it in this way.

Examples

Create a server myserver that uses the foreign-data wrapper postgres_fdw:

CREATE SERVER myserver FOREIGN DATA WRAPPER postgres_fdw OPTIONS (host 'foo', dbname 'foodb', port '5432');

See postgres_fdw for more details.

Compatibility

CREATE SERVER conforms to ISO/IEC 9075-9 (SQL/MED).

See Also

ALTER SERVER, DROP SERVER, CREATE FOREIGN DATA WRAPPER, CREATE FOREIGN TABLE, CREATE USER MAPPING
CREATE STATISTICS

CREATE STATISTICS — define extended statistics

Synopsis

CREATE STATISTICS [ IF NOT EXISTS ] statistics_name
    ON ( expression )
    FROM table_name

CREATE STATISTICS [ IF NOT EXISTS ] statistics_name
    [ ( statistics_kind [, ... ] ) ]
    ON { column_name | ( expression ) }, { column_name | ( expression ) } [, ...]
    FROM table_name

Description

CREATE STATISTICS will create a new extended statistics object tracking data about the specified table, foreign table or materialized view. The statistics object will be created in the current database and will be owned by the user issuing the command.

The CREATE STATISTICS command has two basic forms. The first form allows univariate statistics for a single expression to be collected, providing benefits similar to an expression index without the overhead of index maintenance. This form does not allow the statistics kind to be specified, since the various statistics kinds refer only to multivariate statistics. The second form of the command allows multivariate statistics on multiple columns and/or expressions to be collected, optionally specifying which statistics kinds to include. This form will also automatically cause univariate statistics to be collected on any expressions included in the list.

If a schema name is given (for example, CREATE STATISTICS myschema.mystat ...) then the statistics object is created in the specified schema. Otherwise it is created in the current schema. The name of the statistics object must be distinct from the name of any other statistics object in the same schema.

Parameters

IF NOT EXISTS

Do not throw an error if a statistics object with the same name already exists. A notice is issued in this case. Note that only the name of the statistics object is considered here, not the details of its definition.

statistics_name

The name (optionally schema-qualified) of the statistics object to be created.

statistics_kind

A multivariate statistics kind to be computed in this statistics object. Currently supported kinds are ndistinct, which enables n-distinct statistics, dependencies, which enables functional dependency statistics, and mcv which enables most-common values lists. If this clause is omitted, all supported statistics kinds are included in the statistics object. Univariate expression statistics are built...
CREATE STATISTICS

... automatically if the statistics definition includes any complex expressions rather than just simple column references. For more information, see Section 14.2.2 and Section 74.2.

**column_name**

The name of a table column to be covered by the computed statistics. This is only allowed when building multivariate statistics. At least two column names or expressions must be specified, and their order is not significant.

**expression**

An expression to be covered by the computed statistics. This may be used to build univariate statistics on a single expression, or as part of a list of multiple column names and/or expressions to build multivariate statistics. In the latter case, separate univariate statistics are built automatically for each expression in the list.

**table_name**

The name (optionally schema-qualified) of the table containing the column(s) the statistics are computed on.

### Notes

You must be the owner of a table to create a statistics object reading it. Once created, however, the ownership of the statistics object is independent of the underlying table(s).

Expression statistics are per-expression and are similar to creating an index on the expression, except that they avoid the overhead of index maintenance. Expression statistics are built automatically for each expression in the statistics object definition.

### Examples

Create table `t1` with two functionally dependent columns, i.e., knowledge of a value in the first column is sufficient for determining the value in the other column. Then functional dependency statistics are built on those columns:

```sql
CREATE TABLE t1 (  
a   int,  
b   int
);

INSERT INTO t1 SELECT i/100, i/500  
                   FROM generate_series(1,1000000) s(i);

ANALYZE t1;
-- the number of matching rows will be drastically underestimated:
EXPLAIN ANALYZE SELECT * FROM t1 WHERE (a = 1) AND (b = 0);

CREATE STATISTICS s1 (dependencies) ON a, b FROM t1;

ANALYZE t1;
-- now the row count estimate is more accurate:
```
CREATE STATISTICS

EXPLAIN ANALYZE SELECT * FROM t1 WHERE (a = 1) AND (b = 0);

Without functional-dependency statistics, the planner would assume that the two WHERE conditions are independent, and would multiply their selectivities together to arrive at a much-too-small row count estimate. With such statistics, the planner recognizes that the WHERE conditions are redundant and does not underestimate the row count.

Create table t2 with two perfectly correlated columns (containing identical data), and an MCV list on those columns:

```
CREATE TABLE t2 (
    a int,
    b int
);
```

```
INSERT INTO t2 SELECT mod(i,100), mod(i,100)
    FROM generate_series(1,1000000) s(i);
```

```
CREATE STATISTICS s2 (mcv) ON a, b FROM t2;
```

```
ANALYZE t2;
```

-- valid combination (found in MCV)
```
EXPLAIN ANALYZE SELECT * FROM t2 WHERE (a = 1) AND (b = 1);
```

-- invalid combination (not found in MCV)
```
EXPLAIN ANALYZE SELECT * FROM t2 WHERE (a = 1) AND (b = 2);
```

The MCV list gives the planner more detailed information about the specific values that commonly appear in the table, as well as an upper bound on the selectivities of combinations of values that do not appear in the table, allowing it to generate better estimates in both cases.

Create table t3 with a single timestamp column, and run queries using expressions on that column. Without extended statistics, the planner has no information about the data distribution for the expressions, and uses default estimates. The planner also does not realize that the value of the date truncated to the month is fully determined by the value of the date truncated to the day. Then expression and ndistinct statistics are built on those two expressions:

```
CREATE TABLE t3 (
    a timestamp
);
```

```
INSERT INTO t3 SELECT i FROM generate_series('2020-01-01'::timestamp,
    '2020-12-31'::timestamp,
    '1 minute'::interval)
    s(i);
```

```
ANALYZE t3;
```

-- the number of matching rows will be drastically underestimated:
```
EXPLAIN ANALYZE SELECT * FROM t3
    WHERE date_trunc('month', a) = '2020-01-01'::timestamp;
```
CREATE STATISTICS

EXPLAIN ANALYZE SELECT * FROM t3
   WHERE date_trunc('day', a) BETWEEN '2020-01-01':timestamp AND '2020-06-30':timestamp;

EXPLAIN ANALYZE SELECT date_trunc('month', a), date_trunc('day', a)
   FROM t3 GROUP BY 1, 2;

-- build ndistinct statistics on the pair of expressions (per-expression)-- statistics are built automatically
CREATE STATISTICS s3 (ndistinct) ON date_trunc('month', a),
   date_trunc('day', a) FROM t3;

ANALYZE t3;

-- now the row count estimates are more accurate:
EXPLAIN ANALYZE SELECT * FROM t3
   WHERE date_trunc('month', a) = '2020-01-01':timestamp;

EXPLAIN ANALYZE SELECT * FROM t3
   WHERE date_trunc('day', a) BETWEEN '2020-01-01':timestamp AND '2020-06-30':timestamp;

EXPLAIN ANALYZE SELECT date_trunc('month', a), date_trunc('day', a)
   FROM t3 GROUP BY 1, 2;

Without expression and ndistinct statistics, the planner has no information about the number of distinct
values for the expressions, and has to rely on default estimates. The equality and range conditions are
assumed to have 0.5% selectivity, and the number of distinct values in the expression is assumed to be
the same as for the column (i.e. unique). This results in a significant underestimate of the row count
in the first two queries. Moreover, the planner has no information about the relationship between the
expressions, so it assumes the two WHERE and GROUP BY conditions are independent, and multiplies
their selectivities together to arrive at a severe overestimate of the group count in the aggregate query.
This is further exacerbated by the lack of accurate statistics for the expressions, forcing the planner to use
a default ndistinct estimate for the expression derived from ndistinct for the column. With such statistics,
the planner recognizes that the conditions are correlated, and arrives at much more accurate estimates.

Compatibility

There is no CREATE STATISTICS command in the SQL standard.

See Also

ALTER STATISTICS, DROP STATISTICS
CREATE SUBSCRIPTION

CREATE SUBSCRIPTION — define a new subscription

Synopsis

CREATE SUBSCRIPTION subscription_name
    CONNECTION 'conninfo'
    PUBLICATION publication_name [, ...]
    [ WITH ( subscription_parameter [= value] [, ... ] ) ]

Description

CREATE SUBSCRIPTION adds a new logical-replication subscription. The subscription name must be distinct from the name of any existing subscription in the current database.

A subscription represents a replication connection to the publisher. Hence, in addition to adding definitions in the local catalogs, this command normally creates a replication slot on the publisher.

A logical replication worker will be started to replicate data for the new subscription at the commit of the transaction where this command is run, unless the subscription is initially disabled.

Additional information about subscriptions and logical replication as a whole is available at Section 31.2 and Chapter 31.

Parameters

subscription_name

The name of the new subscription.

CONNECTION 'conninfo'

The libpq connection string defining how to connect to the publisher database. For details see Section 34.1.1.

PUBLICATION publication_name [, ...]

Names of the publications on the publisher to subscribe to.

WITH ( subscription_parameter [= value] [, ... ] )

This clause specifies optional parameters for a subscription.

The following parameters control what happens during subscription creation:

connect (boolean)

Specifies whether the CREATE SUBSCRIPTION command should connect to the publisher at all. The default is true. Setting this to false will force the values of create_slot, en-
CREATE SUBSCRIPTION

abled and copy_data to false. (You cannot combine setting connect to false with setting create_slot, enabled, or copy_data to true.)

Since no connection is made when this option is false, no tables are subscribed, and so after you enable the subscription nothing will be replicated. You will need to then run ALTER SUBSCRIPTION ... REFRESH PUBLICATION for tables to be subscribed.

create_slot(boolean)

Specifies whether the command should create the replication slot on the publisher. The default is true. If set to false, you are responsible for creating the publisher's slot in some other way.

enabled(boolean)

Specifies whether the subscription should be actively replicating or whether it should just be set up but not started yet. The default is true.

slot_name(string)

Name of the publisher's replication slot to use. The default is to use the name of the subscription for the slot name.

Setting slot_name to NONE means there will be no replication slot associated with the subscription. Use this when you will be creating the replication slot later manually. Such subscriptions must also have both enabled and create_slot set to false.

The following parameters control the subscription's replication behavior after it has been created:

binary(boolean)

Specifies whether the subscription will request the publisher to send the data in binary format (as opposed to text). The default is false. Even when this option is enabled, only data types having binary send and receive functions will be transferred in binary.

When doing cross-version replication, it could be that the publisher has a binary send function for some data type, but the subscriber lacks a binary receive function for that type. In such a case, data transfer will fail, and the binary option cannot be used.

copy_data(boolean)

Specifies whether to copy pre-existing data in the publications that are being subscribed to when the replication starts. The default is true.

If the publications contain WHERE clauses, it will affect what data is copied. Refer to the Notes for details.

streaming(boolean)

Specifies whether to enable streaming of in-progress transactions for this subscription. By default, all transactions are fully decoded on the publisher and only then sent to the subscriber as a whole.

synchronous_commit(enum)

The value of this parameter overrides the synchronous_commit setting within this subscription's apply worker processes. The default value is off.

It is safe to use off for logical replication: If the subscriber loses transactions because of missing synchronization, the data will be sent again from the publisher.
A different setting might be appropriate when doing synchronous logical replication. The logical replication workers report the positions of writes and flushes to the publisher, and when using synchronous replication, the publisher will wait for the actual flush. This means that setting `synchronous_commit` for the subscriber to `off` when the subscription is used for synchronous replication might increase the latency for `COMMIT` on the publisher. In this scenario, it can be advantageous to set `synchronous_commit` to `local` or higher.

two_phase (boolean)

Specifies whether two-phase commit is enabled for this subscription. The default is `false`.

When two-phase commit is enabled, prepared transactions are sent to the subscriber at the time of `PREPARE TRANSACTION`, and are processed as two-phase transactions on the subscriber too. Otherwise, prepared transactions are sent to the subscriber only when committed, and are then processed immediately by the subscriber.

The implementation of two-phase commit requires that replication has successfully finished the initial table synchronization phase. So even when `two_phase` is enabled for a subscription, the internal two-phase state remains temporarily “pending” until the initialization phase completes. See column `subtwophasestate` of `pg_subscription` to know the actual two-phase state.

disable_on_error (boolean)

Specifies whether the subscription should be automatically disabled if any errors are detected by subscription workers during data replication from the publisher. The default is `false`.

Notes

See Section 31.8 for details on how to configure access control between the subscription and the publication instance.

When creating a replication slot (the default behavior), `CREATE SUBSCRIPTION` cannot be executed inside a transaction block.

Creating a subscription that connects to the same database cluster (for example, to replicate between databases in the same cluster or to replicate within the same database) will only succeed if the replication slot is not created as part of the same command. Otherwise, the `CREATE SUBSCRIPTION` call will hang. To make this work, create the replication slot separately (using the function `pg_create_logical_replication_slot` with the plugin name `pgoutput`) and create the subscription using the parameter `create_slot = false`. This is an implementation restriction that might be lifted in a future release.

If any table in the publication has a `WHERE` clause, rows for which the `expression` evaluates to false or null will not be published. If the subscription has several publications in which the same table has been published with different `WHERE` clauses, a row will be published if any of the expressions (referring to that publish operation) are satisfied. In the case of different `WHERE` clauses, if one of the publications has no `WHERE` clause (referring to that publish operation) or the publication is declared as `FOR ALL TABLES` or `FOR ALL TABLES IN SCHEMA`, rows are always published regardless of the definition of the other expressions. If the subscriber is a PostgreSQL version before 15 then any row filtering is ignored during the initial data synchronization phase. For this case, the user might want to consider deleting any initially copied data that would be incompatible with subsequent filtering. Because initial data synchronization does not take into account the publication `publish` parameter when copying existing table data, some rows may be copied that would not be replicated using DML. See Section 31.2.2 for examples.

Subscriptions having several publications in which the same table has been published with different column lists are not supported.
CREATE SUBSCRIPTION

We allow non-existent publications to be specified so that users can add those later. This means `pg_subscription` can have non-existent publications.

Examples

Create a subscription to a remote server that replicates tables in the publications `mypublication` and `insert_only` and starts replicating immediately on commit:

```
CREATE SUBSCRIPTION mysub
    CONNECTION 'host=192.168.1.50 port=5432 user=foo
dbname=foodb'
    PUBLICATION mypublication, insert_only;
```

Create a subscription to a remote server that replicates tables in the `insert_only` publication and does not start replicating until enabled at a later time:

```
CREATE SUBSCRIPTION mysub
    CONNECTION 'host=192.168.1.50 port=5432 user=foo
dbname=foodb'
    PUBLICATION insert_only
    WITH (enabled = false);
```

Compatibility

`CREATE SUBSCRIPTION` is a PostgreSQL extension.

[, ... ] ) ] | SET DEFAULT [ ( column_name [, ... ] ) ] } }
```

**Description**

CREATE TABLE will create a new, initially empty table in the current database. The table will be owned by the user issuing the command.

If a schema name is given (for example, CREATE TABLE myschema.mytable ...) then the table is created in the specified schema. Otherwise it is created in the current schema. Temporary tables exist in a special schema, so a schema name cannot be given when creating a temporary table. The name of the table must be distinct from the name of any other relation (table, sequence, index, view, materialized view, or foreign table) in the same schema.

CREATE TABLE also automatically creates a data type that represents the composite type corresponding to one row of the table. Therefore, tables cannot have the same name as any existing data type in the same schema.

The optional constraint clauses specify constraints (tests) that new or updated rows must satisfy for an insert or update operation to succeed. A constraint is an SQL object that helps define the set of valid values in the table in various ways.

There are two ways to define constraints: table constraints and column constraints. A column constraint is defined as part of a column definition. A table constraint definition is not tied to a particular column, and it can encompass more than one column. Every column constraint can also be written as a table constraint; a column constraint is only a notational convenience for use when the constraint only affects one column.

To be able to create a table, you must have USAGE privilege on all column types or the type in the OF clause, respectively.

**Parameters**

**TEMPORARY** or **TEMP**

If specified, the table is created as a temporary table. Temporary tables are automatically dropped at the end of a session, or optionally at the end of the current transaction (see ON COMMIT below). The default search_path includes the temporary schema first and so identically named existing permanent tables are not chosen for new plans while the temporary table exists, unless they are referenced with schema-qualified names. Any indexes created on a temporary table are automatically temporary as well.

The autovacuum daemon cannot access and therefore cannot vacuum or analyze temporary tables. For this reason, appropriate vacuum and analyze operations should be performed via session SQL commands. For example, if a temporary table is going to be used in complex queries, it is wise to run ANALYZE on the temporary table after it is populated.

Optionally, GLOBAL or LOCAL can be written before TEMPORARY or TEMP. This presently makes no difference in PostgreSQL and is deprecated; see Compatibility below.
CREATE TABLE

UNLOGGED

If specified, the table is created as an unlogged table. Data written to unlogged tables is not written
to the write-ahead log (see Chapter 30), which makes them considerably faster than ordinary tables.
However, they are not crash-safe: an unlogged table is automatically truncated after a crash or unclean
shutdown. The contents of an unlogged table are also not replicated to standby servers. Any indexes
created on an unlogged table are automatically unlogged as well.

If this is specified, any sequences created together with the unlogged table (for identity or serial
columns) are also created as unlogged.

IF NOT EXISTS

Do not throw an error if a relation with the same name already exists. A notice is issued in this case.
Note that there is no guarantee that the existing relation is anything like the one that would have been
created.

table_name

The name (optionally schema-qualified) of the table to be created.

OF type_name

Creates a typed table, which takes its structure from the specified composite type (name optionally
schema-qualified). A typed table is tied to its type; for example the table will be dropped if the type
is dropped (with DROP TYPE ... CASCADE).

When a typed table is created, then the data types of the columns are determined by the underlying
composite type and are not specified by the CREATE TABLE command. But the CREATE TABLE
command can add defaults and constraints to the table and can specify storage parameters.

column_name

The name of a column to be created in the new table.

data_type

The data type of the column. This can include array specifiers. For more information on the data types
supported by PostgreSQL, refer to Chapter 8.

COLLATE collation

The COLLATE clause assigns a collation to the column (which must be of a collatable data type). If
not specified, the column data type's default collation is used.

COMPRESSION compression_method

The COMPRESSION clause sets the compression method for the column. Compression is supported
only for variable-width data types, and is used only when the column's storage mode is main or
extended. (See ALTER TABLE for information on column storage modes.) Setting this property
for a partitioned table has no direct effect, because such tables have no storage of their own, but the
configured value will be inherited by newly-created partitions. The supported compression methods
are pglz and lz4. (lz4 is available only if --with-lz4 was used when building PostgreSQL.)
In addition, compression_method can be default to explicitly specify the default behavior,
which is to consult the default_toast_compression setting at the time of data insertion to determine
the method to use.

1833
INHERITS (parent_table [, ... ])

The optional INHERITS clause specifies a list of tables from which the new table automatically inherits all columns. Parent tables can be plain tables or foreign tables.

Use of INHERITS creates a persistent relationship between the new child table and its parent table(s). Schema modifications to the parent(s) normally propagate to children as well, and by default the data of the child table is included in scans of the parent(s).

If the same column name exists in more than one parent table, an error is reported unless the data types of the columns match in each of the parent tables. If there is no conflict, then the duplicate columns are merged to form a single column in the new table. If the column name list of the new table contains a column name that is also inherited, the data type must likewise match the inherited column(s), and the column definitions are merged into one. If the new table explicitly specifies a default value for the column, this default overrides any defaults from inherited declarations of the column. Otherwise, any parents that specify default values for the column must all specify the same default, or an error will be reported.

CHECK constraints are merged in essentially the same way as columns: if multiple parent tables and/or the new table definition contain identically-named CHECK constraints, these constraints must all have the same check expression, or an error will be reported. Constraints having the same name and expression will be merged into one copy. A constraint marked NO INHERIT in a parent will not be considered. Notice that an unnamed CHECK constraint in the new table will never be merged, since a unique name will always be chosen for it.

Column STORAGE settings are also copied from parent tables.

If a column in the parent table is an identity column, that property is not inherited. A column in the child table can be declared identity column if desired.

PARTITION BY { RANGE | LIST | HASH } ( { column_name | ( expression ) } [ opclass ] [, ... ] )

The optional PARTITION BY clause specifies a strategy of partitioning the table. The table thus created is called a partitioned table. The parenthesized list of columns or expressions forms the partition key for the table. When using range or hash partitioning, the partition key can include multiple columns or expressions (up to 32, but this limit can be altered when building PostgreSQL), but for list partitioning, the partition key must consist of a single column or expression.

Range and list partitioning require a btree operator class, while hash partitioning requires a hash operator class. If no operator class is specified explicitly, the default operator class of the appropriate type will be used; if no default operator class exists, an error will be raised. When hash partitioning is used, the operator class used must implement support function 2 (see Section 38.16.3 for details).

A partitioned table is divided into sub-tables (called partitions), which are created using separate CREATE TABLE commands. The partitioned table is itself empty. A data row inserted into the table is routed to a partition based on the value of columns or expressions in the partition key. If no existing partition matches the values in the new row, an error will be reported.

Partitioned tables do not support EXCLUDE constraints; however, you can define these constraints on individual partitions.

See Section 5.11 for more discussion on table partitioning.

PARTITION OF parent_table { FOR VALUES partition_bound_spec | DEFAULT }

Creates the table as a partition of the specified parent table. The table can be created either as a partition for specific values using FOR VALUES or as a default partition using DEFAULT. Any indexes,
CREATE TABLE

constraints and user-defined row-level triggers that exist in the parent table are cloned on the new partition.

The \texttt{partition\_bound\_spec} must correspond to the partitioning method and partition key of the parent table, and must not overlap with any existing partition of that parent. The form with \texttt{IN} is used for list partitioning, the form with \texttt{FROM} and \texttt{TO} is used for range partitioning, and the form with \texttt{WITH} is used for hash partitioning.

\texttt{partition\_bound\_expr} is any variable-free expression (subqueries, window functions, aggregate functions, and set-returning functions are not allowed). Its data type must match the data type of the corresponding partition key column. The expression is evaluated once at table creation time, so it can even contain volatile expressions such as \texttt{CURRENT\_TIMESTAMP}.

When creating a list partition, \texttt{NULL} can be specified to signify that the partition allows the partition key column to be null. However, there cannot be more than one such list partition for a given parent table. \texttt{NULL} cannot be specified for range partitions.

When creating a range partition, the lower bound specified with \texttt{FROM} is an inclusive bound, whereas the upper bound specified with \texttt{TO} is an exclusive bound. That is, the values specified in the \texttt{FROM} list are valid values of the corresponding partition key columns for this partition, whereas those in the \texttt{TO} list are not. Note that this statement must be understood according to the rules of row-wise comparison (Section 9.24.5). For example, given \texttt{PARTITION BY RANGE \texttt{(x, y)}}, a partition bound \texttt{FROM \texttt{(1, 2)} TO \texttt{(3, 4)}} allows \texttt{x=1} with any \texttt{y}\textgreater{}=2, \texttt{x=2} with any non-null \texttt{y}, and \texttt{x=3} with any \texttt{y}<4.

The special values \texttt{MINVALUE} and \texttt{MAXVALUE} may be used when creating a range partition to indicate that there is no lower or upper bound on the column's value. For example, a partition defined using \texttt{FROM \texttt{(MINVALUE)} TO \texttt{(10)}} allows any values less than 10, and a partition defined using \texttt{FROM \texttt{(10)} TO \texttt{(MAXVALUE)}} allows any values greater than or equal to 10.

When creating a range partition involving more than one column, it can also make sense to use \texttt{MAX\textunderscore{}VALUE} as part of the lower bound, and \texttt{MIN\textunderscore{}VALUE} as part of the upper bound. For example, a partition defined using \texttt{FROM \texttt{(0, MAX\textunderscore{}VALUE)} TO \texttt{(10, MAX\textunderscore{}VALUE)}} allows any rows where the first partition key column is greater than 0 and less than or equal to 10. Similarly, a partition defined using \texttt{FROM \texttt{('a', MIN\textunderscore{}VALUE)} TO \texttt{('b', MIN\textunderscore{}VALUE)}} allows any rows where the first partition key column starts with "a".

Note that if \texttt{MINVALUE} or \texttt{MAXVALUE} is used for one column of a partitioning bound, the same value must be used for all subsequent columns. For example, \texttt{(10, MIN\textunderscore{}VALUE, 0)} is not a valid bound; you should write \texttt{(10, MIN\textunderscore{}VALUE, MIN\textunderscore{}VALUE)}.

Also note that some element types, such as \texttt{timestamp}, have a notion of "infinity", which is just another value that can be stored. This is different from \texttt{MINVALUE} and \texttt{MAXVALUE}, which are not real values that can be stored, but rather they are ways of saying that the value is unbounded. \texttt{MAXVALUE} can be thought of as being greater than any other value, including "infinity" and \texttt{MINVALUE} as being less than any other value, including "minus infinity". Thus the range \texttt{FROM \texttt{('infinity')}} \texttt{TO \texttt{(MAX\textunderscore{}VALUE)}} is not an empty range; it allows precisely one value to be stored — "infinity".

If \texttt{DEFAULT} is specified, the table will be created as the default partition of the parent table. This option is not available for hash-partitioned tables. A partition key value not fitting into any other partition of the given parent will be routed to the default partition.

When a table has an existing \texttt{DEFAULT} partition and a new partition is added to it, the default partition must be scanned to verify that it does not contain any rows which properly belong in the new partition. If the default partition contains a large number of rows, this may be slow. The scan will be skipped if the default partition is a foreign table or if it has a constraint which proves that it cannot contain rows which should be placed in the new partition.
When creating a hash partition, a modulus and remainder must be specified. The modulus must be a positive integer, and the remainder must be a non-negative integer less than the modulus. Typically, when initially setting up a hash-partitioned table, you should choose a modulus equal to the number of partitions and assign every table the same modulus and a different remainder (see examples, below). However, it is not required that every partition have the same modulus, only that every modulus which occurs among the partitions of a hash-partitioned table is a factor of the next larger modulus. This allows the number of partitions to be increased incrementally without needing to move all the data at once. For example, suppose you have a hash-partitioned table with 8 partitions, each of which has modulus 8, but find it necessary to increase the number of partitions to 16. You can detach one of the modulus-8 partitions, create two new modulus-16 partitions covering the same portion of the key space (one with a remainder equal to the remainder of the detached partition, and the other with a remainder equal to that value plus 8), and repopulate them with data. You can then repeat this -- perhaps at a later time -- for each modulus-8 partition until none remain. While this may still involve a large amount of data movement at each step, it is still better than having to create a whole new table and move all the data at once.

A partition must have the same column names and types as the partitioned table to which it belongs. Modifications to the column names or types of a partitioned table will automatically propagate to all partitions. CHECK constraints will be inherited automatically by every partition, but an individual partition may specify additional CHECK constraints; additional constraints with the same name and condition as in the parent will be merged with the parent constraint. Defaults may be specified separately for each partition. But note that a partition's default value is not applied when inserting a tuple through a partitioned table.

Rows inserted into a partitioned table will be automatically routed to the correct partition. If no suitable partition exists, an error will occur.

Operations such as TRUNCATE which normally affect a table and all of its inheritance children will cascade to all partitions, but may also be performed on an individual partition. Note that dropping a partition with DROP TABLE requires taking an ACCESS EXCLUSIVE lock on the parent table.

LIKE source_table [ like_option ... ]

The LIKE clause specifies a table from which the new table automatically copies all column names, their data types, and their not-null constraints.

Unlike INHERITS, the new table and original table are completely decoupled after creation is complete. Changes to the original table will not be applied to the new table, and it is not possible to include data of the new table in scans of the original table.

Also unlike INHERITS, columns and constraints copied by LIKE are not merged with similarly named columns and constraints. If the same name is specified explicitly or in another LIKE clause, an error is signaled.

The optional like_option clauses specify which additional properties of the original table to copy. Specifying INCLUDING copies the property, specifying EXCLUDING omits the property. EXCLUDING is the default. If multiple specifications are made for the same kind of object, the last one is used. The available options are:

INCLUDING COMMENTS

Comments for the copied columns, constraints, and indexes will be copied. The default behavior is to exclude comments, resulting in the copied columns and constraints in the new table having no comments.
INCLUDING COMPRESSION

Compression method of the columns will be copied. The default behavior is to exclude compression methods, resulting in columns having the default compression method.

INCLUDING CONSTRAINTS

CHECK constraints will be copied. No distinction is made between column constraints and table constraints. Not-null constraints are always copied to the new table.

INCLUDING DEFAULTS

Default expressions for the copied column definitions will be copied. Otherwise, default expressions are not copied, resulting in the copied columns in the new table having null defaults. Note that copying defaults that call database-modification functions, such as nextval, may create a functional linkage between the original and new tables.

INCLUDING GENERATED

Any generation expressions of copied column definitions will be copied. By default, new columns will be regular base columns.

INCLUDING IDENTITY

Any identity specifications of copied column definitions will be copied. A new sequence is created for each identity column of the new table, separate from the sequences associated with the old table.

INCLUDING INDEXES

Indexes, PRIMARY KEY, UNIQUE, and EXCLUDE constraints on the original table will be created on the new table. Names for the new indexes and constraints are chosen according to the default rules, regardless of how the originals were named. (This behavior avoids possible duplicate-name failures for the new indexes.)

INCLUDING STATISTICS

Extended statistics are copied to the new table.

INCLUDING STORAGE

STORAGE settings for the copied column definitions will be copied. The default behavior is to exclude STORAGE settings, resulting in the copied columns in the new table having type-specific default settings. For more on STORAGE settings, see Section 72.2.

INCLUDING ALL

INCLUDING ALL is an abbreviated form selecting all the available individual options. (It could be useful to write individual EXCLUDING clauses after INCLUDING ALL to select all but some specific options.)

The LIKE clause can also be used to copy column definitions from views, foreign tables, or composite types. Inapplicable options (e.g., INCLUDING INDEXES from a view) are ignored.

CONSTRAINT constraint_name

An optional name for a column or table constraint. If the constraint is violated, the constraint name is present in error messages, so constraint names like col must be positive can be used to communicate helpful constraint information to client applications. (Double-quotes are needed to
specify constraint names that contain spaces.) If a constraint name is not specified, the system generates a name.

NOT NULL
The column is not allowed to contain null values.

NULL
The column is allowed to contain null values. This is the default.

This clause is only provided for compatibility with non-standard SQL databases. Its use is discouraged in new applications.

CHECK ( expression ) [ NO INHERIT ]
The CHECK clause specifies an expression producing a Boolean result which new or updated rows must satisfy for an insert or update operation to succeed. Expressions evaluating to TRUE or UNKNOWN succeed. Should any row of an insert or update operation produce a FALSE result, an error exception is raised and the insert or update does not alter the database. A check constraint specified as a column constraint should reference that column's value only, while an expression appearing in a table constraint can reference multiple columns.

Currently, CHECK expressions cannot contain subqueries nor refer to variables other than columns of the current row (see Section 5.4.1). The system column tableoid may be referenced, but not any other system column.

A constraint marked with NO INHERIT will not propagate to child tables.

When a table has multiple CHECK constraints, they will be tested for each row in alphabetical order by name, after checking NOT NULL constraints. (PostgreSQL versions before 9.5 did not honor any particular firing order for CHECK constraints.)

DEFAULT default_expr
The DEFAULT clause assigns a default data value for the column whose column definition it appears within. The value is any variable-free expression (in particular, cross-references to other columns in the current table are not allowed). Subqueries are not allowed either. The data type of the default expression must match the data type of the column.

The default expression will be used in any insert operation that does not specify a value for the column. If there is no default for a column, then the default is NULL.

GENERATED ALWAYS AS ( generation_expr ) STORED
This clause creates the column as a generated column. The column cannot be written to, and when read the result of the specified expression will be returned.

The keyword STORED is required to signify that the column will be computed on write and will be stored on disk.

The generation expression can refer to other columns in the table, but not other generated columns. Any functions and operators used must be immutable. References to other tables are not allowed.

GENERATED { ALWAYS | BY DEFAULT } AS IDENTITY [ ( sequence_options ) ]
This clause creates the column as an identity column. It will have an implicit sequence attached to it and the column in new rows will automatically have values from the sequence assigned to it. Such a column is implicitly NOT NULL.
The clauses **ALWAYS** and **BY.DEFAULT** determine how explicitly user-specified values are handled in **INSERT** and **UPDATE** commands.

In an **INSERT** command, if **ALWAYS** is selected, a user-specified value is only accepted if the **INSERT** statement specifies **OVERRIDING SYSTEM VALUE**. If **BY DEFAULT** is selected, then the user-specified value takes precedence. See **INSERT** for details. (In the **COPY** command, user-specified values are always used regardless of this setting.)

In an **UPDATE** command, if **ALWAYS** is selected, any update of the column to any value other than **DEFAULT** will be rejected. If **BY DEFAULT** is selected, the column can be updated normally. (There is no **OVERRIDING** clause for the **UPDATE** command.)

The optional **sequence_options** clause can be used to override the options of the sequence. See **CREATE SEQUENCE** for details.

```
UNIQUE [ NULLS [ NOT ] DISTINCT ] (column constraint)
UNIQUE [ NULLS [ NOT ] DISTINCT ] (column_name [, ... ]) [ INCLUDE (column_name [, ...]) ] (table constraint)
```

The **UNIQUE** constraint specifies that a group of one or more columns of a table can contain only unique values. The behavior of a unique table constraint is the same as that of a unique column constraint, with the additional capability to span multiple columns. The constraint therefore enforces that any two rows must differ in at least one of these columns.

For the purpose of a unique constraint, null values are not considered equal, unless **NULLS NOT DISTINCT** is specified.

Each unique constraint should name a set of columns that is different from the set of columns named by any other unique or primary key constraint defined for the table. (Otherwise, redundant unique constraints will be discarded.)

When establishing a unique constraint for a multi-level partition hierarchy, all the columns in the partition key of the target partitioned table, as well as those of all its descendant partitioned tables, must be included in the constraint definition.

Adding a unique constraint will automatically create a unique btree index on the column or group of columns used in the constraint.

The optional **INCLUDE** clause adds to that index one or more columns that are simply “payload”: uniqueness is not enforced on them, and the index cannot be searched on the basis of those columns. However they can be retrieved by an index-only scan. Note that although the constraint is not enforced on included columns, it still depends on them. Consequently, some operations on such columns (e.g., **DROP COLUMN**) can cause cascaded constraint and index deletion.

```
PRIMARY KEY (column constraint)
PRIMARY KEY (column_name [, ... ]) [ INCLUDE (column_name [, ...]) ] (table constraint)
```

The **PRIMARY KEY** constraint specifies that a column or columns of a table can contain only unique (non-duplicate), nonnull values. Only one primary key can be specified for a table, whether as a column constraint or a table constraint.

The primary key constraint should name a set of columns that is different from the set of columns named by any unique constraint defined for the same table. (Otherwise, the unique constraint is redundant and will be discarded.)
CREATE TABLE

PRIMARY KEY enforces the same data constraints as a combination of UNIQUE and NOT NULL. However, identifying a set of columns as the primary key also provides metadata about the design of the schema, since a primary key implies that other tables can rely on this set of columns as a unique identifier for rows.

When placed on a partitioned table, PRIMARY KEY constraints share the restrictions previously described for UNIQUE constraints.

Adding a PRIMARY KEY constraint will automatically create a unique btree index on the column or group of columns used in the constraint.

The optional INCLUDE clause adds to that index one or more columns that are simply “payload”: uniqueness is not enforced on them, and the index cannot be searched on the basis of those columns. However they can be retrieved by an index-only scan. Note that although the constraint is not enforced on included columns, it still depends on them. Consequently, some operations on such columns (e.g., DROP COLUMN) can cause cascaded constraint and index deletion.

EXCLUDE [ USING index_method ] ( exclude_element WITH operator [, ... ] )
index_parameters [ WHERE ( predicate ) ]

The EXCLUDE clause defines an exclusion constraint, which guarantees that if any two rows are compared on the specified column(s) or expression(s) using the specified operator(s), not all of these comparisons will return TRUE. If all of the specified operators test for equality, this is equivalent to a UNIQUE constraint, although an ordinary unique constraint will be faster. However, exclusion constraints can specify constraints that are more general than simple equality. For example, you can specify a constraint that no two rows in the table contain overlapping circles (see Section 8.8) by using the & operator.

Exclusion constraints are implemented using an index, so each specified operator must be associated with an appropriate operator class (see Section 11.10) for the index access method index_method. The operators are required to be commutative. Each exclude_element can optionally specify an operator class and/or ordering options; these are described fully under CREATE INDEX.

The access method must support amgettuple (see Chapter 63); at present this means GIN cannot be used. Although it's allowed, there is little point in using B-tree or hash indexes with an exclusion constraint, because this does nothing that an ordinary unique constraint doesn't do better. So in practice the access method will always be GiST or SP-GiST.

The predicate allows you to specify an exclusion constraint on a subset of the table; internally this creates a partial index. Note that parentheses are required around the predicate.

REFERENCES reftable [ ( refcolumn ) ] ( MATCH matchtype ) ( ON DELETE referential_action ) ( ON UPDATE referential_action ) (column constraint)
FOREIGN KEY ( column_name [, ... ] ) REFERENCES reftable [ ( refcolumn [, ... ] ) ] ( MATCH matchtype ) ( ON DELETE referential_action ) ( ON UPDATE referential_action ) (table constraint)

These clauses specify a foreign key constraint, which requires that a group of one or more columns of the new table must only contain values that match values in the referenced column(s) of some row of the referenced table. If the refcolumn list is omitted, the primary key of the reftable is used. The referenced columns must be the columns of a non-deferrable unique or primary key constraint in the referenced table. The user must have REFERENCES permission on the referenced table (either the whole table, or the specific referenced columns). The addition of a foreign key constraint requires a SHARE ROW EXCLUSIVE lock on the referenced table. Note that foreign key constraints cannot be defined between temporary tables and permanent tables.
A value inserted into the referencing column(s) is matched against the values of the referenced table and referenced columns using the given match type. There are three match types: MATCH FULL, MATCH PARTIAL, and MATCH SIMPLE (which is the default). MATCH FULL will not allow one column of a multicolumn foreign key to be null unless all foreign key columns are null; if they are all null, the row is not required to have a match in the referenced table. MATCH SIMPLE allows any of the foreign key columns to be null; if any of them are null, the row is not required to have a match in the referenced table. MATCH PARTIAL is not yet implemented. (Of course, NOT NULL constraints can be applied to the referencing column(s) to prevent these cases from arising.)

In addition, when the data in the referenced columns is changed, certain actions are performed on the data in this table's columns. The ON DELETE clause specifies the action to perform when a referenced row in the referenced table is being deleted. Likewise, the ON UPDATE clause specifies the action to perform when a referenced column in the referenced table is being updated to a new value. If the row is updated, but the referenced column is not actually changed, no action is done. Referential actions other than the NO ACTION check cannot be deferred, even if the constraint is declared deferrable. There are the following possible actions for each clause:

**NO ACTION**

Produce an error indicating that the deletion or update would create a foreign key constraint violation. If the constraint is deferred, this error will be produced at constraint check time if there still exist any referencing rows. This is the default action.

**RESTRICT**

Produce an error indicating that the deletion or update would create a foreign key constraint violation. This is the same as **NO ACTION** except that the check is not deferrable.

**CASCADE**

Delete any rows referencing the deleted row, or update the values of the referencing column(s) to the new values of the referenced columns, respectively.

**SET NULL** [ ( column_name [, ... ] ) ]

Set all of the referencing columns, or a specified subset of the referencing columns, to null. A subset of columns can only be specified for ON DELETE actions.

**SET DEFAULT** [ ( column_name [, ... ] ) ]

Set all of the referencing columns, or a specified subset of the referencing columns, to their default values. A subset of columns can only be specified for ON DELETE actions. (There must be a row in the referenced table matching the default values, if they are not null, or the operation will fail.)

If the referenced column(s) are changed frequently, it might be wise to add an index to the referencing column(s) so that referential actions associated with the foreign key constraint can be performed more efficiently.

**DEFERRABLE**

This controls whether the constraint can be deferred. A constraint that is not deferrable will be checked immediately after every command. Checking of constraints that are deferrable can be postponed until the end of the transaction (using the SET CONSTRAINTS command). **NOT DEFERRABLE** is the default. Currently, only UNIQUE, PRIMARY KEY, EXCLUDE, and REFERENCES (foreign key) constraints accept this clause. NOT NULL and CHECK constraints are not deferrable. Note that de-
CREATE TABLE

ferrable constraints cannot be used as conflict arbitrators in an INSERT statement that includes an ON CONFLICT DO UPDATE clause.

INITIALLY IMMEDIATE
INITIALLY DEFERRED

If a constraint is deferrable, this clause specifies the default time to check the constraint. If the constraint is INITIALLY IMMEDIATE, it is checked after each statement. This is the default. If the constraint is INITIALLY DEFERRED, it is checked only at the end of the transaction. The constraint check time can be altered with the SET CONSTRAINTS command.

USING method

This optional clause specifies the table access method to use to store the contents for the new table; the method needs be an access method of type TABLE. See Chapter 62 for more information. If this option is not specified, the default table access method is chosen for the new table. See default_table_access_method for more information.

WITH ( storage_parameter [= value] [, ... ] )

This clause specifies optional storage parameters for a table or index; see Storage Parameters below for more information. For backward-compatibility the WITH clause for a table can also include OIDS=FALSE to specify that rows of the new table should not contain OIDs (object identifiers), OIDS=TRUE is not supported anymore.

WITHOUT OIDS

This is backward-compatible syntax for declaring a table WITHOUT OIDS, creating a table WITH OIDS is not supported anymore.

ON COMMIT

The behavior of temporary tables at the end of a transaction block can be controlled using ON COMMIT. The three options are:

PRESERVE ROWS

No special action is taken at the ends of transactions. This is the default behavior.

DELETE ROWS

All rows in the temporary table will be deleted at the end of each transaction block. Essentially, an automatic TRUNCATE is done at each commit. When used on a partitioned table, this is not cascaded to its partitions.

DROP

The temporary table will be dropped at the end of the current transaction block. When used on a partitioned table, this action drops its partitions and when used on tables with inheritance children, it drops the dependent children.

TABLESPACE tablespace_name

The tablespace_name is the name of the tablespace in which the new table is to be created. If not specified, default_tablespace is consulted, or temp_tablespaces if the table is temporary. For partitioned tables, since no storage is required for the table itself, the tablespace specified overrides
CREATE TABLE

default_tablespace as the default tablespace to use for any newly created partitions when no other tablespace is explicitly specified.

USING INDEX TABLESPACE tablespace_name

This clause allows selection of the tablespace in which the index associated with a UNIQUE, PRIMARY KEY, or EXCLUDE constraint will be created. If not specified, default_tablespace is consulted, or temp_tablespaces if the table is temporary.

Storage Parameters

The WITH clause can specify storage parameters for tables, and for indexes associated with a UNIQUE, PRIMARY KEY, or EXCLUDE constraint. Storage parameters for indexes are documented in CREATE INDEX. The storage parameters currently available for tables are listed below. For many of these parameters, as shown, there is an additional parameter with the same name prefixed with toast., which controls the behavior of the table's secondary TOAST table, if any (see Section 72.2 for more information about TOAST). If a table parameter value is set and the equivalent toast. parameter is not, the TOAST table will use the table's parameter value. Specifying these parameters for partitioned tables is not supported, but you may specify them for individual leaf partitions.

fillfactor(integer)

The fillfactor for a table is a percentage between 10 and 100. 100 (complete packing) is the default. When a smaller fillfactor is specified, INSERT operations pack table pages only to the indicated percentage; the remaining space on each page is reserved for updating rows on that page. This gives UPDATE a chance to place the updated copy of a row on the same page as the original, which is more efficient than placing it on a different page. For a table whose entries are never updated, complete packing is the best choice, but in heavily updated tables smaller fillfactors are appropriate. This parameter cannot be set for TOAST tables.

toast_tuple_target(integer)

The toast_tuple_target specifies the minimum tuple length required before we try to compress and/or move long column values into TOAST tables, and is also the target length we try to reduce the length below once toasting begins. This affects columns marked as External (for move), Main (for compression), or Extended (for both) and applies only to new tuples. There is no effect on existing rows. By default this parameter is set to allow at least 4 tuples per block, which with the default block size will be 2040 bytes. Valid values are between 128 bytes and the (block size - header), by default 8160 bytes. Changing this value may not be useful for very short or very long rows. Note that the default setting is often close to optimal, and it is possible that setting this parameter could have negative effects in some cases. This parameter cannot be set for TOAST tables.

parallel_workers(integer)

This sets the number of workers that should be used to assist a parallel scan of this table. If not set, the system will determine a value based on the relation size. The actual number of workers chosen by the planner or by utility statements that use parallel scans may be less, for example due to the setting of max_worker_processes.

autovacuum_enabled, toast.autovacuum_enabled(boolean)

Enables or disables the autovacuum daemon for a particular table. If true, the autovacuum daemon will perform automatic VACUUM and/or ANALYZE operations on this table following the rules discussed in Section 25.1.6. If false, this table will not be autovacuumed, except to prevent transaction ID wraparound. See Section 25.1.5 for more about wraparound prevention. Note that the autovacuum daemon does not run at all (except to prevent transaction ID wraparound) if the autovacuum parameter
CREATE TABLE

is false; setting individual tables' storage parameters does not override that. Therefore there is seldom much point in explicitly setting this storage parameter to true, only to false.

vacuum_index_cleanup, toast.vacuum_index_cleanup (enum)

Forces or disables index cleanup when VACUUM is run on this table. The default value is AUTO. With OFF, index cleanup is disabled, with ON it is enabled, and with AUTO a decision is made dynamically, each time VACUUM runs. The dynamic behavior allows VACUUM to avoid needlessly scanning indexes to remove very few dead tuples. Forcibly disabling all index cleanup can speed up VACUUM very significantly, but may also lead to severely bloated indexes if table modifications are frequent. The INDEX_CLEANUP parameter of VACUUM, if specified, overrides the value of this option.

vacuum_truncate, toast.vacuum_truncate (boolean)

Enables or disables vacuum to try to truncate off any empty pages at the end of this table. The default value is true. If true, VACUUM and autovacuum do the truncation and the disk space for the truncated pages is returned to the operating system. Note that the truncation requires ACCESS EXCLUSIVE lock on the table. The TRUNCATE parameter of VACUUM, if specified, overrides the value of this option.

autovacuum_vacuum_threshold, toast.autovacuum_vacuum_threshold (integer)

Per-table value for autovacuum_vacuum_threshold parameter.

autovacuum_vacuum_scale_factor, toast.autovacuum_vacuum_scale_factor (floating point)

Per-table value for autovacuum_vacuum_scale_factor parameter.

autovacuum_vacuum_insert_threshold, toast.autovacuum_vacuum_insert_threshold (integer)

Per-table value for autovacuum_vacuum_insert_threshold parameter. The special value of -1 may be used to disable insert vacuums on the table.

autovacuum_vacuum_insert_scale_factor, toast.autovacuum_vacuum_insert_scale_factor (floating point)

Per-table value for autovacuum_vacuum_insert_scale_factor parameter.

autovacuum_analyze_threshold (integer)

Per-table value for autovacuum_analyze_threshold parameter.

autovacuum_analyze_scale_factor (floating point)

Per-table value for autovacuum_analyze_scale_factor parameter.

autovacuum_vacuum_cost_delay, toast.autovacuum_vacuum_cost_delay (floating point)

Per-table value for autovacuum_vacuum_cost_delay parameter.

autovacuum_vacuum_cost_limit, toast.autovacuum_vacuum_cost_limit (integer)

Per-table value for autovacuum_vacuum_cost_limit parameter.
autovacuum_freeze_min_age, toast.autovacuum_freeze_min_age(integer)

Per-table value for vacuum_freeze_min_age parameter. Note that autovacuum will ignore per-table
autovacuum_freeze_min_age parameters that are larger than half the system-wide autovacuum_freeze_max_age setting.

autovacuum_freeze_max_age, toast.autovacuum_freeze_max_age(integer)

Per-table value for autovacuum_freeze_max_age parameter. Note that autovacuum will ignore per-table
autovacuum_freeze_max_age parameters that are larger than the system-wide setting (it can only be set smaller).

autovacuum_freeze_table_age, toast.autovacuum_freeze_table_age(integer)

Per-table value for vacuum_freeze_table_age parameter.

autovacuum_multixact_freeze_min_age, toast.autovacuum_multixact_freeze_min_age(integer)

Per-table value for vacuum_multixact_freeze_min_age parameter. Note that autovacuum will ignore per-table
autovacuum_multixact_freeze_min_age parameters that are larger than half the system-wide autovacuum_multixact_freeze_max_age setting.

autovacuum_multixact_freeze_max_age, toast.autovacuum_multixact_freeze_max_age(integer)

Per-table value for autovacuum_multixact_freeze_max_age parameter. Note that autovacuum will ignore per-table
autovacuum_multixact_freeze_max_age parameters that are larger than the system-wide setting (it can only be set smaller).

autovacuum_multixact_freeze_table_age, toast.autovacuum_multixact_freeze_table_age(integer)

Per-table value for vacuum_multixact_freeze_table_age parameter.

log_autovacuum_min_duration, toast.log_autovacuum_min_duration(integer)

Per-table value for log_autovacuum_min_duration parameter.

user_catalog_table (boolean)

Declare the table as an additional catalog table for purposes of logical replication. See Section 49.6.2
for details. This parameter cannot be set for TOAST tables.

Notes

PostgreSQL automatically creates an index for each unique constraint and primary key constraint to enforce uniqueness. Thus, it is not necessary to create an index explicitly for primary key columns. (See CREATE INDEX for more information.)

Unique constraints and primary keys are not inherited in the current implementation. This makes the combination of inheritance and unique constraints rather dysfunctional.

A table cannot have more than 1600 columns. (In practice, the effective limit is usually lower because of tuple-length constraints.)
CREATE TABLE

Examples

Create table films and table distributors:

```
CREATE TABLE films (
  code        char(5) CONSTRAINT firstkey PRIMARY KEY,
  title       varchar(40) NOT NULL,
  did         integer NOT NULL,
  date_prod   date,
  kind        varchar(10),
  len         interval hour to minute
);

CREATE TABLE distributors (
  did    integer PRIMARY KEY GENERATED BY DEFAULT AS IDENTITY,
  name   varchar(40) NOT NULL CHECK (name <> '')
);
```

Create a table with a 2-dimensional array:

```
CREATE TABLE array_int (  
  vector  int[][]
);
```

Define a unique table constraint for the table films. Unique table constraints can be defined on one or more columns of the table:

```
CREATE TABLE films (  
  code        char(5),
  title       varchar(40),
  did         integer,
  date_prod   date,
  kind        varchar(10),
  len         interval hour to minute,
  CONSTRAINT production UNIQUE(date_prod)
);
```

Define a check column constraint:

```
CREATE TABLE distributors (  
  did    integer CHECK (did > 100),
  name   varchar(40)
);
```

Define a check table constraint:

```
CREATE TABLE distributors (  
  did    integer,
  name   varchar(40),
  CONSTRAINT con1 CHECK (did > 100 AND name <> '')
)
CREATE TABLE

CREATE TABLE films (  
  code char(5),  
  title varchar(40),  
  did integer,  
  date_prod date,  
  kind varchar(10),  
  len interval hour to minute,  
  CONSTRAINT code_title PRIMARY KEY(code,title)
  )

CREATE TABLE distributors (  
  did integer PRIMARY KEY,  
  name varchar(40)
  )

CREATE TABLE distributors (  
  did integer,  
  name varchar(40) DEFAULT 'Luso Films',  
  did integer DEFAULT nextval('distributors_serial'),  
  modtime timestamp DEFAULT current_timestamp
  )

CREATE TABLE distributors (  
  did integer CONSTRAINT no_null NOT NULL,  
  name varchar(40) NOT NULL
  )

CREATE TABLE distributors (  
  did integer,
  name varchar(40) NOT NULL,
  PRIMARY KEY(did)
  )

Define a unique constraint for the name column:

CREATE TABLE distributors (  
  did integer,
  name varchar(40) NOT NULL,
  PRIMARY KEY(did)
  )

Define a primary key constraint for table distributors. The following two examples are equivalent, the first using the table constraint syntax, the second the column constraint syntax:

Assign a literal constant default value for the column name, arrange for the default value of column did to be generated by selecting the next value of a sequence object, and make the default value of modtime be the time at which the row is inserted:

Define two NOT NULL column constraints on the table distributors, one of which is explicitly given a name:
CREATE TABLE

  name    varchar(40) UNIQUE
);

The same, specified as a table constraint:

CREATE TABLE distributors (  
did     integer,  
name    varchar(40),  
UNIQUE(name)
);

Create the same table, specifying 70% fill factor for both the table and its unique index:

CREATE TABLE distributors (  
did     integer,  
name    varchar(40),  
UNIQUE(name) WITH (fillfactor=70)
)
WITH (fillfactor=70);

Create table circles with an exclusion constraint that prevents any two circles from overlapping:

CREATE TABLE circles (  
c circle,  
EXCLUDE USING gist (c WITH &&)
);

Create table cinemas in tablespace diskvol1:

CREATE TABLE cinemas (  
id serial,  
name text,  
location text
) TABLESPACE diskvol1;

Create a composite type and a typed table:

CREATE TYPE employee_type AS (name text, salary numeric);

CREATE TABLE employees OF employee_type (  
PRIMARY KEY (name),  
salary WITH OPTIONS DEFAULT 1000
);

Create a range partitioned table:

CREATE TABLE measurement (  
logdate         date not null,  
peaktemp        int,  
unitsales       int
);
CREATE TABLE

) PARTITION BY RANGE (logdate);

Create a range partitioned table with multiple columns in the partition key:

CREATE TABLE measurement_year_month (  
    logdate    date not null,  
    peaktemp   int,  
    unitsales  int  
) PARTITION BY RANGE (EXTRACT(YEAR FROM logdate), EXTRACT(MONTH FROM logdate));

Create a list partitioned table:

CREATE TABLE cities (  
    city_id       bigserial not null,  
    name         text not null,  
    population   bigint  
) PARTITION BY LIST (left(lower(name), 1));

Create a hash partitioned table:

CREATE TABLE orders (  
    order_id     bigint not null,  
    cust_id      bigint not null,  
    status       text  
) PARTITION BY HASH (order_id);

Create partition of a range partitioned table:

CREATE TABLE measurement_y2016m07  
PARTITION OF measurement (  
    unitsales DEFAULT 0  
) FOR VALUES FROM ('2016-07-01') TO ('2016-08-01');

Create a few partitions of a range partitioned table with multiple columns in the partition key:

CREATE TABLE measurement_ym_older  
PARTITION OF measurement_year_month  
FOR VALUES FROM (MINVALUE, MINVALUE) TO (2016, 11);  
CREATE TABLE measurement_ym_y2016m11  
PARTITION OF measurement_year_month  
FOR VALUES FROM (2016, 11) TO (2016, 12);  
CREATE TABLE measurement_ym_y2016m12  
PARTITION OF measurement_year_month  
FOR VALUES FROM (2016, 12) TO (2017, 01);  
CREATE TABLE measurement_ym_y2017m01  
PARTITION OF measurement_year_month  
FOR VALUES FROM (2017, 01) TO (2017, 02);
CREATE TABLE cities_ab
PARTITION OF cities (  
 CONSTRAINT city_id_nonzero CHECK (city_id != 0)  
) FOR VALUES IN ('a', 'b');

Create partition of a list partitioned table that is itself further partitioned and then add a partition to it:

CREATE TABLE cities_ab
PARTITION OF cities (  
 CONSTRAINT city_id_nonzero CHECK (city_id != 0)  
) FOR VALUES IN ('a', 'b') PARTITION BY RANGE (population);

CREATE TABLE cities_ab_10000_to_100000
PARTITION OF cities_ab FOR VALUES FROM (10000) TO (100000);

Create partitions of a hash partitioned table:

CREATE TABLE orders_p1 PARTITION OF orders  
FOR VALUES WITH (MODULUS 4, REMAINDER 0);  
CREATE TABLE orders_p2 PARTITION OF orders  
FOR VALUES WITH (MODULUS 4, REMAINDER 1);  
CREATE TABLE orders_p3 PARTITION OF orders  
FOR VALUES WITH (MODULUS 4, REMAINDER 2);  
CREATE TABLE orders_p4 PARTITION OF orders  
FOR VALUES WITH (MODULUS 4, REMAINDER 3);

Create a default partition:

CREATE TABLE cities_partdef
PARTITION OF cities DEFAULT;

Compatibility

The CREATE TABLE command conforms to the SQL standard, with exceptions listed below.

Temporary Tables

Although the syntax of CREATE TEMPORARY TABLE resembles that of the SQL standard, the effect is not the same. In the standard, temporary tables are defined just once and automatically exist (starting with empty contents) in every session that needs them. PostgreSQL instead requires each session to issue its own CREATE TEMPORARY TABLE command for each temporary table to be used. This allows different sessions to use the same temporary table name for different purposes, whereas the standard’s approach constrains all instances of a given temporary table name to have the same table structure.

The standard’s definition of the behavior of temporary tables is widely ignored. PostgreSQL’s behavior on this point is similar to that of several other SQL databases.

The SQL standard also distinguishes between global and local temporary tables, where a local temporary table has a separate set of contents for each SQL module within each session, though its definition is still
shared across sessions. Since PostgreSQL does not support SQL modules, this distinction is not relevant in PostgreSQL.

For compatibility's sake, PostgreSQL will accept the `GLOBAL` and `LOCAL` keywords in a temporary table declaration, but they currently have no effect. Use of these keywords is discouraged, since future versions of PostgreSQL might adopt a more standard-compliant interpretation of their meaning.

The `ON COMMIT` clause for temporary tables also resembles the SQL standard, but has some differences. If the `ON COMMIT` clause is omitted, SQL specifies that the default behavior is `ON COMMIT DELETE ROWS`. However, the default behavior in PostgreSQL is `ON COMMIT PRESERVE ROWS`. The `ON COMMIT DROP` option does not exist in SQL.

**Non-Deferred Uniqueness Constraints**

When a `UNIQUE` or `PRIMARY KEY` constraint is not deferrable, PostgreSQL checks for uniqueness immediately whenever a row is inserted or modified. The SQL standard says that uniqueness should be enforced only at the end of the statement; this makes a difference when, for example, a single command updates multiple key values. To obtain standard-compliant behavior, declare the constraint as `DEFERRABLE` but not deferred (i.e., `INITIALLY IMMEDIATE`). Be aware that this can be significantly slower than immediate uniqueness checking.

**Column Check Constraints**

The SQL standard says that `CHECK` column constraints can only refer to the column they apply to; only `CHECK` table constraints can refer to multiple columns. PostgreSQL does not enforce this restriction; it treats column and table check constraints alike.

**EXCLUDE Constraint**

The `EXCLUDE` constraint type is a PostgreSQL extension.

**Foreign-Key Constraint Actions**

The ability to specify column lists in the foreign-key actions `SET DEFAULT` and `SET NULL` is a PostgreSQL extension.

**NULL “Constraint”**

The `NULL` “constraint” (actually a non-constraint) is a PostgreSQL extension to the SQL standard that is included for compatibility with some other database systems (and for symmetry with the `NOT NULL` constraint). Since it is the default for any column, its presence is simply noise.

**Constraint Naming**

The SQL standard says that table and domain constraints must have names that are unique across the schema containing the table or domain. PostgreSQL is laxer: it only requires constraint names to be unique across the constraints attached to a particular table or domain. However, this extra freedom does not exist for index-based constraints (`UNIQUE`, `PRIMARY KEY`, and `EXCLUDE` constraints), because the associated index is named the same as the constraint, and index names must be unique across all relations within the same schema.

Currently, PostgreSQL does not record names for `NOT NULL` constraints at all, so they are not subject to the uniqueness restriction. This might change in a future release.
Inheritance

Multiple inheritance via the INHERITS clause is a PostgreSQL language extension. SQL:1999 and later define single inheritance using a different syntax and different semantics. SQL:1999-style inheritance is not yet supported by PostgreSQL.

Zero-Column Tables

PostgreSQL allows a table of no columns to be created (for example, CREATE TABLE foo();). This is an extension from the SQL standard, which does not allow zero-column tables. Zero-column tables are not in themselves very useful, but disallowing them creates odd special cases for ALTER TABLE DROP COLUMN, so it seems cleaner to ignore this spec restriction.

Multiple Identity Columns

PostgreSQL allows a table to have more than one identity column. The standard specifies that a table can have at most one identity column. This is relaxed mainly to give more flexibility for doing schema changes or migrations. Note that the INSERT command supports only one override clause that applies to the entire statement, so having multiple identity columns with different behaviors is not well supported.

Generated Columns

The option STORED is not standard but is also used by other SQL implementations. The SQL standard does not specify the storage of generated columns.

LIKE Clause

While a LIKE clause exists in the SQL standard, many of the options that PostgreSQL accepts for it are not in the standard, and some of the standard's options are not implemented by PostgreSQL.

WITH Clause

The WITH clause is a PostgreSQL extension; storage parameters are not in the standard.

Tablespaces

The PostgreSQL concept of tablespaces is not part of the standard. Hence, the clauses TABLESPACE and USING INDEX TABLESPACE are extensions.

Typed Tables

Typed tables implement a subset of the SQL standard. According to the standard, a typed table has columns corresponding to the underlying composite type as well as one other column that is the “self-referencing column”. PostgreSQL does not support self-referencing columns explicitly.

PARTITION BY Clause

The PARTITION BY clause is a PostgreSQL extension.

PARTITION OF Clause

The PARTITION OF clause is a PostgreSQL extension.

ALTER TABLE, DROP TABLE, CREATE TABLE AS, CREATE TABLESPACE, CREATE TYPE
CREATE TABLE AS

CREATE TABLE AS — define a new table from the results of a query

Synopsis

CREATE [ [ GLOBAL | LOCAL ] { TEMPORARY | TEMP } | UNLOGGED ] TABLE
[ IF NOT EXISTS ] table_name
[ (column_name [, ...] ) ]
[ USING method ]
[ WITH ( storage_parameter [= value] [, ... ] ) | WITHOUT OIDS ]
[ ON COMMIT { PRESERVE ROWS | DELETE ROWS | DROP } ]
[ TABLESPACE tablespace_name ]
AS query
[ WITH [ NO ] DATA ]

Description

CREATE TABLE AS creates a table and fills it with data computed by a SELECT command. The table columns have the names and data types associated with the output columns of the SELECT (except that you can override the column names by giving an explicit list of new column names).

CREATE TABLE AS bears some resemblance to creating a view, but it is really quite different: it creates a new table and evaluates the query just once to fill the new table initially. The new table will not track subsequent changes to the source tables of the query. In contrast, a view re-evaluates its defining SELECT statement whenever it is queried.

CREATE TABLE AS requires CREATE privilege on the schema used for the table.

Parameters

GLOBAL or LOCAL

Ignored for compatibility. Use of these keywords is deprecated; refer to CREATE TABLE for details.

TEMPORARY or TEMP

If specified, the table is created as a temporary table. Refer to CREATE TABLE for details.

UNLOGGED

If specified, the table is created as an unlogged table. Refer to CREATE TABLE for details.

IF NOT EXISTS

Do not throw an error if a relation with the same name already exists. A notice is issued in this case. Refer to CREATE TABLE for details.

table_name

The name (optionally schema-qualified) of the table to be created.
CREATE TABLE AS

column_name

The name of a column in the new table. If column names are not provided, they are taken from the output column names of the query.

USING method

This optional clause specifies the table access method to use to store the contents for the new table; the method needs be an access method of type TABLE. See Chapter 62 for more information. If this option is not specified, the default table access method is chosen for the new table. See default_table_access_method for more information.

WITH ( storage_parameter [= value] [, ... ] )

This clause specifies optional storage parameters for the new table; see Storage Parameters in the CREATE TABLE documentation for more information. For backward-compatibility the WITH clause for a table can also include OIDS=FALSE to specify that rows of the new table should contain no OIDs (object identifiers), OIDS=TRUE is not supported anymore.

WITHOUT OIDS

This is backward-compatible syntax for declaring a table WITHOUT OIDS, creating a table WITH OIDS is not supported anymore.

ON COMMIT

The behavior of temporary tables at the end of a transaction block can be controlled using ON COMMIT. The three options are:

PRESERVE ROWS

No special action is taken at the ends of transactions. This is the default behavior.

DELETE ROWS

All rows in the temporary table will be deleted at the end of each transaction block. Essentially, an automatic TRUNCATE is done at each commit.

DROP

The temporary table will be dropped at the end of the current transaction block.

TABLESPACE tablespace_name

The tablespace_name is the name of the tablespace in which the new table is to be created. If not specified, default_tablespace is consulted, or temp_tablespaces if the table is temporary.

query

A SELECT, TABLE, or VALUES command, or an EXECUTE command that runs a prepared SELECT, TABLE, or VALUES query.

WITH [ NO ] DATA

This clause specifies whether or not the data produced by the query should be copied into the new table. If not, only the table structure is copied. The default is to copy the data.
CREATE TABLE AS

Notes

This command is functionally similar to SELECT INTO, but it is preferred since it is less likely to be confused with other uses of the SELECT INTO syntax. Furthermore, CREATE TABLE AS offers a superset of the functionality offered by SELECT INTO.

Examples

Create a new table films_recent consisting of only recent entries from the table films:

```sql
CREATE TABLE films_recent AS
    SELECT * FROM films WHERE date_prod >= '2002-01-01';
```

To copy a table completely, the short form using the TABLE command can also be used:

```sql
CREATE TABLE films2 AS
    TABLE films;
```

Create a new temporary table films_recent, consisting of only recent entries from the table films, using a prepared statement. The new table will be dropped at commit:

```sql
PREPARE recentfilms(date) AS
    SELECT * FROM films WHERE date_prod > $1;
CREATE TEMP TABLE films_recent ON COMMIT DROP AS
    EXECUTE recentfilms('2002-01-01');
```

Compatibility

CREATE TABLE AS conforms to the SQL standard. The following are nonstandard extensions:

- The standard requires parentheses around the subquery clause; in PostgreSQL, these parentheses are optional.
- In the standard, the WITH [ NO ] DATA clause is required; in PostgreSQL it is optional.
- PostgreSQL handles temporary tables in a way rather different from the standard; see CREATE TABLE for details.
- The WITH clause is a PostgreSQL extension; storage parameters are not in the standard.
- The PostgreSQL concept of tablespaces is not part of the standard. Hence, the clause TABLESPACE is an extension.

CREATE MATERIALIZED VIEW, CREATE TABLE, EXECUTE, SELECT, SELECT INTO, VALUES
CREATE TABLESPACE

CREATE TABLESPACE — define a new tablespace

Synopsis

CREATE TABLESPACE  

tablespace_name

[  
  OWNER {  
    new_owner  |  CURRENT_ROLE  |  CURRENT_USER  |  
    SESSION_USER  }  
  ]

LOCATION 'directory'

[  
  WITH {  
    tablespace_option = value [, ... ]  
  }  
]

Description

CREATE TABLESPACE registers a new cluster-wide tablespace. The tablespace name must be distinct from the name of any existing tablespace in the database cluster.

A tablespace allows superusers to define an alternative location on the file system where the data files containing database objects (such as tables and indexes) can reside.

A user with appropriate privileges can pass `tablespace_name` to CREATE DATABASE, CREATE TABLE, CREATE INDEX or ADD CONSTRAINT to have the data files for these objects stored within the specified tablespace.

Warning

A tablespace cannot be used independently of the cluster in which it is defined; see Section 23.6.

Parameters

`tablespace_name`

The name of a tablespace to be created. The name cannot begin with `pg_`, as such names are reserved for system tablespaces.

`user_name`

The name of the user who will own the tablespace. If omitted, defaults to the user executing the command. Only superusers can create tablespaces, but they can assign ownership of tablespaces to non-superusers.

`directory`

The directory that will be used for the tablespace. The directory must exist (CREATE TABLESPACE will not create it), should be empty, and must be owned by the PostgreSQL system user. The directory must be specified by an absolute path name.

`tablespace_option`

A tablespace parameter to be set or reset. Currently, the only available parameters are `seq_page_cost`, `random_page_cost`, `effective_io_concurrency` and mainte-
CREATE TABLESPACE nance_io_concurrency. Setting these values for a particular tablespace will override the planner's usual estimate of the cost of reading pages from tables in that tablespace, and the executor's prefetching behavior, as established by the configuration parameters of the same name (see seq_page_cost, random_page_cost, effective_io_concurrency, maintenance_io_concurrency). This may be useful if one tablespace is located on a disk which is faster or slower than the remainder of the I/O subsystem.

Notes

Tablespaces are only supported on systems that support symbolic links.

CREATE TABLESPACE cannot be executed inside a transaction block.

Examples

To create a tablespace dbspace at file system location /data/dbs, first create the directory using operating system facilities and set the correct ownership:

```
mkdir /data/dbs
chown postgres:postgres /data/dbs
```

Then issue the tablespace creation command inside PostgreSQL:

```
CREATE TABLESPACE dbspace LOCATION '/data/dbs';
```

To create a tablespace owned by a different database user, use a command like this:

```
CREATE TABLESPACE indexspace OWNER genevieve LOCATION '/data/indexes';
```

Compatibility

CREATE TABLESPACE is a PostgreSQL extension.

CREATE DATABASE, CREATE TABLE, CREATE INDEX, DROP TABLESPACE, ALTER TABLESPACE
CREATE TEXT SEARCH CONFIGURATION

CREATE TEXT SEARCH CONFIGURATION — define a new text search configuration

Synopsis

CREATE TEXT SEARCH CONFIGURATION name (  
    PARSER = parser_name |
    COPY = source_config  
)

Description

CREATE TEXT SEARCH CONFIGURATION creates a new text search configuration. A text search configuration specifies a text search parser that can divide a string into tokens, plus dictionaries that can be used to determine which tokens are of interest for searching.

If only the parser is specified, then the new text search configuration initially has no mappings from token types to dictionaries, and therefore will ignore all words. Subsequent ALTER TEXT SEARCH CONFIGURATION commands must be used to create mappings to make the configuration useful. Alternatively, an existing text search configuration can be copied.

If a schema name is given then the text search configuration is created in the specified schema. Otherwise it is created in the current schema.

The user who defines a text search configuration becomes its owner.

Refer to Chapter 12 for further information.

Parameters

name

The name of the text search configuration to be created. The name can be schema-qualified.

parser_name

The name of the text search parser to use for this configuration.

source_config

The name of an existing text search configuration to copy.

Notes

The PARSER and COPY options are mutually exclusive, because when an existing configuration is copied, its parser selection is copied too.

Compatibility

There is no CREATE TEXT SEARCH CONFIGURATION statement in the SQL standard.
CREATE TEXT SEARCH CONFIGURATION

See Also
ALTER TEXT SEARCH CONFIGURATION, DROP TEXT SEARCH CONFIGURATION
CREATE TEXT SEARCH DICTIONARY

CREATE TEXT SEARCH DICTIONARY — define a new text search dictionary

Synopsis

CREATE TEXT SEARCH DICTIONARY name (  
   TEMPLATE = template  
   [, option = value [, ... ]]  
)

Description

CREATE TEXT SEARCH DICTIONARY creates a new text search dictionary. A text search dictionary specifies a way of recognizing interesting or uninteresting words for searching. A dictionary depends on a text search template, which specifies the functions that actually perform the work. Typically the dictionary provides some options that control the detailed behavior of the template's functions.

If a schema name is given then the text search dictionary is created in the specified schema. Otherwise it is created in the current schema.

The user who defines a text search dictionary becomes its owner.

Refer to Chapter 12 for further information.

Parameters

name

   The name of the text search dictionary to be created. The name can be schema-qualified.

template

   The name of the text search template that will define the basic behavior of this dictionary.

option

   The name of a template-specific option to be set for this dictionary.

value

   The value to use for a template-specific option. If the value is not a simple identifier or number, it must be quoted (but you can always quote it, if you wish).

The options can appear in any order.

Examples

   The following example command creates a Snowball-based dictionary with a nonstandard list of stop words.
CREATE TEXT
SEARCH DICTIONARY

CREATE TEXT SEARCH DICTIONARY my_russian {
    template = snowball,
    language = russian,
    stopwords = myrussian
};

Compatibility

There is no CREATE TEXT SEARCH DICTIONARY statement in the SQL standard.

See Also

ALTER TEXT SEARCH DICTIONARY, DROP TEXT SEARCH DICTIONARY
CREATE TEXT SEARCH PARSER

CREATE TEXT SEARCH PARSER — define a new text search parser

Synopsis

    CREATE TEXT SEARCH PARSER name (  
    START = start_function ,  
    GETTOKEN = gettoken_function ,  
    END = end_function ,  
    LEXTYPES = lextypes_function  
    [, HEADLINE = headline_function ]
    )

Description

CREATE TEXT SEARCH PARSER creates a new text search parser. A text search parser defines a method for splitting a text string into tokens and assigning types (categories) to the tokens. A parser is not particularly useful by itself, but must be bound into a text search configuration along with some text search dictionaries to be used for searching.

If a schema name is given then the text search parser is created in the specified schema. Otherwise it is created in the current schema.

You must be a superuser to use CREATE TEXT SEARCH PARSER. (This restriction is made because an erroneous text search parser definition could confuse or even crash the server.)

Refer to Chapter 12 for further information.

Parameters

    name
      The name of the text search parser to be created. The name can be schema-qualified.

    start_function
      The name of the start function for the parser.

    gettoken_function
      The name of the get-next-token function for the parser.

    end_function
      The name of the end function for the parser.

    lextypes_function
      The name of the lextypes function for the parser (a function that returns information about the set of token types it produces).
CREATE TEXT SEARCH PARSER

headline_function

The name of the headline function for the parser (a function that summarizes a set of tokens).

The function names can be schema-qualified if necessary. Argument types are not given, since the argument list for each type of function is predetermined. All except the headline function are required.

The arguments can appear in any order, not only the one shown above.

Compatibility

There is no CREATE TEXT SEARCH PARSER statement in the SQL standard.

See Also

ALTER TEXT SEARCH PARSER, DROP TEXT SEARCH PARSER
CREATE TEXT SEARCH TEMPLATE

CREATE TEXT SEARCH TEMPLATE — define a new text search template

Synopsis

CREATE TEXT SEARCH TEMPLATE name (  
    [ INIT = init_function , ]  
    LEXIZE = lexize_function )

Description

CREATE TEXT SEARCH TEMPLATE creates a new text search template. Text search templates define the functions that implement text search dictionaries. A template is not useful by itself, but must be instantiated as a dictionary to be used. The dictionary typically specifies parameters to be given to the template functions.

If a schema name is given then the text search template is created in the specified schema. Otherwise it is created in the current schema.

You must be a superuser to use CREATE TEXT SEARCH TEMPLATE. This restriction is made because an erroneous text search template definition could confuse or even crash the server. The reason for separating templates from dictionaries is that a template encapsulates the “unsafe” aspects of defining a dictionary. The parameters that can be set when defining a dictionary are safe for unprivileged users to set, and so creating a dictionary need not be a privileged operation.

Refer to Chapter 12 for further information.

Parameters

name

The name of the text search template to be created. The name can be schema-qualified.

init_function

The name of the init function for the template.

lexize_function

The name of the lexize function for the template.

The function names can be schema-qualified if necessary. Argument types are not given, since the argument list for each type of function is predetermined. The lexize function is required, but the init function is optional.

The arguments can appear in any order, not only the one shown above.

Compatibility

There is no CREATE TEXT SEARCH TEMPLATE statement in the SQL standard.
See Also

ALTER TEXT SEARCH TEMPLATE, DROP TEXT SEARCH TEMPLATE
CREATE TRANSFORM

CREATE TRANSFORM — define a new transform

Synopsis

CREATE [ OR REPLACE ] TRANSFORM FOR type_name LANGUAGE lang_name ( 
   FROM SQL WITH FUNCTION from_sql_function_name [ (argument_type 
   [, ...]) ],
   TO SQL WITH FUNCTION to_sql_function_name [ (argument_type 
   [, ...]) ]
);

Description

CREATE TRANSFORM defines a new transform. CREATE OR REPLACE TRANSFORM will either 
create a new transform, or replace an existing definition.

A transform specifies how to adapt a data type to a procedural language. For example, when writing a 
function in PL/Python using the hstore type, PL/Python has no prior knowledge how to present hstore 
values in the Python environment. Language implementations usually default to using the text representa-
tion, but that is inconvenient when, for example, an associative array or a list would be more appropriate.

A transform specifies two functions:

• A “from SQL” function that converts the type from the SQL environment to the language. This function 
  will be invoked on the arguments of a function written in the language.

• A “to SQL” function that converts the type from the language to the SQL environment. This function 
  will be invoked on the return value of a function written in the language.

It is not necessary to provide both of these functions. If one is not specified, the language-specific default 
behavior will be used if necessary. (To prevent a transformation in a certain direction from happening at 
all, you could also write a transform function that always errors out.)

To be able to create a transform, you must own and have USAGE privilege on the type, have USAGE 
privilege on the language, and own and have EXECUTE privilege on the from-SQL and to-SQL functions, 
if specified.

Parameters

  type_name

  The name of the data type of the transform.

  lang_name

  The name of the language of the transform.

  from_sql_function_name[(argument_type [, ...])]

  The name of the function for converting the type from the SQL environment to the language. It must 
take one argument of type internal and return type internal. The actual argument will be of the
CREATE TRANSFORM

type for the transform, and the function should be coded as if it were. (But it is not allowed to declare
an SQL-level function returning internal without at least one argument of type internal.) The
actual return value will be something specific to the language implementation. If no argument list is
specified, the function name must be unique in its schema.

to_sql_function_name[(argument_type [, ...])]  

The name of the function for converting the type from the language to the SQL environment. It must
take one argument of type internal and return the type that is the type for the transform. The
actual argument value will be something specific to the language implementation. If no argument list
is specified, the function name must be unique in its schema.

Notes

Use DROP TRANSFORM to remove transforms.

Examples

To create a transform for type hstore and language plpython3u, first set up the type and the language:

CREATE TYPE hstore ...;

CREATE EXTENSION plpython3u;

Then create the necessary functions:

CREATE FUNCTION hstore_to_plpython(val internal) RETURNS internal
LANGUAGE C STRICT IMMUTABLE
AS ...;

CREATE FUNCTION plpython_to_hstore(val internal) RETURNS hstore
LANGUAGE C STRICT IMMUTABLE
AS ...;

And finally create the transform to connect them all together:

CREATE TRANSFORM FOR hstore LANGUAGE plpython3u (  
    FROM SQL WITH FUNCTION hstore_to_plpython(internal),  
    TO SQL WITH FUNCTION plpython_to_hstore(internal)  
);

In practice, these commands would be wrapped up in an extension.

The contrib section contains a number of extensions that provide transforms, which can serve as rea-
real-world examples.

Compatibility

This form of CREATE TRANSFORM is a PostgreSQL extension. There is a CREATE TRANSFORM
command in the SQL standard, but it is for adapting data types to client languages. That usage is not
supported by PostgreSQL.

CREATE FUNCTION, CREATE LANGUAGE, CREATE TYPE, DROP TRANSFORM
CREATE TRIGGER

CREATE TRIGGER — define a new trigger

Synopsis

CREATE [ OR REPLACE ] [ CONSTRAINT ] TRIGGER name { BEFORE | AFTER | INSTEAD OF } { event [ OR ... ] }

ON table_name

[ FROM referenced_table_name ]

[ NOT DEFERRABLE | DEFERRABLE ] [ INITIALLY IMMEDIATE |

INITIALLY DEFERRED ]

[ REFERENCING { { OLD | NEW } TABLE

[ AS ] transition_relation_name } [ ... ] ]

[ FOR [ EACH ] { ROW | STATEMENT } ]

[ WHEN ( condition ) ]

EXECUTE { FUNCTION | PROCEDURE } function_name ( arguments )

where event can be one of:

INSERT

UPDATE [ OF column_name [, ... ] ]

DELETE

TRUNCATE

Description

CREATE TRIGGER creates a new trigger. CREATE OR REPLACE TRIGGER will either create a new trigger, or replace an existing trigger. The trigger will be associated with the specified table, view, or foreign table and will execute the specified function function_name when certain operations are performed on that table.

To replace the current definition of an existing trigger, use CREATE OR REPLACE TRIGGER, specifying the existing trigger's name and parent table. All other properties are replaced.

The trigger can be specified to fire before the operation is attempted on a row (before constraints are checked and the INSERT, UPDATE, or DELETE is attempted); or after the operation has completed (after constraints are checked and the INSERT, UPDATE, or DELETE has completed); or instead of the operation (in the case of inserts, updates or deletes on a view). If the trigger fires before or instead of the event, the trigger can skip the operation for the current row, or change the row being inserted (for INSERT and UPDATE operations only). If the trigger fires after the event, all changes, including the effects of other triggers, are “visible” to the trigger.

A trigger that is marked FOR EACH ROW is called once for every row that the operation modifies. For example, a DELETE that affects 10 rows will cause any ON DELETE triggers on the target relation to be called 10 separate times, once for each deleted row. In contrast, a trigger that is marked FOR EACH STATEMENT only executes once for any given operation, regardless of how many rows it modifies (in particular, an operation that modifies zero rows will still result in the execution of any applicable FOR EACH STATEMENT triggers).
Triggers that are specified to fire INSTEAD OF the trigger event must be marked FOR EACH ROW, and can only be defined on views. BEFORE and AFTER triggers on a view must be marked as FOR EACH STATEMENT.

In addition, triggers may be defined to fire for TRUNCATE, though only FOR EACH STATEMENT.

The following table summarizes which types of triggers may be used on tables, views, and foreign tables:

<table>
<thead>
<tr>
<th>When</th>
<th>Event</th>
<th>Row-level</th>
<th>Statement-level</th>
</tr>
</thead>
<tbody>
<tr>
<td>BEFORE</td>
<td>INSERT/UP-DATE/DELETE</td>
<td>Tables and foreign tables</td>
<td>Tables, views, and foreign tables</td>
</tr>
<tr>
<td></td>
<td>TRUNCATE</td>
<td></td>
<td>Tables</td>
</tr>
<tr>
<td>AFTER</td>
<td>INSERT/UP-DATE/DELETE</td>
<td>Tables and foreign tables</td>
<td>Tables, views, and foreign tables</td>
</tr>
<tr>
<td></td>
<td>TRUNCATE</td>
<td></td>
<td>Tables</td>
</tr>
<tr>
<td>INSTEAD OF</td>
<td>INSERT/UP-DATE/DELETE</td>
<td>Views</td>
<td>—</td>
</tr>
<tr>
<td></td>
<td>TRUNCATE</td>
<td></td>
<td>—</td>
</tr>
</tbody>
</table>

Also, a trigger definition can specify a Boolean WHEN condition, which will be tested to see whether the trigger should be fired. In row-level triggers the WHEN condition can examine the old and/or new values of columns of the row. Statement-level triggers can also have WHEN conditions, although the feature is not so useful for them since the condition cannot refer to any values in the table.

If multiple triggers of the same kind are defined for the same event, they will be fired in alphabetical order by name.

When the CONSTRAINT option is specified, this command creates a constraint trigger. This is the same as a regular trigger except that the timing of the trigger firing can be adjusted using SET CONSTRAINTS. Constraint triggers must be AFTER ROW triggers on plain tables (not foreign tables). They can be fired either at the end of the statement causing the triggering event, or at the end of the containing transaction; in the latter case they are said to be deferred. A pending deferred-trigger firing can also be forced to happen immediately by using SET CONSTRAINTS. Constraint triggers are expected to raise an exception when the constraints they implement are violated.

The REFERENCING option enables collection of transition relations, which are row sets that include all of the rows inserted, deleted, or modified by the current SQL statement. This feature lets the trigger see a global view of what the statement did, not just one row at a time. This option is only allowed for an AFTER trigger that is not a constraint trigger; also, if the trigger is an UPDATE trigger, it must not specify a column_name list. OLD_TABLE may only be specified once, and only for a trigger that can fire on UPDATE or DELETE; it creates a transition relation containing the before-images of all rows updated or deleted by the statement. Similarly, NEW_TABLE may only be specified once, and only for a trigger that can fire on UPDATE or INSERT; it creates a transition relation containing the after-images of all rows updated or inserted by the statement.

SELECT does not modify any rows so you cannot create SELECT triggers. Rules and views may provide workable solutions to problems that seem to need SELECT triggers.

Refer to Chapter 39 for more information about triggers.
CREATE TRIGGER

Parameters

name

The name to give the new trigger. This must be distinct from the name of any other trigger for the same table. The name cannot be schema-qualified — the trigger inherits the schema of its table. For a constraint trigger, this is also the name to use when modifying the trigger's behavior using SET CONSTRAINTS.

BEFORE
AFTER
INSTEAD OF

Determines whether the function is called before, after, or instead of the event. A constraint trigger can only be specified as AFTER.

event

One of INSERT, UPDATE, DELETE, or TRUNCATE; this specifies the event that will fire the trigger. Multiple events can be specified using OR, except when transition relations are requested.

For UPDATE events, it is possible to specify a list of columns using this syntax:

UPDATE OF column_name1 [, column_name2 ... ]

The trigger will only fire if at least one of the listed columns is mentioned as a target of the UPDATE command or if one of the listed columns is a generated column that depends on a column that is the target of the UPDATE.

INSTEAD OF UPDATE events do not allow a list of columns. A column list cannot be specified when requesting transition relations, either.

table_name

The name (optionally schema-qualified) of the table, view, or foreign table the trigger is for.

referenced_table_name

The (possibly schema-qualified) name of another table referenced by the constraint. This option is used for foreign-key constraints and is not recommended for general use. This can only be specified for constraint triggers.

DEFERRABLE
NOT DEFERRABLE
INITIALLY IMMEDIATE
INITIALLY DEFERRED

The default timing of the trigger. See the CREATE TABLE documentation for details of these constraint options. This can only be specified for constraint triggers.

REFERENCING

This keyword immediately precedes the declaration of one or two relation names that provide access to the transition relations of the triggering statement.
OLD TABLE
NEW TABLE

This clause indicates whether the following relation name is for the before-image transition relation or the after-image transition relation.

transition_relation_name

The (unqualified) name to be used within the trigger for this transition relation.

FOR EACH ROW
FOR EACH STATEMENT

This specifies whether the trigger function should be fired once for every row affected by the trigger event, or just once per SQL statement. If neither is specified, FOR EACH STATEMENT is the default. Constraint triggers can only be specified FOR EACH ROW.

condition

A Boolean expression that determines whether the trigger function will actually be executed. If WHEN is specified, the function will only be called if the condition returns true. In FOR EACH ROW triggers, the WHEN condition can refer to columns of the old and/or new row values by writing OLD.column_name or NEW.column_name respectively. Of course, INSERT triggers cannot refer to OLD and DELETE triggers cannot refer to NEW.

INSTEAD OF triggers do not support WHEN conditions.

Currently, WHEN expressions cannot contain subqueries.

Note that for constraint triggers, evaluation of the WHEN condition is not deferred, but occurs immediately after the row update operation is performed. If the condition does not evaluate to true then the trigger is not queued for deferred execution.

function_name

A user-supplied function that is declared as taking no arguments and returning type trigger, which is executed when the trigger fires.

In the syntax of CREATE TRIGGER, the keywords FUNCTION and PROCEDURE are equivalent, but the referenced function must in any case be a function, not a procedure. The use of the keyword PROCEDURE here is historical and deprecated.

arguments

An optional comma-separated list of arguments to be provided to the function when the trigger is executed. The arguments are literal string constants. Simple names and numeric constants can be written here, too, but they will all be converted to strings. Please check the description of the implementation language of the trigger function to find out how these arguments can be accessed within the function; it might be different from normal function arguments.

Notes

To create or replace a trigger on a table, the user must have the TRIGGER privilege on the table. The user must also have EXECUTE privilege on the trigger function.

Use DROP TRIGGER to remove a trigger.
Creating a row-level trigger on a partitioned table will cause an identical “clone” trigger to be created on each of its existing partitions; and any partitions created or attached later will have an identical trigger, too. If there is a conflictingly-named trigger on a child partition already, an error occurs unless CREATE OR REPLACE TRIGGER is used, in which case that trigger is replaced with a clone trigger. When a partition is detached from its parent, its clone triggers are removed.

A column-specific trigger (one defined using the UPDATE OF column_name syntax) will fire when any of its columns are listed as targets in the UPDATE command's SET list. It is possible for a column’s value to change even when the trigger is not fired, because changes made to the row's contents by BEFORE UPDATE triggers are not considered. Conversely, a command such as UPDATE ... SET x = x ... will fire a trigger on column x, even though the column's value did not change.

In a BEFORE trigger, the WHEN condition is evaluated just before the function is or would be executed, so using WHEN is not materially different from testing the same condition at the beginning of the trigger function. Note in particular that the NEW row seen by the condition is the current value, as possibly modified by earlier triggers. Also, a BEFORE trigger's WHEN condition is not allowed to examine the system columns of the NEW row (such as ctid), because those won't have been set yet.

In an AFTER trigger, the WHEN condition is evaluated just after the row update occurs, and it determines whether an event is queued to fire the trigger at the end of statement. So when an AFTER trigger's WHEN condition does not return true, it is not necessary to queue an event nor to re-fetch the row at end of statement. This can result in significant speedups in statements that modify many rows, if the trigger only needs to be fired for a few of the rows.

In some cases it is possible for a single SQL command to fire more than one kind of trigger. For instance an INSERT with an ON CONFLICT DO UPDATE clause may cause both insert and update operations, so it will fire both kinds of triggers as needed. The transition relations supplied to triggers are specific to their event type; thus an INSERT trigger will see only the inserted rows, while an UPDATE trigger will see only the updated rows.

Row updates or deletions caused by foreign-key enforcement actions, such as ON UPDATE CASCADE or ON DELETE SET NULL, are treated as part of the SQL command that caused them (note that such actions are never deferred). Relevant triggers on the affected table will be fired, so that this provides another way in which an SQL command might fire triggers not directly matching its type. In simple cases, triggers that request transition relations will see all changes caused in their table by a single original SQL command as a single transition relation. However, there are cases in which the presence of an AFTER ROW trigger that requests transition relations will cause the foreign-key enforcement actions triggered by a single SQL command to be split into multiple steps, each with its own transition relation(s). In such cases, any statement-level triggers that are present will be fired once per creation of a transition relation set, ensuring that the triggers see each affected row in a transition relation once and only once.

Statement-level triggers on a view are fired only if the action on the view is handled by a row-level INSTEAD OF trigger. If the action is handled by an INSTEAD rule, then whatever statements are emitted by the rule are executed in place of the original statement naming the view, so that the triggers that will be fired are those on tables named in the replacement statements. Similarly, if the view is automatically updatable, then the action is handled by automatically rewriting the statement into an action on the view's base table, so that the base table's statement-level triggers are the ones that are fired.

Modifying a partitioned table or a table with inheritance children fires statement-level triggers attached to the explicitly named table, but not statement-level triggers for its partitions or child tables. In contrast, row-level triggers are fired on the rows in affected partitions or child tables, even if they are not explicitly named in the query. If a statement-level trigger has been defined with transition relations named by a REFERENCING clause, then before and after images of rows are visible from all affected partitions or child tables. In the case of inheritance children, the row images include only columns that are present in the table that the trigger is attached to.
Currently, row-level triggers with transition relations cannot be defined on partitions or inheritance child tables. Also, triggers on partitioned tables may not be INSTEAD OF.

Currently, the OR REPLACE option is not supported for constraint triggers.

Replacing an existing trigger within a transaction that has already performed updating actions on the trigger's table is not recommended. Trigger firing decisions, or portions of firing decisions, that have already been made will not be reconsidered, so the effects could be surprising.

There are a few built-in trigger functions that can be used to solve common problems without having to write your own trigger code; see Section 9.28.

**Examples**

Execute the function `check_account_update` whenever a row of the table `accounts` is about to be updated:

```sql
CREATE TRIGGER check_update
    BEFORE UPDATE ON accounts
    FOR EACH ROW
    EXECUTE FUNCTION check_account_update();
```

Modify that trigger definition to only execute the function if column `balance` is specified as a target in the UPDATE command:

```sql
CREATE OR REPLACE TRIGGER check_update
    BEFORE UPDATE OF balance ON accounts
    FOR EACH ROW
    EXECUTE FUNCTION check_account_update();
```

This form only executes the function if column `balance` has in fact changed value:

```sql
CREATE TRIGGER check_update
    BEFORE UPDATE ON accounts
    FOR EACH ROW
    WHEN (OLD.balance IS DISTINCT FROM NEW.balance)
    EXECUTE FUNCTION check_account_update();
```

Call a function to log updates of `accounts`, but only if something changed:

```sql
CREATE TRIGGER log_update
    AFTER UPDATE ON accounts
    FOR EACH ROW
    WHEN (OLD.* IS DISTINCT FROM NEW.*)
    EXECUTE FUNCTION log_account_update();
```

Execute the function `view_insert_row` for each row to insert rows into the tables underlying a view:

```sql
CREATE TRIGGER view_insert
    INSTEAD OF INSERT ON my_view
    FOR EACH ROW
```
CREATE TRIGGER

EXECUTE FUNCTION view_insert_row();

Execute the function check_transfer_balances_to_zero for each statement to confirm that the transfer rows offset to a net of zero:

CREATE TRIGGER transfer_insert
   AFTER INSERT ON transfer
   REFERENCING NEW TABLE AS inserted
   FOR EACH STATEMENT
   EXECUTE FUNCTION check_transfer_balances_to_zero();

Execute the function check_matching_pairs for each row to confirm that changes are made to matching pairs at the same time (by the same statement):

CREATE TRIGGER paired_items_update
   AFTER UPDATE ON paired_items
   REFERENCING NEW TABLE AS newtab OLD TABLE AS oldtab
   FOR EACH ROW
   EXECUTE FUNCTION check_matching_pairs();

Section 39.4 contains a complete example of a trigger function written in C.

Compatibility

The CREATE TRIGGER statement in PostgreSQL implements a subset of the SQL standard. The following functionalities are currently missing:

• While transition table names for AFTER triggers are specified using the REFERENCING clause in the standard way, the row variables used in FOR EACH ROW triggers may not be specified in a REFERENCING clause. They are available in a manner that is dependent on the language in which the trigger function is written, but is fixed for any one language. Some languages effectively behave as though there is a REFERENCING clause containing OLD ROW AS OLD NEW ROW AS NEW.

• The standard allows transition tables to be used with column-specific UPDATE triggers, but then the set of rows that should be visible in the transition tables depends on the trigger's column list. This is not currently implemented by PostgreSQL.

• PostgreSQL only allows the execution of a user-defined function for the triggered action. The standard allows the execution of a number of other SQL commands, such as CREATE TABLE, as the triggered action. This limitation is not hard to work around by creating a user-defined function that executes the desired commands.

SQL specifies that multiple triggers should be fired in time-of-creation order. PostgreSQL uses name order, which was judged to be more convenient.

SQL specifies that BEFORE DELETE triggers on cascaded deletes fire after the cascaded DELETE completes. The PostgreSQL behavior is for BEFORE DELETE to always fire before the delete action, even a cascading one. This is considered more consistent. There is also nonstandard behavior if BEFORE triggers modify rows or prevent updates during an update that is caused by a referential action. This can lead to constraint violations or stored data that does not honor the referential constraint.

The ability to specify multiple actions for a single trigger using OR is a PostgreSQL extension of the SQL standard.
CREATE TRIGGER

The ability to fire triggers for TRUNCATE is a PostgreSQL extension of the SQL standard, as is the ability to define statement-level triggers on views.

CREATE CONSTRAINT TRIGGER is a PostgreSQL extension of the SQL standard. So is the OR REPLACE option.

    [, COLLATABLE = collatable ]
)

CREATE TYPE name

Description

CREATE TYPE registers a new data type for use in the current database. The user who defines a type becomes its owner.
CREATE TYPE

If a schema name is given then the type is created in the specified schema. Otherwise it is created in the current schema. The type name must be distinct from the name of any existing type or domain in the same schema. (Because tables have associated data types, the type name must also be distinct from the name of any existing table in the same schema.)

There are five forms of CREATE TYPE, as shown in the syntax synopsis above. They respectively create a composite type, an enum type, a range type, a base type, or a shell type. The first four of these are discussed in turn below. A shell type is simply a placeholder for a type to be defined later; it is created by issuing CREATE TYPE with no parameters except for the type name. Shell types are needed as forward references when creating range types and base types, as discussed in those sections.

Composite Types

The first form of CREATE TYPE creates a composite type. The composite type is specified by a list of attribute names and data types. An attribute's collation can be specified too, if its data type is collatable. A composite type is essentially the same as the row type of a table, but using CREATE TYPE avoids the need to create an actual table when all that is wanted is to define a type. A stand-alone composite type is useful, for example, as the argument or return type of a function.

To be able to create a composite type, you must have USAGE privilege on all attribute types.

Enumerated Types

The second form of CREATE TYPE creates an enumerated (enum) type, as described in Section 8.7. Enum types take a list of quoted labels, each of which must be less than NAMEDATALEN bytes long (64 bytes in a standard PostgreSQL build). (It is possible to create an enumerated type with zero labels, but such a type cannot be used to hold values before at least one label is added using ALTER TYPE.)

Range Types

The third form of CREATE TYPE creates a new range type, as described in Section 8.17.

The range type's subtype can be any type with an associated b-tree operator class (to determine the ordering of values for the range type). Normally the subtype's default b-tree operator class is used to determine ordering; to use a non-default operator class, specify its name with subtype_opclass. If the subtype is collatable, and you want to use a non-default collation in the range's ordering, specify the desired collation with the collation option.

The optional canonical function must take one argument of the range type being defined, and return a value of the same type. This is used to convert range values to a canonical form, when applicable. See Section 8.17.8 for more information. Creating a canonical function is a bit tricky, since it must be defined before the range type can be declared. To do this, you must first create a shell type, which is a placeholder type that has no properties except a name and an owner. This is done by issuing the command CREATE TYPE name, with no additional parameters. Then the function can be declared using the shell type as argument and result, and finally the range type can be declared using the same name. This automatically replaces the shell type entry with a valid range type.

The optional subtype_diff function must take two values of the subtype type as argument, and return a double precision value representing the difference between the two given values. While this is optional, providing it allows much greater efficiency of GiST indexes on columns of the range type. See Section 8.17.8 for more information.

The optional multirange_type_name parameter specifies the name of the corresponding multirange type. If not specified, this name is chosen automatically as follows. If the range type name contains the
CREATE TYPE

substring range, then the multirange type name is formed by replacement of the range substring with multirange in the range type name. Otherwise, the multirange type name is formed by appending a _multirange suffix to the range type name.

Base Types

The fourth form of CREATE TYPE creates a new base type (scalar type). To create a new base type, you must be a superuser. (This restriction is made because an erroneous type definition could confuse or even crash the server.)

The parameters can appear in any order, not only that illustrated above, and most are optional. You must register two or more functions (using CREATE FUNCTION) before defining the type. The support functions input_function and output_function are required, while the functions receive_function, send_function, type_modifier_input_function, type_modifier_output_function, analyze_function, and subscript_function are optional. Generally these functions have to be coded in C or another low-level language.

The input_function converts the type's external textual representation to the internal representation used by the operators and functions defined for the type. output_function performs the reverse transformation. The input function can be declared as taking one argument of type cstring, or as taking three arguments of types cstring, oid, integer. The first argument is the input text as a C string, the second argument is the type's own OID (except for array types, which instead receive their element type's OID), and the third is the typmod of the destination column, if known (-1 will be passed if not). The input function must return a value of the data type itself. Usually, an input function should be declared STRICT; if it is not, it will be called with a NULL first parameter when reading a NULL input value. The function must still return NULL in this case, unless it raises an error. (This case is mainly meant to support domain input functions, which might need to reject NULL inputs.) The output function must be declared as taking one argument of the new data type. The output function must return type cstring. Output functions are not invoked for NULL values.

The optional receive_function converts the type's external binary representation to the internal representation. If this function is not supplied, the type cannot participate in binary input. The binary representation should be chosen to be cheap to convert to internal form, while being reasonably portable. (For example, the standard integer data types use network byte order as the external binary representation, while the internal representation is in the machine's native byte order.) The receive function should perform adequate checking to ensure that the value is valid. The receive function can be declared as taking one argument of type internal, or as taking three arguments of types internal, oid, integer. The first argument is a pointer to a StringInfo buffer holding the received byte string; the optional arguments are the same as for the text input function. The receive function must return a value of the data type itself. Usually, a receive function should be declared STRICT; if it is not, it will be called with a NULL first parameter when reading a NULL input value. The function must still return NULL in this case, unless it raises an error. (This case is mainly meant to support domain receive functions, which might need to reject NULL inputs.) Similarly, the optional send_function converts from the internal representation to the external binary representation. If this function is not supplied, the type cannot participate in binary output. The send function must be declared as taking one argument of the new data type. The send function must return type bytea. Send functions are not invoked for NULL values.

You should at this point be wondering how the input and output functions can be declared to have results or arguments of the new type, when they have to be created before the new type can be created. The answer is that the type should first be defined as a shell type, which is a placeholder type that has no properties except a name and an owner. This is done by issuing the command CREATE TYPE name, with no additional parameters. Then the C I/O functions can be defined referencing the shell type. Finally, CREATE TYPE with a full definition replaces the shell entry with a complete, valid type definition, after which the new type can be used normally.
The optional `type_modifier_input_function` and `type_modifier_output_function` are needed if the type supports modifiers, that is optional constraints attached to a type declaration, such as `char(5)` or `numeric(30,2)`. PostgreSQL allows user-defined types to take one or more simple constants or identifiers as modifiers. However, this information must be capable of being packed into a single non-negative integer value for storage in the system catalogs. The `type_modifier_input_function` is passed the declared modifier(s) in the form of a `cstring` array. It must check the values for validity (throwing an error if they are wrong), and if they are correct, return a single non-negative integer value that will be stored as the column "typmod". Type modifiers will be rejected if the type does not have a `type_modifier_input_function`. The `type_modifier_output_function` converts the internal integer typmod value back to the correct form for user display. It must return a `cstring` value that is the exact string to append to the type name; for example `numeric`'s function might return `(30,2)`. It is allowed to omit the `type_modifier_output_function`, in which case the default display format is just the stored typmod integer value enclosed in parentheses.

The optional `analyze_function` performs type-specific statistics collection for columns of the data type. By default, `ANALYZE` will attempt to gather statistics using the type's “equals” and “less-than” operators, if there is a default b-tree operator class for the type. For non-scalar types this behavior is likely to be unsuitable, so it can be overridden by specifying a custom analysis function. The analysis function must be declared to take a single argument of type `internal`, and return a `boolean` result. The detailed API for analysis functions appears in `src/include/commands/vacuum.h`.

The optional `subscript_function` allows the data type to be subscripted in SQL commands. Specifying this function does not cause the type to be considered a “true” array type; for example, it will not be a candidate for the result type of `ARRAY[]` constructs. But if subscripting a value of the type is a natural notation for extracting data from it, then a `subscript_function` can be written to define what that means. The subscript function must be declared to take a single argument of type `internal`, and return an `internal` result, which is a pointer to a struct of methods (functions) that implement subscripting. The detailed API for subscript functions appears in `src/include/nodes/subscripting.h`. It may also be useful to read the array implementation in `src/backend/utils/adt/arraysubs.c`, or the simpler code in `contrib/hstore/hstore_subs.c`. Additional information appears in Array Types below.

While the details of the new type's internal representation are only known to the I/O functions and other functions you create to work with the type, there are several properties of the internal representation that must be declared to PostgreSQL. Foremost of these is `internallength`. Base data types can be fixed-length, in which case `internallength` is a positive integer, or variable-length, indicated by setting `internallength` to `VARIABLE`. (Internally, this is represented by setting `typlen` to -1.) The internal representation of all variable-length types must start with a 4-byte integer giving the total length of this value of the type. (Note that the length field is often encoded, as described in Section 72.2; it's unwise to access it directly.)

The optional flag `PASSEDBYVALUE` indicates that values of this data type are passed by value, rather than by reference. Types passed by value must be fixed-length, and their internal representation cannot be larger than the size of the `Datum` type (4 bytes on some machines, 8 bytes on others).

The `alignment` parameter specifies the storage alignment required for the data type. The allowed values equate to alignment on 1, 2, 4, or 8 byte boundaries. Note that variable-length types must have an alignment of at least 4, since they necessarily contain an `int4` as their first component.

The `storage` parameter allows selection of storage strategies for variable-length data types. (Only `plain` is allowed for fixed-length types.) `plain` specifies that data of the type will always be stored in-line and not compressed. `extended` specifies that the system will first try to compress a long data value, and will move the value out of the main table row if it's still too long. `external` allows the value to be moved out of the main table, but the system will not try to compress it. `main` allows compression, but discourages moving the value out of the main table. (Data items with this storage strategy might still be
moved out of the main table if there is no other way to make a row fit, but they will be kept in the main
table preferentially over extended and external items.)

All storage values other than plain imply that the functions of the data type can handle values that
have been toasted, as described in Section 72.2 and Section 38.13.1. The specific other value given merely
determines the default TOAST storage strategy for columns of a toastable data type; users can pick other
strategies for individual columns using ALTER TABLE SET STORAGE.

The like_type parameter provides an alternative method for specifying the basic representation prop-
erties of a data type: copy them from some existing type. The values of internallength, passed-
byvalue, alignment, and storage are copied from the named type. (It is possible, though usually
undesirable, to override some of these values by specifying them along with the LIKE clause.) Specifying
representation this way is especially useful when the low-level implementation of the new type “piggy-
backs” on an existing type in some fashion.

The category and preferred parameters can be used to help control which implicit cast will be
applied in ambiguous situations. Each data type belongs to a category named by a single ASCII character,
and each type is either “preferred” or not within its category. The parser will prefer casting to preferred
types (but only from other types within the same category) when this rule is helpful in resolving overloaded
functions or operators. For more details see Chapter 10. For types that have no implicit casts to or from
any other types, it is sufficient to leave these settings at the defaults. However, for a group of related types
that have implicit casts, it is often helpful to mark them all as belonging to a category and select one
or two of the “most general” types as being preferred within the category. The category parameter is
especially useful when adding a user-defined type to an existing built-in category, such as the numeric or
string types. However, it is also possible to create new entirely-user-defined type categories. Select any
ASCII character other than an upper-case letter to name such a category.

A default value can be specified, in case a user wants columns of the data type to default to something other
than the null value. Specify the default with the DEFAULT key word. (Such a default can be overridden
by an explicit DEFAULT clause attached to a particular column.)

To indicate that a type is a fixed-length array type, specify the type of the array elements using the ELE-
MENT key word. For example, to define an array of 4-byte integers (int4), specify ELEMENT = int4.
For more details, see Array Types below.

To indicate the delimiter to be used between values in the external representation of arrays of this type,
delimiter can be set to a specific character. The default delimiter is the comma (,). Note that the
delimiter is associated with the array element type, not the array type itself.

If the optional Boolean parameter collatable is true, column definitions and expressions of the type
may carry collation information through use of the COLLATE clause. It is up to the implementations of
the functions operating on the type to actually make use of the collation information; this does not happen
automatically merely by marking the type collatable.

Array Types

Whenever a user-defined type is created, PostgreSQL automatically creates an associated array type, whose
name consists of the element type's name prepended with an underscore, and truncated if necessary to keep
it less than NAMEDATALEN bytes long. (If the name so generated collides with an existing type name,
the process is repeated until a non-colliding name is found.) This implicitly-created array type is variable
length and uses the built-in input and output functions array_in and array_out. Furthermore, this
type is what the system uses for constructs such as ARRAY[] over the user-defined type. The array type
tracks any changes in its element type's owner or schema, and is dropped if the element type is.

You might reasonably ask why there is an ELEMENT option, if the system makes the correct array type
automatically. The main case where it's useful to use ELEMENT is when you are making a fixed-length
CREATE TYPE

type that happens to be internally an array of a number of identical things, and you want to allow these things to be accessed directly by subscripting, in addition to whatever operations you plan to provide for the type as a whole. For example, type point is represented as just two floating-point numbers, which can be accessed using point[0] and point[1]. Note that this facility only works for fixed-length types whose internal form is exactly a sequence of identical fixed-length fields. For historical reasons (i.e., this is clearly wrong but it's far too late to change it), subscripting of fixed-length array types starts from zero, rather than from one as for variable-length arrays.

Specifying the SUBSCRIPT option allows a data type to be subscripted, even though the system does not otherwise regard it as an array type. The behavior just described for fixed-length arrays is actually implemented by the SUBSCRIPT handler function raw_array_subscript_handler, which is used automatically if you specify ELEMENT for a fixed-length type without also writing SUBSCRIPT.

When specifying a custom SUBSCRIPT function, it is not necessary to specify ELEMENT unless the SUBSCRIPT handler function needs to consult typelem to find out what to return. Be aware that specifying ELEMENT causes the system to assume that the new type contains, or is somehow physically dependent on, the element type; thus for example changing properties of the element type won't be allowed if there are any columns of the dependent type.

Parameters

name
The name (optionally schema-qualified) of a type to be created.

attribute_name
The name of an attribute (column) for the composite type.

data_type
The name of an existing data type to become a column of the composite type.

collation
The name of an existing collation to be associated with a column of a composite type, or with a range type.

label
A string literal representing the textual label associated with one value of an enum type.

subtype
The name of the element type that the range type will represent ranges of.

subtype_operator_class
The name of a b-tree operator class for the subtype.

canonical_function
The name of the canonicalization function for the range type.

subtype_diff_function
The name of a difference function for the subtype.
CREATE TYPE

multirange_type_name

The name of the corresponding multirange type.

input_function

The name of a function that converts data from the type's external textual form to its internal form.

output_function

The name of a function that converts data from the type's internal form to its external textual form.

receive_function

The name of a function that converts data from the type's external binary form to its internal form.

send_function

The name of a function that converts data from the type's internal form to its external binary form.

type_modifier_input_function

The name of a function that converts an array of modifier(s) for the type into internal form.

type_modifier_output_function

The name of a function that converts the internal form of the type's modifier(s) to external textual form.

analyze_function

The name of a function that performs statistical analysis for the data type.

subscript_function

The name of a function that defines what subscripting a value of the data type does.

internallength

A numeric constant that specifies the length in bytes of the new type's internal representation. The default assumption is that it is variable-length.

alignment

The storage alignment requirement of the data type. If specified, it must be char, int2, int4, or double; the default is int4.

storage

The storage strategy for the data type. If specified, must be plain, external, extended, or main; the default is plain.

like_type

The name of an existing data type that the new type will have the same representation as. The values of internallength, passedbyvalue, alignment, and storage are copied from that type, unless overridden by explicit specification elsewhere in this CREATE TYPE command.
CREATE TYPE

category

The category code (a single ASCII character) for this type. The default is 'U' for "user-defined type". Other standard category codes can be found in Table 53.65. You may also choose other ASCII characters in order to create custom categories.

preferred

True if this type is a preferred type within its type category, else false. The default is false. Be very careful about creating a new preferred type within an existing type category, as this could cause surprising changes in behavior.

default

The default value for the data type. If this is omitted, the default is null.

element

The type being created is an array; this specifies the type of the array elements.

delimiter

The delimiter character to be used between values in arrays made of this type.

collatable

True if this type's operations can use collation information. The default is false.

Notes

Because there are no restrictions on use of a data type once it's been created, creating a base type or range type is tantamount to granting public execute permission on the functions mentioned in the type definition. This is usually not an issue for the sorts of functions that are useful in a type definition. But you might want to think twice before designing a type in a way that would require "secret" information to be used while converting it to or from external form.

Before PostgreSQL version 8.3, the name of a generated array type was always exactly the element type's name with one underscore character (_.) prepended. (Type names were therefore restricted in length to one fewer character than other names.) While this is still usually the case, the array type name may vary from this in case of maximum-length names or collisions with user type names that begin with underscore. Writing code that depends on this convention is therefore deprecated. Instead, use pg_type.typarray to locate the array type associated with a given type.

It may be advisable to avoid using type and table names that begin with underscore. While the server will change generated array type names to avoid collisions with user-given names, there is still risk of confusion, particularly with old client software that may assume that type names beginning with underscores always represent arrays.

Before PostgreSQL version 8.2, the shell-type creation syntax CREATE TYPE name did not exist. The way to create a new base type was to create its input function first. In this approach, PostgreSQL will first see the name of the new data type as the return type of the input function. The shell type is implicitly created in this situation, and then it can be referenced in the definitions of the remaining I/O functions. This approach still works, but is deprecated and might be disallowed in some future release. Also, to avoid accidentally cluttering the catalogs with shell types as a result of simple typos in function definitions, a shell type will only be made this way when the input function is written in C.
CREATE TYPE

Examples

This example creates a composite type and uses it in a function definition:

```
CREATE TYPE compfoo AS (f1 int, f2 text);
CREATE FUNCTION getfoo() RETURNS SETOF compfoo AS $$
    SELECT fooid, fooname FROM foo
$$ LANGUAGE SQL;
```

This example creates an enumerated type and uses it in a table definition:

```
CREATE TYPE bug_status AS ENUM ('new', 'open', 'closed');
CREATE TABLE bug (id serial, description text, status bug_status);
```

This example creates a range type:

```
CREATE TYPE float8_range AS RANGE (subtype = float8, subtype_diff = float8mi);
```

This example creates the base data type `box` and then uses the type in a table definition:

```
CREATE TYPE box;
CREATE FUNCTION my_box_in_function(cstring) RETURNS box AS ...;
CREATE FUNCTION my_box_out_function(box) RETURNS cstring AS ...;
CREATE TYPE box (INTERNALLENGTH = 16, INPUT = my_box_in_function, OUTPUT = my_box_out_function);
CREATE TABLE myboxes (id integer, description box);
```

If the internal structure of `box` were an array of four `float4` elements, we might instead use:

```
CREATE TYPE box (INTERNALLENGTH = 16, INPUT = my_box_in_function, OUTPUT = my_box_out_function, ELEMENT = float4);
```
which would allow a box value's component numbers to be accessed by subscripting. Otherwise the type behaves the same as before.

This example creates a large object type and uses it in a table definition:

```sql
CREATE TYPE bigobj (  
    INPUT = lo_filein, OUTPUT = lo_fileout,  
    INTERNALLENGTH = VARIABLE
);
CREATE TABLE big_objs (  
    id integer,  
    obj bigobj
);
```

More examples, including suitable input and output functions, are in Section 38.13.

**Compatibility**

The first form of the `CREATE TYPE` command, which creates a composite type, conforms to the SQL standard. The other forms are PostgreSQL extensions. The `CREATE TYPE` statement in the SQL standard also defines other forms that are not implemented in PostgreSQL.

The ability to create a composite type with zero attributes is a PostgreSQL-specific deviation from the standard (analogous to the same case in `CREATE TABLE`).

**See Also**

`ALTER TYPE`, `CREATE DOMAIN`, `CREATE FUNCTION`, `DROP TYPE`
CREATE USER

CREATE USER — define a new database role

Synopsis

CREATE USER name [ [ WITH ] option [ ... ] ]

where option can be:

SUPERUSER | NOSUPERUSER
CREATEDB | NOCREATEDB
CREATEROLE | NOCREATEROLE
INHERIT | NOINHERIT
LOGIN | NOLOGIN
REPLICATION | NOREPLICATION
BYPASSRLS | NOBYPASSRLS
CONNECTION LIMIT connlimit
[ ENCRYPTED ] PASSWORD 'password' | PASSWORD NULL
VALID UNTIL 'timestamp'
IN ROLE role_name [, ...]
IN GROUP role_name [, ...]
ROLE role_name [, ...]
ADMIN role_name [, ...]
USER role_name [, ...]
SYSID uid

Description

CREATE USER is now an alias for CREATE ROLE. The only difference is that when the command is spelled CREATE USER, LOGIN is assumed by default, whereas NOLOGIN is assumed when the command is spelled CREATE ROLE.

Compatibility

The CREATE USER statement is a PostgreSQL extension. The SQL standard leaves the definition of users to the implementation.

See Also

CREATE ROLE
CREATE USER MAPPING

CREATE USER MAPPING — define a new mapping of a user to a foreign server

Synopsis

CREATE USER MAPPING [ IF NOT EXISTS ] FOR { user_name | USER | CURRENT_ROLE | CURRENT_USER | PUBLIC }
    SERVER server_name
    [ OPTIONS ( option 'value' [ , ... ] ) ]

Description

CREATE USER MAPPING defines a mapping of a user to a foreign server. A user mapping typically encapsulates connection information that a foreign-data wrapper uses together with the information encapsulated by a foreign server to access an external data resource.

The owner of a foreign server can create user mappings for that server for any user. Also, a user can create a user mapping for their own user name if USAGE privilege on the server has been granted to the user.

Parameters

IF NOT EXISTS

Do not throw an error if a mapping of the given user to the given foreign server already exists. A notice is issued in this case. Note that there is no guarantee that the existing user mapping is anything like the one that would have been created.

user_name

The name of an existing user that is mapped to foreign server. CURRENT_ROLE, CURRENT_USER, and USER match the name of the current user. When PUBLIC is specified, a so-called public mapping is created that is used when no user-specific mapping is applicable.

server_name

The name of an existing server for which the user mapping is to be created.

OPTIONS ( option 'value' [ , ... ] )

This clause specifies the options of the user mapping. The options typically define the actual user name and password of the mapping. Option names must be unique. The allowed option names and values are specific to the server's foreign-data wrapper.

Examples

Create a user mapping for user bob, server foo:

CREATE USER MAPPING FOR bob SERVER foo OPTIONS (user 'bob', password 'secret');
CREATE USER MAPPING

Compatibility

CREATE USER MAPPING conforms to ISO/IEC 9075-9 (SQL/MED).

See Also

ALTER USER MAPPING, DROP USER MAPPING, CREATE FOREIGN DATA WRAPPER, CREATE SERVER
CREATE VIEW

CREATE VIEW — define a new view

Synopsis

CREATE [ OR REPLACE ] [ TEMP | TEMPORARY ] [ RECURSIVE ] VIEW name
[ ( column_name [, ...] ) ]
[ WITH ( view_option_name = view_option_value [, ... ] ) ]
AS query
[ WITH [ CASCADED | LOCAL ] CHECK OPTION ]

Description

CREATE VIEW defines a view of a query. The view is not physically materialized. Instead, the query is run every time the view is referenced in a query.

CREATE OR REPLACE VIEW is similar, but if a view of the same name already exists, it is replaced. The new query must generate the same columns that were generated by the existing view query (that is, the same column names in the same order and with the same data types), but it may add additional columns to the end of the list. The calculations giving rise to the output columns may be completely different.

If a schema name is given (for example, CREATE VIEW myschema.myview ...) then the view is created in the specified schema. Otherwise it is created in the current schema. Temporary views exist in a special schema, so a schema name cannot be given when creating a temporary view. The name of the view must be distinct from the name of any other relation (table, sequence, index, view, materialized view, or foreign table) in the same schema.

Parameters

TEMPORARY or TEMP

If specified, the view is created as a temporary view. Temporary views are automatically dropped at the end of the current session. Existing permanent relations with the same name are not visible to the current session while the temporary view exists, unless they are referenced with schema-qualified names.

If any of the tables referenced by the view are temporary, the view is created as a temporary view (whether TEMPORARY is specified or not).

RECURSIVE

Creates a recursive view. The syntax

CREATE RECURSIVE VIEW [ schema . ] view_name (column_names) AS
SELECT ...;

is equivalent to
CREATE VIEW [ schema . ] view_name AS WITH RECURSIVE view_name
(column_names) AS (SELECT ...) SELECT column_names FROM view_name;

A view column name list must be specified for a recursive view.

name

The name (optionally schema-qualified) of a view to be created.

column_name

An optional list of names to be used for columns of the view. If not given, the column names are
deduced from the query.

WITH ( view_option_name [= view_option_value] [, ... ] )

This clause specifies optional parameters for a view; the following parameters are supported:

check_option(enum)

This parameter may be either local or cascaded, and is equivalent to specifying WITH
[ CASCADED | LOCAL ] CHECK OPTION (see below).

security_barrier(boolean)

This should be used if the view is intended to provide row-level security. See Section 41.5 for
full details.

security_invoker(boolean)

This option causes the underlying base relations to be checked against the privileges of the user
of the view rather than the view owner. See the notes below for full details.

All of the above options can be changed on existing views using ALTER VIEW.

query

A SELECT or VALUES command which will provide the columns and rows of the view.

WITH [ CASCADED | LOCAL ] CHECK OPTION

This option controls the behavior of automatically updatable views. When this option is specified,
INSERT and UPDATE commands on the view will be checked to ensure that new rows satisfy the
view-defining condition (that is, the new rows are checked to ensure that they are visible through the
view). If they are not, the update will be rejected. If the CHECK OPTION is not specified, INSERT
and UPDATE commands on the view are allowed to create rows that are not visible through the view.
The following check options are supported:

LOCAL

New rows are only checked against the conditions defined directly in the view itself. Any condi-
tions defined on underlying base views are not checked (unless they also specify the CHECK
OPTION).

CASCADED

New rows are checked against the conditions of the view and all underlying base views. If the
CHECK OPTION is specified, and neither LOCAL nor CASCADED is specified, then CASCADED
is assumed.
CREATE VIEW

The CHECK OPTION may not be used with RECURSIVE views.

Note that the CHECK OPTION is only supported on views that are automatically updatable, and do not have INSTEAD OF triggers or INSTEAD rules. If an automatically updatable view is defined on top of a base view that has INSTEAD OF triggers, then the LOCAL CHECK OPTION may be used to check the conditions on the automatically updatable view, but the conditions on the base view with INSTEAD OF triggers will not be checked (a cascaded check option will not cascade down to a trigger-updatable view, and any check options defined directly on a trigger-updatable view will be ignored). If the view or any of its base relations has an INSTEAD rule that causes the INSERT or UPDATE command to be rewritten, then all check options will be ignored in the rewritten query, including any checks from automatically updatable views defined on top of the relation with the INSTEAD rule.

**Notes**

Use the DROP VIEW statement to drop views.

Be careful that the names and types of the view's columns will be assigned the way you want. For example:

```sql
CREATE VIEW vista AS SELECT 'Hello World';
```

is bad form because the column name defaults to `column?`; also, the column data type defaults to `text`, which might not be what you wanted. Better style for a string literal in a view's result is something like:

```sql
CREATE VIEW vista AS SELECT text 'Hello World' AS hello;
```

By default, access to the underlying base relations referenced in the view is determined by the permissions of the view owner. In some cases, this can be used to provide secure but restricted access to the underlying tables. However, not all views are secure against tampering; see Section 41.5 for details.

If the view has the security_invoker property set to `true`, access to the underlying base relations is determined by the permissions of the user executing the query, rather than the view owner. Thus, the user of a security invoker view must have the relevant permissions on the view and its underlying base relations.

If any of the underlying base relations is a security invoker view, it will be treated as if it had been accessed directly from the original query. Thus, a security invoker view will always check its underlying base relations using the permissions of the current user, even if it is accessed from a view without the security_invoker property.

If any of the underlying base relations has row-level security enabled, then by default, the row-level security policies of the view owner are applied, and access to any additional relations referred to by those policies is determined by the permissions of the view owner. However, if the view has security_invoker set to `true`, then the policies and permissions of the invoking user are used instead, as if the base relations had been referenced directly from the query using the view.

Functions called in the view are treated the same as if they had been called directly from the query using the view. Therefore, the user of a view must have permissions to call all functions used by the view. Functions in the view are executed with the privileges of the user executing the query or the function owner, depending on whether the functions are defined as SECURITY INVOKER or SECURITY DEFINER. Thus, for example, calling CURRENT_USER directly in a view will always return the invoking user, not the view owner. This is not affected by the view's security_invoker setting, and so a view with security_invoker set to `false` is not equivalent to a SECURITY DEFINER function and those concepts should not be confused.
CREATE VIEW

The user creating or replacing a view must have USAGE privileges on any schemas referred to in the view query, in order to look up the referenced objects in those schemas. Note, however, that this lookup only happens when the view is created or replaced. Therefore, the user of the view only requires the USAGE privilege on the schema containing the view, not on the schemas referred to in the view query, even for a security invoker view.

When CREATE OR REPLACE VIEW is used on an existing view, only the view's defining SELECT rule, plus any WITH ( . . . ) parameters and its CHECK OPTION are changed. Other view properties, including ownership, permissions, and non-SELECT rules, remain unchanged. You must own the view to replace it (this includes being a member of the owning role).

Updatable Views

Simple views are automatically updatable: the system will allow INSERT, UPDATE and DELETE statements to be used on the view in the same way as on a regular table. A view is automatically updatable if it satisfies all of the following conditions:

- The view must have exactly one entry in its FROM list, which must be a table or another updatable view.
- The view definition must not contain WITH, DISTINCT, GROUP BY, HAVING, LIMIT, or OFFSET clauses at the top level.
- The view definition must not contain set operations (UNION, INTERSECT or EXCEPT) at the top level.
- The view's select list must not contain any aggregates, window functions or set-returning functions.

An automatically updatable view may contain a mix of updatable and non-updatable columns. A column is updatable if it is a simple reference to an updatable column of the underlying base relation; otherwise the column is read-only, and an error will be raised if an INSERT or UPDATE statement attempts to assign a value to it.

If the view is automatically updatable the system will convert any INSERT, UPDATE or DELETE statement on the view into the corresponding statement on the underlying base relation. INSERT statements that have an ON CONFLICT UPDATE clause are fully supported.

If an automatically updatable view contains a WHERE condition, the condition restricts which rows of the base relation are available to be modified by UPDATE and DELETE statements on the view. However, an UPDATE is allowed to change a row so that it no longer satisfies the WHERE condition, and thus is no longer visible through the view. Similarly, an INSERT command can potentially insert base-relation rows that do not satisfy the WHERE condition and thus are not visible through the view (ON CONFLICT UPDATE may similarly affect an existing row not visible through the view). The CHECK OPTION may be used to prevent INSERT and UPDATE commands from creating such rows that are not visible through the view.

If an automatically updatable view is marked with the security_barrier property then all the view's WHERE conditions (and any conditions using operators which are marked as LEAKPROOF) will always be evaluated before any conditions that a user of the view has added. See Section 41.5 for full details. Note that, due to this, rows which are not ultimately returned (because they do not pass the user's WHERE conditions) may still end up being locked. EXPLAIN can be used to see which conditions are applied at the relation level (and therefore do not lock rows) and which are not.

A more complex view that does not satisfy all these conditions is read-only by default: the system will not allow an insert, update, or delete on the view. You can get the effect of an updatable view by creating INSTEAD OF triggers on the view, which must convert attempted inserts, etc. on the view into appropriate actions on other tables. For more information see CREATE TRIGGER. Another possibility is to create rules (see CREATE RULE), but in practice triggers are easier to understand and use correctly.
CREATE VIEW

Note that the user performing the insert, update or delete on the view must have the corresponding insert, update or delete privilege on the view. In addition, by default, the view's owner must have the relevant privileges on the underlying base relations, whereas the user performing the update does not need any permissions on the underlying base relations (see Section 41.5). However, if the view has security_invoker set to true, the user performing the update, rather than the view owner, must have the relevant privileges on the underlying base relations.

Examples

Create a view consisting of all comedy films:

```
CREATE VIEW comedies AS
SELECT *
FROM films
WHERE kind = 'Comedy';
```

This will create a view containing the columns that are in the film table at the time of view creation. Though * was used to create the view, columns added later to the table will not be part of the view.

Create a view with LOCAL CHECK OPTION:

```
CREATE VIEW universal_comedies AS
SELECT *
FROM comedies
WHERE classification = 'U'
WITH LOCAL CHECK OPTION;
```

This will create a view based on the comedies view, showing only films with kind = 'Comedy' and classification = 'U'. Any attempt to INSERT or UPDATE a row in the view will be rejected if the new row doesn't have classification = 'U', but the film kind will not be checked.

Create a view with CASCADED CHECK OPTION:

```
CREATE VIEW pg_comedies AS
SELECT *
FROM comedies
WHERE classification = 'PG'
WITH CASCADED CHECK OPTION;
```

This will create a view that checks both the kind and classification of new rows.

Create a view with a mix of updatable and non-updatable columns:

```
CREATE VIEW comedies AS
SELECT f.*,
       country_code_to_name(f.country_code) AS country,
       (SELECT avg(r.rating)
        FROM user_ratings r
        WHERE r.film_id = f.id) AS avg_rating
FROM films f
WHERE f.kind = 'Comedy';
```
This view will support INSERT, UPDATE and DELETE. All the columns from the films table will be updatable, whereas the computed columns country and avg_rating will be read-only.

CREATE VIEW

CREATE RECURSIVE VIEW public.nums_1_100 (n) AS
VALUES (1)
UNION ALL
SELECT n+1 FROM nums_1_100 WHERE n < 100;

Notice that although the recursive view's name is schema-qualified in this CREATE, its internal self-reference is not schema-qualified. This is because the implicitly-created CTE's name cannot be schema-qualified.

Compatibility

CREATE OR REPLACE VIEW is a PostgreSQL language extension. So is the concept of a temporary view. The WITH ( ... ) clause is an extension as well, as are security barrier views and security invoker views.

ALTER VIEW, DROP VIEW, CREATE MATERIALIZED VIEW
DEALLOCATE

DEALLOCATE — deallocate a prepared statement

Synopsis

DEALLOCATE [ PREPARE ] { name | ALL }

Description

DEALLOCATE is used to deallocate a previously prepared SQL statement. If you do not explicitly deallocate a prepared statement, it is deallocated when the session ends.

For more information on prepared statements, see PREPARE.

Parameters

PREPARE

This key word is ignored.

name

The name of the prepared statement to deallocate.

ALL

Deallocation all prepared statements.

Compatibility

The SQL standard includes a DEALLOCATE statement, but it is only for use in embedded SQL.

See Also

EXECUTE, PREPARE
DECLARE

DECLARE — define a cursor

Synopsis

DECLARE name [ BINARY ] [ ASENSITIVE | INSENSITIVE ] [ [ NO ] SCROLL ]
CURSOR [ { WITH | WITHOUT } HOLD ] FOR query

Description

DECLARE allows a user to create cursors, which can be used to retrieve a small number of rows at a time out of a larger query. After the cursor is created, rows are fetched from it using FETCH.

Note

This page describes usage of cursors at the SQL command level. If you are trying to use cursors inside a PL/pgSQL function, the rules are different — see Section 43.7.

Parameters

name

The name of the cursor to be created.

BINARY

Causes the cursor to return data in binary rather than in text format.

ASENSITIVE
INSENSITIVE

Cursor sensitivity determines whether changes to the data underlying the cursor, done in the same transaction, after the cursor has been declared, are visible in the cursor. INSENSITIVE means they are not visible, ASENSITIVE means the behavior is implementation-dependent. A third behavior, SENSITIVE, meaning that such changes are visible in the cursor, is not available in PostgreSQL. In PostgreSQL, all cursors are insensitive; so these key words have no effect and are only accepted for compatibility with the SQL standard.

Specifying INSENSITIVE together with FOR UPDATE or FOR SHARE is an error.

SCROLL
NO SCROLL

SCROLL specifies that the cursor can be used to retrieve rows in a nonsequential fashion (e.g., backward). Depending upon the complexity of the query's execution plan, specifying SCROLL might impose a performance penalty on the query's execution time. NO SCROLL specifies that the cursor cannot be used to retrieve rows in a nonsequential fashion. The default is to allow scrolling in some cases; this is not the same as specifying SCROLL. See Notes below for details.

1898
WITH HOLD
WITHOUT HOLD

WITH HOLD specifies that the cursor can continue to be used after the transaction that created it successfully commits. WITHOUT HOLD specifies that the cursor cannot be used outside of the transaction that created it. If neither WITHOUT HOLD nor WITH HOLD is specified, WITHOUT HOLD is the default.

query

A SELECT or VALUES command which will provide the rows to be returned by the cursor.

The key words ASENSITIVE, BINARY, INSENSITIVE, and SCROLL can appear in any order.

Notes

Normal cursors return data in text format, the same as a SELECT would produce. The BINARY option specifies that the cursor should return data in binary format. This reduces conversion effort for both the server and client, at the cost of more programmer effort to deal with platform-dependent binary data formats. As an example, if a query returns a value of one from an integer column, you would get a string of 1 with a default cursor, whereas with a binary cursor you would get a 4-byte field containing the internal representation of the value (in big-endian byte order).

Binary cursors should be used carefully. Many applications, including psql, are not prepared to handle binary cursors and expect data to come back in the text format.

Note

When the client application uses the “extended query” protocol to issue a FETCH command, the Bind protocol message specifies whether data is to be retrieved in text or binary format. This choice overrides the way that the cursor is defined. The concept of a binary cursor as such is thus obsolete when using extended query protocol — any cursor can be treated as either text or binary.

Unless WITH HOLD is specified, the cursor created by this command can only be used within the current transaction. Thus, DECLARE without WITH HOLD is useless outside a transaction block: the cursor would survive only to the completion of the statement. Therefore PostgreSQL reports an error if such a command is used outside a transaction block. Use BEGIN and COMMIT (or ROLLBACK) to define a transaction block.

If WITH HOLD is specified and the transaction that created the cursor successfully commits, the cursor can continue to be accessed by subsequent transactions in the same session. (But if the creating transaction is aborted, the cursor is removed.) A cursor created with WITH HOLD is closed when an explicit CLOSE command is issued on it, or the session ends. In the current implementation, the rows represented by a held cursor are copied into a temporary file or memory area so that they remain available for subsequent transactions.

WITH HOLD may not be specified when the query includes FOR UPDATE or FOR SHARE.

The SCROLL option should be specified when defining a cursor that will be used to fetch backwards. This is required by the SQL standard. However, for compatibility with earlier versions, PostgreSQL will allow backward fetches without SCROLL, if the cursor's query plan is simple enough that no extra overhead is needed to support it. However, application developers are advised not to rely on using backward fetches from a cursor that has not been created with SCROLL. If NO SCROLL is specified, then backward fetches are disallowed in any case.
Backward fetches are also disallowed when the query includes FOR UPDATE or FOR SHARE; therefore SCROLL may not be specified in this case.

**Caution**

Scrollable cursors may give unexpected results if they invoke any volatile functions (see Section 38.7). When a previously fetched row is re-fetched, the functions might be re-executed, perhaps leading to results different from the first time. It's best to specify NO SCROLL for a query involving volatile functions. If that is not practical, one workaround is to declare the cursor SCROLL WITH HOLD and commit the transaction before reading any rows from it. This will force the entire output of the cursor to be materialized in temporary storage, so that volatile functions are executed exactly once for each row.

If the cursor's query includes FOR UPDATE or FOR SHARE, then returned rows are locked at the time they are first fetched, in the same way as for a regular SELECT command with these options. In addition, the returned rows will be the most up-to-date versions.

**Caution**

It is generally recommended to use FOR UPDATE if the cursor is intended to be used with UPDATE ... WHERE CURRENT OF or DELETE ... WHERE CURRENT OF. Using FOR UPDATE prevents other sessions from changing the rows between the time they are fetched and the time they are updated. Without FOR UPDATE, a subsequent WHERE CURRENT OF command will have no effect if the row was changed since the cursor was created.

Another reason to use FOR UPDATE is that without it, a subsequent WHERE CURRENT OF might fail if the cursor query does not meet the SQL standard's rules for being "simply updatable" (in particular, the cursor must reference just one table and not use grouping or ORDER BY). Cursors that are not simply updatable might work, or might not, depending on plan choice details; so in the worst case, an application might work in testing and then fail in production. If FOR UPDATE is specified, the cursor is guaranteed to be updatable.

The main reason not to use FOR UPDATE with WHERE CURRENT OF is if you need the cursor to be scrollable, or to be isolated from concurrent updates (that is, continue to show the old data). If this is a requirement, pay close heed to the caveats shown above.

The SQL standard only makes provisions for cursors in embedded SQL. The PostgreSQL server does not implement an OPEN statement for cursors; a cursor is considered to be open when it is declared. However, ECPG, the embedded SQL preprocessor for PostgreSQL, supports the standard SQL cursor conventions, including those involving DECLARE and OPEN statements.

You can see all available cursors by querying the pg_cursors system view.

**Examples**

To declare a cursor:

```sql
DECLARE liahona CURSOR FOR SELECT * FROM films;
```

See FETCH for more examples of cursor usage.
Compatibility

The SQL standard allows cursors only in embedded SQL and in modules. PostgreSQL permits cursors to be used interactively.

According to the SQL standard, changes made to insensitive cursors by \texttt{UPDATE \ldots WHERE CURRENT OF} and \texttt{DELETE \ldots WHERE CURRENT OF} statements are visible in that same cursor. PostgreSQL treats these statements like all other data changing statements in that they are not visible in insensitive cursors.

Binary cursors are a PostgreSQL extension.

CLOSE, FETCH, MOVE
DELETE

DELETE — delete rows of a table

Synopsis

[ WITH [ RECURSIVE ] with_query [, ...] ]
DELETE FROM [ ONLY ] table_name [ * ] [ [ AS ] alias ]
[ USING from_item [, ...] ]
[ WHERE condition | WHERE CURRENT OF cursor_name ]
[ RETURNING * | output_expression [ [ AS ] output_name ] [, ...] ]

Description

DELETE deletes rows that satisfy the WHERE clause from the specified table. If the WHERE clause is absent, the effect is to delete all rows in the table. The result is a valid, but empty table.

Tip

TRUNCATE provides a faster mechanism to remove all rows from a table.

There are two ways to delete rows in a table using information contained in other tables in the database: using sub-selects, or specifying additional tables in the USING clause. Which technique is more appropriate depends on the specific circumstances.

The optional RETURNING clause causes DELETE to compute and return value(s) based on each row actually deleted. Any expression using the table's columns, and/or columns of other tables mentioned in USING, can be computed. The syntax of the RETURNING list is identical to that of the output list of SELECT.

You must have the DELETE privilege on the table to delete from it, as well as the SELECT privilege for any table in the USING clause or whose values are read in the condition.

Parameters

with_query

The WITH clause allows you to specify one or more subqueries that can be referenced by name in the DELETE query. See Section 7.8 and SELECT for details.

table_name

The name (optionally schema-qualified) of the table to delete rows from. If ONLY is specified before the table name, matching rows are deleted from the named table only. If ONLY is not specified, matching rows are also deleted from any tables inheriting from the named table. Optionally, * can be specified after the table name to explicitly indicate that descendant tables are included.
**DELETE**

*alias*

A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given `DELETE FROM foo AS f`, the remainder of the `DELETE` statement must refer to this table as `f` not `foo`.

*from_item*

A table expression allowing columns from other tables to appear in the `WHERE` condition. This uses the same syntax as the From clause of a `SELECT` statement; for example, an alias for the table name can be specified. Do not repeat the target table as a `from_item` unless you wish to set up a self-join (in which case it must appear with an alias in the `from_item`).

*condition*

An expression that returns a value of type `boolean`. Only rows for which this expression returns `true` will be deleted.

*cursor_name*

The name of the cursor to use in a `WHERE CURRENT OF` condition. The row to be deleted is the one most recently fetched from this cursor. The cursor must be a non-grouping query on the `DELETE`'s target table. Note that `WHERE CURRENT OF` cannot be specified together with a Boolean condition. See DECLARE for more information about using cursors with `WHERE CURRENT OF`.

*output_expression*

An expression to be computed and returned by the `DELETE` command after each row is deleted. The expression can use any column names of the table named by `table_name` or table(s) listed in `USING`. Write `*` to return all columns.

*output_name*

A name to use for a returned column.

**Outputs**

On successful completion, a `DELETE` command returns a command tag of the form

```
DELETE  count
```

The `count` is the number of rows deleted. Note that the number may be less than the number of rows that matched the `condition` when deletes were suppressed by a `BEFORE DELETE` trigger. If `count` is 0, no rows were deleted by the query (this is not considered an error).

If the `DELETE` command contains a `RETURNING` clause, the result will be similar to that of a `SELECT` statement containing the columns and values defined in the `RETURNING` list, computed over the row(s) deleted by the command.

**Notes**

PostgreSQL lets you reference columns of other tables in the `WHERE` condition by specifying the other tables in the `USING` clause. For example, to delete all films produced by a given producer, one can do:
DELETE FROM films USING producers
   WHERE producer_id = producers.id AND producers.name = 'foo';

What is essentially happening here is a join between `films` and `producers`, with all successfully joined `films` rows being marked for deletion. This syntax is not standard. A more standard way to do it is:

DELETE FROM films
   WHERE producer_id IN (SELECT id FROM producers WHERE name = 'foo');

In some cases the join style is easier to write or faster to execute than the sub-select style.

Examples

Delete all films but musicals:

DELETE FROM films WHERE kind <> 'Musical';

Clear the table `films`:

DELETE FROM films;

Delete completed tasks, returning full details of the deleted rows:

DELETE FROM tasks WHERE status = 'DONE' RETURNING *;

Delete the row of `tasks` on which the cursor `c_tasks` is currently positioned:

DELETE FROM tasks WHERE CURRENT OF c_tasks;

Compatibility

This command conforms to the SQL standard, except that the `USING` and `RETURNING` clauses are PostgreSQL extensions, as is the ability to use `WITH` with `DELETE`.

TRUNCATE
DISCARD

DISCARD — discard session state

Synopsis

DISCARD { ALL | PLANS | SEQUENCES | TEMPORARY | TEMP }

Description

DISCARD releases internal resources associated with a database session. This command is useful for partially or fully resetting the session’s state. There are several subcommands to release different types of resources; the DISCARD ALL variant subsumes all the others, and also resets additional state.

Parameters

PLANS

Releases all cached query plans, forcing re-planning to occur the next time the associated prepared statement is used.

SEQUENCES

Discards all cached sequence-related state, including currval() / lastval() information and any preallocated sequence values that have not yet been returned by nextval(). (See CREATE SEQUENCE for a description of preallocated sequence values.)

TEMPORARY or TEMP

Drops all temporary tables created in the current session.

ALL

Releases all temporary resources associated with the current session and resets the session to its initial state. Currently, this has the same effect as executing the following sequence of statements:

CLOSE ALL;
SET SESSION AUTHORIZATION DEFAULT;
RESET ALL;
DEALLOCATE ALL;
UNLISTEN *;
SELECT pg_advisory_unlock_all();
DISCARD PLANS;
DISCARD TEMP;
DISCARD SEQUENCES;

Notes

DISCARD ALL cannot be executed inside a transaction block.
Compatibility

DISCARD is a PostgreSQL extension.
DO

DO — execute an anonymous code block

Synopsis

DO [ LANGUAGE lang_name ] code

Description

DO executes an anonymous code block, or in other words a transient anonymous function in a procedural language.

The code block is treated as though it were the body of a function with no parameters, returning void. It is parsed and executed a single time.

The optional LANGUAGE clause can be written either before or after the code block.

Parameters

code

The procedural language code to be executed. This must be specified as a string literal, just as in CREATE FUNCTION. Use of a dollar-quoted literal is recommended.

lang_name

The name of the procedural language the code is written in. If omitted, the default is plpgsql.

Notes

The procedural language to be used must already have been installed into the current database by means of CREATE EXTENSION. plpgsql is installed by default, but other languages are not.

The user must have USAGE privilege for the procedural language, or must be a superuser if the language is untrusted. This is the same privilege requirement as for creating a function in the language.

If DO is executed in a transaction block, then the procedure code cannot execute transaction control statements. Transaction control statements are only allowed if DO is executed in its own transaction.

Examples

Grant all privileges on all views in schema public to role webuser:

DO $$
DECLARE r record;
BEGIN
    FOR r IN SELECT table_schema, table_name FROM information_schema.tables
    WHERE table_type = 'VIEW' AND table_schema = 'public'
END$$;
DO

LOOP
    EXECUTE 'GRANT ALL ON ' || quote_ident(r.table_schema) || '.'
    || quote_ident(r.table_name) || ' TO webuser';
END LOOP;
END$$;

Compatibility

There is no `DO` statement in the SQL standard.

See Also

CREATE LANGUAGE
DROP ACCESS METHOD

DROP ACCESS METHOD — remove an access method

Synopsis

```
DROP ACCESS METHOD [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

Description

DROP ACCESS METHOD removes an existing access method. Only superusers can drop access methods.

Parameters

**IF EXISTS**

Do not throw an error if the access method does not exist. A notice is issued in this case.

**name**

The name of an existing access method.

**CASCADE**

Automatically drop objects that depend on the access method (such as operator classes, operator families, and indexes), and in turn all objects that depend on those objects (see Section 5.14).

**RESTRICT**

Refuse to drop the access method if any objects depend on it. This is the default.

Examples

Drop the access method `heptree`:

```
DROP ACCESS METHOD heptree;
```

Compatibility

DROP ACCESS METHOD is a PostgreSQL extension.

See Also

CREATE ACCESS METHOD
DROP AGGREGATE

DROP AGGREGATE — remove an aggregate function

Synopsis

DROP AGGREGATE [ IF EXISTS ] name ( aggregate_signature ) [, ...]
[ CASCADE | RESTRICT ]

where aggregate_signature is:

* | [ argmode ] [ argname ] argtype [ , ... ] |
[ [ argmode ] [ argname ] argtype [ , ... ] ] ORDER BY [ argmode ]
[ argname ] argtype [ , ... ]

Description

DROP AGGREGATE removes an existing aggregate function. To execute this command the current user must be the owner of the aggregate function.

Parameters

IF EXISTS

Do not throw an error if the aggregate does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing aggregate function.

argmode

The mode of an argument: IN or VARIADIC. If omitted, the default is IN.

argname

The name of an argument. Note that DROP AGGREGATE does not actually pay any attention to argument names, since only the argument data types are needed to determine the aggregate function's identity.

argtype

An input data type on which the aggregate function operates. To reference a zero-argument aggregate function, write * in place of the list of argument specifications. To reference an ordered-set aggregate function, write ORDER BY between the direct and aggregated argument specifications.

CASCADE

Automatically drop objects that depend on the aggregate function (such as views using it), and in turn all objects that depend on those objects (see Section 5.14).
DROP AGGREGATE

RESTRICT

Refuse to drop the aggregate function if any objects depend on it. This is the default.

Notes

Alternative syntaxes for referencing ordered-set aggregates are described under ALTER AGGREGATE.

Examples

To remove the aggregate function myavg for type integer:

```
DROP AGGREGATE myavg(integer);
```

To remove the hypothetical-set aggregate function myrank, which takes an arbitrary list of ordering columns and a matching list of direct arguments:

```
DROP AGGREGATE myrank(VARIADIC "any" ORDER BY VARIADIC "any");
```

To remove multiple aggregate functions in one command:

```
DROP AGGREGATE myavg(integer), myavg(bigint);
```

Compatibility

There is no DROP AGGREGATE statement in the SQL standard.

See Also

ALTER AGGREGATE, CREATE AGGREGATE
DROP CAST

DROP CAST — remove a cast

Synopsis

\[
\text{DROP CAST [ IF EXISTS ] (source_type AS target_type) [ CASCADE | RESTRICT ]}
\]

Description

DROP CAST removes a previously defined cast.

To be able to drop a cast, you must own the source or the target data type. These are the same privileges that are required to create a cast.

Parameters

IF EXISTS

Do not throw an error if the cast does not exist. A notice is issued in this case.

source_type

The name of the source data type of the cast.

target_type

The name of the target data type of the cast.

CASCADE

RESTRICT

These key words do not have any effect, since there are no dependencies on casts.

Examples

To drop the cast from type text to type int:

\[
\text{DROP CAST (text AS int)};
\]

Compatibility

The DROP CAST command conforms to the SQL standard.

See Also

CREATE CAST
DROP COLLATION

DROP COLLATION — remove a collation

Synopsis

DROP COLLATION [ IF EXISTS ] name [ CASCADE | RESTRICT ]

Description

DROP COLLATION removes a previously defined collation. To be able to drop a collation, you must own the collation.

Parameters

IF EXISTS
Do not throw an error if the collation does not exist. A notice is issued in this case.

name
The name of the collation. The collation name can be schema-qualified.

CASCADE
Automatically drop objects that depend on the collation, and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT
Refuse to drop the collation if any objects depend on it. This is the default.

Examples

To drop the collation named german:

DROP COLLATION german;

Compatibility

The DROP COLLATION command conforms to the SQL standard, apart from the IF EXISTS option, which is a PostgreSQL extension.

See Also

ALTER COLLATION, CREATE COLLATION
DROP CONVERSION

DROP CONVERSION — remove a conversion

Synopsis

```
DROP CONVERSION [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

Description

DROP CONVERSION removes a previously defined conversion. To be able to drop a conversion, you must own the conversion.

Parameters

**IF EXISTS**

Do not throw an error if the conversion does not exist. A notice is issued in this case.

**name**

The name of the conversion. The conversion name can be schema-qualified.

**CASCADE**

**RESTRICT**

These key words do not have any effect, since there are no dependencies on conversions.

Examples

To drop the conversion named `myname`:

```
DROP CONVERSION myname;
```

Compatibility

There is no DROP CONVERSION statement in the SQL standard, but a DROP TRANSLATION statement that goes along with the CREATE TRANSLATION statement that is similar to the CREATE CONVERSION statement in PostgreSQL.

See Also

ALTER CONVERSION, CREATE CONVERSION
DROP DATABASE

DROP DATABASE — remove a database

Synopsis

DROP DATABASE [ IF EXISTS ] name [ [ WITH ] ( option [, ...] ) ]

where option can be:

FORCE

Description

DROP DATABASE drops a database. It removes the catalog entries for the database and deletes the directory containing the data. It can only be executed by the database owner. It cannot be executed while you are connected to the target database. (Connect to postgres or any other database to issue this command.) Also, if anyone else is connected to the target database, this command will fail unless you use the FORCE option described below.

DROP DATABASE cannot be undone. Use it with care!

Parameters

IF EXISTS

Do not throw an error if the database does not exist. A notice is issued in this case.

name

The name of the database to remove.

FORCE

Attempt to terminate all existing connections to the target database. It doesn't terminate if prepared transactions, active logical replication slots or subscriptions are present in the target database.

This will fail if the current user has no permissions to terminate other connections. Required permissions are the same as with `pg_terminate_backend`, described in Section 9.27.2. This will also fail if we are not able to terminate connections.

Notes

DROP DATABASE cannot be executed inside a transaction block.

This command cannot be executed while connected to the target database. Thus, it might be more convenient to use the program dropdb instead, which is a wrapper around this command.

Compatibility

There is no DROP DATABASE statement in the SQL standard.
See Also
CREATE DATABASE
DROP DOMAIN

DROP DOMAIN — remove a domain

Synopsis

DROP DOMAIN [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]

Description

DROP DOMAIN removes a domain. Only the owner of a domain can remove it.

Parameters

IF EXISTS

Do not throw an error if the domain does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing domain.

CASCADE

Automatically drop objects that depend on the domain (such as table columns), and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the domain if any objects depend on it. This is the default.

Examples

To remove the domain box:

    DROP DOMAIN box;

Compatibility

This command conforms to the SQL standard, except for the IF EXISTS option, which is a PostgreSQL extension.

See Also

CREATE DOMAIN, ALTER DOMAIN
DROP EVENT TRIGGER

DROP EVENT TRIGGER — remove an event trigger

Synopsis

DROP EVENT TRIGGER [ IF EXISTS ] name [ CASCADE | RESTRICT ]

Description

DROP EVENT TRIGGER removes an existing event trigger. To execute this command, the current user must be the owner of the event trigger.

Parameters

IF EXISTS

Do not throw an error if the event trigger does not exist. A notice is issued in this case.

name

The name of the event trigger to remove.

CASCADE

Automatically drop objects that depend on the trigger, and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the trigger if any objects depend on it. This is the default.

Examples

Destroy the trigger snitch:

DROP EVENT TRIGGER snitch;

Compatibility

There is no DROP EVENT TRIGGER statement in the SQL standard.

See Also

CREATE EVENT TRIGGER, ALTER EVENT TRIGGER
DROP EXTENSION

DROP EXTENSION — remove an extension

Synopsis

DROP EXTENSION [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]

Description

DROP EXTENSION removes extensions from the database. Dropping an extension causes its component objects to be dropped as well.

You must own the extension to use DROP EXTENSION.

Parameters

IF EXISTS

Do not throw an error if the extension does not exist. A notice is issued in this case.

name

The name of an installed extension.

CASCADE

Automatically drop objects that depend on the extension, and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the extension if any objects depend on it (other than its own member objects and other extensions listed in the same DROP command). This is the default.

Examples

To remove the extension hstore from the current database:

DROP EXTENSION hstore;

This command will fail if any of hstore's objects are in use in the database, for example if any tables have columns of the hstore type. Add the CASCADE option to forcibly remove those dependent objects as well.

Compatibility

DROP EXTENSION is a PostgreSQL extension.
DROP EXTENSION

See Also
CREATE EXTENSION, ALTER EXTENSION
DROP FOREIGN DATA WRAPPER

DROP FOREIGN DATA WRAPPER — remove a foreign-data wrapper

Synopsis

DROP FOREIGN DATA WRAPPER [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]

Description

DROP FOREIGN DATA WRAPPER removes an existing foreign-data wrapper. To execute this command, the current user must be the owner of the foreign-data wrapper.

Parameters

IF EXISTS

Do not throw an error if the foreign-data wrapper does not exist. A notice is issued in this case.

name

The name of an existing foreign-data wrapper.

CASCADE

Automatically drop objects that depend on the foreign-data wrapper (such as foreign tables and servers), and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the foreign-data wrapper if any objects depend on it. This is the default.

Examples

Drop the foreign-data wrapper dbi:

DROP FOREIGN DATA WRAPPER dbi;

Compatibility

DROP FOREIGN DATA WRAPPER conforms to ISO/IEC 9075-9 (SQL/MED). The IF EXISTS clause is a PostgreSQL extension.

See Also

CREATE FOREIGN DATA WRAPPER, ALTER FOREIGN DATA WRAPPER
DROP FOREIGN TABLE

DROP FOREIGN TABLE — remove a foreign table

Synopsis

DROP FOREIGN TABLE [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]

Description

DROP FOREIGN TABLE removes a foreign table. Only the owner of a foreign table can remove it.

Parameters

IF EXISTS

Do not throw an error if the foreign table does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of the foreign table to drop.

CASCADE

Automatically drop objects that depend on the foreign table (such as views), and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the foreign table if any objects depend on it. This is the default.

Examples

To destroy two foreign tables, films and distributors:

DROP FOREIGN TABLE films, distributors;

Compatibility

This command conforms to ISO/IEC 9075-9 (SQL/MED), except that the standard only allows one foreign table to be dropped per command, and apart from the IF EXISTS option, which is a PostgreSQL extension.

See Also

ALTER FOREIGN TABLE, CREATE FOREIGN TABLE
DROP FUNCTION

DROP FUNCTION — remove a function

Synopsis

```
DROP FUNCTION [ IF EXISTS ] name [ ( [ argmode ] [ argname ] argtype [, ...] ) ] [, ...]
[ CASCADE | RESTRICT ]
```

Description

DROP FUNCTION removes the definition of an existing function. To execute this command the user must be the owner of the function. The argument types to the function must be specified, since several different functions can exist with the same name and different argument lists.

Parameters

IF EXISTS

Do not throw an error if the function does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing function. If no argument list is specified, the name must be unique in its schema.

argmode

The mode of an argument: IN, OUT, INOUT, or VARIADIC. If omitted, the default is IN. Note that DROP FUNCTION does not actually pay any attention to OUT arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the IN, INOUT, and VARIADIC arguments.

argname

The name of an argument. Note that DROP FUNCTION does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

argtype

The data type(s) of the function's arguments (optionally schema-qualified), if any.

CASCADE

Automatically drop objects that depend on the function (such as operators or triggers), and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the function if any objects depend on it. This is the default.
Examples

This command removes the square root function:

```
DROP FUNCTION sqrt(integer);
```

Drop multiple functions in one command:

```
DROP FUNCTION sqrt(integer), sqrt(bigint);
```

If the function name is unique in its schema, it can be referred to without an argument list:

```
DROP FUNCTION update_employee_salaries;
```

Note that this is different from

```
DROP FUNCTION update_employee_salaries();
```

which refers to a function with zero arguments, whereas the first variant can refer to a function with any number of arguments, including zero, as long as the name is unique.

Compatibility

This command conforms to the SQL standard, with these PostgreSQL extensions:

- The standard only allows one function to be dropped per command.
- The IF EXISTS option
- The ability to specify argument modes and names

See Also

CREATE FUNCTION, ALTER FUNCTION, DROP PROCEDURE, DROP ROUTINE
DROP GROUP

DROP GROUP — remove a database role

Synopsis

DROP GROUP [ IF EXISTS ] name [, ...]

Description

DROP GROUP is now an alias for DROP ROLE.

Compatibility

There is no DROP GROUP statement in the SQL standard.

See Also

DROP ROLE
DROP INDEX

DROP INDEX — remove an index

Synopsis

```
DROP INDEX [ CONCURRENTLY ] [ IF EXISTS ] name [, ...] [ CASCADE ] |
RESTRICT ]
```

Description

DROP INDEX drops an existing index from the database system. To execute this command you must be the owner of the index.

Parameters

CONCURRENTLY

Drop the index without locking out concurrent selects, inserts, updates, and deletes on the index's table. A normal DROP INDEX acquires an ACCESS EXCLUSIVE lock on the table, blocking other accesses until the index drop can be completed. With this option, the command instead waits until conflicting transactions have completed.

There are several caveats to be aware of when using this option. Only one index name can be specified, and the CASCADE option is not supported. (Thus, an index that supports a UNIQUE or PRIMARY KEY constraint cannot be dropped this way.) Also, regular DROP INDEX commands can be performed within a transaction block, but DROP INDEX CONCURRENTLY cannot. Lastly, indexes on partitioned tables cannot be dropped using this option.

For temporary tables, DROP INDEX is always non-concurrent, as no other session can access them, and non-concurrent index drop is cheaper.

IF EXISTS

Do not throw an error if the index does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an index to remove.

CASCADE

Automatically drop objects that depend on the index, and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the index if any objects depend on it. This is the default.

Examples

This command will remove the index title_idx:
DROP INDEX title_idx;

Compatibility

DROP INDEX is a PostgreSQL language extension. There are no provisions for indexes in the SQL standard.

See Also

CREATE INDEX
DROP LANGUAGE

DROP LANGUAGE — remove a procedural language

Synopsis

DROP [ PROCEDURAL ] LANGUAGE [ IF EXISTS ] name [ CASCADE | RESTRICT ]

Description

DROP LANGUAGE removes the definition of a previously registered procedural language. You must be a superuser or the owner of the language to use DROP LANGUAGE.

Note

As of PostgreSQL 9.1, most procedural languages have been made into “extensions”, and should therefore be removed with DROP EXTENSION not DROP LANGUAGE.

Parameters

IF EXISTS

Do not throw an error if the language does not exist. A notice is issued in this case.

name

The name of an existing procedural language.

CASCADE

Automatically drop objects that depend on the language (such as functions in the language), and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the language if any objects depend on it. This is the default.

Examples

This command removes the procedural language plsample:

```
DROP LANGUAGE plsample;
```

Compatibility

There is no DROP LANGUAGE statement in the SQL standard.
See Also
ALTER LANGUAGE, CREATE LANGUAGE
DROP MATERIALIZED VIEW

DROP MATERIALIZED VIEW — remove a materialized view

Synopsis

DROP MATERIALIZED VIEW [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]

Description

DROP MATERIALIZED VIEW drops an existing materialized view. To execute this command you must be the owner of the materialized view.

Parameters

IF EXISTS

Do not throw an error if the materialized view does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of the materialized view to remove.

CASCADE

Automatically drop objects that depend on the materialized view (such as other materialized views, or regular views), and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the materialized view if any objects depend on it. This is the default.

Examples

This command will remove the materialized view called order_summary:

DROP MATERIALIZED VIEW order_summary;

Compatibility

DROP MATERIALIZED VIEW is a PostgreSQL extension.

See Also

CREATE MATERIALIZED VIEW, ALTER MATERIALIZED VIEW, REFRESH MATERIALIZED VIEW
DROP OPERATOR

DROP OPERATOR — remove an operator

Synopsis

DROP OPERATOR [ IF EXISTS ] name ( { left_type | NONE } , right_type ) [, ...] [ CASCADE | RESTRICT ]

Description

DROP OPERATOR drops an existing operator from the database system. To execute this command you must be the owner of the operator.

Parameters

IF EXISTS

Do not throw an error if the operator does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing operator.

left_type

The data type of the operator's left operand; write NONE if the operator has no left operand.

right_type

The data type of the operator's right operand.

CASCADE

Automatically drop objects that depend on the operator (such as views using it), and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the operator if any objects depend on it. This is the default.

Examples

Remove the power operator \( a^b \) for type integer:

DROP OPERATOR ^ (integer, integer);

Remove the bitwise-complement prefix operator \(~b\) for type bit:
DROP OPERATOR ~(none, bit);

Remove multiple operators in one command:

DROP OPERATOR ~(none, bit), ^(integer, integer);

Compatibility

There is no DROP OPERATOR statement in the SQL standard.

See Also

CREATE OPERATOR, ALTER OPERATOR
DROP OPERATOR CLASS

DROP OPERATOR CLASS — remove an operator class

Synopsis

DROP OPERATOR CLASS [ IF EXISTS ] name USING index_method [ CASCADE | RESTRICT ]

Description

DROP OPERATOR CLASS drops an existing operator class. To execute this command you must be the owner of the operator class.

DROP OPERATOR CLASS does not drop any of the operators or functions referenced by the class. If there are any indexes depending on the operator class, you will need to specify CASCADE for the drop to complete.

Parameters

IF EXISTS

Do not throw an error if the operator class does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing operator class.

index_method

The name of the index access method the operator class is for.

CASCADE

Automatically drop objects that depend on the operator class (such as indexes), and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the operator class if any objects depend on it. This is the default.

Notes

DROP OPERATOR CLASS will not drop the operator family containing the class, even if there is nothing else left in the family (in particular, in the case where the family was implicitly created by CREATE OPERATOR CLASS). An empty operator family is harmless, but for the sake of tidiness you might wish to remove the family with DROP OPERATOR FAMILY; or perhaps better, use DROP OPERATOR FAMILY in the first place.

Examples

Remove the B-tree operator class widget_ops:

1933
DROP OPERATOR CLASS widget_ops USING btree;

This command will not succeed if there are any existing indexes that use the operator class. Add CASCADE to drop such indexes along with the operator class.

Compatibility

There is no DROP OPERATOR CLASS statement in the SQL standard.

See Also

ALTER OPERATOR CLASS, CREATE OPERATOR CLASS, DROP OPERATOR FAMILY
DROP OPERATOR FAMILY

DROP OPERATOR FAMILY — remove an operator family

Synopsis

DROP OPERATOR FAMILY [ IF EXISTS ] name USING index_method [ CASCADE | RESTRICT ]

Description

DROP OPERATOR FAMILY drops an existing operator family. To execute this command you must be the owner of the operator family.

DROP OPERATOR FAMILY includes dropping any operator classes contained in the family, but it does not drop any of the operators or functions referenced by the family. If there are any indexes depending on operator classes within the family, you will need to specify CASCADE for the drop to complete.

Parameters

IF EXISTS

Do not throw an error if the operator family does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing operator family.

index_method

The name of the index access method the operator family is for.

CASCADE

Automatically drop objects that depend on the operator family, and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the operator family if any objects depend on it. This is the default.

Examples

Remove the B-tree operator family float_ops:

DROP OPERATOR FAMILY float_ops USING btree;

This command will not succeed if there are any existing indexes that use operator classes within the family. Add CASCADE to drop such indexes along with the operator family.
DROP OPERATOR FAMILY

Compatibility

There is no DROP OPERATOR FAMILY statement in the SQL standard.

See Also

ALTER OPERATOR FAMILY, CREATE OPERATOR FAMILY, ALTER OPERATOR CLASS, CREATE OPERATOR CLASS, DROP OPERATOR CLASS
DROP OWNED

DROP OWNED — remove database objects owned by a database role

Synopsis

DROP OWNED BY { name | CURRENT_ROLE | CURRENT_USER | SESSION_USER } [, ...] [ CASCADE | RESTRICT ]

Description

DROP OWNED drops all the objects within the current database that are owned by one of the specified roles. Any privileges granted to the given roles on objects in the current database or on shared objects (databases, tablespaces, configuration parameters) will also be revoked.

Parameters

name
The name of a role whose objects will be dropped, and whose privileges will be revoked.

CASCADE
Automatically drop objects that depend on the affected objects, and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT
Refuse to drop the objects owned by a role if any other database objects depend on one of the affected objects. This is the default.

Notes

DROP OWNED is often used to prepare for the removal of one or more roles. Because DROP OWNED only affects the objects in the current database, it is usually necessary to execute this command in each database that contains objects owned by a role that is to be removed.

Using the CASCADE option might make the command recurse to objects owned by other users.

The REASSIGN OWNED command is an alternative that reassigns the ownership of all the database objects owned by one or more roles. However, REASSIGN OWNED does not deal with privileges for other objects.

Databases and tablespaces owned by the role(s) will not be removed.

See Section 22.4 for more discussion.

Compatibility

The DROP OWNED command is a PostgreSQL extension.
See Also

REASSIGN OWNED, DROP ROLE
DROP POLICY

DROP POLICY — remove a row-level security policy from a table

Synopsis

```
DROP POLICY [ IF EXISTS ] name ON table_name [ CASCADE | RESTRICT ]
```

Description

DROP POLICY removes the specified policy from the table. Note that if the last policy is removed for a table and the table still has row-level security enabled via ALTER TABLE, then the default-deny policy will be used. ALTER TABLE ... DISABLE ROW LEVEL SECURITY can be used to disable row-level security for a table, whether policies for the table exist or not.

Parameters

**IF EXISTS**

Do not throw an error if the policy does not exist. A notice is issued in this case.

**name**

The name of the policy to drop.

**table_name**

The name (optionally schema-qualified) of the table that the policy is on.

**CASCADE**

**RESTRICT**

These key words do not have any effect, since there are no dependencies on policies.

Examples

To drop the policy called p1 on the table named my_table:

```
DROP POLICY p1 ON my_table;
```

Compatibility

DROP POLICY is a PostgreSQL extension.

See Also

CREATE POLICY, ALTER POLICY
DROP PROCEDURE

DROP PROCEDURE — remove a procedure

Synopsis

DROP PROCEDURE [ IF EXISTS ] name [ ( [ argmode ] [ argname ] argtype [, ...] ] ) [, ...]

[ CASCADE | RESTRICT ]

Description

DROP PROCEDURE removes the definition of one or more existing procedures. To execute this command the user must be the owner of the procedure(s). The argument types to the procedure(s) usually must be specified, since several different procedures can exist with the same name and different argument lists.

Parameters

IF EXISTS

Do not throw an error if the procedure does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing procedure.

argmode

The mode of an argument: IN, OUT, INOUT, or VARIADIC. If omitted, the default is IN (but see below).

argname

The name of an argument. Note that DROP PROCEDURE does not actually pay any attention to argument names, since only the argument data types are used to determine the procedure’s identity.

argtype

The data type(s) of the procedure’s arguments (optionally schema-qualified), if any. See below for details.

CASCADE

Automatically drop objects that depend on the procedure, and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the procedure if any objects depend on it. This is the default.

Notes

If there is only one procedure of the given name, the argument list can be omitted. Omit the parentheses too in this case.
In PostgreSQL, it's sufficient to list the input (including \texttt{INOUT}) arguments, because no two routines of the same name are allowed to share the same input-argument list. Moreover, the \texttt{DROP} command will not actually check that you wrote the types of \texttt{OUT} arguments correctly; so any arguments that are explicitly marked \texttt{OUT} are just noise. But writing them is recommendable for consistency with the corresponding \texttt{CREATE} command.

For compatibility with the SQL standard, it is also allowed to write all the argument data types (including those of \texttt{OUT} arguments) without any \texttt{argmode} markers. When this is done, the types of the procedure's \texttt{OUT} argument(s) \textit{will} be verified against the command. This provision creates an ambiguity, in that when the argument list contains \texttt{no argmode} markers, it's unclear which rule is intended. The \texttt{DROP} command will attempt the lookup both ways, and will throw an error if two different procedures are found. To avoid the risk of such ambiguity, it's recommendable to write \texttt{IN} markers explicitly rather than letting them be defaulted, thus forcing the traditional PostgreSQL interpretation to be used.

The lookup rules just explained are also used by other commands that act on existing procedures, such as \texttt{ALTER PROCEDURE} and \texttt{COMMENT ON PROCEDURE}.

\textbf{Examples}

If there is only one procedure \texttt{do_db_maintenance}, this command is sufficient to drop it:

\begin{verbatim}
DROP PROCEDURE do_db_maintenance;
\end{verbatim}

Given this procedure definition:

\begin{verbatim}
CREATE PROCEDURE do_db_maintenance(IN target_schema text, OUT results text) ... 
\end{verbatim}

any one of these commands would work to drop it:

\begin{verbatim}
DROP PROCEDURE do_db_maintenance(IN target_schema text, OUT results text);
DROP PROCEDURE do_db_maintenance(IN text, OUT text);
DROP PROCEDURE do_db_maintenance(IN text);
DROP PROCEDURE do_db_maintenance(text);
DROP PROCEDURE do_db_maintenance(text, text);  -- potentially ambiguous
\end{verbatim}

However, the last example would be ambiguous if there is also, say,

\begin{verbatim}
CREATE PROCEDURE do_db_maintenance(IN target_schema text, IN options text) ... 
\end{verbatim}

\textbf{Compatibility}

This command conforms to the SQL standard, with these PostgreSQL extensions:

\begin{itemize}
  \item The standard only allows one procedure to be dropped per command.
  \item The \texttt{IF EXISTS} option is an extension.
\end{itemize}
• The ability to specify argument modes and names is an extension, and the lookup rules differ when modes are given.

**See Also**

CREATE PROCEDURE, ALTER PROCEDURE, DROP FUNCTION, DROP ROUTINE
DROP PUBLICATION

DROP PUBLICATION — remove a publication

Synopsis

```
DROP PUBLICATION [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

Description

DROP PUBLICATION removes an existing publication from the database.

A publication can only be dropped by its owner or a superuser.

Parameters

IF EXISTS

Do not throw an error if the publication does not exist. A notice is issued in this case.

name

The name of an existing publication.

CASCADE

RESTRICT

These key words do not have any effect, since there are no dependencies on publications.

Examples

Drop a publication:

```
DROP PUBLICATION mypublication;
```

Compatibility

DROP PUBLICATION is a PostgreSQL extension.

See Also

CREATE PUBLICATION, ALTER PUBLICATION
DROP ROLE

DROP ROLE — remove a database role

Synopsis

DROP ROLE [ IF EXISTS ] name [, ...]

Description

DROP ROLE removes the specified role(s). To drop a superuser role, you must be a superuser yourself; to drop non-superuser roles, you must have CREATEROLE privilege.

A role cannot be removed if it is still referenced in any database of the cluster; an error will be raised if so. Before dropping the role, you must drop all the objects it owns (or reassign their ownership) and revoke any privileges the role has been granted on other objects. The REASSIGN OWNED and DROP OWNED commands can be useful for this purpose; see Section 22.4 for more discussion.

However, it is not necessary to remove role memberships involving the role; DROP ROLE automatically revokes any memberships of the target role in other roles, and of other roles in the target role. The other roles are not dropped nor otherwise affected.

Parameters

IF EXISTS

Do not throw an error if the role does not exist. A notice is issued in this case.

name

The name of the role to remove.

Notes

PostgreSQL includes a program dropuser that has the same functionality as this command (in fact, it calls this command) but can be run from the command shell.

Examples

To drop a role:

DROP ROLE jonathan;

Compatibility

The SQL standard defines DROP ROLE, but it allows only one role to be dropped at a time, and it specifies different privilege requirements than PostgreSQL uses.
See Also
CREATE ROLE, ALTER ROLE, SET ROLE
DROP ROUTINE

DROP ROUTINE — remove a routine

Synopsis

Description

DROP ROUTINE removes the definition of one or more existing routines. The term “routine” includes aggregate functions, normal functions, and procedures. See under DROP AGGREGATE, DROP FUNCTION, and DROP PROCEDURE for the description of the parameters, more examples, and further details.

Notes

The lookup rules used by DROP ROUTINE are fundamentally the same as for DROP PROCEDURE; in particular, DROP ROUTINE shares that command's behavior of considering an argument list that has no argmode markers to be possibly using the SQL standard's definition that OUT arguments are included in the list. (DROP AGGREGATE and DROP FUNCTION do not do that.)

In some cases where the same name is shared by routines of different kinds, it is possible for DROP ROUTINE to fail with an ambiguity error when a more specific command (DROP FUNCTION, etc.) would work. Specifying the argument type list more carefully will also resolve such problems.

These lookup rules are also used by other commands that act on existing routines, such as ALTER ROUTINE and COMMENT ON ROUTINE.

Examples

To drop the routine foo for type integer:

DROP ROUTINE foo(integer);

This command will work independent of whether foo is an aggregate, function, or procedure.

Compatibility

This command conforms to the SQL standard, with these PostgreSQL extensions:

• The standard only allows one routine to be dropped per command.

• The IF EXISTS option is an extension.

• The ability to specify argument modes and names is an extension, and the lookup rules differ when modes are given.
• User-definable aggregate functions are an extension.

See Also

DROP AGGREGATE, DROP FUNCTION, DROP PROCEDURE, ALTER ROUTINE

Note that there is no CREATE ROUTINE command.
DROP RULE

DROP RULE — remove a rewrite rule

Synopsis

DROP RULE [ IF EXISTS ] name ON table_name [ CASCADE | RESTRICT ]

Description

DROP RULE drops a rewrite rule.

Parameters

IF EXISTS

Do not throw an error if the rule does not exist. A notice is issued in this case.

name

The name of the rule to drop.

table_name

The name (optionally schema-qualified) of the table or view that the rule applies to.

CASCADE

Automatically drop objects that depend on the rule, and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the rule if any objects depend on it. This is the default.

Examples

To drop the rewrite rule newrule:

DROP RULE newrule ON mytable;

Compatibility

DROP RULE is a PostgreSQL language extension, as is the entire query rewrite system.

See Also

CREATE RULE, ALTER RULE
DROP SCHEMA

DROP SCHEMA — remove a schema

Synopsis

```sql
DROP SCHEMA [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

Description

`DROP SCHEMA` removes schemas from the database.

A schema can only be dropped by its owner or a superuser. Note that the owner can drop the schema (and thereby all contained objects) even if they do not own some of the objects within the schema.

Parameters

- **IF EXISTS**
  Do not throw an error if the schema does not exist. A notice is issued in this case.
- **name**
  The name of a schema.
- **CASCADE**
  Automatically drop objects (tables, functions, etc.) that are contained in the schema, and in turn all objects that depend on those objects (see Section 5.14).
- **RESTRICT**
  Refuse to drop the schema if it contains any objects. This is the default.

Notes

Using the `CASCADE` option might make the command remove objects in other schemas besides the one(s) named.

Examples

To remove schema `mystuff` from the database, along with everything it contains:

```sql
DROP SCHEMA mystuff CASCADE;
```

Compatibility

`DROP SCHEMA` is fully conforming with the SQL standard, except that the standard only allows one schema to be dropped per command, and apart from the `IF EXISTS` option, which is a PostgreSQL extension.
See Also
ALTER SCHEMA, CREATE SCHEMA
DROP SEQUENCE

DROP SEQUENCE — remove a sequence

Synopsis

DROP SEQUENCE [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]

Description

DROP SEQUENCE removes sequence number generators. A sequence can only be dropped by its owner or a superuser.

Parameters

IF EXISTS

Do not throw an error if the sequence does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of a sequence.

CASCADE

Automatically drop objects that depend on the sequence, and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the sequence if any objects depend on it. This is the default.

Examples

To remove the sequence serial:

DROP SEQUENCE serial;

Compatibility

DROP SEQUENCE conforms to the SQL standard, except that the standard only allows one sequence to be dropped per command, and apart from the IF EXISTS option, which is a PostgreSQL extension.

See Also

CREATE SEQUENCE, ALTER SEQUENCE
DROP SERVER

DROP SERVER — remove a foreign server descriptor

Synopsis

DROP SERVER [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]

Description

DROP SERVER removes an existing foreign server descriptor. To execute this command, the current user must be the owner of the server.

Parameters

IF EXISTS

Do not throw an error if the server does not exist. A notice is issued in this case.

name

The name of an existing server.

CASCADE

Automatically drop objects that depend on the server (such as user mappings), and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the server if any objects depend on it. This is the default.

Examples

Drop a server foo if it exists:

DROP SERVER IF EXISTS foo;

Compatibility

DROP SERVER conforms to ISO/IEC 9075-9 (SQL/MED). The IF EXISTS clause is a PostgreSQL extension.

See Also

CREATE SERVER, ALTER SERVER
DROP STATISTICS

DROP STATISTICS — remove extended statistics

Synopsis

```
DROP STATISTICS [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

Description

DROP STATISTICS removes statistics object(s) from the database. Only the statistics object's owner, the schema owner, or a superuser can drop a statistics object.

Parameters

If `IF EXISTS`

Do not throw an error if the statistics object does not exist. A notice is issued in this case.

`name`

The name (optionally schema-qualified) of the statistics object to drop.

CASCADE

RESTRICT

These key words do not have any effect, since there are no dependencies on statistics.

Examples

To destroy two statistics objects in different schemas, without failing if they don't exist:

```
DROP STATISTICS IF EXISTS
    accounting.users_uid_creation,
    public.grants_user_role;
```

Compatibility

There is no `DROP STATISTICS` command in the SQL standard.

See Also

ALTER STATISTICS, CREATE STATISTICS
DROP SUBSCRIPTION

DROP SUBSCRIPTION — remove a subscription

Synopsis

DROP SUBSCRIPTION [ IF EXISTS ] name [ CASCADE | RESTRICT ]

Description

DROP SUBSCRIPTION removes a subscription from the database cluster.

A subscription can only be dropped by a superuser.

DROP SUBSCRIPTION cannot be executed inside a transaction block if the subscription is associated with a replication slot. (You can use ALTER SUBSCRIPTION to unset the slot.)

Parameters

name

The name of a subscription to be dropped.

CASCADE

RESTRICT

These key words do not have any effect, since there are no dependencies on subscriptions.

Notes

When dropping a subscription that is associated with a replication slot on the remote host (the normal state), DROP SUBSCRIPTION will connect to the remote host and try to drop the replication slot (and any remaining table synchronization slots) as part of its operation. This is necessary so that the resources allocated for the subscription on the remote host are released. If this fails, either because the remote host is not reachable or because the remote replication slot cannot be dropped or does not exist or never existed, the DROP SUBSCRIPTION command will fail. To proceed in this situation, disassociate the subscription from the replication slot by executing ALTER SUBSCRIPTION ... SET (slot_name = NONE). After that, DROP SUBSCRIPTION will no longer attempt any actions on a remote host. Note that if the remote replication slot still exists, it (and any related table synchronization slots) should then be dropped manually; otherwise it/they will continue to reserve WAL and might eventually cause the disk to fill up. See also Section 31.2.1.

If a subscription is associated with a replication slot, then DROP SUBSCRIPTION cannot be executed inside a transaction block.

Examples

Drop a subscription:
DROP SUBSCRIPTION mysub;

Compatibility

DROP SUBSCRIPTION is a PostgreSQL extension.

See Also

CREATE SUBSCRIPTION, ALTER SUBSCRIPTION
DROP TABLE

DROP TABLE — remove a table

Synopsis

```
DROP TABLE [ IF EXISTS ] name [ , ... ] [ CASCADE | RESTRICT ]
```

Description

DROP TABLE removes tables from the database. Only the table owner, the schema owner, and superuser can drop a table. To empty a table of rows without destroying the table, use DELETE or TRUNCATE.

DROP TABLE always removes any indexes, rules, triggers, and constraints that exist for the target table. However, to drop a table that is referenced by a view or a foreign-key constraint of another table, CASCADE must be specified. (CASCADE will remove a dependent view entirely, but in the foreign-key case it will only remove the foreign-key constraint, not the other table entirely.)

Parameters

IF EXISTS

Do not throw an error if the table does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of the table to drop.

CASCADE

Automatically drop objects that depend on the table (such as views), and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the table if any objects depend on it. This is the default.

Examples

To destroy two tables, films and distributors:

```
DROP TABLE films, distributors;
```

Compatibility

This command conforms to the SQL standard, except that the standard only allows one table to be dropped per command, and apart from the IF EXISTS option, which is a PostgreSQL extension.

See Also

ALTER TABLE, CREATE TABLE
DROP TABLESPACE

DROP TABLESPACE — remove a tablespace

Synopsis

DROP TABLESPACE [ IF EXISTS ] name

Description

DROP TABLESPACE removes a tablespace from the system.

A tablespace can only be dropped by its owner or a superuser. The tablespace must be empty of all database objects before it can be dropped. It is possible that objects in other databases might still reside in the tablespace even if no objects in the current database are using the tablespace. Also, if the tablespace is listed in the temp_tablespaces setting of any active session, the DROP might fail due to temporary files residing in the tablespace.

Parameters

IF EXISTS

Do not throw an error if the tablespace does not exist. A notice is issued in this case.

name

The name of a tablespace.

Notes

DROP TABLESPACE cannot be executed inside a transaction block.

Examples

To remove tablespace mystuff from the system:

DROP TABLESPACE mystuff;

Compatibility

DROP TABLESPACE is a PostgreSQL extension.

See Also

CREATE TABLESPACE, ALTER TABLESPACE
DROP TEXT SEARCH CONFIGURATION

DROP TEXT SEARCH CONFIGURATION — remove a text search configuration

Synopsis

DROP TEXT SEARCH CONFIGURATION [ IF EXISTS ] name [ CASCADE | RESTRICT ]

Description

DROP TEXT SEARCH CONFIGURATION drops an existing text search configuration. To execute this command you must be the owner of the configuration.

Parameters

IF EXISTS

Do not throw an error if the text search configuration does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing text search configuration.

CASCADE

Automatically drop objects that depend on the text search configuration, and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the text search configuration if any objects depend on it. This is the default.

Examples

Remove the text search configuration my_english:

DROP TEXT SEARCH CONFIGURATION my_english;

This command will not succeed if there are any existing indexes that reference the configuration in to_tsvector calls. Add CASCADE to drop such indexes along with the text search configuration.

Compatibility

There is no DROP TEXT SEARCH CONFIGURATION statement in the SQL standard.

See Also

ALTER TEXT SEARCH CONFIGURATION, CREATE TEXT SEARCH CONFIGURATION
DROP TEXT SEARCH DICTIONARY

DROP TEXT SEARCH DICTIONARY — remove a text search dictionary

Synopsis

DROP TEXT SEARCH DICTIONARY [ IF EXISTS ] name [ CASCADE | RESTRICT ]

Description

DROP TEXT SEARCH DICTIONARY drops an existing text search dictionary. To execute this command you must be the owner of the dictionary.

Parameters

IF EXISTS

Do not throw an error if the text search dictionary does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing text search dictionary.

CASCADE

Automatically drop objects that depend on the text search dictionary, and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the text search dictionary if any objects depend on it. This is the default.

Examples

Remove the text search dictionary english:

DROP TEXT SEARCH DICTIONARY english;

This command will not succeed if there are any existing text search configurations that use the dictionary. Add CASCADE to drop such configurations along with the dictionary.

Compatibility

There is no DROP TEXT SEARCH DICTIONARY statement in the SQL standard.

See Also

ALTER TEXT SEARCH DICTIONARY, CREATE TEXT SEARCH DICTIONARY
DROP TEXT SEARCH PARSER

DROP TEXT SEARCH PARSER — remove a text search parser

Synopsis

```sql
DROP TEXT SEARCH PARSER [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

Description

DROP TEXT SEARCH PARSER drops an existing text search parser. You must be a superuser to use this command.

Parameters

```sql
IF EXISTS

Do not throw an error if the text search parser does not exist. A notice is issued in this case.
```

```sql
name

The name (optionally schema-qualified) of an existing text search parser.
```

```sql
CASCADE

Automatically drop objects that depend on the text search parser, and in turn all objects that depend on those objects (see Section 5.14).
```

```sql
RESTRICT

Refuse to drop the text search parser if any objects depend on it. This is the default.
```

Examples

Remove the text search parser `my_parser`:

```sql
DROP TEXT SEARCH PARSER my_parser;
```

This command will not succeed if there are any existing text search configurations that use the parser. Add CASCADE to drop such configurations along with the parser.

Compatibility

There is no DROP TEXT SEARCH PARSER statement in the SQL standard.

See Also

ALTER TEXT SEARCH PARSER, CREATE TEXT SEARCH PARSER
DROP TEXT SEARCH TEMPLATE

DROP TEXT SEARCH TEMPLATE — remove a text search template

Synopsis

DROP TEXT SEARCH TEMPLATE [ IF EXISTS ] name [ CASCADE | RESTRICT ]

Description

DROP TEXT SEARCH TEMPLATE drops an existing text search template. You must be a superuser to use this command.

Parameters

IF EXISTS

Do not throw an error if the text search template does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing text search template.

CASCADE

Automatically drop objects that depend on the text search template, and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the text search template if any objects depend on it. This is the default.

Examples

Remove the text search template thesaurus:

DROP TEXT SEARCH TEMPLATE thesaurus;

This command will not succeed if there are any existing text search dictionaries that use the template. Add CASCADE to drop such dictionaries along with the template.

Compatibility

There is no DROP TEXT SEARCH TEMPLATE statement in the SQL standard.

See Also

ALTER TEXT SEARCH TEMPLATE, CREATE TEXT SEARCH TEMPLATE
DROP TRANSFORM

DROP TRANSFORM — remove a transform

Synopsis

DROP TRANSFORM [ IF EXISTS ] FOR type_name LANGUAGE lang_name
[ CASCADE | RESTRICT ]

Description

DROP TRANSFORM removes a previously defined transform.

To be able to drop a transform, you must own the type and the language. These are the same privileges that are required to create a transform.

Parameters

IF EXISTS

Do not throw an error if the transform does not exist. A notice is issued in this case.

type_name

The name of the data type of the transform.

lang_name

The name of the language of the transform.

CASCADE

Automatically drop objects that depend on the transform, and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the transform if any objects depend on it. This is the default.

Examples

To drop the transform for type hstore and language plpython3u:

DROP TRANSFORM FOR hstore LANGUAGE plpython3u;

 Compatibility

This form of DROP TRANSFORM is a PostgreSQL extension. See CREATE TRANSFORM for details.
See Also

CREATE TRANSFORM
DROP TRIGGER

DROP TRIGGER — remove a trigger

Synopsis

DROP TRIGGER [ IF EXISTS ] name ON table_name [ CASCADE | RESTRICT ]

Description

DROP TRIGGER removes an existing trigger definition. To execute this command, the current user must be the owner of the table for which the trigger is defined.

Parameters

IF EXISTS

Do not throw an error if the trigger does not exist. A notice is issued in this case.

name

The name of the trigger to remove.

table_name

The name (optionally schema-qualified) of the table for which the trigger is defined.

CASCADE

Automatically drop objects that depend on the trigger, and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the trigger if any objects depend on it. This is the default.

Examples

Destroy the trigger if_dist_exists on the table films:

DROP TRIGGER if_dist_exists ON films;

Compatibility

The DROP TRIGGER statement in PostgreSQL is incompatible with the SQL standard. In the SQL standard, trigger names are not local to tables, so the command is simply DROP TRIGGER name.

See Also

CREATE TRIGGER
DROP TYPE

DROP TYPE — remove a data type

Synopsis

```
DROP TYPE [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

Description

DROP TYPE removes a user-defined data type. Only the owner of a type can remove it.

Parameters

- **IF EXISTS**
  
  Do not throw an error if the type does not exist. A notice is issued in this case.

- **name**
  
  The name (optionally schema-qualified) of the data type to remove.

- **CASCADE**
  
  Automatically drop objects that depend on the type (such as table columns, functions, and operators), and in turn all objects that depend on those objects (see Section 5.14).

- **RESTRICT**
  
  Refuse to drop the type if any objects depend on it. This is the default.

Examples

To remove the data type `box`:

```
DROP TYPE box;
```

Compatibility

This command is similar to the corresponding command in the SQL standard, apart from the **IF EXISTS** option, which is a PostgreSQL extension. But note that much of the **CREATE TYPE** command and the data type extension mechanisms in PostgreSQL differ from the SQL standard.

See Also

ALTER TYPE, CREATE TYPE
DROP USER

DROP USER — remove a database role

Synopsis

DROP USER [ IF EXISTS ] name [, ...]

Description

DROP USER is simply an alternate spelling of DROP ROLE.

Compatibility

The DROP USER statement is a PostgreSQL extension. The SQL standard leaves the definition of users to the implementation.

See Also

DROP ROLE
DROP USER MAPPING

DROP USER MAPPING — remove a user mapping for a foreign server

Synopsis

DROP USER MAPPING [ IF EXISTS ] FOR { user_name | USER | CURRENT_ROLE |
CURRENT_USER | PUBLIC } SERVER server_name

Description

DROP USER MAPPING removes an existing user mapping from foreign server.

The owner of a foreign server can drop user mappings for that server for any user. Also, a user can drop a
user mapping for their own user name if USAGE privilege on the server has been granted to the user.

Parameters

IF EXISTS

Do not throw an error if the user mapping does not exist. A notice is issued in this case.

user_name

User name of the mapping. CURRENT_ROLE, CURRENT_USER, and USER match the name of the
current user. PUBLIC is used to match all present and future user names in the system.

server_name

Server name of the user mapping.

Examples

Drop a user mapping bob, server foo if it exists:

DROP USER MAPPING IF EXISTS FOR bob SERVER foo;

Compatibility

DROP USER MAPPING conforms to ISO/IEC 9075-9 (SQL/MED). The IF EXISTS clause is a Post-
greSQL extension.

See Also

CREATE USER MAPPING, ALTER USER MAPPING
DROP VIEW

DROP VIEW — remove a view

Synopsis

DROP VIEW [ IF EXISTS ] name [ , ... ] [ CASCADE | RESTRICT ]

Description

DROP VIEW drops an existing view. To execute this command you must be the owner of the view.

Parameters

IF EXISTS

Do not throw an error if the view does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of the view to remove.

CASCADE

Automatically drop objects that depend on the view (such as other views), and in turn all objects that depend on those objects (see Section 5.14).

RESTRICT

Refuse to drop the view if any objects depend on it. This is the default.

Examples

This command will remove the view called kinds:

DROP VIEW kinds;

Compatibility

This command conforms to the SQL standard, except that the standard only allows one view to be dropped per command, and apart from the IF EXISTS option, which is a PostgreSQL extension.

See Also

ALTER VIEW, CREATE VIEW
END

END — commit the current transaction

Synopsis

END [ WORK | TRANSACTION ] [ AND [ NO ] CHAIN ]

Description

END commits the current transaction. All changes made by the transaction become visible to others and are guaranteed to be durable if a crash occurs. This command is a PostgreSQL extension that is equivalent to COMMIT.

Parameters

WORK
TRANSACTION

Optional key words. They have no effect.

AND CHAIN

If AND CHAIN is specified, a new transaction is immediately started with the same transaction characteristics (see SET TRANSACTION) as the just finished one. Otherwise, no new transaction is started.

Notes

Use ROLLBACK to abort a transaction.

Issuing END when not inside a transaction does no harm, but it will provoke a warning message.

Examples

To commit the current transaction and make all changes permanent:

END;

Compatibility

END is a PostgreSQL extension that provides functionality equivalent to COMMIT, which is specified in the SQL standard.

See Also

BEGIN, COMMIT, ROLLBACK
EXECUTE

EXECUTE — execute a prepared statement

Synopsis

```
EXECUTE name [ ( parameter [, ...] ) ]
```

Description

EXECUTE is used to execute a previously prepared statement. Since prepared statements only exist for the duration of a session, the prepared statement must have been created by a PREPARE statement executed earlier in the current session.

If the PREPARE statement that created the statement specified some parameters, a compatible set of parameters must be passed to the EXECUTE statement, or else an error is raised. Note that (unlike functions) prepared statements are not overloaded based on the type or number of their parameters; the name of a prepared statement must be unique within a database session.

For more information on the creation and usage of prepared statements, see PREPARE.

Parameters

`name`

The name of the prepared statement to execute.

`parameter`

The actual value of a parameter to the prepared statement. This must be an expression yielding a value that is compatible with the data type of this parameter, as was determined when the prepared statement was created.

Outputs

The command tag returned by EXECUTE is that of the prepared statement, and not EXECUTE.

Examples

Examples are given in Examples in the PREPARE documentation.

Compatibility

The SQL standard includes an EXECUTE statement, but it is only for use in embedded SQL. This version of the EXECUTE statement also uses a somewhat different syntax.

See Also

DEALLOCATE, PREPARE
EXPLAIN

EXPLAIN — show the execution plan of a statement

Synopsis

EXPLAIN [ ( option [, ...] ) ] statement
EXPLAIN [ ANALYZE ] [ VERBOSE ] statement

where option can be one of:

   ANALYZE [ boolean ]
   VERBOSE [ boolean ]
   COSTS [ boolean ]
   SETTINGS [ boolean ]
   BUFFERS [ boolean ]
   WAL [ boolean ]
   TIMING [ boolean ]
   SUMMARY [ boolean ]
   FORMAT { TEXT | XML | JSON | YAML }

Description

This command displays the execution plan that the PostgreSQL planner generates for the supplied statement. The execution plan shows how the table(s) referenced by the statement will be scanned — by plain sequential scan, index scan, etc. — and if multiple tables are referenced, what join algorithms will be used to bring together the required rows from each input table.

The most critical part of the display is the estimated statement execution cost, which is the planner's guess at how long it will take to run the statement (measured in cost units that are arbitrary, but conventionally mean disk page fetches). Actually two numbers are shown: the start-up cost before the first row can be returned, and the total cost to return all the rows. For most queries the total cost is what matters, but in contexts such as a subquery in EXISTS, the planner will choose the smallest start-up cost instead of the smallest total cost (since the executor will stop after getting one row, anyway). Also, if you limit the number of rows to return with a LIMIT clause, the planner makes an appropriate interpolation between the endpoint costs to estimate which plan is really the cheapest.

The ANALYZE option causes the statement to be actually executed, not only planned. Then actual run time statistics are added to the display, including the total elapsed time expended within each plan node (in milliseconds) and the total number of rows it actually returned. This is useful for seeing whether the planner's estimates are close to reality.

Important

Keep in mind that the statement is actually executed when the ANALYZE option is used. Although EXPLAIN will discard any output that a SELECT would return, other side effects of the statement will happen as usual. If you wish to use EXPLAIN ANALYZE on an INSERT, UPDATE, DELETE, CREATE TABLE AS, or EXECUTE statement without letting the command affect your data, use this approach:
BEGIN;
EXPLAIN ANALYZE ...;
ROLLBACK;

Only the ANALYZE and VERBOSE options can be specified, and only in that order, without surrounding the option list in parentheses. Prior to PostgreSQL 9.0, the unparenthesized syntax was the only one supported. It is expected that all new options will be supported only in the parenthesized syntax.

Parameters

ANALYZE

Carry out the command and show actual run times and other statistics. This parameter defaults to FALSE.

VERBOSE

Display additional information regarding the plan. Specifically, include the output column list for each node in the plan tree, schema-qualify table and function names, always label variables in expressions with their range table alias, and always print the name of each trigger for which statistics are displayed. The query identifier will also be displayed if one has been computed, see compute_query_id for more details. This parameter defaults to FALSE.

COSTS

Include information on the estimated startup and total cost of each plan node, as well as the estimated number of rows and the estimated width of each row. This parameter defaults to TRUE.

SETTINGS

Include information on configuration parameters. Specifically, include options affecting query planning with value different from the built-in default value. This parameter defaults to FALSE.

BUFFERS

Include information on buffer usage. Specifically, include the number of shared blocks hit, read, dirtied, and written, the number of local blocks hit, read, dirtied, and written, the number of temp blocks read and written, and the time spent reading and writing data file blocks and temporary file blocks (in milliseconds) if track_io_timing is enabled. A hit means that a read was avoided because the block was found already in cache when needed. Shared blocks contain data from regular tables and indexes; local blocks contain data from temporary tables and indexes; while temporary blocks contain short-term working data used in sorts, hashes, Materialize plan nodes, and similar cases. The number of blocks dirtied indicates the number of previously unmodified blocks that were changed by this query; while the number of blocks written indicates the number of previously-dirtied blocks evicted from cache by this backend during query processing. The number of blocks shown for an upper-level node includes those used by all its child nodes. In text format, only non-zero values are printed. It defaults to FALSE.

WAL

Include information on WAL record generation. Specifically, include the number of records, number of full page images (fpi) and the amount of WAL generated in bytes. In text format, only non-zero values are printed. This parameter may only be used when ANALYZE is also enabled. It defaults to FALSE.
TIMING

Include actual startup time and time spent in each node in the output. The overhead of repeatedly reading the system clock can slow down the query significantly on some systems, so it may be useful to set this parameter to FALSE when only actual row counts, and not exact times, are needed. Run time of the entire statement is always measured, even when node-level timing is turned off with this option. This parameter may only be used when ANALYZE is also enabled. It defaults to TRUE.

SUMMARY

Include summary information (e.g., totaled timing information) after the query plan. Summary information is included by default when ANALYZE is used but otherwise is not included by default, but can be enabled using this option. Planning time in EXPLAIN EXECUTE includes the time required to fetch the plan from the cache and the time required for re-planning, if necessary.

FORMAT

Specify the output format, which can be TEXT, XML, JSON, or YAML. Non-text output contains the same information as the text output format, but is easier for programs to parse. This parameter defaults to TEXT.

boolean

Specifies whether the selected option should be turned on or off. You can write TRUE, ON, or 1 to enable the option, and FALSE, OFF, or 0 to disable it. The boolean value can also be omitted, in which case TRUE is assumed.

statement

Any SELECT, INSERT, UPDATE, DELETE, VALUES, EXECUTE, DECLARE, CREATE TABLE AS, or CREATE MATERIALIZED VIEW AS statement, whose execution plan you wish to see.

Outputs

The command's result is a textual description of the plan selected for the statement, optionally annotated with execution statistics. Section 14.1 describes the information provided.

Notes

In order to allow the PostgreSQL query planner to make reasonably informed decisions when optimizing queries, the pg_statistic data should be up-to-date for all tables used in the query. Normally the autovacuum daemon will take care of that automatically. But if a table has recently had substantial changes in its contents, you might need to do a manual ANALYZE rather than wait for autovacuum to catch up with the changes.

In order to measure the run-time cost of each node in the execution plan, the current implementation of EXPLAIN ANALYZE adds profiling overhead to query execution. As a result, running EXPLAIN ANALYZE on a query can sometimes take significantly longer than executing the query normally. The amount of overhead depends on the nature of the query, as well as the platform being used. The worst case occurs for plan nodes that in themselves require very little time per execution, and on machines that have relatively slow operating system calls for obtaining the time of day.

Examples

To show the plan for a simple query on a table with a single integer column and 10000 rows:
EXPLAIN SELECT * FROM foo;

QUERY PLAN
---------------------------------------------------------
Seq Scan on foo  (cost=0.00..155.00 rows=10000 width=4)
(1 row)

Here is the same query, with JSON output formatting:

EXPLAIN (FORMAT JSON) SELECT * FROM foo;

QUERY PLAN
---------------------------------------------------------
[
  [
    "Plan": {
      "Node Type": "Seq Scan",
      "Relation Name": "foo",
      "Alias": "foo",
      "Startup Cost": 0.00,
      "Total Cost": 155.00,
      "Plan Rows": 10000,
      "Plan Width": 4
    }
  ]
]
(1 row)

If there is an index and we use a query with an indexable WHERE condition, EXPLAIN might show a different plan:

EXPLAIN SELECT * FROM foo WHERE i = 4;

QUERY PLAN
---------------------------------------------------------
Index Scan using fi on foo  (cost=0.00..5.98 rows=1 width=4)
  Index Cond: (i = 4)
(2 rows)

Here is the same query, but in YAML format:

EXPLAIN (FORMAT YAML) SELECT * FROM foo WHERE i='4';

QUERY PLAN
---------------------------------------------------------
- Plan: +
  Node Type: "Index Scan" +
  Scan Direction: "Forward" +
  Index Name: "fi" +
  Relation Name: "foo" +
  Alias: "foo" +
  Startup Cost: 0.00 +
  Total Cost: 5.98 +

1974
XML format is left as an exercise for the reader.

Here is the same plan with cost estimates suppressed:

```
EXPLAIN (COSTS FALSE) SELECT * FROM foo WHERE i = 4;
```

```
QUERY PLAN
-------------------
  Index Scan using fi on foo
  Index Cond: (i = 4)
```

Here is an example of a query plan for a query using an aggregate function:

```
EXPLAIN SELECT sum(i) FROM foo WHERE i < 10;
```

```
QUERY PLAN
-----------------------------------------------------
Aggregate  (cost=23.93..23.93 rows=1 width=4) (actual
time=0.156..0.161 rows=11 loops=1)
  Group Key: foo
  ->  Index Scan using fi on foo  (cost=0.29..9.29 rows=50
      width=8) (actual time=0.039..0.091 rows=99 loops=1)
      Index Cond: ((id > $1) AND (id < $2))
Planning time: 0.197 ms
Execution time: 0.225 ms
```

Of course, the specific numbers shown here depend on the actual contents of the tables involved. Also note that the numbers, and even the selected query strategy, might vary between PostgreSQL releases due to planner improvements. In addition, the ANALYZE command uses random sampling to estimate data
statistics; therefore, it is possible for cost estimates to change after a fresh run of ANALYZE, even if the actual distribution of data in the table has not changed.

**Compatibility**

There is no EXPLAIN statement defined in the SQL standard.

**See Also**

ANALYZE
FETCH

FETCH — retrieve rows from a query using a cursor

Synopsis

FETCH [ direction [ FROM | IN ] ] cursor_name

where direction can be empty or one of:

NEXT
PRIOR
FIRST
LAST
ABSOLUTE count
RELATIVE count
count
ALL
FORWARD
FORWARD count
FORWARD ALL
BACKWARD
BACKWARD count
BACKWARD ALL

Description

FETCH retrieves rows using a previously-created cursor.

A cursor has an associated position, which is used by FETCH. The cursor position can be before the first row of the query result, on any particular row of the result, or after the last row of the result. When created, a cursor is positioned before the first row. After fetching some rows, the cursor is positioned on the row most recently retrieved. If FETCH runs off the end of the available rows then the cursor is left positioned after the last row, or before the first row if fetching backward. FETCH ALL or FETCH BACKWARD ALL will always leave the cursor positioned after the last row or before the first row.

The forms NEXT, PRIOR, FIRST, LAST, ABSOLUTE, RELATIVE fetch a single row after moving the cursor appropriately. If there is no such row, an empty result is returned, and the cursor is left positioned before the first row or after the last row as appropriate.

The forms using FORWARD and BACKWARD retrieve the indicated number of rows moving in the forward or backward direction, leaving the cursor positioned on the last-returned row (or after/before all rows, if the count exceeds the number of rows available).

RELATIVE 0, FORWARD 0, and BACKWARD 0 all request fetching the current row without moving the cursor, that is, re-fetching the most recently fetched row. This will succeed unless the cursor is positioned before the first row or after the last row; in which case, no row is returned.
Note

This page describes usage of cursors at the SQL command level. If you are trying to use cursors inside a PL/pgSQL function, the rules are different — see Section 43.7.3.

Parameters

direction

direction defines the fetch direction and number of rows to fetch. It can be one of the following:

NEXT
Fetch the next row. This is the default if direction is omitted.

PRIOR
Fetch the prior row.

FIRST
Fetch the first row of the query (same as ABSOLUTE 1).

LAST
Fetch the last row of the query (same as ABSOLUTE -1).

ABSOLUTE count
Fetch the count'th row of the query, or the abs(count)'th row from the end if count is negative. Position before first row or after last row if count is out of range; in particular, ABSOLUTE 0 positions before the first row.

RELATIVE count
Fetch the count'th succeeding row, or the abs(count)'th prior row if count is negative. RELATIVE 0 re-fetches the current row, if any.

count
Fetch the next count rows (same as FORWARD count).

ALL
Fetch all remaining rows (same as FORWARD ALL).

FORWARD
Fetch the next row (same as NEXT).

FORWARD count
Fetch the next count rows. FORWARD 0 re-fetches the current row.

FORWARD ALL
Fetch all remaining rows.
BACKWARD

Fetch the prior row (same as PRIOR).

BACKWARD count

Fetch the prior count rows (scanning backwards). BACKWARD 0 re-fetches the current row.

BACKWARD ALL

Fetch all prior rows (scanning backwards).

count

count is a possibly-signed integer constant, determining the location or number of rows to fetch. For
FORWARD and BACKWARD cases, specifying a negative count is equivalent to changing the sense
of FORWARD and BACKWARD.

cursor_name

An open cursor's name.

Outputs

On successful completion, a FETCH command returns a command tag of the form

FETCH count

The count is the number of rows fetched (possibly zero). Note that in psql, the command tag will not
actually be displayed, since psql displays the fetched rows instead.

Notes

The cursor should be declared with the SCROLL option if one intends to use any variants of FETCH other
than FETCH NEXT or FETCH FORWARD with a positive count. For simple queries PostgreSQL will
allow backwards fetch from cursors not declared with SCROLL, but this behavior is best not relied on. If
the cursor is declared with NO SCROLL, no backward fetches are allowed.

ABSOLUTE fetches are not any faster than navigating to the desired row with a relative move: the under-
lying implementation must traverse all the intermediate rows anyway. Negative absolute fetches are even
worse: the query must be read to the end to find the last row, and then traversed backward from there.
However, rewinding to the start of the query (as with FETCH ABSOLUTE 0) is fast.

DECLARE is used to define a cursor. Use MOVE to change cursor position without retrieving data.

Examples

The following example traverses a table using a cursor:

BEGIN WORK;

-- Set up a cursor:
DECLARE liahona SCROLL CURSOR FOR SELECT * FROM films;
-- Fetch the first 5 rows in the cursor liahona:
FETCH FORWARD 5 FROM liahona;

| code  | title                   | did | date_prod | kind   | len  |
|-------|-------------------------+-----+-----------+--------+------|
| BL101 | The Third Man           | 101 | 1949-12-23| Drama   | 01:44|
| BL102 | The African Queen       | 101 | 1951-08-11| Romantic| 01:43|
| JL201 | Une Femme est une Femme | 102 | 1961-03-12| Romantic| 01:25|
| P_301 | Vertigo                 | 103 | 1958-11-14| Action  | 02:08|
| P_302 | Becket                  | 103 | 1964-02-03| Drama   | 02:28|

-- Fetch the previous row:
FETCH PRIOR FROM liahona;

| code  | title        | did | date_prod | kind | len  |
|-------|--------------+-----+-----------+------+------|
| P_301 | Vertigo     | 103 | 1958-11-14| Action| 02:08|

-- Close the cursor and end the transaction:
CLOSE liahona;
COMMIT WORK;

Compatibility

The SQL standard defines FETCH for use in embedded SQL only. The variant of FETCH described here returns the data as if it were a SELECT result rather than placing it in host variables. Other than this point, FETCH is fully upward-compatible with the SQL standard.

The FETCH forms involving FORWARD and BACKWARD, as well as the forms FETCH count and FETCH ALL, in which FORWARD is implicit, are PostgreSQL extensions.

The SQL standard allows only FROM preceding the cursor name; the option to use IN, or to leave them out altogether, is an extension.

[ WITH ADMIN OPTION ]
[ GRANTED BY role_specification ]

where role_specification can be:

[ GROUP ] role_name
| PUBLIC
| CURRENT_ROLE
| CURRENT_USER
| SESSION_USER

**Description**

The **GRANT** command has two basic variants: one that grants privileges on a database object (table, column, view, foreign table, sequence, database, foreign-data wrapper, foreign server, function, procedure,
procedural language, large object, configuration parameter, schema, tablespace, or type), and one that grants membership in a role. These variants are similar in many ways, but they are different enough to be described separately.

**GRANT on Database Objects**

This variant of the `GRANT` command gives specific privileges on a database object to one or more roles. These privileges are added to those already granted, if any.

The key word `PUBLIC` indicates that the privileges are to be granted to all roles, including those that might be created later. `PUBLIC` can be thought of as an implicitly defined group that always includes all roles. Any particular role will have the sum of privileges granted directly to it, privileges granted to any role it is presently a member of, and privileges granted to `PUBLIC`.

If `WITH GRANT OPTION` is specified, the recipient of the privilege can in turn grant it to others. Without a grant option, the recipient cannot do that. Grant options cannot be granted to `PUBLIC`.

If `GRANTED BY` is specified, the specified grantor must be the current user. This clause is currently present in this form only for SQL compatibility.

There is no need to grant privileges to the owner of an object (usually the user that created it), as the owner has all privileges by default. (The owner could, however, choose to revoke some of their own privileges for safety.)

The right to drop an object, or to alter its definition in any way, is not treated as a grantable privilege; it is inherent in the owner, and cannot be granted or revoked. (However, a similar effect can be obtained by granting or revoking membership in the role that owns the object; see below.) The owner implicitly has all grant options for the object, too.

The possible privileges are:

- `SELECT`
- `INSERT`
- `UPDATE`
- `DELETE`
- `TRUNCATE`
- `REFERENCES`
- `TRIGGER`
- `CREATE`
- `CONNECT`
- `TEMPORARY`
- `EXECUTE`
- `USAGE`
- `SET`
- `ALTER SYSTEM`

Specific types of privileges, as defined in Section 5.7.

- `TEMP`

Alternative spelling for `TEMPORARY`.

- `ALL PRIVILEGES`

Grant all of the privileges available for the object's type. The `PRIVILEGES` key word is optional in PostgreSQL, though it is required by strict SQL.
The `FUNCTION` syntax works for plain functions, aggregate functions, and window functions, but not for procedures; use `PROCEDURE` for those. Alternatively, use `ROUTINE` to refer to a function, aggregate function, window function, or procedure regardless of its precise type.

There is also an option to grant privileges on all objects of the same type within one or more schemas. This functionality is currently supported only for tables, sequences, functions, and procedures. `ALL TABLES` also affects views and foreign tables, just like the specific-object `GRANT` command. `ALL FUNCTIONS` also affects aggregate and window functions, but not procedures, again just like the specific-object `GRANT` command. Use `ALL ROUTINES` to include procedures.

**GRANT on Roles**

This variant of the `GRANT` command grants membership in a role to one or more other roles. Membership in a role is significant because it conveys the privileges granted to a role to each of its members.

If `WITH ADMIN OPTION` is specified, the member can in turn grant membership in the role to others, and revoke membership in the role as well. Without the admin option, ordinary users cannot do that. A role is not considered to hold `WITH ADMIN OPTION` on itself. Database superusers can grant or revoke membership in any role to anyone. Roles having `CREATEROLE` privilege can grant or revoke membership in any role that is not a superuser.

If `GRANTED BY` is specified, the grant is recorded as having been done by the specified role. Only database superusers may use this option, except when it names the same role executing the command.

Unlike the case with privileges, membership in a role cannot be granted to `PUBLIC`. Note also that this form of the command does not allow the noise word `GROUP` in `role_specification`.

**Notes**

The `REVOKE` command is used to revoke access privileges.

Since PostgreSQL 8.1, the concepts of users and groups have been unified into a single kind of entity called a role. It is therefore no longer necessary to use the keyword `GROUP` to identify whether a grantee is a user or a group. `GROUP` is still allowed in the command, but it is a noise word.

A user may perform `SELECT`, `INSERT`, etc. on a column if they hold that privilege for either the specific column or its whole table. Granting the privilege at the table level and then revoking it for one column will not do what one might wish: the table-level grant is unaffected by a column-level operation.

When a non-owner of an object attempts to `GRANT` privileges on the object, the command will fail outright if the user has no privileges whatsoever on the object. As long as some privilege is available, the command will proceed, but it will grant only those privileges for which the user has grant options. The `GRANT ALL PRIVILEGES` forms will issue a warning message if no grant options are held, while the other forms will issue a warning if grant options for any of the privileges specifically named in the command are not held. (In principle these statements apply to the object owner as well, but since the owner is always treated as holding all grant options, the cases can never occur.)

It should be noted that database superusers can access all objects regardless of object privilege settings. This is comparable to the rights of `root` in a Unix system. As with `root`, it's unwise to operate as a superuser except when absolutely necessary.

If a superuser chooses to issue a `GRANT` or `REVOKE` command, the command is performed as though it were issued by the owner of the affected object. In particular, privileges granted via such a command will appear to have been granted by the object owner. (For role membership, the membership appears to have been granted by the containing role itself.)
GRANT and REVOKE can also be done by a role that is not the owner of the affected object, but is a member of the role that owns the object, or is a member of a role that holds privileges WITH GRANT OPTION on the object. In this case the privileges will be recorded as having been granted by the role that actually owns the object or holds the privileges WITH GRANT OPTION. For example, if table t1 is owned by role g1, of which role u1 is a member, then u1 can grant privileges on t1 to u2, but those privileges will appear to have been granted directly by g1. Any other member of role g1 could revoke them later.

If the role executing GRANT holds the required privileges indirectly via more than one role membership path, it is unspecified which containing role will be recorded as having done the grant. In such cases it is best practice to use SET ROLE to become the specific role you want to do the GRANT as.

Granting permission on a table does not automatically extend permissions to any sequences used by the table, including sequences tied to SERIAL columns. Permissions on sequences must be set separately.

See Section 5.7 for more information about specific privilege types, as well as how to inspect objects' privileges.

**Examples**

Grant insert privilege to all users on table films:

```
GRANT INSERT ON films TO PUBLIC;
```

Grant all available privileges to user manuel on view kinds:

```
GRANT ALL PRIVILEGES ON kinds TO manuel;
```

Note that while the above will indeed grant all privileges if executed by a superuser or the owner of kinds, when executed by someone else it will only grant those permissions for which the someone else has grant options.

Grant membership in role admins to user joe:

```
GRANT admins TO joe;
```

**Compatibility**

According to the SQL standard, the PRIVILEGES key word in ALL PRIVILEGES is required. The SQL standard does not support setting the privileges on more than one object per command.

PostgreSQL allows an object owner to revoke their own ordinary privileges: for example, a table owner can make the table read-only to themselves by revoking their own INSERT, UPDATE, DELETE, and TRUNCATE privileges. This is not possible according to the SQL standard. The reason is that PostgreSQL treats the owner's privileges as having been granted by the owner to themselves; therefore they can revoke them too. In the SQL standard, the owner's privileges are granted by an assumed entity "_SYSTEM". Not being "_SYSTEM", the owner cannot revoke these rights.

According to the SQL standard, grant options can be granted to PUBLIC; PostgreSQL only supports granting grant options to roles.

The SQL standard allows the GRANTED BY option to specify only CURRENT_USER or CURRENT_ROLE. The other variants are PostgreSQL extensions.
The SQL standard provides for a USAGE privilege on other kinds of objects: character sets, collations, translations.

In the SQL standard, sequences only have a USAGE privilege, which controls the use of the NEXT VALUE FOR expression, which is equivalent to the function `nextval` in PostgreSQL. The sequence privileges SELECT and UPDATE are PostgreSQL extensions. The application of the sequence USAGE privilege to the `currval` function is also a PostgreSQL extension (as is the function itself).

Privileges on databases, tablespaces, schemas, languages, and configuration parameters are PostgreSQL extensions.

REVOKE, ALTER DEFAULT PRIVILEGES
IMPORT FOREIGN SCHEMA

IMPORT FOREIGN SCHEMA — import table definitions from a foreign server

Synopsis

IMPORT FOREIGN SCHEMA remote_schema
    [ { LIMIT TO | EXCEPT } ( table_name [, ...] ) ]
FROM SERVER server_name
    INTO local_schema
    [ OPTIONS ( option 'value' [, ... ] ) ]

Description

IMPORT FOREIGN SCHEMA creates foreign tables that represent tables existing on a foreign server. The new foreign tables will be owned by the user issuing the command and are created with the correct column definitions and options to match the remote tables.

By default, all tables and views existing in a particular schema on the foreign server are imported. Optionally, the list of tables can be limited to a specified subset, or specific tables can be excluded. The new foreign tables are all created in the target schema, which must already exist.

To use IMPORT FOREIGN SCHEMA, the user must have USAGE privilege on the foreign server, as well as CREATE privilege on the target schema.

Parameters

remote_schema

The remote schema to import from. The specific meaning of a remote schema depends on the foreign data wrapper in use.

LIMIT TO ( table_name [, ... ] )

Import only foreign tables matching one of the given table names. Other tables existing in the foreign schema will be ignored.

EXCEPT ( table_name [, ... ] )

Exclude specified foreign tables from the import. All tables existing in the foreign schema will be imported except the ones listed here.

server_name

The foreign server to import from.

local_schema

The schema in which the imported foreign tables will be created.

OPTIONS ( option 'value' [, ... ] )

Options to be used during the import. The allowed option names and values are specific to each foreign data wrapper.
Examples

Import table definitions from a remote schema foreign_films on server film_server, creating the foreign tables in local schema films:

```
IMPORT FOREIGN SCHEMA foreign_films
    FROM SERVER film_server INTO films;
```

As above, but import only the two tables actors and directors (if they exist):

```
IMPORT FOREIGN SCHEMA foreign_films LIMIT TO (actors, directors)
    FROM SERVER film_server INTO films;
```

Compatibility

The IMPORT FOREIGN SCHEMA command conforms to the SQL standard, except that the OPTIONS clause is a PostgreSQL extension.

CREATE FOREIGN TABLE, CREATE SERVER
INSERT

INSERT — create new rows in a table

Synopsis

[ WITH [ RECURSIVE ] with_query [, ...] ]
INSERT INTO table_name [ AS alias ] [ ( column_name [, ...] ) ]
[ OVERRIDING { SYSTEM | USER } VALUE ]
( DEFAULT VALUES | VALUES ( { expression | DEFAULT } [, ...] ) [, ...] )
[ ON CONFLICT [ conflict_target ] conflict_action ]
[ RETURNING * | output_expression [ [ AS ] output_name ] [, ...] ]

where conflict_target can be one of:

( { index_column_name | ( index_expression ) } [ COLLATE collation ] [ opclass ] [, ...] ) [ WHERE index_predicate ]
ON CONSTRAINT constraint_name

and conflict_action is one of:

DO NOTHING
DO UPDATE SET { column_name = { expression | DEFAULT } |
( column_name [, ...] ) = [ ROW ] ( { expression | DEFAULT } [, ...] ) |
( column_name [, ...] ) = ( sub-SELECT ) |
} [, ...]
[ WHERE condition ]

Description

INSERT inserts new rows into a table. One can insert one or more rows specified by value expressions, or zero or more rows resulting from a query.

The target column names can be listed in any order. If no list of column names is given at all, the default is all the columns of the table in their declared order; or the first \( N \) column names, if there are only \( N \) columns supplied by the VALUES clause or query. The values supplied by the VALUES clause or query are associated with the explicit or implicit column list left-to-right.

Each column not present in the explicit or implicit column list will be filled with a default value, either its declared default value or null if there is none.

If the expression for any column is not of the correct data type, automatic type conversion will be attempted.

ON CONFLICT can be used to specify an alternative action to raising a unique constraint or exclusion constraint violation error. (See ON CONFLICT Clause below.)

The optional RETURNING clause causes INSERT to compute and return value(s) based on each row actually inserted (or updated, if an ON CONFLICT DO UPDATE clause was used). This is primarily useful for obtaining values that were supplied by defaults, such as a serial sequence number. However,
any expression using the table’s columns is allowed. The syntax of the RETURNING list is identical to that of the output list of SELECT. Only rows that were successfully inserted or updated will be returned. For example, if a row was locked but not updated because an ON CONFLICT DO UPDATE ... WHERE clause condition was not satisfied, the row will not be returned.

You must have INSERT privilege on a table in order to insert into it. If ON CONFLICT DO UPDATE is present, UPDATE privilege on the table is also required.

If a column list is specified, you only need INSERT privilege on the listed columns. Similarly, when ON CONFLICT DO UPDATE is specified, you only need UPDATE privilege on the column(s) that are listed to be updated. However, ON CONFLICT DO UPDATE also requires SELECT privilege on any column whose values are read in the ON CONFLICT DO UPDATE expressions or condition.

Use of the RETURNING clause requires SELECT privilege on all columns mentioned in RETURNING. If you use the query clause to insert rows from a query, you of course need to have SELECT privilege on any table or column used in the query.

### Parameters

#### Inserting

This section covers parameters that may be used when only inserting new rows. Parameters exclusively used with the ON CONFLICT clause are described separately.

**with_query**

The WITH clause allows you to specify one or more subqueries that can be referenced by name in the INSERT query. See Section 7.8 and SELECT for details.

It is possible for the query (SELECT statement) to also contain a WITH clause. In such a case both sets of with_query can be referenced within the query, but the second one takes precedence since it is more closely nested.

**table_name**

The name (optionally schema-qualified) of an existing table.

**alias**

A substitute name for table_name. When an alias is provided, it completely hides the actual name of the table. This is particularly useful when ON CONFLICT DO UPDATE targets a table named excluded, since that will otherwise be taken as the name of the special table representing rows proposed for insertion.

**column_name**

The name of a column in the table named by table_name. The column name can be qualified with a subfield name or array subscript, if needed. (Inserting into only some fields of a composite column leaves the other fields null.) When referencing a column with ON CONFLICT DO UPDATE, do not include the table's name in the specification of a target column. For example, INSERT INTO table_name ... ON CONFLICT DO UPDATE SET table_name.col = 1 is invalid (this follows the general behavior for UPDATE).

**OVERRIDING SYSTEM VALUE**

If this clause is specified, then any values supplied for identity columns will override the default sequence-generated values.
For an identity column defined as `GENERATED ALWAYS`, it is an error to insert an explicit value
(other than `DEFAULT`) without specifying either `OVERRIDING SYSTEM VALUE` or `OVERRIDING
USER VALUE`. (For an identity column defined as `GENERATED BY DEFAULT`,
`OVERRIDING SYSTEM VALUE` is the normal behavior and specifying it does nothing, but PostgreSQL allows it
as an extension.)

**OVERRIDING USER VALUE**

If this clause is specified, then any values supplied for identity columns are ignored and the default
sequence-generated values are applied.

This clause is useful for example when copying values between tables. Writing `INSERT INTO tbl2
OVERRIDING USER VALUE SELECT * FROM tbl1` will copy from `tbl1` all columns that
are not identity columns in `tbl2` while values for the identity columns in `tbl2` will be generated
by the sequences associated with `tbl2`.

**DEFAULT VALUES**

All columns will be filled with their default values, as if `DEFAULT` were explicitly specified for each
column. (An `OVERRIDING` clause is not permitted in this form.)

**expression**

An expression or value to assign to the corresponding column.

**DEFAULT**

The corresponding column will be filled with its default value. An identity column will be filled with a
new value generated by the associated sequence. For a generated column, specifying this is permitted
but merely specifies the normal behavior of computing the column from its generation expression.

**query**

A query (SELECT statement) that supplies the rows to be inserted. Refer to the SELECT statement
for a description of the syntax.

**output_expression**

An expression to be computed and returned by the INSERT command after each row is inserted or
updated. The expression can use any column names of the table named by `table_name`. Write `*`
to return all columns of the inserted or updated row(s).

**output_name**

A name to use for a returned column.

**ON CONFLICT Clause**

The optional `ON CONFLICT` clause specifies an alternative action to raising a unique violation or ex-
clusion constraint violation error. For each individual row proposed for insertion, either the insertion pro-
cceeds, or, if an arbiter constraint or index specified by `conflict_target` is violated, the alternative
`conflict_action` is taken. `ON CONFLICT DO NOTHING` simply avoids inserting a row as its
alternative action. `ON CONFLICT DO UPDATE` updates the existing row that conflicts with the row
proposed for insertion as its alternative action.
conflict_target can perform unique index inference. When performing inference, it consists of one or more index_column_name columns and/or index_expression expressions, and an optional index_predicate. All table_name unique indexes that, without regard to order, contain exactly the conflict_target-specified columns/expressions are inferred (chosen) as arbiter indexes. If an index_predicate is specified, it must, as a further requirement for inference, satisfy arbiter indexes. Note that this means a non-partial unique index (a unique index without a predicate) will be inferred (and thus used by ON CONFLICT) if such an index satisfying every other criteria is available. If an attempt at inference is unsuccessful, an error is raised.

ON CONFLICT DO UPDATE guarantees an atomic INSERT or UPDATE outcome; provided there is no independent error, one of those two outcomes is guaranteed, even under high concurrency. This is also known as UPSERT — “UPDATE or INSERT”.

conflict_target

Specifies which conflicts ON CONFLICT takes the alternative action on by choosing arbiter indexes. Either performs unique index inference, or names a constraint explicitly. For ON CONFLICT DO NOTHING, it is optional to specify a conflict_target; when omitted, conflicts with all usable constraints (and unique indexes) are handled. For ON CONFLICT DO UPDATE, a conflict_target must be provided.

cconflict_action

conflict_action specifies an alternative ON CONFLICT action. It can be either DO NOTHING, or a DO UPDATE clause specifying the exact details of the UPDATE action to be performed in case of a conflict. The SET and WHERE clauses in ON CONFLICT DO UPDATE have access to the existing row using the table's name (or an alias), and to rows proposed for insertion using the special excluded table. SELECT privilege is required on any column in the target table where corresponding excluded columns are read.

Note that the effects of all per-row BEFORE INSERT triggers are reflected in excluded values, since those effects may have contributed to the row being excluded from insertion.

index_column_name

The name of a table_name column. Used to infer arbiter indexes. Follows CREATE INDEX format. SELECT privilege on index_column_name is required.

index_expression

Similar to index_column_name, but used to infer expressions on table_name columns appearing within index definitions (not simple columns). Follows CREATE INDEX format. SELECT privilege on any column appearing within index_expression is required.

collation

When specified, mandates that corresponding index_column_name or index_expression use a particular collation in order to be matched during inference. Typically this is omitted, as collations usually do not affect whether or not a constraint violation occurs. Follows CREATE INDEX format.

opclass

When specified, mandates that corresponding index_column_name or index_expression use particular operator class in order to be matched during inference. Typically this is omitted, as the equality semantics are often equivalent across a type's operator classes anyway, or because it's
sufficient to trust that the defined unique indexes have the pertinent definition of equality. Follows CREATE INDEX format.

**index_predicate**

Used to allow inference of partial unique indexes. Any indexes that satisfy the predicate (which need not actually be partial indexes) can be inferred. Follows CREATE INDEX format. SELECT privilege on any column appearing within index_predicate is required.

**constraint_name**

Explicitly specifies an arbiter constraint by name, rather than inferring a constraint or index.

**condition**

An expression that returns a value of type boolean. Only rows for which this expression returns true will be updated, although all rows will be locked when the ON CONFLICT DO UPDATE action is taken. Note that condition is evaluated last, after a conflict has been identified as a candidate to update.

Note that exclusion constraints are not supported as arbiters with ON CONFLICT DO UPDATE. In all cases, only NOT DEFERRABLE constraints and unique indexes are supported as arbiters.

**Tip**

It is often preferable to use unique index inference rather than naming a constraint directly using ON CONFLICT ON CONSTRAINT constraint_name. Inference will continue to work correctly when the underlying index is replaced by another more or less equivalent index in an overlapping way, for example when using CREATE UNIQUE INDEX ... CONCURRENTLY before dropping the index being replaced.

**Outputs**

On successful completion, an INSERT command returns a command tag of the form

```
INSERT oid count
```

The count is the number of rows inserted or updated. oid is always 0 (it used to be the OID assigned to the inserted row if count was exactly one and the target table was declared WITH OIDS and 0 otherwise, but creating a table WITH OIDS is not supported anymore).

If the INSERT command contains a RETURNING clause, the result will be similar to that of a SELECT statement containing the columns and values defined in the RETURNING list, computed over the row(s) inserted or updated by the command.
Notes

If the specified table is a partitioned table, each row is routed to the appropriate partition and inserted into it. If the specified table is a partition, an error will occur if one of the input rows violates the partition constraint.

You may also wish to consider using **MERGE**, since that allows mixing **INSERT**, **UPDATE**, and **DELETE** within a single statement. See MERGE.

Examples

Insert a single row into table **films**:

```
INSERT INTO films VALUES
('UA502', 'Bananas', 105, '1971-07-13', 'Comedy', '82 minutes');
```

In this example, the **len** column is omitted and therefore it will have the default value:

```
INSERT INTO films (code, title, did, date_prod, kind)
VALUES ('T_601', 'Yojimbo', 106, '1961-06-16', 'Drama');
```

This example uses the **DEFAULT** clause for the date columns rather than specifying a value:

```
INSERT INTO films VALUES
('UA502', 'Bananas', 105, DEFAULT, 'Comedy', '82 minutes');
```

```
INSERT INTO films (code, title, did, date_prod, kind)
VALUES ('T_601', 'Yojimbo', 106, DEFAULT, 'Drama');
```

To insert a row consisting entirely of default values:

```
INSERT INTO films DEFAULT VALUES;
```

To insert multiple rows using the multirow **VALUES** syntax:

```
INSERT INTO films (code, title, did, date_prod, kind) VALUES
('B6717', 'Tampopo', 110, '1985-02-10', 'Comedy'),
('HG120', 'The Dinner Game', 140, DEFAULT, 'Comedy');
```

This example inserts some rows into table **films** from a table **tmp_films** with the same column layout as **films**:

```
INSERT INTO films SELECT * FROM tmp_films WHERE date_prod < '2004-05-07';
```

This example inserts into array columns:

```
-- Create an empty 3x3 gameboard for noughts-and-crosses
INSERT INTO tictactoe (game, board[1:3][1:3])
```
VALUES (1, '({" "," "," "},{" "," "," "},{" "," "," "});  -- The subscripts in the above example aren't really needed
INSERT INTO ticctactoe (game, board)
VALUES (2, '({X," "," "},{" ",O," "},{" ",X," "});  

Insert a single row into table distributors, returning the sequence number generated by the DEFAULT clause:

INSERT INTO distributors (did, dname) VALUES (DEFAULT, 'XYZ Widgets')
RETURNING did;

Increment the sales count of the salesperson who manages the account for Acme Corporation, and record the whole updated row along with current time in a log table:

WITH upd AS (
UPDATE employees SET sales_count = sales_count + 1 WHERE id =
  (SELECT sales_person FROM accounts WHERE name = 'Acme Corporation')
  RETURNING *
)
INSERT INTO employees_log SELECT *, current_timestamp FROM upd;

Insert or update new distributors as appropriate. Assumes a unique index has been defined that constrains values appearing in the did column. Note that the special excluded table is used to reference values originally proposed for insertion:

INSERT INTO distributors (did, dname)
VALUES (5, 'Gizmo Transglobal'), (6, 'Associated Computing, Inc')
ON CONFLICT (did) DO UPDATE SET dname = EXCLUDED.dname;

Insert a distributor, or do nothing for rows proposed for insertion when an existing, excluded row (a row with a matching constrained column or columns after before row insert triggers fire) exists. Example assumes a unique index has been defined that constrains values appearing in the did column:

INSERT INTO distributors (did, dname) VALUES (7, 'Redline GmbH')
ON CONFLICT (did) DO NOTHING;

Insert or update new distributors as appropriate. Example assumes a unique index has been defined that constrains values appearing in the did column. WHERE clause is used to limit the rows actually updated (any existing row not updated will still be locked, though):

-- Don't update existing distributors based in a certain ZIP code
INSERT INTO distributors AS d (did, dname) VALUES (8, 'Anvil Distribution')
ON CONFLICT (did) DO UPDATE
SET dname = EXCLUDED.dname || ' (formerly ' || d.dname || ')'
WHERE d.zipcode <> '21201';

-- Name a constraint directly in the statement (uses associated
-- index to arbitrate taking the DO NOTHING action)
INSERT INTO distributors (did, dname) VALUES (9, 'Antwerp Design')

ON CONFLICT ON CONSTRAINT distributors_pkey DO NOTHING;

Insert new distributor if possible; otherwise DO NOTHING. Example assumes a unique index has been defined that constrains values appearing in the did column on a subset of rows where the is_active Boolean column evaluates to true:

```
-- This statement could infer a partial unique index on "did"
-- with a predicate of "WHERE is_active", but it could also
-- just use a regular unique constraint on "did"
INSERT INTO distributors (did, dname) VALUES (10, 'Conrad
International')
  ON CONFLICT (did) WHERE is_active DO NOTHING;
```

Compatibility

INSERT conforms to the SQL standard, except that the RETURNING clause is a PostgreSQL extension, as is the ability to use WITH with INSERT, and the ability to specify an alternative action with ON CONFLICT. Also, the case in which a column name list is omitted, but not all the columns are filled from the VALUES clause or query, is disallowed by the standard. If you prefer a more SQL standard conforming statement than ON CONFLICT, see MERGE.

The SQL standard specifies that OVERRIDING SYSTEM VALUE can only be specified if an identity column that is generated always exists. PostgreSQL allows the clause in any case and ignores it if it is not applicable.

Possible limitations of the query clause are documented under SELECT.
LISTEN

LISTEN — listen for a notification

Synopsis

LISTEN channel

Description

LISTEN registers the current session as a listener on the notification channel named channel. If the current session is already registered as a listener for this notification channel, nothing is done.

Whenever the command NOTIFY channel is invoked, either by this session or another one connected to the same database, all the sessions currently listening on that notification channel are notified, and each will in turn notify its connected client application.

A session can be unregistered for a given notification channel with the UNLISTEN command. A session's listen registrations are automatically cleared when the session ends.

The method a client application must use to detect notification events depends on which PostgreSQL application programming interface it uses. With the libpq library, the application issues LISTEN as an ordinary SQL command, and then must periodically call the function PQnotifies to find out whether any notification events have been received. Other interfaces such as libpgtcl provide higher-level methods for handling notify events; indeed, with libpgtcl the application programmer should not even issue LISTEN or UNLISTEN directly. See the documentation for the interface you are using for more details.

Parameters

channel

Name of a notification channel (any identifier).

Notes

LISTEN takes effect at transaction commit. If LISTEN or UNLISTEN is executed within a transaction that later rolls back, the set of notification channels being listened to is unchanged.

A transaction that has executed LISTEN cannot be prepared for two-phase commit.

There is a race condition when first setting up a listening session: if concurrently-committing transactions are sending notify events, exactly which of those will the newly listening session receive? The answer is that the session will receive all events committed after an instant during the transaction's commit step. But that is slightly later than any database state that the transaction could have observed in queries. This leads to the following rule for using LISTEN: first execute (and commit!) that command, then in a new transaction inspect the database state as needed by the application logic, then rely on notifications to find out about subsequent changes to the database state. The first few received notifications might refer to updates already observed in the initial database inspection, but this is usually harmless.

NOTIFY contains a more extensive discussion of the use of LISTEN and NOTIFY.
Examples

Configure and execute a listen/notify sequence from psql:

LISTEN virtual;
NOTIFY virtual;
Asynchronous notification "virtual" received from server process with
PID 8448.

Compatibility

There is no LISTEN statement in the SQL standard.

NOTIFY, UNLISTEN
LOAD

LOAD — load a shared library file

Synopsis

LOAD 'filename'

Description

This command loads a shared library file into the PostgreSQL server's address space. If the file has been loaded already, the command does nothing. Shared library files that contain C functions are automatically loaded whenever one of their functions is called. Therefore, an explicit LOAD is usually only needed to load a library that modifies the server's behavior through "hooks" rather than providing a set of functions.

The library file name is typically given as just a bare file name, which is sought in the server's library search path (set by dynamic_library_path). Alternatively it can be given as a full path name. In either case the platform's standard shared library file name extension may be omitted. See Section 38.10.1 for more information on this topic.

Non-superusers can only apply LOAD to library files located in $libdir/plugins/ — the specified filename must begin with exactly that string. (It is the database administrator's responsibility to ensure that only "safe" libraries are installed there.)

Compatibility

LOAD is a PostgreSQL extension.

CREATE FUNCTION
LOCK

LOCK — lock a table

Synopsis

```
LOCK [ TABLE ] [ ONLY ] name [ * ] [, ...] [ IN lockmode MODE ]
[ NOWAIT ]
```

where lockmode is one of:

- ACCESS SHARE
- ROW SHARE
- ROW EXCLUSIVE
- SHARE UPDATE EXCLUSIVE
- SHARE
- SHARE ROW EXCLUSIVE
- EXCLUSIVE
- ACCESS EXCLUSIVE

Description

LOCK TABLE obtains a table-level lock, waiting if necessary for any conflicting locks to be released. If NOWAIT is specified, LOCK TABLE does not wait to acquire the desired lock: if it cannot be acquired immediately, the command is aborted and an error is emitted. Once obtained, the lock is held for the remainder of the current transaction. (There is no UNLOCK TABLE command; locks are always released at transaction end.)

When a view is locked, all relations appearing in the view definition query are also locked recursively with the same lock mode.

When acquiring locks automatically for commands that reference tables, PostgreSQL always uses the least restrictive lock mode possible. LOCK TABLE provides for cases when you might need more restrictive locking. For example, suppose an application runs a transaction at the READ COMMITTED isolation level and needs to ensure that data in a table remains stable for the duration of the transaction. To achieve this you could obtain SHARE lock mode over the table before querying. This will prevent concurrent data changes and ensure subsequent reads of the table see a stable view of committed data, because SHARE lock mode conflicts with the ROW EXCLUSIVE lock acquired by writers, and your LOCK TABLE name IN SHARE MODE statement will wait until any concurrent holders of ROW EXCLUSIVE mode locks commit or roll back. Thus, once you obtain the lock, there are no uncommitted writes outstanding; furthermore none can begin until you release the lock.

To achieve a similar effect when running a transaction at the REPEATABLE READ or SERIALIZABLE isolation level, you have to execute the LOCK TABLE statement before executing any SELECT or data modification statement. A REPEATABLE READ or SERIALIZABLE transaction's view of data will be frozen when its first SELECT or data modification statement begins. A LOCK TABLE later in the transaction will still prevent concurrent writes — but it won't ensure that what the transaction reads corresponds to the latest committed values.

If a transaction of this sort is going to change the data in the table, then it should use SHARE ROW EXCLUSIVE lock mode instead of SHARE mode. This ensures that only one transaction of this type runs at a time. Without this, a deadlock is possible: two transactions might both acquire SHARE mode, and then be unable to also acquire ROW EXCLUSIVE mode to actually perform their updates. (Note that a transaction's own locks never conflict, so a transaction can acquire ROW EXCLUSIVE mode when it holds SHARE mode — but not if anyone else holds SHARE mode.) To avoid deadlocks, make sure all transactions acquire locks on the same objects in the same order, and if multiple lock modes are involved for a single object, then transactions should always acquire the most restrictive mode first.
More information about the lock modes and locking strategies can be found in Section 13.3.

Parameters

\textit{name}

The name (optionally schema-qualified) of an existing table to lock. If \texttt{ONLY} is specified before the table name, only that table is locked. If \texttt{ONLY} is not specified, the table and all its descendant tables (if any) are locked. Optionally, \texttt{*} can be specified after the table name to explicitly indicate that descendant tables are included.

The command \texttt{LOCK TABLE a, b;} is equivalent to \texttt{LOCK TABLE a;} \texttt{LOCK TABLE b;} The tables are locked one-by-one in the order specified in the \texttt{LOCK TABLE} command.

\textit{lockmode}

The lock mode specifies which locks this lock conflicts with. Lock modes are described in Section 13.3.

If no lock mode is specified, then \texttt{ACCESS EXCLUSIVE}, the most restrictive mode, is used.

\texttt{NOWAIT}

Specifies that \texttt{LOCK TABLE} should not wait for any conflicting locks to be released: if the specified lock(s) cannot be acquired immediately without waiting, the transaction is aborted.

Notes

\texttt{LOCK TABLE ... IN ACCESS SHARE MODE} requires \texttt{SELECT} privileges on the target table.
\texttt{LOCK TABLE ... IN ROW EXCLUSIVE MODE} requires \texttt{INSERT}, \texttt{UPDATE}, \texttt{DELETE}, or \texttt{TRUNCATE} privileges on the target table. All other forms of \texttt{LOCK} require table-level \texttt{UPDATE}, \texttt{DELETE}, or \texttt{TRUNCATE} privileges.

The user performing the lock on the view must have the corresponding privilege on the view. In addition, by default, the view's owner must have the relevant privileges on the underlying base relations, whereas the user performing the lock does not need any permissions on the underlying base relations. However, if the view has \texttt{security_invoker} set to \texttt{true} (see \texttt{CREATE VIEW}), the user performing the lock, rather than the view owner, must have the relevant privileges on the underlying base relations.

\texttt{LOCK TABLE} is useless outside a transaction block: the lock would remain held only to the completion of the statement. Therefore PostgreSQL reports an error if \texttt{LOCK} is used outside a transaction block. Use \texttt{BEGIN} and \texttt{COMMIT} (or \texttt{ROLLBACK}) to define a transaction block.

\texttt{LOCK TABLE} only deals with table-level locks, and so the mode names involving \texttt{ROW} are all misnomers. These mode names should generally be read as indicating the intention of the user to acquire row-level locks within the locked table. Also, \texttt{ROW EXCLUSIVE} mode is a shareable table lock. Keep in mind that all the lock modes have identical semantics so far as \texttt{LOCK TABLE} is concerned, differing only in the rules about which modes conflict with which. For information on how to acquire an actual row-level lock, see Section 13.3.2 and The Locking Clause in the \texttt{SELECT} documentation.

Examples

Obtain a \texttt{SHARE} lock on a primary key table when going to perform inserts into a foreign key table:
BEGIN WORK;
LOCK TABLE films IN SHARE MODE;
SELECT id FROM films
  WHERE name = 'Star Wars: Episode I - The Phantom Menace';
-- Do ROLLBACK if record was not returned
INSERT INTO films_user_comments VALUES
  (_id_, 'GREAT! I was waiting for it for so long!');
COMMIT WORK;

Take a SHARE ROW EXCLUSIVE lock on a primary key table when going to perform a delete operation:

BEGIN WORK;
LOCK TABLE films IN SHARE ROW EXCLUSIVE MODE;
DELETE FROM films_user_comments WHERE id IN
  (SELECT id FROM films WHERE rating < 5);
DELETE FROM films WHERE rating < 5;
COMMIT WORK;

Compatibility

There is no LOCK TABLE in the SQL standard, which instead uses SET TRANSACTION to specify concurrency levels on transactions. PostgreSQL supports that too; see SET TRANSACTION for details.

Except for ACCESS SHARE, ACCESS EXCLUSIVE, and SHARE UPDATE EXCLUSIVE lock modes, the PostgreSQL lock modes and the LOCK TABLE syntax are compatible with those present in Oracle.
**MERGE**

MERGE — conditionally insert, update, or delete rows of a table

**Synopsis**

```
[ WITH with_query [, ...] ]
MERGE INTO target_table_name [ [ AS ] target_alias ]
USING data_source ON join_condition
  when_clause [...]

where data_source is:

{ source_table_name | ( source_query ) } [ [ AS ] source_alias ]

and when_clause is:

{ WHEN MATCHED [ AND condition ] THEN { merge_update | merge_delete | DO NOTHING } |
  WHEN NOT MATCHED [ AND condition ] THEN { merge_insert | DO NOTHING } }

and merge_insert is:

INSERT [ { column_name [, ...] } ]
[ OVERRIDING { SYSTEM | USER } VALUE ]
{ VALUES ( { expression | DEFAULT } [, ...] ) | DEFAULT VALUES }

and merge_update is:

UPDATE SET { column_name = { expression | DEFAULT } |
  ( column_name [, ...] ) = ( { expression | DEFAULT } 
  [, ...] ) ] [, ...]

and merge_delete is:

DELETE
```

**Description**

MERGE performs actions that modify rows in the `target_table_name`, using the `data_source`. MERGE provides a single SQL statement that can conditionally INSERT, UPDATE or DELETE rows, a task that would otherwise require multiple procedural language statements.

First, the MERGE command performs a join from `data_source` to `target_table_name` producing zero or more candidate change rows. For each candidate change row, the status of MATCHED or NOT MATCHED is set just once, after which WHEN clauses are evaluated in the order specified. For each candidate change row, the first clause to evaluate as true is executed. No more than one WHEN clause is executed for any candidate change row.

MERGE actions have the same effect as regular UPDATE, INSERT, or DELETE commands of the same names. The syntax of those commands is different, notably that there is no WHERE clause and no matching
name is specified. All actions refer to the `target_table_name`, though modifications to other tables may be made using triggers.

When `DO NOTHING` is specified, the source row is skipped. Since actions are evaluated in their specified order, `DO NOTHING` can be handy to skip non-interesting source rows before more fine-grained handling.

There is no separate `MERGE` privilege. If you specify an update action, you must have the `UPDATE` privilege on the column(s) of the `target_table_name` that are referred to in the `SET` clause. If you specify an insert action, you must have the `INSERT` privilege on the `target_table_name`. If you specify a delete action, you must have the `DELETE` privilege on the `target_table_name`. Privileges are tested once at statement start and are checked whether or not particular `WHEN` clauses are executed. You will require the `SELECT` privilege on the `data_source` and any column(s) of the `target_table_name` referred to in a condition.

`MERGE` is not supported if the `target_table_name` is a materialized view, foreign table, or if it has any rules defined on it.

**Parameters**

`target_table_name`

The name (optionally schema-qualified) of the target table to merge into.

`target_alias`

A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given `MERGE INTO foo AS f`, the remainder of the `MERGE` statement must refer to this table as `f` not `foo`.

`source_table_name`

The name (optionally schema-qualified) of the source table, view, or transition table.

`source_query`

A query (SELECT statement or VALUES statement) that supplies the rows to be merged into the `target_table_name`. Refer to the SELECT statement or VALUES statement for a description of the syntax.

`source_alias`

A substitute name for the data source. When an alias is provided, it completely hides the actual name of the table or the fact that a query was issued.

`join_condition`

`join_condition` is an expression resulting in a value of type boolean (similar to a `WHERE` clause) that specifies which rows in the `data_source` match rows in the `target_table_name`.

**Warning**

Only columns from `target_table_name` that attempt to match `data_source` rows should appear in `join_condition`. `join_condition` subexpressions that only refer-
ence \textit{target_table_name} columns can affect which action is taken, often in surprising ways.

\textbf{when\_clause}

At least one \texttt{WHEN} clause is required.

If the \texttt{WHEN} clause specifies \texttt{WHEN MATCHED} and the candidate change row matches a row in the \textit{target_table_name}, the \texttt{WHEN} clause is executed if the \texttt{condition} is absent or it evaluates to \texttt{true}.

Conversely, if the \texttt{WHEN} clause specifies \texttt{WHEN NOT MATCHED} and the candidate change row does not match a row in the \textit{target_table_name}, the \texttt{WHEN} clause is executed if the \texttt{condition} is absent or it evaluates to \texttt{true}.

\textbf{condition}

An expression that returns a value of type \texttt{boolean}. If this expression for a \texttt{WHEN} clause returns \texttt{true}, then the action for that clause is executed for that row.

A condition on a \texttt{WHEN MATCHED} clause can refer to columns in both the source and the target relations. A condition on a \texttt{WHEN NOT MATCHED} clause can only refer to columns from the source relation, since by definition there is no matching target row. Only the system attributes from the target table are accessible.

\textbf{merge\_insert}

The specification of an \texttt{INSERT} action that inserts one row into the target table. The target column names can be listed in any order. If no list of column names is given at all, the default is all the columns of the table in their declared order.

Each column not present in the explicit or implicit column list will be filled with a default value, either its declared default value or null if there is none.

If the expression for any column is not of the correct data type, automatic type conversion will be attempted.

If \texttt{target_table_name} is a partitioned table, each row is routed to the appropriate partition and inserted into it. If \texttt{target_table_name} is a partition, an error will occur if any input row violates the partition constraint.

Column names may not be specified more than once. \texttt{INSERT} actions cannot contain sub-selects.

Only one \texttt{VALUES} clause can be specified. The \texttt{VALUES} clause can only refer to columns from the source relation, since by definition there is no matching target row.

\textbf{merge\_update}

The specification of an \texttt{UPDATE} action that updates the current row of the \texttt{target_table_name}. Column names may not be specified more than once.

Neither a table name nor a \texttt{WHERE} clause are allowed.

\textbf{merge\_delete}

Specifies a \texttt{DELETE} action that deletes the current row of the \texttt{target_table_name}. Do not include the table name or any other clauses, as you would normally do with a \texttt{DELETE} command.

\texttt{2005}
column_name

The name of a column in the target_table_name. The column name can be qualified with a subfield name or array subscript, if needed. (Inserting into only some fields of a composite column leaves the other fields null.) Do not include the table’s name in the specification of a target column.

OVERRIDING SYSTEM VALUE

Without this clause, it is an error to specify an explicit value (other than DEFAULT) for an identity column defined as GENERATED ALWAYS. This clause overrides that restriction.

OVERRIDING USER VALUE

If this clause is specified, then any values supplied for identity columns defined as GENERATED BY DEFAULT are ignored and the default sequence-generated values are applied.

DEFAULT VALUES

All columns will be filled with their default values. (An OVERRIDING clause is not permitted in this form.)

expression

An expression to assign to the column. If used in a WHEN MATCHED clause, the expression can use values from the original row in the target table, and values from the data_source row. If used in a WHEN NOT MATCHED clause, the expression can use values from the data_source.

DEFAULT

Set the column to its default value (which will be NULL if no specific default expression has been assigned to it).

with_query

The WITH clause allows you to specify one or more subqueries that can be referenced by name in the MERGE query. See Section 7.8 and SELECT for details.

Outputs

On successful completion, a MERGE command returns a command tag of the form

MERGE total_count

The total_count is the total number of rows changed (whether inserted, updated, or deleted). If total_count is 0, no rows were changed in any way.

Notes

The following steps take place during the execution of MERGE.

1. Perform any BEFORE STATEMENT triggers for all actions specified, whether or not their WHEN clauses match.

2. Perform a join from source to target table. The resulting query will be optimized normally and will produce a set of candidate change rows. For each candidate change row,
a. Evaluate whether each row is MATCHED or NOT MATCHED.

b. Test each WHEN condition in the order specified until one returns true.

c. When a condition returns true, perform the following actions:
   i. Perform any BEFORE ROW triggers that fire for the action's event type.
   ii. Perform the specified action, invoking any check constraints on the target table.
   iii. Perform any AFTER ROW triggers that fire for the action's event type.

3. Perform any AFTER STATEMENT triggers for actions specified, whether or not they actually occur. This is similar to the behavior of an UPDATE statement that modifies no rows.

In summary, statement triggers for an event type (say, INSERT) will be fired whenever we specify an action of that kind. In contrast, row-level triggers will fire only for the specific event type being executed. So a MERGE command might fire statement triggers for both UPDATE and INSERT, even though only UPDATE row triggers were fired.

You should ensure that the join produces at most one candidate change row for each target row. In other words, a target row shouldn't join to more than one data source row. If it does, then only one of the candidate change rows will be used to modify the target row; later attempts to modify the row will cause an error. This can also occur if row triggers make changes to the target table and the rows so modified are then subsequently also modified by MERGE. If the repeated action is an INSERT, this will cause a uniqueness violation, while a repeated UPDATE or DELETE will cause a cardinality violation; the latter behavior is required by the SQL standard. This differs from historical PostgreSQL behavior of joins in UPDATE and DELETE statements where second and subsequent attempts to modify the same row are simply ignored.

If a WHEN clause omits an AND sub-clause, it becomes the final reachable clause of that kind (MATCHED or NOT MATCHED). If a later WHEN clause of that kind is specified it would be provably unreachable and an error is raised. If no final reachable clause is specified of either kind, it is possible that no action will be taken for a candidate change row.

The order in which rows are generated from the data source is indeterminate by default. A source_query can be used to specify a consistent ordering, if required, which might be needed to avoid deadlocks between concurrent transactions.

There is no RETURNING clause with MERGE. Actions of INSERT, UPDATE and DELETE cannot contain RETURNING or WITH clauses.

When MERGE is run concurrently with other commands that modify the target table, the usual transaction isolation rules apply; see Section 13.2 for an explanation on the behavior at each isolation level. You may also wish to consider using INSERT ... ON CONFLICT as an alternative statement which offers the ability to run an UPDATE if a concurrent INSERT occurs. There are a variety of differences and restrictions between the two statement types and they are not interchangeable.

Examples

Perform maintenance on CustomerAccounts based upon new Transactions.

MERGE INTO CustomerAccount CA
USING RecentTransactions T
ON T.CustomerId = CA.CustomerId
WHEN MATCHED THEN
  UPDATE SET Balance = Balance + TransactionValue
WHEN NOT MATCHED THEN
  INSERT (CustomerId, Balance)
  VALUES (T.CustomerId, T.TransactionValue);

Notice that this would be exactly equivalent to the following statement because the MATCHED result does not change during execution.

MERGE INTO CustomerAccount CA
USING (Select CustomerId, TransactionValue From RecentTransactions) AS T
  ON CA.CustomerId = T.CustomerId
WHEN NOT MATCHED THEN
  INSERT (CustomerId, Balance)
  VALUES (T.CustomerId, T.TransactionValue)
WHEN MATCHED THEN
  UPDATE SET Balance = Balance + TransactionValue;

Attempt to insert a new stock item along with the quantity of stock. If the item already exists, instead update the stock count of the existing item. Don't allow entries that have zero stock.

MERGE INTO wines w
USING wine_stock_changes s
  ON s.winename = w.winename
  WHEN NOT MATCHED AND s.stock_delta > 0 THEN
    INSERT VALUES(s.winename, s.stock_delta)
  WHEN MATCHED AND w.stock + s.stock_delta > 0 THEN
    UPDATE SET stock = w.stock + s.stock_delta
  WHEN MATCHED THEN
    DELETE;

The wine_stock_changes table might be, for example, a temporary table recently loaded into the database.

Compatibility

This command conforms to the SQL standard.

The WITH clause and DO NOTHING action are extensions to the SQL standard.
MOVE

MOVE — position a cursor

Synopsis

MOVE [ direction [ FROM | IN ] ] cursor_name

where direction can be empty or one of:

NEXT
PRIOR
FIRST
LAST
ABSOLUTE count
RELATIVE count
count
ALL
FORWARD
FORWARD count
FORWARD ALL
BACKWARD
BACKWARD count
BACKWARD ALL

Description

MOVE repositions a cursor without retrieving any data. MOVE works exactly like the FETCH command, except it only positions the cursor and does not return rows.

The parameters for the MOVE command are identical to those of the FETCH command; refer to FETCH for details on syntax and usage.

Outputs

On successful completion, a MOVE command returns a command tag of the form

MOVE count

The count is the number of rows that a FETCH command with the same parameters would have returned (possibly zero).

Examples

BEGIN WORK;
DECLARE liahona CURSOR FOR SELECT * FROM films;

-- Skip the first 5 rows:
MOVE FORWARD 5 IN liahona;
MOVE 5

-- Fetch the 6th row from the cursor liahona:
FETCH 1 FROM liahona;

<table>
<thead>
<tr>
<th>code</th>
<th>title</th>
<th>did</th>
<th>date_prod</th>
<th>kind</th>
<th>len</th>
</tr>
</thead>
<tbody>
<tr>
<td>P_303</td>
<td>48 Hrs</td>
<td>103</td>
<td>1982-10-22</td>
<td>Action</td>
<td>01:37</td>
</tr>
</tbody>
</table>

(1 row)

-- Close the cursor liahona and end the transaction:
CLOSE liahona;
COMMIT WORK;

Compatibility

There is no MOVE statement in the SQL standard.

CLOSE, DECLARE, FETCH
NOTIFY

NOTIFY — generate a notification

Synopsis

NOTIFY channel [ , payload ]

Description

The NOTIFY command sends a notification event together with an optional “payload” string to each client application that has previously executed LISTEN channel for the specified channel name in the current database. Notifications are visible to all users.

NOTIFY provides a simple interprocess communication mechanism for a collection of processes accessing the same PostgreSQL database. A payload string can be sent along with the notification, and higher-level mechanisms for passing structured data can be built by using tables in the database to pass additional data from notifier to listener(s).

The information passed to the client for a notification event includes the notification channel name, the notifying session's server process PID, and the payload string, which is an empty string if it has not been specified.

It is up to the database designer to define the channel names that will be used in a given database and what each one means. Commonly, the channel name is the same as the name of some table in the database, and the notify event essentially means, “I changed this table, take a look at it to see what's new”. But no such association is enforced by the NOTIFY and LISTEN commands. For example, a database designer could use several different channel names to signal different sorts of changes to a single table. Alternatively, the payload string could be used to differentiate various cases.

When NOTIFY is used to signal the occurrence of changes to a particular table, a useful programming technique is to put the NOTIFY in a statement trigger that is triggered by table updates. In this way, notification happens automatically when the table is changed, and the application programmer cannot accidentally forget to do it.

NOTIFY interacts with SQL transactions in some important ways. Firstly, if a NOTIFY is executed inside a transaction, the notify events are not delivered until and unless the transaction is committed. This is appropriate, since if the transaction is aborted, all the commands within it have had no effect, including NOTIFY. But it can be disconcerting if one is expecting the notification events to be delivered immediately. Secondly, if a listening session receives a notification signal while it is within a transaction, the notification event will not be delivered to its connected client until just after the transaction is completed (either committed or aborted). Again, the reasoning is that if a notification were delivered within a transaction that was later aborted, one would want the notification to be undone somehow — but the server cannot “take back” a notification once it has sent it to the client. So notification events are only delivered between transactions. The upshot of this is that applications using NOTIFY for real-time signaling should try to keep their transactions short.

If the same channel name is signaled multiple times with identical payload strings within the same transaction, only one instance of the notification event is delivered to listeners. On the other hand, notifications with distinct payload strings will always be delivered as distinct notifications. Similarly, notifications from different transactions will never get folded into one notification. Except for dropping later instances of
duplicate notifications, NOTIFY guarantees that notifications from the same transaction get delivered in
the order they were sent. It is also guaranteed that messages from different transactions are delivered in
the order in which the transactions committed.

It is common for a client that executes NOTIFY to be listening on the same notification channel itself.
In that case it will get back a notification event, just like all the other listening sessions. Depending on
the application logic, this could result in useless work, for example, reading a database table to find the
same updates that that session just wrote out. It is possible to avoid such extra work by noticing whether
the notifying session's server process PID (supplied in the notification event message) is the same as one's
own session's PID (available from libpq). When they are the same, the notification event is one's own work
bouncing back, and can be ignored.

Parameters

channel

Name of the notification channel to be signaled (any identifier).

payload

The “payload” string to be communicated along with the notification. This must be specified as a
simple string literal. In the default configuration it must be shorter than 8000 bytes. (If binary data
or large amounts of information need to be communicated, it's best to put it in a database table and
send the key of the record.)

Notes

There is a queue that holds notifications that have been sent but not yet processed by all listening sessions.
If this queue becomes full, transactions calling NOTIFY will fail at commit. The queue is quite large (8GB
in a standard installation) and should be sufficiently sized for almost every use case. However, no cleanup
can take place if a session executes LISTEN and then enters a transaction for a very long time. Once the
queue is half full you will see warnings in the log file pointing you to the session that is preventing cleanup.
In this case you should make sure that this session ends its current transaction so that cleanup can proceed.

The function pg_notification_queue_usage returns the fraction of the queue that is currently
occupied by pending notifications. See Section 9.26 for more information.

A transaction that has executed NOTIFY cannot be prepared for two-phase commit.

pg_notify

To send a notification you can also use the function pg_notify(text, text). The function takes
the channel name as the first argument and the payload as the second. The function is much easier to use
than the NOTIFY command if you need to work with non-constant channel names and payloads.

Examples

Configure and execute a listen/notify sequence from psql:

LISTEN virtual;
NOTIFY virtual;
Asynchronous notification "virtual" received from server process with
PID 8448.
NOTIFY virtual, 'This is the payload';
Asynchronous notification "virtual" with payload "This is the payload"
received from server process with PID 8448.

LISTEN foo;
SELECT pg_notify('fo' || 'o', 'pay' || 'load');
Asynchronous notification "foo" with payload "payload" received from
server process with PID 14728.

Compatibility

There is no NOTIFY statement in the SQL standard.

LISTEN, UNLISTEN
**PREPARE**

PREPARE — prepare a statement for execution

**Synopsis**

```
PREPARE name [ ( data_type [, ...] ) ] AS statement
```

**Description**

PREPARE creates a prepared statement. A prepared statement is a server-side object that can be used to optimize performance. When the PREPARE statement is executed, the specified statement is parsed, analyzed, and rewritten. When an EXECUTE command is subsequently issued, the prepared statement is planned and executed. This division of labor avoids repetitive parse analysis work, while allowing the execution plan to depend on the specific parameter values supplied.

Prepared statements can take parameters: values that are substituted into the statement when it is executed. When creating the prepared statement, refer to parameters by position, using $1, $2, etc. A corresponding list of parameter data types can optionally be specified. When a parameter’s data type is not specified or is declared as unknown, the type is inferred from the context in which the parameter is first referenced (if possible). When executing the statement, specify the actual values for these parameters in the EXECUTE statement. Refer to EXECUTE for more information about that.

Prepared statements only last for the duration of the current database session. When the session ends, the prepared statement is forgotten, so it must be recreated before being used again. This also means that a single prepared statement cannot be used by multiple simultaneous database clients; however, each client can create their own prepared statement to use. Prepared statements can be manually cleaned up using the DEALLOCATE command.

Prepared statements potentially have the largest performance advantage when a single session is being used to execute a large number of similar statements. The performance difference will be particularly significant if the statements are complex to plan or rewrite, e.g., if the query involves a join of many tables or requires the application of several rules. If the statement is relatively simple to plan and rewrite but relatively expensive to execute, the performance advantage of prepared statements will be less noticeable.

**Parameters**

- **name**
  
  An arbitrary name given to this particular prepared statement. It must be unique within a single session and is subsequently used to execute or deallocate a previously prepared statement.

- **data_type**
  
  The data type of a parameter to the prepared statement. If the data type of a particular parameter is unspecified or is specified as unknown, it will be inferred from the context in which the parameter is first referenced. To refer to the parameters in the prepared statement itself, use $1, $2, etc.

- **statement**
  
  Any SELECT, INSERT, UPDATE, DELETE, or VALUES statement.
Notes

A prepared statement can be executed with either a generic plan or a custom plan. A generic plan is the same across all executions, while a custom plan is generated for a specific execution using the parameter values given in that call. Use of a generic plan avoids planning overhead, but in some situations a custom plan will be much more efficient to execute because the planner can make use of knowledge of the parameter values. (Of course, if the prepared statement has no parameters, then this is moot and a generic plan is always used.)

By default (that is, when plan_cache_mode is set to auto), the server will automatically choose whether to use a generic or custom plan for a prepared statement that has parameters. The current rule for this is that the first five executions are done with custom plans and the average estimated cost of those plans is calculated. Then a generic plan is created and its estimated cost is compared to the average custom-plan cost. Subsequent executions use the generic plan if its cost is not so much higher than the average custom-plan cost as to make repeated replanning seem preferable.

This heuristic can be overridden, forcing the server to use either generic or custom plans, by setting plan_cache_mode to force_generic_plan or force_custom_plan respectively. This setting is primarily useful if the generic plan's cost estimate is badly off for some reason, allowing it to be chosen even though its actual cost is much more than that of a custom plan.

To examine the query plan PostgreSQL is using for a prepared statement, use EXPLAIN, for example

```
EXPLAIN EXECUTE name(parameter_values);
```

If a generic plan is in use, it will contain parameter symbols $n, while a custom plan will have the supplied parameter values substituted into it.

For more information on query planning and the statistics collected by PostgreSQL for that purpose, see the ANALYZE documentation.

Although the main point of a prepared statement is to avoid repeated parse analysis and planning of the statement, PostgreSQL will force re-analysis and re-planning of the statement before using it whenever database objects used in the statement have undergone definitional (DDL) changes or their planner statistics have been updated since the previous use of the prepared statement. Also, if the value of search_path changes from one use to the next, the statement will be re-parsed using the new search_path. (This latter behavior is new as of PostgreSQL 9.3.) These rules make use of a prepared statement semantically almost equivalent to re-submitting the same query text over and over, but with a performance benefit if no object definitions are changed, especially if the best plan remains the same across uses. An example of a case where the semantic equivalence is not perfect is that if the statement refers to a table by an unqualified name, and then a new table of the same name is created in a schema appearing earlier in the search_path, no automatic re-parse will occur since no object used in the statement changed. However, if some other change forces a re-parse, the new table will be referenced in subsequent uses.

You can see all prepared statements available in the session by querying the pg_prepared_statements system view.

Examples

Create a prepared statement for an INSERT statement, and then execute it:

```
PREPARE fooplan (int, text, bool, numeric) AS
    INSERT INTO foo VALUES($1, $2, $3, $4);
```
EXECUTE fooplan(1, 'Hunter Valley', 't', 200.00);

Create a prepared statement for a SELECT statement, and then execute it:

PREPARE usrrptplan (int) AS
    SELECT * FROM users u, logs l WHERE u.usrid=$1 AND u.usrid=l.usrid
    AND l.date = $2;
EXECUTE usrrptplan(1, current_date);

In this example, the data type of the second parameter is not specified, so it is inferred from the context in which $2 is used.

Compatibility

The SQL standard includes a PREPARE statement, but it is only for use in embedded SQL. This version of the PREPARE statement also uses a somewhat different syntax.

DEALLOCATE, EXECUTE
**PREPARE TRANSACTION**

PREPARE TRANSACTION — prepare the current transaction for two-phase commit

**Synopsis**

PREPARE TRANSACTION  transaction_id

**Description**

PREPARE TRANSACTION prepares the current transaction for two-phase commit. After this command, the transaction is no longer associated with the current session; instead, its state is fully stored on disk, and there is a very high probability that it can be committed successfully, even if a database crash occurs before the commit is requested.

Once prepared, a transaction can later be committed or rolled back with COMMIT PREPARED or ROLLBACK PREPARED, respectively. Those commands can be issued from any session, not only the one that executed the original transaction.

From the point of view of the issuing session, PREPARE TRANSACTION is not unlike a ROLLBACK command: after executing it, there is no active current transaction, and the effects of the prepared transaction are no longer visible. (The effects will become visible again if the transaction is committed.)

If the PREPARE TRANSACTION command fails for any reason, it becomes a ROLLBACK: the current transaction is canceled.

**Parameters**

*transaction_id*

An arbitrary identifier that later identifies this transaction for COMMIT PREPARED or ROLLBACK PREPARED. The identifier must be written as a string literal, and must be less than 200 bytes long. It must not be the same as the identifier used for any currently prepared transaction.

**Notes**

PREPARE TRANSACTION is not intended for use in applications or interactive sessions. Its purpose is to allow an external transaction manager to perform atomic global transactions across multiple databases or other transactional resources. Unless you're writing a transaction manager, you probably shouldn't be using PREPARE TRANSACTION.

This command must be used inside a transaction block. Use BEGIN to start one.

It is not currently allowed to PREPARE a transaction that has executed any operations involving temporary tables or the session's temporary namespace, created any cursors WITH HOLD, or executed LISTEN, UNLISTEN, or NOTIFY. Those features are too tightly tied to the current session to be useful in a transaction to be prepared.

If the transaction modified any run-time parameters with SET (without the LOCAL option), those effects persist after PREPARE TRANSACTION, and will not be affected by any later COMMIT PREPARED or
ROLLBACK PREPARED. Thus, in this one respect PREPARE TRANSACTION acts more like COMMIT than ROLLBACK.

All currently available prepared transactions are listed in the pg_prepared_xacts system view.

---

**Caution**

It is unwise to leave transactions in the prepared state for a long time. This will interfere with the ability of VACUUM to reclaim storage, and in extreme cases could cause the database to shut down to prevent transaction ID wraparound (see Section 25.1.5). Keep in mind also that the transaction continues to hold whatever locks it held. The intended usage of the feature is that a prepared transaction will normally be committed or rolled back as soon as an external transaction manager has verified that other databases are also prepared to commit.

If you have not set up an external transaction manager to track prepared transactions and ensure they get closed out promptly, it is best to keep the prepared-transaction feature disabled by setting max_prepared_transactions to zero. This will prevent accidental creation of prepared transactions that might then be forgotten and eventually cause problems.

---

**Examples**

Prepare the current transaction for two-phase commit, using foobar as the transaction identifier:

```
PREPARE TRANSACTION 'foobar';
```

**Compatibility**

PREPARE TRANSACTION is a PostgreSQL extension. It is intended for use by external transaction management systems, some of which are covered by standards (such as X/Open XA), but the SQL side of those systems is not standardized.

COMMIT PREPARED, ROLLBACK PREPARED
REASSIGN OWNED

REASSIGN OWNED — change the ownership of database objects owned by a database role

Synopsis

REASSIGN OWNED BY { old_role | CURRENT_ROLE | CURRENT_USER |
SESSION_USER } [, ...]
TO { new_role | CURRENT_ROLE | CURRENT_USER |
SESSION_USER }

Description

REASSIGN OWNED instructs the system to change the ownership of database objects owned by any of the old_roles to new_role.

Parameters

old_role

The name of a role. The ownership of all the objects within the current database, and of all shared objects (databases, tablespaces), owned by this role will be reassigned to new_role.

new_role

The name of the role that will be made the new owner of the affected objects.

Notes

REASSIGN OWNED is often used to prepare for the removal of one or more roles. Because REASSIGN OWNED does not affect objects within other databases, it is usually necessary to execute this command in each database that contains objects owned by a role that is to be removed.

REASSIGN OWNED requires membership on both the source role(s) and the target role.

The DROP OWNED command is an alternative that simply drops all the database objects owned by one or more roles.

The REASSIGN OWNED command does not affect any privileges granted to the old_roles on objects that are not owned by them. Likewise, it does not affect default privileges created with ALTER DEFAULT PRIVILEGES. Use DROP OWNED to revoke such privileges.

See Section 22.4 for more discussion.

Compatibility

The REASSIGN OWNED command is a PostgreSQL extension.

See Also

DROP OWNED, DROP ROLE, ALTER DATABASE
REFRESH MATERIALIZED VIEW

REFRESH MATERIALIZED VIEW — replace the contents of a materialized view

Synopsis

REFRESH MATERIALIZED VIEW [ CONCURRENTLY ] name
[ WITH [ NO ] DATA ]

Description

REFRESH MATERIALIZED VIEW completely replaces the contents of a materialized view. To execute this command you must be the owner of the materialized view. The old contents are discarded. If WITH DATA is specified (or defaults) the backing query is executed to provide the new data, and the materialized view is left in a scannable state. If WITH NO DATA is specified no new data is generated and the materialized view is left in an unscannable state.

CONCURRENTLY and WITH NO DATA may not be specified together.

Parameters

CONCURRENTLY

Refresh the materialized view without locking out concurrent selects on the materialized view. Without this option a refresh which affects a lot of rows will tend to use fewer resources and complete more quickly, but could block other connections which are trying to read from the materialized view. This option may be faster in cases where a small number of rows are affected.

This option is only allowed if there is at least one UNIQUE index on the materialized view which uses only column names and includes all rows; that is, it must not be an expression index or include a WHERE clause.

This option may not be used when the materialized view is not already populated.

Even with this option only one REFRESH at a time may run against any one materialized view.

name

The name (optionally schema-qualified) of the materialized view to refresh.

Notes

If there is an ORDER BY clause in the materialized view’s defining query, the original contents of the materialized view will be ordered that way; but REFRESH MATERIALIZED VIEW does not guarantee to preserve that ordering.

Examples

This command will replace the contents of the materialized view called order_summary using the query from the materialized view’s definition, and leave it in a scannable state:
REFRESH MATERIALIZED VIEW order_summary;

This command will free storage associated with the materialized view annual_statistics_basis and leave it in an unscannable state:

REFRESH MATERIALIZED VIEW annual_statistics_basis WITH NO DATA;

Compatibility

REFRESH MATERIALIZED VIEW is a PostgreSQL extension.

CREATE MATERIALIZED VIEW, ALTER MATERIALIZED VIEW, DROP MATERIALIZED VIEW
REINDEX

REINDEX — rebuild indexes

Synopsis

REINDEX \{ \( \text{option} \ [, \ldots] \) \} \{ INDEX | TABLE | SCHEMA | DATABASE | SYSTEM \} \{ CONCURRENTLY \} \text{name}

where \text{option} can be one of:

- CONCURRENTLY [ boolean ]
- TABLESPACE \text{new_tablespace}
- VERBOSE [ boolean ]

Description

REINDEX rebuilds an index using the data stored in the index's table, replacing the old copy of the index. There are several scenarios in which to use REINDEX:

- An index has become corrupted, and no longer contains valid data. Although in theory this should never happen, in practice indexes can become corrupted due to software bugs or hardware failures. REINDEX provides a recovery method.

- An index has become “bloated”, that is it contains many empty or nearly-empty pages. This can occur with B-tree indexes in PostgreSQL under certain uncommon access patterns. REINDEX provides a way to reduce the space consumption of the index by writing a new version of the index without the dead pages. See Section 25.2 for more information.

- You have altered a storage parameter (such as fillfactor) for an index, and wish to ensure that the change has taken full effect.

- If an index build fails with the CONCURRENTLY option, this index is left as “invalid”. Such indexes are useless but it can be convenient to use REINDEX to rebuild them. Note that only REINDEX INDEX is able to perform a concurrent build on an invalid index.

Parameters

INDEX

Recreate the specified index. This form of REINDEX cannot be executed inside a transaction block when used with a partitioned index.

TABLE

Recreate all indexes of the specified table. If the table has a secondary “TOAST” table, that is reindexed as well. This form of REINDEX cannot be executed inside a transaction block when used with a partitioned table.
REINDEX

SCHEMA

Recreate all indexes of the specified schema. If a table of this schema has a secondary "TOAST" table, that is reindexed as well. Indexes on shared system catalogs are also processed. This form of REINDEX cannot be executed inside a transaction block.

DATABASE

Recreate all indexes within the current database. Indexes on shared system catalogs are also processed. This form of REINDEX cannot be executed inside a transaction block.

SYSTEM

Recreate all indexes on system catalogs within the current database. Indexes on shared system catalogs are included. Indexes on user tables are not processed. This form of REINDEX cannot be executed inside a transaction block.

name

The name of the specific index, table, or database to be reindexed. Index and table names can be schema-qualified. Presently, REINDEX DATABASE and REINDEX SYSTEM can only reindex the current database, so their parameter must match the current database's name.

CONCURRENTLY

When this option is used, PostgreSQL will rebuild the index without taking any locks that prevent concurrent inserts, updates, or deletes on the table; whereas a standard index rebuild locks out writes (but not reads) on the table until it's done. There are several caveats to be aware of when using this option — see Rebuilding Indexes Concurrently below.

For temporary tables, REINDEX is always non-concurrent, as no other session can access them, and non-concurrent reindex is cheaper.

TABLESPACE

Specifies that indexes will be rebuilt on a new tablespace.

VERBOSE

Prints a progress report as each index is reindexed.

boolean

Specifies whether the selected option should be turned on or off. You can write TRUE, ON, or 1 to enable the option, and FALSE, OFF, or 0 to disable it. The boolean value can also be omitted, in which case TRUE is assumed.

new_tablespace

The tablespace where indexes will be rebuilt.

Notes

If you suspect corruption of an index on a user table, you can simply rebuild that index, or all indexes on the table, using REINDEX INDEX or REINDEX TABLE.

Things are more difficult if you need to recover from corruption of an index on a system table. In this case it's important for the system to not have used any of the suspect indexes itself. (Indeed, in this sort...
of scenario you might find that server processes are crashing immediately at start-up, due to reliance on the corrupted indexes.) To recover safely, the server must be started with the \texttt{-P} option, which prevents it from using indexes for system catalog lookups.

One way to do this is to shut down the server and start a single-user PostgreSQL server with the \texttt{-P} option included on its command line. Then, \texttt{REINDEX DATABASE}, \texttt{REINDEX SYSTEM}, \texttt{REINDEX TABLE}, or \texttt{REINDEX INDEX} can be issued, depending on how much you want to reconstruct. If in doubt, use \texttt{REINDEX SYSTEM} to select reconstruction of all system indexes in the database. Then quit the single-user server session and restart the regular server. See the postgres reference page for more information about how to interact with the single-user server interface.

Alternatively, a regular server session can be started with \texttt{-P} included in its command line options. The method for doing this varies across clients, but in all libpq-based clients, it is possible to set the \texttt{PGOPTIONS} environment variable to \texttt{-P} before starting the client. Note that while this method does not require locking out other clients, it might still be wise to prevent other users from connecting to the damaged database until repairs have been completed.

\texttt{REINDEX} is similar to a drop and recreate of the index in that the index contents are rebuilt from scratch. However, the locking considerations are rather different. \texttt{REINDEX} locks out writes but not reads of the index's parent table. It also takes an \texttt{ACCESS EXCLUSIVE} lock on the specific index being processed, which will block reads that attempt to use that index. In particular, the query planner tries to take an \texttt{ACCESS SHARE} lock on every index of the table, regardless of the query, and so \texttt{REINDEX} blocks virtually any queries except for some prepared queries whose plan has been cached and which don't use this very index. In contrast, \texttt{DROP INDEX} momentarily takes an \texttt{ACCESS EXCLUSIVE} lock on the parent table, blocking both writes and reads. The subsequent \texttt{CREATE INDEX} locks out writes but not reads; since the index is not there, no read will attempt to use it, meaning that there will be no blocking but reads might be forced into expensive sequential scans.

Reindexing a single index or table requires being the owner of that index or table. Reindexing a schema or database requires being the owner of that schema or database. Note specifically that it's thus possible for non-superusers to rebuild indexes of tables owned by other users. However, as a special exception, when \texttt{REINDEX DATABASE}, \texttt{REINDEX SCHEMA} or \texttt{REINDEX SYSTEM} is issued by a non-superuser, indexes on shared catalogs will be skipped unless the user owns the catalog (which typically won't be the case). Of course, superusers can always reindex anything.

Reindexing partitioned indexes or partitioned tables is supported with \texttt{REINDEX INDEX} or \texttt{REINDEX TABLE}, respectively. Each partition of the specified partitioned relation is reindexed in a separate transaction. Those commands cannot be used inside a transaction block when working on a partitioned table or index.

When using the \texttt{TABLESPACE} clause with \texttt{REINDEX} on a partitioned index or table, only the tablespace references of the leaf partitions are updated. As partitioned indexes are not updated, it is recommended to separately use \texttt{ALTER TABLE ONLY} on them so as any new partitions attached inherit the new tablespace. On failure, it may not have moved all the indexes to the new tablespace. Re-running the command will rebuild all the leaf partitions and move previously-unprocessed indexes to the new tablespace.

If \texttt{SCHEMA}, \texttt{DATABASE} or \texttt{SYSTEM} is used with \texttt{TABLESPACE}, system relations are skipped and a single \texttt{WARNING} will be generated. Indexes on TOAST tables are rebuilt, but not moved to the new tablespace.

**Rebuilding Indexes Concurrently**

Rebuilding an index can interfere with regular operation of a database. Normally PostgreSQL locks the table whose index is rebuild against writes and performs the entire index build with a single scan of the table. Other transactions can still read the table, but if they try to insert, update, or delete rows in the table they will block until the index rebuild is finished. This could have a severe effect if the system is a live
REINDEX

production database. Very large tables can take many hours to be indexed, and even for smaller tables, an
index rebuild can lock out writers for periods that are unacceptably long for a production system.

PostgreSQL supports rebuilding indexes with minimum locking of writes. This method is invoked by
specifying the `CONCURRENTLY` option of `REINDEX`. When this option is used, PostgreSQL must perform
two scans of the table for each index that needs to be rebuilt and wait for termination of all existing
transactions that could potentially use the index. This method requires more total work than a standard
index rebuild and takes significantly longer to complete as it needs to wait for unfinished transactions
that might modify the index. However, since it allows normal operations to continue while the index is being
rebuilt, this method is useful for rebuilding indexes in a production environment. Of course, the extra CPU,
memory and I/O load imposed by the index rebuild may slow down other operations.

The following steps occur in a concurrent reindex. Each step is run in a separate transaction. If there are
multiple indexes to be rebuilt, then each step loops through all the indexes before moving to the next step.

1. A new transient index definition is added to the catalog `pg_index`. This definition will be used to
   replace the old index. A `SHARE UPDATE EXCLUSIVE` lock at session level is taken on the indexes
   being reindexed as well as their associated tables to prevent any schema modification while processing.

2. A first pass to build the index is done for each new index. Once the index is built, its flag `pg_index.indisready`
is switched to “true” to make it ready for inserts, making it visible to other sessions once the transaction that performed the build is finished. This step is done in a separate transaction for each index.

3. Then a second pass is performed to add tuples that were added while the first pass was running. This
   step is also done in a separate transaction for each index.

4. All the constraints that refer to the index are changed to refer to the new index definition, and the
   names of the indexes are changed. At this point, `pg_index.indisvalid` is switched to “true” for
   the new index and to “false” for the old, and a cache invalidation is done causing all sessions that
   referenced the old index to be invalidated.

5. The old indexes have `pg_index.indisready` switched to “false” to prevent any new tuple insertions, after waiting for running queries that might reference the old index to complete.

6. The old indexes are dropped. The `SHARE UPDATE EXCLUSIVE` session locks for the indexes and
   the table are released.

If a problem arises while rebuilding the indexes, such as a uniqueness violation in a unique index, the
`REINDEX` command will fail but leave behind an “invalid” new index in addition to the pre-existing one.
This index will be ignored for querying purposes because it might be incomplete; however it will still
consume update overhead. The `psql \d` command will report such an index as `INVALID`:

```
postgres=# \d tab
   Table "public.tab"
Column  | Type   | Modifiers
--------+---------+-----------
col     | integer |------------
Indexes:
   "idx" btree (col)
   "idx_ccnew" btree (col) INVALID
```

If the index marked `INVALID` is suffixed `ccnew`, then it corresponds to the transient index created during
the concurrent operation, and the recommended recovery method is to drop it using `DROP INDEX`, then
attempt `REINDEX CONCURRENTLY` again. If the invalid index is instead suffixed `ccold`, it corresponds
to the original index which could not be dropped; the recommended recovery method is to just drop said index, since the rebuild proper has been successful.

Regular index builds permit other regular index builds on the same table to occur simultaneously, but only one concurrent index build can occur on a table at a time. In both cases, no other types of schema modification on the table are allowed meanwhile. Another difference is that a regular REINDEX TABLE or REINDEX INDEX command can be performed within a transaction block, but REINDEX CONCURRENTLY cannot.

Like any long-running transaction, REINDEX on a table can affect which tuples can be removed by concurrent VACUUM on any other table.

REINDEX SYSTEM does not support CONCURRENTLY since system catalogs cannot be reindexed concurrently.

Furthermore, indexes for exclusion constraints cannot be reindexed concurrently. If such an index is named directly in this command, an error is raised. If a table or database with exclusion constraint indexes is reindexed concurrently, those indexes will be skipped. (It is possible to reindex such indexes without the CONCURRENTLY option.)

Each backend running REINDEX will report its progress in the pg_stat_progress_create_index view. See Section 28.4.2 for details.

Examples

Rebuild a single index:

REINDEX INDEX my_index;

Rebuild all the indexes on the table my_table:

REINDEX TABLE my_table;

Rebuild all indexes in a particular database, without trusting the system indexes to be valid already:

$ export PGOPTIONS="-P"
$ psql broken_db
...
broken_db=> REINDEX DATABASE broken_db;
broken_db=> \q

Rebuild indexes for a table, without blocking read and write operations on involved relations while reindexing is in progress:

REINDEX TABLE CONCURRENTLY my_broken_table;

Compatibility

There is no REINDEX command in the SQL standard.

See Also

CREATE INDEX, DROP INDEX, reindexdb, Section 28.4.2
**RELEASE SAVEPOINT**

RELEASE SAVEPOINT — destroy a previously defined savepoint

**Synopsis**

```
RELEASE [ SAVEPOINT ] savepoint_name
```

**Description**

RELEASE SAVEPOINT destroys a savepoint previously defined in the current transaction.

Destroying a savepoint makes it unavailable as a rollback point, but it has no other user visible behavior. It does not undo the effects of commands executed after the savepoint was established. (To do that, see `ROLLBACK TO SAVEPOINT`.) Destroying a savepoint when it is no longer needed allows the system to reclaim some resources earlier than transaction end.

RELEASE SAVEPOINT also destroys all savepoints that were established after the named savepoint was established.

**Parameters**

`savepoint_name`

The name of the savepoint to destroy.

**Notes**

Specifying a savepoint name that was not previously defined is an error.

It is not possible to release a savepoint when the transaction is in an aborted state.

If multiple savepoints have the same name, only the one that was most recently defined is released.

**Examples**

To establish and later destroy a savepoint:

```
BEGIN;
    INSERT INTO table1 VALUES (3);
    SAVEPOINT my_savepoint;
    INSERT INTO table1 VALUES (4);
    RELEASE SAVEPOINT my_savepoint;
COMMIT;
```

The above transaction will insert both 3 and 4.

**Compatibility**

This command conforms to the SQL standard. The standard specifies that the key word `SAVEPOINT` is mandatory, but PostgreSQL allows it to be omitted.
See Also
BEGIN, COMMIT, ROLLBACK, ROLLBACK TO SAVEPOINT, SAVEPOINT
RESET

RESET — restore the value of a run-time parameter to the default value

Synopsis

```
RESET configuration_parameter
RESET ALL
```

Description

RESET restores run-time parameters to their default values. RESET is an alternative spelling for

```
SET configuration_parameter TO DEFAULT
```

Refer to SET for details.

The default value is defined as the value that the parameter would have had, if no SET had ever been issued for it in the current session. The actual source of this value might be a compiled-in default, the configuration file, command-line options, or per-database or per-user default settings. This is subtly different from defining it as “the value that the parameter had at session start”, because if the value came from the configuration file, it will be reset to whatever is specified by the configuration file now. See Chapter 20 for details.

The transactional behavior of RESET is the same as SET: its effects will be undone by transaction rollback.

Parameters

```
configuration_parameter
```

Name of a settable run-time parameter. Available parameters are documented in Chapter 20 and on the SET reference page.

```
ALL
```

Resets all settable run-time parameters to default values.

Examples

Set the timezone configuration variable to its default value:

```
RESET timezone;
```

Compatibility

RESET is a PostgreSQL extension.

[ GRANTED BY role_specification ]
[ CASCADE | RESTRICT ]

REVOKE [ ADMIN OPTION FOR ]
role_name [, ...] FROM role_specification [, ...]
[ GRANTED BY role_specification ]
[ CASCADE | RESTRICT ]

where role_specification can be:

[ GROUP ] role_name
| PUBLIC
| CURRENT_ROLE
| CURRENT_USER
| SESSION_USER

Description

The REVOKE command revokes previously granted privileges from one or more roles. The key word PUBLIC refers to the implicitly defined group of all roles.

See the description of the GRANT command for the meaning of the privilege types.

Note that any particular role will have the sum of privileges granted directly to it, privileges granted to any role it is presently a member of, and privileges granted to PUBLIC. Thus, for example, revoking SELECT privilege from PUBLIC does not necessarily mean that all roles have lost SELECT privilege on the object; those who have it granted directly or via another role will still have it. Similarly, revoking SELECT from a user might not prevent that user from using SELECT if PUBLIC or another membership role still has SELECT rights.

If GRANT OPTION FOR is specified, only the grant option for the privilege is revoked, not the privilege itself. Otherwise, both the privilege and the grant option are revoked.

If a user holds a privilege with grant option and has granted it to other users then the privileges held by those other users are called dependent privileges. If the privilege or the grant option held by the first user is being revoked and dependent privileges exist, those dependent privileges are also revoked if CASCADE is specified; if it is not, the revoke action will fail. This recursive revocation only affects privileges that were granted through a chain of users that is traceable to the user that is the subject of this REVOKE command. Thus, the affected users might effectively keep the privilege if it was also granted through other users.

When revoking privileges on a table, the corresponding column privileges (if any) are automatically revoked on each column of the table, as well. On the other hand, if a role has been granted privileges on a table, then revoking the same privileges from individual columns will have no effect.

When revoking membership in a role, GRANT OPTION is instead called ADMIN OPTION, but the behavior is similar. This form of the command also allows a GRANTED BY option, but that option is
currently ignored (except for checking the existence of the named role). Note also that this form of the command does not allow the noise word GROUP in role_specification.

**Notes**

A user can only revoke privileges that were granted directly by that user. If, for example, user A has granted a privilege with grant option to user B, and user B has in turn granted it to user C, then user A cannot revoke the privilege directly from C. Instead, user A could revoke the grant option from user B and use the CASCADE option so that the privilege is in turn revoked from user C. For another example, if both A and B have granted the same privilege to C, A can revoke their own grant but not B’s grant, so C will still effectively have the privilege.

When a non-owner of an object attempts to REVOKE privileges on the object, the command will fail outright if the user has no privileges whatsoever on the object. As long as some privilege is available, the command will proceed, but it will revoke only those privileges for which the user has grant options. The REVOKE ALL PRIVILEGES forms will issue a warning message if no grant options are held, while the other forms will issue a warning if grant options for any of the privileges specifically named in the command are not held. (In principle these statements apply to the object owner as well, but since the owner is always treated as holding all grant options, the cases can never occur.)

If a superuser chooses to issue a GRANT or REVOKE command, the command is performed as though it were issued by the owner of the affected object. Since all privileges ultimately come from the object owner (possibly indirectly via chains of grant options), it is possible for a superuser to revoke all privileges, but this might require use of CASCADE as stated above.

REVOKE can also be done by a role that is not the owner of the affected object, but is a member of the role that owns the object, or is a member of a role that holds privileges WITH GRANT OPTION on the object. In this case the command is performed as though it were issued by the containing role that actually owns the object or holds the privileges WITH GRANT OPTION. For example, if table t1 is owned by role g1, of which role u1 is a member, then u1 can revoke privileges on t1 that are recorded as being granted by g1. This would include grants made by u1 as well as by other members of role g1.

If the role executing REVOKE holds privileges indirectly via more than one role membership path, it is unspecified which containing role will be used to perform the command. In such cases it is best practice to use SET ROLE to become the specific role you want to do the REVOKE as. Failure to do so might lead to revoking privileges other than the ones you intended, or not revoking anything at all.

See Section 5.7 for more information about specific privilege types, as well as how to inspect objects’ privileges.

**Examples**

Revoke insert privilege for the public on table films:

```sql
REVOKE INSERT ON films FROM PUBLIC;
```

Revoke all privileges from user manuel on view kinds:

```sql
REVOKE ALL PRIVILEGES ON kinds FROM manuel;
```

Note that this actually means “revoke all privileges that I granted”.

Revoke membership in role admins from user joe:

```sql
```
REVOKE admins FROM joe;

Compatibility

The compatibility notes of the GRANT command apply analogously to REVOKE. The keyword RESTRICT or CASCADE is required according to the standard, but PostgreSQL assumes RESTRICT by default.

GRANT, ALTER DEFAULT PRIVILEGES
ROLLBACK

ROLLBACK — abort the current transaction

Synopsis

ROLLBACK [ WORK | TRANSACTION ] [ AND [ NO ] CHAIN ]

Description

ROLLBACK rolls back the current transaction and causes all the updates made by the transaction to be discarded.

Parameters

WORK
TRANSACTION

Optional key words. They have no effect.

AND CHAIN

If AND CHAIN is specified, a new transaction is immediately started with the same transaction characteristics (see SET TRANSACTION) as the just finished one. Otherwise, no new transaction is started.

Notes

Use COMMIT to successfully terminate a transaction.

Issuing ROLLBACK outside of a transaction block emits a warning and otherwise has no effect. ROLLBACK AND CHAIN outside of a transaction block is an error.

Examples

To abort all changes:

ROLLBACK;

Compatibility

The command ROLLBACK conforms to the SQL standard. The form ROLLBACK TRANSACTION is a PostgreSQL extension.

See Also

BEGIN, COMMIT, ROLLBACK TO SAVEPOINT
ROLLBACK PREPARED

ROLLBACK PREPARED — cancel a transaction that was earlier prepared for two-phase commit

Synopsis

ROLLBACK PREPARED transaction_id

Description

ROLLBACK PREPARED rolls back a transaction that is in prepared state.

Parameters

transaction_id

The transaction identifier of the transaction that is to be rolled back.

Notes

To roll back a prepared transaction, you must be either the same user that executed the transaction originally, or a superuser. But you do not have to be in the same session that executed the transaction.

This command cannot be executed inside a transaction block. The prepared transaction is rolled back immediately.

All currently available prepared transactions are listed in the pg_prepared_xacts system view.

Examples

Roll back the transaction identified by the transaction identifier foobar:

ROLLBACK PREPARED 'foobar';

Compatibility

ROLLBACK PREPARED is a PostgreSQL extension. It is intended for use by external transaction management systems, some of which are covered by standards (such as X/Open XA), but the SQL side of those systems is not standardized.

See Also

PREPARE TRANSACTION, COMMIT PREPARED
ROLLBACK TO SAVEPOINT

ROLLBACK TO SAVEPOINT — roll back to a savepoint

Synopsis

ROLLBACK [ WORK | TRANSACTION ] TO [ SAVEPOINT ] savepoint_name

Description

Roll back all commands that were executed after the savepoint was established. The savepoint remains valid and can be rolled back to again later, if needed.

ROLLBACK TO SAVEPOINT implicitly destroys all savepoints that were established after the named savepoint.

Parameters

savepoint_name

The savepoint to roll back to.

Notes

Use RELEASE SAVEPOINT to destroy a savepoint without discarding the effects of commands executed after it was established.

Specifying a savepoint name that has not been established is an error.

Cursors have somewhat non-transactional behavior with respect to savepoints. Any cursor that is opened inside a savepoint will be closed when the savepoint is rolled back. If a previously opened cursor is affected by a FETCH or MOVE command inside a savepoint that is later rolled back, the cursor remains at the position that FETCH left it pointing to (that is, the cursor motion caused by FETCH is not rolled back). Closing a cursor is not undone by rolling back, either. However, other side-effects caused by the cursor's query (such as side-effects of volatile functions called by the query) are rolled back if they occur during a savepoint that is later rolled back. A cursor whose execution causes a transaction to abort is put in a cannot-execute state, so while the transaction can be restored using ROLLBACK TO SAVEPOINT, the cursor can no longer be used.

Examples

To undo the effects of the commands executed after my_savepoint was established:

ROLLBACK TO SAVEPOINT my_savepoint;

Cursor positions are not affected by savepoint rollback:

BEGIN;
DECLARE foo CURSOR FOR SELECT 1 UNION SELECT 2;

SAVEPOINT foo;

FETCH 1 FROM foo;
?column?
----------
  1

ROLLBACK TO SAVEPOINT foo;

FETCH 1 FROM foo;
?column?
----------
  2

COMMIT;

Compatibility

The SQL standard specifies that the key word SAVEPOINT is mandatory, but PostgreSQL and Oracle allow it to be omitted. SQL allows only WORK, not TRANSACTION, as a noise word after ROLLBACK. Also, SQL has an optional clause AND [ NO ] CHAIN which is not currently supported by PostgreSQL. Otherwise, this command conforms to the SQL standard.

See Also
BEGIN, COMMIT, RELEASE SAVEPOINT, ROLLBACK, SAVEPOINT
SAVEPOINT

SAVEPOINT — define a new savepoint within the current transaction

Synopsis

SAVEPOINT savepoint_name

Description

SAVEPOINT establishes a new savepoint within the current transaction.

A savepoint is a special mark inside a transaction that allows all commands that are executed after it was established to be rolled back, restoring the transaction state to what it was at the time of the savepoint.

Parameters

savepoint_name

The name to give to the new savepoint.

Notes

Use ROLLBACK TO to rollback to a savepoint. Use RELEASE SAVEPOINT to destroy a savepoint, keeping the effects of commands executed after it was established.

Savepoints can only be established when inside a transaction block. There can be multiple savepoints defined within a transaction.

Examples

To establish a savepoint and later undo the effects of all commands executed after it was established:

BEGIN;
    INSERT INTO table1 VALUES (1);
    SAVEPOINT my_savepoint;
    INSERT INTO table1 VALUES (2);
    ROLLBACK TO SAVEPOINT my_savepoint;
    INSERT INTO table1 VALUES (3);
COMMIT;

The above transaction will insert the values 1 and 3, but not 2.

To establish and later destroy a savepoint:

BEGIN;
    INSERT INTO table1 VALUES (3);
    SAVEPOINT my_savepoint;
SAVEPOINT

```
INSERT INTO table1 VALUES (4);
RELEASE SAVEPOINT my_savepoint;
COMMIT;
```

The above transaction will insert both 3 and 4.

**Compatibility**

SQL requires a savepoint to be destroyed automatically when another savepoint with the same name is established. In PostgreSQL, the old savepoint is kept, though only the more recent one will be used when rolling back or releasing. (Releasing the newer savepoint with `RELEASE SAVEPOINT` will cause the older one to again become accessible to `ROLLBACK TO SAVEPOINT` and `RELEASE SAVEPOINT`.) Otherwise, `SAVEPOINT` is fully SQL conforming.

**See Also**

`BEGIN`, `COMMIT`, `RELEASE SAVEPOINT`, `ROLLBACK`, `ROLLBACK TO SAVEPOINT`
SECURITY LABEL

SECURITY LABEL — define or change a security label applied to an object

Synopsis

SECURITY LABEL [ FOR provider ] ON { TABLE object_name | COLUMN table_name.column_name | AGGREGATE aggregate_name ( aggregate_signature ) | DATABASE object_name | DOMAIN object_name | EVENT TRIGGER object_name | FOREIGN TABLE object_name | FUNCTION function_name [ ( [ argmode ] [ argname ] argtype [, ...] ] ) ] | LARGE OBJECT large_object_oid | MATERIALIZED VIEW object_name | [ PROCEDURAL ] LANGUAGE object_name | PROCEDURE procedure_name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ] | PUBLICATION object_name | ROLE object_name | ROUTINE routine_name [ ( [ [ argmode ] [ argname ] argtype [, ...] ] ) ] | SCHEMA object_name | SEQUENCE object_name | SUBSCRIPTION object_name | TABLESPACE object_name | TYPE object_name | VIEW object_name } IS 'label'

where aggregate_signature is:

* |
[ argmode ] [ argname ] argtype [, ... ] |
[ [ argmode ] [ argname ] argtype [, ... ] ] ORDER BY [ argmode ]
[ argname ] argtype [, ... ]

Description

SECURITY LABEL applies a security label to a database object. An arbitrary number of security labels, one per label provider, can be associated with a given database object. Label providers are loadable modules which register themselves by using the function register_label_provider.
The label provider determines whether a given label is valid and whether it is permissible to assign that label to a given object. The meaning of a given label is likewise at the discretion of the label provider. PostgreSQL places no restrictions on whether or how a label provider must interpret security labels; it merely provides a mechanism for storing them. In practice, this facility is intended to allow integration with label-based mandatory access control (MAC) systems such as SELinux. Such systems make all access control decisions based on object labels, rather than traditional discretionary access control (DAC) concepts such as users and groups.

**Parameters**

- `object_name`
- `table_name.column_name`
- `aggregate_name`
- `function_name`
- `procedure_name`
- `routine_name`

  The name of the object to be labeled. Names of objects that reside in schemas (tables, functions, etc.) can be schema-qualified.

- `provider`

  The name of the provider with which this label is to be associated. The named provider must be loaded and must consent to the proposed labeling operation. If exactly one provider is loaded, the provider name may be omitted for brevity.

- `argmode`

  The mode of a function, procedure, or aggregate argument: **IN**, **OUT**, **INOUT**, or **VARIADIC**. If omitted, the default is **IN**. Note that SECURITY LABEL does not actually pay any attention to **OUT** arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the **IN**, **INOUT**, and **VARIADIC** arguments.

- `argname`

  The name of a function, procedure, or aggregate argument. Note that SECURITY LABEL does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

- `argtype`

  The data type of a function, procedure, or aggregate argument.

- `large_object_oid`

  The OID of the large object.

**PROCEDURAL**

This is a noise word.
label

The new security label, written as a string literal; or NULL to drop the security label.

Examples

The following example shows how the security label of a table might be changed.

```
SECURITY LABEL FOR selinux ON TABLE mytable IS
'system_u:object_r:sepgsql_table_t:s0';
```

Compatibility

There is no SECURITY LABEL command in the SQL standard.

[ CYCLE column_name [, ...] SET cycle_mark_col_name
[ TO cycle_mark_value DEFAULT cycle_mark_default ]
USING cycle_path_col_name ]

TABLE [ ONLY ] table_name [ * ]

Description

SELECT retrieves rows from zero or more tables. The general processing of SELECT is as follows:

1. All queries in the WITH list are computed. These effectively serve as temporary tables that can be referenced in the FROM list. A WITH query that is referenced more than once in FROM is computed only once, unless specified otherwise with NOT MATERIALIZED. (See WITH Clause below.)

2. All elements in the FROM list are computed. (Each element in the FROM list is a real or virtual table.) If more than one element is specified in the FROM list, they are cross-joined together. (See FROM Clause below.)

3. If the WHERE clause is specified, all rows that do not satisfy the condition are eliminated from the output. (See WHERE Clause below.)

4. If the GROUP BY clause is specified, or if there are aggregate function calls, the output is combined into groups of rows that match on one or more values, and the results of aggregate functions are computed. If the HAVING clause is present, it eliminates groups that do not satisfy the given condition. (See GROUP BY Clause and HAVING Clause below.)

5. The actual output rows are computed using the SELECT output expressions for each selected row or row group. (See SELECT List below.)

6. SELECT DISTINCT eliminates duplicate rows from the result. SELECT DISTINCT ON eliminates rows that match on all the specified expressions. SELECT ALL (the default) will return all candidate rows, including duplicates. (See DISTINCT Clause below.)

7. Using the operators UNION, INTERSECT, and EXCEPT, the output of more than one SELECT statement can be combined to form a single result set. The UNION operator returns all rows that are in one or both of the result sets. The INTERSECT operator returns all rows that are strictly in both result sets. The EXCEPT operator returns the rows that are in the first result set but not in the second. In all three cases, duplicate rows are eliminated unless ALL is specified. The noise word DISTINCT can be added to explicitly specify eliminating duplicate rows. Notice that DISTINCT is the default behavior here, even though ALL is the default for SELECT itself. (See UNION Clause, INTERSECT Clause, and EXCEPT Clause below.)

8. If the ORDER BY clause is specified, the returned rows are sorted in the specified order. If ORDER BY is not given, the rows are returned in whatever order the system finds fastest to produce. (See ORDER BY Clause below.)
9. If the LIMIT (or FETCH FIRST) or OFFSET clause is specified, the SELECT statement only returns a subset of the result rows. (See LIMIT Clause below.)

10. If FOR UPDATE, FOR NO KEY UPDATE, FOR SHARE or FOR KEY SHARE is specified, the SELECT statement locks the selected rows against concurrent updates. (See The Locking Clause below.)

You must have SELECT privilege on each column used in a SELECT command. The use of FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE or FOR KEY SHARE requires UPDATE privilege as well (for at least one column of each table so selected).

Parameters

WITH Clause

The WITH clause allows you to specify one or more subqueries that can be referenced by name in the primary query. The subqueries effectively act as temporary tables or views for the duration of the primary query. Each subquery can be a SELECT, TABLE, VALUES, INSERT, UPDATE or DELETE statement. When writing a data-modifying statement (INSERT, UPDATE or DELETE) in WITH, it is usual to include a RETURNING clause. It is the output of RETURNING, not the underlying table that the statement modifies, that forms the temporary table that is read by the primary query. If RETURNING is omitted, the statement is still executed, but it produces no output so it cannot be referenced as a table by the primary query.

A name (without schema qualification) must be specified for each WITH query. Optionally, a list of column names can be specified; if this is omitted, the column names are inferred from the subquery.

If RECURSIVE is specified, it allows a SELECT subquery to reference itself by name. Such a subquery must have the form

```sql
non_recursive_term UNION [ ALL | DISTINCT ] recursive_term
```

where the recursive self-reference must appear on the right-hand side of the UNION. Only one recursive self-reference is permitted per query. Recursive data-modifying statements are not supported, but you can use the results of a recursive SELECT query in a data-modifying statement. See Section 7.8 for an example.

Another effect of RECURSIVE is that WITH queries need not be ordered: a query can reference another one that is later in the list. (However, circular references, or mutual recursion, are not implemented.) Without RECURSIVE, WITH queries can only reference sibling WITH queries that are earlier in the WITH list.

When there are multiple queries in the WITH clause, RECURSIVE should be written only once, immediately after WITH. It applies to all queries in the WITH clause, though it has no effect on queries that do not use recursion or forward references.

The optional SEARCH clause computes a search sequence column that can be used for ordering the results of a recursive query in either breadth-first or depth-first order. The supplied column name list specifies the row key that is to be used for keeping track of visited rows. A column named search_seq_col_name will be added to the result column list of the WITH query. This column can be ordered by in the outer query to achieve the respective ordering. See Section 7.8.2.1 for examples.

The optional CYCLE clause is used to detect cycles in recursive queries. The supplied column name list specifies the row key that is to be used for keeping track of visited rows. A column named cycle_mark_col_name will be added to the result column list of the WITH query. This column will be set to cycle_mark_value when a cycle has been detected, else to cycle_mark_default. Furthermore, processing of the recursive union will stop when a cycle has been detected. cycle_mark_value and cycle_mark_default must be constants and they must be coercible to a common data type,
and the data type must have an inequality operator. (The SQL standard requires that they be Boolean constants or character strings, but PostgreSQL does not require that.) By default, TRUE and FALSE (of type boolean) are used. Furthermore, a column named cycle_path_col_name will be added to the result column list of the WITH query. This column is used internally for tracking visited rows. See Section 7.8.2.2 for examples.

Both the SEARCH and the CYCLE clause are only valid for recursive WITH queries. The with_query must be a UNION (or UNION ALL) of two SELECT (or equivalent) commands (no nested UNIONs). If both clauses are used, the column added by the SEARCH clause appears before the columns added by the CYCLE clause.

The primary query and the WITH queries are all (notionally) executed at the same time. This implies that the effects of a data-modifying statement in WITH cannot be seen from other parts of the query, other than by reading its RETURNING output. If two such data-modifying statements attempt to modify the same row, the results are unspecified.

A key property of WITH queries is that they are normally evaluated only once per execution of the primary query, even if the primary query refers to them more than once. In particular, data-modifying statements are guaranteed to be executed once and only once, regardless of whether the primary query reads all or any of their output.

However, a WITH query can be marked NOT MATERIALIZED to remove this guarantee. In that case, the WITH query can be folded into the primary query much as though it were a simple sub-SELECT in the primary query's FROM clause. This results in duplicate computations if the primary query refers to that WITH query more than once; but if each such use requires only a few rows of the WITH query's total output, NOT MATERIALIZED can provide a net savings by allowing the queries to be optimized jointly. NOT MATERIALIZED is ignored if it is attached to a WITH query that is recursive or is not side-effect-free (i.e., is not a plain SELECT containing no volatile functions).

By default, a side-effect-free WITH query is folded into the primary query if it is used exactly once in the primary query's FROM clause. This allows joint optimization of the two query levels in situations where that should be semantically invisible. However, such folding can be prevented by marking the WITH query as MATERIALIZED. That might be useful, for example, if the WITH query is being used as an optimization fence to prevent the planner from choosing a bad plan. PostgreSQL versions before v12 never did such folding, so queries written for older versions might rely on WITH to act as an optimization fence.

See Section 7.8 for additional information.

**FROM Clause**

The FROM clause specifies one or more source tables for the SELECT. If multiple sources are specified, the result is the Cartesian product (cross join) of all the sources. But usually qualification conditions are added (via WHERE) to restrict the returned rows to a small subset of the Cartesian product.

The FROM clause can contain the following elements:

* `table_name`

  The name (optionally schema-qualified) of an existing table or view. If ONLY is specified before the table name, only that table is scanned. If ONLY is not specified, the table and all its descendant tables (if any) are scanned. Optionally, * can be specified after the table name to explicitly indicate that descendant tables are included.

* `alias`

  A substitute name for the FROM item containing the alias. An alias is used for brevity or to eliminate ambiguity for self-joins (where the same table is scanned multiple times). When an alias is provided,
it completely hides the actual name of the table or function; for example given `FROM foo AS f`, the remainder of the `SELECT` must refer to this `FROM` item as `f` not `foo`. If an alias is written, a column alias list can also be written to provide substitute names for one or more columns of the table.

```sql
TABLESAMPLE sampling_method ( argument [, ...] ) [ REPEATABLE ( seed ) ]
```

A `TABLESAMPLE` clause after a `table_name` indicates that the specified `sampling_method` should be used to retrieve a subset of the rows in that table. This sampling precedes the application of any other filters such as `WHERE` clauses. The standard PostgreSQL distribution includes two sampling methods, `BERNOULLI` and `SYSTEM`, and other sampling methods can be installed in the database via extensions.

The `BERNOULLI` and `SYSTEM` sampling methods each accept a single `argument` which is the fraction of the table to sample, expressed as a percentage between 0 and 100. This argument can be any real-valued expression. (Other sampling methods might accept more or different arguments.) These two methods each return a randomly-chosen sample of the table that will contain approximately the specified percentage of the table's rows. The `BERNOULLI` method scans the whole table and selects or ignores individual rows independently with the specified probability. The `SYSTEM` method does block-level sampling with each block having the specified chance of being selected; all rows in each selected block are returned. The `SYSTEM` method is significantly faster than the `BERNOULLI` method when small sampling percentages are specified, but it may return a less-random sample of the table as a result of clustering effects.

The optional `REPEATABLE` clause specifies a `seed` number or expression to use for generating random numbers within the sampling method. The seed value can be any non-null floating-point value. Two queries that specify the same seed and `argument` values will select the same sample of the table, if the table has not been changed meanwhile. But different seed values will usually produce different samples. If `REPEATABLE` is not given then a new random sample is selected for each query, based upon a system-generated seed. Note that some add-on sampling methods do not accept `REPEATABLE`, and will always produce new samples on each use.

```sql
select
```

A sub-`SELECT` can appear in the `FROM` clause. This acts as though its output were created as a temporary table for the duration of this single `SELECT` command. Note that the sub-`SELECT` must be surrounded by parentheses, and an alias must be provided for it. A `VALUES` command can also be used here.

```sql
with_query_name
```

A `WITH` query is referenced by writing its name, just as though the query's name were a table name. (In fact, the `WITH` query hides any real table of the same name for the purposes of the primary query. If necessary, you can refer to a real table of the same name by schema-qualifying the table's name.) An alias can be provided in the same way as for a table.

```sql
function_name
```

Function calls can appear in the `FROM` clause. (This is especially useful for functions that return result sets, but any function can be used.) This acts as though the function's output were created as a temporary table for the duration of this single `SELECT` command. If the function's result type is composite (including the case of a function with multiple `OUT` parameters), each attribute becomes a separate column in the implicit table.

When the optional `WITH ORDINALITY` clause is added to the function call, an additional column of type `bigint` will be appended to the function's result column(s). This column numbers the rows of the function's result set, starting from 1. By default, this column is named `ordinality`. 
An alias can be provided in the same way as for a table. If an alias is written, a column alias list can also be written to provide substitute names for one or more attributes of the function's composite return type, including the ordinality column if present.

Multiple function calls can be combined into a single FROM-clause item by surrounding them with ROWS FROM( ... ). The output of such an item is the concatenation of the first row from each function, then the second row from each function, etc. If some of the functions produce fewer rows than others, null values are substituted for the missing data, so that the total number of rows returned is always the same as for the function that produced the most rows.

If the function has been defined as returning the record data type, then an alias or the key word AS must be present, followed by a column definition list in the form (column_name data_type [, ... ]). The column definition list must match the actual number and types of columns returned by the function.

When using the ROWS FROM( ... ) syntax, if one of the functions requires a column definition list, it's preferred to put the column definition list after the function call inside ROWS FROM( ... ). A column definition list can be placed after the ROWS FROM( ... ) construct only if there's just a single function and no WITH ORDINALITY clause.

To use ORDINALITY together with a column definition list, you must use the ROWS FROM( ... ) syntax and put the column definition list inside ROWS FROM( ... ).

**join_type**

One of

- [ INNER ] JOIN
- LEFT [ OUTER ] JOIN
- RIGHT [ OUTER ] JOIN
- FULL [ OUTER ] JOIN
- CROSS JOIN

For the INNER and OUTER join types, a join condition must be specified, namely exactly one of NATURAL, ON join_condition, or USING (join_column [, ...]). See below for the meaning. For CROSS JOIN, none of these clauses can appear.

A JOIN clause combines two FROM items, which for convenience we will refer to as “tables”, though in reality they can be any type of FROM item. Use parentheses if necessary to determine the order of nesting. In the absence of parentheses, JOINs nest left-to-right. In any case JOIN binds more tightly than the commas separating FROM-list items.

CROSS JOIN and INNER JOIN produce a simple Cartesian product, the same result as you get from listing the two tables at the top level of FROM, but restricted by the join condition (if any). CROSS JOIN is equivalent to INNER JOIN ON (TRUE), that is, no rows are removed by qualification. These join types are just a notational convenience, since they do nothing you couldn't do with plain FROM and WHERE.

LEFT OUTER JOIN returns all rows in the qualified Cartesian product (i.e., all combined rows that pass its join condition), plus one copy of each row in the left-hand table for which there was no right-hand row that passed the join condition. This left-hand row is extended to the full width of the joined table by inserting null values for the right-hand columns. Note that only the JOIN clause's own condition is considered while deciding which rows have matches. Outer conditions are applied afterwards.
Conversely, RIGHT OUTER JOIN returns all the joined rows, plus one row for each unmatched right-hand row (extended with nulls on the left). This is just a notational convenience, since you could convert it to a LEFT OUTER JOIN by switching the left and right tables.

FULL OUTER JOIN returns all the joined rows, plus one row for each unmatched left-hand row (extended with nulls on the right), plus one row for each unmatched right-hand row (extended with nulls on the left).

ON join_condition

join_condition is an expression resulting in a value of type boolean (similar to a WHERE clause) that specifies which rows in a join are considered to match.

USING ( join_column [, ...] ) [ AS join_using_alias ]

A clause of the form USING ( a, b, ... ) is shorthand for ON left_table.a = right_table.a AND left_table.b = right_table.b .... Also, USING implies that only one of each pair of equivalent columns will be included in the join output, not both.

If a join_using_alias name is specified, it provides a table alias for the join columns. Only the join columns listed in the USING clause are addressable by this name. Unlike a regular alias, this does not hide the names of the joined tables from the rest of the query. Also unlike a regular alias, you cannot write a column alias list — the output names of the join columns are the same as they appear in the USING list.

NATURAL

NATURAL is shorthand for a USING list that mentions all columns in the two tables that have matching names. If there are no common column names, NATURAL is equivalent to ON TRUE.

LATERAL

The LATERAL key word can precede a sub-SELECT FROM item. This allows the sub-SELECT to refer to columns of FROM items that appear before it in the FROM list. (Without LATERAL, each sub-SELECT is evaluated independently and so cannot cross-reference any other FROM item.)

LATERAL can also precede a function-call FROM item, but in this case it is a noise word, because the function expression can refer to earlier FROM items in any case.

A LATERAL item can appear at top level in the FROM list, or within a JOIN tree. In the latter case it can also refer to any items that are on the left-hand side of a JOIN that it is on the right-hand side of.

When a FROM item contains LATERAL cross-references, evaluation proceeds as follows: for each row of the FROM item providing the cross-referenced column(s), or set of rows of multiple FROM items providing the columns, the LATERAL item is evaluated using that row or row set’s values of the columns. The resulting row(s) are joined as usual with the rows they were computed from. This is repeated for each row or set of rows from the column source table(s).

The column source table(s) must be INNER or LEFT joined to the LATERAL item, else there would not be a well-defined set of rows from which to compute each set of rows for the LATERAL item. Thus, although a construct such as X RIGHT JOIN LATERAL Y is syntactically valid, it is not actually allowed for Y to reference X.

WHERE Clause

The optional WHERE clause has the general form
WHERE condition

where condition is any expression that evaluates to a result of type boolean. Any row that does not satisfy this condition will be eliminated from the output. A row satisfies the condition if it returns true when the actual row values are substituted for any variable references.

**GROUP BY Clause**

The optional GROUP BY clause has the general form

GROUP BY [ ALL | DISTINCT ] grouping_element [, ...]

GROUP BY will condense into a single row all selected rows that share the same values for the grouped expressions. An expression used inside a grouping_element can be an input column name, or the name or ordinal number of an output column (SELECT list item), or an arbitrary expression formed from input-column values. In case of ambiguity, a GROUP BY name will be interpreted as an input-column name rather than an output column name.

If any of GROUPING SETS, ROLLUP or CUBE are present as grouping elements, then the GROUP BY clause as a whole defines some number of independent grouping sets. The effect of this is equivalent to constructing a UNION ALL between subqueries with the individual grouping sets as their GROUP BY clauses. The optional DISTINCT clause removes duplicate sets before processing; it does not transform the UNION ALL into a UNION DISTINCT. For further details on the handling of grouping sets see Section 7.2.4.

Aggregate functions, if any are used, are computed across all rows making up each group, producing a separate value for each group. (If there are aggregate functions but no GROUP BY clause, the query is treated as having a single group comprising all the selected rows.) The set of rows fed to each aggregate function can be further filtered by attaching a FILTER clause to the aggregate function call; see Section 4.2.7 for more information. When a FILTER clause is present, only those rows matching it are included in the input to that aggregate function.

When GROUP BY is present, or any aggregate functions are present, it is not valid for the SELECT list expressions to refer to ungrouped columns except within aggregate functions or when the ungrouped column is functionally dependent on the grouped columns, since there would otherwise be more than one possible value to return for an ungrouped column. A functional dependency exists if the grouped columns (or a subset thereof) are the primary key of the table containing the ungrouped column.

Keep in mind that all aggregate functions are evaluated before evaluating any “scalar” expressions in the HAVING clause or SELECT list. This means that, for example, a CASE expression cannot be used to skip evaluation of an aggregate function; see Section 4.2.14.

Currently, FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE and FOR KEY SHARE cannot be specified with GROUP BY.

**HAVING Clause**

The optional HAVING clause has the general form

HAVING condition

where condition is the same as specified for the WHERE clause.
HAVING eliminates group rows that do not satisfy the condition. HAVING is different from WHERE: WHERE filters individual rows before the application of GROUP BY, while HAVING filters group rows created by GROUP BY. Each column referenced in condition must unambiguously reference a grouping column, unless the reference appears within an aggregate function or the ungrouped column is functionally dependent on the grouping columns.

The presence of HAVING turns a query into a grouped query even if there is no GROUP BY clause. This is the same as what happens when the query contains aggregate functions but no GROUP BY clause. All the selected rows are considered to form a single group, and the SELECT list and HAVING clause can only reference table columns from within aggregate functions. Such a query will emit a single row if the HAVING condition is true, zero rows if it is not true.

Currently, FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE and FOR KEY SHARE cannot be specified with HAVING.

**WINDOW Clause**

The optional WINDOW clause has the general form

```
WINDOW window_name AS ( window_definition ) [, ...]
```

where window_name is a name that can be referenced from OVER clauses or subsequent window definitions, and window_definition is

```
[ existing_window_name ]
[ PARTITION BY expression [, ...] ]
[ ORDER BY expression [ ASC | DESC | USING operator ] [ NULLS { FIRST | LAST } ] [, ... ] ]
[ frame_clause ]
```

If an existing_window_name is specified it must refer to an earlier entry in the WINDOW list; the new window copies its partitioning clause from that entry, as well as its ordering clause if any. In this case the new window cannot specify its own PARTITION BY clause, and it can specify ORDER BY only if the copied window does not have one. The new window always uses its own frame clause; the copied window must not specify a frame clause.

The elements of the PARTITION BY list are interpreted in much the same fashion as elements of a GROUP BY clause, except that they are always simple expressions and never the name or number of an output column. Another difference is that these expressions can contain aggregate function calls, which are not allowed in a regular GROUP BY clause. They are allowed here because windowing occurs after grouping and aggregation.

Similarly, the elements of the ORDER BY list are interpreted in much the same fashion as elements of a statement-level ORDER BY clause, except that the expressions are always taken as simple expressions and never the name or number of an output column.

The optional frame_clause defines the window frame for window functions that depend on the frame (not all do). The window frame is a set of related rows for each row of the query (called the current row). The frame_clause can be one of

```
{ RANGE | ROWS | GROUPS } frame_start [ frame_exclusion ]
{ RANGE | ROWS | GROUPS } BETWEEN frame_start AND frame_end
[ frame_exclusion ]
```
where frame_start and frame_end can be one of

UNBOUNDED PRECEDING
offset PRECEDING
CURRENT ROW
offset FOLLOWING
UNBOUNDED FOLLOWING

and frame_exclusion can be one of

EXCLUDE CURRENT ROW
EXCLUDE GROUP
EXCLUDE TIES
EXCLUDE NO OTHERS

If frame_end is omitted it defaults to CURRENT ROW. Restrictions are that frame_start cannot be UNBOUNDED FOLLOWING, frame_end cannot be UNBOUNDED PRECEDING, and the frame_end choice cannot appear earlier in the above list of frame_start and frame_end options than the frame_start choice does — for example RANGE BETWEEN CURRENT ROW AND offset PRECEDING is not allowed.

The default framing option is RANGE UNBOUNDED PRECEDING, which is the same as RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW; it sets the frame to be all rows from the partition start up through the current row’s last peer (a row that the window’s ORDER BY clause considers equivalent to the current row; all rows are peers if there is no ORDER BY). In general, UNBOUNDED PRECEDING means that the frame starts with the first row of the partition, and similarly UNBOUNDED FOLLOWING means that the frame ends with the last row of the partition, regardless of RANGE, ROWS or GROUPS mode. In ROWS mode, CURRENT ROW means that the frame starts or ends with the current row; but in RANGE or GROUPS mode it means that the frame starts or ends with the current row’s first or last peer in the ORDER BY ordering. The offset PRECEDING and offset FOLLOWING options vary in meaning depending on the frame mode. In ROWS mode, the offset is an integer indicating that the frame starts or ends that many rows before or after the current row. In GROUPS mode, the offset is an integer indicating that the frame starts or ends that many peer groups before or after the current row’s peer group, where a peer group is a group of rows that are equivalent according to the window’s ORDER BY clause. In RANGE mode, use of an offset option requires that there be exactly one ORDER BY column in the window definition. Then the frame contains those rows whose ordering column value is no more than offset less than (for PRECEDING) or more than (for FOLLOWING) the current row’s ordering column value. In these cases the data type of the offset expression depends on the data type of the ordering column. For numeric ordering columns it is typically of the same type as the ordering column, but for datetime ordering columns it is an interval. In all these cases, the value of the offset must be non-null and non-negative. Also, while the offset does not have to be a simple constant, it cannot contain variables, aggregate functions, or window functions.

The frame_exclusion option allows rows around the current row to be excluded from the frame, even if they would be included according to the frame start and frame end options. EXCLUDE CURRENT ROW excludes the current row from the frame. EXCLUDE GROUP excludes the current row and its ordering peers from the frame. EXCLUDE TIES excludes any peers of the current row from the frame, but not the current row itself. EXCLUDE NO OTHERS simply specifies explicitly the default behavior of not excluding the current row or its peers.

Beware that the ROWS mode can produce unpredictable results if the ORDER BY ordering does not order the rows uniquely. The RANGE and GROUPS modes are designed to ensure that rows that are peers in the ORDER BY ordering are treated alike: all rows of a given peer group will be in the frame or excluded from it.
SELECT

The purpose of a \textit{WINDOW} clause is to specify the behavior of \textit{window functions} appearing in the query's \texttt{SELECT} list or \texttt{ORDER BY} clause. These functions can reference the \texttt{WINDOW} clause entries by name in their \texttt{OVER} clauses. A \texttt{WINDOW} clause entry does not have to be referenced anywhere, however; if it is not used in the query it is simply ignored. It is possible to use window functions without any \texttt{WINDOW} clause at all, since a window function call can specify its window definition directly in its \texttt{OVER} clause. However, the \texttt{WINDOW} clause saves typing when the same window definition is needed for more than one window function.

Currently, \texttt{FOR NO KEY UPDATE}, \texttt{FOR UPDATE}, \texttt{FOR SHARE} and \texttt{FOR KEY SHARE} cannot be specified with \texttt{WINDOW}.

Window functions are described in detail in Section 3.5, Section 4.2.8, and Section 7.2.5.

\textbf{SELECT List}

The \texttt{SELECT} list (between the key words \texttt{SELECT} and \texttt{FROM}) specifies expressions that form the output rows of the \texttt{SELECT} statement. The expressions can (and usually do) refer to columns computed in the \texttt{FROM} clause.

Just as in a table, every output column of a \texttt{SELECT} has a name. In a simple \texttt{SELECT} this name is just used to label the column for display, but when the \texttt{SELECT} is a sub-query of a larger query, the name is seen by the larger query as the column name of the virtual table produced by the sub-query. To specify the name to use for an output column, write \texttt{AS output\_name} after the column's expression. (You can omit \texttt{AS}, but only if the desired output name does not match any PostgreSQL keyword (see Appendix C). For protection against possible future keyword additions, it is recommended that you always either write \texttt{AS} or double-quote the output name.) If you do not specify a column name, a name is chosen automatically by PostgreSQL. If the column's expression is a simple column reference then the chosen name is the same as that column's name. In more complex cases a function or type name may be used, or the system may fall back on a generated name such as \texttt{?column?}.

An output column's name can be used to refer to the column's value in \texttt{ORDER BY} and \texttt{GROUP BY} clauses, but not in the \texttt{WHERE} or \texttt{HAVING} clauses; there you must write out the expression instead.

Instead of an expression, \texttt{*} can be written in the output list as a shorthand for all the columns of the selected rows. Also, you can write \texttt{table\_name.}\texttt{*} as a shorthand for the columns coming from just that table. In these cases it is not possible to specify new names with \texttt{AS}; the output column names will be the same as the table columns' names.

According to the SQL standard, the expressions in the output list should be computed before applying \texttt{DISTINCT}, \texttt{ORDER BY}, or \texttt{LIMIT}. This is obviously necessary when using \texttt{DISTINCT}, since otherwise it's not clear what values are being made distinct. However, in many cases it is convenient if output expressions are computed after \texttt{ORDER BY} and \texttt{LIMIT}; particularly if the output list contains any volatile or expensive functions. With that behavior, the order of function evaluations is more intuitive and there will not be evaluations corresponding to rows that never appear in the output. PostgreSQL will effectively evaluate output expressions after sorting and limiting, so long as those expressions are not referenced in \texttt{DISTINCT}, \texttt{ORDER BY} or \texttt{GROUP BY}. (As a counterexample, \texttt{SELECT f(x) FROM tab ORDER BY 1} clearly must evaluate \( f(x) \) before sorting.) Output expressions that contain set-returning functions are effectively evaluated after sorting and before limiting, so that \texttt{LIMIT} will act to cut off the output from a set-returning function.

\textbf{Note}

PostgreSQL versions before 9.6 did not provide any guarantees about the timing of evaluation of output expressions versus sorting and limiting; it depended on the form of the chosen query plan.
**DISTINCT Clause**

If `SELECT DISTINCT` is specified, all duplicate rows are removed from the result set (one row is kept from each group of duplicates). `SELECT ALL` specifies the opposite: all rows are kept; that is the default.

`SELECT DISTINCT ON ( expression [, , ... ] )` keeps only the first row of each set of rows where the given expressions evaluate to equal. The `DISTINCT ON` expressions are interpreted using the same rules as for `ORDER BY` (see above). Note that the “first row” of each set is unpredictable unless `ORDER BY` is used to ensure that the desired row appears first. For example:

```
SELECT DISTINCT ON (location) location, time, report
  FROM weather_reports
  ORDER BY location, time DESC;
```

retrieves the most recent weather report for each location. But if we had not used `ORDER BY` to force descending order of time values for each location, we'd have gotten a report from an unpredictable time for each location.

The `DISTINCT ON` expression(s) must match the leftmost `ORDER BY` expression(s). The `ORDER BY` clause will normally contain additional expression(s) that determine the desired precedence of rows within each `DISTINCT ON` group.

Currently, `FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE` and `FOR KEY SHARE` cannot be specified with `DISTINCT`.

**UNION Clause**

The `UNION` clause has this general form:

```
select_statement UNION [ ALL | DISTINCT ] select_statement
```

`select_statement` is any `SELECT` statement without an `ORDER BY`, `LIMIT`, `FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE`, or `FOR KEY SHARE` clause. (`ORDER BY` and `LIMIT` can be attached to a subexpression if it is enclosed in parentheses. Without parentheses, these clauses will be taken to apply to the result of the `UNION`, not to its right-hand input expression.)

The `UNION` operator computes the set union of the rows returned by the involved `SELECT` statements. A row is in the set union of two result sets if it appears in at least one of the result sets. The two `SELECT` statements that represent the direct operands of the `UNION` must produce the same number of columns, and corresponding columns must be of compatible data types.

The result of `UNION` does not contain any duplicate rows unless the `ALL` option is specified. `ALL` prevents elimination of duplicates. (Therefore, `UNION ALL` is usually significantly quicker than `UNION`; use `ALL` when you can.) `DISTINCT` can be written to explicitly specify the default behavior of eliminating duplicate rows.

Multiple `UNION` operators in the same `SELECT` statement are evaluated left to right, unless otherwise indicated by parentheses.

Currently, `FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE` and `FOR KEY SHARE` cannot be specified either for a `UNION` result or for any input of a `UNION`.

**INTERSECT Clause**

The `INTERSECT` clause has this general form:
The `INTERSECT` operator computes the set intersection of the rows returned by the involved SELECT statements. A row is in the intersection of two result sets if it appears in both result sets.

The result of `INTERSECT` does not contain any duplicate rows unless the `ALL` option is specified. With `ALL`, a row that has \( m \) duplicates in the left table and \( n \) duplicates in the right table will appear \( \min(m,n) \) times in the result set. `DISTINCT` can be written to explicitly specify the default behavior of eliminating duplicate rows.

Multiple `INTERSECT` operators in the same SELECT statement are evaluated left to right, unless parentheses dictate otherwise. `INTERSECT` binds more tightly than `UNION`. That is, `A \cup B \cap C` will be read as `A \cup (B \cap C)`.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE` and `FOR KEY SHARE` cannot be specified either for an `INTERSECT` result or for any input of an `INTERSECT`.

**EXCEPT Clause**

The `EXCEPT` clause has this general form:

\[
\text{select_statement \ EXCEPT [ ALL | DISTINCT ] select_statement}
\]

`select_statement` is any SELECT statement without an ORDER BY, LIMIT, FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE, or FOR KEY SHARE clause.

The `EXCEPT` operator computes the set of rows that are in the result of the left SELECT statement but not in the result of the right one.

The result of `EXCEPT` does not contain any duplicate rows unless the `ALL` option is specified. With `ALL`, a row that has \( m \) duplicates in the left table and \( n \) duplicates in the right table will appear \( \max(m-n,0) \) times in the result set. `DISTINCT` can be written to explicitly specify the default behavior of eliminating duplicate rows.

Multiple `EXCEPT` operators in the same SELECT statement are evaluated left to right, unless parentheses dictate otherwise. `EXCEPT` binds at the same level as `UNION`.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE` and `FOR KEY SHARE` cannot be specified either for an `EXCEPT` result or for any input of an `EXCEPT`.

**ORDER BY Clause**

The optional ORDER BY clause has this general form:

\[
\text{ORDER BY expression [ ASC | DESC | USING operator ] [ NULLS { FIRST | LAST } ] [, ...]}
\]

The `ORDER BY` clause causes the result rows to be sorted according to the specified expression(s). If two rows are equal according to the leftmost expression, they are compared according to the next expression and so on. If they are equal according to all specified expressions, they are returned in an implementation-dependent order.
Each *expression* can be the name or ordinal number of an output column (SELECT list item), or it can be an arbitrary expression formed from input-column values.

The ordinal number refers to the ordinal (left-to-right) position of the output column. This feature makes it possible to define an ordering on the basis of a column that does not have a unique name. This is never absolutely necessary because it is always possible to assign a name to an output column using the AS clause.

It is also possible to use arbitrary expressions in the ORDER BY clause, including columns that do not appear in the SELECT output list. Thus the following statement is valid:

```
SELECT name FROM distributors ORDER BY code;
```

A limitation of this feature is that an ORDER BY clause applying to the result of a UNION, INTERSECT, or EXCEPT clause can only specify an output column name or number, not an expression.

If an ORDER BY expression is a simple name that matches both an output column name and an input column name, ORDER BY will interpret it as the output column name. This is the opposite of the choice that GROUP BY will make in the same situation. This inconsistency is made to be compatible with the SQL standard.

Optionally one can add the key word ASC (ascending) or DESC (descending) after any expression in the ORDER BY clause. If not specified, ASC is assumed by default. Alternatively, a specific ordering operator name can be specified in the USING clause. An ordering operator must be a less-than or greater-than member of some B-tree operator family. ASC is usually equivalent to USING < and DESC is usually equivalent to USING >. (But the creator of a user-defined data type can define exactly what the default sort ordering is, and it might correspond to operators with other names.)

If NULLS LAST is specified, null values sort after all non-null values; if NULLS FIRST is specified, null values sort before all non-null values. If neither is specified, the default behavior is NULLS LAST when ASC is specified or implied, and NULLS FIRST when DESC is specified (thus, the default is to act as though nulls are larger than non-nulls). When USING is specified, the default nulls ordering depends on whether the operator is a less-than or greater-than operator.

Note that ordering options apply only to the expression they follow; for example ORDER BY x, y DESC does not mean the same thing as ORDER BY x DESC, y DESC.

Character-string data is sorted according to the collation that applies to the column being sorted. That can be overridden at need by including a COLLATE clause in the expression, for example ORDER BY mycolumn COLLATE "en_US". For more information see Section 4.2.10 and Section 24.2.

**LIMIT Clause**

The LIMIT clause consists of two independent sub-clauses:

```
LIMIT  { count  |  ALL  }
OFFSET  start
```

The parameter `count` specifies the maximum number of rows to return, while `start` specifies the number of rows to skip before starting to return rows. When both are specified, `start` rows are skipped before starting to count the `count` rows to be returned.

If the `count` expression evaluates to NULL, it is treated as LIMIT ALL, i.e., no limit. If `start` evaluates to NULL, it is treated the same as OFFSET 0.
SELECT

SQL:2008 introduced a different syntax to achieve the same result, which PostgreSQL also supports. It is:

```
OFFSET start { ROW | ROWS }
FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } { ONLY | WITH TIES }
```

In this syntax, the `start` or `count` value is required by the standard to be a literal constant, a parameter, or a variable name; as a PostgreSQL extension, other expressions are allowed, but will generally need to be enclosed in parentheses to avoid ambiguity. If `count` is omitted in a `FETCH` clause, it defaults to 1. The `WITH TIES` option is used to return any additional rows that tie for the last place in the result set according to the `ORDER BY` clause; `ORDER BY` is mandatory in this case, and `SKIP LOCKED` is not allowed. `ROW` and `ROWS` as well as `FIRST` and `NEXT` are noise words that don't influence the effects of these clauses. According to the standard, the `OFFSET` clause must come before the `FETCH` clause if both are present; but PostgreSQL is laxer and allows either order.

When using `LIMIT`, it is a good idea to use an `ORDER BY` clause that constrains the result rows into a unique order. Otherwise you will get an unpredictable subset of the query's rows — you might be asking for the tenth through twentieth rows, but tenth through twentieth in what ordering? You don't know what ordering unless you specify `ORDER BY`.

The query planner takes `LIMIT` into account when generating a query plan, so you are very likely to get different plans (yielding different row orders) depending on what you use for `LIMIT` and `OFFSET`. Thus, using different `LIMIT/OFFSET` values to select different subsets of a query result will give inconsistent results unless you enforce a predictable result ordering with `ORDER BY`. This is not a bug; it is an inherent consequence of the fact that SQL does not promise to deliver the results of a query in any particular order unless `ORDER BY` is used to constrain the order.

It is even possible for repeated executions of the same `LIMIT` query to return different subsets of the rows of a table, if there is not an `ORDER BY` to enforce selection of a deterministic subset. Again, this is not a bug; determinism of the results is simply not guaranteed in such a case.

### The Locking Clause

```
FOR UPDATE, FOR NO KEY UPDATE, FOR SHARE and FOR KEY SHARE are locking clauses; they affect how SELECT locks rows as they are obtained from the table.
```

The locking clause has the general form

```
FOR lock_strength [ OF table_name [, ... ] ] [ NOWAIT | SKIP LOCKED ]
```

where `lock_strength` can be one of

```
UPDATE
NO KEY UPDATE
SHARE
KEY SHARE
```

For more information on each row-level lock mode, refer to Section 13.3.2.

To prevent the operation from waiting for other transactions to commit, use either the `NOWAIT` or `SKIP LOCKED` option. With `NOWAIT`, the statement reports an error, rather than waiting, if a selected row cannot be locked immediately. With `SKIP LOCKED`, any selected rows that cannot be immediately locked are skipped. Skipping locked rows provides an inconsistent view of the data, so this is not suitable for general
SELECT

purpose work, but can be used to avoid lock contention with multiple consumers accessing a queue-like table. Note that NOWAIT and SKIP LOCKED apply only to the row-level lock(s) — the required ROW SHARE table-level lock is still taken in the ordinary way (see Chapter 13). You can use LOCK with the NOWAIT option first, if you need to acquire the table-level lock without waiting.

If specific tables are named in a locking clause, then only rows coming from those tables are locked; any other tables used in the SELECT are simply read as usual. A locking clause without a table list affects all tables used in the statement. If a locking clause is applied to a view or sub-query, it affects all tables used in the view or sub-query. However, these clauses do not apply to WITH queries referenced by the primary query. If you want row locking to occur within a WITH query, specify a locking clause within the WITH query.

Multiple locking clauses can be written if it is necessary to specify different locking behavior for different tables. If the same table is mentioned (or implicitly affected) by more than one locking clause, then it is processed as if it was only specified by the strongest one. Similarly, a table is processed as NOWAIT if that is specified in any of the clauses affecting it. Otherwise, it is processed as SKIP LOCKED if that is specified in any of the clauses affecting it.

The locking clauses cannot be used in contexts where returned rows cannot be clearly identified with individual table rows; for example they cannot be used with aggregation.

When a locking clause appears at the top level of a SELECT query, the rows that are locked are exactly those that are returned by the query; in the case of a join query, the rows locked are those that contribute to returned join rows. In addition, rows that satisfied the query conditions as of the query snapshot will be locked, although they will not be returned if they were updated after the snapshot and no longer satisfy the query conditions. If a LIMIT is used, locking stops once enough rows have been returned to satisfy the limit (but note that rows skipped over by OFFSET will get locked). Similarly, if a locking clause is used in a cursor’s query, only rows actually fetched or stepped past by the cursor will be locked.

When a locking clause appears in a sub-SELECT, the rows locked are those returned to the outer query by the sub-query. This might involve fewer rows than inspection of the sub-query alone would suggest, since conditions from the outer query might be used to optimize execution of the sub-query. For example,

```
SELECT * FROM (SELECT * FROM mytable FOR UPDATE) ss WHERE col1 = 5;
```

will lock only rows having col1 = 5, even though that condition is not textually within the sub-query.

Previous releases failed to preserve a lock which is upgraded by a later savepoint. For example, this code:

```
BEGIN;
SELECT * FROM mytable WHERE key = 1 FOR UPDATE;
SAVEPOINT s;
UPDATE mytable SET ... WHERE key = 1;
ROLLBACK TO s;
```

would fail to preserve the FOR UPDATE lock after the ROLLBACK TO. This has been fixed in release 9.3.

Caution

It is possible for a SELECT command running at the READ COMMITTED transaction isolation level and using ORDER BY and a locking clause to return rows out of order. This is because ORDER BY is applied first. The command sorts the result, but might then block trying to obtain a lock on one or more of the rows. Once the SELECT unblocks, some of the ordering column values might
have been modified, leading to those rows appearing to be out of order (though they are in order in terms of the original column values). This can be worked around at need by placing the FOR UPDATE/SHARE clause in a sub-query, for example

```
SELECT * FROM (SELECT * FROM mytable FOR UPDATE) ss ORDER BY column1;
```

Note that this will result in locking all rows of mytable, whereas FOR UPDATE at the top level would lock only the actually returned rows. This can make for a significant performance difference, particularly if the ORDER BY is combined with LIMIT or other restrictions. So this technique is recommended only if concurrent updates of the ordering columns are expected and a strictly sorted result is required.

At the REPEATABLE READ or SERIALIZABLE transaction isolation level this would cause a serialization failure (with an SQLSTATE of '40001'), so there is no possibility of receiving rows out of order under these isolation levels.

### TABLE Command

The command

```
TABLE name
```

is equivalent to

```
SELECT * FROM name
```

It can be used as a top-level command or as a space-saving syntax variant in parts of complex queries. Only the WITH, UNION, INTERSECT, EXCEPT, ORDER BY, LIMIT, OFFSET, FETCH and FOR locking clauses can be used with TABLE; the WHERE clause and any form of aggregation cannot be used.

### Examples

To join the table films with the table distributors:

```
SELECT f.title, f.did, d.name, f.date_prod, f.kind
FROM distributors d, films f
WHERE f.did = d.did
```

<table>
<thead>
<tr>
<th>title</th>
<th>did</th>
<th>name</th>
<th>date_prod</th>
<th>kind</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Third Man</td>
<td>101</td>
<td>British Lion</td>
<td>1949-12-23</td>
<td>Drama</td>
</tr>
<tr>
<td>The African Queen</td>
<td>101</td>
<td>British Lion</td>
<td>1951-08-11</td>
<td>Romantic</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

To sum the column len of all films and group the results by kind:

```
SELECT kind, sum(len) AS total FROM films GROUP BY kind;
```
SELECT

<table>
<thead>
<tr>
<th>kind</th>
<th>total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action</td>
<td>07:34</td>
</tr>
<tr>
<td>Comedy</td>
<td>02:58</td>
</tr>
<tr>
<td>Drama</td>
<td>14:28</td>
</tr>
<tr>
<td>Musical</td>
<td>06:42</td>
</tr>
<tr>
<td>Romantic</td>
<td>04:38</td>
</tr>
</tbody>
</table>

To sum the column len of all films, group the results by kind and show those group totals that are less than 5 hours:

SELECT kind, sum(len) AS total
FROM films
GROUP BY kind
HAVING sum(len) < interval '5 hours';

<table>
<thead>
<tr>
<th>kind</th>
<th>total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Comedy</td>
<td>02:58</td>
</tr>
<tr>
<td>Romantic</td>
<td>04:38</td>
</tr>
</tbody>
</table>

The following two examples are identical ways of sorting the individual results according to the contents of the second column (name):

SELECT * FROM distributors ORDER BY name;
SELECT * FROM distributors ORDER BY 2;

did |       name
-----+------------------
109 | 20th Century Fox
110 | Bavaria Atelier
101 | British Lion
107 | Columbia
102 | Jean Luc Godard
113 | Luso films
104 | Mosfilm
103 | Paramount
106 | Toho
105 | United Artists
111 | Walt Disney
112 | Warner Bros.
108 | Westward

The next example shows how to obtain the union of the tables distributors and actors, restricting the results to those that begin with the letter W in each table. Only distinct rows are wanted, so the key word ALL is omitted.

distributors:               actors:
<table>
<thead>
<tr>
<th>did</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>108</td>
<td>Westward</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Woody Allen</td>
</tr>
</tbody>
</table>
SELECT distributors.name
    FROM distributors
    WHERE distributors.name LIKE 'W%'
UNION
SELECT actors.name
    FROM actors
    WHERE actors.name LIKE 'W%';

<table>
<thead>
<tr>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Walt Disney</td>
</tr>
<tr>
<td>Walter Matthau</td>
</tr>
<tr>
<td>Warner Bros.</td>
</tr>
<tr>
<td>Warren Beatty</td>
</tr>
<tr>
<td>Westward</td>
</tr>
<tr>
<td>Woody Allen</td>
</tr>
</tbody>
</table>

This example shows how to use a function in the FROM clause, both with and without a column definition list:

CREATE FUNCTION distributors(int) RETURNS SETOF distributors AS $$
    SELECT * FROM distributors WHERE did = $1;
$$ LANGUAGE SQL;

SELECT * FROM distributors(111);

<table>
<thead>
<tr>
<th>did</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>111</td>
<td>Walt Disney</td>
</tr>
</tbody>
</table>

CREATE FUNCTION distributors_2(int) RETURNS SETOF record AS $$
    SELECT * FROM distributors WHERE did = $1;
$$ LANGUAGE SQL;

SELECT * FROM distributors_2(111) AS (f1 int, f2 text);

<table>
<thead>
<tr>
<th>f1</th>
<th>f2</th>
</tr>
</thead>
<tbody>
<tr>
<td>111</td>
<td>Walt Disney</td>
</tr>
</tbody>
</table>

Here is an example of a function with an ordinality column added:

SELECT * FROM unnest(ARRAY['a','b','c','d','e','f']) WITH ORDINALITY;

<table>
<thead>
<tr>
<th>unnest</th>
<th>ordinality</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>1</td>
</tr>
<tr>
<td>b</td>
<td>2</td>
</tr>
<tr>
<td>c</td>
<td>3</td>
</tr>
<tr>
<td>d</td>
<td>4</td>
</tr>
<tr>
<td>e</td>
<td>5</td>
</tr>
<tr>
<td>f</td>
<td>6</td>
</tr>
</tbody>
</table>
This example shows how to use a simple WITH clause:

WITH t AS (
    SELECT random() as x FROM generate_series(1, 3)
)
SELECT * FROM t
UNION ALL
SELECT * FROM t

<table>
<thead>
<tr>
<th>x</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.534150459803641</td>
</tr>
<tr>
<td>0.520092216785997</td>
</tr>
<tr>
<td>0.0735620250925422</td>
</tr>
<tr>
<td>0.534150459803641</td>
</tr>
<tr>
<td>0.520092216785997</td>
</tr>
<tr>
<td>0.0735620250925422</td>
</tr>
</tbody>
</table>

Notice that the WITH query was evaluated only once, so that we got two sets of the same three random values.

This example uses WITH RECURSIVE to find all subordinates (direct or indirect) of the employee Mary, and their level of indirectness, from a table that shows only direct subordinates:

WITH RECURSIVE employee_recursive(distance, employee_name, manager_name) AS (
    SELECT 1, employee_name, manager_name
    FROM employee
    WHERE manager_name = 'Mary'
    UNION ALL
    SELECT er.distance + 1, e.employee_name, e.manager_name
    FROM employee_recursive er, employee e
    WHERE er.employee_name = e.manager_name
)
SELECT distance, employee_name FROM employee_recursive;

Notice the typical form of recursive queries: an initial condition, followed by UNION, followed by the recursive part of the query. Be sure that the recursive part of the query will eventually return no tuples, or else the query will loop indefinitely. (See Section 7.8 for more examples.)

This example uses LATERAL to apply a set-returning function get_product_names() for each row of the manufacturers table:

SELECT m.name AS mname, pname
FROM manufacturers m, LATERAL get_product_names(m.id) pname;

Manufacturers not currently having any products would not appear in the result, since it is an inner join. If we wished to include the names of such manufacturers in the result, we could do:

SELECT m.name AS mname, pname
FROM manufacturers m
Compatibility

Of course, the SELECT statement is compatible with the SQL standard. But there are some extensions and some missing features.

Omitted FROM Clauses

PostgreSQL allows one to omit the FROM clause. It has a straightforward use to compute the results of simple expressions:

```
SELECT 2+2;
```

<table>
<thead>
<tr>
<th>?column?</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
</tr>
</tbody>
</table>

Some other SQL databases cannot do this except by introducing a dummy one-row table from which to do the SELECT.

Empty SELECT Lists

The list of output expressions after SELECT can be empty, producing a zero-column result table. This is not valid syntax according to the SQL standard. PostgreSQL allows it to be consistent with allowing zero-column tables. However, an empty list is not allowed when DISTINCT is used.

Omitting the AS Key Word

In the SQL standard, the optional key word AS can be omitted before an output column name whenever the new column name is a valid column name (that is, not the same as any reserved keyword). PostgreSQL is slightly more restrictive: AS is required if the new column name matches any keyword at all, reserved or not. Recommended practice is to use AS or double-quote output column names, to prevent any possible conflict against future keyword additions.

In FROM items, both the standard and PostgreSQL allow AS to be omitted before an alias that is an unreserved keyword. But this is impractical for output column names, because of syntactic ambiguities.

ONLY and Inheritance

The SQL standard requires parentheses around the table name when writing ONLY, for example SELECT * FROM ONLY (tab1), ONLY (tab2) WHERE .... PostgreSQL considers these parentheses to be optional.

PostgreSQL allows a trailing * to be written to explicitly specify the non-ONLY behavior of including child tables. The standard does not allow this.

(These points apply equally to all SQL commands supporting the ONLY option.)

TABLESAMPLE Clause Restrictions

The TABLESAMPLE clause is currently accepted only on regular tables and materialized views. According to the SQL standard it should be possible to apply it to any FROM item.
Function Calls in \texttt{FROM}

PostgreSQL allows a function call to be written directly as a member of the \texttt{FROM} list. In the SQL standard it would be necessary to wrap such a function call in a sub-\texttt{SELECT}; that is, the syntax \texttt{FROM func(...)} \textit{alias} is approximately equivalent to \texttt{FROM LATERAL (SELECT func(...)) alias}. Note that \texttt{LATERAL} is considered to be implicit; this is because the standard requires \texttt{LATERAL} semantics for an \texttt{UNNEST()} item in \texttt{FROM}. PostgreSQL treats \texttt{UNNEST()} the same as other set-returning functions.

Namespace Available to \texttt{GROUP BY} and \texttt{ORDER BY}

In the SQL-92 standard, an \texttt{ORDER BY} clause can only use output column names or numbers, while a \texttt{GROUP BY} clause can only use expressions based on input column names. PostgreSQL extends each of these clauses to allow the other choice as well (but it uses the standard’s interpretation if there is ambiguity). PostgreSQL also allows both clauses to specify arbitrary expressions. Note that names appearing in an expression will always be taken as input-column names, not as output-column names.

SQL:1999 and later use a slightly different definition which is not entirely upward compatible with SQL-92. In most cases, however, PostgreSQL will interpret an \texttt{ORDER BY} or \texttt{GROUP BY} expression the same way SQL:1999 does.

Functional Dependencies

PostgreSQL recognizes functional dependency (allowing columns to be omitted from \texttt{GROUP BY}) only when a table’s primary key is included in the \texttt{GROUP BY} list. The SQL standard specifies additional conditions that should be recognized.

\texttt{LIMIT} and \texttt{OFFSET}

The clauses \texttt{LIMIT} and \texttt{OFFSET} are PostgreSQL-specific syntax, also used by MySQL. The SQL:2008 standard has introduced the clauses \texttt{OFFSET \ldots FETCH \{FIRST|NEXT\} \ldots} for the same functionality, as shown above in \texttt{LIMIT Clause}. This syntax is also used by IBM DB2. (Applications written for Oracle frequently use a workaround involving the automatically generated \texttt{rownum} column, which is not available in PostgreSQL, to implement the effects of these clauses.)

\texttt{FOR NO KEY UPDATE}, \texttt{FOR UPDATE}, \texttt{FOR SHARE}, \texttt{FOR KEY SHARE}

Although \texttt{FOR UPDATE} appears in the SQL standard, the standard allows it only as an option of \texttt{DECLARE CURSOR}. PostgreSQL allows it in any \texttt{SELECT} query as well as in sub-\texttt{SELECTs}, but this is an extension. The \texttt{FOR NO KEY UPDATE}, \texttt{FOR SHARE} and \texttt{FOR KEY SHARE} variants, as well as the \texttt{NOWAIT} and \texttt{SKIP LOCKED} options, do not appear in the standard.

Data-Modifying Statements in \texttt{WITH}

PostgreSQL allows \texttt{INSERT}, \texttt{UPDATE}, and \texttt{DELETE} to be used as \texttt{WITH} queries. This is not found in the SQL standard.

Nonstandard Clauses

\texttt{DISTINCT ON ( \ldots \ )} is an extension of the SQL standard.

\texttt{ROWS FROM ( \ldots \ )} is an extension of the SQL standard.

The \texttt{MATERIALIZED} and \texttt{NOT MATERIALIZED} options of \texttt{WITH} are extensions of the SQL standard.
SELECT INTO

SELECT INTO — define a new table from the results of a query

Synopsis

[ WITH [ RECURSIVE ] with_query [, ...] ]
SELECT [ ALL | DISTINCT [ ON ( expression [, ...] ) ] ]
* | expression [ [ AS ] output_name ] [, ...]
INTO [ TEMPORARY | TEMP | UNLOGGED ] [ TABLE ] new_table
[ FROM from_item [, ...] ]
[ WHERE condition ]
[ GROUP BY expression [, ...] ]
[ HAVING condition ]
[ WINDOW window_name AS ( window_definition ) [, ...] ]
[ { UNION | INTERSECT | EXCEPT } [ ALL | DISTINCT ] select ]
[ ORDER BY expression [ ASC | DESC | USING operator ] [ NULLS
FIRST | LAST ] [, ...] ]
[ LIMIT { count | ALL } ]
[ OFFSET start [ ROW | ROWS ] ]
[ FETCH { FIRST | NEXT } { count } { ROW | ROWS } ONLY ]
[ FOR { UPDATE | SHARE } [ OF table_name [, ...] ] [ NOWAIT ]
[ ... ] ]

Description

SELECT INTO creates a new table and fills it with data computed by a query. The data is not returned to the client, as it is with a normal SELECT. The new table's columns have the names and data types associated with the output columns of the SELECT.

Parameters

TEMPORARY or TEMP

If specified, the table is created as a temporary table. Refer to CREATE TABLE for details.

UNLOGGED

If specified, the table is created as an unlogged table. Refer to CREATE TABLE for details.

new_table

The name (optionally schema-qualified) of the table to be created.

All other parameters are described in detail under SELECT.

Notes

CREATE TABLE AS is functionally similar to SELECT INTO. CREATE TABLE AS is the recommended syntax, since this form of SELECT INTO is not available in ECPG or PL/pgSQL, because they interpret
the INTO clause differently. Furthermore, 

```sql
CREATE TABLE AS
```

offers a superset of the functionality provided by 

```sql
SELECT INTO
```

In contrast to 

```sql
CREATE TABLE AS
```

, 

```sql
SELECT INTO
```

does not allow specifying properties like a table's access method with 

```sql
USING method
```

or the table's tablespace with 

```sql
TABLESPACE tablespace_name
```

. Use 

```sql
CREATE TABLE AS
```

if necessary. Therefore, the default table access method is chosen for the new table. See 

```sql
default_table_access_method
```

for more information.

### Examples

Create a new table 

```sql
films_recent
```

consisting of only recent entries from the table 

```sql
films
```

:

```sql
SELECT * INTO films_recent FROM films WHERE date_prod >= '2002-01-01';
```

### Compatibility

The SQL standard uses 

```sql
SELECT INTO
```

to represent selecting values into scalar variables of a host program, rather than creating a new table. This indeed is the usage found in ECPG (see Chapter 36) and PL/pgSQL (see Chapter 43). The PostgreSQL usage of 

```sql
SELECT INTO
```

to represent table creation is historical. Some other SQL implementations also use 

```sql
SELECT INTO
```

in this way (but most SQL implementations support 

```sql
CREATE TABLE AS
```

instead). Apart from such compatibility considerations, it is best to use 

```sql
CREATE TABLE AS
```

for this purpose in new code.

CREATE TABLE AS
SET

SET — change a run-time parameter

Synopsis

```
SET [ SESSION | LOCAL ] configuration_parameter { TO | = } { value | 'value' | DEFAULT }
SET [ SESSION | LOCAL ] TIME_ZONE { timezone | LOCAL | DEFAULT }
```

Description

The SET command changes run-time configuration parameters. Many of the run-time parameters listed in Chapter 20 can be changed on-the-fly with SET. (Some parameters can only be changed by superusers and users who have been granted SET privilege on that parameter. There are also parameters that cannot be changed after server or session start.) SET only affects the value used by the current session.

If SET (or equivalently SET SESSION) is issued within a transaction that is later aborted, the effects of the SET command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another SET.

The effects of SET LOCAL last only till the end of the current transaction, whether committed or not. A special case is SET followed by SET LOCAL within a single transaction: the SET LOCAL value will be seen until the end of the transaction, but afterwards (if the transaction is committed) the SET value will take effect.

The effects of SET or SET LOCAL are also canceled by rolling back to a savepoint that is earlier than the command.

If SET LOCAL is used within a function that has a SET option for the same variable (see CREATE FUNCTION), the effects of the SET LOCAL command disappear at function exit; that is, the value in effect when the function was called is restored anyway. This allows SET LOCAL to be used for dynamic or repeated changes of a parameter within a function, while still having the convenience of using the SET option to save and restore the caller's value. However, a regular SET command overrides any surrounding function's SET option; its effects will persist unless rolled back.

Note

In PostgreSQL versions 8.0 through 8.2, the effects of a SET LOCAL would be canceled by releasing an earlier savepoint, or by successful exit from a PL/pgSQL exception block. This behavior has been changed because it was deemed unintuitive.

Parameters

SESSION

Specifies that the command takes effect for the current session. (This is the default if neither SESSION nor LOCAL appears.)
LOCAL

Specifies that the command takes effect for only the current transaction. After COMMIT or ROLL-BACK, the session-level setting takes effect again. Issuing this outside of a transaction block emits a warning and otherwise has no effect.

configuration_parameter

Name of a settable run-time parameter. Available parameters are documented in Chapter 20 and below.

value

New value of parameter. Values can be specified as string constants, identifiers, numbers, or comma-separated lists of these, as appropriate for the particular parameter. DEFAULT can be written to specify resetting the parameter to its default value (that is, whatever value it would have had if no SET had been executed in the current session).

Besides the configuration parameters documented in Chapter 20, there are a few that can only be adjusted using the SET command or that have a special syntax:

SCHEMA

SET SCHEMA 'value' is an alias for SET search_path TO value. Only one schema can be specified using this syntax.

NAMES

SET NAMES value is an alias for SET client_encoding TO value.

SEED

Sets the internal seed for the random number generator (the function random). Allowed values are floating-point numbers between -1 and 1, which are then multiplied by $2^{31}$ - 1.

The seed can also be set by invoking the function setseed:

SELECT setseed(value);

TIME ZONE

SET TIME ZONE value is an alias for SET timezone TO value. The syntax SET TIME ZONE allows special syntax for the time zone specification. Here are examples of valid values:

'PST8PDT'

The time zone for Berkeley, California.

'Europe/Rome'

The time zone for Italy.

-7

The time zone 7 hours west from UTC (equivalent to PDT). Positive values are east from UTC.
SET

INTERVAL '08:00' HOUR TO MINUTE

The time zone 8 hours west from UTC (equivalent to PST).

LOCAL
DEFAULT

Set the time zone to your local time zone (that is, the server's default value of timezone).

Timezone settings given as numbers or intervals are internally translated to POSIX timezone syntax. For example, after SET TIME ZONE -7, SHOW TIME ZONE would report <-07>+07.

See Section 8.5.3 for more information about time zones.

Notes

The function set_config provides equivalent functionality; see Section 9.27.1. Also, it is possible to UPDATE the pg_settings system view to perform the equivalent of SET.

Examples

Set the schema search path:

SET search_path TO my_schema, public;

Set the style of date to traditional POSTGRES with “day before month” input convention:

SET datestyle TO postgres, dmy;

Set the time zone for Berkeley, California:

SET TIME ZONE 'PST8PDT';

Set the time zone for Italy:

SET TIME ZONE 'Europe/Rome';

Compatibility

SET TIME ZONE extends syntax defined in the SQL standard. The standard allows only numeric time zone offsets while PostgreSQL allows more flexible time-zone specifications. All other SET features are PostgreSQL extensions.

RESET, SHOW
SET CONSTRAINTS

SET CONSTRAINTS — set constraint check timing for the current transaction

Synopsis

SET CONSTRAINTS { ALL | name [, ...] } { DEFERRED | IMMEDIATE }

Description

SET CONSTRAINTS sets the behavior of constraint checking within the current transaction. IMMEDIATE constraints are checked at the end of each statement. DEFERRED constraints are not checked until transaction commit. Each constraint has its own IMMEDIATE or DEFERRED mode.

Upon creation, a constraint is given one of three characteristics: DEFERRABLE INITIALLY DEFERRED, DEFERRABLE INITIALLY IMMEDIATE, or NOT DEFERRABLE. The third class is always IMMEDIATE and is not affected by the SET CONSTRAINTS command. The first two classes start every transaction in the indicated mode, but their behavior can be changed within a transaction by SET CONSTRAINTS.

SET CONSTRAINTS with a list of constraint names changes the mode of just those constraints (which must all be deferrable). Each constraint name can be schema-qualified. The current schema search path is used to find the first matching name if no schema name is specified. SET CONSTRAINTS ALL changes the mode of all deferrable constraints.

When SET CONSTRAINTS changes the mode of a constraint from DEFERRED to IMMEDIATE, the new mode takes effect retroactively: any outstanding data modifications that would have been checked at the end of the transaction are instead checked during the execution of the SET CONSTRAINTS command. If any such constraint is violated, the SET CONSTRAINTS fails (and does not change the constraint mode). Thus, SET CONSTRAINTS can be used to force checking of constraints to occur at a specific point in a transaction.

Currently, only UNIQUE, PRIMARY KEY, REFERENCES (foreign key), and EXCLUDE constraints are affected by this setting. NOT NULL and CHECK constraints are always checked immediately when a row is inserted or modified (not at the end of the statement). Uniqueness and exclusion constraints that have not been declared DEFERRABLE are also checked immediately.

The firing of triggers that are declared as “constraint triggers” is also controlled by this setting — they fire at the same time that the associated constraint should be checked.

Notes

Because PostgreSQL does not require constraint names to be unique within a schema (but only per-table), it is possible that there is more than one match for a specified constraint name. In this case SET CONSTRAINTS will act on all matches. For a non-schema-qualified name, once a match or matches have been found in some schema in the search path, schemas appearing later in the path are not searched.

This command only alters the behavior of constraints within the current transaction. Issuing this outside of a transaction block emits a warning and otherwise has no effect.
Compatibility

This command complies with the behavior defined in the SQL standard, except for the limitation that, in PostgreSQL, it does not apply to NOT NULL and CHECK constraints. Also, PostgreSQL checks non-deferrable uniqueness constraints immediately, not at end of statement as the standard would suggest.
SET ROLE

SET ROLE — set the current user identifier of the current session

Synopsis

```
SET [ SESSION | LOCAL ] ROLE role_name
SET [ SESSION | LOCAL ] ROLE NONE
RESET ROLE
```

Description

This command sets the current user identifier of the current SQL session to be `role_name`. The role name can be written as either an identifier or a string literal. After `SET ROLE`, permissions checking for SQL commands is carried out as though the named role were the one that had logged in originally.

The specified `role_name` must be a role that the current session user is a member of. (If the session user is a superuser, any role can be selected.)

The `SESSION` and `LOCAL` modifiers act the same as for the regular `SET` command.

`SET ROLE NONE` sets the current user identifier to the current session user identifier, as returned by `session_user`. `RESET ROLE` sets the current user identifier to the connection-time setting specified by the command-line options, `ALTER ROLE`, or `ALTER DATABASE`, if any such settings exist. Otherwise, `RESET ROLE` sets the current user identifier to the current session user identifier. These forms can be executed by any user.

Notes

Using this command, it is possible to either add privileges or restrict one's privileges. If the session user role has the `INHERIT` attribute, then it automatically has all the privileges of every role that it could `SET ROLE` to; in this case `SET ROLE` effectively drops all the privileges assigned directly to the session user and to the other roles it is a member of, leaving only the privileges available to the named role. On the other hand, if the session user role has the `NOINHERIT` attribute, `SET ROLE` drops the privileges assigned directly to the session user and instead acquires the privileges available to the named role.

In particular, when a superuser chooses to `SET ROLE` to a non-superuser role, they lose their superuser privileges.

`SET ROLE` has effects comparable to `SET SESSION AUTHORIZATION`, but the privilege checks involved are quite different. Also, `SET SESSION AUTHORIZATION` determines which roles are allowable for later `SET ROLE` commands, whereas changing roles with `SET ROLE` does not change the set of roles allowed to a later `SET ROLE`.

`SET ROLE` does not process session variables as specified by the role's `ALTER ROLE` settings; this only happens during login.

`SET ROLE` cannot be used within a `SECURITY DEFINER` function.

Examples
SELECT SESSION_USER, CURRENT_USER;

| session_user | current_user |
|--------------+--------------|
| peter        | peter        |

SET ROLE 'paul';

SELECT SESSION_USER, CURRENT_USER;

<table>
<thead>
<tr>
<th>session_user</th>
<th>current_user</th>
</tr>
</thead>
<tbody>
<tr>
<td>peter</td>
<td>paul</td>
</tr>
</tbody>
</table>

**Compatibility**

PostgreSQL allows identifier syntax ("rolename"), while the SQL standard requires the role name to be written as a string literal. SQL does not allow this command during a transaction; PostgreSQL does not make this restriction because there is no reason to. The SESSION and LOCAL modifiers are a PostgreSQL extension, as is the RESET syntax.

**See Also**

SET SESSION AUTHORIZATION
SET SESSION AUTHORIZATION

SET SESSION AUTHORIZATION — set the session user identifier and the current user identifier of the current session

Synopsis

```sql
SET [ SESSION | LOCAL ] SESSION AUTHORIZATION user_name
SET [ SESSION | LOCAL ] SESSION AUTHORIZATION DEFAULT
RESET SESSION AUTHORIZATION
```

Description

This command sets the session user identifier and the current user identifier of the current SQL session to be `user_name`. The user name can be written as either an identifier or a string literal. Using this command, it is possible, for example, to temporarily become an unprivileged user and later switch back to being a superuser.

The session user identifier is initially set to be the (possibly authenticated) user name provided by the client. The current user identifier is normally equal to the session user identifier, but might change temporarily in the context of `SECURITY DEFINER` functions and similar mechanisms; it can also be changed by `SET ROLE`. The current user identifier is relevant for permission checking.

The session user identifier can be changed only if the initial session user (the `authenticated user`) had the superuser privilege. Otherwise, the command is accepted only if it specifies the authenticated user name.

The `SESSION` and `LOCAL` modifiers act the same as for the regular `SET` command.

The `DEFAULT` and `RESET` forms reset the session and current user identifiers to be the originally authenticated user name. These forms can be executed by any user.

Notes

`SET SESSION AUTHORIZATION` cannot be used within a `SECURITY DEFINER` function.

Examples

```sql
SELECT SESSION_USER, CURRENT_USER;

<table>
<thead>
<tr>
<th>session_user</th>
<th>current_user</th>
</tr>
</thead>
<tbody>
<tr>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>peter</td>
<td>peter</td>
</tr>
</tbody>
</table>

SET SESSION AUTHORIZATION 'paul';

SELECT SESSION_USER, CURRENT_USER;

<table>
<thead>
<tr>
<th>session_user</th>
<th>current_user</th>
</tr>
</thead>
<tbody>
<tr>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>--------------</td>
<td>--------------</td>
</tr>
</tbody>
</table>
```

2075
Compatibility

The SQL standard allows some other expressions to appear in place of the literal `user_name`, but these options are not important in practice. PostgreSQL allows identifier syntax (`"username"`), which SQL does not. SQL does not allow this command during a transaction; PostgreSQL does not make this restriction because there is no reason to. The `SESSION` and `LOCAL` modifiers are a PostgreSQL extension, as is the `RESET` syntax.

The privileges necessary to execute this command are left implementation-defined by the standard.

`SET ROLE`
SET TRANSACTION

SET TRANSACTION — set the characteristics of the current transaction

Synopsis

SET TRANSACTION  transaction_mode  [,  ...]
SET TRANSACTION  SNAPSHOT  snapshot_id
SET SESSION  CHARACTERISTICS  AS TRANSACTION  transaction_mode  [,  ...]

where  transaction_mode  is one of:

- ISOLATION  LEVEL  {  SERIALIZABLE  |  REPEATABLE  READ  |  READ  COMMITTED
- READ  UNCOMMITTED  }
- READ  WRITE  |  READ  ONLY
- [  NOT  ]  DEFERRABLE

Description

The  SET  TRANSACTION  command  sets  the  characteristics  of  the  current  transaction.  It  has  no  effect  on
any  subsequent  transactions.  SET  SESSION  CHARACTERISTICS  sets  the  default  transaction  charac-
teristics  for  subsequent  transactions  of  a  session.  These  defaults  can  be  overridden  by  SET  TRANSAC-
TION  for  an  individual  transaction.

The  available  transaction  characteristics  are  the  transaction  isolation  level,  the  transaction  access  mode
(read/write  or  read-only),  and  the  deferrable  mode.  In  addition,  a  snapshot  can  be  selected,  though  only
for  the  current  transaction,  not  as  a  session  default.

The  isolation  level  of  a  transaction  determines  what  data  the  transaction  can  see  when  other  transactions
are  running  concurrently:

READ  COMMITTED

A  statement  can  only  see  rows  committed  before  it  began.  This  is  the  default.

REPEATABLE  READ

All  statements  of  the  current  transaction  can  only  see  rows  committed  before  the  first  query  or  da-
ta-modification  statement  was  executed  in  this  transaction.

SERIALIZABLE

All  statements  of  the  current  transaction  can  only  see  rows  committed  before  the  first  query  or  da-
ta-modification  statement  was  executed  in  this  transaction.  If  a  pattern  of  reads  and  writes  among
concurrent  serializable  transactions  would  create  a  situation  which  could  not  have  occurred  for  any
serial  (one-at-a-time)  execution  of  those  transactions,  one  of  them  will  be  rolled  back  with  a  seri-
alization_failure  error.

The  SQL  standard  defines  one  additional  level,  READ  UNCOMMITTED.  In  PostgreSQL  READ  UNCOM-
MITTED  is  treated  as  READ  COMMITTED.
The transaction isolation level cannot be changed after the first query or data-modification statement (SELECT, INSERT, DELETE, UPDATE, FETCH, or COPY) of a transaction has been executed. See Chapter 13 for more information about transaction isolation and concurrency control.

The transaction access mode determines whether the transaction is read/write or read-only. Read/write is the default. When a transaction is read-only, the following SQL commands are disallowed: INSERT, UPDATE, DELETE, and COPY FROM if the table they would write to is not a temporary table; all CREATE, ALTER, and DROP commands; COMMENT, GRANT, REVOKE, TRUNCATE; and EXPLAIN ANALYZE and EXECUTE if the command they would execute is among those listed. This is a high-level notion of read-only that does not prevent all writes to disk.

The DEFERRABLE transaction property has no effect unless the transaction is also SERIALIZABLE and READ ONLY. When all three of these properties are selected for a transaction, the transaction may block when first acquiring its snapshot, after which it is able to run without the normal overhead of a SERIALIZABLE transaction and without any risk of contributing to or being canceled by a serialization failure. This mode is well suited for long-running reports or backups.

The SET TRANSACTION_SNAPSHOT command allows a new transaction to run with the same snapshot as an existing transaction. The pre-existing transaction must have exported its snapshot with the pg_export_snapshot function (see Section 9.27.5). That function returns a snapshot identifier, which must be given to SET TRANSACTION SNAPSHOT to specify which snapshot is to be imported. The identifier must be written as a string literal in this command, for example '000003A1-1'. SET TRANSACTION_SNAPSHOT can only be executed at the start of a transaction, before the first query or data-modification statement (SELECT, INSERT, DELETE, UPDATE, FETCH, or COPY) of the transaction. Furthermore, the transaction must already be set to SERIALIZABLE or REPEATABLE_READ isolation level (otherwise, the snapshot would be discarded immediately, since READ_COMMITTED mode takes a new snapshot for each command). If the importing transaction uses SERIALIZABLE isolation level, then the transaction that exported the snapshot must also use that isolation level. Also, a non-read-only serializable transaction cannot import a snapshot from a read-only transaction.

Notes

If SET TRANSACTION is executed without a prior START TRANSACTION or BEGIN, it emits a warning and otherwise has no effect.

It is possible to dispense with SET TRANSACTION by instead specifying the desired transaction_modes in BEGIN or START TRANSACTION. But that option is not available for SET TRANSACTION_SNAPSHOT.

The session default transaction modes can also be set or examined via the configuration parameters default_transaction_isolation, default_transaction_read_only, and default_transaction_deferrable. (In fact SET SESSION CHARACTERISTICS is just a verbose equivalent for setting these variables with SET.) This means the defaults can be set in the configuration file, via ALTER DATABASE, etc. Consult Chapter 20 for more information.

The current transaction's modes can similarly be set or examined via the configuration parameters transaction_isolation, transaction_read_only, and transaction_deferrable. Setting one of these parameters acts the same as the corresponding SET TRANSACTION option, with the same restrictions on when it can be done. However, these parameters cannot be set in the configuration file, or from any source other than live SQL.

Examples

To begin a new transaction with the same snapshot as an already existing transaction, first export the snapshot from the existing transaction. That will return the snapshot identifier, for example:
BEGIN TRANSACTION ISOLATION LEVEL REPEATABLE READ;
SELECT pg_export_snapshot();
pg_export_snapshot
-------------
00000003-0000001B-1
(1 row)

Then give the snapshot identifier in a SET TRANSACTION SNAPSHOT command at the beginning of the newly opened transaction:

BEGIN TRANSACTION ISOLATION LEVEL REPEATABLE READ;
SET TRANSACTION SNAPSHOT '00000003-0000001B-1';

Compatibility

These commands are defined in the SQL standard, except for the DEFERRABLE transaction mode and the SET TRANSACTION SNAPSHOT form, which are PostgreSQL extensions.

SERIALIZABLE is the default transaction isolation level in the standard. In PostgreSQL the default is ordinarily READ COMMITTED, but you can change it as mentioned above.

In the SQL standard, there is one other transaction characteristic that can be set with these commands: the size of the diagnostics area. This concept is specific to embedded SQL, and therefore is not implemented in the PostgreSQL server.

The SQL standard requires commas between successive transaction_modes, but for historical reasons PostgreSQL allows the commas to be omitted.
SHOW

SHOW — show the value of a run-time parameter

Synopsis

SHOW name
SHOW ALL

Description

SHOW will display the current setting of run-time parameters. These variables can be set using the SET statement, by editing the postgresql.conf configuration file, through the PGOPTIONS environmental variable (when using libpq or a libpq-based application), or through command-line flags when starting the postgres server. See Chapter 20 for details.

Parameters

name

The name of a run-time parameter. Available parameters are documented in Chapter 20 and on the SET reference page. In addition, there are a few parameters that can be shown but not set:

SERVER_VERSION

Shows the server's version number.

SERVER_ENCODING

Shows the server-side character set encoding. At present, this parameter can be shown but not set, because the encoding is determined at database creation time.

LC_COLLATE

Shows the database's locale setting for collation (text ordering). At present, this parameter can be shown but not set, because the setting is determined at database creation time.

LC_CTYPE

Shows the database's locale setting for character classification. At present, this parameter can be shown but not set, because the setting is determined at database creation time.

IS_SUPERUSER

True if the current role has superuser privileges.

ALL

Show the values of all configuration parameters, with descriptions.

Notes

The function current_setting produces equivalent output; see Section 9.27.1. Also, the pg_settings system view produces the same information.
Examples

Show the current setting of the parameter DateStyle:

```sql
SHOW DateStyle;
DateStyle
-----------
ISO, MDY
(1 row)
```

Show the current setting of the parameter geqo:

```sql
SHOW geqo;
geqo
------
on
(1 row)
```

Show all settings:

```sql
SHOW ALL;
+---------------------------------+-------+----------------------------------+
| name                            | setting | description                      |
+---------------------------------+-------+----------------------------------+
| allow_system_table_mods         | off    | Allows modifications of the      |
|                                 |        | structure of ...                 |
| xmloption                       | content| Sets whether XML data in implicit|
| parsing ...                     |        |                                 |
| zero_damaged_pages              | off    | Continues processing past damaged|
| page headers.                  |        |                                 |
+---------------------------------+-------+----------------------------------+
(196 rows)
```

Compatibility

The `SHOW` command is a PostgreSQL extension.

`SET`, `RESET`
START TRANSACTION

START TRANSACTION — start a transaction block

Synopsis

START TRANSACTION [ transaction_mode [, ...] ]

where transaction_mode is one of:

    ISOLATION LEVEL { SERIALIZABLE | REPEATABLE READ | READ COMMITTED
                 | READ UNCOMMITTED }
    READ WRITE | READ ONLY
    [ NOT ] DEFERRABLE

Description

This command begins a new transaction block. If the isolation level, read/write mode, or deferrable mode is specified, the new transaction has those characteristics, as if SET TRANSACTION was executed. This is the same as the BEGIN command.

Parameters

Refer to SET TRANSACTION for information on the meaning of the parameters to this statement.

Compatibility

In the standard, it is not necessary to issue START TRANSACTION to start a transaction block: any SQL command implicitly begins a block. PostgreSQL's behavior can be seen as implicitly issuing a COMMIT after each command that does not follow START TRANSACTION (or BEGIN), and it is therefore often called “autocommit”. Other relational database systems might offer an autocommit feature as a convenience.

The DEFERRABLE transaction_mode is a PostgreSQL language extension.

The SQL standard requires commas between successive transaction_modes, but for historical reasons PostgreSQL allows the commas to be omitted.

See also the compatibility section of SET TRANSACTION.

TRUNCATE

TRUNCATE — empty a table or set of tables

Synopsis

TRUNCATE [ TABLE ] [ ONLY ] name [ * ] [, ... ]
   [ RESTART IDENTITY | CONTINUE IDENTITY ] [ CASCADE | RESTRICT ]

Description

TRUNCATE quickly removes all rows from a set of tables. It has the same effect as an unqualified DELETE on each table, but since it does not actually scan the tables it is faster. Furthermore, it reclaims disk space immediately, rather than requiring a subsequent VACUUM operation. This is most useful on large tables.

Parameters

name

The name (optionally schema-qualified) of a table to truncate. If ONLY is specified before the table name, only that table is truncated. If ONLY is not specified, the table and all its descendant tables (if any) are truncated. Optionally, * can be specified after the table name to explicitly indicate that descendant tables are included.

RESTART IDENTITY

Automatically restart sequences owned by columns of the truncated table(s).

CONTINUE IDENTITY

Do not change the values of sequences. This is the default.

CASCADE

Automatically truncate all tables that have foreign-key references to any of the named tables, or to any tables added to the group due to CASCADE.

RESTRICT

Refuse to truncate if any of the tables have foreign-key references from tables that are not listed in the command. This is the default.

Notes

You must have the TRUNCATE privilege on a table to truncate it.

TRUNCATE acquires an ACCESS EXCLUSIVE lock on each table it operates on, which blocks all other concurrent operations on the table. When RESTART IDENTITY is specified, any sequences that are to be restarted are likewise locked exclusively. If concurrent access to a table is required, then the DELETE command should be used instead.
TRUNCATE cannot be used on a table that has foreign-key references from other tables, unless all such tables are also truncated in the same command. Checking validity in such cases would require table scans, and the whole point is not to do one. The CASCADE option can be used to automatically include all dependent tables — but be very careful when using this option, or else you might lose data you did not intend to! Note in particular that when the table to be truncated is a partition, siblings partitions are left untouched, but cascading occurs to all referencing tables and all their partitions with no distinction.

TRUNCATE will not fire any ON DELETE triggers that might exist for the tables. But it will fire ON TRUNCATE triggers. If ON TRUNCATE triggers are defined for any of the tables, then all BEFORE TRUNCATE triggers are fired before any truncation happens, and all AFTER TRUNCATE triggers are fired after the last truncation is performed and any sequences are reset. The triggers will fire in the order that the tables are to be processed (first those listed in the command, and then any that were added due to cascading).

TRUNCATE is not MVCC-safe. After truncation, the table will appear empty to concurrent transactions, if they are using a snapshot taken before the truncation occurred. See Section 13.6 for more details.

TRUNCATE is transaction-safe with respect to the data in the tables: the truncation will be safely rolled back if the surrounding transaction does not commit.

When RESTART IDENTITY is specified, the implied ALTER SEQUENCE RESTART operations are also done transactionally; that is, they will be rolled back if the surrounding transaction does not commit. Be aware that if any additional sequence operations are done on the restarted sequences before the transaction rolls back, the effects of these operations on the sequences will be rolled back, but not their effects on currval(); that is, after the transaction currval() will continue to reflect the last sequence value obtained inside the failed transaction, even though the sequence itself may no longer be consistent with that. This is similar to the usual behavior of currval() after a failed transaction.

TRUNCATE can be used for foreign tables if supported by the foreign data wrapper, for instance, see postgres_fdw.

Examples

Truncate the tables bigtable and fattable:

```
TRUNCATE bigtable, fattable;
```

The same, and also reset any associated sequence generators:

```
TRUNCATE bigtable, fattable RESTART IDENTITY;
```

Truncate the table othertable, and cascade to any tables that reference othertable via foreign-key constraints:

```
TRUNCATE othertable CASCADE;
```

Compatibility

The SQL:2008 standard includes a TRUNCATE command with the syntax TRUNCATE TABLE table-name. The clauses CONTINUE IDENTITY/RESTART IDENTITY also appear in that standard, but have slightly different though related meanings. Some of the concurrency behavior of this command is left implementation-defined by the standard, so the above notes should be considered and compared with other implementations if necessary.

DELETE
UNLISTEN

UNLISTEN — stop listening for a notification

Synopsis

UNLISTEN { channel | * }

Description

UNLISTEN is used to remove an existing registration for NOTIFY events. UNLISTEN cancels any existing registration of the current PostgreSQL session as a listener on the notification channel named channel. The special wildcard * cancels all listener registrations for the current session.

NOTIFY contains a more extensive discussion of the use of LISTEN and NOTIFY.

Parameters

channel

Name of a notification channel (any identifier).

* 

All current listen registrations for this session are cleared.

Notes

You can unlisten something you were not listening for; no warning or error will appear.

At the end of each session, UNLISTEN * is automatically executed.

A transaction that has executed UNLISTEN cannot be prepared for two-phase commit.

Examples

To make a registration:

LISTEN virtual;
NOTIFY virtual;
Asynchronous notification "virtual" received from server process with PID 8448.

Once UNLISTEN has been executed, further NOTIFY messages will be ignored:

UNLISTEN virtual;
NOTIFY virtual;
-- no NOTIFY event is received
Compatibility

There is no UNLISTEN command in the SQL standard.

See Also

LISTEN, NOTIFY
UPDATE

UPDATE — update rows of a table

Synopsis

[ WITH [ RECURSIVE ] with_query [, ...] ]
UPDATE [ ONLY ] table_name [ * ] [ [ AS ] alias ]
    SET { column_name = { expression | DEFAULT } |
        ( column_name [, ...] ) = [ ROW ] ( { expression | DEFAULT } |
        [, ...] ) |
        ( column_name [, ...] ) = ( sub-SELECT )
    } [, ...]
    [ FROM from_item [, ...] ]
    [ WHERE condition | WHERE CURRENT OF cursor_name ]
    [ RETURNING * | output_expression [ [ AS ] output_name ] [, ... ] ]

Description

UPDATE changes the values of the specified columns in all rows that satisfy the condition. Only the columns to be modified need be mentioned in the SET clause; columns not explicitly modified retain their previous values.

There are two ways to modify a table using information contained in other tables in the database: using sub-selects, or specifying additional tables in the FROM clause. Which technique is more appropriate depends on the specific circumstances.

The optional RETURNING clause causes UPDATE to compute and return value(s) based on each row actually updated. Any expression using the table's columns, and/or columns of other tables mentioned in FROM, can be computed. The new (post-update) values of the table's columns are used. The syntax of the RETURNING list is identical to that of the output list of SELECT.

You must have the UPDATE privilege on the table, or at least on the column(s) that are listed to be updated. You must also have the SELECT privilege on any column whose values are read in the expressions or condition.

Parameters

with_query

The WITH clause allows you to specify one or more subqueries that can be referenced by name in the UPDATE query. See Section 7.8 and SELECT for details.

table_name

The name (optionally schema-qualified) of the table to update. If ONLY is specified before the table name, matching rows are updated in the named table only. If ONLY is not specified, matching rows are also updated in any tables inheriting from the named table. Optionally, * can be specified after the table name to explicitly indicate that descendant tables are included.
**UPDATE**

**alias**

A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given `UPDATE foo AS f`, the remainder of the UPDATE statement must refer to this table as `f` not `foo`.

**column_name**

The name of a column in the table named by `table_name`. The column name can be qualified with a subfield name or array subscript, if needed. Do not include the table's name in the specification of a target column — for example, `UPDATE table_name SET table_name.col = 1` is invalid.

**expression**

An expression to assign to the column. The expression can use the old values of this and other columns in the table.

**DEFAULT**

Set the column to its default value (which will be NULL if no specific default expression has been assigned to it). An identity column will be set to a new value generated by the associated sequence. For a generated column, specifying this is permitted but merely specifies the normal behavior of computing the column from its generation expression.

**sub-SELECT**

A `SELECT` sub-query that produces as many output columns as are listed in the parenthesized column list preceding it. The sub-query must yield no more than one row when executed. If it yields one row, its column values are assigned to the target columns; if it yields no rows, NULL values are assigned to the target columns. The sub-query can refer to old values of the current row of the table being updated.

**from_item**

A table expression allowing columns from other tables to appear in the WHERE condition and update expressions. This uses the same syntax as the FROM clause of a SELECT statement; for example, an alias for the table name can be specified. Do not repeat the target table as a from_item unless you intend a self-join (in which case it must appear with an alias in the from_item).

**condition**

An expression that returns a value of type boolean. Only rows for which this expression returns true will be updated.

**cursor_name**

The name of the cursor to use in a WHERE CURRENT OF condition. The row to be updated is the one most recently fetched from this cursor. The cursor must be a non-grouping query on the UPDATE's target table. Note that WHERE CURRENT OF cannot be specified together with a Boolean condition. See DECLARE for more information about using cursors with WHERE CURRENT OF.

**output_expression**

An expression to be computed and returned by the UPDATE command after each row is updated. The expression can use any column names of the table named by `table_name` or table(s) listed in FROM. Write * to return all columns.

**output_name**

A name to use for a returned column.
**Outputs**

On successful completion, an `UPDATE` command returns a command tag of the form

```
UPDATE count
```

The `count` is the number of rows updated, including matched rows whose values did not change. Note that the number may be less than the number of rows that matched the `condition` when updates were suppressed by a `BEFORE UPDATE` trigger. If `count` is 0, no rows were updated by the query (this is not considered an error).

If the `UPDATE` command contains a `RETURNING` clause, the result will be similar to that of a `SELECT` statement containing the columns and values defined in the `RETURNING` list, computed over the row(s) updated by the command.

**Notes**

When a `FROM` clause is present, what essentially happens is that the target table is joined to the tables mentioned in the `from_item` list, and each output row of the join represents an update operation for the target table. When using `FROM` you should ensure that the join produces at most one output row for each row to be modified. In other words, a target row shouldn't join to more than one row from the other table(s). If it does, then only one of the join rows will be used to update the target row, but which one will be used is not readily predictable.

Because of this indeterminacy, referencing other tables only within sub-selects is safer, though often harder to read and slower than using a join.

In the case of a partitioned table, updating a row might cause it to no longer satisfy the partition constraint of the containing partition. In that case, if there is some other partition in the partition tree for which this row satisfies its partition constraint, then the row is moved to that partition. If there is no such partition, an error will occur. Behind the scenes, the row movement is actually a `DELETE` and `INSERT` operation.

There is a possibility that a concurrent `UPDATE` or `DELETE` on the row being moved will get a serialization failure error. Suppose session 1 is performing an `UPDATE` on a partition key, and meanwhile a concurrent session 2 for which this row is visible performs an `UPDATE` or `DELETE` operation on this row. In such case, session 2's `UPDATE` or `DELETE` will detect the row movement and raise a serialization failure error (which always returns with an SQLSTATE code `40001`). Applications may wish to retry the transaction if this occurs. In the usual case where the table is not partitioned, or where there is no row movement, session 2 would have identified the newly updated row and carried out the `UPDATE/DELETE` on this new row version.

Note that while rows can be moved from local partitions to a foreign-table partition (provided the foreign data wrapper supports tuple routing), they cannot be moved from a foreign-table partition to another partition.

An attempt of moving a row from one partition to another will fail if a foreign key is found to directly reference an ancestor of the source partition that is not the same as the ancestor that's mentioned in the `UPDATE` query.

**Examples**

Change the word `Drama` to `Dramatic` in the column `kind` of the table `films`:  

---

2090
UPDATE films SET kind = 'Dramatic' WHERE kind = 'Drama';

Adjust temperature entries and reset precipitation to its default value in one row of the table weather:

UPDATE weather SET temp_lo = temp_lo+1, temp_hi = temp_lo+15, prcp = DEFAULT
WHERE city = 'San Francisco' AND date = '2003-07-03';

Perform the same operation and return the updated entries:

UPDATE weather SET temp_lo = temp_lo+1, temp_hi = temp_lo+15, prcp = DEFAULT
WHERE city = 'San Francisco' AND date = '2003-07-03'
RETURNING temp_lo, temp_hi, prcp;

Use the alternative column-list syntax to do the same update:

UPDATE weather SET (temp_lo, temp_hi, prcp) = (temp_lo+1, temp_lo+15, DEFAULT)
WHERE city = 'San Francisco' AND date = '2003-07-03';

Increment the sales count of the salesperson who manages the account for Acme Corporation, using the FROM clause syntax:

UPDATE employees SET sales_count = sales_count + 1 FROM accounts
WHERE accounts.name = 'Acme Corporation'
AND employees.id = accounts.sales_person;

Perform the same operation, using a sub-select in the WHERE clause:

UPDATE employees SET sales_count = sales_count + 1 WHERE id =
(SELECT sales_person FROM accounts WHERE name = 'Acme Corporation');

Update contact names in an accounts table to match the currently assigned salespeople:

UPDATE accounts SET (contact_first_name, contact_last_name) =
(SELECT first_name, last_name FROM employees
WHERE employees.id = accounts.sales_person);

A similar result could be accomplished with a join:

UPDATE accounts SET contact_first_name = first_name,
contact_last_name = last_name
FROM employees WHERE employees.id = accounts.sales_person;

However, the second query may give unexpected results if employees.id is not a unique key, whereas the first query is guaranteed to raise an error if there are multiple id matches. Also, if there is no match for a particular accounts.sales_person entry, the first query will set the corresponding name fields to NULL, whereas the second query will not update that row at all.
Update statistics in a summary table to match the current data:

```sql
UPDATE summary s SET (sum_x, sum_y, avg_x, avg_y) =
    (SELECT sum(x), sum(y), avg(x), avg(y) FROM data d
     WHERE d.group_id = s.group_id);
```

Attempt to insert a new stock item along with the quantity of stock. If the item already exists, instead update the stock count of the existing item. To do this without failing the entire transaction, use savepoints:

```sql
BEGIN;
-- other operations
SAVEPOINT sp1;
INSERT INTO wines VALUES('Chateau Lafite 2003', '24');
-- Assume the above fails because of a unique key violation,
-- so now we issue these commands:
ROLLBACK TO sp1;
UPDATE wines SET stock = stock + 24 WHERE winename = 'Chateau Lafite 2003';
-- continue with other operations, and eventually
COMMIT;
```

Change the `kind` column of the table `films` in the row on which the cursor `c_films` is currently positioned:

```sql
UPDATE films SET kind = 'Dramatic' WHERE CURRENT OF c_films;
```

**Compatibility**

This command conforms to the SQL standard, except that the `FROM` and `RETURNING` clauses are PostgreSQL extensions, as is the ability to use `WITH` with `UPDATE`.

Some other database systems offer a `FROM` option in which the target table is supposed to be listed again within `FROM`. That is not how PostgreSQL interprets `FROM`. Be careful when porting applications that use this extension.

According to the standard, the source value for a parenthesized sub-list of target column names can be any row-valued expression yielding the correct number of columns. PostgreSQL only allows the source value to be a row constructor or a sub-`SELECT`. An individual column's updated value can be specified as `DEFAULT` in the row-constructor case, but not inside a sub-`SELECT`.

2092
VACUUM

VACUUM — garbage-collect and optionally analyze a database

Synopsis

VACUUM [ ( option [, ...] ) ] [ table_and_columns [, ...] ]
VACUUM [ FULL ] [ FREEZE ] [ VERBOSE ] [ ANALYZE ] [ table_and_columns [, ...] ]

where option can be one of:

FULL [ boolean ]
FREEZE [ boolean ]
VERBOSE [ boolean ]
ANALYZE [ boolean ]
DISABLE_PAGE_SKIPPING [ boolean ]
SKIP_LOCKED [ boolean ]
INDEX_CLEANUP { AUTO | ON | OFF }
PROCESS_TOAST [ boolean ]
TRUNCATE [ boolean ]
PARALLEL integer

and table_and_columns is:

table_name [ ( column_name [, ...] ) ]

Description

VACUUM reclaims storage occupied by dead tuples. In normal PostgreSQL operation, tuples that are deleted or obsoleted by an update are not physically removed from their table; they remain present until a VACUUM is done. Therefore it’s necessary to do VACUUM periodically, especially on frequently-updated tables.

Without a table_and_columns list, VACUUM processes every table and materialized view in the current database that the current user has permission to vacuum. With a list, VACUUM processes only those table(s).

VACUUM ANALYZE performs a VACUUM and then an ANALYZE for each selected table. This is a handy combination form for routine maintenance scripts. See ANALYZE for more details about its processing.

Plain VACUUM (without FULL) simply reclaims space and makes it available for re-use. This form of the command can operate in parallel with normal reading and writing of the table, as an exclusive lock is not obtained. However, extra space is not returned to the operating system (in most cases); it’s just kept available for re-use within the same table. It also allows us to leverage multiple CPUs in order to process indexes. This feature is known as parallel vacuum. To disable this feature, one can use PARALLEL option and specify parallel workers as zero. VACUUM FULL rewrites the entire contents of the table into a new disk file with no extra space, allowing unused space to be returned to the operating system. This form is much slower and requires an ACCESS EXCLUSIVE lock on each table while it is being processed.

When the option list is surrounded by parentheses, the options can be written in any order. Without parentheses, options must be specified in exactly the order shown above. The parenthesized syntax was added in PostgreSQL 9.0; the unparenthesized syntax is deprecated.
**Parameters**

**FULL**

Selects “full” vacuum, which can reclaim more space, but takes much longer and exclusively locks the table. This method also requires extra disk space, since it writes a new copy of the table and doesn't release the old copy until the operation is complete. Usually this should only be used when a significant amount of space needs to be reclaimed from within the table.

**FREEZE**

Selects aggressive “freezing” of tuples. Specifying `FREEZE` is equivalent to performing `VACUUM` with the `vacuum_freeze_min_age` and `vacuum_freeze_table_age` parameters set to zero. Aggressive freezing is always performed when the table is rewritten, so this option is redundant when `FULL` is specified.

**VERBOSE**

Prints a detailed vacuum activity report for each table.

**ANALYZE**

Updates statistics used by the planner to determine the most efficient way to execute a query.

**DISABLE_PAGE_SKIPPING**

Normally, `VACUUM` will skip pages based on the visibility map. Pages where all tuples are known to be frozen can always be skipped, and those where all tuples are known to be visible to all transactions may be skipped except when performing an aggressive vacuum. Furthermore, except when performing an aggressive vacuum, some pages may be skipped in order to avoid waiting for other sessions to finish using them. This option disables all page-skipping behavior, and is intended to be used only when the contents of the visibility map are suspect, which should happen only if there is a hardware or software issue causing database corruption.

**SKIP_LOCKED**

Specifies that `VACUUM` should not wait for any conflicting locks to be released when beginning work on a relation; if a relation cannot be locked immediately without waiting, the relation is skipped. Note that even with this option, `VACUUM` may still block when opening the relation's indexes. Additionally, `VACUUM ANALYZE` may still block when acquiring sample rows from partitions, table inheritance children, and some types of foreign tables. Also, while `VACUUM` ordinarily processes all partitions of specified partitioned tables, this option will cause `VACUUM` to skip all partitions if there is a conflicting lock on the partitioned table.

**INDEX_CLEANUP**

Normally, `VACUUM` will skip index vacuuming when there are very few dead tuples in the table. The cost of processing all of the table's indexes is expected to greatly exceed the benefit of removing dead index tuples when this happens. This option can be used to force `VACUUM` to process indexes when there are more than zero dead tuples. The default is `AUTO`, which allows `VACUUM` to skip index vacuuming when appropriate. If `INDEX_CLEANUP` is set to `ON`, `VACUUM` will conservatively remove all dead tuples from indexes. This may be useful for backwards compatibility with earlier releases of PostgreSQL where this was the standard behavior.

`INDEX_CLEANUP` can also be set to `OFF` to force `VACUUM` to *always* skip index vacuuming, even when there are many dead tuples in the table. This may be useful when it is necessary to make `VACUUM`
run as quickly as possible to avoid imminent transaction ID wraparound (see Section 25.1.5). However, the wraparound failsafe mechanism controlled by vacuum_failsafe_age will generally trigger automatically to avoid transaction ID wraparound failure, and should be preferred. If index cleanup is not performed regularly, performance may suffer, because as the table is modified indexes will accumulate dead tuples and the table itself will accumulate dead line pointers that cannot be removed until index cleanup is completed.

This option has no effect for tables that have no index and is ignored if the FULL option is used. It also has no effect on the transaction ID wraparound failsafe mechanism. When triggered it will skip index vacuuming, even when INDEX_CLEANUP is set to ON.

**PROCESS_TOAST**

Specifies that VACUUM should attempt to process the corresponding TOAST table for each relation, if one exists. This is usually the desired behavior and is the default. Setting this option to false may be useful when it is only necessary to vacuum the main relation. This option is required when the FULL option is used.

**TRUNCATE**

Specifies that VACUUM should attempt to truncate off any empty pages at the end of the table and allow the disk space for the truncated pages to be returned to the operating system. This is normally the desired behavior and is the default unless the vacuum_truncate option has been set to false for the table to be vacuumed. Setting this option to false may be useful to avoid ACCESS EXCLUSIVE lock on the table that the truncation requires. This option is ignored if the FULL option is used.

**PARALLEL**

Perform index vacuum and index cleanup phases of VACUUM in parallel using integer background workers (for the details of each vacuum phase, please refer to Table 28.41). The number of workers used to perform the operation is equal to the number of indexes on the relation that support parallel vacuum which is limited by the number of workers specified with PARALLEL option if any which is further limited by max_parallel_maintenance_workers. An index can participate in parallel vacuum if and only if the size of the index is more than min_parallel_index_scan_size. Please note that it is not guaranteed that the number of parallel workers specified in integer will be used during execution. It is possible for a vacuum to run with fewer workers than specified, or even with no workers at all. Only one worker can be used per index. So parallel workers are launched only when there are at least 2 indexes in the table. Workers for vacuum are launched before the start of each phase and exit at the end of the phase. These behaviors might change in a future release. This option can't be used with the FULL option.

**boolean**

Specifies whether the selected option should be turned on or off. You can write TRUE, ON, or 1 to enable the option, and FALSE, OFF, or 0 to disable it. The boolean value can also be omitted, in which case TRUE is assumed.

**integer**

Specifies a non-negative integer value passed to the selected option.

**table_name**

The name (optionally schema-qualified) of a specific table or materialized view to vacuum. If the specified table is a partitioned table, all of its leaf partitions are vacuumed.

VACUUM

column_name

The name of a specific column to analyze. Defaults to all columns. If a column list is specified, ANALYZE must also be specified.

Outputs

When VERBOSE is specified, VACUUM emits progress messages to indicate which table is currently being processed. Various statistics about the tables are printed as well.

Notes

To vacuum a table, one must ordinarily be the table’s owner or a superuser. However, database owners are allowed to vacuum all tables in their databases, except shared catalogs. (The restriction for shared catalogs means that a true database-wide VACUUM can only be performed by a superuser.) VACUUM will skip over any tables that the calling user does not have permission to vacuum.

VACUUM cannot be executed inside a transaction block.

For tables with GIN indexes, VACUUM (in any form) also completes any pending index insertions, by moving pending index entries to the appropriate places in the main GIN index structure. See Section 69.4.1 for details.

We recommend that all databases be vacuumed regularly in order to remove dead rows. PostgreSQL includes an “autovacuum” facility which can automate routine vacuum maintenance. For more information about automatic and manual vacuuming, see Section 25.1.

The FULL option is not recommended for routine use, but might be useful in special cases. An example is when you have deleted or updated most of the rows in a table and would like the table to physically shrink to occupy less disk space and allow faster table scans. VACUUM FULL will usually shrink the table more than a plain VACUUM would.

The PARALLEL option is used only for vacuum purposes. If this option is specified with the ANALYZE option, it does not affect ANALYZE.

VACUUM causes a substantial increase in I/O traffic, which might cause poor performance for other active sessions. Therefore, it is sometimes advisable to use the cost-based vacuum delay feature. For parallel vacuum, each worker sleeps in proportion to the work done by that worker. See Section 20.4.4 for details.

Each backend running VACUUM without the FULL option will report its progress in the pg_stat_progress_vacuum view. Backends running VACUUM FULL will instead report their progress in the pg_stat_progress_cluster view. See Section 28.4.3 and Section 28.4.4 for details.

Examples

To clean a single table onek, analyze it for the optimizer and print a detailed vacuum activity report:

VACUUM (VERBOSE, ANALYZE) onek;

Compatibility

There is no VACUUM statement in the SQL standard.

VALUES

VALUES — compute a set of rows

Synopsis

VALUES ( expression [, ...] ) [, ...]
[ ORDER BY sort_expression [ ASC | DESC | USING operator ]
[, ...] ]
[ LIMIT { count | ALL } ]
[ OFFSET start [ ROW | ROWS ] ]
[ FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } ONLY ]

Description

VALUES computes a row value or set of row values specified by value expressions. It is most commonly used to generate a “constant table” within a larger command, but it can be used on its own.

When more than one row is specified, all the rows must have the same number of elements. The data types of the resulting table’s columns are determined by combining the explicit or inferred types of the expressions appearing in that column, using the same rules as for UNION (see Section 10.5).

Within larger commands, VALUES is syntactically allowed anywhere that SELECT is. Because it is treated like a SELECT by the grammar, it is possible to use the ORDER BY, LIMIT (or equivalently FETCH FIRST), and OFFSET clauses with a VALUES command.

Parameters

equation

expression

A constant or expression to compute and insert at the indicated place in the resulting table (set of rows). In a VALUES list appearing at the top level of an INSERT, an expression can be replaced by DEFAULT to indicate that the destination column’s default value should be inserted. DEFAULT cannot be used when VALUES appears in other contexts.

sort_expression

An expression or integer constant indicating how to sort the result rows. This expression can refer to the columns of the VALUES result as column1, column2, etc. For more details see ORDER BY Clause in the SELECT documentation.

operator

A sorting operator. For details see ORDER BY Clause in the SELECT documentation.

count

The maximum number of rows to return. For details see LIMIT Clause in the SELECT documentation.

start

The number of rows to skip before starting to return rows. For details see LIMIT Clause in the SELECT documentation.
Notes

VALUES lists with very large numbers of rows should be avoided, as you might encounter out-of-memory failures or poor performance. VALUES appearing within INSERT is a special case (because the desired column types are known from the INSERT's target table, and need not be inferred by scanning the VALUES list), so it can handle larger lists than are practical in other contexts.

Examples

A bare VALUES command:

VALUES (1, 'one'), (2, 'two'), (3, 'three');

This will return a table of two columns and three rows. It's effectively equivalent to:

SELECT 1 AS column1, 'one' AS column2
UNION ALL
SELECT 2, 'two'
UNION ALL
SELECT 3, 'three';

More usually, VALUES is used within a larger SQL command. The most common use is in INSERT:

INSERT INTO films (code, title, did, date_prod, kind)
VALUES ('T_601', 'Yojimbo', 106, '1961-06-16', 'Drama');

In the context of INSERT, entries of a VALUES list can be DEFAULT to indicate that the column default should be used here instead of specifying a value:

INSERT INTO films VALUES
('UA502', 'Bananas', 105, DEFAULT, 'Comedy', '82 minutes'),
('T_601', 'Yojimbo', 106, DEFAULT, 'Drama', DEFAULT);

VALUES can also be used where a sub-SELECT might be written, for example in a FROM clause:

SELECT f.*
FROM films f, (VALUES('MGM', 'Horror'), ('UA', 'Sci-Fi')) AS t (studio, kind)
WHERE f.studio = t.studio AND f.kind = t.kind;

UPDATE employees SET salary = salary * v.increase
FROM (VALUES(1, 200000, 1.2), (2, 400000, 1.4)) AS v (depno, target, increase)
WHERE employees.depno = v.depno AND employees.sales >= v.target;

Note that an AS clause is required when VALUES is used in a FROM clause, just as is true for SELECT. It is not required that the AS clause specify names for all the columns, but it's good practice to do so. (The default column names for VALUES are column1, column2, etc. in PostgreSQL, but these names might be different in other database systems.)
When \texttt{VALUES} is used in \texttt{INSERT}, the values are all automatically coerced to the corresponding destination column. When it's used in other contexts, it might be necessary to specify the correct data type. If the entries are all quoted literal constants, coercing the first is sufficient to determine the assumed type for all:

\begin{verbatim}
SELECT * FROM machines
WHERE ip_address IN (VALUES('192.168.0.1'::inet), ('192.168.0.10'), ('192.168.1.43'));
\end{verbatim}

\textbf{Tip}

For simple \texttt{IN} tests, it's better to rely on the list-of-scalars form of \texttt{IN} than to write a \texttt{VALUES} query as shown above. The list of scalars method requires less writing and is often more efficient.

\section*{Compatibility}

\texttt{VALUES} conforms to the SQL standard. \texttt{LIMIT} and \texttt{OFFSET} are PostgreSQL extensions; see also under \texttt{SELECT}.

\section*{See Also}

\texttt{INSERT}, \texttt{SELECT}
PostgreSQL Client Applications

This part contains reference information for PostgreSQL client applications and utilities. Not all of these commands are of general utility; some might require special privileges. The common feature of these applications is that they can be run on any host, independent of where the database server resides.

When specified on the command line, user and database names have their case preserved — the presence of spaces or special characters might require quoting. Table names and other identifiers do not have their case preserved, except where documented, and might require quoting.

clusterdb

clusterdb — cluster a PostgreSQL database

Synopsis

clusterdb[connection-option...][--verbose|-v][--table|--table=table][dbname]
clusterdb[connection-option...][--verbose|-v][--all|--all]-a

Description

clusterdb is a utility for reclustering tables in a PostgreSQL database. It finds tables that have previously been clustered, and clusters them again on the same index that was last used. Tables that have never been clustered are not affected.

clusterdb is a wrapper around the SQL command CLUSTER. There is no effective difference between clustering databases via this utility and via other methods for accessing the server.

Options

clusterdb accepts the following command-line arguments:

-a
--all

Cluster all databases.

[-d] dbname
[--dbname=] dbname

Specifies the name of the database to be clustered, when -a|--all is not used. If this is not specified, the database name is read from the environment variable PGDATABASE. If that is not set, the user name specified for the connection is used. The dbname can be a connection string. If so, connection string parameters will override any conflicting command line options.

-e
--echo

Echo the commands that clusterdb generates and sends to the server.

-q
--quiet

Do not display progress messages.

-t table
--table=table

Cluster table only. Multiple tables can be clustered by writing multiple -t switches.
clusterdb

- \( v \) 
  \(--\text{verbose}\) 
  Print detailed information during processing.

- \( V \) 
  \(--\text{version}\) 
  Print the clusterdb version and exit.

- \( \text{-?} \) 
  \(--\text{help}\) 
  Show help about clusterdb command line arguments, and exit.

cclusterdb also accepts the following command-line arguments for connection parameters:

- \( \text{-h host} \) 
  \(--\text{host}\text{=}\text{host}\) 
  Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

- \( \text{-p port} \) 
  \(--\text{port}\text{=}\text{port}\) 
  Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

- \( \text{-U username} \) 
  \(--\text{username}\text{=}\text{username}\) 
  User name to connect as.

- \( \text{-w} \) 
  \(--\text{no-password}\) 
  Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

- \( \text{-W} \) 
  \(--\text{password}\) 
  Force clusterdb to prompt for a password before connecting to a database.

  This option is never essential, since clusterdb will automatically prompt for a password if the server demands password authentication. However, clusterdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing \(-W\) to avoid the extra connection attempt.

- \( \text{--maintenance-db}\text{=}\text{dbname}\) 
  Specifies the name of the database to connect to to discover which databases should be clustered, when \(-a\|--\text{all}\) is used. If not specified, the postgres database will be used, or if that does not exist, template1 will be used. This can be a connection string. If so, connection string parameters will override any conflicting command line options. Also, connection string parameters other than the database name itself will be re-used when connecting to other databases.
Environment

PGDATABASE
PGHOST
PGPORT
PGUSER

  Default connection parameters

PG_COLOR

  Specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 34.15).

Diagnostics

In case of difficulty, see CLUSTER and psql for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Examples

To cluster the database test:

$ clusterdb test

To cluster a single table foo in a database named xyzzy:

$ clusterdb --table=foo xyzzy

See Also

CLUSTER
createdb

createdb — create a new PostgreSQL database

Synopsis

createdb [connection-option...] [option...] [dbname [description]]

Description

createdb creates a new PostgreSQL database.

Normally, the database user who executes this command becomes the owner of the new database. How-
ever, a different owner can be specified via the \(-O\) option, if the executing user has appropriate privileges.

createdb is a wrapper around the SQL command CREATE DATABASE. There is no effective difference between creating databases via this utility and via other methods for accessing the server.

Options

createdb accepts the following command-line arguments:

dbname

Specifies the name of the database to be created. The name must be unique among all PostgreSQL databases in this cluster. The default is to create a database with the same name as the current system user.

description

Specifies a comment to be associated with the newly created database.

-D tablespace
--tablespace=tablespace

Specifies the default tablespace for the database. (This name is processed as a double-quoted identi-
fier.)

-e
--echo

Echo the commands that createdb generates and sends to the server.

-E encoding
--encoding=encoding

Specifies the character encoding scheme to be used in this database. The character sets supported by the PostgreSQL server are described in Section 24.3.1.

-l locale
--locale=locale

Specifies the locale to be used in this database. This is equivalent to specifying both --lc-collate and --lc-ctype.
--lc-collate=locale

Specifies the LC_COLLATE setting to be used in this database.

--lc-ctype=locale

Specifies the LC_CTYPE setting to be used in this database.

--icu-locale=locale

Specifies the ICU locale ID to be used in this database, if the ICU locale provider is selected.

--locale-provider={libc|icu}

Specifies the locale provider for the database's default collation.

-o owner
--owner=owner

Specifies the database user who will own the new database. (This name is processed as a double-quoted identifier.)

-S template
--strategy=strategy

Specifies the database creation strategy. See CREATE DATABASE STRATEGY for more details.

-T template
--template=template

Specifies the template database from which to build this database. (This name is processed as a double-quoted identifier.)

-V
--version

Print the createdb version and exit.

-?
--help

Show help about createdb command line arguments, and exit.

The options -D, -I, -E, -O, and -T correspond to options of the underlying SQL command CREATE DATABASE; see there for more information about them.

createdb also accepts the following command-line arguments for connection parameters:

-h host
--host=host

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

-p port
--port=port

Specifies the TCP port or the local Unix domain socket file extension on which the server is listening for connections.
-U username
--username=username

User name to connect as.

-w
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W
--password

Force createdb to prompt for a password before connecting to a database.

This option is never essential, since createdb will automatically prompt for a password if the server demands password authentication. However, createdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

--maintenance-db=dbname

Specifies the name of the database to connect to when creating the new database. If not specified, the postgres database will be used; if that does not exist (or if it is the name of the new database being created), template1 will be used. This can be a connection string. If so, connection string parameters will override any conflicting command line options.

Environment

PGDATABASE

If set, the name of the database to create, unless overridden on the command line.

PGHOST
PGPORT
PGUSER

Default connection parameters. PGUSER also determines the name of the database to create, if it is not specified on the command line or by PGDATABASE.

PG_COLOR

Specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 34.15).

Diagnostics

In case of difficulty, see CREATE DATABASE and psql for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.
Examples

To create the database demo using the default database server:

$ createdb demo

To create the database demo using the server on host eden, port 5000, using the template0 template database, here is the command-line command and the underlying SQL command:

$ createdb -p 5000 -h eden -T template0 -e demo
CREATE DATABASE demo TEMPLATE template0;

See Also

dropdb, CREATE DATABASE
createuser

createuser — define a new PostgreSQL user account

Synopsis

createuser [connection-option...] [option...] [username]

Description

createuser creates a new PostgreSQL user (or more precisely, a role). Only superusers and users with
CREATEROLE privilege can create new users, so createuser must be invoked by someone who can connect
as a superuser or a user with CREATEROLE privilege.

If you wish to create a new superuser, you must connect as a superuser, not merely with CREATEROLE
privilege. Being a superuser implies the ability to bypass all access permission checks within the database,
so superuser access should not be granted lightly.

createuser is a wrapper around the SQL command CREATE ROLE. There is no effective difference be-
tween creating users via this utility and via other methods for accessing the server.

Options

createuser accepts the following command-line arguments:

username

Specifies the name of the PostgreSQL user to be created. This name must be different from all existing
roles in this PostgreSQL installation.

-c number
--connection-limit=number

Set a maximum number of connections for the new user. The default is to set no limit.

-d
--createdb

The new user will be allowed to create databases.

-D
--no-createdb

The new user will not be allowed to create databases. This is the default.

-e
--echo

Echo the commands that createuser generates and sends to the server.

-E
--encrypted

This option is obsolete but still accepted for backward compatibility.
createuser

-g role
--role=role

Indicates role to which this role will be added immediately as a new member. Multiple roles to which this role will be added as a member can be specified by writing multiple -g switches.

-i
--inherit

The new role will automatically inherit privileges of roles it is a member of. This is the default.

-I
--no-inherit

The new role will not automatically inherit privileges of roles it is a member of.

--interactive

Prompt for the user name if none is specified on the command line, and also prompt for whichever of the options -d/-D, -r/-R, -s/-S is not specified on the command line. (This was the default behavior up to PostgreSQL 9.1.)

-l
--login

The new user will be allowed to log in (that is, the user name can be used as the initial session user identifier). This is the default.

-L
--no-login

The new user will not be allowed to log in. (A role without login privilege is still useful as a means of managing database permissions.)

-P
--pwprompt

If given, createuser will issue a prompt for the password of the new user. This is not necessary if you do not plan on using password authentication.

-r
--createrole

The new user will be allowed to create new roles (that is, this user will have CREATEROLE privilege).

-R
--no-createrole

The new user will not be allowed to create new roles. This is the default.

-s
--superuser

The new user will be a superuser.

-S
--no-superuser

The new user will not be a superuser. This is the default.
-V
--version

Print the createuser version and exit.

--replication

The new user will have the REPLICATION privilege, which is described more fully in the documentation for CREATE ROLE.

--no-replication

The new user will not have the REPLICATION privilege, which is described more fully in the documentation for CREATE ROLE.

-?
--help

Show help about createuser command line arguments, and exit.

createuser also accepts the following command-line arguments for connection parameters:

-h host
--host=host

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

-p port
--port=port

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

-U username
--username=username

User name to connect as (not the user name to create).

-w
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W
--password

Force createuser to prompt for a password (for connecting to the server, not for the password of the new user).

This option is never essential, since createuser will automatically prompt for a password if the server demands password authentication. However, createuser will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.
Environment

PGHOST
PGPORT
PGUSER

Default connection parameters

PG_COLOR

Specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 34.15).

Diagnostics

In case of difficulty, see CREATE ROLE and psql for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Examples

To create a user joe on the default database server:

$ createuser joe

To create a user joe on the default database server with prompting for some additional attributes:

$ createuser --interactive joe
Shall the new role be a superuser? (y/n) n
Shall the new role be allowed to create databases? (y/n) n
Shall the new role be allowed to create more new roles? (y/n) n

To create the same user joe using the server on host eden, port 5000, with attributes explicitly specified, taking a look at the underlying command:

$ createuser -h eden -p 5000 -S -D -R -e joe
CREATE ROLE joe NOSUPERUSER NOCREATEDB NOCREATEROLE INHERIT LOGIN;

To create the user joe as a superuser, and assign a password immediately:

$ createuser -P -s -e joe
Enter password for new role: xyzzy
Enter it again: xyzzy
CREATE ROLE joe PASSWORD 'md5b5f5ba1a423792b526f799ae4eb3d59e' SUPERUSER CREATEDB CREATEROLE INHERIT LOGIN;

In the above example, the new password isn't actually echoed when typed, but we show what was typed for clarity. As you see, the password is encrypted before it is sent to the client.

dropuser, CREATE ROLE
**dropdb**

dropdb — remove a PostgreSQL database

**Synopsis**

dropdb [connection-option...][option...]{dbname}

**Description**

dropdb destroys an existing PostgreSQL database. The user who executes this command must be a database superuser or the owner of the database.

dropdb is a wrapper around the SQL command DROP DATABASE. There is no effective difference between dropping databases via this utility and via other methods for accessing the server.

**Options**

dropdb accepts the following command-line arguments:

*dbname*

  Specifies the name of the database to be removed.

*-e*  
--echo

  Echo the commands that dropdb generates and sends to the server.

*-f*  
--force

  Attempt to terminate all existing connections to the target database before dropping it. See DROP DATABASE for more information on this option.

*-i*  
--interactive

  Issues a verification prompt before doing anything destructive.

*-V*  
--version

  Print the dropdb version and exit.

--if-exists

  Do not throw an error if the database does not exist. A notice is issued in this case.

*-?*  
--help

  Show help about dropdb command line arguments, and exit.
dropdb also accepts the following command-line arguments for connection parameters:

- `-h host`
  `--host=host`

  Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

- `-p port`
  `--port=port`

  Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

- `-U username`
  `--username=username`

  User name to connect as.

- `-w`  
  `--no-password`

  Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

- `-W`  
  `--password`

  Force dropdb to prompt for a password before connecting to a database.

  This option is never essential, since dropdb will automatically prompt for a password if the server demands password authentication. However, dropdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

- `--maintenance-db=dbname`

  Specifies the name of the database to connect to in order to drop the target database. If not specified, the `postgres` database will be used; if that does not exist (or is the database being dropped), `template1` will be used. This can be a connection string. If so, connection string parameters will override any conflicting command line options.

### Environment

- `PGHOST`
- `PGPORT`
- `PGUSER`

  Default connection parameters

- `PG_COLOR`

  Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 34.15).
Diagnoses

In case of difficulty, see DROP DATABASE and psql for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Examples

To destroy the database demo on the default database server:

$ dropdb demo

To destroy the database demo using the server on host eden, port 5000, with verification and a peek at the underlying command:

$ dropdb -p 5000 -h eden -i -e demo
Database "demo" will be permanently deleted.
Are you sure? (y/n) y
DROP DATABASE demo;

createdb, DROP DATABASE
**dropuser**

dropuser — remove a PostgreSQL user account

**Synopsis**

```
dropuser [connection-option...] [option...] [username]
```

**Description**

dropuser removes an existing PostgreSQL user. Only superusers and users with the CREATEROLE privilege can remove PostgreSQL users. (To remove a superuser, you must yourself be a superuser.)

dropuser is a wrapper around the SQL command `DROP ROLE`. There is no effective difference between dropping users via this utility and via other methods for accessing the server.

**Options**

dropuser accepts the following command-line arguments:

- **username**
  Specifies the name of the PostgreSQL user to be removed. You will be prompted for a name if none is specified on the command line and the `-i/--interactive` option is used.

- **-e**
  --echo
  Echo the commands that dropuser generates and sends to the server.

- **-i**
  --interactive
  Prompt for confirmation before actually removing the user, and prompt for the user name if none is specified on the command line.

- **-V**
  --version
  Print the dropuser version and exit.

- **--if-exists**
  Do not throw an error if the user does not exist. A notice is issued in this case.

- **--help**
  Show help about dropuser command line arguments, and exit.

dropuser also accepts the following command-line arguments for connection parameters:
dropuser

-h host
--host=host

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

-p port
--port=port

 Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

-U username
--username=username

User name to connect as (not the user name to drop).

-w
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W
--password

Force dropuser to prompt for a password before connecting to a database.

This option is never essential, since dropuser will automatically prompt for a password if the server demands password authentication. However, dropuser will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

Environment

PGHOST
PGPORT
PGUSER

Default connection parameters

PG_COLOR

Specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 34.15).

Diagnostics

In case of difficulty, see DROP ROLE and psql for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.
Examples

To remove user *joe* from the default database server:

```
$ dropuser joe
```

To remove user *joe* using the server on host *eden*, port 5000, with verification and a peek at the underlying command:

```
$ dropuser -p 5000 -h eden -i -e joe
Role "joe" will be permanently removed.
Are you sure? (y/n) y
DROP ROLE joe;
```

createuser, DROP ROLE
**ecpg**

  ecpg — embedded SQL C preprocessor

**Synopsis**

  ecpg [option...] file...

**Description**

  ecpg is the embedded SQL preprocessor for C programs. It converts C programs with embedded SQL
  statements to normal C code by replacing the SQL invocations with special function calls. The output files
  can then be processed with any C compiler tool chain.

  ecpg will convert each input file given on the command line to the corresponding C output file. If an
  input file name does not have any extension, .pgc is assumed. The file's extension will be replaced by
  .c to construct the output file name. But the output file name can be overridden using the -o option.

  If an input file name is just -, ecpg reads the program from standard input (and writes to standard output,
  unless that is overridden with -o).

  This reference page does not describe the embedded SQL language. See Chapter 36 for more information
  on that topic.

**Options**

  ecpg accepts the following command-line arguments:

  -c

    Automatically generate certain C code from SQL code. Currently, this works for EXEC SQL TYPE.

  -C mode

    Set a compatibility mode. mode can be INFORMIX, INFORMIX_SE, or ORACLE.

  -D symbol

    Define a C preprocessor symbol.

  -h

    Process header files. When this option is specified, the output file extension becomes .h not .c, and
    the default input file extension is .pgh not .pgc. Also, the -c option is forced on.

  -i

    Parse system include files as well.

  -I directory

    Specify an additional include path, used to find files included via EXEC SQL INCLUDE. Defaults are
    . (current directory), /usr/local/include, the PostgreSQL include directory which is defined
    at compile time (default: /usr/local/pgsql/include), and /usr/include, in that order.
-o filename

Specifies that `ecpg` should write all its output to the given `filename`. Write `-o -` to send all output to standard output.

-r option

Selects run-time behavior. `Option` can be one of the following:

no_indicator

Do not use indicators but instead use special values to represent null values. Historically there have been databases using this approach.

prepare

Prepare all statements before using them. Libecpg will keep a cache of prepared statements and reuse a statement if it gets executed again. If the cache runs full, libecpg will free the least used statement.

questionmarks

Allow question mark as placeholder for compatibility reasons. This used to be the default long ago.

-t

Turn on autocommit of transactions. In this mode, each SQL command is automatically committed unless it is inside an explicit transaction block. In the default mode, commands are committed only when `EXEC SQL COMMIT` is issued.

-v

Print additional information including the version and the "include" path.

--version

Print the `ecpg` version and exit.

-?

--help

Show help about `ecpg` command line arguments, and exit.

Notes

When compiling the preprocessed C code files, the compiler needs to be able to find the ECPG header files in the PostgreSQL include directory. Therefore, you might have to use the `-I` option when invoking the compiler (e.g., `-I/usr/local/pgsql/include`).

Programs using C code with embedded SQL have to be linked against the `libecpg` library, for example using the linker options `-L/usr/local/pgsql/lib -lecpg`.

The value of either of these directories that is appropriate for the installation can be found out using `pg_config`. 

2121
Examples

If you have an embedded SQL C source file named `prog1.pgc`, you can create an executable program using the following sequence of commands:

```
ecpg prog1.pgc
cc -I/usr/local/pgsql/include -c prog1.c
cc -o prog1 prog1.o -L/usr/local/pgsql/lib -lecpg
```
**pg_amcheck**

pg_amcheck — checks for corruption in one or more PostgreSQL databases

**Synopsis**

```
pg_amcheck [option...][dbname]
```

**Description**

pg_amcheck supports running amcheck's corruption checking functions against one or more databases, with options to select which schemas, tables and indexes to check, which kinds of checking to perform, and whether to perform the checks in parallel, and if so, the number of parallel connections to establish and use.

Only ordinary and toast table relations, materialized views, sequences, and btree indexes are currently supported. Other relation types are silently skipped.

If `dbname` is specified, it should be the name of a single database to check, and no other database selection options should be present. Otherwise, if any database selection options are present, all matching databases will be checked. If no such options are present, the default database will be checked. Database selection options include `--all`, `--database` and `--exclude-database`. They also include `--relation`, `--exclude-relation`, `--table`, `--exclude-table`, `--index`, and `--exclude-index`, but only when such options are used with a three-part pattern (e.g. `mydb*.myschema*.myrel*`). Finally, they include `--schema` and `--exclude-schema` when such options are used with a two-part pattern (e.g. `mydb*.myschema*`).

`dbname` can also be a connection string.

**Options**

The following command-line options control what is checked:

- `-a`
  `--all`

  Check all databases, except for any excluded via `--exclude-database`.

- `-d pattern`
  `--database=pattern`

  Check databases matching the specified `pattern`, except for any excluded by `--exclude-database`. This option can be specified more than once.

- `-D pattern`
  `--exclude-database=pattern`

  Exclude databases matching the given `pattern`. This option can be specified more than once.

- `-i pattern`
  `--index=pattern`

  Check indexes matching the specified `pattern`, unless they are otherwise excluded. This option can be specified more than once.
This is similar to the `--relation` option, except that it applies only to indexes, not to other relation types.

```
-I pattern
--exclude-index=pattern
```

Exclude indexes matching the specified `pattern`. This option can be specified more than once.

This is similar to the `--exclude-relation` option, except that it applies only to indexes, not other relation types.

```
-r pattern
--relation=pattern
```

Check relations matching the specified `pattern`, unless they are otherwise excluded. This option can be specified more than once.

Patterns may be unqualified, e.g. `myrel*`, or they may be schema-qualified, e.g. `myschema*.myrel*` or database-qualified and schema-qualified, e.g. `mydb*.myschema*.myrel*`. A database-qualified pattern will add matching databases to the list of databases to be checked.

```
-R pattern
--exclude-relation=pattern
```

Exclude relations matching the specified `pattern`. This option can be specified more than once.

As with `--relation`, the `pattern` may be unqualified, schema-qualified, or database- and schema-qualified.

```
-s pattern
--schema=pattern
```

Check tables and indexes in schemas matching the specified `pattern`, unless they are otherwise excluded. This option can be specified more than once.

To select only tables in schemas matching a particular pattern, consider using something like `--table=SCHEMAPAT.* --no-dependent-indexes`. To select only indexes, consider using something like `--index=SCHEMAPAT.*`.

A schema pattern may be database-qualified. For example, you may write `--schema=mydb*.myschema*` to select schemas matching `myschema*` in databases matching `mydb*`.

```
-S pattern
--exclude-schema=pattern
```

Exclude tables and indexes in schemas matching the specified `pattern`. This option can be specified more than once.

As with `--schema`, the pattern may be database-qualified.

```
-t pattern
--table=pattern
```

Check tables matching the specified `pattern`, unless they are otherwise excluded. This option can be specified more than once.
This is similar to the --relation option, except that it applies only to tables, materialized views, and sequences, not to indexes.

-T pattern
--exclude-table=pattern

Exclude tables matching the specified pattern. This option can be specified more than once.

This is similar to the --exclude-relation option, except that it applies only to tables, materialized views, and sequences, not to indexes.

--no-dependent-indexes

By default, if a table is checked, any btree indexes of that table will also be checked, even if they are not explicitly selected by an option such as --index or --relation. This option suppresses that behavior.

--no-dependent-toast

By default, if a table is checked, its toast table, if any, will also be checked, even if it is not explicitly selected by an option such as --table or --relation. This option suppresses that behavior.

--no-strict-names

By default, if an argument to --database, --table, --index, or --relation matches no objects, it is a fatal error. This option downgrades that error to a warning.

The following command-line options control checking of tables:

--exclude-toast-pointers

By default, whenever a toast pointer is encountered in a table, a lookup is performed to ensure that it references apparently-valid entries in the toast table. These checks can be quite slow, and this option can be used to skip them.

--on-error-stop

After reporting all corruptions on the first page of a table where corruption is found, stop processing that table relation and move on to the next table or index.

Note that index checking always stops after the first corrupt page. This option only has meaning relative to table relations.

--skip=option

If all-frozen is given, table corruption checks will skip over pages in all tables that are marked as all frozen.

If all-visible is given, table corruption checks will skip over pages in all tables that are marked as all visible.

By default, no pages are skipped. This can be specified as none, but since this is the default, it need not be mentioned.

--startblock=block

Start checking at the specified block number. An error will occur if the table relation being checked has fewer than this number of blocks. This option does not apply to indexes, and is probably only useful when checking a single table relation. See --endblock for further caveats.
--endblock=block

End checking at the specified block number. An error will occur if the table relation being checked has fewer than this number of blocks. This option does not apply to indexes, and is probably only useful when checking a single table relation. If both a regular table and a toast table are checked, this option will apply to both, but higher-numbered toast blocks may still be accessed while validating toast pointers, unless that is suppressed using --exclude-toast-pointers.

The following command-line options control checking of B-tree indexes:

--heapallindexed

For each index checked, verify the presence of all heap tuples as index tuples in the index using amcheck's heapallindexed option.

--parent-check

For each btree index checked, use amcheck's bt_index_parent_check function, which performs additional checks of parent/child relationships during index checking.

The default is to use amcheck's bt_index_check function, but note that use of the --rootdescend option implicitly selects bt_index_parent_check.

--rootdescend

For each index checked, re-find tuples on the leaf level by performing a new search from the root page for each tuple using amcheck's rootdescend option.

Use of this option implicitly also selects the --parent-check option.

This form of verification was originally written to help in the development of btree index features. It may be of limited use or even of no use in helping detect the kinds of corruption that occur in practice. It may also cause corruption checking to take considerably longer and consume considerably more resources on the server.

Warning

The extra checks performed against B-tree indexes when the --parent-check option or the --rootdescend option is specified require relatively strong relation-level locks. These checks are the only checks that will block concurrent data modification from INSERT, UPDATE, and DELETE commands.

The following command-line options control the connection to the server:

-h hostname
--host=hostname

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

-p port
--port=port

 Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.
pg_amcheck

-\texttt{U} \hspace{1cm} \texttt{--username=username}

User name to connect as.

-\texttt{w} \hspace{1cm} \texttt{--no-password}

Never issue a password prompt. If the server requires password authentication and a password is not
available by other means such as a \texttt{.pgpass} file, the connection attempt will fail. This option can
be useful in batch jobs and scripts where no user is present to enter a password.

-\texttt{W} \hspace{1cm} \texttt{--password}

Force \texttt{pg_amcheck} to prompt for a password before connecting to a database.

This option is never essential, since \texttt{pg_amcheck} will automatically prompt for a password if the server
demands password authentication. However, \texttt{pg_amcheck} will waste a connection attempt finding out
that the server wants a password. In some cases it is worth typing \texttt{-W} to avoid the extra connection
attempt.

\texttt{--maintenance-db=dbname}

Specifies a database or connection string to be used to discover the list of databases to be checked. If
neither \texttt{--all} nor any option including a database pattern is used, no such connection is required and
this option does nothing. Otherwise, any connection string parameters other than the database name
which are included in the value for this option will also be used when connecting to the databases
being checked. If this option is omitted, the default is \texttt{postgres} or, if that fails, \texttt{template1}.

Other options are also available:

-\texttt{e} \hspace{1cm} \texttt{--echo}

Echo to stdout all SQL sent to the server.

-\texttt{j num} \hspace{1cm} \texttt{--jobs=num}

Use \texttt{num} concurrent connections to the server, or one per object to be checked, whichever is less.

The default is to use a single connection.

-\texttt{p} \hspace{1cm} \texttt{--progress}

Show progress information. Progress information includes the number of relations for which checking
has been completed, and the total size of those relations. It also includes the total number of relations
that will eventually be checked, and the estimated size of those relations.

-\texttt{v} \hspace{1cm} \texttt{--verbose}

Print more messages. In particular, this will print a message for each relation being checked, and will
increase the level of detail shown for server errors.
-v
--version

Print the pg_amcheck version and exit.

--install-missing
--install-missing=\textit{schema}

Install any missing extensions that are required to check the database(s). If not yet installed, each extension's objects will be installed into the given \textit{schema}, or if not specified into schema \textit{pg_catalog}.

At present, the only required extension is \textit{amcheck}.

-?
--help

Show help about pg_amcheck command line arguments, and exit.

\textbf{Notes}

\textit{pg_amcheck} is designed to work with PostgreSQL 14.0 and later.

\textbf{See Also}

\textit{amcheck}
pg_basebackup

pg_basebackup — take a base backup of a PostgreSQL cluster

Synopsis

pg_basebackup [option...]

Description

pg_basebackup is used to take a base backup of a running PostgreSQL database cluster. The backup is taken without affecting other clients of the database, and can be used both for point-in-time recovery (see Section 26.3) and as the starting point for a log-shipping or streaming-replication standby server (see Section 27.2).

pg_basebackup makes an exact copy of the database cluster's files, while making sure the server is put into and out of backup mode automatically. Backups are always taken of the entire database cluster; it is not possible to back up individual databases or database objects. For selective backups, another tool such as pg_dump must be used.

The backup is made over a regular PostgreSQL connection that uses the replication protocol. The connection must be made with a user ID that has REPLICATION permissions (see Section 22.2) or is a superuser, and pg_hba.conf must permit the replication connection. The server must also be configured with max_wal_senders set high enough to provide at least one walsender for the backup plus one for WAL streaming (if used).

There can be multiple pg_basebackup running at the same time, but it is usually better from a performance point of view to take only one backup, and copy the result.

pg_basebackup can make a base backup from not only a primary server but also a standby. To take a backup from a standby, set up the standby so that it can accept replication connections (that is, set max_wal_senders and hot_standby, and configure its pg_hba.conf appropriately). You will also need to enable full_page_writes on the primary.

Note that there are some limitations in taking a backup from a standby:

• The backup history file is not created in the database cluster backed up.

• pg_basebackup cannot force the standby to switch to a new WAL file at the end of backup. When you are using -X none, if write activity on the primary is low, pg_basebackup may need to wait a long time for the last WAL file required for the backup to be switched and archived. In this case, it may be useful to run pg_switch_wal on the primary in order to trigger an immediate WAL file switch.

• If the standby is promoted to be primary during backup, the backup fails.

• All WAL records required for the backup must contain sufficient full-page writes, which requires you to enable full_page_writes on the primary and not to use a tool in your archive_library to remove full-page writes from WAL files.

Whenever pg_basebackup is taking a base backup, the server's pg_stat_progress_basebackup view will report the progress of the backup. See Section 28.4.5 for details.
Options

The following command-line options control the location and format of the output:

-D directory
--pgdata=directory

Sets the target directory to write the output to. pg_basebackup will create this directory (and any missing parent directories) if it does not exist. If it already exists, it must be empty.

When the backup is in tar format, the target directory may be specified as -- (dash), causing the tar file to be written to stdout.

This option is required.

-F format
--format=format

Selects the format for the output. format can be one of the following:

p
plain

Write the output as plain files, with the same layout as the source server's data directory and tablespaces. When the cluster has no additional tablespaces, the whole database will be placed in the target directory. If the cluster contains additional tablespaces, the main data directory will be placed in the target directory, but all other tablespaces will be placed in the same absolute path as they have on the source server. (See --tablespace-mapping to change that.)

This is the default format.

t
tar

Write the output as tar files in the target directory. The main data directory's contents will be written to a file named base.tar, and each other tablespace will be written to a separate tar file named after that tablespace's OID.

If the target directory is specified as -- (dash), the tar contents will be written to standard output, suitable for piping to (for example) gzip. This is only allowed if the cluster has no additional tablespaces and WAL streaming is not used.

-R
--write-recovery-conf

Creates a standby.signal file and appends connection settings to the postgresql.auto.conf file in the target directory (or within the base archive file when using tar format). This eases setting up a standby server using the results of the backup.

The postgresql.auto.conf file will record the connection settings and, if specified, the replication slot that pg_basebackup is using, so that streaming replication will use the same settings later on.

-t target
--target=target

Instructs the server where to place the base backup. The default target is client, which specifies that the backup should be sent to the machine where pg_basebackup is running. If the target is instead
set to server:/some/path, the backup will be stored on the machine where the server is running in the /some/path directory. Storing a backup on the server requires superuser privileges or having privileges of the pg_write_server_files role. If the target is set to blackhole, the contents are discarded and not stored anywhere. This should only be used for testing purposes, as you will not end up with an actual backup.

Since WAL streaming is implemented by pg_basebackup rather than by the server, this option cannot be used together with -Xstream. Since that is the default, when this option is specified, you must also specify either -Xfetch or -Xnone.

-T olddir=newdir
--tablespace-mapping=olddir=newdir

Relocates the tablespace in directory olddir to newdir during the backup. To be effective, olddir must exactly match the path specification of the tablespace as it is defined on the source server. (But it is not an error if there is no tablespace in olddir on the source server.) Meanwhile newdir is a directory in the receiving host's filesystem. As with the main target directory, newdir need not exist already, but if it does exist it must be empty. Both olddir and newdir must be absolute paths. If either path needs to contain an equal sign (=), precede that with a backslash. This option can be specified multiple times for multiple tablespaces.

If a tablespace is relocated in this way, the symbolic links inside the main data directory are updated to point to the new location. So the new data directory is ready to be used for a new server instance with all tablespaces in the updated locations.

Currently, this option only works with plain output format; it is ignored if tar format is selected.

--waldir=waldir

Sets the directory to write WAL (write-ahead log) files to. By default WAL files will be placed in the pg_wal subdirectory of the target directory, but this option can be used to place them elsewhere. waldir must be an absolute path. As with the main target directory, waldir need not exist already, but if it does exist it must be empty. This option can only be specified when the backup is in plain format.

-X method
--wal-method=method

Includes the required WAL (write-ahead log) files in the backup. This will include all write-ahead logs generated during the backup. Unless the method none is specified, it is possible to start a postmaster in the target directory without the need to consult the log archive, thus making the output a completely standalone backup.

The following methods for collecting the write-ahead logs are supported:

n
none

Don't include write-ahead logs in the backup.

f
fetch

The write-ahead log files are collected at the end of the backup. Therefore, it is necessary for the source server's wal_keep_size parameter to be set high enough that the required log data is not
removed before the end of the backup. If the required log data has been recycled before it's time to transfer it, the backup will fail and be unusable.

When tar format is used, the write-ahead log files will be included in the base.tar file.

s
stream

Stream write-ahead log data while the backup is being taken. This method will open a second connection to the server and start streaming the write-ahead log in parallel while running the backup. Therefore, it will require two replication connections not just one. As long as the client can keep up with the write-ahead log data, using this method requires no extra write-ahead logs to be saved on the source server.

When tar format is used, the write-ahead log files will be written to a separate file named pg_{wal}.tar (if the server is a version earlier than 10, the file will be named pg_xlog.tar).

This value is the default.

-z
--gzip

Enables gzip compression of tar file output, with the default compression level. Compression is only available when using the tar format, and the suffix .gz will automatically be added to all tar filenames.

-z level
-z [{client|server}]-method[:detail]
--compress=level
--compress=[{client|server}]-method[:detail]

Requests compression of the backup. If client or server is included, it specifies where the compression is to be performed. Compressing on the server will reduce transfer bandwidth but will increase server CPU consumption. The default is client except when --target is used. In that case, the backup is not being sent to the client, so only server compression is sensible. When -Xstream, which is the default, is used, server-side compression will not be applied to the WAL. To compress the WAL, use client-side compression, or specify -Xfetch.

The compression method can be set to gzip, lz4, zstd, or none for no compression. A compression detail string can optionally be specified. If the detail string is an integer, it specifies the compression level. Otherwise, it should be a comma-separated list of items, each of the form keyword or keyword=value. Currently, the supported keywords are level and workers.

If no compression level is specified, the default compression level will be used. If only a level is specified without mentioning an algorithm, gzip compression will be used if the level is greater than 0, and no compression will be used if the level is 0.

When the tar format is used with gzip, lz4, or zstd, the suffix .gz, .lz4, or .zst, respectively, will be automatically added to all tar filenames. When the plain format is used, client-side compression may not be specified, but it is still possible to request server-side compression. If this is done, the server will compress the backup for transmission, and the client will decompress and extract it.

When this option is used in combination with -Xstream, pg_{wal}.tar will be compressed using gzip if client-side gzip compression is selected, but will not be compressed if any other compression algorithm is selected, or if server-side compression is selected.

The following command-line options control the generation of the backup and the invocation of the program:
-c {fast|spread}
--checkpoint={fast|spread}

Sets checkpoint mode to fast (immediate) or spread (the default) (see Section 26.3.3).

-C
--create-slot

Specifies that the replication slot named by the --slot option should be created before starting the backup. An error is raised if the slot already exists.

-l label
--label=label

Sets the label for the backup. If none is specified, a default value of “pg_basebackup base backup” will be used.

-n
--no-clean

By default, when pg_basebackup aborts with an error, it removes any directories it might have created before discovering that it cannot finish the job (for example, the target directory and write-ahead log directory). This option inhibits tidying-up and is thus useful for debugging.

Note that tablespace directories are not cleaned up either way.

-N
--no-sync

By default, pg_basebackup will wait for all files to be written safely to disk. This option causes pg_basebackup to return without waiting, which is faster, but means that a subsequent operating system crash can leave the base backup corrupt. Generally, this option is useful for testing but should not be used when creating a production installation.

-P
--progress

Enables progress reporting. Turning this on will deliver an approximate progress report during the backup. Since the database may change during the backup, this is only an approximation and may not end at exactly 100%. In particular, when WAL log is included in the backup, the total amount of data cannot be estimated in advance, and in this case the estimated target size will increase once it passes the total estimate without WAL.

-r rate
--max-rate=rate

Sets the maximum transfer rate at which data is collected from the source server. This can be useful to limit the impact of pg_basebackup on the server. Values are in kilobytes per second. Use a suffix of M to indicate megabytes per second. A suffix of k is also accepted, and has no effect. Valid values are between 32 kilobytes per second and 1024 megabytes per second.

This option always affects transfer of the data directory. Transfer of WAL files is only affected if the collection method is fetch.

-S slotname
--slot=slotname

This option can only be used together with -X stream. It causes WAL streaming to use the specified replication slot. If the base backup is intended to be used as a streaming-replication standby using a
replication slot, the standby should then use the same replication slot name as primary_slot_name. This ensures that the primary server does not remove any necessary WAL data in the time between the end of the base backup and the start of streaming replication on the new standby.

The specified replication slot has to exist unless the option --C is also used.

If this option is not specified and the server supports temporary replication slots (version 10 and later), then a temporary replication slot is automatically used for WAL streaming.

-v
--verbose

Enables verbose mode. Will output some extra steps during startup and shutdown, as well as show the exact file name that is currently being processed if progress reporting is also enabled.

--manifest-checksums=algorithm

Specifies the checksum algorithm that should be applied to each file included in the backup manifest. Currently, the available algorithms are NONE, CRC32C, SHA224, SHA256, SHA384, and SHA512. The default is CRC32C.

If NONE is selected, the backup manifest will not contain any checksums. Otherwise, it will contain a checksum of each file in the backup using the specified algorithm. In addition, the manifest will always contain a SHA256 checksum of its own contents. The SHA algorithms are significantly more CPU-intensive than CRC32C, so selecting one of them may increase the time required to complete the backup.

Using a SHA hash function provides a cryptographically secure digest of each file for users who wish to verify that the backup has not been tampered with, while the CRC32C algorithm provides a checksum that is much faster to calculate; it is good at catching errors due to accidental changes but is not resistant to malicious modifications. Note that, to be useful against an adversary who has access to the backup, the backup manifest would need to be stored securely elsewhere or otherwise verified not to have been modified since the backup was taken.

pg_verifybackup can be used to check the integrity of a backup against the backup manifest.

--manifest-force-encode

Forces all filenames in the backup manifest to be hex-encoded. If this option is not specified, only non-UTF8 filenames are hex-encoded. This option is mostly intended to test that tools which read a backup manifest file properly handle this case.

--no-estimate-size

Prevents the server from estimating the total amount of backup data that will be streamed, resulting in the backup_total column in the pg_stat_progress_basebackup view always being NULL.

Without this option, the backup will start by enumerating the size of the entire database, and then go back and send the actual contents. This may make the backup take slightly longer, and in particular it will take longer before the first data is sent. This option is useful to avoid such estimation time if it's too long.

This option is not allowed when using --progress.

--no-manifest

Disables generation of a backup manifest. If this option is not specified, the server will generate and send a backup manifest which can be verified using pg_verifybackup. The manifest is a list of every
file present in the backup with the exception of any WAL files that may be included. It also stores the size, last modification time, and an optional checksum for each file.

--no-slot

Prevents the creation of a temporary replication slot for the backup.

By default, if log streaming is selected but no slot name is given with the \texttt{-S} option, then a temporary replication slot is created (if supported by the source server).

The main purpose of this option is to allow taking a base backup when the server has no free replication slots. Using a replication slot is almost always preferred, because it prevents needed WAL from being removed by the server during the backup.

--no-verify-checksums

Disables verification of checksums, if they are enabled on the server the base backup is taken from.

By default, checksums are verified and checksum failures will result in a non-zero exit status. However, the base backup will not be removed in such a case, as if the \texttt{--no-clean} option had been used. Checksum verification failures will also be reported in the \texttt{pg_stat_database} view.

The following command-line options control the connection to the source server:

\texttt{-d connstr}

\texttt{--dbname=connstr}

Specifies parameters used to connect to the server, as a connection string; these will override any conflicting command line options.

The option is called \texttt{--dbname} for consistency with other client applications, but because pg_basebackup doesn't connect to any particular database in the cluster, any database name in the connection string will be ignored.

\texttt{-h host}

\texttt{--host=host}

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for a Unix domain socket. The default is taken from the \texttt{PGHOST} environment variable, if set, else a Unix domain socket connection is attempted.

\texttt{-p port}

\texttt{--port=port}

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the \texttt{PGPORT} environment variable, if set, or a compiled-in default.

\texttt{-s interval}

\texttt{--status-interval=interval}

Specifies the number of seconds between status packets sent back to the source server. Smaller values allow more accurate monitoring of backup progress from the server. A value of zero disables periodic status updates completely, although an update will still be sent when requested by the server, to avoid timeout-based disconnects. The default value is 10 seconds.

\texttt{-U username}

\texttt{--username=username}

Specifies the user name to connect as.
-w
--no-password

Prevents issuing a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W
--password

Forces pg_basebackup to prompt for a password before connecting to the source server.

This option is never essential, since pg_basebackup will automatically prompt for a password if the server demands password authentication. However, pg_basebackup will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

Other options are also available:

-V
--version

Prints the pg_basebackup version and exits.

-?
--help

Shows help about pg_basebackup command line arguments, and exits.

Environment

This utility, like most other PostgreSQL utilities, uses the environment variables supported by libpq (see Section 34.15).

The environment variable PG_COLOR specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

Notes

At the beginning of the backup, a checkpoint needs to be performed on the source server. This can take some time (especially if the option --checkpoint=fast is not used), during which pg_basebackup will appear to be idle.

The backup will include all files in the data directory and tablespaces, including the configuration files and any additional files placed in the directory by third parties, except certain temporary files managed by PostgreSQL. But only regular files and directories are copied, except that symbolic links used for tablespaces are preserved. Symbolic links pointing to certain directories known to PostgreSQL are copied as empty directories. Other symbolic links and special device files are skipped. See Section 54.4 for the precise details.

In plain format, tablespaces will be backed up to the same path they have on the source server, unless the option --tablespace-mapping is used. Without this option, running a plain format base backup on the same host as the server will not work if tablespaces are in use, because the backup would have to be written to the same directory locations as the original tablespaces.
When tar format is used, it is the user's responsibility to unpack each tar file before starting a PostgreSQL server that uses the data. If there are additional tablespaces, the tar files for them need to be unpacked in the correct locations. In this case the symbolic links for those tablespaces will be created by the server according to the contents of the `tablespace_map` file that is included in the `base.tar` file.

`pg_basebackup` works with servers of the same or an older major version, down to 9.1. However, WAL streaming mode (`-X stream`) only works with server version 9.3 and later, and tar format (`--format=tar`) only works with server version 9.5 and later.

`pg_basebackup` will preserve group permissions for data files if group permissions are enabled on the source cluster.

**Examples**

To create a base backup of the server at `mydbserver` and store it in the local directory `/usr/local/pgsql/data`:

```
$ pg_basebackup -h mydbserver -D /usr/local/pgsql/data
```

To create a backup of the local server with one compressed tar file for each tablespace, and store it in the directory `backup`, showing a progress report while running:

```
$ pg_basebackup -D backup -Ft -z -P
```

To create a backup of a single-tablespace local database and compress this with `bzip2`:

```
$ pg_basebackup -D - -Ft -X fetch | bzip2 > backup.tar.bz2
```

(This command will fail if there are multiple tablespaces in the database.)

To create a backup of a local database where the tablespace in `/opt/ts` is relocated to `./backup/ts`:

```
$ pg_basebackup -D backup/data -T /opt/ts=$(pwd)/backup/ts
```

To create a backup of a local server with one tar file for each tablespace compressed with `gzip` at level 9, stored in the directory `backup`:

```
$ pg_basebackup -D backup -Ft --compress=gzip:9
```

pgbench

pgbench — run a benchmark test on PostgreSQL

Synopsis

pgbench -i [option...][dbname]
pgbench [option...][dbname]

Description

pgbench is a simple program for running benchmark tests on PostgreSQL. It runs the same sequence of SQL commands over and over, possibly in multiple concurrent database sessions, and then calculates the average transaction rate (transactions per second). By default, pgbench tests a scenario that is loosely based on TPC-B, involving five SELECT, UPDATE, and INSERT commands per transaction. However, it is easy to test other cases by writing your own transaction script files.

Typical output from pgbench looks like:

```
transaction type: <builtin: TPC-B (sort of)>
scaling factor: 10
query mode: simple
number of clients: 10
number of threads: 1
maximum number of tries: 1
number of transactions per client: 1000
number of transactions actually processed: 10000/10000
number of failed transactions: 0 (0.000%)
latency average = 11.013 ms
latency stddev = 7.351 ms
initial connection time = 45.758 ms
tps = 896.967014 (without initial connection time)
```

The first seven lines report some of the most important parameter settings. The sixth line reports the maximum number of tries for transactions with serialization or deadlock errors (see Failures and Serialization/Deadlock Retries for more information). The eighth line reports the number of transactions completed and intended (the latter being just the product of number of clients and number of transactions per client); these will be equal unless the run failed before completion or some SQL command(s) failed. (In -T mode, only the actual number of transactions is printed.) The next line reports the number of failed transactions due to serialization or deadlock errors (see Failures and Serialization/Deadlock Retries for more information). The last line reports the number of transactions per second.

The default TPC-B-like transaction test requires specific tables to be set up beforehand. pgbench should be invoked with the -i (initialize) option to create and populate these tables. (When you are testing a custom script, you don't need this step, but will instead need to do whatever setup your test needs.) Initialization looks like:

```
pgbench -i [ other-options ] dbname
```

where dbname is the name of the already-created database to test in. (You may also need -h, -p, and/or -U options to specify how to connect to the database server.)
Caution

pgbench -i creates four tables pgbench_accounts, pgbench_branches, pgbench_history, and pgbench_tellers, destroying any existing tables of these names. Be very careful to use another database if you have tables having these names!

At the default “scale factor” of 1, the tables initially contain this many rows:

<table>
<thead>
<tr>
<th>table</th>
<th># of rows</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgbench_branches</td>
<td>1</td>
</tr>
<tr>
<td>pgbench_tellers</td>
<td>10</td>
</tr>
<tr>
<td>pgbench_accounts</td>
<td>100000</td>
</tr>
<tr>
<td>pgbench_history</td>
<td>0</td>
</tr>
</tbody>
</table>

You can (and, for most purposes, probably should) increase the number of rows by using the \(-s\) (scale factor) option. The \(-F\) (fillfactor) option might also be used at this point.

Once you have done the necessary setup, you can run your benchmark with a command that doesn't include \(-i\), that is

```
pgbench [ options ] dbname
```

In nearly all cases, you'll need some options to make a useful test. The most important options are \(-c\) (number of clients), \(-t\) (number of transactions), \(-T\) (time limit), and \(-f\) (specify a custom script file). See below for a full list.

**Options**

The following is divided into three subsections. Different options are used during database initialization and while running benchmarks, but some options are useful in both cases.

**Initialization Options**

pgbench accepts the following command-line initialization arguments:

- `dbname`

  Specifies the name of the database to test in. If this is not specified, the environment variable `PGDATABASE` is used. If that is not set, the user name specified for the connection is used.

- `\(-i\)`
  \(--initialize\)

  Required to invoke initialization mode.

- `\(-I \ init_steps\)`
  \(--init-steps=\ init_steps\)

  Perform just a selected set of the normal initialization steps. `\ init_steps` specifies the initialization steps to be performed, using one character per step. Each step is invoked in the specified order. The default is `dtgvp`. The available steps are:

  2. `d`: Create database.
  1. `t`: Create tables.
  3. `g`: Generate data.
  9. `v`: Verify consistency.

d (Drop)

Drop any existing pgbench tables.

t (create Tables)

Create the tables used by the standard pgbench scenario, namely pgbench_accounts, pgbench_branches, pgbench_history, and pgbench_tellers.

g or G (Generate data, client-side or server-side)

Generate data and load it into the standard tables, replacing any data already present.

With g (client-side data generation), data is generated in pgbench client and then sent to the server. This uses the client/server bandwidth extensively through a COPY. pgbench uses the FREEZE option with version 14 or later of PostgreSQL to speed up subsequent VACUUM, unless partitions are enabled. Using g causes logging to print one message every 100,000 rows while generating data for the pgbench_accounts table.

With G (server-side data generation), only small queries are sent from the pgbench client and then data is actually generated in the server. No significant bandwidth is required for this variant, but the server will do more work. Using G causes logging not to print any progress message while generating data.

The default initialization behavior uses client-side data generation (equivalent to g).

v (Vacuum)

Invoke VACUUM on the standard tables.

p (create Primary keys)

Create primary key indexes on the standard tables.

f (create Foreign keys)

Create foreign key constraints between the standard tables. (Note that this step is not performed by default.)

-F fillfactor
--fillfactor=fillfactor

Create the pgbench_accounts, pgbench_tellers and pgbench_branches tables with the given fillfactor. Default is 100.

-n
--no-vacuum

Perform no vacuuming during initialization. (This option suppresses the v initialization step, even if it was specified in -I.)

-q
--quiet

Switch logging to quiet mode, producing only one progress message per 5 seconds. The default logging prints one message each 100,000 rows, which often outputs many lines per second (especially on good hardware).

This setting has no effect if G is specified in -I.
--scale=scale_factor

Multiply the number of rows generated by the scale factor. For example, --scale=100 will create 10,000,000 rows in the pgbench_accounts table. Default is 1. When the scale is 20,000 or larger, the columns used to hold account identifiers (aid columns) will switch to using larger integers (bigint), in order to be big enough to hold the range of account identifiers.

--foreign-keys

Create foreign key constraints between the standard tables. (This option adds the f step to the initialization step sequence, if it is not already present.)

--index-tablespace=index_tablespace

Create indexes in the specified tablespace, rather than the default tablespace.

--partition-method=NAME

Create a partitioned pgbench_accounts table with NAME method. Expected values are range or hash. This option requires that --partitions is set to non-zero. If unspecified, default is range.

--partitions=NUM

Create a partitioned pgbench_accounts table with NUM partitions of nearly equal size for the scaled number of accounts. Default is 0, meaning no partitioning.

--tablespace=tablespace

Create tables in the specified tablespace, rather than the default tablespace.

--unlogged-tables

Create all tables as unlogged tables, rather than permanent tables.

**Benchmarking Options**

pgbench accepts the following command-line benchmarking arguments:

-b scriptname[@weight]
--builtin=scriptname[@weight]

Add the specified built-in script to the list of scripts to be executed. Available built-in scripts are: tpcb-like, simple-update and select-only. Unambiguous prefixes of built-in names are accepted. With the special name list, show the list of built-in scripts and exit immediately.

Optionally, write an integer weight after @ to adjust the probability of selecting this script versus other ones. The default weight is 1. See below for details.

-c clients
--client=clients

Number of clients simulated, that is, number of concurrent database sessions. Default is 1.

-C
--connect

Establish a new connection for each transaction, rather than doing it just once per client session. This is useful to measure the connection overhead.
-d
--debug

Print debugging output.

-D varname=value
--define=varname=value

Define a variable for use by a custom script (see below). Multiple -D options are allowed.

-f filename[@weight]
--file=filename[@weight]

Add a transaction script read from filename to the list of scripts to be executed.

Optionally, write an integer weight after @ to adjust the probability of selecting this script versus other ones. The default weight is 1. (To use a script file name that includes an @ character, append a weight so that there is no ambiguity, for example filen@me@1.) See below for details.

-j threads
--jobs=threads

Number of worker threads within pgbench. Using more than one thread can be helpful on multi-CPU machines. Clients are distributed as evenly as possible among available threads. Default is 1.

-l
--log

Write information about each transaction to a log file. See below for details.

-L limit
--latency-limit=limit

Transactions that last more than limit milliseconds are counted and reported separately, as late.

When throttling is used (--rate=...), transactions that lag behind schedule by more than limit ms, and thus have no hope of meeting the latency limit, are not sent to the server at all. They are counted and reported separately as skipped.

When the --max-tries option is used, a transaction which fails due to a serialization anomaly or from a deadlock will not be retried if the total time of all its tries is greater than limit ms. To limit only the time of tries and not their number, use --max-tries=0. By default, the option --max-tries is set to 1 and transactions with serialization/deadlock errors are not retried. See Failures and Serialization/Deadlock Retries for more information about retrying such transactions.

-M querymode
--protocol=querymode

Protocol to use for submitting queries to the server:

• simple: use simple query protocol.

• extended: use extended query protocol.

• prepared: use extended query protocol with prepared statements.

In the prepared mode, pgbench reuses the parse analysis result starting from the second query iteration, so pgbench runs faster than in other modes.

The default is simple query protocol. (See Chapter 54 for more information.)
-n
--no-vacuum

Perform no vacuuming before running the test. This option is necessary if you are running a custom test scenario that does not include the standard tables pgbench_accounts, pgbench_branches, pgbench_history, and pgbench_tellers.

-N
--skip-some-updates

-P sec
--progress=sec

Show progress report every sec seconds. The report includes the time since the beginning of the run, the TPS since the last report, and the transaction latency average, standard deviation, and the number of failed transactions since the last report. Under throttling (-R), the latency is computed with respect to the transaction scheduled start time, not the actual transaction beginning time, thus it also includes the average schedule lag time. When --max-tries is used to enable transaction retries after serialization/deadlock errors, the report includes the number of retried transactions and the sum of all retries.

-r
--report-per-command

Report the following statistics for each command after the benchmark finishes: the average per-state-ment latency (execution time from the perspective of the client), the number of failures and the number of retries after serialization or deadlock errors in this command. The report displays retry statistics only if the --max-tries option is not equal to 1.

-R rate
--rate=rate

Execute transactions targeting the specified rate instead of running as fast as possible (the default). The rate is given in transactions per second. If the targeted rate is above the maximum possible rate, the rate limit won't impact the results.

The rate is targeted by starting transactions along a Poisson-distributed schedule time line. The expected start time schedule moves forward based on when the client first started, not when the previous transaction ended. That approach means that when transactions go past their original scheduled end time, it is possible for later ones to catch up again.

When throttling is active, the transaction latency reported at the end of the run is calculated from the scheduled start times, so it includes the time each transaction had to wait for the previous transaction to finish. The wait time is called the schedule lag time, and its average and maximum are also reported separately. The transaction latency with respect to the actual transaction start time, i.e., the time spent executing the transaction in the database, can be computed by subtracting the schedule lag time from the reported latency.

If --latency-limit is used together with --rate, a transaction can lag behind so much that it is already over the latency limit when the previous transaction ends, because the latency is calculated from the scheduled start time. Such transactions are not sent to the server, but are skipped altogether and counted separately.

A high schedule lag time is an indication that the system cannot process transactions at the specified rate, with the chosen number of clients and threads. When the average transaction execution time
is longer than the scheduled interval between each transaction, each successive transaction will fall
further behind, and the schedule lag time will keep increasing the longer the test run is. When that
happens, you will have to reduce the specified transaction rate.

-s scale_factor
--scale=scale_factor

Report the specified scale factor in pgbench's output. With the built-in tests, this is not necessary; the
correct scale factor will be detected by counting the number of rows in the pgbench_branches
table. However, when testing only custom benchmarks (-f option), the scale factor will be reported
as 1 unless this option is used.

-S
--select-only

Run built-in select-only script. Shorthand for -b select-only.

-t transactions
--transactions=transactions

Number of transactions each client runs. Default is 10.

-T seconds
--time=seconds

Run the test for this many seconds, rather than a fixed number of transactions per client. -t and -
T are mutually exclusive.

-v
--vacuum-all

Vacuum all four standard tables before running the test. With neither -n nor -v, pgbench will vacuum
the pgbench_tellers and pgbench_branches tables, and will truncate pgbench_history.

--aggregate-interval=seconds

Length of aggregation interval (in seconds). May be used only with -l option. With this option, the
log contains per-interval summary data, as described below.

--failures-detailed

Report failures in per-transaction and aggregation logs, as well as in the main and per-script reports,
grouped by the following types:

- serialization failures;
- deadlock failures;

See Failures and Serialization/Deadlock Retries for more information.

--log-prefix=prefix

Set the filename prefix for the log files created by --log. The default is pgbench_log.

--max-tries=number_of_tries

Enable retries for transactions with serialization/deadlock errors and set the maximum number of
these tries. This option can be combined with the --latency-limit option which limits the to-
tal time of all transaction tries; moreover, you cannot use an unlimited number of tries (--max-
tries=0) without --latency-limit or --time. The default value is 1 and transactions with serialization/deadlock errors are not retried. See Failures and Serialization/Deadlock Retries for more information about retrying such transactions.

--progress-timestamp

When showing progress (option -P), use a timestamp (Unix epoch) instead of the number of seconds since the beginning of the run. The unit is in seconds, with millisecond precision after the dot. This helps compare logs generated by various tools.

--random-seed=seed

Set random generator seed. Seeds the system random number generator, which then produces a sequence of initial generator states, one for each thread. Values for seed may be: time (the default, the seed is based on the current time), rand (use a strong random source, failing if none is available), or an unsigned decimal integer value. The random generator is invoked explicitly from a pgbench script (random... functions) or implicitly (for instance option --rate uses it to schedule transactions). When explicitly set, the value used for seeding is shown on the terminal. Any value allowed for seed may also be provided through the environment variable PGBENCH_RANDOM_SEED. To ensure that the provided seed impacts all possible uses, put this option first or use the environment variable.

Setting the seed explicitly allows to reproduce a pgbench run exactly, as far as random numbers are concerned. As the random state is managed per thread, this means the exact same pgbench run for an identical invocation if there is one client per thread and there are no external or data dependencies. From a statistical viewpoint reproducing runs exactly is a bad idea because it can hide the performance variability or improve performance unduly, e.g., by hitting the same pages as a previous run. However, it may also be of great help for debugging, for instance re-running a tricky case which leads to an error. Use wisely.

--sampling-rate=rate

Sampling rate, used when writing data into the log, to reduce the amount of log generated. If this option is given, only the specified fraction of transactions are logged. 1.0 means all transactions will be logged, 0.05 means only 5% of the transactions will be logged.

Remember to take the sampling rate into account when processing the log file. For example, when computing TPS values, you need to multiply the numbers accordingly (e.g., with 0.01 sample rate, you’ll only get 1/100 of the actual TPS).

--show-script=scriptname

Show the actual code of builtin script scriptname on stderr, and exit immediately.

--verbose-errors

Print messages about all errors and failures (errors without retrying) including which limit for retries was exceeded and how far it was exceeded for the serialization/deadlock failures. (Note that in this case the output can be significantly increased.). See Failures and Serialization/Deadlock Retries for more information.

Common Options

pgbench also accepts the following common command-line arguments for connection parameters:

- h hostname
--host=hostname

The database server’s host name
-p port
--port=port

The database server's port number

-U login
--username=login

The user name to connect as

-V
--version

Print the pgbench version and exit.

-?
--help

Show help about pgbench command line arguments, and exit.

**Exit Status**

A successful run will exit with status 0. Exit status 1 indicates static problems such as invalid command-line options or internal errors which are supposed to never occur. Early errors that occur when starting benchmark such as initial connection failures also exit with status 1. Errors during the run such as database errors or problems in the script will result in exit status 2. In the latter case, pgbench will print partial results.

**Environment**

PGDATABASE
PGHOST
PGPORT
PGUSER

Default connection parameters.

This utility, like most other PostgreSQL utilities, uses the environment variables supported by libpq (see Section 34.15).

The environment variable PG_COLOR specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

**Notes**

**What Is the “Transaction” Actually Performed in pgbench?**

pgbench executes test scripts chosen randomly from a specified list. The scripts may include built-in scripts specified with -b and user-provided scripts specified with -f. Each script may be given a relative weight specified after an @ so as to change its selection probability. The default weight is 1. Scripts with a weight of 0 are ignored.

The default built-in transaction script (also invoked with -b tpcb-like) issues seven commands per transaction over randomly chosen aid, tid, bid and delta. The scenario is inspired by the TPC-B benchmark, but is not actually TPC-B, hence the name.
1. BEGIN;

2. UPDATE pgbench_accounts SET abalance = abalance + :delta WHERE aid = :aid;

3. SELECT abalance FROM pgbench_accounts WHERE aid = :aid;

4. UPDATE pgbench_tellers SET tbalance = tbalance + :delta WHERE tid = :tid;

5. UPDATE pgbench_branches SET bbalance = bbalance + :delta WHERE bid = :bid;

6. INSERT INTO pgbench_history (tid, bid, aid, delta, mtime) VALUES (:tid, :bid, :aid, :delta, CURRENT_TIMESTAMP);

7. END;

If you select the simple-update built-in (also -N), steps 4 and 5 aren't included in the transaction. This will avoid update contention on these tables, but it makes the test case even less like TPC-B.

If you select the select-only built-in (also -S), only the SELECT is issued.

Custom Scripts

pgbench has support for running custom benchmark scenarios by replacing the default transaction script (described above) with a transaction script read from a file (-f option). In this case a “transaction” counts as one execution of a script file.

A script file contains one or more SQL commands terminated by semicolons. Empty lines and lines beginning with -- are ignored. Script files can also contain “meta commands”, which are interpreted by pgbench itself, as described below.

Note

Before PostgreSQL 9.6, SQL commands in script files were terminated by newlines, and so they could not be continued across lines. Now a semicolon is required to separate consecutive SQL commands (though an SQL command does not need one if it is followed by a meta command). If you need to create a script file that works with both old and new versions of pgbench, be sure to write each SQL command on a single line ending with a semicolon.

It is assumed that pgbench scripts do not contain incomplete blocks of SQL transactions. If at runtime the client reaches the end of the script without completing the last transaction block, it will be aborted.

There is a simple variable-substitution facility for script files. Variable names must consist of letters (including non-Latin letters), digits, and underscores, with the first character not being a digit. Variables can be set by the command-line -D option, explained above, or by the meta commands explained below. In addition to any variables preset by -D command-line options, there are a few variables that are preset automatically, listed in Table 290. A value specified for these variables using -D takes precedence over the automatic presets. Once set, a variable's value can be inserted into an SQL command by writing :variable. When running more than one client session, each session has its own set of variables. pgbench supports up to 255 variable uses in one statement.
Table 290. pgbench Automatic Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>client_id</td>
<td>unique number identifying the client session (starts from zero)</td>
</tr>
<tr>
<td>default_seed</td>
<td>seed used in hash and pseudorandom permutation functions by default</td>
</tr>
<tr>
<td>random_seed</td>
<td>random generator seed (unless overwritten with -D)</td>
</tr>
<tr>
<td>scale</td>
<td>current scale factor</td>
</tr>
</tbody>
</table>

Script file meta commands begin with a backslash (\) and normally extend to the end of the line, although they can be continued to additional lines by writing backslash-return. Arguments to a meta command are separated by white space. These meta commands are supported:

```
\gset [prefix] \aset [prefix]
```

These commands may be used to end SQL queries, taking the place of the terminating semicolon (;).

When the `\gset` command is used, the preceding SQL query is expected to return one row, the columns of which are stored into variables named after column names, and prefixed with `prefix` if provided.

When the `\aset` command is used, all combined SQL queries (separated by `\;`) have their columns stored into variables named after column names, and prefixed with `prefix` if provided. If a query returns no row, no assignment is made and the variable can be tested for existence to detect this. If a query returns more than one row, the last value is kept.

`\gset` and `\aset` cannot be used in pipeline mode, since the query results are not yet available by the time the commands would need them.

The following example puts the final account balance from the first query into variable `abalance`, and fills variables `p_two` and `p_three` with integers from the third query. The result of the second query is discarded. The result of the two last combined queries are stored in variables `four` and `five`.

```
UPDATE pgbench_accounts
  SET abalance = abalance + :delta
WHERE aid = :aid
RETURNING abalance \gset
-- compound of two queries
SELECT 1 \;
SELECT 2 AS two, 3 AS three \gset p_
SELECT 4 AS four \; SELECT 5 AS five \aset
```

```
\if expression
\elif expression
\else
\endif
```

This group of commands implements nestable conditional blocks, similarly to `psql`'s `\if expression`. Conditional expressions are identical to those with `\set`, with non-zero values interpreted as true.

```
\set varname expression
```

Sets variable `varname` to a value calculated from `expression`. The expression may contain the `NULL` constant, Boolean constants `TRUE` and `FALSE`, integer constants such as 5432, double con-
Constants such as 3.14159, references to variables :\texttt{variable}, operators with their usual SQL precedence and associativity, function calls, SQL CASE generic conditional expressions and parentheses.

Functions and most operators return NULL on NULL input.

For conditional purposes, non zero numerical values are TRUE, zero numerical values and NULL are FALSE.

Too large or small integer and double constants, as well as integer arithmetic operators (+, -, *, and /) raise errors on overflows.

When no final ELSE clause is provided to a CASE, the default value is NULL.

Examples:

\begin{verbatim}
\set ntellers 10 * :scale
\set aid (1021 * random(1, 100000 * :scale)) \% \( (100000 * :scale) + 1 \)
\set divx CASE WHEN :x <> 0 THEN :y/:x ELSE NULL END
\end{verbatim}

\begin{verbatim}
\sleep number [ us | ms | s ]
\end{verbatim}

Causes script execution to sleep for the specified duration in microseconds (us), milliseconds (ms) or seconds (s). If the unit is omitted then seconds are the default. number can be either an integer constant or a :\texttt{variable} reference to a variable having an integer value.

Example:

\begin{verbatim}
\sleep 10 ms
\end{verbatim}

\begin{verbatim}
\setshell varname command [ argument ... ]
\end{verbatim}

Sets variable varname to the result of the shell command command with the given argument(s). The command must return an integer value through its standard output.

\texttt{command} and each \texttt{argument} can be either a text constant or a :\texttt{variable} reference to a variable. If you want to use an \texttt{argument} starting with a colon, write an additional colon at the beginning of \texttt{argument}.

Example:

\begin{verbatim}
\setshell variable_to_be_assigned command
literal_argument :variable ::literal_starting_with_colon
\end{verbatim}

\begin{verbatim}
\shell command [ argument ... ]
\end{verbatim}

Same as \texttt{\setshell}, but the result of the command is discarded.

Example:

\begin{verbatim}
\shell command
literal_argument :variable ::literal_starting_with_colon
\end{verbatim}
These commands delimit the start and end of a pipeline of SQL statements. In pipeline mode, statements are sent to the server without waiting for the results of previous statements. See Section 34.5 for more details. Pipeline mode requires the use of extended query protocol.

**Built-in Operators**

The arithmetic, bitwise, comparison and logical operators listed in Table 291 are built into pgbench and may be used in expressions appearing in \set. The operators are listed in increasing precedence order. Except as noted, operators taking two numeric inputs will produce a double value if either input is double, otherwise they produce an integer result.

**Table 291. pgbench Operators**

</tbody>
</table>

The `random` function generates values using a uniform distribution, that is all the values are drawn within the specified range with equal probability. The `random_exponential`, `random_gaussian` and `random_zipfian` functions require an additional double parameter which determines the precise shape of the distribution.

- For an exponential distribution, `parameter` controls the distribution by truncating a quickly-decreasing exponential distribution at `parameter`, and then projecting onto integers between the bounds. To be precise, with

\[
f(x) = \exp(-parameter \times (x - min) / (max - min + 1)) / (1 - \exp(-parameter))
\]

Then value \( i \) between \( min \) and \( max \) inclusive is drawn with probability: \( f(i) - f(i + 1) \).

Intuitively, the larger the `parameter`, the more frequently values close to `min` are accessed, and the less frequently values close to `max` are accessed. The closer to 0 `parameter` is, the flatter (more uniform) the access distribution. A crude approximation of the distribution is that the most frequent 1% values in the range, close to `min`, are drawn `parameter`% of the time. The `parameter` value must be strictly positive.

- For a Gaussian distribution, the interval is mapped onto a standard normal distribution (the classical bell-shaped Gaussian curve) truncated at \(-parameter\) on the left and \(+parameter\) on the right. Values in the middle of the interval are more likely to be drawn. To be precise, if \( PHI(x) \) is the cumulative distribution function of the standard normal distribution, with mean \( mu \) defined as \((max + min) / 2.0\), with

\[
f(x) = PHI(2.0 \times parameter \times (x - mu) / (max - min + 1)) / (2.0 \times PHI(parameter) - 1)
\]

then value \( i \) between \( min \) and \( max \) inclusive is drawn with probability: \( f(i + 0.5) - f(i - 0.5) \). Intuitively, the larger the `parameter`, the more frequently values close to the middle of the interval are drawn, and the less frequently values close to the `min` and `max` bounds. About 67% of values are drawn from the middle \(1.0 / parameter\), that is a relative \(0.5 / parameter\) around the mean, and 95% in the middle \(2.0 / parameter\), that is a relative \(1.0 / parameter\) around the mean; for instance, if `parameter` is 4.0, 67% of values are drawn from the middle quarter \((1.0 / 4.0)\) of the interval (i.e., from \(3.0 / 8.0\) to \(5.0 / 8.0\)) and 95% from the middle half \((2.0 / 4.0)\) of the interval (second and third quartiles). The minimum allowed `parameter` value is 2.0.

- `random_zipfian` generates a bounded Zipfian distribution. `parameter` defines how skewed the distribution is. The larger the `parameter`, the more frequently values closer to the beginning of the in-
The distribution is such that, assuming the range starts from 1, the ratio of the probability of drawing $k$ versus drawing $k+1$ is $((k+1)/k)**\text{parameter}$. For example, \texttt{random_zipfian(1, ..., 2.5)} produces the value 1 about $(2/1)**2.5 = 5.66$ times more frequently than 2, which itself is produced $(3/2)**2.5 = 2.76$ times more frequently than 3, and so on.

\texttt{pgbench}'s implementation is based on "Non-Uniform Random Variate Generation", Luc Devroye, p. 550-551, Springer 1986. Due to limitations of that algorithm, the \texttt{parameter} value is restricted to the range $[1.001, 1000]$.

**Note**

When designing a benchmark which selects rows non-uniformly, be aware that the rows chosen may be correlated with other data such as IDs from a sequence or the physical row ordering, which may skew performance measurements.

To avoid this, you may wish to use the \texttt{permute} function, or some other additional step with similar effect, to shuffle the selected rows and remove such correlations.

Hash functions \texttt{hash}, \texttt{hash_murmur2} and \texttt{hash_fnv1a} accept an input value and an optional seed parameter. In case the seed isn't provided the value of \texttt{:default_seed} is used, which is initialized randomly unless set by the command-line \texttt{-D} option.

\texttt{permute} accepts an input value, a size, and an optional seed parameter. It generates a pseudorandom permutation of integers in the range $[0, \text{size})$, and returns the index of the input value in the permuted values. The permutation chosen is parameterized by the seed, which defaults to \texttt{:default_seed}, if not specified. Unlike the hash functions, \texttt{permute} ensures that there are no collisions or holes in the output values. Input values outside the interval are interpreted modulo the size. The function raises an error if the size is not positive. \texttt{permute} can be used to scatter the distribution of non-uniform random functions such as \texttt{random_zipfian} or \texttt{random_exponential} so that values drawn more often are not trivially correlated. For instance, the following \texttt{pgbench} script simulates a possible real world workload typical for social media and blogging platforms where a few accounts generate excessive load:

\begin{verbatim}
\set size 1000000
\set r random_zipfian(1, :size, 1.07)
\set k 1 + permute(:r, :size)
\end{verbatim}

In some cases several distinct distributions are needed which don't correlate with each other and this is when the optional seed parameter comes in handy:

\begin{verbatim}
\set k1 1 + permute(:r, :size, :default_seed + 123)
\set k2 1 + permute(:r, :size, :default_seed + 321)
\end{verbatim}

A similar behavior can also be approximated with \texttt{hash}:

\begin{verbatim}
\set size 1000000
\set r random_zipfian(1, 100 * :size, 1.07)
\set k 1 + abs(hash(:r)) % :size
\end{verbatim}

However, since \texttt{hash} generates collisions, some values will not be reachable and others will be more frequent than expected from the original distribution.
As an example, the full definition of the built-in TPC-B-like transaction is:

\set aid random(1, 100000 * :scale)
\set bid random(1, 1 * :scale)
\set tid random(1, 10 * :scale)
\set delta random(-5000, 5000)
BEGIN;
UPDATE pgbench_accounts SET abalance = abalance + :delta WHERE aid = :aid;
SELECT abalance FROM pgbench_accounts WHERE aid = :aid;
UPDATE pgbench_tellers SET tbalance = tbalance + :delta WHERE tid = :tid;
UPDATE pgbench_branches SET bbalance = bbalance + :delta WHERE bid = :bid;
INSERT INTO pgbench_history (tid, bid, aid, delta, mtime) VALUES (:tid, :bid, :aid, :delta, CURRENT_TIMESTAMP);
END;

This script allows each iteration of the transaction to reference different, randomly-chosen rows. (This example also shows why it’s important for each client session to have its own variables — otherwise they’d not be independently touching different rows.)

**Per-Transaction Logging**

With the -l option (but without the --aggregate-interval option), pgbench writes information about each transaction to a log file. The log file will be named prefix.nnn, where prefix defaults to pgbench_log, and nnn is the PID of the pgbench process. The prefix can be changed by using the --log-prefix option. If the -j option is 2 or higher, so that there are multiple worker threads, each will have its own log file. The first worker will use the same name for its log file as in the standard single worker case. The additional log files for the other workers will be named prefix.nnn.mmm, where mmm is a sequential number for each worker starting with 1.

Each line in a log file describes one transaction. It contains the following space-separated fields:

*client_id*

identifies the client session that ran the transaction

*transaction_no*

counts how many transactions have been run by that session

*time*

transaction's elapsed time, in microseconds

*script_no*

identifies the script file that was used for the transaction (useful when multiple scripts are specified with -f or -b)

*time_epoch*

transaction's completion time, as a Unix-epoch time stamp
time_us
fractional-second part of transaction's completion time, in microseconds

schedule_lag
transaction start delay, that is the difference between the transaction's scheduled start time and the
time it actually started, in microseconds (present only if --rate is specified)

retries
count of retries after serialization or deadlock errors during the transaction (present only if --max-
tries is not equal to one)

When both --rate and --latency-limit are used, the time for a skipped transaction will be re-
ported as skipped. If the transaction ends with a failure, its time will be reported as failed. If you
use the --failures-detailed option, the time of the failed transaction will be reported as seri-
ализация or deadlock depending on the type of failure (see Failures and Serialization/Deadlock
Retries for more information).

Here is a snippet of a log file generated in a single-client run:

0 199 2241 0 1175850568 995598
0 200 2465 0 1175850568 998079
0 201 2513 0 1175850569 608
0 202 2038 0 1175850569 2663

Another example with --rate=100 and --latency-limit=5 (note the additional schedule_lag column):

0 81 4621 0 1412881037 912698 3005
0 82 6173 0 1412881037 914578 4304
0 83 skipped 0 1412881037 914578 5217
0 83 skipped 0 1412881037 914578 5099
0 83 4722 0 1412881037 916203 3108
0 84 4142 0 1412881037 918023 2333
0 85 2465 0 1412881037 919759 740

In this example, transaction 82 was late, because its latency (6.173 ms) was over the 5 ms limit. The next
two transactions were skipped, because they were already late before they were even started.

The following example shows a snippet of a log file with failures and retries, with the maximum number
of tries set to 10 (note the additional retries column):

3 0 47423 0 1499414498 34501 3
3 1 8333 0 1499414498 42848 0
3 2 8358 0 1499414498 51219 0
4 0 72345 0 1499414498 59433 6
1 3 41718 0 1499414498 67879 4
1 4 8416 0 1499414498 76311 0
3 3 33235 0 1499414498 84469 3
0 0 failed 0 1499414498 84905 9
2 0 failed 0 1499414498 86248 9
3 4 8307 0 1499414498 92788 0
If the `--failures-detailed` option is used, the type of failure is reported in the `time` like this:

```
3 0 47423 0 1499414498 34501 3
3 1 8333 0 1499414498 42848 0
3 2 8358 0 1499414498 51219 0
4 0 72345 0 1499414498 59433 6
1 3 41718 0 1499414498 67879 4
1 4 8416 0 1499414498 76311 0
3 3 33235 0 1499414498 84469 3
0 0 serialization 0 1499414498 84905 9
2 0 serialization 0 1499414498 86248 9
3 4 8307 0 1499414498 92788 0
```

When running a long test on hardware that can handle a lot of transactions, the log files can become very large. The `--sampling-rate` option can be used to log only a random sample of transactions.

### Aggregated Logging

With the `--aggregate-interval` option, a different format is used for the log files. Each log line describes one aggregation interval. It contains the following space-separated fields:

- `interval_start`: start time of the interval, as a Unix-epoch time stamp
- `num_transactions`: number of transactions within the interval
- `sum_latency`: sum of transaction latencies
- `sum_latency_2`: sum of squares of transaction latencies
- `min_latency`: minimum transaction latency
- `max_latency`: maximum transaction latency
- `sum_lag`: sum of transaction start delays (zero unless `--rate` is specified)
- `sum_lag_2`: sum of squares of transaction start delays (zero unless `--rate` is specified)
- `min_lag`: minimum transaction start delay (zero unless `--rate` is specified)
max_lag

maximum transaction start delay (zero unless \--rate is specified)

skipped

number of transactions skipped because they would have started too late (zero unless \--rate and \--latency-limit are specified)

retried

number of retried transactions (zero unless \--max-tries is not equal to one)

retries

number of retries after serialization or deadlock errors (zero unless \--max-tries is not equal to one)

serialization_failures

number of transactions that got a serialization error and were not retried afterwards (zero unless \--failures-detailed is specified)

deadlock_failures

number of transactions that got a deadlock error and were not retried afterwards (zero unless \--failures-detailed is specified)

Here is some example output generated with these options:

```
pgbench --aggregate-interval=10 --time=20 --client=10 --log --rate=1000 --latency-limit=10 --failures-detailed --max-tries=10 test
```

```
1650260552  5178  26171317  177284491527  1136  44462  2647617  7321113867  0
  9866  64  7564  28340  4148  0
1650260562  4808  25573984  220121792172  1171  62083  3037380  9666800914  0
  9998  598  7392  26621  4527  0
```

Notice that while the plain (unaggregated) log format shows which script was used for each transaction, the aggregated format does not. Therefore if you need per-script data, you need to aggregate the data on your own.

**Per-Statement Report**

With the \--r option, pgbench collects the following statistics for each statement:

- **latency** — elapsed transaction time for each statement. pgbench reports an average value of all successful runs of the statement.

- The number of failures in this statement. See Failures and Serialization/Deadlock Retries for more information.

- The number of retries after a serialization or a deadlock error in this statement. See Failures and Serialization/Deadlock Retries for more information.

The report displays retry statistics only if the \--max-tries option is not equal to 1.
All values are computed for each statement executed by every client and are reported after the benchmark has finished.

For the default script, the output will look similar to this:

```
starting vacuum...end.
transaction type: <builtin: TPC-B (sort of)>
scaling factor: 1
query mode: simple
number of clients: 10
number of threads: 1
maximum number of tries: 1
number of transactions per client: 1000
number of transactions actually processed: 10000/10000
number of failed transactions: 0 (0.000%)
number of transactions above the 50.0 ms latency limit: 1311/10000 (13.110 %)
latency average = 28.488 ms
latency stddev = 21.009 ms
initial connection time = 69.068 ms
tps = 346.224794 (without initial connection time)
statement latencies in milliseconds and failures:
  0.012  0  \set aid random(1, 100000 * :scale)
  0.002  0  \set bid random(1, 1 * :scale)
  0.002  0  \set tid random(1, 10 * :scale)
  0.002  0  \set delta random(-5000, 5000)
  0.319  0  BEGIN;
  0.834  0  UPDATE pgbench_accounts SET abalance = abalance + :delta
  WHERE aid = :aid;
  0.641  0  SELECT abalance FROM pgbench_accounts WHERE aid = :aid;
  11.126  0  UPDATE pgbench_tellers SET tbalance = tbalance + :delta
  WHERE tid = :tid;
  12.961  0  UPDATE pgbench_branches SET bbalance = bbalance + :delta
  WHERE bid = :bid;
  0.634  0  INSERT INTO pgbench_history (tid, bid, aid, delta, mtime)
  VALUES (:tid, :bid, :aid, :delta, CURRENT_TIMESTAMP);
  1.957  0  END;
```

Another example of output for the default script using serializable default transaction isolation level (PGOPTIONS='c default_transaction_isolation=serializable' pgbench ...):

```
starting vacuum...end.
transaction type: <builtin: TPC-B (sort of)>
scaling factor: 1
query mode: simple
number of clients: 10
number of threads: 1
maximum number of tries: 10
number of transactions per client: 1000
number of transactions actually processed: 6317/10000
number of failed transactions: 3683 (36.830%)
number of transactions retried: 7667 (76.670%)
total number of retries: 45339
```
number of transactions above the 50.0 ms latency limit: 106/6317
(1.678 %)
latency average = 17.016 ms
latency stddev = 13.283 ms
initial connection time = 45.017 ms
tps = 186.792667 (without initial connection time)

If multiple script files are specified, all statistics are reported separately for each script file.

Note that collecting the additional timing information needed for per-statement latency computation adds some overhead. This will slow average execution speed and lower the computed TPS. The amount of slowdown varies significantly depending on platform and hardware. Comparing average TPS values with and without latency reporting enabled is a good way to measure if the timing overhead is significant.

Failures and Serialization/Deadlock Retries

When executing pgbench, there are three main types of errors:

- Errors of the main program. They are the most serious and always result in an immediate exit from pgbench with the corresponding error message. They include:
  - errors at the beginning of pgbench (e.g. an invalid option value);
  - errors in the initialization mode (e.g. the query to create tables for built-in scripts fails);
  - errors before starting threads (e.g. could not connect to the database server, syntax error in the meta command, thread creation failure);
  - internal pgbench errors (which are supposed to never occur...).

- Errors when the thread manages its clients (e.g. the client could not start a connection to the database server / the socket for connecting the client to the database server has become invalid). In such cases all clients of this thread stop while other threads continue to work.

- Direct client errors. They lead to immediate exit from pgbench with the corresponding error message only in the case of an internal pgbench error (which are supposed to never occur...). Otherwise in the worst case they only lead to the abortion of the failed client while other clients continue their run (but some client errors are handled without an abortion of the client and reported separately, see below).
Later in this section it is assumed that the discussed errors are only the direct client errors and they are not internal pgbench errors.

A client’s run is aborted in case of a serious error; for example, the connection with the database server was lost or the end of script was reached without completing the last transaction. In addition, if execution of an SQL or meta command fails for reasons other than serialization or deadlock errors, the client is aborted. Otherwise, if an SQL command fails with serialization or deadlock errors, the client is not aborted. In such cases, the current transaction is rolled back, which also includes setting the client variables as they were before the run of this transaction (it is assumed that one transaction script contains only one transaction; see What Is the “Transaction” Actually Performed in pgbench? for more information). Transactions with serialization or deadlock errors are repeated after rollbacks until they complete successfully or reach the maximum number of tries (specified by the \texttt{--max-tries} option) / the maximum time of retries (specified by the \texttt{--latency-limit} option) / the end of benchmark (specified by the \texttt{--time} option). If the last trial run fails, this transaction will be reported as failed but the client is not aborted and continues to work.

\begin{note}
Without specifying the \texttt{--max-tries} option, a transaction will never be retried after a serialization or deadlock error because its default value is 1. Use an unlimited number of tries (\texttt{--max-tries=0}) and the \texttt{--latency-limit} option to limit only the maximum time of tries. You can also use the \texttt{--time} option to limit the benchmark duration under an unlimited number of tries.

Be careful when repeating scripts that contain multiple transactions: the script is always retried completely, so successful transactions can be performed several times.

Be careful when repeating transactions with shell commands. Unlike the results of SQL commands, the results of shell commands are not rolled back, except for the variable value of the \texttt{\setshell} command.
\end{note}

The latency of a successful transaction includes the entire time of transaction execution with rollbacks and retries. The latency is measured only for successful transactions and commands but not for failed transactions or commands.

The main report contains the number of failed transactions. If the \texttt{--max-tries} option is not equal to 1, the main report also contains statistics related to retries: the total number of retried transactions and total number of retries. The per-script report inherits all these fields from the main report. The per-statement report displays retry statistics only if the \texttt{--max-tries} option is not equal to 1.

If you want to group failures by basic types in per-transaction and aggregation logs, as well as in the main and per-script reports, use the \texttt{--failures-detailed} option. If you also want to distinguish all errors and failures (errors without retrying) by type including which limit for retries was exceeded and how much it was exceeded by for the serialization/deadlock failures, use the \texttt{--verbose-errors} option.

\section*{Good Practices}

It is very easy to use pgbench to produce completely meaningless numbers. Here are some guidelines to help you get useful results.

In the first place, \textit{never} believe any test that runs for only a few seconds. Use the \texttt{\textendash t} or \texttt{\textendash T} option to make the run last at least a few minutes, so as to average out noise. In some cases you could need hours to get numbers that are reproducible. It’s a good idea to try the test run a few times, to find out if your numbers are reproducible or not.
For the default TPC-B-like test scenario, the initialization scale factor (-s) should be at least as large as the largest number of clients you intend to test (-c); else you'll mostly be measuring update contention. There are only -s rows in the pgbench_branches table, and every transaction wants to update one of them, so -c values in excess of -s will undoubtedly result in lots of transactions blocked waiting for other transactions.

The default test scenario is also quite sensitive to how long it's been since the tables were initialized: accumulation of dead rows and dead space in the tables changes the results. To understand the results you must keep track of the total number of updates and when vacuuming happens. If autovacuum is enabled it can result in unpredictable changes in measured performance.

A limitation of pgbench is that it can itself become the bottleneck when trying to test a large number of client sessions. This can be alleviated by running pgbench on a different machine from the database server, although low network latency will be essential. It might even be useful to run several pgbench instances concurrently, on several client machines, against the same database server.

Security

If untrusted users have access to a database that has not adopted a secure schema usage pattern, do not run pgbench in that database. pgbench uses unqualified names and does not manipulate the search path.
pg_config

pg_config — retrieve information about the installed version of PostgreSQL

Synopsis

pg_config [option...]

Description

The pg_config utility prints configuration parameters of the currently installed version of PostgreSQL. It is intended, for example, to be used by software packages that want to interface to PostgreSQL to facilitate finding the required header files and libraries.

Options

To use pg_config, supply one or more of the following options:

--bindir

Print the location of user executables. Use this, for example, to find the psql program. This is normally also the location where the pg_config program resides.

--docdir

Print the location of documentation files.

--htmldir

Print the location of HTML documentation files.

--includedir

Print the location of C header files of the client interfaces.

--pkgincludedir

Print the location of other C header files.

--includedir-server

Print the location of C header files for server programming.

--libdir

Print the location of object code libraries.

--pkglibdir

Print the location of dynamically loadable modules, or where the server would search for them. (Other architecture-dependent data files might also be installed in this directory.)
--localedir
Print the location of locale support files. (This will be an empty string if locale support was not con-
figured when PostgreSQL was built.)

--mandir
Print the location of manual pages.

--sharedir
Print the location of architecture-independent support files.

--sysconfdir
Print the location of system-wide configuration files.

--pgxs
Print the location of extension makefiles.

--configure
Print the options that were given to the configure script when PostgreSQL was configured for
building. This can be used to reproduce the identical configuration, or to find out with what options a
binary package was built. (Note however that binary packages often contain vendor-specific custom
patches.) See also the examples below.

--cc
Print the value of the CC variable that was used for building PostgreSQL. This shows the C compiler
used.

--cppflags
Print the value of the CPPFLAGS variable that was used for building PostgreSQL. This shows C
compiler switches needed at preprocessing time (typically, -I switches).

--cflags
Print the value of the CFLAGS variable that was used for building PostgreSQL. This shows C compiler
switches.

--cflags_sl
Print the value of the CFLAGS_SL variable that was used for building PostgreSQL. This shows extra
C compiler switches used for building shared libraries.

--ldflags
Print the value of the LDFLAGS variable that was used for building PostgreSQL. This shows linker
switches.

--ldflags_ex
Print the value of the LDFLAGS_EX variable that was used for building PostgreSQL. This shows linker switches used for building executables only.
--ldflags_sl

Print the value of the LDFLAGS_SL variable that was used for building PostgreSQL. This shows linker switches used for building shared libraries only.

--libs

Print the value of the LIBS variable that was used for building PostgreSQL. This normally contains -l switches for external libraries linked into PostgreSQL.

--version

Print the version of PostgreSQL.

-?
--help

Show help about pg_config command line arguments, and exit.

If more than one option is given, the information is printed in that order, one item per line. If no options are given, all available information is printed, with labels.

Notes

The options --docdir, --pkgincludedir, --localedir, --mandir, --sharedir, --sysconfdir, --cc, --cppflags, --cflags, --cflags_sl, --ldflags, --ldflags_sl, and --libs were added in PostgreSQL 8.1. The option --htmldir was added in PostgreSQL 8.4. The option --ldflags_ex was added in PostgreSQL 9.0.

Example

To reproduce the build configuration of the current PostgreSQL installation, run the following command:

eval ./configure `pg_config --configure`

The output of pg_config --configure contains shell quotation marks so arguments with spaces are represented correctly. Therefore, using eval is required for proper results.
pg_dump

pg_dump — extract a PostgreSQL database into a script file or other archive file

Synopsis

pg_dump [connection-option...] [option...] [dbname]

Description

pg_dump is a utility for backing up a PostgreSQL database. It makes consistent backups even if the database is being used concurrently. pg_dump does not block other users accessing the database (readers or writers).

pg_dump only dumps a single database. To back up an entire cluster, or to back up global objects that are common to all databases in a cluster (such as roles and tablespaces), use pg_dumpall.

Dumps can be output in script or archive file formats. Script dumps are plain-text files containing the SQL commands required to reconstruct the database to the state it was in at the time it was saved. To restore from such a script, feed it to psql. Script files can be used to reconstruct the database even on other machines and other architectures; with some modifications, even on other SQL database products.

The alternative archive file formats must be used with pg_restore to rebuild the database. They allow pg_restore to be selective about what is restored, or even to reorder the items prior to being restored. The archive file formats are designed to be portable across architectures.

When used with one of the archive file formats and combined with pg_restore, pg_dump provides a flexible archival and transfer mechanism. pg_dump can be used to backup an entire database, then pg_restore can be used to examine the archive and/or select which parts of the database are to be restored. The most flexible output file formats are the “custom” format (-Fc) and the “directory” format (-Fd). They allow for selection and reordering of all archived items, support parallel restoration, and are compressed by default. The “directory” format is the only format that supports parallel dumps.

While running pg_dump, one should examine the output for any warnings (printed on standard error), especially in light of the limitations listed below.

Options

The following command-line options control the content and format of the output.

dbname

Specifies the name of the database to be dumped. If this is not specified, the environment variable PGDATABASE is used. If that is not set, the user name specified for the connection is used.

-a
--data-only

Dump only the data, not the schema (data definitions). Table data, large objects, and sequence values are dumped.
This option is similar to, but for historical reasons not identical to, specifying --section=data.

-b  
--blobs

Include large objects in the dump. This is the default behavior except when --schema, --table, or --schema-only is specified. The -b switch is therefore only useful to add large objects to dumps where a specific schema or table has been requested. Note that blobs are considered data and therefore will be included when --data-only is used, but not when --schema-only is.

-B  
--no-blobs

Exclude large objects in the dump.

When both -b and -B are given, the behavior is to output large objects, when data is being dumped, see the -b documentation.

-c  
--clean

Output commands to clean (drop) database objects prior to outputting the commands for creating them. (Unless --if-exists is also specified, restore might generate some harmless error messages, if any objects were not present in the destination database.)

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call pg_restore.

-C  
--create

Begin the output with a command to create the database itself and reconnect to the created database. (With a script of this form, it doesn't matter which database in the destination installation you connect to before running the script.) If --clean is also specified, the script drops and recreates the target database before reconnecting to it.

With --create, the output also includes the database's comment if any, and any configuration variable settings that are specific to this database, that is, any ALTER DATABASE ... SET ... and ALTER ROLE ... IN DATABASE ... SET ... commands that mention this database. Access privileges for the database itself are also dumped, unless --no-acl is specified.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call pg_restore.

-e pattern  
--extension=pattern

Dump only extensions matching pattern. When this option is not specified, all non-system extensions in the target database will be dumped. Multiple extensions can be selected by writing multiple -e switches. The pattern parameter is interpreted as a pattern according to the same rules used by psql's \d commands (see Patterns), so multiple extensions can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards.

Any configuration relation registered by pg_extension_config_dump is included in the dump if its extension is specified by --extension.
-E encoding
--encoding=encoding

Create the dump in the specified character set encoding. By default, the dump is created in the database encoding. (Another way to get the same result is to set the PGCLIENTENCODING environment variable to the desired dump encoding.) The supported encodings are described in Section 24.3.1.

-f file
--file=file

Send output to the specified file. This parameter can be omitted for file based output formats, in which case the standard output is used. It must be given for the directory output format however, where it specifies the target directory instead of a file. In this case the directory is created by pg_dump and must not exist before.

-F format
--format=format

Selects the format of the output. format can be one of the following:

p
plain

Output a plain-text SQL script file (the default).

c
custom

Output a custom-format archive suitable for input into pg_restore. Together with the directory output format, this is the most flexible output format in that it allows manual selection and reordering of archived items during restore. This format is also compressed by default.

d
directory

Output a directory-format archive suitable for input into pg_restore. This will create a directory with one file for each table and blob being dumped, plus a so-called Table of Contents file describing the dumped objects in a machine-readable format that pg_restore can read. A directory format archive can be manipulated with standard Unix tools; for example, files in an uncompressed archive can be compressed with the gzip tool. This format is compressed by default and also supports parallel dumps.

t	tar

Output a tar-format archive suitable for input into pg_restore. The tar format is compatible with the directory format: extracting a tar-format archive produces a valid directory-format archive. However, the tar format does not support compression. Also, when using tar format the relative order of table data items cannot be changed during restore.
pg_dump

-\( j \) \( n_{\text{jobs}} \)
--jobs=\( n_{\text{jobs}} \)

Run the dump in parallel by dumping \( n_{\text{jobs}} \) tables simultaneously. This option may reduce the time needed to perform the dump but it also increases the load on the database server. You can only use this option with the directory output format because this is the only output format where multiple processes can write their data at the same time.

\( \text{pg
dump} \) will open \( n_{\text{jobs}} + 1 \) connections to the database, so make sure your max_connections setting is high enough to accommodate all connections.

Requesting exclusive locks on database objects while running a parallel dump could cause the dump to fail. The reason is that the \( \text{pg
dump} \) leader process requests shared locks on the objects that the worker processes are going to dump later in order to make sure that nobody deletes them and makes them go away while the dump is running. If another client then requests an exclusive lock on a table, that lock will not be granted but will be queued waiting for the shared lock of the leader process to be released. Consequently any other access to the table will not be granted either and will queue after the exclusive lock request. This includes the worker process trying to dump the table. Without any precautions this would be a classic deadlock situation. To detect this conflict, the \( \text{pg
dump} \) worker process requests another shared lock using the NOWAIT option. If the worker process is not granted this shared lock, somebody else must have requested an exclusive lock in the meantime and there is no way to continue with the dump, so \( \text{pg
dump} \) has no choice but to abort the dump.

To perform a parallel dump, the database server needs to support synchronized snapshots, a feature that was introduced in PostgreSQL 9.2 for primary servers and 10 for standbys. With this feature, database clients can ensure they see the same data set even though they use different connections. \( \text{pg
dump} \ -j \) uses multiple database connections; it connects to the database once with the leader process and once again for each worker job. Without the synchronized snapshot feature, the different worker jobs wouldn't be guaranteed to see the same data in each connection, which could lead to an inconsistent backup.

-\( n \) \( \text{pattern} \)
--schema=\( \text{pattern} \)

Dump only schemas matching \( \text{pattern} \); this selects both the schema itself, and all its contained objects. When this option is not specified, all non-system schemas in the target database will be dumped. Multiple schemas can be selected by writing multiple -\( n \) switches. The \( \text{pattern} \) parameter is interpreted as a pattern according to the same rules used by \( \text{psql}'s \) \( \text{\textbackslash d} \) commands (see Patterns below), so multiple schemas can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards; see Examples below.

Note
When -\( n \) is specified, \( \text{pg
dump} \) makes no attempt to dump any other database objects that the selected schema(s) might depend upon. Therefore, there is no guarantee that the results of a specific-schema dump can be successfully restored by themselves into a clean database.

Note
Non-schema objects such as blobs are not dumped when -\( n \) is specified. You can add blobs back to the dump with the --blobs switch.
pg_dump

-N pattern
--exclude-schema=pattern

Do not dump any schemas matching pattern. The pattern is interpreted according to the same rules as for -n. -N can be given more than once to exclude schemas matching any of several patterns.

When both -n and -N are given, the behavior is to dump just the schemas that match at least one -n switch but no -N switches. If -N appears without -n, then schemas matching -N are excluded from what is otherwise a normal dump.

-o
--no-owner

Do not output commands to set ownership of objects to match the original database. By default, pg_dump issues ALTER OWNER or SET SESSION AUTHORIZATION statements to set ownership of created database objects. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify -O.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call pg_restore.

-R
--no-reconnect

This option is obsolete but still accepted for backwards compatibility.

-s
--schema-only

Dump only the object definitions (schema), not data.

This option is the inverse of --data-only. It is similar to, but for historical reasons not identical to, specifying --section=pre-data --section=post-data.

(Do not confuse this with the --schema option, which uses the word “schema” in a different meaning.)

To exclude table data for only a subset of tables in the database, see --exclude-table-data.

-S username
--superuser=superuser

Specify the superuser user name to use when disabling triggers. This is relevant only if --disable-triggers is used. (Usually, it's better to leave this out, and instead start the resulting script as superuser.)

-t pattern
--table=pattern

Dump only tables with names matching pattern. Multiple tables can be selected by writing multiple -t switches. The pattern parameter is interpreted as a pattern according to the same rules used by psql's \d commands (see Patterns below), so multiple tables can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards; see Examples below.

As well as tables, this option can be used to dump the definition of matching views, materialized views, foreign tables, and sequences. It will not dump the contents of views or materialized views,
and the contents of foreign tables will only be dumped if the corresponding foreign server is specified with --include-foreign-data.

The -n and -N switches have no effect when -t is used, because tables selected by -t will be dumped regardless of those switches, and non-table objects will not be dumped.

**Note**

When -t is specified, pg_dump makes no attempt to dump any other database objects that the selected table(s) might depend upon. Therefore, there is no guarantee that the results of a specific-table dump can be successfully restored by themselves into a clean database.

-T pattern
--exclude-table=pattern

Do not dump any tables matching pattern. The pattern is interpreted according to the same rules as for -t. -T can be given more than once to exclude tables matching any of several patterns.

When both -t and -T are given, the behavior is to dump just the tables that match at least one -t switch but no -T switches. If -T appears without -t, then tables matching -T are excluded from what is otherwise a normal dump.

-v
--verbose

Specifies verbose mode. This will cause pg_dump to output detailed object comments and start/stop times to the dump file, and progress messages to standard error. Repeating the option causes additional debug-level messages to appear on standard error.

-V
--version

Print the pg_dump version and exit.

-x
--no-privileges
--no-acl

Prevent dumping of access privileges (grant/revoke commands).

-z 0..9
--compress=0..9

Specify the compression level to use. Zero means no compression. For the custom and directory archive formats, this specifies compression of individual table-data segments, and the default is to compress at a moderate level. For plain text output, setting a nonzero compression level causes the entire output file to be compressed, as though it had been fed through gzip; but the default is not to compress. The tar archive format currently does not support compression at all.

--binary-upgrade

This option is for use by in-place upgrade utilities. Its use for other purposes is not recommended or supported. The behavior of the option may change in future releases without notice.
--column-inserts
--attribute-inserts

Dump data as INSERT commands with explicit column names (INSERT INTO table (column, ...) VALUES ...). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL databases. Any error during reloading will cause only rows that are part of the problematic INSERT to be lost, rather than the entire table contents.

--disable-dollar-quoting

This option disables the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

--disable-triggers

This option is relevant only when creating a data-only dump. It instructs pg_dump to include commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if you have referential integrity checks or other triggers on the tables that you do not want to invoke during data reload.

Presently, the commands emitted for --disable-triggers must be done as superuser. So, you should also specify a superuser name with -S, or preferably be careful to start the resulting script as a superuser.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call pg_restore.

--enable-row-security

This option is relevant only when dumping the contents of a table which has row security. By default, pg_dump will set row_security to off, to ensure that all data is dumped from the table. If the user does not have sufficient privileges to bypass row security, then an error is thrown. This parameter instructs pg_dump to set row_security to on instead, allowing the user to dump the parts of the contents of the table that they have access to.

Note that if you use this option currently, you probably also want the dump be in INSERT format, as the COPY FROM during restore does not support row security.

--exclude-table-data=pattern

Do not dump data for any tables matching pattern. The pattern is interpreted according to the same rules as for -t. --exclude-table-data can be given more than once to exclude tables matching any of several patterns. This option is useful when you need the definition of a particular table even though you do not need the data in it.

To exclude data for all tables in the database, see --schema-only.

--extra-float-digits=ndigits

Use the specified value of extra_float_digits when dumping floating-point data, instead of the maximum available precision. Routine dumps made for backup purposes should not use this option.

--if-exists

Use conditional commands (i.e., add an IF EXISTS clause) when cleaning database objects. This option is not valid unless --clean is also specified.
--include-foreign-data=foreignserver

Dump the data for any foreign table with a foreign server matching foreignserver pattern. Multiple foreign servers can be selected by writing multiple --include-foreign-data switches. Also, the foreignserver parameter is interpreted as a pattern according to the same rules used by psql's \d commands (see Patterns below), so multiple foreign servers can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards; see Examples below. The only exception is that an empty pattern is disallowed.

Note

When --include-foreign-data is specified, pg_dump does not check that the foreign table is writable. Therefore, there is no guarantee that the results of a foreign table dump can be successfully restored.

--inserts

Dump data as INSERT commands (rather than COPY). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL databases. Any error during reloading will cause only rows that are part of the problematic INSERT to be lost, rather than the entire table contents. Note that the restore might fail altogether if you have rearranged column order. The --column-inserts option is safe against column order changes, though even slower.

--load-via-partition-root

When dumping data for a table partition, make the COPY or INSERT statements target the root of the partitioning hierarchy that contains it, rather than the partition itself. This causes the appropriate partition to be re-determined for each row when the data is loaded. This may be useful when reloading data on a server where rows do not always fall into the same partitions as they did on the original server. That could happen, for example, if the partitioning column is of type text and the two systems have different definitions of the collation used to sort the partitioning column.

It is best not to use parallelism when restoring from an archive made with this option, because pg_restore will not know exactly which partition(s) a given archive data item will load data into. This could result in inefficiency due to lock conflicts between parallel jobs, or perhaps even reload failures due to foreign key constraints being set up before all the relevant data is loaded.

--lock-wait-timeout=timeout

Do not wait forever to acquire shared table locks at the beginning of the dump. Instead fail if unable to lock a table within the specified timeout. The timeout may be specified in any of the formats accepted by SET statement_timeout. (Allowed formats vary depending on the server version you are dumping from, but an integer number of milliseconds is accepted by all versions.)

--no-comments

Do not dump comments.

--no-publications

Do not dump publications.

--no-security-labels

Do not dump security labels.
pg_dump

--no-subscriptions

Do not dump subscriptions.

--no-sync

By default, pg_dump will wait for all files to be written safely to disk. This option causes pg_dump to return without waiting, which is faster, but means that a subsequent operating system crash can leave the dump corrupt. Generally, this option is useful for testing but should not be used when dumping data from production installation.

--no-table-access-method

Do not output commands to select table access methods. With this option, all objects will be created with whichever table access method is the default during restore.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call pg_restore.

--no-tablespaces

Do not output commands to select tablespaces. With this option, all objects will be created with whichever tablespace is the default during restore.

This option is ignored when emitting an archive (non-text) output file. For the archive formats, you can specify the option when you call pg_restore.

--no-toast-compression

Do not output commands to set TOAST compression methods. With this option, all columns will be restored with the default compression setting.

--no-unlogged-table-data

Do not dump the contents of unlogged tables and sequences. This option has no effect on whether or not the table and sequence definitions (schema) are dumped; it only suppresses dumping the table and sequence data. Data in unlogged tables and sequences is always excluded when dumping from a standby server.

--on-conflict-do-nothing

Add ON CONFLICT DO NOTHING to INSERT commands. This option is not valid unless --inserts, --column-inserts or --rows-per-insert is also specified.

--quote-all-identifiers

Force quoting of all identifiers. This option is recommended when dumping a database from a server whose PostgreSQL major version is different from pg_dump's, or when the output is intended to be loaded into a server of a different major version. By default, pg_dump quotes only identifiers that are reserved words in its own major version. This sometimes results in compatibility issues when dealing with servers of other versions that may have slightly different sets of reserved words. Using --quote-all-identifiers prevents such issues, at the price of a harder-to-read dump script.

--rows-per-insert=nrows

Dump data as INSERT commands (rather than COPY). Controls the maximum number of rows per INSERT command. The value specified must be a number greater than zero. Any error during reload-
pg_dump

ing will cause only rows that are part of the problematic INSERT to be lost, rather than the entire table contents.

--section=sectionname

Only dump the named section. The section name can be pre-data, data, or post-data. This option can be specified more than once to select multiple sections. The default is to dump all sections.

The data section contains actual table data, large-object contents, and sequence values. Post-data items include definitions of indexes, triggers, rules, and constraints other than validated check constraints. Pre-data items include all other data definition items.

--serializable-deferrable

Use a serializable transaction for the dump, to ensure that the snapshot used is consistent with later database states; but do this by waiting for a point in the transaction stream at which no anomalies can be present, so that there isn't a risk of the dump failing or causing other transactions to roll back with a serialization_failure. See Chapter 13 for more information about transaction isolation and concurrency control.

This option is not beneficial for a dump which is intended only for disaster recovery. It could be useful for a dump used to load a copy of the database for reporting or other read-only load sharing while the original database continues to be updated. Without it the dump may reflect a state which is not consistent with any serial execution of the transactions eventually committed. For example, if batch processing techniques are used, a batch may show as closed in the dump without all of the items which are in the batch appearing.

This option will make no difference if there are no read-write transactions active when pg_dump is started. If read-write transactions are active, the start of the dump may be delayed for an indeterminate length of time. Once running, performance with or without the switch is the same.

--snapshot=snapshotname

Use the specified synchronized snapshot when making a dump of the database (see Table 9.94 for more details).

This option is useful when needing to synchronize the dump with a logical replication slot (see Chapter 49) or with a concurrent session.

In the case of a parallel dump, the snapshot name defined by this option is used rather than taking a new snapshot.

--strict-names

Require that each extension (--extension), schema (--schema) and table (--table) qualifier match at least one extension/schema/table in the database to be dumped. Note that if none of the extension/schema/table qualifiers find matches, pg_dump will generate an error even without --strict-names.

This option has no effect on --exclude-schema, --exclude-table, or --exclude-table-data. An exclude pattern failing to match any objects is not considered an error.

--use-set-session-authorization

Output SQL-standard SET SESSION AUTHORIZATION commands instead of ALTER OWNER commands to determine object ownership. This makes the dump more standards-compatible, but depending on the history of the objects in the dump, might not restore properly. Also, a dump using
SET SESSION AUTHORIZATION will certainly require superuser privileges to restore correctly, whereas ALTER OWNER requires lesser privileges.

-? --help

Show help about pg_dump command line arguments, and exit.

The following command-line options control the database connection parameters.

-d dbname
--dbname=dbname

Specifies the name of the database to connect to. This is equivalent to specifying dbname as the first non-option argument on the command line. The dbname can be a connection string. If so, connection string parameters will override any conflicting command line options.

-h host
--host=host

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the PGHOST environment variable, if set, else a Unix domain socket connection is attempted.

-p port
--port=port

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the PGPORT environment variable, if set, or a compiled-in default.

-U username
--username=username

User name to connect as.

-w --no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W --password

Force pg_dump to prompt for a password before connecting to a database.

This option is never essential, since pg_dump will automatically prompt for a password if the server demands password authentication. However, pg_dump will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

--role=rolename

Specifies a role name to be used to create the dump. This option causes pg_dump to issue a SET ROLE rolename command after connecting to the database. It is useful when the authenticated user (specified by -U) lacks privileges needed by pg_dump, but can switch to a role with the required privileges.
rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows dumps to be made without violating the policy.

Environment

**PGDATABASE**

**PGHOST**

**PGOPTIONS**

**PGPORT**

**PGUSER**

Default connection parameters.

**PG_COLOR**

Specifies whether to use color in diagnostic messages. Possible values are *always*, *auto* and *never*.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 34.15).

Diagnostics

`pg_dump` internally executes `SELECT` statements. If you have problems running `pg_dump`, make sure you are able to select information from the database using, for example, `psql`. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

The database activity of `pg_dump` is normally collected by the cumulative statistics system. If this is undesirable, you can set parameter `track_counts` to false via `PGOPTIONS` or the `ALTER USER` command.

Notes

If your database cluster has any local additions to the `template1` database, be careful to restore the output of `pg_dump` into a truly empty database; otherwise you are likely to get errors due to duplicate definitions of the added objects. To make an empty database without any local additions, copy from `template0` not `template1`, for example:

```
CREATE DATABASE foo WITH TEMPLATE template0;
```

When a data-only dump is chosen and the option `--disable-triggers` is used, `pg_dump` emits commands to disable triggers on user tables before inserting the data, and then commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs might be left in the wrong state.

The dump file produced by `pg_dump` does not contain the statistics used by the optimizer to make query planning decisions. Therefore, it is wise to run `ANALYZE` after restoring from a dump file to ensure optimal performance; see Section 25.1.3 and Section 25.1.6 for more information.

Because `pg_dump` is used to transfer data to newer versions of PostgreSQL, the output of `pg_dump` can be expected to load into PostgreSQL server versions newer than `pg_dump`'s version. `pg_dump` can also dump from PostgreSQL servers older than its own version. (Currently, servers back to version 9.2 are supported.) However, `pg_dump` cannot dump from PostgreSQL servers newer than its own major version;
it will refuse to even try, rather than risk making an invalid dump. Also, it is not guaranteed that `pg_dump`’s output can be loaded into a server of an older major version — not even if the dump was taken from a server of that version. Loading a dump file into an older server may require manual editing of the dump file to remove syntax not understood by the older server. Use of the `--quote-all-identifiers` option is recommended in cross-version cases, as it can prevent problems arising from varying reserved-word lists in different PostgreSQL versions.

When dumping logical replication subscriptions, `pg_dump` will generate `CREATE SUBSCRIPTION` commands that use the `connect = false` option, so that restoring the subscription does not make remote connections for creating a replication slot or for initial table copy. That way, the dump can be restored without requiring network access to the remote servers. It is then up to the user to reрактиivate the subscriptions in a suitable way. If the involved hosts have changed, the connection information might have to be changed. It might also be appropriate to truncate the target tables before initiating a new full table copy. If users intend to copy initial data during refresh they must create the slot with `two_phase = false`. After the initial sync, the `two_phase` option will be automatically enabled by the subscriber if the subscription had been originally created with `two_phase = true` option.

Examples

To dump a database called `mydb` into an SQL-script file:

```bash
$ pg_dump mydb > db.sql
```

To reload such a script into a (freshly created) database named `newdb`:

```bash
$ psql -d newdb -f db.sql
```

To dump a database into a custom-format archive file:

```bash
$ pg_dump -Fc mydb > db.dump
```

To dump a database into a directory-format archive:

```bash
$ pg_dump -Fd mydb -f dumpdir
```

To dump a database into a directory-format archive in parallel with 5 worker jobs:

```bash
$ pg_dump -Fd mydb -j 5 -f dumpdir
```

To reload an archive file into a (freshly created) database named `newdb`:

```bash
$ pg_restore -d newdb db.dump
```

To reload an archive file into the same database it was dumped from, discarding the current contents of that database:

```bash
$ pg_restore -d postgres --clean --create db.dump
```

To dump a single table named `mytab`:
$ pg_dump -t mytab mydb > db.sql
To dump all tables whose names start with emp in the detroit schema, except for the table named employee_log:

$ pg_dump -t 'detroit.emp*' -T detroit.employee_log mydb > db.sql
To dump all schemas whose names start with east or west and end in gsm, excluding any schemas whose names contain the word test:

$ pg_dump -n 'east*gsm' -n 'west*gsm' -N '*test*' mydb > db.sql
The same, using regular expression notation to consolidate the switches:

$ pg_dump -n '(east|west)*gsm' -N '*test*' mydb > db.sql
To dump all database objects except for tables whose names begin with ts_:

$ pg_dump -T 'ts_*' mydb > db.sql
To specify an upper-case or mixed-case name in -t and related switches, you need to double-quote the name; else it will be folded to lower case (see Patterns below). But double quotes are special to the shell, so in turn they must be quoted. Thus, to dump a single table with a mixed-case name, you need something like

$ pg_dump -t "\"MixedCaseName\"" mydb > mytab.sql

pg_dumpall

pg_dumpall — extract a PostgreSQL database cluster into a script file

Synopsis

pg_dumpall [connection-option...] [option...]

Description

pg_dumpall is a utility for writing out ("dumping") all PostgreSQL databases of a cluster into one script file. The script file contains SQL commands that can be used as input to psql to restore the databases. It does this by calling pg_dump for each database in the cluster. pg_dumpall also dumps global objects that are common to all databases, namely database roles, table spaces, and privilege grants for configuration parameters. (pg_dump does not save these objects.)

Since pg_dumpall reads tables from all databases you will most likely have to connect as a database superuser in order to produce a complete dump. Also you will need superuser privileges to execute the saved script in order to be allowed to add roles and create databases.

The SQL script will be written to the standard output. Use the -f|--file option or shell operators to redirect it into a file.

pg_dumpall needs to connect several times to the PostgreSQL server (once per database). If you use password authentication it will ask for a password each time. It is convenient to have a ~/.pgpass file in such cases. See Section 34.16 for more information.

Options

The following command-line options control the content and format of the output.

- a
  --data-only

  Dump only the data, not the schema (data definitions).

- c
  --clean

  Include SQL commands to clean (drop) databases before recreating them. DROP commands for roles and table spaces are added as well.

- E encoding
  --encoding=encoding

  Create the dump in the specified character set encoding. By default, the dump is created in the database encoding. (Another way to get the same result is to set the PGCLIENTENCODING environment variable to the desired dump encoding.)

- f filename
  --file=filename

  Send output to the specified file. If this is omitted, the standard output is used.
pg_dumpall

-\(g\)
  --globals-only
  Dump only global objects (roles and tablespaces), no databases.

-o
  --no-owner
  Do not output commands to set ownership of objects to match the original database. By default, pg_dumpall issues ALTER OWNER or SET SESSION AUTHORIZATION statements to set ownership of created schema elements. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify -O.

-r
  --roles-only
  Dump only roles, no databases or tablespaces.

-s
  --schema-only
  Dump only the object definitions (schema), not data.

-S username
  --superuser=username
  Specify the superuser user name to use when disabling triggers. This is relevant only if --disable-triggers is used. (Usually, it's better to leave this out, and instead start the resulting script as superuser.)

-t
  --tablespaces-only
  Dump only tablespaces, no databases or roles.

-v
  --verbose
  Specifies verbose mode. This will cause pg_dumpall to output start/stop times to the dump file, and progress messages to standard error. Repeating the option causes additional debug-level messages to appear on standard error. The option is also passed down to pg_dump.

-V
  --version
  Print the pg_dumpall version and exit.

-x
  --no-privileges
  --no-acl
  Prevent dumping of access privileges (grant/revoke commands).

--binary-upgrade
  This option is for use by in-place upgrade utilities. Its use for other purposes is not recommended or supported. The behavior of the option may change in future releases without notice.
--column-inserts
--attribute-inserts

Dump data as INSERT commands with explicit column names (INSERT INTO table (column, ...) VALUES ...). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL databases.

--disable-dollar-quoting

This option disables the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

--disable-triggers

This option is relevant only when creating a data-only dump. It instructs pg_dumpall to include commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if you have referential integrity checks or other triggers on the tables that you do not want to invoke during data reload.

Presently, the commands emitted for --disable-triggers must be done as superuser. So, you should also specify a superuser name with -S, or preferably be careful to start the resulting script as a superuser.

--exclude-database=pattern

Do not dump databases whose name matches pattern. Multiple patterns can be excluded by writing multiple --exclude-database switches. The pattern parameter is interpreted as a pattern according to the same rules used by psql's \d commands (see Patterns below), so multiple databases can also be excluded by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent shell wildcard expansion.

--extra-float-digits=ndigits

Use the specified value of extra_float_digits when dumping floating-point data, instead of the maximum available precision. Routine dumps made for backup purposes should not use this option.

--if-exists

Use conditional commands (i.e., add an IF EXISTS clause) to drop databases and other objects. This option is not valid unless --clean is also specified.

--inserts

Dump data as INSERT commands (rather than COPY). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL databases. Note that the restore might fail altogether if you have rearranged column order. The --column-inserts option is safer, though even slower.

--load-via-partition-root

When dumping data for a table partition, make the COPY or INSERT statements target the root of the partitioning hierarchy that contains it, rather than the partition itself. This causes the appropriate partition to be re-determined for each row when the data is loaded. This may be useful when reloading data on a server where rows do not always fall into the same partitions as they did on the original server. That could happen, for example, if the partitioning column is of type text and the two systems have different definitions of the collation used to sort the partitioning column.
--lock-wait-timeout=timeout

Do not wait forever to acquire shared table locks at the beginning of the dump. Instead, fail if unable to lock a table within the specified timeout. The timeout may be specified in any of the formats accepted by SET statement_timeout.

--no-comments

Do not dump comments.

--no-publications

Do not dump publications.

--no-role-passwords

Do not dump passwords for roles. When restored, roles will have a null password, and password authentication will always fail until the password is set. Since password values aren't needed when this option is specified, the role information is read from the catalog view pg_roles instead of pg_authid. Therefore, this option also helps if access to pg_authid is restricted by some security policy.

--no-security-labels

Do not dump security labels.

--no-subscriptions

Do not dump subscriptions.

--no-sync

By default, pg_dumpall will wait for all files to be written safely to disk. This option causes pg_dumpall to return without waiting, which is faster, but means that a subsequent operating system crash can leave the dump corrupt. Generally, this option is useful for testing but should not be used when dumping data from production installation.

--no-table-access-method

Do not output commands to select table access methods. With this option, all objects will be created with whichever table access method is the default during restore.

--no-tablespaces

Do not output commands to create tablespaces nor select tablespaces for objects. With this option, all objects will be created in whichever tablespace is the default during restore.

--no-toast-compression

Do not output commands to set TOAST compression methods. With this option, all columns will be restored with the default compression setting.

--no-unlogged-table-data

Do not dump the contents of unlogged tables. This option has no effect on whether or not the table definitions (schema) are dumped; it only suppresses dumping the table data.
--on-conflict-do-nothing

Add ON CONFLICT DO NOTHING to INSERT commands. This option is not valid unless --inserts or --column-inserts is also specified.

--quote-all-identifiers

Force quoting of all identifiers. This option is recommended when dumping a database from a server whose PostgreSQL major version is different from pg_dumpall's, or when the output is intended to be loaded into a server of a different major version. By default, pg_dumpall quotes only identifiers that are reserved words in its own major version. This sometimes results in compatibility issues when dealing with servers of other versions that may have slightly different sets of reserved words. Using --quote-all-identifiers prevents such issues, at the price of a harder-to-read dump script.

--rows-per-insert=nrows

Dump data as INSERT commands (rather than COPY). Controls the maximum number of rows per INSERT command. The value specified must be a number greater than zero. Any error during reloading will cause only rows that are part of the problematic INSERT to be lost, rather than the entire table contents.

--use-set-session-authorization

Output SQL-standard SET SESSION AUTHORIZATION commands instead of ALTER OWNER commands to determine object ownership. This makes the dump more standards compatible, but depending on the history of the objects in the dump, might not restore properly.

-?
--help

Show help about pg_dumpall command line arguments, and exit.

The following command-line options control the database connection parameters.

-d connstr
--dbname=connstr

Specifies parameters used to connect to the server, as a connection string; these will override any conflicting command line options.

The option is called --dbname for consistency with other client applications, but because pg_dumpall needs to connect to many databases, the database name in the connection string will be ignored. Use the -l option to specify the name of the database used for the initial connection, which will dump global objects and discover what other databases should be dumped.

-h host
--host=host

Specifies the host name of the machine on which the database server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the PGHOST environment variable, if set, else a Unix domain socket connection is attempted.

-l dbname
--database=dbname

Specifies the name of the database to connect to for dumping global objects and discovering what other databases should be dumped. If not specified, the postgres database will be used, and if that does not exist, template1 will be used.
-p port
--port=port

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the PGPORT environment variable, if set, or a compiled-in default.

-U username
--username=username

User name to connect as.

-w
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W
--password

Force pg_dumpall to prompt for a password before connecting to a database.

This option is never essential, since pg_dumpall will automatically prompt for a password if the server demands password authentication. However, pg_dumpall will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

Note that the password prompt will occur again for each database to be dumped. Usually, it's better to set up a ~/.pgpass file than to rely on manual password entry.

--role=rolename

Specifies a role name to be used to create the dump. This option causes pg_dumpall to issue a SET ROLE rolename command after connecting to the database. It is useful when the authenticated user (specified by -U) lacks privileges needed by pg_dumpall, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows dumps to be made without violating the policy.

Environment

PGHOST
PGOPTIONS
PGPORT
PGUSER

Default connection parameters

PG_COLOR

Specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 34.15).
Notes

Since pg_dumpall calls pg_dump internally, some diagnostic messages will refer to pg_dump.

The --clean option can be useful even when your intention is to restore the dump script into a fresh cluster. Use of --clean authorizes the script to drop and re-create the built-in postgres and template1 databases, ensuring that those databases will retain the same properties (for instance, locale and encoding) that they had in the source cluster. Without the option, those databases will retain their existing database-level properties, as well as any pre-existing contents.

Once restored, it is wise to run ANALYZE on each database so the optimizer has useful statistics. You can also run vacuumdb -a -z to analyze all databases.

The dump script should not be expected to run completely without errors. In particular, because the script will issue CREATE ROLE for every role existing in the source cluster, it is certain to get a “role already exists” error for the bootstrap superuser, unless the destination cluster was initialized with a different bootstrap superuser name. This error is harmless and should be ignored. Use of the --clean option is likely to produce additional harmless error messages about non-existent objects, although you can minimize those by adding --if-exists.

pg_dumpall requires all needed tablespace directories to exist before the restore; otherwise, database creation will fail for databases in non-default locations.

Examples

To dump all databases:

$ pg_dumpall > db.out

To reload database(s) from this file, you can use:

$ psql -f db.out postgres

It is not important to which database you connect here since the script file created by pg_dumpall will contain the appropriate commands to create and connect to the saved databases. An exception is that if you specified --clean, you must connect to the postgres database initially; the script will attempt to drop other databases immediately, and that will fail for the database you are connected to.

See Also

Check pg_dump for details on possible error conditions.
pg_isready

pg_isready — check the connection status of a PostgreSQL server

Synopsis

    pg_isready [connection-option...] [option...]

Description

    pg_isready is a utility for checking the connection status of a PostgreSQL database server. The exit status
    specifies the result of the connection check.

Options

    -d dbname
    --dbname=dbname

    Specifies the name of the database to connect to. The dbname can be a connection string. If so,
    connection string parameters will override any conflicting command line options.

    -h hostname
    --host=hostname

    Specifies the host name of the machine on which the server is running. If the value begins with a slash,
    it is used as the directory for the Unix-domain socket.

    -p port
    --port=port

    Specifies the TCP port or the local Unix-domain socket file extension on which the server is listening
    for connections. Defaults to the value of the PGPORT environment variable or, if not set, to the port
    specified at compile time, usually 5432.

    -q
    --quiet

    Do not display status message. This is useful when scripting.

    -t seconds
    --timeout=seconds

    The maximum number of seconds to wait when attempting connection before returning that the server
    is not responding. Setting to 0 disables. The default is 3 seconds.

    -U username
    --username=username

    Connect to the database as the user username instead of the default.

    -V
    --version

    Print the pg_isready version and exit.
pg_isready

-?
--help

Show help about pg_isready command line arguments, and exit.

Exit Status

pg_isready returns 0 to the shell if the server is accepting connections normally, 1 if the server is rejecting connections (for example during startup), 2 if there was no response to the connection attempt, and 3 if no attempt was made (for example due to invalid parameters).

Environment

pg_isready, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 34.15).

The environment variable PG_COLOR specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

Notes

It is not necessary to supply correct user name, password, or database name values to obtain the server status; however, if incorrect values are provided, the server will log a failed connection attempt.

Examples

Standard Usage:

$ pg_isready
/tmp:5432 - accepting connections
$ echo $? 0

Running with connection parameters to a PostgreSQL cluster in startup:

$ pg_isready -h localhost -p 5433
localhost:5433 - rejecting connections
$ echo $? 1

Running with connection parameters to a non-responsive PostgreSQL cluster:

$ pg_isready -h someremotehost
someremotehost:5432 - no response
$ echo $? 2
pg_receivewal

pg_receivewal — stream write-ahead logs from a PostgreSQL server

Synopsis

pg_receivewal [option...]

Description

pg_receivewal is used to stream the write-ahead log from a running PostgreSQL cluster. The write-ahead log is streamed using the streaming replication protocol, and is written to a local directory of files. This directory can be used as the archive location for doing a restore using point-in-time recovery (see Section 26.3).

pg_receivewal streams the write-ahead log in real time as it's being generated on the server, and does not wait for segments to complete like archive_library does. For this reason, it is not necessary to set archive_timeout when using pg_receivewal.

Unlike the WAL receiver of a PostgreSQL standby server, pg_receivewal by default flushes WAL data only when a WAL file is closed. The option --synchronous must be specified to flush WAL data in real time. Since pg_receivewal does not apply WAL, you should not allow it to become a synchronous standby when synchronous_commit equals remote_apply. If it does, it will appear to be a standby that never catches up, and will cause transaction commits to block. To avoid this, you should either configure an appropriate value for synchronous_standby_names, or specify application_name for pg_receivewal that does not match it, or change the value of synchronous_commit to something other than remote_apply.

The write-ahead log is streamed over a regular PostgreSQL connection and uses the replication protocol. The connection must be made with a user having REPLICATION permissions (see Section 22.2) or a superuser, and pg_hba.conf must permit the replication connection. The server must also be configured with max_wal_senders set high enough to leave at least one session available for the stream.

The starting point of the write-ahead log streaming is calculated when pg_receivewal starts:

1. First, scan the directory where the WAL segment files are written and find the newest completed segment file, using as the starting point the beginning of the next WAL segment file.

2. If a starting point cannot be calculated with the previous method, and if a replication slot is used, an extra READ_REPLICATION_SLOT command is issued to retrieve the slot’s restart_lsn to use as the starting point. This option is only available when streaming write-ahead logs from PostgreSQL 15 and up.

3. If a starting point cannot be calculated with the previous method, the latest WAL flush location is used as reported by the server from an IDENTIFY_SYSTEM command.

If the connection is lost, or if it cannot be initially established, with a non-fatal error, pg_receivewal will retry the connection indefinitely, and reestablish streaming as soon as possible. To avoid this behavior, use the -n parameter.

In the absence of fatal errors, pg_receivewal will run until terminated by the SIGINT signal (Control+C).
### Options

- **-D directory**
  --directory=directory

  Directory to write the output to.

  This parameter is required.

- **-E lsn**
  --endpos=lsn

  Automatically stop replication and exit with normal exit status 0 when receiving reaches the specified LSN.

  If there is a record with LSN exactly equal to *lsn*, the record will be processed.

- **--if-not-exists**

  Do not error out when **--create-slot** is specified and a slot with the specified name already exists.

- **-n**
  --no-loop

  Don't loop on connection errors. Instead, exit right away with an error.

- **--no-sync**

  This option causes *pg_receivewal* to not force WAL data to be flushed to disk. This is faster, but means that a subsequent operating system crash can leave the WAL segments corrupt. Generally, this option is useful for testing but should not be used when doing WAL archiving on a production deployment.

  This option is incompatible with **--synchronous**.

- **-s interval**
  --status-interval=interval

  Specifies the number of seconds between status packets sent back to the server. This allows for easier monitoring of the progress from server. A value of zero disables the periodic status updates completely, although an update will still be sent when requested by the server, to avoid timeout disconnect.

  The default value is 10 seconds.

- **-S slotname**
  --slot=slotname

  Require *pg_receivewal* to use an existing replication slot (see Section 27.2.6). When this option is used, *pg_receivewal* will report a flush position to the server, indicating when each segment has been synchronized to disk so that the server can remove that segment if it is not otherwise needed.

  When the replication client of *pg_receivewal* is configured on the server as a synchronous standby, then using a replication slot will report the flush position to the server, but only when a WAL file is closed. Therefore, that configuration will cause transactions on the primary to wait for a long time and effectively not work satisfactorily. The option **--synchronous** (see below) must be specified in addition to make this work correctly.
pg_receivewal

--synchronous

Flush the WAL data to disk immediately after it has been received. Also send a status packet back to the server immediately after flushing, regardless of --status-interval.

This option should be specified if the replication client of pg_receivewal is configured on the server as a synchronous standby, to ensure that timely feedback is sent to the server.

-v
--verbose

Enables verbose mode.

-Z level
-Z method[::detail]
--compress=level
--compress=method[::detail]

Enables compression of write-ahead logs.

The compression method can be set to gzip, lz4 (if PostgreSQL was compiled with --with-lz4) or none for no compression. A compression detail string can optionally be specified. If the detail string is an integer, it specifies the compression level. Otherwise, it should be a comma-separated list of items, each of the form keyword or keyword=value. Currently, the only supported keyword is level.

If no compression level is specified, the default compression level will be used. If only a level is specified without mentioning an algorithm, gzip compression will be used if the level is greater than 0, and no compression will be used if the level is 0.

The suffix .gz will automatically be added to all filenames when using gzip, and the suffix .lz4 is added when using lz4.

The following command-line options control the database connection parameters.

-d connstr
--dbname=connstr

Specifies parameters used to connect to the server, as a connection string; these will override any conflicting command line options.

The option is called --dbname for consistency with other client applications, but because pg_receivewal doesn't connect to any particular database in the cluster, database name in the connection string will be ignored.

-h host
--host=host

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the PGHOST environment variable, if set, else a Unix domain socket connection is attempted.

-p port
--port=port

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the PGPORT environment variable, if set, or a compiled-in default.
pg_receivewal

- U username
--username=username

User name to connect as.

-w
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W
--password

Force pg_receivewal to prompt for a password before connecting to a database.

This option is never essential, since pg_receivewal will automatically prompt for a password if the server demands password authentication. However, pg_receivewal will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing –W to avoid the extra connection attempt.

pg_receivewal can perform one of the two following actions in order to control physical replication slots:

--create-slot

Create a new physical replication slot with the name specified in --slot, then exit.

--drop-slot

Drop the replication slot with the name specified in --slot, then exit.

Other options are also available:

-V
--version

Print the pg_receivewal version and exit.

-?
--help

Show help about pg_receivewal command line arguments, and exit.

Exit Status

pg_receivewal will exit with status 0 when terminated by the SIGINT signal. (That is the normal way to end it. Hence it is not an error.) For fatal errors or other signals, the exit status will be nonzero.

Environment

This utility, like most other PostgreSQL utilities, uses the environment variables supported by libpq (see Section 34.15).

The environment variable PG_COLOR specifies whether to use color in diagnostic messages. Possible values are always, auto and never.
Notes

When using `pg_receivewal` instead of `archive_library` as the main WAL backup method, it is strongly recommended to use replication slots. Otherwise, the server is free to recycle or remove write-ahead log files before they are backed up, because it does not have any information, either from `archive_library` or the replication slots, about how far the WAL stream has been archived. Note, however, that a replication slot will fill up the server's disk space if the receiver does not keep up with fetching the WAL data.

`pg_receivewal` will preserve group permissions on the received WAL files if group permissions are enabled on the source cluster.

Examples

To stream the write-ahead log from the server at `mydbserver` and store it in the local directory `/usr/local/pgsql/archive`:

```bash
$ pg_receivewal -h mydbserver -D /usr/local/pgsql/archive
```

See Also

`pg_basebackup`
**pg_recvlogical**

*pg_recvlogical* — control PostgreSQL logical decoding streams

**Synopsis**

```bash
pg_recvlogical [option...]
```

**Description**

`pg_recvlogical` controls logical decoding replication slots and streams data from such replication slots.

It creates a replication-mode connection, so it is subject to the same constraints as *pg_receivewal*, plus those for logical replication (see Chapter 49).

`pg_recvlogical` has no equivalent to the logical decoding SQL interface's peek and get modes. It sends replay confirmations for data lazily as it receives it and on clean exit. To examine pending data on a slot without consuming it, use `pg_logical_slot_peek_changes`.

**Options**

At least one of the following options must be specified to select an action:

---

**--create-slot**

Create a new logical replication slot with the name specified by *--slot*, using the output plugin specified by *--plugin*, for the database specified by *--dbname*.

The *--two-phase* can be specified with *--create-slot* to enable two-phase decoding.

**--drop-slot**

Drop the replication slot with the name specified by *--slot*, then exit.

**--start**

Begin streaming changes from the logical replication slot specified by *--slot*, continuing until terminated by a signal. If the server side change stream ends with a server shutdown or disconnect, retry in a loop unless *--no-loop* is specified.

The stream format is determined by the output plugin specified when the slot was created.

The connection must be to the same database used to create the slot.

*--create-slot* and *--start* can be specified together. *--drop-slot* cannot be combined with another action.

The following command-line options control the location and format of the output and other replication behavior:
-E  lsn
--endpos=lsn

In --start mode, automatically stop replication and exit with normal exit status 0 when receiving
reaches the specified LSN. If specified when not in --start mode, an error is raised.

If there's a record with LSN exactly equal to lsn, the record will be output.

The --endpos option is not aware of transaction boundaries and may truncate output partway
through a transaction. Any partially output transaction will not be consumed and will be replayed
again when the slot is next read from. Individual messages are never truncated.

-f  filename
--file=filename

Write received and decoded transaction data into this file. Use – for stdout.

-F  interval_seconds
--fsync-interval=interval_seconds

Specifies how often pg_recvlogical should issue fsync() calls to ensure the output file is safely
flushed to disk.

The server will occasionally request the client to perform a flush and report the flush position to the
server. This setting is in addition to that, to perform flushes more frequently.

Specifying an interval of 0 disables issuing fsync() calls altogether, while still reporting progress
to the server. In this case, data could be lost in the event of a crash.

-I  lsn
--startpos=lsn

In --start mode, start replication from the given LSN. For details on the effect of this, see the
documentation in Chapter 49 and Section 54.4. Ignored in other modes.

--if-not-exists

Do not error out when --create-slot is specified and a slot with the specified name already
exists.

-n
--no-loop

When the connection to the server is lost, do not retry in a loop, just exit.

-o name[=value]
--option=name[=value]

Pass the option name to the output plugin with, if specified, the option value value. Which options
exist and their effects depends on the used output plugin.

-P  plugin
--plugin=plugin

When creating a slot, use the specified logical decoding output plugin. See Chapter 49. This option
has no effect if the slot already exists.
-s interval_seconds
--status-interval=interval_seconds

This option has the same effect as the option of the same name in pg_receivewal. See the description there.

-S slot_name
--slot=slot_name

In --start mode, use the existing logical replication slot named slot_name. In --create-slot mode, create the slot with this name. In --drop-slot mode, delete the slot with this name.

-t
--two-phase

Enables two-phase decoding. This option should only be specified with --create-slot

-v
--verbose

Enables verbose mode.

The following command-line options control the database connection parameters.

-d dbname
--dbname=dbname

The database to connect to. See the description of the actions for what this means in detail. The dbname can be a connection string. If so, connection string parameters will override any conflicting command line options. Defaults to the user name.

-h hostname-or-ip
--host=hostname-or-ip

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the PGHOST environment variable, if set, else a Unix domain socket connection is attempted.

-p port
--port=port

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the PGPORT environment variable, if set, or a compiled-in default.

-U user
--username=user

User name to connect as. Defaults to current operating system user name.

-w
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.
-W
--password

Force pg_recvlogical to prompt for a password before connecting to a database.

This option is never essential, since pg_recvlogical will automatically prompt for a password if the server demands password authentication. However, pg_recvlogical will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

The following additional options are available:

-v
--version

Print the pg_recvlogical version and exit.

-?
--help

Show help about pg_recvlogical command line arguments, and exit.

Environment

This utility, like most other PostgreSQL utilities, uses the environment variables supported by libpq (see Section 34.15).

The environment variable PG_COLOR specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

Notes

pg_recvlogical will preserve group permissions on the received WAL files if group permissions are enabled on the source cluster.

Examples

See Section 49.1 for an example.

pg_receivewal
pg_restore

pg_restore — restore a PostgreSQL database from an archive file created by pg_dump

Synopsis

pg_restore [connection-option...] [option...] [filename]

Description

pg_restore is a utility for restoring a PostgreSQL database from an archive created by pg_dump in one of the non-plain-text formats. It will issue the commands necessary to reconstruct the database to the state it was in at the time it was saved. The archive files also allow pg_restore to be selective about what is restored, or even to reorder the items prior to being restored. The archive files are designed to be portable across architectures.

pg_restore can operate in two modes. If a database name is specified, pg_restore connects to that database and restores archive contents directly into the database. Otherwise, a script containing the SQL commands necessary to rebuild the database is created and written to a file or standard output. This script output is equivalent to the plain text output format of pg_dump. Some of the options controlling the output are therefore analogous to pg_dump options.

Obviously, pg_restore cannot restore information that is not present in the archive file. For instance, if the archive was made using the “dump data as INSERT commands” option, pg_restore will not be able to load the data using COPY statements.

Options

pg_restore accepts the following command line arguments.

filename

Specifies the location of the archive file (or directory, for a directory-format archive) to be restored. If not specified, the standard input is used.

-a
--data-only

Restore only the data, not the schema (data definitions). Table data, large objects, and sequence values are restored, if present in the archive.

This option is similar to, but for historical reasons not identical to, specifying --section=data.

-c
--clean

Clean (drop) database objects before recreating them. (Unless --if-exists is used, this might generate some harmless error messages, if any objects were not present in the destination database.)

-C
--create

Create the database before restoring into it. If --clean is also specified, drop and recreate the target database before connecting to it.
With --create, pg_restore also restores the database’s comment if any, and any configuration variable settings that are specific to this database, that is, any ALTER DATABASE ... SET ... and ALTER ROLE ... IN DATABASE ... SET ... commands that mention this database. Access privileges for the database itself are also restored, unless --no-acl is specified.

When this option is used, the database named with -d is used only to issue the initial DROP DATABASE and CREATE DATABASE commands. All data is restored into the database name that appears in the archive.

-d dbname
--dbname=dbname

Connect to database dbname and restore directly into the database. The dbname can be a connection string. If so, connection string parameters will override any conflicting command line options.

-e
--exit-on-error

Exit if an error is encountered while sending SQL commands to the database. The default is to continue and to display a count of errors at the end of the restoration.

-f filename
--file=filename

Specify output file for generated script, or for the listing when used with -l. Use – for stdout.

-F format
--format=format

Specify format of the archive. It is not necessary to specify the format, since pg_restore will determine the format automatically. If specified, it can be one of the following:

c
  custom

  The archive is in the custom format of pg_dump.

d
directory

  The archive is a directory archive.

 t
tar

  The archive is a tar archive.

-I index
--index=index

Restore definition of named index only. Multiple indexes may be specified with multiple -I switches.

-j number-of-jobs
--jobs=number-of-jobs

Run the most time-consuming steps of pg_restore — those that load data, create indexes, or create constraints — concurrently, using up to number-of-jobs concurrent sessions. This option can
dramatically reduce the time to restore a large database to a server running on a multiprocessor machine. This option is ignored when emitting a script rather than connecting directly to a database server.

Each job is one process or one thread, depending on the operating system, and uses a separate connection to the server.

The optimal value for this option depends on the hardware setup of the server, of the client, and of the network. Factors include the number of CPU cores and the disk setup. A good place to start is the number of CPU cores on the server, but values larger than that can also lead to faster restore times in many cases. Of course, values that are too high will lead to decreased performance because of thrashing.

Only the custom and directory archive formats are supported with this option. The input must be a regular file or directory (not, for example, a pipe or standard input). Also, multiple jobs cannot be used together with the option --single-transaction.

-1
--list

List the table of contents of the archive. The output of this operation can be used as input to the -L option. Note that if filtering switches such as -n or -t are used with -1, they will restrict the items listed.

- L  list-file
--use-list=list-file

Restore only those archive elements that are listed in list-file, and restore them in the order they appear in the file. Note that if filtering switches such as -n or -t are used with -L, they will further restrict the items restored.

list-file is normally created by editing the output of a previous -l operation. Lines can be moved or removed, and can also be commented out by placing a semicolon (;) at the start of the line. See below for examples.

- n  schema
--schema=schema

Restore only objects that are in the named schema. Multiple schemas may be specified with multiple -n switches. This can be combined with the -t option to restore just a specific table.

-N schema
--exclude-schema=schema

Do not restore objects that are in the named schema. Multiple schemas to be excluded may be specified with multiple -N switches.

When both -n and -N are given for the same schema name, the -N switch wins and the schema is excluded.

-O
--no-owner

Do not output commands to set ownership of objects to match the original database. By default, pg_restore issues ALTER OWNER or SET SESSION AUTHORIZATION statements to set ownership of created schema elements. These statements will fail unless the initial connection to the database is
made by a superuser (or the same user that owns all of the objects in the script). With -O, any user name can be used for the initial connection, and this user will own all the created objects.

```
-P function-name(argtype [, ...])
--function=function-name(argtype [, ...])
```

Restore the named function only. Be careful to spell the function name and arguments exactly as they appear in the dump file's table of contents. Multiple functions may be specified with multiple -P switches.

```
-R
--no-reconnect
```

This option is obsolete but still accepted for backwards compatibility.

```
-s
--schema-only
```

Restore only the schema (data definitions), not data, to the extent that schema entries are present in the archive.

This option is the inverse of --data-only. It is similar to, but for historical reasons not identical to, specifying --section=pre-data --section=post-data.

(Do not confuse this with the --schema option, which uses the word “schema” in a different meaning.)

```
-S username
--superuser=username
```

Specify the superuser user name to use when disabling triggers. This is relevant only if --disable-triggers is used.

```
-t table
--table=table
```

Restore definition and/or data of only the named table. For this purpose, “table” includes views, materialized views, sequences, and foreign tables. Multiple tables can be selected by writing multiple -t switches. This option can be combined with the -n option to specify table(s) in a particular schema.

---

**Note**

When -t is specified, pg_restore makes no attempt to restore any other database objects that the selected table(s) might depend upon. Therefore, there is no guarantee that a specific-table restore into a clean database will succeed.

---

**Note**

This flag does not behave identically to the -t flag of pg_dump. There is not currently any provision for wild-card matching in pg_restore, nor can you include a schema name within its -t. And, while pg_dump's -t flag will also dump subsidiary objects (such as indexes) of the selected table(s), pg_restore's -t flag does not include such subsidiary objects.
Note

In versions prior to PostgreSQL 9.6, this flag matched only tables, not any other type of relation.

-T trigger
--trigger=trigger

Restore named trigger only. Multiple triggers may be specified with multiple -T switches.

-v
--verbose

Specifies verbose mode. This will cause pg_restore to output detailed object comments and start/stop times to the output file, and progress messages to standard error. Repeating the option causes additional debug-level messages to appear on standard error.

-V
--version

Print the pg_restore version and exit.

-x
--no-privileges
--no-acl

Prevent restoration of access privileges (grant/revoke commands).

-l
--single-transaction

Execute the restore as a single transaction (that is, wrap the emitted commands in BEGIN/COMMIT). This ensures that either all the commands complete successfully, or no changes are applied. This option implies --exit-on-error.

--disable-triggers

This option is relevant only when performing a data-only restore. It instructs pg_restore to execute commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if you have referential integrity checks or other triggers on the tables that you do not want to invoke during data reload.

Presently, the commands emitted for --disable-triggers must be done as superuser. So you should also specify a superuser name with -S or, preferably, run pg_restore as a PostgreSQL superuser.

--enable-row-security

This option is relevant only when restoring the contents of a table which has row security. By default, pg_restore will set row_security to off, to ensure that all data is restored in to the table. If the user does not have sufficient privileges to bypass row security, then an error is thrown. This parameter instructs pg_restore to set row_security to on instead, allowing the user to attempt to restore the contents of the table with row security enabled. This might still fail if the user does not have the right to insert the rows from the dump into the table.
Note that this option currently also requires the dump be in INSERT format, as COPY FROM does not support row security.

--if-exists

Use conditional commands (i.e., add an IF EXISTS clause) to drop database objects. This option is not valid unless --clean is also specified.

--no-comments

Do not output commands to restore comments, even if the archive contains them.

--no-data-for-failed-tables

By default, table data is restored even if the creation command for the table failed (e.g., because it already exists). With this option, data for such a table is skipped. This behavior is useful if the target database already contains the desired table contents. For example, auxiliary tables for PostgreSQL extensions such as PostGIS might already be loaded in the target database; specifying this option prevents duplicate or obsolete data from being loaded into them.

This option is effective only when restoring directly into a database, not when producing SQL script output.

--no-publications

Do not output commands to restore publications, even if the archive contains them.

--no-security-labels

Do not output commands to restore security labels, even if the archive contains them.

--no-subscriptions

Do not output commands to restore subscriptions, even if the archive contains them.

--no-table-access-method

Do not output commands to select table access methods. With this option, all objects will be created with whichever access method is the default during restore.

--no-tablespaces

Do not output commands to select tablespaces. With this option, all objects will be created in whichever tablespace is the default during restore.

--section=sectionname

Only restore the named section. The section name can be pre-data, data, or post-data. This option can be specified more than once to select multiple sections. The default is to restore all sections.

The data section contains actual table data as well as large-object definitions. Post-data items consist of definitions of indexes, triggers, rules and constraints other than validated check constraints. Pre-data items consist of all other data definition items.

--strict-names

Require that each schema (-n/--schema) and table (-t/--table) qualifier match at least one schema/table in the backup file.
pg_restore

--use-set-session-authorization

Output SQL-standard SET SESSION AUTHORIZATION commands instead of ALTER OWNER commands to determine object ownership. This makes the dump more standards-compatible, but depending on the history of the objects in the dump, might not restore properly.

-?
--help

Show help about pg_restore command line arguments, and exit.

pg_restore also accepts the following command line arguments for connection parameters:

-h host
--host=host

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the PGHOST environment variable, if set, else a Unix domain socket connection is attempted.

-p port
--port=port

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the PGPORT environment variable, if set, or a compiled-in default.

-U username
--username=username

User name to connect as.

-w
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W
--password

Force pg_restore to prompt for a password before connecting to a database.

This option is never essential, since pg_restore will automatically prompt for a password if the server demands password authentication. However, pg_restore will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

--role=rolename

Specifies a role name to be used to perform the restore. This option causes pg_restore to issue a SET ROLE rolename command after connecting to the database. It is useful when the authenticated user (specified by -U) lacks privileges needed by pg_restore, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows restores to be performed without violating the policy.
Environment

PGHOST
PGOPTIONS
PGPORT
PGUSER

Default connection parameters

PG_COLOR

Specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 34.15). However, it does not read PGDATABASE when a database name is not supplied.

Diagnostics

When a direct database connection is specified using the -d option, pg_restore internally executes SQL statements. If you have problems running pg_restore, make sure you are able to select information from the database using, for example, psql. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Notes

If your installation has any local additions to the template1 database, be careful to load the output of pg_restore into a truly empty database; otherwise you are likely to get errors due to duplicate definitions of the added objects. To make an empty database without any local additions, copy from template0 not template1, for example:

CREATE DATABASE foo WITH TEMPLATE template0;

The limitations of pg_restore are detailed below.

• When restoring data to a pre-existing table and the option --disable-triggers is used, pg_restore emits commands to disable triggers on user tables before inserting the data, then emits commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs might be left in the wrong state.

• pg_restore cannot restore large objects selectively; for instance, only those for a specific table. If an archive contains large objects, then all large objects will be restored, or none of them if they are excluded via -L, -t, or other options.

See also the pg_dump documentation for details on limitations of pg_dump.

Once restored, it is wise to run ANALYZE on each restored table so the optimizer has useful statistics; see Section 25.1.3 and Section 25.1.6 for more information.

Examples

Assume we have dumped a database called mydb into a custom-format dump file:
To drop the database and recreate it from the dump:

```
$ dropdb mydb
$ pg_restore -C -d postgres db.dump
```

The database named in the `-d` switch can be any database existing in the cluster; `pg_restore` only uses it to issue the `CREATE DATABASE` command for `mydb`. With `-C`, data is always restored into the database name that appears in the dump file.

To reload the dump into a new database called `newdb`:

```
$ createdb -T template0 newdb
$ pg_restore -d newdb db.dump
```

Notice we don't use `-C`, and instead connect directly to the database to be restored into. Also note that we clone the new database from `template0` not `template1`, to ensure it is initially empty.

To reorder database items, it is first necessary to dump the table of contents of the archive:

```
$ pg_restore -l db.dump > db.list
```

The listing file consists of a header and one line for each item, e.g.:

```
;
; Archive created at Mon Sep 14 13:55:39 2009
;   dbname: DBDEMOS
;   TOC Entries: 81
;   Compression: 9

Semicolons start a comment, and the numbers at the start of lines refer to the internal archive ID assigned to each item.

Lines in the file can be commented out, deleted, and reordered. For example:
could be used as input to `pg_restore` and would only restore items 10 and 6, in that order:

```
$ pg_restore -L db.list db.dump
```

pg_verifybackup — verify the integrity of a base backup of a PostgreSQL cluster

**Synopsis**

```
pg_verifybackup [option...]
```

**Description**

`pg_verifybackup` is used to check the integrity of a database cluster backup taken using `pg_basebackup` against a `backup_manifest` generated by the server at the time of the backup. The backup must be stored in the "plain" format; a "tar" format backup can be checked after extracting it.

It is important to note that the validation which is performed by `pg_verifybackup` does not and cannot include every check which will be performed by a running server when attempting to make use of the backup. Even if you use this tool, you should still perform test restores and verify that the resulting databases work as expected and that they appear to contain the correct data. However, `pg_verifybackup` can detect many problems that commonly occur due to storage problems or user error.

Backup verification proceeds in four stages. First, `pg_verifybackup` reads the `backup_manifest` file. If that file does not exist, cannot be read, is malformed, or fails verification against its own internal checksum, `pg_verifybackup` will terminate with a fatal error.

Second, `pg_verifybackup` will attempt to verify that the data files currently stored on disk are exactly the same as the data files which the server intended to send, with some exceptions that are described below. Extra and missing files will be detected, with a few exceptions. This step will ignore the presence or absence of, or any modifications to, `postgresql.auto.conf`, `standby.signal`, and `recovery.signal`, because it is expected that these files may have been created or modified as part of the process of taking the backup. It also won't complain about a `backup_manifest` file in the target directory or about anything inside `pg_wal`, even though these files won't be listed in the backup manifest. Only files are checked; the presence or absence of directories is not verified, except indirectly: if a directory is missing, any files it should have contained will necessarily also be missing.

Next, `pg_verifybackup` will checksum all the files, compare the checksums against the values in the manifest, and emit errors for any files for which the computed checksum does not match the checksum stored in the manifest. This step is not performed for any files which produced errors in the previous step, since they are already known to have problems. Files which were ignored in the previous step are also ignored in this step.

Finally, `pg_verifybackup` will use the manifest to verify that the write-ahead log records which will be needed to recover the backup are present and that they can be read and parsed. The `backup_manifest` contains information about which write-ahead log records will be needed, and `pg_verifybackup` will use that information to invoke `pg_waldump` to parse those write-ahead log records. The `--quiet` flag will be used, so that `pg_waldump` will only report errors, without producing any other output. While this level of verification is sufficient to detect obvious problems such as a missing file or one whose internal checksums do not match, they aren't extensive enough to detect every possible problem that might occur when attempting to recover. For instance, a server bug that produces write-ahead log records that have the correct checksums but specify nonsensical actions can't be detected by this method.

Note that if extra WAL files which are not required to recover the backup are present, they will not be checked by this tool, although a separate invocation of `pg_waldump` could be used for that purpose.
Also note that WAL verification is version-specific: you must use the version of `pg_verifybackup`, and thus of `pg_waldump`, which pertains to the backup being checked. In contrast, the data file integrity checks should work with any version of the server that generates a `backup_manifest` file.

**Options**

`pg_verifybackup` accepts the following command-line arguments:

- `-e`  
  `--exit-on-error`

  Exit as soon as a problem with the backup is detected. If this option is not specified, `pg_verifybackup` will continue checking the backup even after a problem has been detected, and will report all problems detected as errors.

- `-i path`  
  `--ignore=path`

  Ignore the specified file or directory, which should be expressed as a relative path name, when comparing the list of data files actually present in the backup to those listed in the `backup_manifest` file. If a directory is specified, this option affects the entire subtree rooted at that location. Complaints about extra files, missing files, file size differences, or checksum mismatches will be suppressed if the relative path name matches the specified path name. This option can be specified multiple times.

- `-m path`  
  `--manifest-path=path`

  Use the manifest file at the specified path, rather than one located in the root of the backup directory.

- `-n`  
  `--no-parse-wal`

  Don't attempt to parse write-ahead log data that will be needed to recover from this backup.

- `-q`  
  `--quiet`

  Don't print anything when a backup is successfully verified.

- `-s`  
  `--skip-checksums`

  Do not verify data file checksums. The presence or absence of files and the sizes of those files will still be checked. This is much faster, because the files themselves do not need to be read.

- `-w path`  
  `--wal-directory=path`

  Try to parse WAL files stored in the specified directory, rather than in `pg_wal`. This may be useful if the backup is stored in a separate location from the WAL archive.

Other options are also available:

- `-V`  
  `--version`

  Print the `pg_verifybackup` version and exit.
-?
--help

Show help about pg_verifybackup command line arguments, and exit.

Examples

To create a base backup of the server at mydbserver and verify the integrity of the backup:

```
$ pg_basebackup -h mydbserver -D /usr/local/pgsql/data
$ pg_verifybackup /usr/local/pgsql/data
```

To create a base backup of the server at mydbserver, move the manifest somewhere outside the backup directory, and verify the backup:

```
$ pg_basebackup -h mydbserver -D /usr/local/pgsql/backup1234
$ mv /usr/local/pgsql/backup1234/backup_manifest /my/secure/location/backup_manifest.1234
$ pg_verifybackup -m /my/secure/location/backup_manifest.1234 /usr/local/pgsql/backup1234
```

To verify a backup while ignoring a file that was added manually to the backup directory, and also skipping checksum verification:

```
$ pg_basebackup -h mydbserver -D /usr/local/pgsql/data
$ edit /usr/local/pgsql/data/note.to.self
$ pg_verifybackup --ignore=note.to.self --skip-checksums /usr/local/pgsql/data
```

psql

psql — PostgreSQL interactive terminal

Synopsis

psql [option...][dbname [username]]

Description

psql is a terminal-based front-end to PostgreSQL. It enables you to type in queries interactively, issue them to PostgreSQL, and see the query results. Alternatively, input can be from a file or from command line arguments. In addition, psql provides a number of meta-commands and various shell-like features to facilitate writing scripts and automating a wide variety of tasks.

Options

-a
--echo-all

Print all nonempty input lines to standard output as they are read. (This does not apply to lines read interactively.) This is equivalent to setting the variable ECHO to all.

-A
--no-align

Switches to unaligned output mode. (The default output mode is aligned.) This is equivalent to \pset format unaligned.

-b
--echo-errors

Print failed SQL commands to standard error output. This is equivalent to setting the variable ECHO to errors.

-c command
--command=command

Specifies that psql is to execute the given command string, command. This option can be repeated and combined in any order with the -f option. When either -c or -f is specified, psql does not read commands from standard input; instead it terminates after processing all the -c and -f options in sequence.

command must be either a command string that is completely parsable by the server (i.e., it contains no psql-specific features), or a single backslash command. Thus you cannot mix SQL and psql meta-commands within a -c option. To achieve that, you could use repeated -c options or pipe the string into psql, for example:

psql -c '\x' -c 'SELECT * FROM foo;'

or
psql

```bash
echo '\x \ SELECT * FROM foo;' | psql
```

(``` is the separator meta-command.)

Each SQL command string passed to \-c is sent to the server as a single request. Because of this, the server executes it as a single transaction even if the string contains multiple SQL commands, unless there are explicit BEGIN/COMMIT commands included in the string to divide it into multiple transactions. (See Section 54.2.2.1 for more details about how the server handles multi-query strings.)

If having several commands executed in one transaction is not desired, use repeated \-c commands or feed multiple commands to psql's standard input, either using echo as illustrated above, or via a shell here-document, for example:

```bash
psql <<EOF
\x
SELECT * FROM foo;
EOF
```

--csv

Switches to CSV (Comma-Separated Values) output mode. This is equivalent to \psset format csv.

-\ -dbname
--dbname=dbname

Specifies the name of the database to connect to. This is equivalent to specifying `dbname` as the first non-option argument on the command line. The `dbname` can be a connection string. If so, connection string parameters will override any conflicting command line options.

-e
--echo-queries

Copy all SQL commands sent to the server to standard output as well. This is equivalent to setting the variable ECHO to queries.

-E
--echo-hidden

Echo the actual queries generated by \\ and other backslash commands. You can use this to study psql's internal operations. This is equivalent to setting the variable ECHO_HIDDEN to on.

-\ -filename
--file=filename

Read commands from the file `filename`, rather than standard input. This option can be repeated and combined in any order with the \-c option. When either \-c or \-f is specified, psql does not read commands from standard input; instead it terminates after processing all the \-c and \-f options in sequence. Except for that, this option is largely equivalent to the meta-command ```.

If `filename` is \- (hyphen), then standard input is read until an EOF indication or ``` meta-command. This can be used to intersperse interactive input with input from files. Note however that Readline is not used in this case (much as if \-n had been specified).
Using this option is subtly different from writing `psql < filename`. In general, both will do what you expect, but using `-f` enables some nice features such as error messages with line numbers. There is also a slight chance that using this option will reduce the start-up overhead. On the other hand, the variant using the shell's input redirection is (in theory) guaranteed to yield exactly the same output you would have received had you entered everything by hand.

```
-F separator
--field-separator=separator
```

Use `separator` as the field separator for unaligned output. This is equivalent to `\pset fieldsep` or `\f`.

```
-h hostname
--host=hostname
```

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix-domain socket.

```
-H
--html
```

Switches to HTML output mode. This is equivalent to `\pset format html` or the `\H` command.

```
-l
--list
```

List all available databases, then exit. Other non-connection options are ignored. This is similar to the meta-command `\list`.

When this option is used, `psql` will connect to the database `postgres`, unless a different database is named on the command line (option `-d` or non-option argument, possibly via a service entry, but not via an environment variable).

```
-L filename
--log-file=filename
```

Write all query output into file `filename`, in addition to the normal output destination.

```
-n
--no-readline
```

Do not use Readline for line editing and do not use the command history (see the section called “Command-Line Editing” below).

```
-o filename
--output=filename
```

Put all query output into file `filename`. This is equivalent to the command `\o`.

```
-p port
--port=port
```

Specifies the TCP port or the local Unix-domain socket file extension on which the server is listening for connections. Defaults to the value of the `PGPORT` environment variable or, if not set, to the port specified at compile time, usually 5432.
-P assignment
--pset=assignment

Specifies printing options, in the style of \pset. Note that here you have to separate name and value with an equal sign instead of a space. For example, to set the output format to LaTeX, you could write -P format=latex.

-q
--quiet

Specifies that psql should do its work quietly. By default, it prints welcome messages and various informational output. If this option is used, none of this happens. This is useful with the -c option. This is equivalent to setting the variable QUIET to on.

-R separator
--record-separator=separator

Use separator as the record separator for unaligned output. This is equivalent to \pset recordsep.

-s
--single-step

Run in single-step mode. That means the user is prompted before each command is sent to the server, with the option to cancel execution as well. Use this to debug scripts.

-S
--single-line

Runs in single-line mode where a newline terminates an SQL command, as a semicolon does.

**Note**

This mode is provided for those who insist on it, but you are not necessarily encouraged to use it. In particular, if you mix SQL and meta-commands on a line the order of execution might not always be clear to the inexperienced user.

-t
--tuples-only

Turn off printing of column names and result row count footers, etc. This is equivalent to \t or \pset tuples_only.

-T table_options
--table-attr=table_options

Specifies options to be placed within the HTML table tag. See \pset tableattr for details.

-U username
--username=username

Connect to the database as the user username instead of the default. (You must have permission to do so, of course.)
Perform a variable assignment, like the \set meta-command. Note that you must separate name and
value, if any, by an equal sign on the command line. To unset a variable, leave off the equal sign. To set
a variable with an empty value, use the equal sign but leave off the value. These assignments are done
during command line processing, so variables that reflect connection state will get overwritten later.

Print the psql version and exit.

Never issue a password prompt. If the server requires password authentication and a password is not
available from other sources such as a .pgpass file, the connection attempt will fail. This option
can be useful in batch jobs and scripts where no user is present to enter a password.

Note that this option will remain set for the entire session, and so it affects uses of the meta-command
\connect as well as the initial connection attempt.

Force psql to prompt for a password before connecting to a database, even if the password will not
be used.

If the server requires password authentication and a password is not available from other sources
such as a .pgpass file, psql will prompt for a password in any case. However, psql will waste a
connection attempt finding out that the server wants a password. In some cases it is worth typing –W
to avoid the extra connection attempt.

Note that this option will remain set for the entire session, and so it affects uses of the meta-command
\connect as well as the initial connection attempt.

Turn on the expanded table formatting mode. This is equivalent to \x or \pset expanded.

Do not read the start-up file (neither the system-wide psqlrc file nor the user's ~/.psqlrc file).

Set the field separator for unaligned output to a zero byte. This is equivalent to \pset field-
sep_zero.

Set the record separator for unaligned output to a zero byte. This is useful for interfacing, for example,
with xargs -0. This is equivalent to \pset recordsep_zero.
-1
--single-transaction

This option can only be used in combination with one or more -c and/or -f options. It causes psql to issue a BEGIN command before the first such option and a COMMIT command after the last one, thereby wrapping all the commands into a single transaction. If any of the commands fails and the variable ON_ERROR_STOP was set, a ROLLBACK command is sent instead. This ensures that either all the commands complete successfully, or no changes are applied.

If the commands themselves contain BEGIN, COMMIT, or ROLLBACK, this option will not have the desired effects. Also, if an individual command cannot be executed inside a transaction block, specifying this option will cause the whole transaction to fail.

-?
--help[=topic]

Show help about psql and exit. The optional topic parameter (defaulting to options) selects which part of psql is explained: commands describes psql's backslash commands; options describes the command-line options that can be passed to psql; and variables shows help about psql configuration variables.

Exit Status

psql returns 0 to the shell if it finished normally, 1 if a fatal error of its own occurs (e.g., out of memory, file not found), 2 if the connection to the server went bad and the session was not interactive, and 3 if an error occurred in a script and the variable ON_ERROR_STOP was set.

Usage

Connecting to a Database

psql is a regular PostgreSQL client application. In order to connect to a database you need to know the name of your target database, the host name and port number of the server, and what user name you want to connect as. psql can be told about those parameters via command line options, namely -d, -h, -p, and -U respectively. If an argument is found that does not belong to any option it will be interpreted as the database name (or the user name, if the database name is already given). Not all of these options are required; there are useful defaults. If you omit the host name, psql will connect via a Unix-domain socket to a server on the local host, or via TCP/IP to localhost on machines that don't have Unix-domain sockets. The default port number is determined at compile time. Since the database server uses the same default, you will not have to specify the port in most cases. The default user name is your operating-system user name, as is the default database name. Note that you cannot just connect to any database under any user name. Your database administrator should have informed you about your access rights.

When the defaults aren't quite right, you can save yourself some typing by setting the environment variables PGDATABASE, PGHOST, PGPORT and/or PGUSER to appropriate values. (For additional environment variables, see Section 34.15.) It is also convenient to have a ~/.pgpass file to avoid regularly having to type in passwords. See Section 34.16 for more information.

An alternative way to specify connection parameters is in a conninfo string or a URI, which is used instead of a database name. This mechanism give you very wide control over the connection. For example:

$ psql "service=myservice sslmode=require"
$ psql postgresql://dbmaster:5433/mydb?sslmode=require
This way you can also use LDAP for connection parameter lookup as described in Section 34.18. See Section 34.1.2 for more information on all the available connection options.

If the connection could not be made for any reason (e.g., insufficient privileges, server is not running on the targeted host, etc.), psql will return an error and terminate.

If both standard input and standard output are a terminal, then psql sets the client encoding to “auto”, which will detect the appropriate client encoding from the locale settings (LC_CTYPE environment variable on Unix systems). If this doesn't work out as expected, the client encoding can be overridden using the environment variable PGCLIENTENCODING.

### Entering SQL Commands

In normal operation, psql provides a prompt with the name of the database to which psql is currently connected, followed by the string =>. For example:

```
$ psql testdb
psql (15beta2)
Type "help" for help.

testdb=>
```

At the prompt, the user can type in SQL commands. Ordinarily, input lines are sent to the server when a command-terminating semicolon is reached. An end of line does not terminate a command. Thus commands can be spread over several lines for clarity. If the command was sent and executed without error, the results of the command are displayed on the screen.

If untrusted users have access to a database that has not adopted a secure schema usage pattern, begin your session by removing publicly-writable schemas from search_path. One can add options=-csearch_path= to the connection string or issue SELECT pg_catalog.set_config('search_path', '', false) before other SQL commands. This consideration is not specific to psql; it applies to every interface for executing arbitrary SQL commands.

Whenever a command is executed, psql also polls for asynchronous notification events generated by LISTEN and NOTIFY.

While C-style block comments are passed to the server for processing and removal, SQL-standard comments are removed by psql.

### Meta-Commands

Anything you enter in psql that begins with an unquoted backslash is a psql meta-command that is processed by psql itself. These commands make psql more useful for administration or scripting. Metacommands are often called slash or backslash commands.

The format of a psql command is the backslash, followed immediately by a command verb, then any arguments. The arguments are separated from the command verb and each other by any number of whitespace characters.

To include whitespace in an argument you can quote it with single quotes. To include a single quote in an argument, write two single quotes within single-quoted text. Anything contained in single quotes is furthermore subject to C-like substitutions for \n (new line), \t (tab), \b (backspace), \r (carriage return), \f (form feed), \d (octal), and \x (hexadecimal). A backslash preceding any other character within single-quoted text quotes that single character, whatever it is.
If an unquoted colon (:) followed by a psql variable name appears within an argument, it is replaced by the variable's value, as described in SQL Interpolation below. The forms :'variable_name' and :"variable_name" described there work as well. The :{variable_name} syntax allows testing whether a variable is defined. It is substituted by TRUE or FALSE. Escaping the colon with a backslash protects it from substitution.

Within an argument, text that is enclosed in backquotes (`) is taken as a command line that is passed to the shell. The output of the command (with any trailing newline removed) replaces the backquoted text. Within the text enclosed in backquotes, no special quoting or other processing occurs, except that appearances of :variable_name where variable_name is a psql variable name are replaced by the variable's value. Also, appearances of :'variable_name' are replaced by the variable's value suitably quoted to become a single shell command argument. (The latter form is almost always preferable, unless you are very sure of what is in the variable.) Because carriage return and line feed characters cannot be safely quoted on all platforms, the :'variable_name' form prints an error message and does not substitute the variable value when such characters appear in the value.

Some commands take an SQL identifier (such as a table name) as argument. These arguments follow the syntax rules of SQL: Unquoted letters are forced to lowercase, while double quotes (" ) protect letters from case conversion and allow incorporation of whitespace into the identifier. Within double quotes, paired double quotes reduce to a single double quote in the resulting name. For example, FOO"BAR"BAZ is interpreted as fooBARbaz, and "A weird" name becomes A weird" name.

Parsing for arguments stops at the end of the line, or when another unquoted backslash is found. An unquoted backslash is taken as the beginning of a new meta-command. The special sequence \\ (two backslashes) marks the end of arguments and continues parsing SQL commands, if any. That way SQL and psql commands can be freely mixed on a line. But in any case, the arguments of a meta-command cannot continue beyond the end of the line.

Many of the meta-commands act on the current query buffer. This is simply a buffer holding whatever SQL command text has been typed but not yet sent to the server for execution. This will include previous input lines as well as any text appearing before the meta-command on the same line.

The following meta-commands are defined:

\a

If the current table output format is unaligned, it is switched to aligned. If it is not unaligned, it is set to unaligned. This command is kept for backwards compatibility. See \pset for a more general solution.

\c or \connect [ -reuse-previous=on|off ] [ dbname [ username ] [ host ] [ port ] [ conninfo ]

Establishes a new connection to a PostgreSQL server. The connection parameters to use can be specified either using a positional syntax (one or more of database name, user, host, and port), or using a conninfo connection string as detailed in Section 34.1.1. If no arguments are given, a new connection is made using the same parameters as before.

Specifying any of dbname, username, host or port as - is equivalent to omitting that parameter.

The new connection can re-use connection parameters from the previous connection; not only database name, user, host, and port, but other settings such as sslmode. By default, parameters are re-used in the positional syntax, but not when a conninfo string is given. Passing a first argument of -reuse-previous=on or -reuse-previous=off overrides that default. If parameters are re-used, then any parameter not explicitly specified as a positional parameter or in the conninfo string is taken from the existing connection's parameters. An exception is that if the host setting is changed
from its previous value using the positional syntax, any hostaddr setting present in the existing connection's parameters is dropped. Also, any password used for the existing connection will be re-used only if the user, host, and port settings are not changed. When the command neither specifies nor reuses a particular parameter, the libpq default is used.

If the new connection is successfully made, the previous connection is closed. If the connection attempt fails (wrong user name, access denied, etc.), the previous connection will be kept if psql is in interactive mode. But when executing a non-interactive script, the old connection is closed and an error is reported. That may or may not terminate the script; if it does not, all database-accessing commands will fail until another \connect command is successfully executed. This distinction was chosen as a user convenience against typos on the one hand, and a safety mechanism that scripts are not accidentally acting on the wrong database on the other hand. Note that whenever a \connect command attempts to re-use parameters, the values re-used are those of the last successful connection, not of any failed attempts made subsequently. However, in the case of a non-interactive \connect failure, no parameters are allowed to be re-used later, since the script would likely be expecting the values from the failed \connect to be re-used.

Examples:

=> \c mydb myuser host.dom 6432
=> \c service=foo
=> \c "host=localhost port=5432 dbname=mydb connect_timeout=10 sslmode=disable"
=> \c -reuse-previous=on sslmode=require -- changes only sslmode
=> \c postgresql://tom@localhost/mydb?application_name=myapp

\C [ title ]

Sets the title of any tables being printed as the result of a query or unset any such title. This command is equivalent to \pset title title. (The name of this command derives from “caption”, as it was previously only used to set the caption in an HTML table.)

\cd [ directory ]

Changes the current working directory to directory. Without argument, changes to the current user's home directory.

Tip

To print your current working directory, use \! pwd.

\conninfo

Outputs information about the current database connection.

\copy { table [ ( column_list ) ] } from { 'filename' | program 'command' | stdin | pstdin } [ [ with ] ( option [ , ... ] ) ] [ where condition ] \copy { table [ ( column_list ) ] | ( query ) } to { 'filename' | program 'command' | stdout | pstdout } [ [ with ] ( option [ , ... ] ) ]

Performs a frontend (client) copy. This is an operation that runs an SQL COPY command, but instead of the server reading or writing the specified file, psql reads or writes the file and routes the data...
between the server and the local file system. This means that file accessibility and privileges are those of the local user, not the server, and no SQL superuser privileges are required.

When `program` is specified, `command` is executed by `psql` and the data passed from or to `command` is routed between the server and the client. Again, the execution privileges are those of the local user, not the server, and no SQL superuser privileges are required.

For `\copy ... from stdin`, data rows are read from the same source that issued the command, continuing until `\.` is read or the stream reaches EOF. This option is useful for populating tables in-line within an SQL script file. For `\copy ... to stdout`, output is sent to the same place as `psql` command output, and the `COPY` command status is not printed (since it might be confused with a data row). To read/write `psql`'s standard input or output regardless of the current command source or `\o` option, write `from pstdin` or `to pstdout`.

The syntax of this command is similar to that of the SQL `COPY` command. All options other than the data source/destination are as specified for `COPY`. Because of this, special parsing rules apply to the `\copy` meta-command. Unlike most other meta-commands, the entire remainder of the line is always taken to be the arguments of `\copy`, and neither variable interpolation nor backquote expansion are performed in the arguments.

### Tip

Another way to obtain the same result as `\copy ... to` is to use the SQL `COPY ... TO STDOUT` command and terminate it with `\g filename` or `\g |program`. Unlike `\copy`, this method allows the command to span multiple lines; also, variable interpolation and backquote expansion can be used.

### Tip

These operations are not as efficient as the SQL `COPY` command with a file or program data source or destination, because all data must pass through the client/server connection. For large amounts of data the SQL command might be preferable.

`\copyright`

Shows the copyright and distribution terms of PostgreSQL.

 Executes the current query buffer (like `\g`) and shows the results in a crosstab grid. The query must return at least three columns. The output column identified by `colV` becomes a vertical header and the output column identified by `colH` becomes a horizontal header. `colD` identifies the output column to display within the grid. `sortcolH` identifies an optional sort column for the horizontal header.

Each column specification can be a column number (starting at 1) or a column name. The usual SQL case folding and quoting rules apply to column names. If omitted, `colV` is taken as column 1 and `colH` as column 2. `colH` must differ from `colV`. If `colD` is not specified, then there must be exactly three columns in the query result, and the column that is neither `colV` nor `colH` is taken to be `colD`.

The vertical header, displayed as the leftmost column, contains the values found in column `colV`, in the same order as in the query results, but with duplicates removed.
The horizontal header, displayed as the first row, contains the values found in column colH, with duplicates removed. By default, these appear in the same order as in the query results. But if the optional sortcolH argument is given, it identifies a column whose values must be integer numbers, and the values from colH will appear in the horizontal header sorted according to the corresponding sortcolH values.

Inside the crosstab grid, for each distinct value x of colH and each distinct value y of colV, the cell located at the intersection (x, y) contains the value of the colD column in the query result row for which the value of colH is x and the value of colV is y. If there is no such row, the cell is empty. If there are multiple such rows, an error is reported.

`\d[S+] [ pattern ]`

For each relation (table, view, materialized view, index, sequence, or foreign table) or composite type matching the pattern, show all columns, their types, the tablespace (if not the default) and any special attributes such as NOT NULL or defaults. Associated indexes, constraints, rules, and triggers are also shown. For foreign tables, the associated foreign server is shown as well. (“Matching the pattern” is defined in Patterns below.)

For some types of relation, `\d` shows additional information for each column: column values for sequences, indexed expressions for indexes, and foreign data wrapper options for foreign tables.

The command form `\d+` is identical, except that more information is displayed: any comments associated with the columns of the table are shown, as is the presence of OIDs in the table, the view definition if the relation is a view, a non-default replica identity setting and the access method name if the relation has an access method.

By default, only user-created objects are shown; supply a pattern or the S modifier to include system objects.

**Note**

If `\d` is used without a pattern argument, it is equivalent to `\dtvmsE` which will show a list of all visible tables, views, materialized views, sequences and foreign tables. This is purely a convenience measure.

`\da[S] [ pattern ]`

Lists aggregate functions, together with their return type and the data types they operate on. If pattern is specified, only aggregates whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the S modifier to include system objects.

`\dA[+] [ pattern ]`

Lists access methods. If pattern is specified, only access methods whose names match the pattern are shown. If + is appended to the command name, each access method is listed with its associated handler function and description.

`\dAc[+] [access-method-pattern [input-type-pattern]]`

Lists operator classes (see Section 38.16.1). If access-method-pattern is specified, only operator classes associated with access methods whose names match that pattern are listed. If input-type-pattern is specified, only operator classes associated with input types whose names
match that pattern are listed. If + is appended to the command name, each operator class is listed with its associated operator family and owner.

\dAf[+] \[access-method-pattern [input-type-pattern]]

Lists operator families (see Section 38.16.5). If access-method-pattern is specified, only operator families associated with access methods whose names match that pattern are listed. If input-type-pattern is specified, only operator families associated with input types whose names match that pattern are listed. If + is appended to the command name, each operator family is listed with its owner.

\dAo[+] \[access-method-pattern [operator-family-pattern]]

Lists operators associated with operator families (see Section 38.16.2). If access-method-pattern is specified, only members of operator families associated with access methods whose names match that pattern are listed. If operator-family-pattern is specified, only members of operator families whose names match that pattern are listed. If + is appended to the command name, each operator is listed with its sort operator family (if it is an ordering operator).

\dAp[+] \[access-method-pattern [operator-family-pattern]]

Lists support functions associated with operator families (see Section 38.16.3). If access-method-pattern is specified, only functions of operator families associated with access methods whose names match that pattern are listed. If operator-family-pattern is specified, only functions of operator families whose names match that pattern are listed. If + is appended to the command name, functions are displayed verbosely, with their actual parameter lists.

\db[+] \[pattern \]

Lists tablespaces. If pattern is specified, only tablespaces whose names match the pattern are shown. If + is appended to the command name, each tablespace is listed with its associated options, on-disk size, permissions and description.

\dc[S+][pattern \]

Lists conversions between character-set encodings. If pattern is specified, only conversions whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the S modifier to include system objects. If + is appended to the command name, each object is listed with its associated description.

\dconfig[+] \[pattern \]

Lists server configuration parameters and their values. If pattern is specified, only parameters whose names match the pattern are listed. Without a pattern, only parameters that are set to non-default values are listed. (Use \dconfig * to see all parameters.) If + is appended to the command name, each parameter is listed with its data type, context in which the parameter can be set, and access privileges (if non-default access privileges have been granted).

\dC[+] \[pattern \]

Lists type casts. If pattern is specified, only casts whose source or target types match the pattern are listed. If + is appended to the command name, each object is listed with its associated description.

\dd[S][pattern \]

Shows the descriptions of objects of type constraint, operator class, operator family, rule, and trigger. All other comments may be viewed by the respective backslash commands for those object types.
\dd displays descriptions for objects matching the *pattern*, or of visible objects of the appropriate type if no argument is given. But in either case, only objects that have a description are listed. By default, only user-created objects are shown; supply a pattern or the $S$ modifier to include system objects.

Descriptions for objects can be created with the `COMMENT` SQL command.

\dd[p+][pattern]

Lists domains. If *pattern* is specified, only domains whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the $S$ modifier to include system objects. If + is appended to the command name, each object is listed with its associated permissions and description.

\ddp[pattern]

Lists default access privilege settings. An entry is shown for each role (and schema, if applicable) for which the default privilege settings have been changed from the built-in defaults. If *pattern* is specified, only entries whose role name or schema name matches the pattern are listed.

The `ALTER DEFAULT PRIVILEGES` command is used to set default access privileges. The meaning of the privilege display is explained in Section 5.7.

\ddE[p+][pattern]
\ddi[p+][pattern]
\ddm[p+][pattern]
\dds[p+][pattern]
\ddt[p+][pattern]
\ddv[p+][pattern]

In this group of commands, the letters E, i, m, s, t, and v stand for foreign table, index, materialized view, sequence, table, and view, respectively. You can specify any or all of these letters, in any order, to obtain a listing of objects of these types. For example, \ddt lists tables and indexes. If + is appended to the command name, each object is listed with its persistence status (permanent, temporary, or unlogged), physical size on disk, and associated description if any. If *pattern* is specified, only objects whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the $S$ modifier to include system objects.

\des[p+][pattern]

Lists foreign servers (mnemonic: “external servers”). If *pattern* is specified, only those servers whose name matches the pattern are listed. If the form \des is used, a full description of each server is shown, including the server's access privileges, type, version, options, and description.

\det[p+][pattern]

Lists foreign tables (mnemonic: “external tables”). If *pattern* is specified, only entries whose table name or schema name matches the pattern are listed. If the form \det is used, generic options and the foreign table description are also displayed.

\deu[p+][pattern]

Lists user mappings (mnemonic: “external users”). If *pattern* is specified, only those mappings whose user names match the pattern are listed. If the form \deu is used, additional information about each mapping is shown.
Caution

\deu+ might also display the user name and password of the remote user, so care should be taken not to disclose them.

\dew[+] [ pattern ]

Lists foreign-data wrappers (mnemonic: “external wrappers”). If pattern is specified, only those foreign-data wrappers whose name matches the pattern are listed. If the form \deu+ is used, the access privileges, options, and description of the foreign-data wrapper are also shown.

\df[anptwS+] [ pattern [ arg_pattern ... ] ]

Lists functions, together with their result data types, argument data types, and function types, which are classified as “agg” (aggregate), “normal”, “procedure”, “trigger”, or “window”. To display only functions of specific type(s), add the corresponding letters a, n, p, t, or w to the command. If pattern is specified, only functions whose names match the pattern are shown. Any additional arguments are type-name patterns, which are matched to the type names of the first, second, and so on arguments of the function. (Matching functions can have more arguments than what you specify. To prevent that, write a dash – as the last arg_pattern.) By default, only user-created objects are shown; supply a pattern or the S modifier to include system objects. If the form \df+ is used, additional information about each function is shown, including volatility, parallel safety, owner, security classification, access privileges, language, source code and description.

\dF[+] [ pattern ]

Lists text search configurations. If pattern is specified, only configurations whose names match the pattern are shown. If the form \dF+ is used, a full description of each configuration is shown, including the underlying text search parser and the dictionary list for each parser token type.

\dFd[+] [ pattern ]

Lists text search dictionaries. If pattern is specified, only dictionaries whose names match the pattern are shown. If the form \dFd+ is used, additional information is shown about each selected dictionary, including the underlying text search template and the option values.

\dFp[+] [ pattern ]

Lists text search parsers. If pattern is specified, only parsers whose names match the pattern are shown. If the form \dFp+ is used, a full description of each parser is shown, including the underlying functions and the list of recognized token types.

\dFt[+] [ pattern ]

Lists text search templates. If pattern is specified, only templates whose names match the pattern are shown. If the form \dFt+ is used, additional information is shown about each template, including the underlying function names.

\dg[S+] [ pattern ]

Lists database roles. (Since the concepts of “users” and “groups” have been unified into “roles”, this command is now equivalent to \du.) By default, only user-created roles are shown; supply the S modifier to include system roles. If pattern is specified, only those roles whose names match the
pattern are listed. If the form \d+g+ is used, additional information is shown about each role; currently
this adds the comment for each role.

\dl[+]
This is an alias for \lo_list, which shows a list of large objects. If + is appended to the command
name, each large object is listed with its associated permissions, if any.

\dL[S+] [ pattern ]
Lists procedural languages. If pattern is specified, only languages whose names match the pattern
are listed. By default, only user-created languages are shown; supply the S modifier to include system
objects. If + is appended to the command name, each language is listed with its call handler, validator,
access privileges, and whether it is a system object.

\dn[S+] [ pattern ]
Lists schemas (namespaces). If pattern is specified, only schemas whose names match the pattern
are listed. By default, only user-created objects are shown; supply a pattern or the S modifier to
include system objects. If + is appended to the command name, each object is listed with its associated
permissions and description, if any.

\do[S+] [ pattern [ arg_pattern [ arg_pattern ] ] ]
Lists operators with their operand and result types. If pattern is specified, only operators whose
names match the pattern are listed. If one arg_pattern is specified, only prefix operators whose
right argument's type name matches that pattern are listed. If two arg_patterns are specified, only
binary operators whose argument type names match those patterns are listed. (Alternatively, write -
for the unused argument of a unary operator.) By default, only user-created objects are shown; supply
a pattern or the S modifier to include system objects. If + is appended to the command name, additional
information about each operator is shown, currently just the name of the underlying function.

\dO[S+] [ pattern ]
Lists collations. If pattern is specified, only collations whose names match the pattern are listed.
By default, only user-created objects are shown; supply a pattern or the S modifier to include system
objects. If + is appended to the command name, each collation is listed with its associated description,
if any. Note that only collations usable with the current database's encoding are shown, so the results
may vary in different databases of the same installation.

\dp [ pattern ]
Lists tables, views and sequences with their associated access privileges. If pattern is specified,
only tables, views and sequences whose names match the pattern are listed.

The GRANT and REVOKE commands are used to set access privileges. The meaning of the privilege
display is explained in Section 5.7.

\dP[itn+] [ pattern ]
Lists partitioned relations. If pattern is specified, only entries whose name matches the pattern are
listed. The modifiers t (tables) and i (indexes) can be appended to the command, filtering the kind
of relations to list. By default, partitioned tables and indexes are listed.

If the modifier n ("nested") is used, or a pattern is specified, then non-root partitioned relations are
included, and a column is shown displaying the parent of each partitioned relation.

2226
If + is appended to the command name, the sum of the sizes of each relation's partitions is also displayed, along with the relation's description. If n is combined with +, two sizes are shown: one including the total size of directly-attached leaf partitions, and another showing the total size of all partitions, including indirectly attached sub-partitions.

\drds [ role-pattern [ database-pattern ] ]

Lists defined configuration settings. These settings can be role-specific, database-specific, or both. role-pattern and database-pattern are used to select specific roles and databases to list, respectively. If omitted, or if * is specified, all settings are listed, including those not role-specific or database-specific, respectively.

The ALTER ROLE and ALTER DATABASE commands are used to define per-role and per-database configuration settings.

\dRp[+] [ pattern ]

Lists replication publications. If pattern is specified, only those publications whose names match the pattern are listed. If + is appended to the command name, the tables and schemas associated with each publication are shown as well.

\dRs[+] [ pattern ]

Lists replication subscriptions. If pattern is specified, only those subscriptions whose names match the pattern are listed. If + is appended to the command name, additional properties of the subscriptions are shown.

\dT[S+] [ pattern ]

Lists data types. If pattern is specified, only types whose names match the pattern are listed. If + is appended to the command name, each type is listed with its internal name and size, its allowed values if it is an enum type, and its associated permissions. By default, only user-created objects are shown; supply a pattern or the S modifier to include system objects.

\du[S+] [ pattern ]

Lists database roles. (Since the concepts of “users” and “groups” have been unified into “roles”, this command is now equivalent to \dg.) By default, only user-created roles are shown; supply the S modifier to include system roles. If pattern is specified, only those roles whose names match the pattern are listed. If the form \du+ is used, additional information is shown about each role; currently this adds the comment for each role.

\dx[+] [ pattern ]

Lists installed extensions. If pattern is specified, only those extensions whose names match the pattern are listed. If the form \dx+ is used, all the objects belonging to each matching extension are listed.

\dX [ pattern ]

Lists extended statistics. If pattern is specified, only those extended statistics whose names match the pattern are listed.

The status of each kind of extended statistics is shown in a column named after its statistic kind (e.g. Ndistinct). defined means that it was requested when creating the statistics, and NULL means it wasn't requested. You can use pg_stats_ext if you'd like to know whether ANALYZE was run and statistics are available to the planner.
Lists event triggers. If \texttt{pattern} is specified, only those event triggers whose names match the pattern are listed. If + is appended to the command name, each object is listed with its associated description.

If \texttt{filename} is specified, the file is edited; after the editor exits, the file's content is copied into the current query buffer. If no \texttt{filename} is given, the current query buffer is copied to a temporary file which is then edited in the same fashion. Or, if the current query buffer is empty, the most recently executed query is copied to a temporary file and edited in the same fashion.

If you edit a file or the previous query, and you quit the editor without modifying the file, the query buffer is cleared. Otherwise, the new contents of the query buffer are re-parsed according to the normal rules of psql, treating the whole buffer as a single line. Any complete queries are immediately executed; that is, if the query buffer contains or ends with a semicolon, everything up to that point is executed and removed from the query buffer. Whatever remains in the query buffer is redisplayed. Type semicolon or \texttt{\g} to send it, or \texttt{\r} to cancel it by clearing the query buffer.

Treating the buffer as a single line primarily affects meta-commands: whatever is in the buffer after a meta-command will be taken as argument(s) to the meta-command, even if it spans multiple lines. (Thus you cannot make meta-command-using scripts this way. Use \texttt{\i} for that.)

If a line number is specified, psql will position the cursor on the specified line of the file or query buffer. Note that if a single all-digits argument is given, psql assumes it is a line number, not a file name.

Tip

See Environment, below, for how to configure and customize your editor.

Prints the evaluated arguments to standard output, separated by spaces and followed by a newline. This can be useful to intersperse information in the output of scripts. For example:

$$=> \texttt{\echo `date`}$$

Tue Oct 26 21:40:57 CEST 1999

If the first argument is an unquoted \texttt{-n} the trailing newline is not written (nor is the first argument).

Tip

If you use the \texttt{\o} command to redirect your query output you might wish to use \texttt{\qecho} instead of this command. See also \texttt{\warn}.

This command fetches and edits the definition of the named function or procedure, in the form of a \texttt{CREATE OR REPLACE FUNCTION} or \texttt{CREATE OR REPLACE PROCEDURE} command. Editing is done in the same way as for \texttt{\edit}. If you quit the editor without saving, the statement is 2228
discarded. If you save and exit the editor, the updated command is executed immediately if you added a semicolon to it. Otherwise it is redisplayed; type semicolon or \g to send it, or \r to cancel.

The target function can be specified by name alone, or by name and arguments, for example foo(integer, text). The argument types must be given if there is more than one function of the same name.

If no function is specified, a blank CREATE FUNCTION template is presented for editing.

If a line number is specified, psql will position the cursor on the specified line of the function body. (Note that the function body typically does not begin on the first line of the file.)

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of \ef, and neither variable interpolation nor backquote expansion are performed in the arguments.

Tip
See Environment, below, for how to configure and customize your editor.

\encoding [ encoding ]
Sets the client character set encoding. Without an argument, this command shows the current encoding.

\errverbose
Repeats the most recent server error message at maximum verbosity, as though VERBOSITY were set to verbose and SHOW_CONTEXT were set to always.

\ev [ view_name [ line_number ] ]
This command fetches and edits the definition of the named view, in the form of a CREATE OR REPLACE VIEW command. Editing is done in the same way as for \edit. If you quit the editor without saving, the statement is discarded. If you save and exit the editor, the updated command is executed immediately if you added a semicolon to it. Otherwise it is redisplayed; type semicolon or \g to send it, or \r to cancel.

If no view is specified, a blank CREATE VIEW template is presented for editing.

If a line number is specified, psql will position the cursor on the specified line of the view definition.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of \ev, and neither variable interpolation nor backquote expansion are performed in the arguments.

\f [ string ]
Sets the field separator for unaligned query output. The default is the vertical bar (|). It is equivalent to \pset fieldsep.

\g [ (option=value [ ... ] ) ] [ filename ]
\g [ (option=value [ ... ] ) ] [ \ | command ]
Sends the current query buffer to the server for execution.
If parentheses appear after `\g`, they surround a space-separated list of *option=value* formatting-option clauses, which are interpreted in the same way as `\pset option value` commands, but take effect only for the duration of this query. In this list, spaces are not allowed around `=` signs, but are required between option clauses. If `=value` is omitted, the named *option* is changed in the same way as for `\pset option` with no explicit *value*.

If a *filename* or `|` *command* argument is given, the query's output is written to the named file or piped to the given shell command, instead of displaying it as usual. The file or command is written to only if the query successfully returns zero or more tuples, not if the query fails or is a non-data-returning SQL command.

If the current query buffer is empty, the most recently sent query is re-executed instead. Except for that behavior, `\g` without any arguments is essentially equivalent to a semicolon. With arguments, `\g` provides a "one-shot" alternative to the `\o` command, and additionally allows one-shot adjustments of the output formatting options normally set by `\pset`.

When the last argument begins with `|`, the entire remainder of the line is taken to be the *command* to execute, and neither variable interpolation nor backquote expansion are performed in it. The rest of the line is simply passed literally to the shell.

`\gdesc`

Shows the description (that is, the column names and data types) of the result of the current query buffer. The query is not actually executed; however, if it contains some type of syntax error, that error will be reported in the normal way.

If the current query buffer is empty, the most recently sent query is described instead.

`\getenv psql_var env_var`

Gets the value of the environment variable *env_var* and assigns it to the psql variable *psql_var*. If *env_var* is not defined in the psql process's environment, *psql_var* is not changed. Example:

```sql
=> \getenv home HOME
=> \echo :home
/home/postgres
```

`\gexec`

Sends the current query buffer to the server, then treats each column of each row of the query's output (if any) as an SQL statement to be executed. For example, to create an index on each column of *my_table*:

```sql
=> SELECT format('create index on my_table(%I)', attname)
  -> FROM pg_attribute
  -> WHERE attrelid = 'my_table'::regclass AND attnum > 0
  -> ORDER BY attnum
  -> \gexec
CREATE INDEX
CREATE INDEX
CREATE INDEX
CREATE INDEX
```

The generated queries are executed in the order in which the rows are returned, and left-to-right within each row if there is more than one column. NULL fields are ignored. The generated queries are
sent literally to the server for processing, so they cannot be psql meta-commands nor contain psql variable references. If any individual query fails, execution of the remaining queries continues unless ON_ERROR_STOP is set. Execution of each query is subject to ECHO processing. (Setting ECHO to all or queries is often advisable when using \gexec.) Query logging, single-step mode, timing, and other query execution features apply to each generated query as well.

If the current query buffer is empty, the most recently sent query is re-executed instead.

\gset [ prefix ]

Sends the current query buffer to the server and stores the query's output into psql variables (see Variables below). The query to be executed must return exactly one row. Each column of the row is stored into a separate variable, named the same as the column. For example:

```bash
=> SELECT 'hello' AS var1, 10 AS var2
-> \gset
=> \echo :var1 :var2
hello 10
```

If you specify a prefix, that string is prepended to the query's column names to create the variable names to use:

```bash
=> SELECT 'hello' AS var1, 10 AS var2
-> \gset result_
=> \echo :result_var1 :result_var2
hello 10
```

If a column result is NULL, the corresponding variable is unset rather than being set.

If the query fails or does not return one row, no variables are changed.

If the current query buffer is empty, the most recently sent query is re-executed instead.

\gx [ (option=value [ ... ]) ] [ filename ]
\gx [ (option=value [ ... ]) ] [ | command ]

\gx is equivalent to \g, except that it forces expanded output mode for this query, as if expand-ed=on were included in the list of \pset options. See also \x.

\h or \help [ command ]

Gives syntax help on the specified SQL command. If command is not specified, then psql will list all the commands for which syntax help is available. If command is an asterisk (*), then syntax help on all SQL commands is shown.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of \help, and neither variable interpolation nor backquote expansion are performed in the arguments.

---

**Note**

To simplify typing, commands that consists of several words do not have to be quoted. Thus it is fine to type \help alter table.
\H or \html

Turns on HTML query output format. If the HTML format is already on, it is switched back to the default aligned text format. This command is for compatibility and convenience, but see \pset about setting other output options.

\i or \include filename

Reads input from the file filename and executes it as though it had been typed on the keyboard.

If filename is – (hyphen), then standard input is read until an EOF indication or \q meta-command. This can be used to intersperse interactive input with input from files. Note that Readline behavior will be used only if it is active at the outermost level.

**Note**

If you want to see the lines on the screen as they are read you must set the variable ECHO to all.

\if expression
\elif expression
\else
\endif

This group of commands implements nestable conditional blocks. A conditional block must begin with an \if and end with an \endif. In between there may be any number of \elif clauses, which may optionally be followed by a single \else clause. Ordinary queries and other types of backslash commands may (and usually do) appear between the commands forming a conditional block.

The \if and \elif commands read their argument(s) and evaluate them as a Boolean expression. If the expression yields true then processing continues normally; otherwise, lines are skipped until a matching \elif, \else, or \endif is reached. Once an \if or \elif test has succeeded, the arguments of later \elif commands in the same block are not evaluated but are treated as false. Lines following an \else are processed only if no earlier matching \if or \elif succeeded.

The expression argument of an \if or \elif command is subject to variable interpolation and backquote expansion, just like any other backslash command argument. After that it is evaluated like the value of an on/off option variable. So a valid value is any unambiguous case-insensitive match for one of: true, false, 1, 0, on, off, yes, no. For example, t, T, and tR will all be considered to be true.

Expressions that do not properly evaluate to true or false will generate a warning and be treated as false.

Lines being skipped are parsed normally to identify queries and backslash commands, but queries are not sent to the server, and backslash commands other than conditionals (\if, \elif, \else, \endif) are ignored. Conditional commands are checked only for valid nesting. Variable references in skipped lines are not expanded, and backquote expansion is not performed either.

All the backslash commands of a given conditional block must appear in the same source file. If EOF is reached on the main input file or an \include-ed file before all local \if-blocks have been closed, then psql will raise an error.

Here is an example:
-- check for the existence of two separate records in the database and store
-- the results in separate psql variables
SELECT
  EXISTS(SELECT 1 FROM customer WHERE customer_id = 123) as is_customer,
  EXISTS(SELECT 1 FROM employee WHERE employee_id = 456) as is_employee
\gset
\if :is_customer
  SELECT * FROM customer WHERE customer_id = 123;
\elif :is_employee
  \echo 'is not a customer but is an employee'
  SELECT * FROM employee WHERE employee_id = 456;
\else
  \if yes
    \echo 'not a customer or employee'
  \else
    \echo 'this will never print'
  \endif
\endif
\ir or \include_relative filename

The \ir command is similar to \i, but resolves relative file names differently. When executing in interactive mode, the two commands behave identically. However, when invoked from a script, \ir interprets file names relative to the directory in which the script is located, rather than the current working directory.

\l[+] or \list[+] [ pattern ]

List the databases in the server and show their names, owners, character set encodings, and access privileges. If pattern is specified, only databases whose names match the pattern are listed. If + is appended to the command name, database sizes, default tablespaces, and descriptions are also displayed. (Size information is only available for databases that the current user can connect to.)

\lo_export loid filename

Reads the large object with OID loid from the database and writes it to filename. Note that this is subtly different from the server function lo_export, which acts with the permissions of the user that the database server runs as and on the server's file system.

**Tip**

Use \lo_list to find out the large object's OID.

\lo_import filename [ comment ]

Stores the file into a PostgreSQL large object. Optionally, it associates the given comment with the object. Example:
foo=> \lo_import '/home/peter/pictures/photo.xcf' 'a picture of me'
\lo_import 152801

The response indicates that the large object received object ID 152801, which can be used to access
the newly-created large object in the future. For the sake of readability, it is recommended to always
associate a human-readable comment with every object. Both OIDs and comments can be viewed
with the \lo_list command.

Note that this command is subtly different from the server-side lo_import because it acts as the
local user on the local file system, rather than the server's user and file system.

\lo_list[+]

Shows a list of all PostgreSQL large objects currently stored in the database, along with any comments
provided for them. If + is appended to the command name, each large object is listed with its associated
permissions, if any.

\lo_unlink loid

Deletes the large object with OID loid from the database.

Tip

Use \lo_list to find out the large object’s OID.

\o or \out [ filename ]
\o or \out [ command ]

Arranges to save future query results to the file filename or pipe future results to the shell command
command. If no argument is specified, the query output is reset to the standard output.

If the argument begins with |, then the entire remainder of the line is taken to be the command to
eexecute, and neither variable interpolation nor backquote expansion are performed in it. The rest of
the line is simply passed literally to the shell.

“Query results” includes all tables, command responses, and notices obtained from the database server,
as well as output of various backslash commands that query the database (such as \d); but not error
messages.

Tip

To intersperse text output in between query results, use \qecho.

\p or \print

Print the current query buffer to the standard output. If the current query buffer is empty, the most
recently executed query is printed instead.

\password [ username ]

Changes the password of the specified user (by default, the current user). This command prompts for
the new password, encrypts it, and sends it to the server as an ALTER ROLE command. This makes
sure that the new password does not appear in cleartext in the command history, the server log, or elsewhere.

\prompt [ text ] name

Prompts the user to supply text, which is assigned to the variable name. An optional prompt string, text, can be specified. (For multiword prompts, surround the text with single quotes.)

By default, \prompt uses the terminal for input and output. However, if the \-f command line switch was used, \prompt uses standard input and standard output.

\pset [ option [ value ] ]

This command sets options affecting the output of query result tables. option indicates which option is to be set. The semantics of value vary depending on the selected option. For some options, omitting value causes the option to be toggled or unset, as described under the particular option. If no such behavior is mentioned, then omitting value just results in the current setting being displayed.

\pset without any arguments displays the current status of all printing options.

Adjustable printing options are:

border

The value must be a number. In general, the higher the number the more borders and lines the tables will have, but details depend on the particular format. In HTML format, this will translate directly into the border=... attribute. In most other formats only values 0 (no border), 1 (internal dividing lines), and 2 (table frame) make sense, and values above 2 will be treated the same as border = 2. The latex and latex-longtable formats additionally allow a value of 3 to add dividing lines between data rows.

columns

Sets the target width for the wrapped format, and also the width limit for determining whether output is wide enough to require the pager or switch to the vertical display in expanded auto mode. Zero (the default) causes the target width to be controlled by the environment variable COLUMNS, or the detected screen width if COLUMNS is not set. In addition, if columns is zero then the wrapped format only affects screen output. If columns is nonzero then file and pipe output is wrapped to that width as well.

csv_fieldsep

Specifies the field separator to be used in CSV output format. If the separator character appears in a field's value, that field is output within double quotes, following standard CSV rules. The default is a comma.

expanded (or x)

If value is specified it must be either on or off, which will enable or disable expanded mode, or auto. If value is omitted the command toggles between the on and off settings. When expanded mode is enabled, query results are displayed in two columns, with the column name on the left and the data on the right. This mode is useful if the data wouldn't fit on the screen in the normal “horizontal” mode. In the auto setting, the expanded mode is used whenever the query output has more than one column and is wider than the screen; otherwise, the regular mode is used. The auto setting is only effective in the aligned and wrapped formats. In other formats, it always behaves as if the expanded mode is off.
fieldsep

Specifies the field separator to be used in unaligned output format. That way one can create, for example, tab-separated output, which other programs might prefer. To set a tab as field separator, type `\pset fieldsep '\t'`. The default field separator is `'|'` (a vertical bar).

fieldsep_zero

Sets the field separator to use in unaligned output format to a zero byte.

footer

If `value` is specified it must be either `on` or `off` which will enable or disable display of the table footer (the `(n rows)` count). If `value` is omitted the command toggles footer display on or off.

format

Sets the output format to one of `aligned`, `asciidoc`, `csv`, `html`, `latex`, `latex-longtable`, `troff-ms`, `unaligned`, or `wrapped`. Unique abbreviations are allowed.

aligned format is the standard, human-readable, nicely formatted text output; this is the default.

unaligned format writes all columns of a row on one line, separated by the currently active field separator. This is useful for creating output that might be intended to be read in by other programs, for example, tab-separated or comma-separated format. However, the field separator character is not treated specially if it appears in a column's value; so CSV format may be better suited for such purposes.

csv format writes column values separated by commas, applying the quoting rules described in RFC 4180\(^1\). This output is compatible with the CSV format of the server's `COPY` command. A header line with column names is generated unless the `tuples_only` parameter is on. Titles and footers are not printed. Each row is terminated by the system-dependent end-of-line character, which is typically a single newline (`\n`) for Unix-like systems or a carriage return and newline sequence (`\r\n`) for Microsoft Windows. Field separator characters other than comma can be selected with `\pset csv_fieldsep`.

wrapped format is like `aligned` but wraps wide data values across lines to make the output fit in the target column width. The target width is determined as described under the `columns` option. Note that `psql` will not attempt to wrap column header titles; therefore, `wrapped` format behaves the same as `aligned` if the total width needed for column headers exceeds the target.

The `asciidoc`, `html`, `latex`, `latex-longtable`, and `troff-ms` formats put out tables that are intended to be included in documents using the respective mark-up language. They are not complete documents! This might not be necessary in HTML, but in LaTeX you must have a complete document wrapper. The `latex` format uses LaTeX's `tabular` environment. The `latex-longtable` format requires the LaTeX `longtable` and `booktabs` packages.

linestyle

Sets the border line drawing style to one of `ascii`, `old-ascii`, or `unicode`. Unique abbreviations are allowed. (That would mean one letter is enough.) The default setting is `ascii`. This option only affects the `aligned` and `wrapped` output formats.

ascii style uses plain ASCII characters. Newlines in data are shown using a `+` symbol in the right-hand margin. When the `wrapped` format wraps data from one line to the next without a

\(^1\) https://tools.ietf.org/html/rfc4180
newline character, a dot (.) is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

old-ascii style uses plain ASCII characters, using the formatting style used in PostgreSQL 8.4 and earlier. Newlines in data are shown using a : symbol in place of the left-hand column separator. When the data is wrapped from one line to the next without a newline character, a ; symbol is used in place of the left-hand column separator.

unicode style uses Unicode box-drawing characters. Newlines in data are shown using a carriage return symbol in the right-hand margin. When the data is wrapped from one line to the next without a newline character, an ellipsis symbol is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

When the border setting is greater than zero, the linestyle option also determines the characters with which the border lines are drawn. Plain ASCII characters work everywhere, but Unicode characters look nicer on displays that recognize them.

null

Sets the string to be printed in place of a null value. The default is to print nothing, which can easily be mistaken for an empty string. For example, one might prefer \pset null ' (null)'.

numericlocale

If value is specified it must be either on or off which will enable or disable display of a locale-specific character to separate groups of digits to the left of the decimal marker. If value is omitted the command toggles between regular and locale-specific numeric output.

pager

Controls use of a pager program for query and psql help output. If the environment variable PSQL_PAGER or PAGER is set, the output is piped to the specified program. Otherwise a platform-dependent default program (such as more) is used.

When using the \watch command to execute a query repeatedly, the environment variable PSQL_WATCH_PAGER is used to find the pager program instead, on Unix systems. This is configured separately because it may confuse traditional pagers, but can be used to send output to tools that understand psql’s output format (such as pspg --stream).

When the pager option is off, the pager program is not used. When the pager option is on, the pager is used when appropriate, i.e., when the output is to a terminal and will not fit on the screen. The pager option can also be set to always, which causes the pager to be used for all terminal output regardless of whether it fits on the screen. \pset pager without a value toggles pager use on and off.

pager_min_lines

If pager_min_lines is set to a number greater than the page height, the pager program will not be called unless there are at least this many lines of output to show. The default setting is 0.

recordsep

Specifies the record (line) separator to use in unaligned output format. The default is a newline character.

recordsep_zero

Sets the record separator to use in unaligned output format to a zero byte.
pelattr (or T)

In HTML format, this specifies attributes to be placed inside the table tag. This could for example be `cellpadding` or `bgcolor`. Note that you probably don’t want to specify `border` here, as that is already taken care of by \pset border. If no value is given, the table attributes are unset.

In latex-longtable format, this controls the proportional width of each column containing a left-aligned data type. It is specified as a whitespace-separated list of values, e.g., '0.2 0.2 0.6'. Unspecified output columns use the last specified value.

title (or C)

Sets the table title for any subsequently printed tables. This can be used to give your output descriptive tags. If no value is given, the title is unset.

tuples_only (or t)

If value is specified it must be either on or off which will enable or disable tuples-only mode. If value is omitted the command toggles between regular and tuples-only output. Regular output includes extra information such as column headers, titles, and various footers. In tuples-only mode, only actual table data is shown.

unicode_border_linestyle

Sets the border drawing style for the unicode line style to one of single or double.

unicode_column_linestyle

Sets the column drawing style for the unicode line style to one of single or double.

unicode_header_linestyle

Sets the header drawing style for the unicode line style to one of single or double.

Illustrations of how these different formats look can be seen in Examples, below.

**Tip**

There are various shortcut commands for \pset. See \a, \C, \f, \H, \t, \T, and \x.

\q or \quit

Quits the psql program. In a script file, only execution of that script is terminated.

\qecho text [ ... ]

This command is identical to \echo except that the output will be written to the query output channel, as set by \o.

\r or \reset

Resets (clears) the query buffer.
\s [ filename ]

Print psql's command line history to filename. If filename is omitted, the history is written to the standard output (using the pager if appropriate). This command is not available if psql was built without Readline support.

\set [ name [ value [ ... ] ] ]

Sets the psql variable name to value, or if more than one value is given, to the concatenation of all of them. If only one argument is given, the variable is set to an empty-string value. To unset a variable, use the \unset command.

\set without any arguments displays the names and values of all currently-set psql variables.

Valid variable names can contain letters, digits, and underscores. See Variables below for details. Variable names are case-sensitive.

Certain variables are special, in that they control psql's behavior or are automatically set to reflect connection state. These variables are documented in Variables, below.

**Note**

This command is unrelated to the SQL command SET.

\setenv name [ value ]

Sets the environment variable name to value, or if the value is not supplied, unsets the environment variable. Example:

```
testdb=> \setenv PAGER less
testdb=> \setenv LESS -imx4F
```

\sf[+] function_description

This command fetches and shows the definition of the named function or procedure, in the form of a CREATE OR REPLACE FUNCTION or CREATE OR REPLACE PROCEDURE command. The definition is printed to the current query output channel, as set by \o.

The target function can be specified by name alone, or by name and arguments, for example foo(integer, text). The argument types must be given if there is more than one function of the same name.

If + is appended to the command name, then the output lines are numbered, with the first line of the function body being line 1.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of \sf, and neither variable interpolation nor backquote expansion are performed in the arguments.

\sv[+] view_name

This command fetches and shows the definition of the named view, in the form of a CREATE OR REPLACE VIEW command. The definition is printed to the current query output channel, as set by \o.
If + is appended to the command name, then the output lines are numbered from 1.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of \sv, and neither variable interpolation nor backquote expansion are performed in the arguments.

\t

Toggles the display of output column name headings and row count footer. This command is equivalent to \pset tuples_only and is provided for convenience.

\T table_options

Specifies attributes to be placed within the table tag in HTML output format. This command is equivalent to \pset tableattr table_options.

\timing [ on | off ]

With a parameter, turns displaying of how long each SQL statement takes on or off. Without a parameter, toggles the display between on and off. The display is in milliseconds; intervals longer than 1 second are also shown in minutes:seconds format, with hours and days fields added if needed.

\unset name

Unsets (deletes) the psql variable name.

Most variables that control psql's behavior cannot be unset; instead, an \unset command is interpreted as setting them to their default values. See Variables below.

\w or \write filename
\w or \write | command

Writes the current query buffer to the file filename or pipes it to the shell command command. If the current query buffer is empty, the most recently executed query is written instead.

If the argument begins with |, then the entire remainder of the line is taken to be the command to execute, and neither variable interpolation nor backquote expansion are performed in it. The rest of the line is simply passed literally to the shell.

\warn text [ ... ]

This command is identical to \echo except that the output will be written to psql’s standard error channel, rather than standard output.

\watch [ seconds ]

Repeatedly execute the current query buffer (as \g does) until interrupted or the query fails. Wait the specified number of seconds (default 2) between executions. Each query result is displayed with a header that includes the \pset title string (if any), the time as of query start, and the delay interval.

If the current query buffer is empty, the most recently sent query is re-executed instead.

\x [ on | off | auto ]

Sets or toggles expanded table formatting mode. As such it is equivalent to \pset expanded.
\z [ pattern ]

Lists tables, views and sequences with their associated access privileges. If a pattern is specified, only tables, views and sequences whose names match the pattern are listed.

This is an alias for \dp ("display privileges").

\! [ command ]

With no argument, escapes to a sub-shell; psql resumes when the sub-shell exits. With an argument, executes the shell command command.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of \!, and neither variable interpolation nor backquote expansion are performed in the arguments. The rest of the line is simply passed literally to the shell.

\? [ topic ]

Shows help information. The optional topic parameter (defaulting to commands) selects which part of psql is explained: commands describes psql's backslash commands; options describes the command-line options that can be passed to psql; and variables shows help about psql configuration variables.

\;

Backslash-semicolon is not a meta-command in the same way as the preceding commands; rather, it simply causes a semicolon to be added to the query buffer without any further processing.

Normally, psql will dispatch an SQL command to the server as soon as it reaches the command-ending semicolon, even if more input remains on the current line. Thus for example entering

```
select 1; select 2; select 3;
```

will result in the three SQL commands being individually sent to the server, with each one's results being displayed before continuing to the next command. However, a semicolon entered as \; will not trigger command processing, so that the command before it and the one after are effectively combined and sent to the server in one request. So for example

```
select 1\; select 2\; select 3;
```

results in sending the three SQL commands to the server in a single request, when the non-backslashed semicolon is reached. The server executes such a request as a single transaction, unless there are explicit BEGIN/COMMIT commands included in the string to divide it into multiple transactions. (See Section 54.2.2.1 for more details about how the server handles multi-query strings.)

Patterns

The various \d commands accept a pattern parameter to specify the object name(s) to be displayed. In the simplest case, a pattern is just the exact name of the object. The characters within a pattern are normally folded to lower case, just as in SQL names; for example, \dt FOO will display the table named foo. As in SQL names, placing double quotes around a pattern stops folding to lower case. Should you need to include an actual double quote character in a pattern, write it as a pair of double quotes within a double-quote sequence; again this is in accord with the rules for SQL quoted identifiers. For example, \dt "FOO""BAR" will display the table named FOO"BAR (not foo"bar). Unlike the normal rules for SQL names, you can put double quotes around just part of a pattern, for instance \dt FOO"FOO"BAR will display the table named fooFOObar.
Whenever the *pattern* parameter is omitted completely, the `\d` commands display all objects that are visible in the current schema search path — this is equivalent to using `*` as the pattern. (An object is said to be *visible* if its containing schema is in the search path and no object of the same kind and name appears earlier in the search path. This is equivalent to the statement that the object can be referenced by name without explicit schema qualification.) To see all objects in the database regardless of visibility, use `*.*` as the pattern.

Within a pattern, `*` matches any sequence of characters (including no characters) and `?` matches any single character. (This notation is comparable to Unix shell file name patterns.) For example, `\dt int*` displays tables whose names begin with `int`. But within double quotes, `*` and `?` lose these special meanings and are just matched literally.

A relation pattern that contains a dot (`.`) is interpreted as a schema name pattern followed by an object name pattern. For example, `\dt foo*.bar*` displays all tables whose table name includes `bar` that are in schemas whose schema name starts with `foo`. When no dot appears, then the pattern matches only objects that are visible in the current schema search path. Again, a dot within double quotes loses its special meaning and is matched literally. A relation pattern that contains two dots (`.`) is interpreted as a database name followed by a schema name pattern followed by an object name pattern. The database name portion will not be treated as a pattern and must match the name of the currently connected database, else an error will be raised.

A schema pattern that contains a dot (`.`) is interpreted as a database name followed by a schema name pattern. For example, `\dn mydb.*foo*` displays all schemas whose schema name includes `foo`. The database name portion will not be treated as a pattern and must match the name of the currently connected database, else an error will be raised.

Advanced users can use regular-expression notations such as character classes, for example `[0-9]` to match any digit. All regular expression special characters work as specified in Section 9.7.3, except for . which is taken as a separator as mentioned above, `*` which is translated to the regular-expression notation `.`, `?` which is translated to `.` and `$` which is matched literally. You can emulate these pattern characters at need by writing `?` for `.`, `(R+ |)` for `R*`, or `(R |)` for `R?`. `$` is not needed as a regular-expression character since the pattern must match the whole name, unlike the usual interpretation of regular expressions (in other words, `$` is automatically appended to your pattern). Write `*` at the beginning and/or end if you don't wish the pattern to be anchored. Note that within double quotes, all regular expression special characters lose their special meanings and are matched literally. Also, the regular expression special characters are matched literally in operator name patterns (i.e., the argument of `\do`).

### Advanced Features

#### Variables

psql provides variable substitution features similar to common Unix command shells. Variables are simply name/value pairs, where the value can be any string of any length. The name must consist of letters (including non-Latin letters), digits, and underscores.

To set a variable, use the psql meta-command `\set`. For example,

```
   testdb=> \set foo bar
```

sets the variable `foo` to the value `bar`. To retrieve the content of the variable, precede the name with a colon, for example:

```
   testdb=> \echo :foo
   bar
```

2242
This works in both regular SQL commands and meta-commands; there is more detail in SQL Interpolation, below.

If you call `\set` without a second argument, the variable is set to an empty-string value. To unset (i.e., delete) a variable, use the command `\unset`. To show the values of all variables, call `\set` without any argument.

```
Note
The arguments of `\set` are subject to the same substitution rules as with other commands. Thus you can construct interesting references such as `\set :foo 'something'` and get “soft links” or “variable variables” of Perl or PHP fame, respectively. Unfortunately (or fortunately?), there is no way to do anything useful with these constructs. On the other hand, `\set bar :foo` is a perfectly valid way to copy a variable.
```

A number of these variables are treated specially by psql. They represent certain option settings that can be changed at run time by altering the value of the variable, or in some cases represent changeable state of psql. By convention, all specially treated variables' names consist of all upper-case ASCII letters (and possibly digits and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes.

Variables that control psql's behavior generally cannot be unset or set to invalid values. An `\unset` command is allowed but is interpreted as setting the variable to its default value. A `\set` command without a second argument is interpreted as setting the variable to on, for control variables that accept that value, and is rejected for others. Also, control variables that accept the values on and off will also accept other common spellings of Boolean values, such as true and false.

The specially treated variables are:

**AUTOCOMMIT**

When on (the default), each SQL command is automatically committed upon successful completion. To postpone commit in this mode, you must enter a `BEGIN` or `START TRANSACTION` SQL command. When off or unset, SQL commands are not committed until you explicitly issue `COMMIT` or `END`. The autocommit-off mode works by issuing an implicit `BEGIN` for you, just before any command that is not already in a transaction block and is not itself a `BEGIN` or other transaction-control command, nor a command that cannot be executed inside a transaction block (such as `VACUUM`).

```
Note
In autocommit-off mode, you must explicitly abandon any failed transaction by entering `ABORT` or `ROLLBACK`. Also keep in mind that if you exit the session without committing, your work will be lost.
```

```
Note
The autocommit-on mode is PostgreSQL's traditional behavior, but autocommit-off is closer to the SQL spec. If you prefer autocommit-off, you might wish to set it in the system-wide `psqlrc` file or your `~/.psqlrc` file.
```
COMP_KEYWORD_CASE

Determines which letter case to use when completing an SQL key word. If set to lower or upper, the completed word will be in lower or upper case, respectively. If set to preserve-lower or preserve-upper (the default), the completed word will be in the case of the word already entered, but words being completed without anything entered will be in lower or upper case, respectively.

DBNAME

The name of the database you are currently connected to. This is set every time you connect to a database (including program start-up), but can be changed or unset.

ECHO

If set to all, all nonempty input lines are printed to standard output as they are read. (This does not apply to lines read interactively.) To select this behavior on program start-up, use the switch -a. If set to queries, psql prints each query to standard output as it is sent to the server. The switch to select this behavior is -e. If set to errors, then only failed queries are displayed on standard error output. The switch for this behavior is -b. If set to none (the default), then no queries are displayed.

ECHO_HIDDEN

When this variable is set to on and a backslash command queries the database, the query is first shown. This feature helps you to study PostgreSQL internals and provide similar functionality in your own programs. (To select this behavior on program start-up, use the switch -E.) If you set this variable to the value noexec, the queries are just shown but are not actually sent to the server and executed. The default value is off.

ENCODING

The current client character set encoding. This is set every time you connect to a database (including program start-up), and when you change the encoding with \encoding, but it can be changed or unset.

ERROR

true if the last SQL query failed, false if it succeeded. See also SQLSTATE.

FETCH_COUNT

If this variable is set to an integer value greater than zero, the results of SELECT queries are fetched and displayed in groups of that many rows, rather than the default behavior of collecting the entire result set before display. Therefore only a limited amount of memory is used, regardless of the size of the result set. Settings of 100 to 1000 are commonly used when enabling this feature. Keep in mind that when using this feature, a query might fail after having already displayed some rows.

Tip

Although you can use any output format with this feature, the default aligned format tends to look bad because each group of FETCH_COUNT rows will be formatted separately, leading to varying column widths across the row groups. The other output formats work better.

HIDE_TABLEAM

If this variable is set to true, a table's access method details are not displayed. This is mainly useful for regression tests.
**HIDE_TOAST_COMPRESSION**

If this variable is set to `true`, column compression method details are not displayed. This is mainly useful for regression tests.

**HISTCONTROL**

If this variable is set to `ignore_space`, lines which begin with a space are not entered into the history list. If set to a value of `ignore_dups`, lines matching the previous history line are not entered. A value of `ignore_both` combines the two options. If set to `none` (the default), all lines read in interactive mode are saved on the history list.

**Note**

This feature was shamelessly plagiarized from Bash.

**HISTFILE**

The file name that will be used to store the history list. If unset, the file name is taken from the `PSQL_HISTORY` environment variable. If that is not set either, the default is `~/.psql_history`, or `%APPDATA%\postgresql\psql_history` on Windows. For example, putting:

```
\set HISTFILE ~/.psql_history--:DBNAME
```

in `~/.psqlrc` will cause `psql` to maintain a separate history for each database.

**Note**

This feature was shamelessly plagiarized from Bash.

**HISTSIZE**

The maximum number of commands to store in the command history (default 500). If set to a negative value, no limit is applied.

**Note**

This feature was shamelessly plagiarized from Bash.

**HOST**

The database server host you are currently connected to. This is set every time you connect to a database (including program start-up), but can be changed or unset.

**IGNOREEOF**

If set to 1 or less, sending an EOF character (usually `Control+D`) to an interactive session of `psql` will terminate the application. If set to a larger numeric value, that many consecutive EOF characters
must be typed to make an interactive session terminate. If the variable is set to a non-numeric value, it is interpreted as 10. The default is 0.

**Note**

This feature was shamelessly plagiarized from Bash.

**LASTOID**

The value of the last affected OID, as returned from an `INSERT` or `\lo_import` command. This variable is only guaranteed to be valid until after the result of the next SQL command has been displayed. PostgreSQL servers since version 12 do not support OID system columns anymore, thus `LASTOID` will always be 0 following `INSERT` when targeting such servers.

**LAST_ERROR_MESSAGE**

**LAST_ERROR_SQLSTATE**

The primary error message and associated SQLSTATE code for the most recent failed query in the current `psql` session, or an empty string and `00000` if no error has occurred in the current session.

**ON_ERROR_ROLLBACK**

When set to `on`, if a statement in a transaction block generates an error, the error is ignored and the transaction continues. When set to `interactive`, such errors are only ignored in interactive sessions, and not when reading script files. When set to `off` (the default), a statement in a transaction block that generates an error aborts the entire transaction. The error rollback mode works by issuing an implicit `SAVEPOINT` for you, just before each command that is in a transaction block, and then rolling back to the savepoint if the command fails.

**ON_ERROR_STOP**

By default, command processing continues after an error. When this variable is set to `on`, processing will instead stop immediately. In interactive mode, `psql` will return to the command prompt; otherwise, `psql` will exit, returning error code 3 to distinguish this case from fatal error conditions, which are reported using error code 1. In either case, any currently running scripts (the top-level script, if any, and any other scripts which it may have invoked) will be terminated immediately. If the top-level command string contained multiple SQL commands, processing will stop with the current command.

**PORT**

The database server port to which you are currently connected. This is set every time you connect to a database (including program start-up), but can be changed or unset.

**PROMPT1**

**PROMPT2**

**PROMPT3**

These specify what the prompts `psql` issues should look like. See Prompting below.

**QUIET**

Setting this variable to `on` is equivalent to the command line option `-q`. It is probably not too useful in interactive mode.
ROW_COUNT

The number of rows returned or affected by the last SQL query, or 0 if the query failed or did not report a row count.

SERVER_VERSION_NAME  
SERVER_VERSION_NUM

The server's version number as a string, for example 9.6.2, 10.1 or 11beta1, and in numeric form, for example 90602 or 100001. These are set every time you connect to a database (including program start-up), but can be changed or unset.

SHOW_ALL_RESULTS

When this variable is set to off, only the last result of a combined query (;) is shown instead of all of them. The default is on. The off behavior is for compatibility with older versions of psql.

SHOW_CONTEXT

This variable can be set to the values never, errors, or always to control whether CONTEXT fields are displayed in messages from the server. The default is errors (meaning that context will be shown in error messages, but not in notice or warning messages). This setting has no effect when VERBOSITY is set to terse or sqlstate. (See also \errverbose, for use when you want a verbose version of the error you just got.)

SINGLELINE

Setting this variable to on is equivalent to the command line option -S.

SINGLESTEP

Setting this variable to on is equivalent to the command line option -s.

SQLSTATE

The error code (see Appendix A) associated with the last SQL query's failure, or 00000 if it succeeded.

USER

The database user you are currently connected as. This is set every time you connect to a database (including program start-up), but can be changed or unset.

VERBOSITY

This variable can be set to the values default, verbose, terse, or sqlstate to control the verbosity of error reports. (See also \errverbose, for use when you want a verbose version of the error you just got.)

VERSION  
VERSION_NAME  
VERSION_NUM

These variables are set at program start-up to reflect psql's version, respectively as a verbose string, a short string (e.g., 9.6.2, 10.1, or 11beta1), and a number (e.g., 90602 or 100001). They can be changed or unset.
SQL Interpolation

A key feature of psql variables is that you can substitute ("interpolate") them into regular SQL statements, as well as the arguments of meta-commands. Furthermore, psql provides facilities for ensuring that variable values used as SQL literals and identifiers are properly quoted. The syntax for interpolating a value without any quoting is to prepend the variable name with a colon (:). For example,

```
set foo 'my_table'
```
```
SELECT * FROM :foo;
```

would query the table `my_table`. Note that this may be unsafe: the value of the variable is copied literally, so it can contain unbalanced quotes, or even backslash commands. You must make sure that it makes sense where you put it.

When a value is to be used as an SQL literal or identifier, it is safest to arrange for it to be quoted. To quote the value of a variable as an SQL literal, write a colon followed by the variable name in single quotes. To quote the value as an SQL identifier, write a colon followed by the variable name in double quotes. These constructs deal correctly with quotes and other special characters embedded within the variable value. The previous example would be more safely written this way:

```
set foo 'my_table'
```
```
SELECT * FROM :"foo";
```

Variable interpolation will not be performed within quoted SQL literals and identifiers. Therefore, a construction such as `':foo'` doesn't work to produce a quoted literal from a variable's value (and it would be unsafe if it did work, since it wouldn't correctly handle quotes embedded in the value).

One example use of this mechanism is to copy the contents of a file into a table column. First load the file into a variable and then interpolate the variable's value as a quoted string:

```
set content `cat my_file.txt`
```
```
INSERT INTO my_table VALUES (:'content');
```

(Note that this still won't work if `my_file.txt` contains NUL bytes. psql does not support embedded NUL bytes in variable values.)

Since colons can legally appear in SQL commands, an apparent attempt at interpolation (that is, `:name`, `:'name'`, or `:"name"`) is not replaced unless the named variable is currently set. In any case, you can escape a colon with a backslash to protect it from substitution.

The `:(?name)` special syntax returns TRUE or FALSE depending on whether the variable exists or not, and is thus always substituted, unless the colon is backslash-escaped.

The colon syntax for variables is standard SQL for embedded query languages, such as ECPG. The colon syntaxes for array slices and type casts are PostgreSQL extensions, which can sometimes conflict with the standard usage. The colon-quote syntax for escaping a variable's value as an SQL literal or identifier is a psql extension.

Prompting

The prompts psql issues can be customized to your preference. The three variables `PROMPT1`, `PROMPT2`, and `PROMPT3` contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when psql requests a new command. Prompt 2 is issued when
more input is expected during command entry, for example because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you are running an SQL COPY FROM
STDIN command and you need to type in a row value on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (%) is encountered. Depending on the next character, certain other text is substituted instead. Defined substitutions are:

%M
The full host name (with domain name) of the database server, or [local] if the connection is over
a Unix domain socket, or [local:/dir/name], if the Unix domain socket is not at the compiled
in default location.

%m
The host name of the database server, truncated at the first dot, or [local] if the connection is over
a Unix domain socket.

%>
The port number at which the database server is listening.

%n
The database session user name. (The expansion of this value might change during a database session
as the result of the command SET SESSION AUTHORIZATION.)

%/The name of the current database.

%~
Like %/, but the output is ~ (tilde) if the database is your default database.

%#
If the session user is a database superuser, then a #, otherwise a >. (The expansion of this value might
change during a database session as the result of the command SET SESSION AUTHORIZATION.)

%p
The process ID of the backend currently connected to.

%R
In prompt 1 normally =, but @ if the session is in an inactive branch of a conditional block, or ^ if in
single-line mode, or ! if the session is disconnected from the database (which can happen if \connect fails). In prompt 2 %R is replaced by a character that depends on why psql expects more input:
- if the command simply wasn’t terminated yet, but * if there is an unfinished /* . . . */ comment,
a single quote if there is an unfinished quoted string, a double quote if there is an unfinished quoted
identifier, a dollar sign if there is an unfinished dollar-quoted string, or ( if there is an unmatched left
parenthesis. In prompt 3 %R doesn’t produce anything.

%x
Transaction status: an empty string when not in a transaction block, or * when in a transaction block,
or ! when in a failed transaction block, or ? when the transaction state is indeterminate (for example,
because there is no connection).
The line number inside the current statement, starting from 1.

The character with the indicated octal code is substituted.

The value of the psql variable name. See Variables, above, for details.

The output of command, similar to ordinary “back-tick” substitution.

Prompts can contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. In order for the line editing features of Readline to work properly, these non-printing control characters must be designated as invisible by surrounding them with [% and %]. Multiple pairs of these can occur within the prompt. For example:

testdb=> \set PROMPT1 '%%033[1;33;40m%%n@%/%R%%033[0m%%# ' 
results in a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals.

Whitespace of the same width as the most recent output of PROMPT1. This can be used as a PROMPT2 setting, so that multi-line statements are aligned with the first line, but there is no visible secondary prompt.

To insert a percent sign into your prompt, write %%. The default prompts are '%//%R%x%# ' for prompts 1 and 2, and '>> ' for prompt 3.

Note
This feature was shamelessly plagiarized from tcsh.

Command-Line Editing

psql uses the Readline or libedit library, if available, for convenient line editing and retrieval. The command history is automatically saved when psql exits and is reloaded when psql starts up. Type up-arrow or control-P to retrieve previous lines.

You can also use tab completion to fill in partially-typed keywords and SQL object names in many (by no means all) contexts. For example, at the start of a command, typing ins and pressing TAB will fill in insert into . Then, typing a few characters of a table or schema name and pressing TAB will fill in the unfinished name, or offer a menu of possible completions when there's more than one. (Depending on the library in use, you may need to press TAB more than once to get a menu.)

Tab completion for SQL object names requires sending queries to the server to find possible matches. In some contexts this can interfere with other operations. For example, after BEGIN it will be too late to issue
SET TRANSACTION ISOLATION LEVEL if a tab-completion query is issued in between. If you do not want tab completion at all, you can turn it off permanently by putting this in a file named .inputrc in your home directory:

```
$if psql
   set disable-completion on
$endif

(This is not a psql but a Readline feature. Read its documentation for further details.)

The -n (--no-readline) command line option can also be useful to disable use of Readline for a single run of psql. This prevents tab completion, use or recording of command line history, and editing of multi-line commands. It is particularly useful when you need to copy-and-paste text that contains TAB characters.

Environment

COLUMNS

If \pset columns is zero, controls the width for the wrapped format and width for determining if wide output requires the pager or should be switched to the vertical format in expanded auto mode.

PGDATABASE
PGHOST
PGPORT
PGUSER

Default connection parameters (see Section 34.15).

PG_COLOR

Specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

PSQL_EDITOR
EDITOR
VISUAL

Editor used by the \e, \ef, and \ev commands. These variables are examined in the order listed; the first that is set is used. If none of them is set, the default is to use vi on Unix systems or notepad.exe on Windows systems.

PSQL_EDITOR_LINENUMBER_ARG

When \e, \ef, or \ev is used with a line number argument, this variable specifies the command-line argument used to pass the starting line number to the user's editor. For editors such as Emacs or vi, this is a plus sign. Include a trailing space in the value of the variable if there needs to be space between the option name and the line number. Examples:

```
PSQL_EDITOR_LINENUMBER_ARG='+'
PSQL_EDITOR_LINENUMBER_ARG='--line '
```

The default is + on Unix systems (corresponding to the default editor vi, and useful for many other common editors); but there is no default on Windows systems.
PSQL_HISTORY

Alternative location for the command history file. Tilde (~) expansion is performed.

PSQL_PAGER
PAGER

If a query's results do not fit on the screen, they are piped through this command. Typical values are more or less. Use of the pager can be disabled by setting PSQL_PAGER or PAGER to an empty string, or by adjusting the pager-related options of the \pset command. These variables are examined in the order listed; the first that is set is used. If none of them is set, the default is to use more on most platforms, but less on Cygwin.

PSQL_WATCH_PAGER

When a query is executed repeatedly with the \watch command, a pager is not used by default. This behavior can be changed by setting PSQL_WATCH_PAGER to a pager command, on Unix systems. The pspg pager (not part of PostgreSQL but available in many open source software distributions) can display the output of \watch if started with the option --stream.

PSQLRC

Alternative location of the user's .psqlrc file. Tilde (~) expansion is performed.

SHELL

Command executed by the \! command.

TMPDIR

Directory for storing temporary files. The default is /tmp.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 34.15).

Files

psqlrc and ~/.psqlrc

Unless it is passed an -X option, psql attempts to read and execute commands from the system-wide startup file (psqlrc) and then the user's personal startup file (~/.psqlrc), after connecting to the database but before accepting normal commands. These files can be used to set up the client and/or the server to taste, typically with \set and SET commands.

The system-wide startup file is named psqlrc and is sought in the installation's “system configuration” directory, which is most reliably identified by running pg_config --sysconfdir. By default this directory will be ../etc/ relative to the directory containing the PostgreSQL executables. The name of this directory can be set explicitly via the PGSYSCONFDIR environment variable.

The user's personal startup file is named .psqlrc and is sought in the invoking user's home directory. On Windows, which lacks such a concept, the personal startup file is named %APPDATA% \postgresql\psqlrc.conf. The location of the user's startup file can be set explicitly via the PSQLRC environment variable.

Both the system-wide startup file and the user's personal startup file can be made psql-version-specific by appending a dash and the PostgreSQL major or minor release number to the file name, for example
~/.psqlrc-9.2 or ~/.psqlrc-9.2.5. The most specific version-matching file will be read in preference to a non-version-specific file.

`.psql_history`

The command-line history is stored in the file `~/.psql_history`, or `%APPDATA%\postgresql\psql_history` on Windows.

The location of the history file can be set explicitly via the HISTFILE psql variable or the PSQL_HISTORY environment variable.

**Notes**

- `psql` works best with servers of the same or an older major version. Backslash commands are particularly likely to fail if the server is of a newer version than `psql` itself. However, backslash commands of the `\d` family should work with servers of versions back to 9.2, though not necessarily with servers newer than `psql` itself. The general functionality of running SQL commands and displaying query results should also work with servers of a newer major version, but this cannot be guaranteed in all cases.

If you want to use `psql` to connect to several servers of different major versions, it is recommended that you use the newest version of `psql`. Alternatively, you can keep around a copy of `psql` from each major version and be sure to use the version that matches the respective server. But in practice, this additional complication should not be necessary.

- Before PostgreSQL 9.6, the `-c` option implied `-X (--no-psqlrc)`; this is no longer the case.

- Before PostgreSQL 8.4, `psql` allowed the first argument of a single-letter backslash command to start directly after the command, without intervening whitespace. Now, some whitespace is required.

**Notes for Windows Users**

`psql` is built as a “console application”. Since the Windows console windows use a different encoding than the rest of the system, you must take special care when using 8-bit characters within `psql`. If `psql` detects a problematic console code page, it will warn you at startup. To change the console code page, two things are necessary:

- Set the code page by entering `cmd.exe /c chcp 1252`. (1252 is a code page that is appropriate for German; replace it with your value.) If you are using Cygwin, you can put this command in `/etc/profile`.

- Set the console font to Lucida Console, because the raster font does not work with the ANSI code page.

**Examples**

The first example shows how to spread a command over several lines of input. Notice the changing prompt:

```
  testdb=> CREATE TABLE my_table (  
  testdb(>    first integer not null default 0,  
  testdb(>    second text)  
  testdb-> ;  
  CREATE TABLE

Now look at the table definition again:
```
testdb=> \d my_table
  Table "public.my_table"
    Column | Type       | Collation | Nullable | Default
    ------+-----------+-----------+----------+---------
     first | integer   |           | not null | 0
     second| text      |           |          |

Now we change the prompt to something more interesting:

testdb=> \set PROMPT1 '%n@%m %~%R%# '
peter@localhost testdb=>

Let's assume you have filled the table with data and want to take a look at it:

peter@localhost testdb=> SELECT * FROM my_table;

    first | second
       ---+--------
          1 | one
          2 | two
          3 | three
          4 | four
(4 rows)

You can display tables in different ways by using the \pset command:

peter@localhost testdb=> \pset border 2
Border style is 2.
peter@localhost testdb=> SELECT * FROM my_table;

+-------+--------+
| first | second |
|-------+--------|
 | 1 | one |
 | 2 | two |
 | 3 | three |
 | 4 | four |
+-------+--------+
(4 rows)

peter@localhost testdb=> \pset border 0
Border style is 0.
peter@localhost testdb=> SELECT * FROM my_table;

+-------+--------+
| first | second |
|-------+--------|
 | 1 | one |
 | 2 | two |
 | 3 | three |
 | 4 | four |
+-------+--------+
(4 rows)

peter@localhost testdb=> \pset border 1
Border style is 1.
psql

peter@localhost testdb=> \pset format csv
Output format is csv.
peter@localhost testdb=> \pset tuples_only
Tuples only is on.
peter@localhost testdb=> SELECT second, first FROM my_table;
one,1
two,2
three,3
four,4

Alternatively, use the short commands:

peter@localhost testdb=> \a \t \x
Output format is aligned.
Tuples only is off.
Expanded display is on.
peter@localhost testdb=> SELECT * FROM my_table;
- [ RECORD 1 ] -
  first | 1
  second | one
- [ RECORD 2 ] -
  first | 2
  second | two
- [ RECORD 3 ] -
  first | 3
  second | three
- [ RECORD 4 ] -
  first | 4
  second | four

Also, these output format options can be set for just one query by using \g:

peter@localhost testdb=> SELECT * FROM my_table
peter@localhost testdb-> \g (format=aligned tuples_only=off expanded=on)
- [ RECORD 1 ] -
  first | 1
  second | one
- [ RECORD 2 ] -
  first | 2
  second | two
- [ RECORD 3 ] -
  first | 3
  second | three
Here is an example of using the `\df` command to find only functions with names matching `int*pl` and whose second argument is of type `bigint`:

```
testdb=> \df int*pl * bigint

List of functions

<table>
<thead>
<tr>
<th>Schema</th>
<th>Name</th>
<th>Result data type</th>
<th>Argument data types</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>pg_catalog</td>
<td>int28pl</td>
<td>bigint</td>
<td>smallint, bigint</td>
<td>func</td>
</tr>
<tr>
<td>pg_catalog</td>
<td>int48pl</td>
<td>bigint</td>
<td>integer, bigint</td>
<td>func</td>
</tr>
<tr>
<td>pg_catalog</td>
<td>int8pl</td>
<td>bigint</td>
<td>bigint, bigint</td>
<td>func</td>
</tr>
</tbody>
</table>

(3 rows)
```

When suitable, query results can be shown in a crosstab representation with the `\crosstabview` command:

```
testdb=> \crosstabview first second

first | second |
-------+--------|
1 | one    |
2 | two    |
3 | three  |
4 | four   |

(4 rows)
```

This second example shows a multiplication table with rows sorted in reverse numerical order and columns with an independent, ascending numerical order.
reindexdb

reindexdb — reindex a PostgreSQL database

Synopsis

reindexdb [connection-option...] [option...] [-S|--schema schema] ... [-t|--table table] ... [-i|--index index] ... [dbname]
reindexdb [connection-option...] [option...] -a|--all
reindexdb [connection-option...] [option...] -s|--system [dbname]

Description

reindexdb is a utility for rebuilding indexes in a PostgreSQL database.

reindexdb is a wrapper around the SQL command REINDEX. There is no effective difference between reindexing databases via this utility and via other methods for accessing the server.

Options

reindexdb accepts the following command-line arguments:

-a
--all

Reindex all databases.

--concurrently

Use the CONCURRENTLY option. See REINDEX, where all the caveats of this option are explained in detail.

[-d] dbname
[--dbname=] dbname

Specifies the name of the database to be reindexed, when -a/--all is not used. If this is not specified, the database name is read from the environment variable PGDATABASE. If that is not set, the user name specified for the connection is used. The dbname can be a connection string. If so, connection string parameters will override any conflicting command line options.

-e
--echo

Echo the commands that reindexdb generates and sends to the server.

-i index
--index=index

Recreate index only. Multiple indexes can be recreated by writing multiple -i switches.
-j njobs
--jobs=njobs

Execute the reindex commands in parallel by running njobs commands simultaneously. This option may reduce the processing time but it also increases the load on the database server.

reindexdb will open njobs connections to the database, so make sure your max_connections setting is high enough to accommodate all connections.

Note that this option is incompatible with the --index and --system options.

-q
--quiet

Do not display progress messages.

-s
--system

Reindex database's system catalogs only.

-S schema
--schema=schema

Reindex schema only. Multiple schemas can be reindexed by writing multiple -S switches.

-t table
--table=table

Reindex table only. Multiple tables can be reindexed by writing multiple -t switches.

--tablespace=tablespace

Specifies the tablespace where indexes are rebuilt. (This name is processed as a double-quoted identifier.)

-v
--verbose

Print detailed information during processing.

-V
--version

Print the reindexdb version and exit.

-?
--help

Show help about reindexdb command line arguments, and exit.

reindexdb also accepts the following command-line arguments for connection parameters:

-h host
--host=host

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.
-p port
--port=port
  Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

-U username
--username=username
  User name to connect as.

-w
--no-password
  Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W
--password
  Force reindexdb to prompt for a password before connecting to a database.

  This option is never essential, since reindexdb will automatically prompt for a password if the server demands password authentication. However, reindexdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

--maintenance-db=dbname
  Specifies the name of the database to connect to to discover which databases should be reindexed, when -a/--all is used. If not specified, the postgres database will be used, or if that does not exist, template1 will be used. This can be a connection string. If so, connection string parameters will override any conflicting command line options. Also, connection string parameters other than the database name itself will be re-used when connecting to other databases.

Environment

PGDATABASE
PGHOST
PGPORT
PGUSER

  Default connection parameters

PG_COLOR

  Specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 34.15).

Diagnostics

In case of difficulty, see REINDEX and psql for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.
Notes

reindexdb might need to connect several times to the PostgreSQL server, asking for a password each time. It is convenient to have a ~/.pgpass file in such cases. See Section 34.16 for more information.

Examples

To reindex the database test:

$ reindexdb test

To reindex the table foo and the index bar in a database named abcd:

$ reindexdb --table=foo --index=bar abcd

See Also

REINDEX
vacuumdb

vacuumdb — garbage-collect and analyze a PostgreSQL database

Synopsis

```
vacuumdb [connection-option...] [option...] [-t | --table table [(column [...])]] ... [dbname]
vacuumdb [connection-option...] [option...] -a | --all
```

Description

vacuumdb is a utility for cleaning a PostgreSQL database. vacuumdb will also generate internal statistics used by the PostgreSQL query optimizer.

vacuumdb is a wrapper around the SQL command VACUUM. There is no effective difference between vacuuming and analyzing databases via this utility and via other methods for accessing the server.

Options

vacuumdb accepts the following command-line arguments:

-a
   --all

Vacuum all databases.

[-d] dbname
   [-dbname=] dbname

Specifies the name of the database to be cleaned or analyzed, when -a|--all is not used. If this is not specified, the database name is read from the environment variable PGDATABASE. If that is not set, the user name specified for the connection is used. The dbname can be a connection string. If so, connection string parameters will override any conflicting command line options.

--disable-page-skipping

Disable skipping pages based on the contents of the visibility map.

Note

This option is only available for servers running PostgreSQL 9.6 and later.

-e
   --echo

Echo the commands that vacuumdb generates and sends to the server.
vacuumdb

-\( f \)
--full

Perform “full” vacuuming.

-\( F \)
--freeze

Aggressively “freeze” tuples.

--force-index-cleanup

Always remove index entries pointing to dead tuples.

**Note**

This option is only available for servers running PostgreSQL 12 and later.

-\( j \) \( njobs \)
--jobs=\( njobs \)

Execute the vacuum or analyze commands in parallel by running \( njobs \) commands simultaneously. This option may reduce the processing time but it also increases the load on the database server.

vacuumdb will open \( njobs \) connections to the database, so make sure your max_connections setting is high enough to accommodate all connections.

Note that using this mode together with the \(-f\) (FULL) option might cause deadlock failures if certain system catalogs are processed in parallel.

--min-mxid-age \( mxid\_age \)

Only execute the vacuum or analyze commands on tables with a multixact ID age of at least \( mx\_id\_age \). This setting is useful for prioritizing tables to process to prevent multixact ID wraparound (see Section 25.1.5.1).

For the purposes of this option, the multixact ID age of a relation is the greatest of the ages of the main relation and its associated TOAST table, if one exists. Since the commands issued by vacuumdb will also process the TOAST table for the relation if necessary, it does not need to be considered separately.

**Note**

This option is only available for servers running PostgreSQL 9.6 and later.

--min-xid-age \( xid\_age \)

Only execute the vacuum or analyze commands on tables with a transaction ID age of at least \( xid\_age \). This setting is useful for prioritizing tables to process to prevent transaction ID wraparound (see Section 25.1.5).

For the purposes of this option, the transaction ID age of a relation is the greatest of the ages of the main relation and its associated TOAST table, if one exists. Since the commands issued by vacuumdb will also process the TOAST table for the relation if necessary, it does not need to be considered separately.
**--no-index-cleanup**
Do not remove index entries pointing to dead tuples.

**Note**
This option is only available for servers running PostgreSQL 9.6 and later.

**--no-process-toast**
Skip the TOAST table associated with the table to vacuum, if any.

**Note**
This option is only available for servers running PostgreSQL 12 and later.

**--no-truncate**
Do not truncate empty pages at the end of the table.

**Note**
This option is only available for servers running PostgreSQL 12 and later.

**-P parallel_workers**
**--parallel=parallel_workers**
Specify the number of parallel workers for *parallel vacuum*. This allows the vacuum to leverage multiple CPUs to process indexes. See VACUUM.

**Note**
This option is only available for servers running PostgreSQL 13 and later.

**-q**
**--quiet**
Do not display progress messages.

**--skip-locked**
Skip relations that cannot be immediately locked for processing.
Note

This option is only available for servers running PostgreSQL 12 and later.

-t table [ (column [, ...]) ]
--table=table [ (column [, ...]) ]

Clean or analyze table only. Column names can be specified only in conjunction with the --analyze or --analyze-only options. Multiple tables can be vacuumed by writing multiple -t switches.

Tip

If you specify columns, you probably have to escape the parentheses from the shell. (See examples below.)

-v
--verbose

Print detailed information during processing.

-V
--version

Print the vacuumdb version and exit.

-z
--analyze

Also calculate statistics for use by the optimizer.

-Z
--analyze-only

Only calculate statistics for use by the optimizer (no vacuum).

--analyze-in-stages

Only calculate statistics for use by the optimizer (no vacuum), like --analyze-only. Run three stages of analyze; the first stage uses the lowest possible statistics target (see default_statistics_target) to produce usable statistics faster, and subsequent stages build the full statistics.

This option is only useful to analyze a database that currently has no statistics or has wholly incorrect ones, such as if it is newly populated from a restored dump or by pg_upgrade. Be aware that running with this option in a database with existing statistics may cause the query optimizer choices to become transiently worse due to the low statistics targets of the early stages.

-?
--help

Show help about vacuumdb command line arguments, and exit.
vacuumdb also accepts the following command-line arguments for connection parameters:

- `h host`
- `--host=host`

  Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

- `p port`
- `--port=port`

  Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

- `U username`
- `--username=username`

  User name to connect as.

- `w`
- `--no-password`

  Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

- `W`
- `--password`

  Force vacuumdb to prompt for a password before connecting to a database.

  This option is never essential, since vacuumdb will automatically prompt for a password if the server demands password authentication. However, vacuumdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

- `--maintenance-db=dbname`

  Specifies the name of the database to connect to to discover which databases should be vacuumed, when `-a` or `--all` is used. If not specified, the `postgres` database will be used, or if that does not exist, `template1` will be used. This can be a connection string. If so, connection string parameters will override any conflicting command line options. Also, connection string parameters other than the database name itself will be re-used when connecting to other databases.

**Environment**

- `PGDATABASE`
- `PGHOST`
- `PGPORT`
- `PGUSER`

  Default connection parameters

- `PG_COLOR`

  Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

---

2265
This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 34.15).

Diagnostics

In case of difficulty, see VACUUM and psql for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Notes

vacuumdb might need to connect several times to the PostgreSQL server, asking for a password each time. It is convenient to have a ~/.pgpass file in such cases. See Section 34.16 for more information.

Examples

To clean the database test:

$ vacuumdb test

To clean and analyze for the optimizer a database named bigdb:

$ vacuumdb --analyze bigdb

To clean a single table foo in a database named xyzzy, and analyze a single column bar of the table for the optimizer:

$ vacuumdb --analyze --verbose --table='foo(bar)' xyzzy

initdb

initdb — create a new PostgreSQL database cluster

Synopsis

initdb [option...] [--pgdata|D] directory

Description

initdb creates a new PostgreSQL database cluster. A database cluster is a collection of databases that are managed by a single server instance.

Creating a database cluster consists of creating the directories in which the database data will live, generating the shared catalog tables (tables that belong to the whole cluster rather than to any particular database), and creating the postres, template1, and template0 databases. The postres database is a default database meant for use by users, utilities and third party applications. template1 and template0 are meant as source databases to be copied by later CREATE DATABASE commands. template0 should never be modified, but you can add objects to template1, which by default will be copied into databases created later. See Section 23.3 for more details.

Although initdb will attempt to create the specified data directory, it might not have permission if the parent directory of the desired data directory is root-owned. To initialize in such a setup, create an empty data directory as root, then use chown to assign ownership of that directory to the database user account, then su to become the database user to run initdb.

initdb must be run as the user that will own the server process, because the server needs to have access to the files and directories that initdb creates. Since the server cannot be run as root, you must not run initdb as root either. (It will in fact refuse to do so.)

For security reasons the new cluster created by initdb will only be accessible by the cluster owner by default. The --allow-group-access option allows any user in the same group as the cluster owner to read files in the cluster. This is useful for performing backups as a non-privileged user.

initdb initializes the database cluster's default locale and character set encoding. These can also be set separately for each database when it is created. initdb determines those settings for the template databases, which will serve as the default for all other databases. By default, initdb uses the locale provider libc, takes the locale settings from the environment, and determines the encoding from the locale settings. This is almost always sufficient, unless there are special requirements.

To choose a different locale for the cluster, use the option --locale. There are also individual options --lc-* (see below) to set values for the individual locale categories. Note that inconsistent settings for different locale categories can give nonsensical results, so this should be used with care.

Alternatively, the ICU library can be used to provide locale services. (Again, this only sets the default for subsequently created databases.) To select this option, specify --locale-provider=icu. To choose the specific ICU locale ID to apply, use the option --icu-locale. Note that for implementation reasons and to support legacy code, initdb will still select and initialize libc locale settings when the ICU locale provider is used.

When initdb runs, it will print out the locale settings it has chosen. If you have complex requirements or specified multiple options, it is advisable to check that the result matches what was intended.

More details about locale settings can be found in Section 24.1.
To alter the default encoding, use the `--encoding`. More details can be found in Section 24.3.

### Options

**-A authmethod**

```bash
--auth=authmethod
```

This option specifies the default authentication method for local users used in `pg_hba.conf` (host and local lines). See Section 21.1 for an overview of valid values.

`initdb` will prepopulate `pg_hba.conf` entries using the specified authentication method for non-replication as well as replication connections.

Do not use `trust` unless you trust all local users on your system. `trust` is the default for ease of installation.

**--auth-host=authmethod**

This option specifies the authentication method for local users via TCP/IP connections used in `pg_hba.conf` (host lines).

**--auth-local=authmethod**

This option specifies the authentication method for local users via Unix-domain socket connections used in `pg_hba.conf` (local lines).

**-D directory**

```bash
--pgdata=directory
```

This option specifies the directory where the database cluster should be stored. This is the only information required by `initdb`, but you can avoid writing it by setting the `PGDATA` environment variable, which can be convenient since the database server (`postgres`) can find the database directory later by the same variable.

**-E encoding**

```bash
--encoding=encoding
```

Selects the encoding of the template databases. This will also be the default encoding of any database you create later, unless you override it then. The default is derived from the locale, or `SQL_ASCII` if that does not work. The character sets supported by the PostgreSQL server are described in Section 24.3.1.

**-g**

```bash
--allow-group-access
```

Allows users in the same group as the cluster owner to read all cluster files created by `initdb`. This option is ignored on Windows as it does not support POSIX-style group permissions.

**--icu-locale=locale**

Specifies the ICU locale ID, if the ICU locale provider is used.

**-k**

```bash
--data-checksums
```

Use checksums on data pages to help detect corruption by the I/O system that would otherwise be silent. Enabling checksums may incur a noticeable performance penalty. If set, checksums are calcu-
lated for all objects, in all databases. All checksum failures will be reported in the `pg_stat_database` view. See Section 30.2 for details.

```--locale=locale```

Sets the default locale for the database cluster. If this option is not specified, the locale is inherited from the environment that `initdb` runs in. Locale support is described in Section 24.1.

```--lc-collate=locale```
```--lc-ctype=locale```
```--lc-messages=locale```
```--lc-monetary=locale```
```--lc-numeric=locale```
```--lc-time=locale```

Like `--locale`, but only sets the locale in the specified category.

```--no-locale```

Equivalent to `--locale=C`.

```--locale-provider={ libc | icu }```

This option sets the locale provider for databases created in the new cluster. It can be overridden in the `CREATE DATABASE` command when new databases are subsequently created. The default is `libc`.

```-N```
```--no-sync```

By default, `initdb` will wait for all files to be written safely to disk. This option causes `initdb` to return without waiting, which is faster, but means that a subsequent operating system crash can leave the data directory corrupt. Generally, this option is useful for testing, but should not be used when creating a production installation.

```--no-instructions```

By default, `initdb` will write instructions for how to start the cluster at the end of its output. This option causes `initdb` to cause those instructions to be left out. This is primarily intended for use by tools that wrap `initdb` in platform-specific behavior, where those instructions are likely to be incorrect.

```--pwfile=filename```

Makes `initdb` read the database superuser's password from a file. The first line of the file is taken as the password.

```-S```
```--sync-only```

Safely write all database files to disk and exit. This does not perform any of the normal `initdb` operations. Generally, this option is useful for ensuring reliable recovery after changing `fsync` from `off` to `on`.

```--text-search-config=config```

Sets the default text search configuration. See `default_text_search_config` for further information.
initdb

- U username
  --username=username

Selects the user name of the database superuser. This defaults to the name of the effective user running initdb. It is really not important what the superuser's name is, but one might choose to keep the customary name postgres, even if the operating system user's name is different.

-W
--pwprompt

Makes initdb prompt for a password to give the database superuser. If you don't plan on using password authentication, this is not important. Otherwise you won't be able to use password authentication until you have a password set up.

-X directory
--waldir=directory

This option specifies the directory where the write-ahead log should be stored.

--wal-segsize=size

Set the WAL segment size, in megabytes. This is the size of each individual file in the WAL log. The default size is 16 megabytes. The value must be a power of 2 between 1 and 1024 (megabytes). This option can only be set during initialization, and cannot be changed later.

It may be useful to adjust this size to control the granularity of WAL log shipping or archiving. Also, in databases with a high volume of WAL, the sheer number of WAL files per directory can become a performance and management problem. Increasing the WAL file size will reduce the number of WAL files.

Other, less commonly used, options are also available:

-d
--debug

Print debugging output from the bootstrap backend and a few other messages of lesser interest for the general public. The bootstrap backend is the program initdb uses to create the catalog tables. This option generates a tremendous amount of extremely boring output.

--discard-caches

Run the bootstrap backend with the debug_discard_caches=1 option. This takes a very long time and is only of use for deep debugging.

-L directory

Specifies where initdb should find its input files to initialize the database cluster. This is normally not necessary. You will be told if you need to specify their location explicitly.

-n
--no-clean

By default, when initdb determines that an error prevented it from completely creating the database cluster, it removes any files it might have created before discovering that it cannot finish the job. This option inhibits tidying-up and is thus useful for debugging.

Other options:

2271
initdb

-\v
--version

Print the initdb version and exit.

-\?
--help

Show help about initdb command line arguments, and exit.

Environment

PGDATA

Specifies the directory where the database cluster is to be stored; can be overridden using the -D option.

PG_COLOR

Specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

TZ

Specifies the default time zone of the created database cluster. The value should be a full time zone name (see Section 8.5.3).

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 34.15).

Notes

initdb can also be invoked via pg_ctl initdb.

pg_ctl, postgres, Section 21.1
pg_archivecleanup

pg_archivecleanup — clean up PostgreSQL WAL archive files

Synopsis

pg_archivecleanup [option...] archivelocation oldestkeptwalfile

Description

pg_archivecleanup is designed to be used as an archive_cleanup_command to clean up WAL file archives when running as a standby server (see Section 27.2). pg_archivecleanup can also be used as a standalone program to clean WAL file archives.

To configure a standby server to use pg_archivecleanup, put this into its postgresql.conf configuration file:

archive_cleanup_command = 'pg_archivecleanup archivelocation %r'

where archivelocation is the directory from which WAL segment files should be removed.

When used within archive_cleanup_command, all WAL files logically preceding the value of the %r argument will be removed from archivelocation. This minimizes the number of files that need to be retained, while preserving crash-restart capability. Use of this parameter is appropriate if the archivelocation is a transient staging area for this particular standby server, but not when the archivelocation is intended as a long-term WAL archive area, or when multiple standby servers are recovering from the same archive location.

When used as a standalone program all WAL files logically preceding the oldestkeptwalfile will be removed from archivelocation. In this mode, if you specify a .partial or .backup file name, then only the file prefix will be used as the oldestkeptwalfile. This treatment of .backup file name allows you to remove all WAL files archived prior to a specific base backup without error. For example, the following example will remove all files older than WAL file name 000000010000003700000010:

pg_archivecleanup -d archive 000000010000003700000010.00000020.backup

Options

pg_archivecleanup accepts the following command-line arguments:
pg_archivecleanup

-\(d\)
  
  Print lots of debug logging output on stderr.

-\(n\)
  
  Print the names of the files that would have been removed on stdout (performs a dry run).

-\(V\)
  --version
  
  Print the pg_archivecleanup version and exit.

-\(x\) extension
  
  Provide an extension that will be stripped from all file names before deciding if they should be deleted. This is typically useful for cleaning up archives that have been compressed during storage, and therefore have had an extension added by the compression program. For example: -\(x\) .gz.

-\(?\)
  --help
  
  Show help about pg_archivecleanup command line arguments, and exit.

Environment

The environment variable PG_COLOR specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

Notes

pg_archivecleanup is designed to work with PostgreSQL 8.0 and later when used as a standalone utility, or with PostgreSQL 9.0 and later when used as an archive cleanup command.

pg_archivecleanup is written in C and has an easy-to-modify source code, with specifically designated sections to modify for your own needs.

Examples

On Linux or Unix systems, you might use:

```
archive_cleanup_command = 'pg_archivecleanup -d /mnt/standby/archive %r 2>>cleanup.log'
```

where the archive directory is physically located on the standby server, so that the archive_command is accessing it across NFS, but the files are local to the standby. This will:

• produce debugging output in cleanup.log

• remove no-longer-needed files from the archive directory
pg_checksums

pg_checksums — enable, disable or check data checksums in a PostgreSQL database cluster

Synopsis

pg_checksums [option...][ -D|--pgdata ]datadir

Description

pg_checksums checks, enables or disables data checksums in a PostgreSQL cluster. The server must be shut down cleanly before running pg_checksums. When verifying checksums, the exit status is zero if there are no checksum errors, and nonzero if at least one checksum failure is detected. When enabling or disabling checksums, the exit status is nonzero if the operation failed.

When verifying checksums, every file in the cluster is scanned. When enabling checksums, each relation file block with a changed checksum is rewritten in-place. Disabling checksums only updates the file pg_control.

Options

The following command-line options are available:

-D directory
--pgdata=directory

Specifies the directory where the database cluster is stored.

-c
--check

Checks checksums. This is the default mode if nothing else is specified.

-d
--disable

Disables checksums.

-e
--enable

Enables checksums.

-f filenode
--filenode=filenode

Only validate checksums in the relation with filenode filenode.

-N
--no-sync

By default, pg_checksums will wait for all files to be written safely to disk. This option causes pg_checksums to return without waiting, which is faster, but means that a subsequent operating
system crash can leave the updated data directory corrupt. Generally, this option is useful for testing but should not be used on a production installation. This option has no effect when using --check.

-\texttt{P}
--progress

Enable progress reporting. Turning this on will deliver a progress report while checking or enabling checksums.

-\texttt{v}
--verbose

Enable verbose output. Lists all checked files.

-\texttt{V}
--version

Print the \texttt{pg\_checksums} version and exit.

-\texttt{?}
--help

Show help about \texttt{pg\_checksums} command line arguments, and exit.

\section*{Environment}

\texttt{PGDATA}

Specifies the directory where the database cluster is stored; can be overridden using the \texttt{--check} option.

\texttt{PG\_COLOR}

Specifies whether to use color in diagnostic messages. Possible values are \texttt{always, auto} and \texttt{never}.

\section*{Notes}

Enabling checksums in a large cluster can potentially take a long time. During this operation, the cluster or other programs that write to the data directory must not be started or else data loss may occur.

When using a replication setup with tools which perform direct copies of relation file blocks (for example \texttt{pg\_rewind}), enabling or disabling checksums can lead to page corruptions in the shape of incorrect checksums if the operation is not done consistently across all nodes. When enabling or disabling checksums in a replication setup, it is thus recommended to stop all the clusters before switching them all consistently. Destroying all standbys, performing the operation on the primary and finally recreating the standbys from scratch is also safe.

If \texttt{pg\_checksums} is aborted or killed while enabling or disabling checksums, the cluster's data checksum configuration remains unchanged, and \texttt{pg\_checksums} can be re-run to perform the same operation.
pg_controldata

pg_controldata — display control information of a PostgreSQL database cluster

Synopsis

pg_controldata [option][[-D|--pgdata] datadir]

Description

pg_controldata prints information initialized during initdb, such as the catalog version. It also shows information about write-ahead logging and checkpoint processing. This information is cluster-wide, and not specific to any one database.

This utility can only be run by the user who initialized the cluster because it requires read access to the data directory. You can specify the data directory on the command line, or use the environment variable PGDATA. This utility supports the options -V and --version, which print the pg_controldata version and exit. It also supports options -? and --help, which output the supported arguments.

Environment

PGDATA

Default data directory location

PG_COLOR

Specifies whether to use color in diagnostic messages. Possible values are always, auto and never.
pg_ctl

pg_ctl — initialize, start, stop, or control a PostgreSQL server

Synopsis

pg_ctl init[db] [-D datadir] [-s] [-o initdb-options]
pg_ctl stop [-D datadir] [-m smart] | [fast] | [immediate] | [-W] [-t seconds] [-s]
pg_ctl restart [-D datadir] [-m smart] | [fast] | [immediate] | [-W] [-t seconds] [-s] [-o options] [-c]
pg_ctl reload [-D datadir] [-s]
pg_ctl status [-D datadir]
pg_ctl promote [-D datadir] [-W] [-t seconds] [-s]
pg_ctl logrotate [-D datadir] [-s]
pg_ctl kill signal_name process_id

On Microsoft Windows, also:

pg_ctl unregister [-N servicename]

Description

pg_ctl is a utility for initializing a PostgreSQL database cluster, starting, stopping, or restarting the PostgreSQL database server (postgres), or displaying the status of a running server. Although the server can be started manually, pg_ctl encapsulates tasks such as redirecting log output and properly detaching from the terminal and process group. It also provides convenient options for controlled shutdown.

The init or initdb mode creates a new PostgreSQL database cluster, that is, a collection of databases that will be managed by a single server instance. This mode invokes the initdb command. See initdb for details.

start mode launches a new server. The server is started in the background, and its standard input is attached to /dev/null (or nul on Windows). On Unix-like systems, by default, the server’s standard output and standard error are sent to pg_ctl’s standard output (not standard error). The standard output of pg_ctl should then be redirected to a file or piped to another process such as a log rotating program like rotatelogs; otherwise postgres will write its output to the controlling terminal (from the background) and will not leave the shell’s process group. On Windows, by default the server’s standard output and standard error are sent to the terminal. These default behaviors can be changed by using -l to append the server’s output to a log file. Use of either -l or output redirection is recommended.
pg_ctl

stop mode shuts down the server that is running in the specified data directory. Three different shutdown methods can be selected with the --m option. “Smart” mode disallows new connections, then waits for all existing clients to disconnect. If the server is in hot standby, recovery and streaming replication will be terminated once all clients have disconnected. “Fast” mode (the default) does not wait for clients to disconnect. All active transactions are rolled back and clients are forcibly disconnected, then the server is shut down. “Immediate” mode will abort all server processes immediately, without a clean shutdown. This choice will lead to a crash-recovery cycle during the next server start.

restart mode effectively executes a stop followed by a start. This allows changing the postgres command-line options, or changing configuration-file options that cannot be changed without restarting the server. If relative paths were used on the command line during server start, restart might fail unless pg_ctl is executed in the same current directory as it was during server start.

reload mode simply sends the postgres server process a SIGHUP signal, causing it to reread its configuration files (postgresql.conf, pg_hba.conf, etc.). This allows changing configuration-file options that do not require a full server restart to take effect.

status mode checks whether a server is running in the specified data directory. If it is, the server's PID and the command line options that were used to invoke it are displayed. If the server is not running, pg_ctl returns an exit status of 3. If an accessible data directory is not specified, pg_ctl returns an exit status of 4.

promote mode commands the standby server that is running in the specified data directory to end standby mode and begin read-write operations.

logrotate mode rotates the server log file. For details on how to use this mode with external log rotation tools, see Section 25.3.

kill mode sends a signal to a specified process. This is primarily valuable on Microsoft Windows which does not have a built-in kill command. Use --help to see a list of supported signal names.

register mode registers the PostgreSQL server as a system service on Microsoft Windows. The -S option allows selection of service start type, either “auto” (start service automatically on system startup) or “demand” (start service on demand).

unregister mode unregisters a system service on Microsoft Windows. This undoes the effects of the register command.

Options

-c
--core-files

Attempt to allow server crashes to produce core files, on platforms where this is possible, by lifting any soft resource limit placed on core files. This is useful in debugging or diagnosing problems by allowing a stack trace to be obtained from a failed server process.

-D datadir
--pgdata=datadir

Specifies the file system location of the database configuration files. If this option is omitted, the environment variable PGDATA is used.

-l filename
--log=filename

Append the server log output to filename. If the file does not exist, it is created. The umask is set to 077, so access to the log file is disallowed to other users by default.
-m mode
--mode=mode

Specifies the shutdown mode. mode can be smart, fast, or immediate, or the first letter of one of these three. If this option is omitted, fast is the default.

-o options
--options=options

Specifies options to be passed directly to the postgres command. -o can be specified multiple times, with all the given options being passed through.

The options should usually be surrounded by single or double quotes to ensure that they are passed through as a group.

-o initdb-options
--options=initdb-options

Specifies options to be passed directly to the initdb command. -o can be specified multiple times, with all the given options being passed through.

The initdb-options should usually be surrounded by single or double quotes to ensure that they are passed through as a group.

-p path

Specifies the location of the postgres executable. By default the postgres executable is taken from the same directory as pg_ctl, or failing that, the hard-wired installation directory. It is not necessary to use this option unless you are doing something unusual and get errors that the postgres executable was not found.

In init mode, this option analogously specifies the location of the initdb executable.

-s
--silent

Print only errors, no informational messages.

-t seconds
--timeout=seconds

Specifies the maximum number of seconds to wait when waiting for an operation to complete (see option -w). Defaults to the value of the PGCTLTIMEOUT environment variable or, if not set, to 60 seconds.

-V
--version

Print the pg_ctl version and exit.

-w
--wait

Wait for the operation to complete. This is supported for the modes start, stop, restart, promote, and register, and is the default for those modes.

When waiting, pg_ctl repeatedly checks the server’s PID file, sleeping for a short amount of time between checks. Startup is considered complete when the PID file indicates that the server is ready to
accept connections. Shutdown is considered complete when the server removes the PID file. `pg_ctl` returns an exit code based on the success of the startup or shutdown.

If the operation does not complete within the timeout (see option `-t`), then `pg_ctl` exits with a nonzero exit status. But note that the operation might continue in the background and eventually succeed.

- `-W`
- `--no-wait`

Do not wait for the operation to complete. This is the opposite of the option `-w`.

If waiting is disabled, the requested action is triggered, but there is no feedback about its success. In that case, the server log file or an external monitoring system would have to be used to check the progress and success of the operation.

In prior releases of PostgreSQL, this was the default except for the `stop` mode.

- `-?`
- `--help`

Show help about `pg_ctl` command line arguments, and exit.

If an option is specified that is valid, but not relevant to the selected operating mode, `pg_ctl` ignores it.

### Options for Windows

- `-e` `source`

Name of the event source for `pg_ctl` to use for logging to the event log when running as a Windows service. The default is `PostgreSQL`. Note that this only controls messages sent from `pg_ctl` itself; once started, the server will use the event source specified by its `event_source` parameter. Should the server fail very early in startup, before that parameter has been set, it might also log using the default event source name `PostgreSQL`.

- `-N` `servicename`

Name of the system service to register. This name will be used as both the service name and the display name. The default is `PostgreSQL`.

- `-P` `password`

Password for the user to run the service as.

- `-S` `start-type`

Start type of the system service. `start-type` can be `auto`, or `demand`, or the first letter of one of these two. If this option is omitted, `auto` is the default.

- `-U` `username`

User name for the user to run the service as. For domain users, use the format `DOMAIN\username`.

### Environment

`PGCTLTIMEOUT`

Default limit on the number of seconds to wait when waiting for startup or shutdown to complete. If not set, the default is 60 seconds.
PGDATA

Default data directory location.

Most `pg_ctl` modes require knowing the data directory location; therefore, the `-D` option is required unless `PGDATA` is set.

`pg_ctl`, like most other PostgreSQL utilities, also uses the environment variables supported by `libpq` (see Section 34.15).

For additional variables that affect the server, see `postgres`.

Files

`postmaster.pid`

`pg_ctl` examines this file in the data directory to determine whether the server is currently running.

`postmaster.opts`

If this file exists in the data directory, `pg_ctl` (in `restart` mode) will pass the contents of the file as options to `postgres`, unless overridden by the `-o` option. The contents of this file are also displayed in `status` mode.

Examples

Starting the Server

To start the server, waiting until the server is accepting connections:

```
$ pg_ctl start
```

To start the server using port 5433, and running without `fsync`, use:

```
$ pg_ctl -o "-F -p 5433" start
```

Stopping the Server

To stop the server, use:

```
$ pg_ctl stop
```

The `-m` option allows control over how the server shuts down:

```
$ pg_ctl stop -m smart
```

Restarting the Server

Restarting the server is almost equivalent to stopping the server and starting it again, except that by default, `pg_ctl` saves and reuses the command line options that were passed to the previously-running instance.

To restart the server using the same options as before, use:

```
```
$ pg_ctl restart

But if -o is specified, that replaces any previous options. To restart using port 5433, disabling fsync upon restart:

$ pg_ctl -o "-F -p 5433" restart

**Showing the Server Status**

Here is sample status output from pg_ctl:

$ pg_ctl status

```
pg_ctl: server is running (PID: 13718)
/usr/local/pgsql/bin/postgres "-D" "/usr/local/pgsql/data" "-p" "5433"
"-B" "128"
```

The second line is the command that would be invoked in restart mode.

**See Also**

initdb, postgres
pg_resetwal

pg_resetwal — reset the write-ahead log and other control information of a PostgreSQL database cluster

Synopsis

pg_resetwal [-f|--force] [-n|--dry-run] [option...][ -D|--pgdata] datadir

Description

pg_resetwal clears the write-ahead log (WAL) and optionally resets some other control information stored in the pg_control file. This function is sometimes needed if these files have become corrupted. It should be used only as a last resort, when the server will not start due to such corruption.

After running this command, it should be possible to start the server, but bear in mind that the database might contain inconsistent data due to partially-committed transactions. You should immediately dump your data, run initdb, and reload. After reload, check for inconsistencies and repair as needed.

This utility can only be run by the user who installed the server, because it requires read/write access to the data directory. For safety reasons, you must specify the data directory on the command line. pg_resetwal does not use the environment variable PGDATA.

If pg_resetwal complains that it cannot determine valid data for pg_control, you can force it to proceed anyway by specifying the -f (force) option. In this case plausible values will be substituted for the missing data. Most of the fields can be expected to match, but manual assistance might be needed for the next OID, next transaction ID and epoch, next multitransaction ID and offset, and WAL starting location fields. These fields can be set using the options discussed below. If you are not able to determine correct values for all these fields, -f can still be used, but the recovered database must be treated with even more suspicion than usual: an immediate dump and reload is imperative. Do not execute any data-modifying operations in the database before you dump, as any such action is likely to make the corruption worse.

Options

-f
--force

Force pg_resetwal to proceed even if it cannot determine valid data for pg_control, as explained above.

-n
--dry-run

The -n|--dry-run option instructs pg_resetwal to print the values reconstructed from pg_control and values about to be changed, and then exit without modifying anything. This is mainly a debugging tool, but can be useful as a sanity check before allowing pg_resetwal to proceed for real.

-v
--version

Display version information, then exit.
The following options are only needed when `pg_resetwal` is unable to determine appropriate values by reading `pg_control`. Safe values can be determined as described below. For values that take numeric arguments, hexadecimal values can be specified by using the prefix `0x`.

- `-c xid,xid`  
  `--commit-timestamp-ids=xid,xid`

Manually set the oldest and newest transaction IDs for which the commit time can be retrieved.

A safe value for the oldest transaction ID for which the commit time can be retrieved (first part) can be determined by looking for the numerically smallest file name in the directory `pg_commit_ts` under the data directory. Conversely, a safe value for the newest transaction ID for which the commit time can be retrieved (second part) can be determined by looking for the numerically greatest file name in the same directory. The file names are in hexadecimal.

- `-e xid_epoch`  
  `--epoch=xid_epoch`

Manually set the next transaction ID's epoch.

The transaction ID epoch is not actually stored anywhere in the database except in the field that is set by `pg_resetwal`, so any value will work so far as the database itself is concerned. You might need to adjust this value to ensure that replication systems such as Slony-I and Skytools work correctly — if so, an appropriate value should be obtainable from the state of the downstream replicated database.

- `-l walfile`  
  `--next-wal-file=walfile`

Manually set the WAL starting location by specifying the name of the next WAL segment file.

The name of next WAL segment file should be larger than any WAL segment file name currently existing in the directory `pg_wal` under the data directory. These names are also in hexadecimal and have three parts. The first part is the “timeline ID” and should usually be kept the same. For example, if `0000000010000003200000004A` is the largest entry in `pg_wal`, use `-l 0000000010000003200000004B` or higher.

Note that when using nondefault WAL segment sizes, the numbers in the WAL file names are different from the LSNs that are reported by system functions and system views. This option takes a WAL file name, not an LSN.

- `-m mxid,mxid`  
  `--multixact-ids=mxid,mxid`

Manually set the next and oldest multitransaction ID.

---

**Note**

`pg_resetwal` itself looks at the files in `pg_wal` and chooses a default `-l` setting beyond the last existing file name. Therefore, manual adjustment of `-l` should only be needed if you are aware of WAL segment files that are not currently present in `pg_wal`, such as entries in an offline archive; or if the contents of `pg_wal` have been lost entirely.
A safe value for the next multitransaction ID (first part) can be determined by looking for the numerically largest file name in the directory `pg_multixact/offsets` under the data directory, adding one, and then multiplying by 65536 (0x10000). Conversely, a safe value for the oldest multitransaction ID (second part of `-m`) can be determined by looking for the numerically smallest file name in the same directory and multiplying by 65536. The file names are in hexadecimal, so the easiest way to do this is to specify the option value in hexadecimal and append four zeroes.

```
-o oid
--next-oid=oid
```

Manually set the next OID.

There is no comparably easy way to determine a next OID that's beyond the largest one in the database, but fortunately it is not critical to get the next-OID setting right.

```
-O mxoff
--multixact-offset=mxoff
```

Manually set the next multitransaction offset.

A safe value can be determined by looking for the numerically largest file name in the directory `pg_multixact/members` under the data directory, adding one, and then multiplying by 52352 (0xCC80). The file names are in hexadecimal. There is no simple recipe such as the ones for other options of appending zeroes.

```
--wal-segsize=wal_segment_size
```

Set the new WAL segment size, in megabytes. The value must be set to a power of 2 between 1 and 1024 (megabytes). See the same option of initdb for more information.

```
Note

While `pg_resetwal` will set the WAL starting address beyond the latest existing WAL segment file, some segment size changes can cause previous WAL file names to be reused. It is recommended to use `-l` together with this option to manually set the WAL starting address if WAL file name overlap will cause problems with your archiving strategy.
```

```
-u xid
--oldest-transaction-id=xid
```

Manually set the oldest unfrozen transaction ID.

A safe value can be determined by looking for the numerically smallest file name in the directory `pg_xact` under the data directory and then multiplying by 1048576 (0x100000). Note that the file names are in hexadecimal. It is usually easiest to specify the option value in hexadecimal too. For example, if 0007 is the smallest entry in `pg_xact`, `-u 0x700000` will work (five trailing zeroes provide the proper multiplier).

```
-x xid
--next-transaction-id=xid
```

Manually set the next transaction ID.

A safe value can be determined by looking for the numerically largest file name in the directory `pg_xact` under the data directory, adding one, and then multiplying by 1048576 (0x100000). Note
that the file names are in hexadecimal. It is usually easiest to specify the option value in hexadecimal too. For example, if 0011 is the largest entry in pg_xact, `-x 0x1200000` will work (five trailing zeroes provide the proper multiplier).

### Environment

**PG_COLOR**

Specifies whether to use color in diagnostic messages. Possible values are *always*, *auto* and *never*.

### Notes

This command must not be used when the server is running. `pg_resetwal` will refuse to start up if it finds a server lock file in the data directory. If the server crashed then a lock file might have been left behind; in that case you can remove the lock file to allow `pg_resetwal` to run. But before you do so, make doubly certain that there is no server process still alive.

`pg_resetwal` works only with servers of the same major version.

pg_rewind

pg_rewind — synchronize a PostgreSQL data directory with another data directory that was forked from it

Synopsis

pg_rewind [option...] { -D | --target-pgdata } directory { --source-pgdata=directory | --source-server=connstr }

Description

pg_rewind is a tool for synchronizing a PostgreSQL cluster with another copy of the same cluster, after the clusters' timelines have diverged. A typical scenario is to bring an old primary server back online after failover as a standby that follows the new primary.

After a successful rewind, the state of the target data directory is analogous to a base backup of the source data directory. Unlike taking a new base backup or using a tool like rsync, pg_rewind does not require comparing or copying unchanged relation blocks in the cluster. Only changed blocks from existing relation files are copied; all other files, including new relation files, configuration files, and WAL segments, are copied in full. As such the rewind operation is significantly faster than other approaches when the database is large and only a small fraction of blocks differ between the clusters.

pg_rewind examines the timeline histories of the source and target clusters to determine the point where they diverged, and expects to find WAL in the target cluster's pg_wal directory reaching all the way back to the point of divergence. The point of divergence can be found either on the target timeline, the source timeline, or their common ancestor. In the typical failover scenario where the target cluster was shut down soon after the divergence, this is not a problem, but if the target cluster ran for a long time after the divergence, its old WAL files might no longer be present. In this case, you can manually copy them from the WAL archive to the pg_wal directory, or run pg_rewind with the -c option to automatically retrieve them from the WAL archive. The use of pg_rewind is not limited to failover, e.g., a standby server can be promoted, run some write transactions, and then rewound to become a standby again.

After running pg_rewind, WAL replay needs to complete for the data directory to be in a consistent state. When the target server is started again it will enter archive recovery and replay all WAL generated in the source server from the last checkpoint before the point of divergence. If some of the WAL was no longer available in the source server when pg_rewind was run, and therefore could not be copied by the pg_rewind session, it must be made available when the target server is started. This can be done by creating a recovery.signal file in the target data directory and by configuring a suitable restore_command in postgresql.conf.

pg_rewind requires that the target server either has the wal_log_hints option enabled in postgresql.conf or data checksums enabled when the cluster was initialized with initdb. Neither of these are currently on by default. full_page_writes must also be set to on, but is enabled by default.

Warning

If pg_rewind fails while processing, then the data folder of the target is likely not in a state that can be recovered. In such a case, taking a new fresh backup is recommended.

As pg_rewind copies configuration files entirely from the source, it may be required to correct the configuration used for recovery before restarting the target server, especially if the target is
pg_rewind

reintroduced as a standby of the source. If you restart the server after the rewind operation has finished but without configuring recovery, the target may again diverge from the primary.

pg_rewind will fail immediately if it finds files it cannot write directly to. This can happen for example when the source and the target server use the same file mapping for read-only SSL keys and certificates. If such files are present on the target server it is recommended to remove them before running pg_rewind. After doing the rewind, some of those files may have been copied from the source, in which case it may be necessary to remove the data copied and restore back the set of links used before the rewind.

Options

pg_rewind accepts the following command-line arguments:

-D directory
--target-pgdata=directory

This option specifies the target data directory that is synchronized with the source. The target server must be shut down cleanly before running pg_rewind

--source-pgdata=directory

Specifies the file system path to the data directory of the source server to synchronize the target with. This option requires the source server to be cleanly shut down.

--source-server=connstr

Specifies a libpq connection string to connect to the source PostgreSQL server to synchronize the target with. The connection must be a normal (non-replication) connection with a role having sufficient permissions to execute the functions used by pg_rewind on the source server (see Notes section for details) or a superuser role. This option requires the source server to be running and accepting connections.

-R
--write-recovery-conf

Create standby.signal and append connection settings to postgresql.auto.conf in the output directory. --source-server is mandatory with this option.

-n
--dry-run

Do everything except actually modifying the target directory.

-N
--no-sync

By default, pg_rewind will wait for all files to be written safely to disk. This option causes pg_rewind to return without waiting, which is faster, but means that a subsequent operating system crash can leave the data directory corrupt. Generally, this option is useful for testing but should not be used on a production installation.

-P
--progress

Enables progress reporting. Turning this on will deliver an approximate progress report while copying data from the source cluster.
pg_rewind

-c
--restore-target-wal

Use restore_command defined in the target cluster configuration to retrieve WAL files from the WAL archive if these files are no longer available in the pg_wal directory.

--config-file=filename

Use the specified main server configuration file for the target cluster. This affects pg_rewind when it uses internally the postgres command for the rewind operation on this cluster (when retrieving restore_command with the option -c/--restore-target-wal and when forcing a completion of crash recovery).

--debug

Print verbose debugging output that is mostly useful for developers debugging pg_rewind.

--no-ensure-shutdown

pg_rewind requires that the target server is cleanly shut down before rewinding. By default, if the target server is not shut down cleanly, pg_rewind starts the target server in single-user mode to complete crash recovery first, and stops it. By passing this option, pg_rewind skips this and errors out immediately if the server is not cleanly shut down. Users are expected to handle the situation themselves in that case.

-V
--version

Display version information, then exit.

-?
--help

Show help, then exit.

Environment

When --source-server option is used, pg_rewind also uses the environment variables supported by libpq (see Section 34.15).

The environment variable PG_COLOR specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

Notes

When executing pg_rewind using an online cluster as source, a role having sufficient permissions to execute the functions used by pg_rewind on the source cluster can be used instead of a superuser. Here is how to create such a role, named rewind_user here:

CREATE USER rewind_user LOGIN;
GRANT EXECUTE ON function pg_catalog.pg_ls_dir(text, boolean, boolean) TO rewind_user;
GRANT EXECUTE ON function pg_catalog.pg_stat_file(text, boolean) TO rewind_user;
When executing `pg_rewind` using an online cluster as source which has been recently promoted, it is necessary to execute a **CHECKPOINT** after promotion such that its control file reflects up-to-date timeline information, which is used by `pg_rewind` to check if the target cluster can be rewound using the designated source cluster.

### How It Works

The basic idea is to copy all file system-level changes from the source cluster to the target cluster:

1. Scan the WAL log of the target cluster, starting from the last checkpoint before the point where the source cluster’s timeline history forked off from the target cluster. For each WAL record, record each data block that was touched. This yields a list of all the data blocks that were changed in the target cluster, after the source cluster forked off. If some of the WAL files are no longer available, try re-running `pg_rewind` with the `-c` option to search for the missing files in the WAL archive.

2. Copy all those changed blocks from the source cluster to the target cluster, either using direct file system access (`--source-pgdata`) or SQL (`--source-server`). Relation files are now in a state equivalent to the moment of the last completed checkpoint prior to the point at which the WAL timelines of the source and target diverged plus the current state on the source of any blocks changed on the target after that divergence.

3. Copy all other files, including new relation files, WAL segments, `pg_xact`, and configuration files from the source cluster to the target cluster. Similarly to base backups, the contents of the directories `pg_dynshmem/`, `pg_notify/`, `pg_replslot/`, `pg_serial/`, `pg_snapshots/`, `pg_stat_tmp/`, and `pg_subtrans/` are omitted from the data copied from the source cluster. The files `backup_label`, `tablespace_map`, `pg_internal.init`, `postmaster.opts`, and `postmaster.pid`, as well as any file or directory beginning with `pgsql_tmp`, are omitted.

4. Create a `backup_label` file to begin WAL replay at the checkpoint created at failover and configure the `pg_control` file with a minimum consistency LSN defined as the result of `pg_current_wal_insert_lsn()` when rewinding from a live source or the last checkpoint LSN when rewinding from a stopped source.

5. When starting the target, PostgreSQL replays all the required WAL, resulting in a data directory in a consistent state.
pg_test_fsync

pg_test_fsync — determine fastest wal_sync_method for PostgreSQL

Synopsis

pg_test_fsync [option...]

Description

pg_test_fsync is intended to give you a reasonable idea of what the fastest wal_sync_method is on your specific system, as well as supplying diagnostic information in the event of an identified I/O problem. However, differences shown by pg_test_fsync might not make any significant difference in real database throughput, especially since many database servers are not speed-limited by their write-ahead logs. pg_test_fsync reports average file sync operation time in microseconds for each wal_sync_method, which can also be used to inform efforts to optimize the value of commit_delay.

Options

pg_test_fsync accepts the following command-line options:

- f
  --filename

  Specifies the file name to write test data in. This file should be in the same file system that the pg_wal directory is or will be placed in. (pg_wal contains the WAL files.) The default is pg_test_fsync.out in the current directory.

- s
  --secs-per-test

  Specifies the number of seconds for each test. The more time per test, the greater the test's accuracy, but the longer it takes to run. The default is 5 seconds, which allows the program to complete in under 2 minutes.

- V
  --version

  Print the pg_test_fsync version and exit.

- ?
  --help

  Show help about pg_test_fsync command line arguments, and exit.

Environment

The environment variable PG_COLOR specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

pgtest
pg_test_timing

pg_test_timing — measure timing overhead

Synopsis

pg_test_timing [option...]

Description

pg_test_timing is a tool to measure the timing overhead on your system and confirm that the system time never moves backwards. Systems that are slow to collect timing data can give less accurate EXPLAIN ANALYZE results.

Options

pg_test_timing accepts the following command-line options:

- \(-d\) duration
  --duration=duration

  Specifies the test duration, in seconds. Longer durations give slightly better accuracy, and are more likely to discover problems with the system clock moving backwards. The default test duration is 3 seconds.

- \(-V\)
  --version

  Print the pg_test_timing version and exit.

- \(-?\)
  --help

  Show help about pg_test_timing command line arguments, and exit.

Usage

Interpreting Results

Good results will show most (>90%) individual timing calls take less than one microsecond. Average per loop overhead will be even lower, below 100 nanoseconds. This example from an Intel i7-860 system using a TSC clock source shows excellent performance:

Testing timing overhead for 3 seconds.
Per loop time including overhead: 35.96 ns
Histogram of timing durations:

<table>
<thead>
<tr>
<th>&lt; us</th>
<th>% of total</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>96.40465</td>
<td>80435604</td>
</tr>
<tr>
<td>2</td>
<td>3.59518</td>
<td>2999652</td>
</tr>
<tr>
<td>4</td>
<td>0.00015</td>
<td>126</td>
</tr>
</tbody>
</table>
Measuring Executor Timing Overhead

When the query executor is running a statement using `EXPLAIN ANALYZE`, individual operations are timed as well as showing a summary. The overhead of your system can be checked by counting rows with the `psql` program:

```sql
CREATE TABLE t AS SELECT * FROM generate_series(1,100000);
\timing
SELECT COUNT(*) FROM t;
EXPLAIN ANALYZE SELECT COUNT(*) FROM t;
```

The i7-860 system measured runs the count query in 9.8 ms while the `EXPLAIN ANALYZE` version takes 16.6 ms, each processing just over 100,000 rows. That 6.8 ms difference means the timing overhead per row is 68 ns, about twice what `pg_test_timing` estimated it would be. Even that relatively small amount of overhead is making the fully timed count statement take almost 70% longer. On more substantial queries, the timing overhead would be less problematic.

Changing Time Sources

On some newer Linux systems, it's possible to change the clock source used to collect timing data at any time. A second example shows the slowdown possible from switching to the slower `acpi_pm` time source, on the same system used for the fast results above:

```bash
# cat /sys/devices/system/clocksource/clocksource0/
available_clocksource
tsc hpet acpi_pm
# echo acpi_pm > /sys/devices/system/clocksource/clocksource0/
current_clocksource
# pg_test_timing
Per loop time including overhead: 722.92 ns
```

In this configuration, the sample `EXPLAIN ANALYZE` above takes 115.9 ms. That's 1061 ns of timing overhead, again a small multiple of what's measured directly by this utility. That much timing overhead means the actual query itself is only taking a tiny fraction of the accounted for time, most of it is being consumed in overhead instead. In this configuration, any `EXPLAIN ANALYZE` totals involving many timed operations would be inflated significantly by timing overhead.

FreeBSD also allows changing the time source on the fly, and it logs information about the timer selected during boot:
Other systems may only allow setting the time source on boot. On older Linux systems the "clock" kernel setting is the only way to make this sort of change. And even on some more recent ones, the only option you'll see for a clock source is "jiffies". Jiffies are the older Linux software clock implementation, which can have good resolution when it's backed by fast enough timing hardware, as in this example:

$ cat /sys/devices/system/clocksource/clocksource0/
available_clocksource
jiffies
$ dmesg | grep time.c
time.c: Using 3.579545 MHz WALL PM GTOD PIT/TSC timer.
time.c: Detected 2400.153 MHz processor.
$ pg_test_timing
Testing timing overhead for 3 seconds.
Per timing duration including loop overhead: 97.75 ns
Histogram of timing durations:
< us % of total count
 1 90.23734 27694571
 2 9.75277 2993204
 4 0.00981 3010
 8 0.00007 22
16 0.00000 1
32 0.00000 1

Clock Hardware and Timing Accuracy

Collecting accurate timing information is normally done on computers using hardware clocks with various levels of accuracy. With some hardware the operating systems can pass the system clock time almost directly to programs. A system clock can also be derived from a chip that simply provides timing interrupts, periodic ticks at some known time interval. In either case, operating system kernels provide a clock source that hides these details. But the accuracy of that clock source and how quickly it can return results varies based on the underlying hardware.

Inaccurate time keeping can result in system instability. Test any change to the clock source very carefully. Operating system defaults are sometimes made to favor reliability over best accuracy. And if you are using a virtual machine, look into the recommended time sources compatible with it. Virtual hardware faces additional difficulties when emulating timers, and there are often per operating system settings suggested by vendors.

The Time Stamp Counter (TSC) clock source is the most accurate one available on current generation CPUs. It's the preferred way to track the system time when it's supported by the operating system and the TSC clock is reliable. There are several ways that TSC can fail to provide an accurate timing source, making it unreliable. Older systems can have a TSC clock that varies based on the CPU temperature, making it unusable for timing. Trying to use TSC on some older multicore CPUs can give a reported time that's inconsistent among multiple cores. This can result in the time going backwards, a problem
this program checks for. And even the newest systems can fail to provide accurate TSC timing with very aggressive power saving configurations.

Newer operating systems may check for the known TSC problems and switch to a slower, more stable clock source when they are seen. If your system supports TSC time but doesn't default to that, it may be disabled for a good reason. And some operating systems may not detect all the possible problems correctly, or will allow using TSC even in situations where it's known to be inaccurate.

The High Precision Event Timer (HPET) is the preferred timer on systems where it's available and TSC is not accurate. The timer chip itself is programmable to allow up to 100 nanosecond resolution, but you may not see that much accuracy in your system clock.

Advanced Configuration and Power Interface (ACPI) provides a Power Management (PM) Timer, which Linux refers to as the acpi_pm. The clock derived from acpi_pm will at best provide 300 nanosecond resolution.

Timers used on older PC hardware include the 8254 Programmable Interval Timer (PIT), the real-time clock (RTC), the Advanced Programmable Interrupt Controller (APIC) timer, and the Cyclone timer. These timers aim for millisecond resolution.

EXPLAIN
pg_upgrade

pg_upgrade — upgrade a PostgreSQL server instance

Synopsis

```
pg_upgrade -b oldbindir [-B newbindir] -d oldconfigdir -D newconfigdir [option...]
```

Description

pg_upgrade (formerly called pg_migrator) allows data stored in PostgreSQL data files to be upgraded to a later PostgreSQL major version without the data dump/reload typically required for major version upgrades, e.g., from 9.5.8 to 9.6.4 or from 10.7 to 11.2. It is not required for minor version upgrades, e.g., from 9.6.2 to 9.6.3 or from 10.1 to 10.2.

Major PostgreSQL releases regularly add new features that often change the layout of the system tables, but the internal data storage format rarely changes. pg_upgrade uses this fact to perform rapid upgrades by creating new system tables and simply reusing the old user data files. If a future major release ever changes the data storage format in a way that makes the old data format unreadable, pg_upgrade will not be usable for such upgrades. (The community will attempt to avoid such situations.)

pg_upgrade does its best to make sure the old and new clusters are binary-compatible, e.g., by checking for compatible compile-time settings, including 32/64-bit binaries. It is important that any external modules are also binary compatible, though this cannot be checked by pg_upgrade.

pg_upgrade supports upgrades from 9.2.X and later to the current major release of PostgreSQL, including snapshot and beta releases.

Options

pg_upgrade accepts the following command-line arguments:

- `-b bindir`
  `-old-bindir=bindir`

  the old PostgreSQL executable directory; environment variable PGBINOLD

- `-B bindir`
  `-new-bindir=bindir`

  the new PostgreSQL executable directory; default is the directory where pg_upgrade resides; environment variable PGINNEW

- `-c`
  `-check`

  check clusters only, don't change any data

- `-d configdir`
  `-old-datadir=configdir`

  the old database cluster configuration directory; environment variable PGDATAOLD
pg_upgrade

-D configdir
--new-datadir=configdir
the new database cluster configuration directory; environment variable PGDATANEW

-j njobs
--jobs=njobs
number of simultaneous processes or threads to use

-k
--link
use hard links instead of copying files to the new cluster

-N
--no-sync
By default, pg_upgrade will wait for all files of the upgraded cluster to be written safely to disk. This option causes pg_upgrade to return without waiting, which is faster, but means that a subsequent operating system crash can leave the data directory corrupt. Generally, this option is useful for testing but should not be used on a production installation.

-o options
--old-options options
options to be passed directly to the old postgres command; multiple option invocations are appended

-O options
--new-options options
options to be passed directly to the new postgres command; multiple option invocations are appended

-p port
--old-port=port
the old cluster port number; environment variable PGPORTOLD

-P port
--new-port=port
the new cluster port number; environment variable PGPORTNEW

-r
--retain
retain SQL and log files even after successful completion

-s dir
--socketdir=dir
directory to use for postmaster sockets during upgrade; default is current working directory; environment variable PGSOCKETDIR

-U username
--username=username
cluster’s install user name; environment variable PGUSER
Usage

These are the steps to perform an upgrade with pg_upgrade:

1. **Optionally move the old cluster**

   If you are using a version-specific installation directory, e.g., /opt/PostgreSQL/15, you do not need to move the old cluster. The graphical installers all use version-specific installation directories.

   If your installation directory is not version-specific, e.g., /usr/local/pgsql, it is necessary to move the current PostgreSQL install directory so it does not interfere with the new PostgreSQL installation. Once the current PostgreSQL server is shut down, it is safe to rename the PostgreSQL installation directory; assuming the old directory is /usr/local/pgsql, you can do:

   ```
   mv /usr/local/pgsql /usr/local/pgsql.old
   ```

   to rename the directory.

2. **For source installs, build the new version**

   Build the new PostgreSQL source with `configure` flags that are compatible with the old cluster. `pg_upgrade` will check `pg_controldata` to make sure all settings are compatible before starting the upgrade.

3. **Install the new PostgreSQL binaries**

   Install the new server’s binaries and support files. `pg_upgrade` is included in a default installation.

   For source installs, if you wish to install the new server in a custom location, use the `prefix` variable:

   ```
   make prefix=/usr/local/pgsql.new install
   ```
4. **Initialize the new PostgreSQL cluster**
   Initialize the new cluster using `initdb`. Again, use compatible `initdb` flags that match the old cluster. Many prebuilt installers do this step automatically. There is no need to start the new cluster.

5. **Install extension shared object files**
   Many extensions and custom modules, whether from `contrib` or another source, use shared object files (or DLLs), e.g., `pgcrypto.so`. If the old cluster used these, shared object files matching the new server binary must be installed in the new cluster, usually via operating system commands. Do not load the schema definitions, e.g., `CREATE EXTENSION pgcrypto`, because these will be duplicated from the old cluster. If extension updates are available, `pg_upgrade` will report this and create a script that can be run later to update them.

6. **Copy custom full-text search files**
   Copy any custom full text search files (dictionary, synonym, thesaurus, stop words) from the old to the new cluster.

7. **Adjust authentication**
   `pg_upgrade` will connect to the old and new servers several times, so you might want to set authentication to `peer` in `pg_hba.conf` or use a `~/.pgpass` file (see Section 34.16).

8. **Stop both servers**
   Make sure both database servers are stopped using, on Unix, e.g.:

   ```
   pg_ctl -D /opt/PostgreSQL/9.6 stop
   pg_ctl -D /opt/PostgreSQL/15 stop
   ```

   or on Windows, using the proper service names:

   ```
   NET STOP postgresql-9.6
   NET STOP postgresql-15
   ```

   Streaming replication and log-shipping standby servers can remain running until a later step.

9. **Prepare for standby server upgrades**
   If you are upgrading standby servers using methods outlined in section Step 11, verify that the old standby servers are caught up by running `pg_controldata` against the old primary and standby clusters. Verify that the “Latest checkpoint location” values match in all clusters. (There will be a mismatch if old standby servers were shut down before the old primary or if the old standby servers are still running.) Also, make sure `wal_level` is not set to `minimal` in the `postgresql.conf` file on the new primary cluster.

10. **Run pg_upgrade**
    Always run the `pg_upgrade` binary of the new server, not the old one. `pg_upgrade` requires the specification of the old and new cluster's data and executable (`bin`) directories. You can also specify user and port values, and whether you want the data files linked or cloned instead of the default copy behavior.

    If you use link mode, the upgrade will be much faster (no file copying) and use less disk space, but you will not be able to access your old cluster once you start the new cluster after the upgrade. Link mode
also requires that the old and new cluster data directories be in the same file system. (Tablespaces and \texttt{pg\_wal} can be on different file systems.) Clone mode provides the same speed and disk space advantages but does not cause the old cluster to be unusable once the new cluster is started. Clone mode also requires that the old and new data directories be in the same file system. This mode is only available on certain operating systems and file systems.

The \texttt{--jobs} option allows multiple CPU cores to be used for copying/linking of files and to dump and reload database schemas in parallel; a good place to start is the maximum of the number of CPU cores and tablespaces. This option can dramatically reduce the time to upgrade a multi-database server running on a multiprocessor machine.

For Windows users, you must be logged into an administrative account, and then start a shell as the \texttt{postgres} user and set the proper path:

\begin{verbatim}
RUNAS /USER:postgres "CMD.EXE"
SET PATH=%PATH%;C:\Program Files\PostgreSQL\15\bin;
\end{verbatim}

and then run \texttt{pg\_upgrade} with quoted directories, e.g.:

\begin{verbatim}
pg\_upgrade.exe
   --old-datadir "C:/Program Files/PostgreSQL/9.6/data"
   --new-datadir "C:/Program Files/PostgreSQL/15/data"
   --old-bindir "C:/Program Files/PostgreSQL/9.6/bin"
   --new-bindir "C:/Program Files/PostgreSQL/15/bin"
\end{verbatim}

Once started, \texttt{pg\_upgrade} will verify the two clusters are compatible and then do the upgrade. You can use \texttt{pg\_upgrade} \texttt{--check} to perform only the checks, even if the old server is still running. \texttt{pg\_upgrade} \texttt{--check} will also outline any manual adjustments you will need to make after the upgrade. If you are going to be using link or clone mode, you should use the option \texttt{--link} or \texttt{--clone} with \texttt{--check} to enable mode-specific checks. \texttt{pg\_upgrade} requires write permission in the current directory.

Obviously, no one should be accessing the clusters during the upgrade. \texttt{pg\_upgrade} defaults to running servers on port 50432 to avoid unintended client connections. You can use the same port number for both clusters when doing an upgrade because the old and new clusters will not be running at the same time. However, when checking an old running server, the old and new port numbers must be different.

If an error occurs while restoring the database schema, \texttt{pg\_upgrade} will exit and you will have to revert to the old cluster as outlined in Step 17 below. To try \texttt{pg\_upgrade} again, you will need to modify the old cluster so the \texttt{pg\_upgrade} schema restore succeeds. If the problem is a \texttt{contrib} module, you might need to uninstall the \texttt{contrib} module from the old cluster and install it in the new cluster after the upgrade, assuming the module is not being used to store user data.

11. Upgrade streaming replication and log-shipping standby servers

If you used link mode and have Streaming Replication (see Section 27.2.5) or Log-Shipping (see Section 27.2) standby servers, you can follow these steps to quickly upgrade them. You will not be running \texttt{pg\_upgrade} on the standby servers, but rather \texttt{rsync} on the primary. Do not start any servers yet.

If you did not use link mode, do not have or do not want to use \texttt{rsync}, or want an easier solution, skip the instructions in this section and simply recreate the standby servers once \texttt{pg\_upgrade} completes and the new primary is running.
1. **Install the new PostgreSQL binaries on standby servers**
   Make sure the new binaries and support files are installed on all standby servers.

2. **Make sure the new standby data directories do not exist**
   Make sure the new standby data directories do not exist or are empty. If initdb was run, delete the standby servers’ new data directories.

3. **Install extension shared object files**
   Install the same extension shared object files on the new standbys that you installed in the new primary cluster.

4. **Stop standby servers**
   If the standby servers are still running, stop them now using the above instructions.

5. **Save configuration files**
   Save any configuration files from the old standbys’ configuration directories you need to keep, e.g., `postgresql.conf` (and any files included by it), `postgresql.auto.conf`, `pg_hba.conf`, because these will be overwritten or removed in the next step.

6. **Run rsync**
   When using link mode, standby servers can be quickly upgraded using rsync. To accomplish this, from a directory on the primary server that is above the old and new database cluster directories, run this on the primary for each standby server:

   ```
   rsync --archive --delete --hard-links --size-only --no-inc-recursive old_cluster new_cluster remote_dir
   ````
   
   where `old_cluster` and `new_cluster` are relative to the current directory on the primary, and `remote_dir` is above the old and new cluster directories on the standby. The directory structure under the specified directories on the primary and standbys must match. Consult the rsync manual page for details on specifying the remote directory, e.g.,

   ```
   rsync --archive --delete --hard-links --size-only --no-inc-recursive /opt/PostgreSQL/9.5 \\
   /opt/PostgreSQL/9.6 standby.example.com:/opt/PostgreSQL
   ```

   You can verify what the command will do using rsync's `--dry-run` option. While rsync must be run on the primary for at least one standby, it is possible to run rsync on an upgraded standby to upgrade other standbys, as long as the upgraded standby has not been started.

   What this does is to record the links created by pg_upgrade’s link mode that connect files in the old and new clusters on the primary server. It then finds matching files in the standby’s old cluster and creates links for them in the standby’s new cluster. Files that were not linked on the primary are copied from the primary to the standby. (They are usually small.) This provides
rapid standby upgrades. Unfortunately, rsync needlessly copies files associated with temporary and unlogged tables because these files don't normally exist on standby servers.

If you have tablespaces, you will need to run a similar rsync command for each tablespace directory, e.g.:

```bash
rsync --archive --delete --hard-links --size-only --no-inc-recursive /vol1/pg_tblsp/PG_9.5_201510051 \ 
   /vol1/pg_tblsp/PG_9.6_201608131 standby.example.com:/vol1/pg_tblsp
```

If you have relocated pg_wal outside the data directories, rsync must be run on those directories too.

7. Configure streaming replication and log-shipping standby servers

Configure the servers for log shipping. (You do not need to run `pg_backup_start()` and `pg_backup_stop()` or take a file system backup as the standbys are still synchronized with the primary.)

12. Restore `pg_hba.conf`

If you modified `pg_hba.conf`, restore its original settings. It might also be necessary to adjust other configuration files in the new cluster to match the old cluster, e.g., `postgresql.conf` (and any files included by it), `postgresql.auto.conf`.

13. Start the new server

The new server can now be safely started, and then any rsync'ed standby servers.

14. Post-upgrade processing

If any post-upgrade processing is required, `pg_upgrade` will issue warnings as it completes. It will also generate script files that must be run by the administrator. The script files will connect to each database that needs post-upgrade processing. Each script should be run using:

```bash
psql --username=postgres --file=script.sql postgres
```

The scripts can be run in any order and can be deleted once they have been run.

---

**Caution**

In general it is unsafe to access tables referenced in rebuild scripts until the rebuild scripts have run to completion; doing so could yield incorrect results or poor performance. Tables not referenced in rebuild scripts can be accessed immediately.

---

15. Statistics

Because optimizer statistics are not transferred by `pg_upgrade`, you will be instructed to run a command to regenerate that information at the end of the upgrade. You might need to set connection parameters to match your new cluster.
16. **Delete old cluster**

Once you are satisfied with the upgrade, you can delete the old cluster's data directories by running the script mentioned when `pg_upgrade` completes. (Automatic deletion is not possible if you have user-defined table spaces inside the old data directory.) You can also delete the old installation directories (e.g., `bin`, `share`).

17. **Reverting to old cluster**

If, after running `pg_upgrade`, you wish to revert to the old cluster, there are several options:

- If the `--check` option was used, the old cluster was unmodified; it can be restarted.
- If the `--link` option was *not* used, the old cluster was unmodified; it can be restarted.
- If the `--link` option was used, the data files might be shared between the old and new cluster:
  - If `pg_upgrade` aborted before linking started, the old cluster was unmodified; it can be restarted.
  - If you did *not* start the new cluster, the old cluster was unmodified except that, when linking started, a `.old` suffix was appended to `$PGDATA/global/pg_control`. To reuse the old cluster, remove the `.old` suffix from `$PGDATA/global/pg_control`; you can then restart the old cluster.
  - If you did start the new cluster, it has written to shared files and it is unsafe to use the old cluster. The old cluster will need to be restored from backup in this case.

**Notes**

`pg_upgrade` creates various working files, such as schema dumps, stored within `pg_upgrade_output.d` in the directory of the new cluster. Each run creates a new subdirectory named with a timestamp formatted as per ISO 8601 (%Y%m%dT%H%M%S), where all the generated files are stored.

`pg_upgrade` launches short-lived postmasters in the old and new data directories. Temporary Unix socket files for communication with these postmasters are, by default, made in the current working directory. In some situations the path name for the current directory might be too long to be a valid socket name. In that case you can use the `-s` option to put the socket files in some directory with a shorter path name. For security, be sure that that directory is not readable or writable by any other users. (This is not supported on Windows.)

All failure, rebuild, and reindex cases will be reported by `pg_upgrade` if they affect your installation; post-upgrade scripts to rebuild tables and indexes will be generated automatically. If you are trying to automate the upgrade of many clusters, you should find that clusters with identical database schemas require the same post-upgrade steps for all cluster upgrades; this is because the post-upgrade steps are based on the database schemas, and not user data.

For deployment testing, create a schema-only copy of the old cluster, insert dummy data, and upgrade that.

`pg_upgrade` does not support upgrading of databases containing table columns using these `reg*` OID-referencing system data types:

- `regcollation`
- `regconfig`
- `regdictionary`
- `regnamespace`
If you want to use link mode and you do not want your old cluster to be modified when the new cluster is started, consider using the clone mode. If that is not available, make a copy of the old cluster and upgrade that in link mode. To make a valid copy of the old cluster, use `rsync` to create a dirty copy of the old cluster while the server is running, then shut down the old server and run `rsync --checksum` again to update the copy with any changes to make it consistent. (`--checksum` is necessary because `rsync` only has file modification-time granularity of one second.) You might want to exclude some files, e.g., `postmaster.pid`, as documented in Section 26.3.3. If your file system supports file system snapshots or copy-on-write file copies, you can use that to make a backup of the old cluster and tablespaces, though the snapshot and copies must be created simultaneously or while the database server is down.

initdb, pg_ctl, pg_dump, postgres
pg_waldump

pg_waldump — display a human-readable rendering of the write-ahead log of a PostgreSQL database cluster

Synopsis

pg_waldump [option...] [startseg [endseg]]

Description

pg_waldump displays the write-ahead log (WAL) and is mainly useful for debugging or educational purposes.

This utility can only be run by the user who installed the server, because it requires read-only access to the data directory.

Options

The following command-line options control the location and format of the output:

startseg

Start reading at the specified log segment file. This implicitly determines the path in which files will be searched for, and the timeline to use.

endseg

Stop after reading the specified log segment file.

-b
--b kp-deta ils

Output detailed information about backup blocks.

-B block
--block=block

Only display records that modify the given block. The relation must also be provided with --rela tion or -R.

-e end
--end=end

Stop reading at the specified WAL location, instead of reading to the end of the log stream.

-f
--follow

After reaching the end of valid WAL, keep polling once per second for new WAL to appear.

-F fork
--fork=fork

If provided, only display records that modify blocks in the given fork. The valid values are main for the main fork, fsm for the free space map, vm for the visibility map, and init for the init fork.
-n limit
--limit=limit
Display the specified number of records, then stop.

-p path
--path=path
Specifies a directory to search for log segment files or a directory with a pg_wal subdirectory that
contains such files. The default is to search in the current directory, the pg_wal subdirectory of the
current directory, and the pg_wal subdirectory of PGDATA.

-q
--quiet
Do not print any output, except for errors. This option can be useful when you want to know whether
a range of WAL records can be successfully parsed but don't care about the record contents.

-r rmgr
--rmgr=rmgr
Only display records generated by the specified resource manager. You can specify the option multiple
times to select multiple resource managers. If list is passed as name, print a list of valid resource
manager names, and exit.

Extensions may define custom resource managers, but pg_waldump does not load the extension mod-
ule and therefore does not recognize custom resource managers by name. Instead, you can specify
the custom resource managers as custom### where "###" is the three-digit resource manager ID. Names of this form will always be considered valid.

-R tblspc/db/rel
--relation=tblspc/db/rel
Only display records that modify blocks in the given relation. The relation is specified with tablespace
OID, database OID, and relfilenode separated by slashes, for example 1234/12345/12345. This
is the same format used for relations in the program's output.

-s start
--start=start
WAL location at which to start reading. The default is to start reading the first valid log record found
in the earliest file found.

-t timeline
--timeline=timeline
Timeline from which to read log records. The default is to use the value in startseg, if that is
specified; otherwise, the default is 1.

-V
--version
Print the pg_waldump version and exit.

-w
--fullpage
Only display records that include full page images.
pg_waldump

-x xid
--xid=xid

Only display records marked with the given transaction ID.

-z
--stats[]=record

Display summary statistics (number and size of records and full-page images) instead of individual records. Optionally generate statistics per-record instead of per-rmgr.

If pg_waldump is terminated by signal SIGINT (Control+C, the summary of the statistics computed is displayed up to the termination point. This operation is not supported on Windows.

-?
--help

Show help about pg_waldump command line arguments, and exit.

Environment

PGDATA

Data directory; see also the -p option.

PG_COLOR

Specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

Notes

Can give wrong results when the server is running.

Only the specified timeline is displayed (or the default, if none is specified). Records in other timelines are ignored.

pg_waldump cannot read WAL files with suffix .partial. If those files need to be read, .partial suffix needs to be removed from the file name.

Section 30.6
**postgres**

postgres — PostgreSQL database server

**Synopsis**

`postgres [option...]`

**Description**

`postgres` is the PostgreSQL database server. In order for a client application to access a database it connects (over a network or locally) to a running `postgres` instance. The `postgres` instance then starts a separate server process to handle the connection.

One `postgres` instance always manages the data of exactly one database cluster. A database cluster is a collection of databases that is stored at a common file system location (the “data area”). More than one `postgres` instance can run on a system at one time, so long as they use different data areas and different communication ports (see below). When `postgres` starts it needs to know the location of the data area. The location must be specified by the `-D` option or the `PGDATA` environment variable; there is no default. Typically, `-D` or `PGDATA` points directly to the data area directory created by `initdb`. Other possible file layouts are discussed in Section 20.2.

By default `postgres` starts in the foreground and prints log messages to the standard error stream. In practical applications `postgres` should be started as a background process, perhaps at boot time.

The `postgres` command can also be called in single-user mode. The primary use for this mode is during bootstrapping by `initdb`. Sometimes it is used for debugging or disaster recovery; note that running a single-user server is not truly suitable for debugging the server, since no realistic interprocess communication and locking will happen. When invoked in single-user mode from the shell, the user can enter queries and the results will be printed to the screen, but in a form that is more useful for developers than end users. In the single-user mode, the session user will be set to the user with ID 1, and implicit superuser powers are granted to this user. This user does not actually have to exist, so the single-user mode can be used to manually recover from certain kinds of accidental damage to the system catalogs.

**Options**

`postgres` accepts the following command-line arguments. For a detailed discussion of the options consult Chapter 20. You can save typing most of these options by setting up a configuration file. Some (safe) options can also be set from the connecting client in an application-dependent way to apply only for that session. For example, if the environment variable `PGOPTIONS` is set, then libpq-based clients will pass that string to the server, which will interpret it as `postgres` command-line options.

**General Purpose**

`-B nbuffers`

Sets the number of shared buffers for use by the server processes. The default value of this parameter is chosen automatically by `initdb`. Specifying this option is equivalent to setting the `shared_buffers` configuration parameter.
### -c name=value

Sets a named run-time parameter. The configuration parameters supported by PostgreSQL are described in Chapter 20. Most of the other command line options are in fact short forms of such a parameter assignment. `-c` can appear multiple times to set multiple parameters.

### -C name

Prints the value of the named run-time parameter, and exits. (See the `-c` option above for details.) This returns values from `postgresql.conf`, modified by any parameters supplied in this invocation. It does not reflect parameters supplied when the cluster was started.

This can be used on a running server for most parameters. However, the server must be shut down for some runtime-computed parameters (e.g., `shared_memory_size`, `shared_memory_size_in_huge_pages`, and `wal_segment_size`).

This option is meant for other programs that interact with a server instance, such as `pg_ctl`, to query configuration parameter values. User-facing applications should instead use `SHOW` or the `pg_settings` view.

### -d debug-level

Sets the debug level. The higher this value is set, the more debugging output is written to the server log. Values are from 1 to 5. It is also possible to pass `-d 0` for a specific session, which will prevent the server log level of the parent `postgres` process from being propagated to this session.

### -D datadir

Specifies the file system location of the database configuration files. See Section 20.2 for details.

### -e

Sets the default date style to “European”, that is `DMY` ordering of input date fields. This also causes the day to be printed before the month in certain date output formats. See Section 8.5 for more information.

### -F

Disables `fsync` calls for improved performance, at the risk of data corruption in the event of a system crash. Specifying this option is equivalent to disabling the `fsync` configuration parameter. Read the detailed documentation before using this!

### -h hostname

Specifies the IP host name or address on which `postgres` is to listen for TCP/IP connections from client applications. The value can also be a comma-separated list of addresses, or `*` to specify listening on all available interfaces. An empty value specifies not listening on any IP addresses, in which case only Unix-domain sockets can be used to connect to the server. Defaults to listening only on localhost. Specifying this option is equivalent to setting the `listen_addresses` configuration parameter.

### -i

Allows remote clients to connect via TCP/IP (Internet domain) connections. Without this option, only local connections are accepted. This option is equivalent to setting `listen_addresses` to `*` in `postgresql.conf` or via `-h`.

This option is deprecated since it does not allow access to the full functionality of `listen_addresses`. It's usually better to set `listen_addresses` directly.
-k directory

Specifies the directory of the Unix-domain socket on which `postgres` is to listen for connections from client applications. The value can also be a comma-separated list of directories. An empty value specifies not listening on any Unix-domain sockets, in which case only TCP/IP sockets can be used to connect to the server. The default value is normally `/tmp`, but that can be changed at build time. Specifying this option is equivalent to setting the `unix_socket_directories` configuration parameter.

-l

Enables secure connections using SSL. PostgreSQL must have been compiled with support for SSL for this option to be available. For more information on using SSL, refer to Section 19.9.

-N max-connections

Sets the maximum number of client connections that this server will accept. The default value of this parameter is chosen automatically by `initdb`. Specifying this option is equivalent to setting the `max_connections` configuration parameter.

-p port

Specifies the TCP/IP port or local Unix domain socket file extension on which `postgres` is to listen for connections from client applications. Defaults to the value of the `PGPORT` environment variable, or if `PGPORT` is not set, then defaults to the value established during compilation (normally 5432). If you specify a port other than the default port, then all client applications must specify the same port using either command-line options or `PGPORT`.

-s

Print time information and other statistics at the end of each command. This is useful for benchmarking or for use in tuning the number of buffers.

-S work-mem

Specifies the base amount of memory to be used by sorts and hash tables before resorting to temporary disk files. See the description of the `work_mem` configuration parameter in Section 20.4.1.

-V

--version

Print the `postgres` version and exit.

--name=value

Sets a named run-time parameter; a shorter form of -c.

--describe-config

This option dumps out the server's internal configuration variables, descriptions, and defaults in tabledelimited `COPY` format. It is designed primarily for use by administration tools.

-?

--help

Show help about `postgres` command line arguments, and exit.
Semi-Internal Options

The options described here are used mainly for debugging purposes, and in some cases to assist with recovery of severely damaged databases. There should be no reason to use them in a production database setup. They are listed here only for use by PostgreSQL system developers. Furthermore, these options might change or be removed in a future release without notice.

\[-f ( s \mid i \mid o \mid b \mid t \mid n \mid m \mid h )\]

Forbids the use of particular scan and join methods: \(s\) and \(i\) disable sequential and index scans respectively, \(o\), \(b\) and \(t\) disable index-only scans, bitmap index scans, and TID scans respectively, while \(n\), \(m\), and \(h\) disable nested-loop, merge and hash joins respectively.

Neither sequential scans nor nested-loop joins can be disabled completely; the \(-fs\) and \(-fn\) options simply discourage the optimizer from using those plan types if it has any other alternative.

\(-n\)

This option is for debugging problems that cause a server process to die abnormally. The ordinary strategy in this situation is to notify all other server processes that they must terminate and then reinitialize the shared memory and semaphores. This is because an errant server process could have corrupted some shared state before terminating. This option specifies that \texttt{postgres} will not reinitialize shared data structures. A knowledgeable system programmer can then use a debugger to examine shared memory and semaphore state.

\(-O\)

Allows the structure of system tables to be modified. This is used by \texttt{initdb}.

\(-P\)

Ignore system indexes when reading system tables, but still update the indexes when modifying the tables. This is useful when recovering from damaged system indexes.

\(-t p a[rser] \mid p l[anner] \mid e[xecutor]\)

Print timing statistics for each query relating to each of the major system modules. This option cannot be used together with the \(-s\) option.

\(-T\)

This option is for debugging problems that cause a server process to die abnormally. The ordinary strategy in this situation is to notify all other server processes that they must terminate and then reinitialize the shared memory and semaphores. This is because an errant server process could have corrupted some shared state before terminating. This option specifies that \texttt{postgres} will stop all other server processes by sending the signal \texttt{SIGSTOP}, but will not cause them to terminate. This permits system programmers to collect core dumps from all server processes by hand.

\(-v protocol\)

Specifies the version number of the frontend/backend protocol to be used for a particular session. This option is for internal use only.

\(-W seconds\)

A delay of this many seconds occurs when a new server process is started, after it conducts the authentication procedure. This is intended to give an opportunity to attach to the server process with a debugger.
Options for Single-User Mode

The following options only apply to the single-user mode (see Single-User Mode below).

--single

Selects the single-user mode. This must be the first argument on the command line.

database

Specifies the name of the database to be accessed. This must be the last argument on the command line. If it is omitted it defaults to the user name.

-E

Echo all commands to standard output before executing them.

-j

Use semicolon followed by two newlines, rather than just newline, as the command entry terminator.

-r filename

Send all server log output to filename. This option is only honored when supplied as a command-line option.

Environment

PGCLIENTENCODING

Default character encoding used by clients. (The clients can override this individually.) This value can also be set in the configuration file.

PGDATA

Default data directory location

PGDATESTYLE

Default value of the DateStyle run-time parameter. (The use of this environment variable is deprecated.)

PGPORT

Default port number (preferably set in the configuration file)

Diagnostics

A failure message mentioning semget or shmget probably indicates you need to configure your kernel to provide adequate shared memory and semaphores. For more discussion see Section 19.4. You might be able to postpone reconfiguring your kernel by decreasing shared_buffers to reduce the shared memory consumption of PostgreSQL, and/or by reducing max_connections to reduce the semaphore consumption.

A failure message suggesting that another server is already running should be checked carefully, for example by using the command
$ ps ax | grep postgres

or

$ ps -ef | grep postgres

depending on your system. If you are certain that no conflicting server is running, you can remove the lock file mentioned in the message and try again.

A failure message indicating inability to bind to a port might indicate that that port is already in use by some non-PostgreSQL process. You might also get this error if you terminate postgres and immediately restart it using the same port; in this case, you must simply wait a few seconds until the operating system closes the port before trying again. Finally, you might get this error if you specify a port number that your operating system considers to be reserved. For example, many versions of Unix consider port numbers under 1024 to be “trusted” and only permit the Unix superuser to access them.

Notes

The utility command pg_ctl can be used to start and shut down the postgres server safely and comfortably.

If at all possible, do not use SIGKILL to kill the main postgres server. Doing so will prevent postgres from freeing the system resources (e.g., shared memory and semaphores) that it holds before terminating. This might cause problems for starting a fresh postgres run.

To terminate the postgres server normally, the signals SIGTERM, SIGINT, or SIGQUIT can be used. The first will wait for all clients to terminate before quitting, the second will forcefully disconnect all clients, and the third will quit immediately without proper shutdown, resulting in a recovery run during restart.

The SIGHUP signal will reload the server configuration files. It is also possible to send SIGHUP to an individual server process, but that is usually not sensible.

To cancel a running query, send the SIGINT signal to the process running that command. To terminate a backend process cleanly, send SIGTERM to that process. See also pg_cancel_backend and pg_terminate_backend in Section 9.27.2 for the SQL-callable equivalents of these two actions.

The postgres server uses SIGQUIT to tell subordinate server processes to terminate without normal cleanup. This signal should not be used by users. It is also unwise to send SIGKILL to a server process — the main postgres process will interpret this as a crash and will force all the sibling processes to quit as part of its standard crash-recovery procedure.

Bugs

The -- options will not work on FreeBSD or OpenBSD. Use -c instead. This is a bug in the affected operating systems; a future release of PostgreSQL will provide a workaround if this is not fixed.

Single-User Mode

To start a single-user mode server, use a command like

```
postgres --single -D /usr/local/pgsql/data other-options my_database
```
Provide the correct path to the database directory with -D, or make sure that the environment variable PGDATA is set. Also specify the name of the particular database you want to work in.

Normally, the single-user mode server treats newline as the command entry terminator; there is no intelligence about semicolons, as there is in psql. To continue a command across multiple lines, you must type backslash just before each newline except the last one. The backslash and adjacent newline are both dropped from the input command. Note that this will happen even when within a string literal or comment.

But if you use the -j command line switch, a single newline does not terminate command entry; instead, the sequence semicolon-newline-newline does. That is, type a semicolon immediately followed by a completely empty line. Backslash-newline is not treated specially in this mode. Again, there is no intelligence about such a sequence appearing within a string literal or comment.

In either input mode, if you type a semicolon that is not just before or part of a command entry terminator, it is considered a command separator. When you do type a command entry terminator, the multiple statements you've entered will be executed as a single transaction.

To quit the session, type EOF (Control+D, usually). If you've entered any text since the last command entry terminator, then EOF will be taken as a command entry terminator, and another EOF will be needed to exit.

Note that the single-user mode server does not provide sophisticated line-editing features (no command history, for example). Single-user mode also does not do any background processing, such as automatic checkpoints or replication.

**Examples**

To start postgres in the background using default values, type:

```sh
$ nohup postgres >logfile 2>&1 </dev/null &
```

To start postgres with a specific port, e.g., 1234:

```sh
$ postgres -p 1234
```

To connect to this server using psql, specify this port with the -p option:

```sh
$ psql -p 1234
```

or set the environment variable PGPORT:

```sh
$ export PGPORT=1234
$ psql
```

Named run-time parameters can be set in either of these styles:

```sh
$ postgres -c work_mem=1234
$ postgres --work_mem=1234
```

Either form overrides whatever setting might exist for work_mem in postgresql.conf. Notice that underscores in parameter names can be written as either underscore or dash on the command line. Except
for short-term experiments, it's probably better practice to edit the setting in `postgresql.conf` than to rely on a command-line switch to set a parameter.

Chapter 52. Overview of PostgreSQL Internals

Author

This chapter originated as part of [sim98] Stefan Simkovics' Master's Thesis prepared at Vienna University of Technology under the direction of O.Univ.Prof.Dr. Georg Gottlob and Univ.Ass. Mag. Katrin Seyr.

This chapter gives an overview of the internal structure of the backend of PostgreSQL. After having read the following sections you should have an idea of how a query is processed. This chapter is intended to help the reader understand the general sequence of operations that occur within the backend from the point at which a query is received, to the point at which the results are returned to the client.

52.1. The Path of a Query

Here we give a short overview of the stages a query has to pass to obtain a result.

1. A connection from an application program to the PostgreSQL server has to be established. The application program transmits a query to the server and waits to receive the results sent back by the server.

2. The parser stage checks the query transmitted by the application program for correct syntax and creates a query tree.

3. The rewrite system takes the query tree created by the parser stage and looks for any rules (stored in the system catalogs) to apply to the query tree. It performs the transformations given in the rule bodies.

One application of the rewrite system is in the realization of views. Whenever a query against a view (i.e., a virtual table) is made, the rewrite system rewrites the user’s query to a query that accesses the base tables given in the view definition instead.

4. The planner/optimizer takes the (rewritten) query tree and creates a query plan that will be the input to the executor.

It does so by first creating all possible paths leading to the same result. For example if there is an index on a relation to be scanned, there are two paths for the scan. One possibility is a simple sequential scan and the other possibility is to use the index. Next the cost for the execution of each path is estimated and the cheapest path is chosen. The cheapest path is expanded into a complete plan that the executor can use.

5. The executor recursively steps through the plan tree and retrieves rows in the way represented by the plan. The executor makes use of the storage system while scanning relations, performs sorts and joins, evaluates qualifications and finally hands back the rows derived.

In the following sections we will cover each of the above listed items in more detail to give a better understanding of PostgreSQL’s internal control and data structures.

52.2. How Connections Are Established

PostgreSQL implements a “process per user” client/server model. In this model, every client process connects to exactly one backend process. As we do not know ahead of time how many connections will be
made, we have to use a “supervisor process” that spawns a new backend process every time a connection is requested. This supervisor process is called postmaster and listens at a specified TCP/IP port for incoming connections. Whenever it detects a request for a connection, it spawns a new backend process. Those backend processes communicate with each other and with other processes of the instance using semaphores and shared memory to ensure data integrity throughout concurrent data access.

The client process can be any program that understands the PostgreSQL protocol described in Chapter 54. Many clients are based on the C-language library libpq, but several independent implementations of the protocol exist, such as the Java JDBC driver.

Once a connection is established, the client process can send a query to the backend process it’s connected to. The query is transmitted using plain text, i.e., there is no parsing done in the client. The backend process parses the query, creates an execution plan, executes the plan, and returns the retrieved rows to the client by transmitting them over the established connection.

52.3. The Parser Stage

The parser stage consists of two parts:

- The parser defined in gram.y and scan.l is built using the Unix tools bison and flex.
- The transformation process does modifications and augmentations to the data structures returned by the parser.

52.3.1. Parser

The parser has to check the query string (which arrives as plain text) for valid syntax. If the syntax is correct a parse tree is built up and handed back; otherwise an error is returned. The parser and lexer are implemented using the well-known Unix tools bison and flex.

The lexer is defined in the file scan.l and is responsible for recognizing identifiers, the SQL key words etc. For every key word or identifier that is found, a token is generated and handed to the parser.

The parser is defined in the file gram.y and consists of a set of grammar rules and actions that are executed whenever a rule is fired. The code of the actions (which is actually C code) is used to build up the parse tree.

The file scan.l is transformed to the C source file scan.c using the program flex and gram.y is transformed to gram.c using bison. After these transformations have taken place a normal C compiler can be used to create the parser. Never make any changes to the generated C files as they will be overwritten the next time flex or bison is called.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
</table>

The mentioned transformations and compilations are normally done automatically using the make-files shipped with the PostgreSQL source distribution.

A detailed description of bison or the grammar rules given in gram.y would be beyond the scope of this manual. There are many books and documents dealing with flex and bison. You should be familiar with bison before you start to study the grammar given in gram.y otherwise you won't understand what happens there.
52.3.2. Transformation Process

The parser stage creates a parse tree using only fixed rules about the syntactic structure of SQL. It does not make any lookups in the system catalogs, so there is no possibility to understand the detailed semantics of the requested operations. After the parser completes, the transformation process takes the tree handed back by the parser as input and does the semantic interpretation needed to understand which tables, functions, and operators are referenced by the query. The data structure that is built to represent this information is called the query tree.

The reason for separating raw parsing from semantic analysis is that system catalog lookups can only be done within a transaction, and we do not wish to start a transaction immediately upon receiving a query string. The raw parsing stage is sufficient to identify the transaction control commands (BEGIN, ROLLBACK, etc.), and these can then be correctly executed without any further analysis. Once we know that we are dealing with an actual query (such as SELECT or UPDATE), it is okay to start a transaction if we’re not already in one. Only then can the transformation process be invoked.

The query tree created by the transformation process is structurally similar to the raw parse tree in most places, but it has many differences in detail. For example, a FuncCall node in the parse tree represents something that looks syntactically like a function call. This might be transformed to either a FuncExpr or Aggref node depending on whether the referenced name turns out to be an ordinary function or an aggregate function. Also, information about the actual data types of columns and expression results is added to the query tree.

52.4. The PostgreSQL Rule System

PostgreSQL supports a powerful rule system for the specification of views and ambiguous view updates. Originally the PostgreSQL rule system consisted of two implementations:

- The first one worked using row level processing and was implemented deep in the executor. The rule system was called whenever an individual row had been accessed. This implementation was removed in 1995 when the last official release of the Berkeley Postgres project was transformed into Postgres95.

- The second implementation of the rule system is a technique called query rewriting. The rewrite system is a module that exists between the parser stage and the planner/optimizer. This technique is still implemented.

The query rewriter is discussed in some detail in Chapter 41, so there is no need to cover it here. We will only point out that both the input and the output of the rewriter are query trees, that is, there is no change in the representation or level of semantic detail in the trees. Rewriting can be thought of as a form of macro expansion.

52.5. Planner/Optimizer

The task of the planner/optimizer is to create an optimal execution plan. A given SQL query (and hence, a query tree) can be actually executed in a wide variety of different ways, each of which will produce the same set of results. If it is computationally feasible, the query optimizer will examine each of these possible execution plans, ultimately selecting the execution plan that is expected to run the fastest.

Note

In some situations, examining each possible way in which a query can be executed would take an excessive amount of time and memory. In particular, this occurs when executing queries involving

2327
large numbers of join operations. In order to determine a reasonable (not necessarily optimal) query plan in a reasonable amount of time, PostgreSQL uses a Genetic Query Optimizer (see Chapter 61) when the number of joins exceeds a threshold (see geqo_threshold).

The planner's search procedure actually works with data structures called paths, which are simply cut-down representations of plans containing only as much information as the planner needs to make its decisions. After the cheapest path is determined, a full-fledged plan tree is built to pass to the executor. This represents the desired execution plan in sufficient detail for the executor to run it. In the rest of this section we'll ignore the distinction between paths and plans.

52.5.1. Generating Possible Plans

The planner/optimizer starts by generating plans for scanning each individual relation (table) used in the query. The possible plans are determined by the available indexes on each relation. There is always the possibility of performing a sequential scan on a relation, so a sequential scan plan is always created. Assume an index is defined on a relation (for example a B-tree index) and a query contains the restriction relation.attribute OPR constant. If relation.attribute happens to match the key of the B-tree index and OPR is one of the operators listed in the index's operator class, another plan is created using the B-tree index to scan the relation. If there are further indexes present and the restrictions in the query happen to match a key of an index, further plans will be considered. Index scan plans are also generated for indexes that have a sort ordering that can match the query's ORDER BY clause (if any), or a sort ordering that might be useful for merge joining (see below).

If the query requires joining two or more relations, plans for joining relations are considered after all feasible plans have been found for scanning single relations. The three available join strategies are:

- **nested loop join**: The right relation is scanned once for every row found in the left relation. This strategy is easy to implement but can be very time consuming. (However, if the right relation can be scanned with an index scan, this can be a good strategy. It is possible to use values from the current row of the left relation as keys for the index scan of the right.)

- **merge join**: Each relation is sorted on the join attributes before the join starts. Then the two relations are scanned in parallel, and matching rows are combined to form join rows. This kind of join is attractive because each relation has to be scanned only once. The required sorting might be achieved either by an explicit sort step, or by scanning the relation in the proper order using an index on the join key.

- **hash join**: the right relation is first scanned and loaded into a hash table, using its join attributes as hash keys. Next the left relation is scanned and the appropriate values of every row found are used as hash keys to locate the matching rows in the table.

When the query involves more than two relations, the final result must be built up by a tree of join steps, each with two inputs. The planner examines different possible join sequences to find the cheapest one.

If the query uses fewer than geqo_threshold relations, a near-exhaustive search is conducted to find the best join sequence. The planner preferentially considers joins between any two relations for which there exists a corresponding join clause in the WHERE qualification (i.e., for which a restriction like where rel1.attr1=rel2.attr2 exists). Join pairs with no join clause are considered only when there is no other choice, that is, a particular relation has no available join clauses to any other relation. All possible plans are generated for every join pair considered by the planner, and the one that is (estimated to be) the cheapest is chosen.

When geqo_threshold is exceeded, the join sequences considered are determined by heuristics, as described in Chapter 61. Otherwise the process is the same.
The finished plan tree consists of sequential or index scans of the base relations, plus nested-loop, merge, or hash join nodes as needed, plus any auxiliary steps needed, such as sort nodes or aggregate-function calculation nodes. Most of these plan node types have the additional ability to do selection (discarding rows that do not meet a specified Boolean condition) and projection (computation of a derived column set based on given column values, that is, evaluation of scalar expressions where needed). One of the responsibilities of the planner is to attach selection conditions from the WHERE clause and computation of required output expressions to the most appropriate nodes of the plan tree.

52.6. Executor

The executor takes the plan created by the planner/optimizer and recursively processes it to extract the required set of rows. This is essentially a demand-pull pipeline mechanism. Each time a plan node is called, it must deliver one more row, or report that it is done delivering rows.

To provide a concrete example, assume that the top node is a MergeJoin node. Before any merge can be done two rows have to be fetched (one from each subplan). So the executor recursively calls itself to process the subplans (it starts with the subplan attached to lef
tree). The new top node (the top node of the left subplan) is, let's say, a Sort node and again recursion is needed to obtain an input row. The child node of the Sort might be a SeqScan node, representing actual reading of a table. Execution of this node causes the executor to fetch a row from the table and return it up to the calling node. The Sort node will repeatedly call its child to obtain all the rows to be sorted. When the input is exhausted (as indicated by the child node returning a NULL instead of a row), the Sort code performs the sort, and finally is able to return its first output row, namely the first one in sorted order. It keeps the remaining rows stored so that it can deliver them in sorted order in response to later demands.

The MergeJoin node similarly demands the first row from its right subplan. Then it compares the two rows to see if they can be joined; if so, it returns a join row to its caller. On the next call, or immediately if it cannot join the current pair of inputs, it advances to the next row of one table or the other (depending on how the comparison came out), and again checks for a match. Eventually, one subplan or the other is exhausted, and the MergeJoin node returns NULL to indicate that no more join rows can be formed.

Complex queries can involve many levels of plan nodes, but the general approach is the same: each node computes and returns its next output row each time it is called. Each node is also responsible for applying any selection or projection expressions that were assigned to it by the planner.

The executor mechanism is used to evaluate all four basic SQL query types: SELECT, INSERT, UPDATE, and DELETE. For SELECT, the top-level executor code only needs to send each row returned by the query plan tree off to the client. INSERT ... SELECT, UPDATE, and DELETE are effectively SELECTs under a special top-level plan node called ModifyTable.

INSERT ... SELECT feeds the rows up to ModifyTable for insertion. For UPDATE, the planner arranges that each computed row includes all the updated column values, plus the TID (tuple ID, or row ID) of the original target row; this data is fed up to the ModifyTable node, which uses the information to create a new updated row and mark the old row deleted. For DELETE, the only column that is actually returned by the plan is the TID, and the ModifyTable node simply uses the TID to visit each target row and mark it deleted.

A simple INSERT ... VALUES command creates a trivial plan tree consisting of a single Result node, which computes just one result row, feeding that up to ModifyTable to perform the insertion.
Chapter 53. System Catalogs

The system catalogs are the place where a relational database management system stores schema metadata, such as information about tables and columns, and internal bookkeeping information. PostgreSQL's system catalogs are regular tables. You can drop and recreate the tables, add columns, insert and update values, and severely mess up your system that way. Normally, one should not change the system catalogs by hand, there are normally SQL commands to do that. (For example, CREATE DATABASE inserts a row into the pg_database catalog — and actually creates the database on disk.) There are some exceptions for particularly esoteric operations, but many of those have been made available as SQL commands over time, and so the need for direct manipulation of the system catalogs is ever decreasing.

53.1. Overview

Table 53.1 lists the system catalogs. More detailed documentation of each catalog follows below.

Most system catalogs are copied from the template database during database creation and are thereafter database-specific. A few catalogs are physically shared across all databases in a cluster; these are noted in the descriptions of the individual catalogs.

Table 53.1. System Catalogs

<table>
<thead>
<tr>
<th>Catalog Name</th>

</tr>
</tbody>
</table>
53.2. pg_aggregate

The catalog `pg_aggregate` stores information about aggregate functions. An aggregate function is a function that operates on a set of values (typically one column from each row that matches a query condition) and returns a single value computed from all these values. Typical aggregate functions are `sum`, `count`, and `max`. Each entry in `pg_aggregate` is an extension of an entry in `pg_proc`. The `pg_proc` entry carries the aggregate's name, input and output data types, and other information that is similar to ordinary functions.

Table 53.2. `pg_aggregate` Columns

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aggfnoid regproc (references pg_proc.oid)</td>
<td>OID of the aggregate function</td>
</tr>
<tr>
<td>aggkind char</td>

</thead>
<tbody>
<tr>
<td>Approximate average size (in bytes) of the transition state data for moving-aggregate mode, or zero to use a default estimate</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>agginivaltext</th>
</tr>
</thead>
<tbody>
<tr>
<td>The initial value of the transition state. This is a text field containing the initial value in its external string representation. If this field is null, the transition state value starts out null.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>aggminivaltext</th>
</tr>
</thead>
<tbody>
<tr>
<td>The initial value of the transition state for moving-aggregate mode. This is a text field containing the initial value in its external string representation. If this field is null, the transition state value starts out null.</td>
</tr>
</tbody>
</table>

New aggregate functions are registered with the CREATE AGGREGATE command. See Section 38.12 for more information about writing aggregate functions and the meaning of the transition functions, etc.

### 53.3. pg_am

The catalog pg_am stores information about relation access methods. There is one row for each access method supported by the system. Currently, only tables and indexes have access methods. The requirements for table and index access methods are discussed in detail in Chapter 62 and Chapter 63 respectively.

#### Table 53.3. pg_am Columns

<table>
<thead>
<tr>
<th>Column Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
</tr>
</tbody>
</table>

| oid oid |

2333
System Catalogs

<table>
<thead>
<tr>
<th><strong>Column Type</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>amname</td>
<td>Name of the access method</td>
</tr>
<tr>
<td>amhandler regproc (references pg_proc.oid)</td>
<td>OID of a handler function that is responsible for supplying information about the access method</td>
</tr>
<tr>
<td>amtype char</td>
<td>$t$ = table (including materialized views), $i$ = index.</td>
</tr>
</tbody>
</table>

**Note**

Before PostgreSQL 9.6, pg_am contained many additional columns representing properties of index access methods. That data is now only directly visible at the C code level. However, pg_index_column_has_property() and related functions have been added to allow SQL queries to inspect index access method properties; see Table 9.74.

### 53.4. pg_amop

The catalog pg_amop stores information about operators associated with access method operator families. There is one row for each operator that is a member of an operator family. A family member can be either a search operator or an ordering operator. An operator can appear in more than one family, but cannot appear in more than one search position nor more than one ordering position within a family. (It is allowed, though unlikely, for an operator to be used for both search and ordering purposes.)

**Table 53.4. pg_amop Columns**

<table>
<thead>
<tr>
<th><strong>Column Type</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>oid oid</td>
<td>Row identifier</td>
</tr>
<tr>
<td>amopfamily oid (references pg_opfamily.oid)</td>
<td>The operator family this entry is for</td>
</tr>
<tr>
<td>amoplefttype oid (references pg_type.oid)</td>
<td>Left-hand input data type of operator</td>
</tr>
<tr>
<td>amoprighttype oid (references pg_type.oid)</td>
<td>Right-hand input data type of operator</td>
</tr>
<tr>
<td>amopstrategy int2</td>
<td>Operator strategy number</td>
</tr>
<tr>
<td>amoppurpose char</td>
<td>Operator purpose, either s for search or o for ordering</td>
</tr>
<tr>
<td>amopopr oid (references pg_operator.oid)</td>
<td>OID of the operator</td>
</tr>
<tr>
<td>amopmethod oid (references pg_am.oid)</td>
<td>Index access method operator family is for</td>
</tr>
</tbody>
</table>
| amopsortfamily oid (references pg_opfamily.oid) | }
A "search" operator entry indicates that an index of this operator family can be searched to find all rows satisfying \texttt{WHERE indexed\_column operator constant}. Obviously, such an operator must return \texttt{boolean}, and its left-hand input type must match the index's column data type.

An "ordering" operator entry indicates that an index of this operator family can be scanned to return rows in the order represented by \texttt{ORDER BY indexed\_column operator constant}. Such an operator could return any sortable data type, though again its left-hand input type must match the index's column data type. The exact semantics of the \texttt{ORDER BY} are specified by the \texttt{amopsortfamily} column, which must reference a B-tree operator family for the operator's result type.

\begin{table}[h]
\centering
\begin{tabular}{|l|l|}
\hline
\textbf{Column Type} & \textbf{Description} \\
\hline
\texttt{oid} & \texttt{oid} Row identifier \\
\hline
\texttt{amprocfamily oid references pg\_opfamily.oid} & The operator family this entry is for \\
\hline
\texttt{amproclefttype oid references pg\_type.oid} & Left-hand input data type of associated operator \\
\hline
\texttt{amprocrighthttype oid references pg\_type.oid} & Right-hand input data type of associated operator \\
\hline
\texttt{amprocnnum int2} & Support function number \\
\hline
\texttt{amproc regproc references pg\_proc.oid} & OID of the function \\
\hline
\end{tabular}
\caption{\texttt{pg\_amproc Columns}}
\end{table}

\textbf{Note}

At present, it's assumed that the sort order for an ordering operator is the default for the referenced operator family, i.e., \texttt{ASC NULLS LAST}. This might someday be relaxed by adding additional columns to specify sort options explicitly.

An entry's \texttt{amopmethod} must match the \texttt{opmethod} of its containing operator family (including \texttt{amopmethod} here is an intentional denormalization of the catalog structure for performance reasons). Also, \texttt{amproclefttype} and \texttt{amprocrighthttype} must match the \texttt{oprleft} and \texttt{oprright} fields of the referenced \texttt{pg\_operator} entry.

### 53.5. \texttt{pg\_amproc}

The catalog \texttt{pg\_amproc} stores information about support functions associated with access method operator families. There is one row for each support function belonging to an operator family.

The usual interpretation of the \texttt{amproclefttype} and \texttt{amprocrighthttype} fields is that they identify the left and right input types of the operator(s) that a particular support function function supports. For some access
methods these match the input data type(s) of the support function itself, for others not. There is a notion of “default” support functions for an index, which are those with `amproclefttype` and `amprocrighttype` both equal to the index operator class's `opcintype`.

### 53.6. `pg_attrdef`

The catalog `pg_attrdef` stores column default values. The main information about columns is stored in `pg_attribute`. Only columns for which a default value has been explicitly set will have an entry here.

**Table 53.6. `pg_attrdef` Columns**

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>oid</code></td>
<td>Row identifier</td>
</tr>
<tr>
<td><code>adrelid</code></td>
<td>(references <code>pg_class.oid</code>) The table this column belongs to</td>
</tr>
<tr>
<td><code>adnum</code></td>
<td>(references <code>pg_attribute.attnum</code>) The number of the column</td>
</tr>
<tr>
<td><code>adbin</code></td>
<td><code>pg_node_tree</code> The column default value, in <code>nodeToString()</code> representation. Use <code>pg_get_expr(adbin, adrelid)</code> to convert it to an SQL expression.</td>
</tr>
</tbody>
</table>

### 53.7. `pg_attribute`

The catalog `pg_attribute` stores information about table columns. There will be exactly one `pg_attribute` row for every column in every table in the database. (There will also be attribute entries for indexes, and indeed all objects that have `pg_class` entries.)

The term attribute is equivalent to column and is used for historical reasons.

**Table 53.7. `pg_attribute` Columns**

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>attrelid</code></td>
<td>(references <code>pg_class.oid</code>) The table this column belongs to</td>
</tr>
<tr>
<td><code>attname</code></td>
<td>The column name</td>
</tr>
<tr>
<td><code>atttypid</code></td>
<td>(references <code>pg_type.oid</code>) The data type of this column (zero for a dropped column)</td>
</tr>
<tr>
<td><code>attstattrgnt</code></td>
<td><code>int4</code> <code>attstattrgnt</code> controls the level of detail of statistics accumulated for this column by <code>ANALYZE</code>. A zero value indicates that no statistics should be collected. A negative value says to use the system default statistics target. The exact meaning of positive values is data type-dependent. For scalar data types, <code>attstattrgnt</code> is both the target number of “most common values” to collect, and the target number of histogram bins to create.</td>
</tr>
<tr>
<td><code>attlen</code></td>
<td><code>int2</code> A copy of <code>pg_type.typlen</code> of this column's type</td>
</tr>
<tr>
<td><code>attnum</code></td>
<td><code>int2</code></td>
</tr>
<tr>
<td>Column Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------</td>
</tr>
<tr>
<td>attndims</td>
<td>The number of the column. Ordinary columns are numbered from 1 up. System columns, such as ctid, have (arbitrary) negative numbers.</td>
</tr>
<tr>
<td>attcacheoff</td>
<td>Number of dimensions, if the column is an array type; otherwise 0. (Presently, the number of dimensions of an array is not enforced, so any nonzero value effectively means “it’s an array”.)</td>
</tr>
<tr>
<td>atttypmod</td>
<td>Always -1 in storage, but when loaded into a row descriptor in memory this might be updated to cache the offset of the attribute within the row.</td>
</tr>
<tr>
<td>attbyval</td>
<td>A copy of pg_type.typbyval of this column's type</td>
</tr>
<tr>
<td>attalign</td>
<td>A copy of pg_type.typalign of this column's type</td>
</tr>
<tr>
<td>attstorage</td>
<td>Normally a copy of pg_type.typstorage of this column's type. For TOAST-able data types, this can be altered after column creation to control storage policy.</td>
</tr>
<tr>
<td>attcompression</td>
<td>The current compression method of the column. Typically this is ‘\0’ to specify use of the current default setting (see default_toast_compression). Otherwise, ‘p’ selects pglz compression, while ‘l’ selects LZ4 compression. However, this field is ignored whenever attstorage does not allow compression.</td>
</tr>
<tr>
<td>attnotnull</td>
<td>This represents a not-null constraint.</td>
</tr>
<tr>
<td>atthasdef</td>
<td>This column has a default expression or generation expression, in which case there will be a corresponding entry in the pg_attrdef catalog that actually defines the expression. (Check attgenerated to determine whether this is a default or a generation expression.)</td>
</tr>
<tr>
<td>atthasmissing</td>
<td>This column has a value which is used where the column is entirely missing from the row, as happens when a column is added with a non-volatile DEFAULT value after the row is created. The actual value used is stored in the attmissingval column.</td>
</tr>
<tr>
<td>attidentity</td>
<td>If a zero byte (’\0’), then not an identity column. Otherwise, a = generated always, d = generated by default.</td>
</tr>
<tr>
<td>attgenerated</td>
<td>If a zero byte (’\0’), then not a generated column. Otherwise, s = stored. (Other values might be added in the future.)</td>
</tr>
<tr>
<td>attisdropped</td>
<td>This column has been dropped and is no longer valid. A dropped column is still physically present in the table, but is ignored by the parser and so cannot be accessed via SQL.</td>
</tr>
<tr>
<td>attislocal</td>
<td></td>
</tr>
</tbody>
</table>
### System Catalogs

**Column Type**

**Description**

This column is defined locally in the relation. Note that a column can be locally defined and inherited simultaneously.

<table>
<thead>
<tr>
<th>attinhcount</th>
<th>int4</th>
</tr>
</thead>

<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>attmissingval</th>
<th>anyarray</th>
</tr>
</thead>
<tbody>
<tr>
<td>This column has a one element array containing the value used when the column is entirely missing from the row, as happens when the column is added with a non-volatile DEFAULT value after the row is created. The value is only used when atthasmissing is true. If there is no value the column is null.</td>
<td></td>
</tr>
</tbody>
</table>

In a dropped column's pg_attribute entry, atttypid is reset to zero, but attlen and the other fields copied from pg_type are still valid. This arrangement is needed to cope with the situation where the dropped column's data type was later dropped, and so there is no pg_type row anymore. attlen and the other fields can be used to interpret the contents of a row of the table.

# 53.8. pg_authid

The catalog pg_authid contains information about database authorization identifiers (roles). A role subsumes the concepts of “users” and “groups”. A user is essentially just a role with the rolcanlogin flag set. Any role (with or without rolcanlogin) can have other roles as members; see pg_auth_members.

Since this catalog contains passwords, it must not be publicly readable. pg_roles is a publicly readable view on pg_authid that blanks out the password field.

Chapter 22 contains detailed information about user and privilege management.

Because user identities are cluster-wide, pg_authid is shared across all databases of a cluster: there is only one copy of pg_authid per cluster, not one per database.

### Table 53.8. pg_authid Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
</tr>
<tr>
<td>Row identifier</td>
<td></td>
</tr>
<tr>
<td>rolname</td>
<td>name</td>
</tr>
<tr>

<tr>
<td>rolcreaterole bool</td>
<td>Role can create more roles</td>
</tr>
<tr>
<td>rolcreatedb bool</td>
<td>Role can create databases</td>
</tr>
<tr>
<td>rolcanlogin bool</td>
<td>Role can log in. That is, this role can be given as the initial session authorization identifier.</td>
</tr>
<tr>
<td>roireplication bool</td>
<td>Role is a replication role. A replication role can initiate replication connections and create and drop replication slots.</td>
</tr>
<tr>
<td>rolbypassrls bool</td>
<td>Role bypasses every row-level security policy, see Section 5.8 for more information.</td>
</tr>
<tr>
<td>rolconnlimit int4</td>
<td>For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit.</td>
</tr>
<tr>
<td>rolpassword text</td>
<td>Password (possibly encrypted); null if none. The format depends on the form of encryption used.</td>
</tr>
<tr>
<td>rovaliduntil timestamptz</td>
<td>Password expiry time (only used for password authentication); null if no expiration</td>
</tr>
</tbody>
</table>

For an MD5 encrypted password, `rolpassword` column will begin with the string `md5` followed by a 32-character hexadecimal MD5 hash. The MD5 hash will be of the user's password concatenated to their user name. For example, if user `joe` has password `xyzzy`, PostgreSQL will store the md5 hash of `xyzzyjoe`.

If the password is encrypted with SCRAM-SHA-256, it has the format:

```
SCRAM-SHA-256$<iteration count>::<salt>::<StoredKey>::<ServerKey>
```

where `salt`, `StoredKey` and `ServerKey` are in Base64 encoded format. This format is the same as that specified by RFC 5803.

A password that does not follow either of those formats is assumed to be unencrypted.

### 53.9. pg_auth_members

The catalog `pg_auth_members` shows the membership relations between roles. Any non-circular set of relationships is allowed.

Because user identities are cluster-wide, `pg_auth_members` is shared across all databases of a cluster: there is only one copy of `pg_auth_members` per cluster, not one per database.

---

1 https://tools.ietf.org/html/rfc5803
Table 53.9. pg_auth_members Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>roleid oid (references pg_authid.oid)</td>
<td>ID of a role that has a member</td>
</tr>
<tr>
<td>member oid (references pg_authid.oid)</td>
<td>ID of a role that is a member of roleid</td>
</tr>
<tr>
<td>grantor oid (references pg_authid.oid)</td>
<td>ID of the role that granted this membership</td>
</tr>
<tr>
<td>admin_option boolean</td>
<td>True if member can grant membership in roleid to others</td>
</tr>
</tbody>
</table>

53.10. pg_cast

The catalog pg_cast stores data type conversion paths, both built-in and user-defined.

It should be noted that pg_cast does not represent every type conversion that the system knows how to perform; only those that cannot be deduced from some generic rule. For example, casting between a domain and its base type is not explicitly represented in pg_cast. Another important exception is that “automatic I/O conversion casts”, those performed using a data type’s own I/O functions to convert to or from text or other string types, are not explicitly represented in pg_cast.

Table 53.10. pg_cast Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid oid</td>
<td>Row identifier</td>
</tr>
<tr>
<td>castsource oid (references pg_type.oid)</td>
<td>OID of the source data type</td>
</tr>
<tr>
<td>casttarget oid (references pg_type.oid)</td>
<td>OID of the target data type</td>
</tr>
<tr>
<td>castfunc oid (references pg_proc.oid)</td>
<td>The OID of the function to use to perform this cast. Zero is stored if the cast method doesn't require a function.</td>
</tr>
<tr>
<td>castcontext char</td>
<td>Indicates what contexts the cast can be invoked in. e means only as an explicit cast (using CAST or :: syntax). a means implicitly in assignment to a target column, as well as explicitly. i means implicitly in expressions, as well as the other cases.</td>
</tr>
<tr>
<td>castmethod char</td>
<td>Indicates how the cast is performed. f means that the function specified in the castfunc field is used. i means that the input/output functions are used. b means that the types are binary-coercible, thus no conversion is required.</td>
</tr>
</tbody>
</table>

The cast functions listed in pg_cast must always take the cast source type as their first argument type, and return the cast destination type as their result type. A cast function can have up to three arguments. The second argument, if present, must be type integer; it receives the type modifier associated with the destination type, or -1 if there is none. The third argument, if present, must be type boolean; it receives true if the cast is an explicit cast, false otherwise.
It is legitimate to create a `pg_cast` entry in which the source and target types are the same, if the associated function takes more than one argument. Such entries represent “length coercion functions” that coerce values of the type to be legal for a particular type modifier value.

When a `pg_cast` entry has different source and target types and a function that takes more than one argument, it represents converting from one type to another and applying a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

## 53.11. `pg_class`

The catalog `pg_class` catalogs tables and most everything else that has columns or is otherwise similar to a table. This includes indexes (but see also `pg_index`), sequences (but see also `pg_sequence`), views, materialized views, composite types, and TOAST tables; see `relkind`. Below, when we mean all of these kinds of objects we speak of “relations”. Not all columns are meaningful for all relation types.

### Table 53.11. `pg_class` Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>oid</code> <code>oid</code></td>
<td>Row identifier</td>
</tr>
<tr>
<td><code>relname</code> <code>name</code></td>
<td>Name of the table, index, view, etc.</td>
</tr>
<tr>
<td><code>relnamespace</code> <code>oid</code> (references <code>pg_namespace.oid</code>)</td>
<td>The OID of the namespace that contains this relation</td>
</tr>
<tr>
<td><code>reltype</code> <code>oid</code> (references <code>pg_type.oid</code>)</td>
<td>The OID of the data type that corresponds to this table's row type, if any; zero for indexes, sequences, and toast tables, which have no <code>pg_type</code> entry</td>
</tr>
<tr>
<td><code>reloftype</code> <code>oid</code> (references <code>pg_type.oid</code>)</td>
<td>For typed tables, the OID of the underlying composite type; zero for all other relations</td>
</tr>
<tr>
<td><code>relowner</code> <code>oid</code> (references <code>pg_authid.oid</code>)</td>
<td>Owner of the relation</td>
</tr>
<tr>
<td><code>relam</code> <code>oid</code> (references <code>pg_am.oid</code>)</td>
<td>If this is a table or an index, the access method used (heap, B-tree, hash, etc.); otherwise zero (zero occurs for sequences, as well as relations without storage, such as views)</td>
</tr>
<tr>
<td><code>relfilenode</code> <code>oid</code></td>
<td>Name of the on-disk file of this relation; zero means this is a “mapped” relation whose disk file name is determined by low-level state</td>
</tr>
<tr>
<td><code>reltablespace</code> <code>oid</code> (references <code>pg_tablespace.oid</code>)</td>
<td>The tablespace in which this relation is stored. If zero, the database's default tablespace is implied. (Not meaningful if the relation has no on-disk file.)</td>
</tr>
<tr>
<td><code>relpages</code> <code>int4</code></td>
<td>Size of the on-disk representation of this table in pages (of size <code>BLCKSZ</code>). This is only an estimate used by the planner. It is updated by <code>VACUUM</code>, <code>ANALYZE</code>, and a few DDL commands such as <code>CREATE INDEX</code>.</td>
</tr>
</tbody>
</table>
| `reltuples` `float4` | Number of live rows in the table. This is only an estimate used by the planner. It is updated by `VACUUM`, `ANALYZE`, and a few DDL commands such as `CREATE INDEX`. If the table
<table>

<td>True if table or index has (or once had) any inheritance children</td>
</tr>
<tr>
<td>relrowsecurity bool</td>
<td>True if table has row-level security enabled; see pg_policy catalog</td>
</tr>
<tr>
<td>relforcerowsecurity bool</td>
<td>True if row-level security (when enabled) will also apply to table owner; see pg_policy catalog</td>
</tr>
<tr>
<td>relispopulated bool</td>
<td>True if relation is populated (this is true for all relations other than some materialized views)</td>
</tr>
<tr>
<td>relreplident char</td>
<td>Columns used to form “replica identity” for rows: d = default (primary key, if any), n = nothing, f = all columns, i = index with indisreplident set (same as nothing if the index used has been dropped)</td>
</tr>
<tr>
<td>relispartition bool</td>
<td>True if table or index is a partition</td>
</tr>
<tr>
<td>relrewrite oid</td>
<td>(references pg_class.oid)</td>
</tr>
</tbody>
</table>
### Column Type

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>relfrozenxid xid</td>
<td>All transaction IDs before this one have been replaced with a permanent (“frozen”) transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to prevent transaction ID wraparound or to allow \texttt{pg_xact} to be shrunk. Zero (Invalid-TransactionId) if the relation is not a table.</td>
</tr>
<tr>
<td>relminmxid xid</td>
<td>All multixact IDs before this one have been replaced by a transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to prevent multixact ID wraparound or to allow \texttt{pg_multixact} to be shrunk. Zero (InvalidMultiXactId) if the relation is not a table.</td>
</tr>
<tr>
<td>relacl aclitem[]</td>
<td>Access privileges; see Section 5.7 for details</td>
</tr>
<tr>
<td>reloptions text[]</td>
<td>Access-method-specific options, as “keyword=value” strings</td>
</tr>
<tr>
<td>relpartbound pg_node_tree</td>
<td>If table is a partition (see relispartition), internal representation of the partition bound</td>
</tr>
</tbody>
</table>

Several of the Boolean flags in \texttt{pg\_class} are maintained lazily: they are guaranteed to be true if that's the correct state, but may not be reset to false immediately when the condition is no longer true. For example, \texttt{relhasindex} is set by \texttt{CREATE INDEX}, but it is never cleared by \texttt{DROP INDEX}. Instead, \texttt{VACUUM} clears \texttt{relhasindex} if it finds the table has no indexes. This arrangement avoids race conditions and improves concurrency.

## 53.12. \texttt{pg\_collation}

The catalog \texttt{pg\_collation} describes the available collations, which are essentially mappings from an SQL name to operating system locale categories. See Section 24.2 for more information.

### Table 53.12. \texttt{pg\_collation} Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid oid</td>
<td>Row identifier</td>
</tr>
<tr>
<td>collname name</td>
<td>Collation name (unique per namespace and encoding)</td>
</tr>
<tr>
<td>collnamespace oid (references \texttt{pg_namespace.oid})</td>
<td>The OID of the namespace that contains this collation</td>
</tr>
<tr>
<td>collowner oid (references \texttt{pg_authid.oid})</td>
<td>Owner of the collation</td>
</tr>
<tr>
<td>collprovider char</td>
<td>Provider of the collation: \texttt{d} = database default, \texttt{c} = libc, \texttt{i} = icu</td>
</tr>
<tr>
<td>collisdeterministic bool</td>
<td>Is the collation deterministic?</td>
</tr>
</tbody>
</table>
System Catalogs

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>collencoding</td>
<td>int4</td>
</tr>
<tr>
<td></td>
<td>Encoding in which the collation is applicable, or -1 if it works for any encoding</td>
</tr>
<tr>
<td>collcollate</td>
<td>text</td>
</tr>
<tr>
<td></td>
<td>LC_COLLATE for this collation object</td>
</tr>
<tr>
<td>collctype</td>
<td>text</td>
</tr>
<tr>
<td></td>
<td>LC_CTYPE for this collation object</td>
</tr>
<tr>
<td>colliculocale</td>
<td>text</td>
</tr>
<tr>
<td></td>
<td>ICU locale ID for this collation object</td>
</tr>
<tr>
<td>collversion</td>
<td>text</td>
</tr>
<tr>
<td></td>
<td>Provider-specific version of the collation. This is recorded when the collation is created and then checked when it is used, to detect changes in the collation definition that could lead to data corruption.</td>
</tr>
</tbody>
</table>

Note that the unique key on this catalog is (collname, collencoding, collnamespace) not just (collname, collnamespace). PostgreSQL generally ignores all collations that do not have collencoding equal to either the current database's encoding or -1, and creation of new entries with the same name as an entry with collencoding = -1 is forbidden. Therefore it is sufficient to use a qualified SQL name (schema.name) to identify a collation, even though this is not unique according to the catalog definition. The reason for defining the catalog this way is that initdb fills it in at cluster initialization time with entries for all locales available on the system, so it must be able to hold entries for all encodings that might ever be used in the cluster.

In the template0 database, it could be useful to create collations whose encoding does not match the database encoding, since they could match the encodings of databases later cloned from template0. This would currently have to be done manually.

53.13. pg_constraint

The catalog pg_constraint stores check, primary key, unique, foreign key, and exclusion constraints on tables. (Column constraints are not treated specially. Every column constraint is equivalent to some table constraint.) Not-null constraints are represented in the pg_attribute catalog, not here.

User-defined constraint triggers (created with CREATE CONSTRAINT TRIGGER) also give rise to an entry in this table.

Check constraints on domains are stored here, too.

Table 53.13. pg_constraint Columns

<table>
<thead>
<tr>

<td>bool This constraint is defined locally for the relation. It is a non-inheritable constraint.</td>
</tr>
<tr>
<td>conkey</td>
<td>int2[] (references pg_attribute.attnum) If a table constraint (including foreign keys, but not constraint triggers), list of the constrained columns</td>
</tr>
<tr>
<td>confkey</td>
<td>int2[] (references pg_attribute.attnum) If a foreign key, list of the referenced columns</td>
</tr>
<tr>
<td>conpfeqop</td>
<td>oid[] (references pg_operator.oid) If a foreign key, list of the equality operators for PK = FK comparisons</td>
</tr>
</tbody>
</table>
### Table 53.14. pg_conversion Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>oid</strong></td>
<td>oid</td>
</tr>
<tr>
<td><strong>conname</strong></td>
<td>Conversion name (unique within a namespace)</td>
</tr>
<tr>
<td><strong>connamespace</strong></td>
<td>oid (references pg_namespace.oid)</td>
</tr>
<tr>
<td><strong>conowner</strong></td>
<td>oid (references pg_authid.oid)</td>
</tr>
<tr>
<td><strong>conforencoding</strong></td>
<td>int4 (pg_encoding_to_char() can translate this number to the encoding name)</td>
</tr>
<tr>
<td><strong>contoencoding</strong></td>
<td>int4 (pg_encoding_to_char() can translate this number to the encoding name)</td>
</tr>
</tbody>
</table>

In the case of an exclusion constraint, **conkey** is only useful for constraint elements that are simple column references. For other cases, a zero appears in **conkey** and the associated index must be consulted to discover the expression that is constrained. (**conkey** thus has the same contents as **pg_index.indkey** for the index.)

**Note**

pg_class.relchecks needs to agree with the number of check-constraint entries found in this table for each relation.

## 53.14. pg_conversion

The catalog pg_conversion describes encoding conversion functions. See CREATE CONVERSION for more information.
### System Catalogs

<table>
<thead>
<tr>
<th>Column Type</th>

<td>bool</td>
</tr>
<tr>
<td></td>
<td>True if this is the default conversion</td>
</tr>
</tbody>
</table>

#### 53.15. `pg_database`

The catalog `pg_database` stores information about the available databases. Databases are created with the `CREATE DATABASE` command. Consult Chapter 23 for details about the meaning of some of the parameters.

Unlike most system catalogs, `pg_database` is shared across all databases of a cluster: there is only one copy of `pg_database` per cluster, not one per database.

**Table 53.15. `pg_database` Columns**

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>Locale provider for this database: c = libc, i = icu</td>
</tr>
<tr>
<td>datistemplate</td>
<td>bool</td>
</tr>
<tr>
<td></td>
<td>If true, then this database can be cloned by any user with <code>CREATEDB</code> privileges; if false, then only superusers or the owner of the database can clone it.</td>
</tr>
<tr>
<td>datallowconn</td>
<td>bool</td>
</tr>
<tr>
<td></td>
<td>If false then no one can connect to this database. This is used to protect the template0 database from being altered.</td>
</tr>
<tr>
<td>datconnlimit</td>
<td>int4</td>
</tr>
<tr>
<td></td>
<td>Sets maximum number of concurrent connections that can be made to this database. -1 means no limit.</td>
</tr>
<tr>
<td>datfrozenxid</td>
<td>xid</td>
</tr>
<tr>
<td></td>
<td>All transaction IDs before this one have been replaced with a permanent (“frozen”) transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent transaction ID wraparound or to allow <code>pg_xact</code> to be shrunk. It is the minimum of the per-table <code>pg_class.relfrozenxid</code> values.</td>
</tr>
<tr>
<td>datminmxid</td>
<td>xid</td>
</tr>
<tr>
<td></td>
<td>All multixact IDs before this one have been replaced with a transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent multixact IDs...</td>
</tr>
</tbody>
</table>
53.16. `pg_db_role_setting`

The catalog `pg_db_role_setting` records the default values that have been set for run-time configuration variables, for each role and database combination.

Unlike most system catalogs, `pg_db_role_setting` is shared across all databases of a cluster: there is only one copy of `pg_db_role_setting` per cluster, not one per database.

**Table 53.16. `pg_db_role_setting` Columns**

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>setdatabase oid</td>
<td>(references <code>pg_database</code>.oid)</td>
</tr>
<tr>
<td>setrole oid</td>
<td>(references <code>pg_authid</code>.oid)</td>
</tr>
<tr>
<td>setconfig text[]</td>
<td>Defaults for run-time configuration variables</td>
</tr>
</tbody>
</table>

53.17. `pg_default_acl`

The catalog `pg_default_acl` stores initial privileges to be assigned to newly created objects.

**Table 53.17. `pg_default_acl` Columns**

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
</tr>
</tbody>
</table>
A `pg_default_acl` entry shows the initial privileges to be assigned to an object belonging to the indicated user. There are currently two types of entry: "global" entries with `defaclnamespace = 0`, and "per-schema" entries that reference a particular schema. If a global entry is present then it overrides the normal hard-wired default privileges for the object type. A per-schema entry, if present, represents privileges to be added to the global or hard-wired default privileges.

Note that when an ACL entry in another catalog is null, it is taken to represent the hard-wired default privileges for its object, not whatever might be in `pg_default_acl` at the moment. `pg_default_acl` is only consulted during object creation.

### 53.18. `pg_depend`

The catalog `pg_depend` records the dependency relationships between database objects. This information allows `DROP` commands to find which other objects must be dropped by `DROP CASCADE` or prevent dropping in the `DROP RESTRICT` case.

See also `pg_shdepend`, which performs a similar function for dependencies involving objects that are shared across a database cluster.

#### Table 53.18. `pg_depend` Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deptype</td>
<td>char</td>
</tr>
<tr>
<td></td>
<td>A code defining the specific semantics of this dependency relationship; see text</td>
</tr>
</tbody>
</table>

In all cases, a `pg_depend` entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

**DEPENDENCY_NORMAL (n)**

A normal relationship between separately-created objects. The dependent object can be dropped without affecting the referenced object. The referenced object can only be dropped by specifying `CASCADE`, in which case the dependent object is dropped, too. Example: a table column has a normal dependency on its data type.

**DEPENDENCY_AUTO (a)**

The dependent object can be dropped separately from the referenced object, and should be automatically dropped (regardless of `RESTRICT` or `CASCADE` mode) if the referenced object is dropped. Example: a named constraint on a table is made auto-dependent on the table, so that it will go away if the table is dropped.

**DEPENDENCY_INTERNAL (i)**

The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation. A direct `DROP` of the dependent object will be disallowed outright (we'll tell the user to issue a `DROP` against the referenced object, instead). A `DROP` of the referenced object will result in automatically dropping the dependent object whether `CASCADE` is specified or not. If the dependent object has to be dropped due to a dependency on some other object being removed, its drop is converted to a drop of the referenced object, so that `NORMAL` and `AUTO` dependencies of the dependent object behave much like they were dependencies of the referenced object. Example: a view's `ON SELECT` rule is made internally dependent on the view, preventing it from being dropped while the view remains. Dependencies of the rule (such as tables it refers to) act as if they were dependencies of the view.

**DEPENDENCY_PARTITION_PRI (P)**

**DEPENDENCY_PARTITION_SEC (S)**

The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation; however, unlike `INTERNAL`, there is more than one such referenced object. The dependent object must not be dropped unless at least one of these referenced objects is dropped; if any one is, the dependent object should be dropped whether or not `CASCADE` is specified. Also unlike `INTERNAL`, a drop of some other object that the dependent object depends on does not result in automatic deletion of any partition-referenced object. Hence, if the drop does not cascade to at least one of these objects via some other path, it will be refused. (In most cases, the dependent object shares all its non-partition dependencies with at least one partition-referenced object, so that this restriction does not result in blocking any cascaded delete.) Primary and secondary partition dependencies behave identically except that the primary dependency is preferred for use in error messages; hence, a partition-dependent object should have one primary partition dependency and one or more secondary partition dependencies. Note that partition dependencies are made in addition to, not instead of, any dependencies the object would normally have. This simplifies `ATTACH/DETACH PARTITION` operations: the partition dependencies need only be added or removed. Example: a child partitioned index is made partition-dependent on both the partition table it is on and the parent partitioned index, so that it goes away if either of those is dropped, but not otherwise. The dependency
on the parent index is primary, so that if the user tries to drop the child partitioned index, the error message will suggest dropping the parent index instead (not the table).

DEPENDENCY_EXTENSION (e)

The dependent object is a member of the extension that is the referenced object (see `pg_extension`). The dependent object can be dropped only via `DROP EXTENSION` on the referenced object. Functionally this dependency type acts the same as an INTERNAL dependency, but it's kept separate for clarity and to simplify `pg_dump`.

DEPENDENCY_AUTO_EXTENSION (x)

The dependent object is not a member of the extension that is the referenced object (and so it should not be ignored by `pg_dump`), but it cannot function without the extension and should be auto-dropped if the extension is. The dependent object may be dropped on its own as well. Functionally this dependency type acts the same as an AUTO dependency, but it's kept separate for clarity and to simplify `pg_dump`.

Other dependency flavors might be needed in future.

Note that it's quite possible for two objects to be linked by more than one `pg_depend` entry. For example, a child partitioned index would have both a partition-type dependency on its associated partition table, and an auto dependency on each column of that table that it indexes. This sort of situation expresses the union of multiple dependency semantics. A dependent object can be dropped without CASCADE if any of its dependencies satisfies its condition for automatic dropping. Conversely, all the dependencies' restrictions about which objects must be dropped together must be satisfied.

Most objects created during initdb are considered "pinned", which means that the system itself depends on them. Therefore, they are never allowed to be dropped. Also, knowing that pinned objects will not be dropped, the dependency mechanism doesn't bother to make `pg_depend` entries showing dependencies on them. Thus, for example, a table column of type `numeric` notionally has a NORMAL dependency on the `numeric` data type, but no such entry actually appears in `pg_depend`.

53.19. **pg_description**

The catalog `pg_description` stores optional descriptions (comments) for each database object. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` commands. Descriptions of many built-in system objects are provided in the initial contents of `pg_description`.

See also `pg_shdescription`, which performs a similar function for descriptions involving objects that are shared across a database cluster.

**Table 53.19. pg_description Columns**

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid oid</td>
<td>(references any OID column) The OID of the object this description pertains to</td>
</tr>
<tr>

</tr>
</tbody>
</table>
System Catalogs

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arbitrary text that serves as the description of this object</td>
<td></td>
</tr>
</tbody>
</table>

### 53.20. pg_enum

The `pg_enum` catalog contains entries showing the values and labels for each enum type. The internal representation of a given enum value is actually the OID of its associated row in `pg_enum`. 

#### Table 53.20. pg_enum Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
</tr>
<tr>
<td>Row identifier</td>
<td></td>
</tr>
<tr>
<td>enumtypid oid</td>
<td>(references pg_type.oid)</td>
</tr>
<tr>
<td>The OID of the pg_type entry owning this enum value</td>
<td></td>
</tr>
<tr>
<td>enumsortorder</td>
<td>float4</td>
</tr>
<tr>
<td>The sort position of this enum value within its enum type</td>
<td></td>
</tr>
<tr>
<td>enunlabel</td>
<td>name</td>
</tr>
<tr>
<td>The textual label for this enum value</td>
<td></td>
</tr>
</tbody>
</table>

The OIDs for `pg_enum` rows follow a special rule: even-numbered OIDs are guaranteed to be ordered in the same way as the sort ordering of their enum type. That is, if two even OIDs belong to the same enum type, the smaller OID must have the smaller `enumsortorder` value. Odd-numbered OID values need bear no relationship to the sort order. This rule allows the enum comparison routines to avoid catalog lookups in many common cases. The routines that create and alter enum types attempt to assign even OIDs to enum values whenever possible.

When an enum type is created, its members are assigned sort-order positions 1..n. But members added later might be given negative or fractional values of `enumsortorder`. The only requirement on these values is that they be correctly ordered and unique within each enum type.

### 53.21. pg_event_trigger

The catalog `pg_event_trigger` stores event triggers. See Chapter 40 for more information.

#### Table 53.21. pg_event_trigger Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
</tr>
<tr>

|                  | D = trigger is disabled, R = trigger fires in “replica” mode, A = 
|                  | trigger fires always.                         |
| evttags text[]   | Command tags for which this trigger will fire. If NULL, the firing of this trigger is not re-
|                  | stricted on the basis of the command tag.     |

## 53.22. `pg_extension`

The catalog `pg_extension` stores information about the installed extensions. See Section 38.17 for details about extensions.

### Table 53.22. `pg_extension` Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid oid</td>
<td>Row identifier</td>
</tr>
<tr>
<td>extname name</td>
<td>Name of the extension</td>
</tr>
<tr>
<td>extowner oid</td>
<td>(references pg_authid.oid)</td>
</tr>
<tr>
<td>Owner of the extension</td>
<td></td>
</tr>
<tr>
<td>extnamespace oid</td>
<td>(references pg_namespace.oid)</td>
</tr>
<tr>
<td>Schema containing the extension's exported objects</td>
<td></td>
</tr>
<tr>
<td>extrelocatable bool</td>
<td>True if extension can be relocated to another schema</td>
</tr>
<tr>
<td>extversion text</td>
<td>Version name for the extension</td>
</tr>
<tr>
<td>extconfig oid[]</td>
<td>(references pg_class.oid)</td>
</tr>
<tr>
<td>Array of regclass OIDs for the extension's configuration table(s), or NULL if none</td>
<td></td>
</tr>
<tr>
<td>extcondition text[]</td>
<td>Array of WHERE-clause filter conditions for the extension's configuration table(s), or NULL if none</td>
</tr>
</tbody>
</table>

Note that unlike most catalogs with a “namespace” column, `extnamespace` is not meant to imply that the extension belongs to that schema. Extension names are never schema-qualified. Rather, `extnamespace` indicates the schema that contains most or all of the extension’s objects. If `extrelocatable` is true, then this schema must in fact contain all schema-qualifiable objects belonging to the extension.

## 53.23. `pg_foreign_data_wrapper`

The catalog `pg_foreign_data_wrapper` stores foreign-data wrapper definitions. A foreign-data wrapper is the mechanism by which external data, residing on foreign servers, is accessed.
Table 53.23. pg_foreign_data_wrapper Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
</tr>
<tr>
<td>fdwname</td>
<td>name</td>
</tr>
<tr>
<td>fdwowner oid (references pg_authid.oid)</td>
<td>Owner of the foreign-data wrapper</td>
</tr>
<tr>
<td>fdwhandler oid (references pg_proc.oid)</td>
<td>References a handler function that is responsible for supplying execution routines for the foreign-data wrapper. Zero if no handler is provided</td>
</tr>
<tr>
<td>fdwvalidator oid (references pg_proc.oid)</td>
<td>References a validator function that is responsible for checking the validity of the options given to the foreign-data wrapper, as well as options for foreign servers and user mappings using the foreign-data wrapper. Zero if no validator is provided</td>
</tr>
<tr>
<td>fdwacl aclitem[]</td>
<td>Access privileges; see Section 5.7 for details</td>
</tr>
<tr>
<td>fdwoptions text []</td>
<td>Foreign-data wrapper specific options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

53.24. pg_foreign_server

The catalog pg_foreign_server stores foreign server definitions. A foreign server describes a source of external data, such as a remote server. Foreign servers are accessed via foreign-data wrappers.

Table 53.24. pg_foreign_server Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
</tr>
<tr>
<td>srvname</td>
<td>name</td>
</tr>
<tr>
<td>srvowner oid (references pg_authid.oid)</td>
<td>Owner of the foreign server</td>
</tr>
<tr>
<td>srvfdw oid (references pg_foreign_data_wrapper.oid)</td>
<td>OID of the foreign-data wrapper of this foreign server</td>
</tr>
<tr>
<td>srvtype text</td>
<td>Type of the server (optional)</td>
</tr>
<tr>
<td>srvversion text</td>
<td>Version of the server (optional)</td>
</tr>
<tr>
<td>srvacl aclitem[]</td>
<td>Access privileges; see Section 5.7 for details</td>
</tr>
<tr>
<td>srvoptions text []</td>
<td>Foreign server specific options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>
53.25. pg_foreign_table

The catalog pg_foreign_table contains auxiliary information about foreign tables. A foreign table is primarily represented by a pg_class entry, just like a regular table. Its pg_foreign_table entry contains the information that is pertinent only to foreign tables and not any other kind of relation.

Table 53.25. pg_foreign_table Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ftrelid oid (references pg_class.oid)</td>
<td>The OID of the pg_class entry for this foreign table</td>
</tr>
<tr>
<td>ftserver oid (references pg_foreign_server.oid)</td>
<td>OID of the foreign server for this foreign table</td>
</tr>
<tr>
<td>ftoptions text</td>
<td>Foreign table options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

53.26. pg_index

The catalog pg_index contains part of the information about indexes. The rest is mostly in pg_class.

Table 53.26. pg_index Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>indexrelid oid (references pg_class.oid)</td>
<td>The OID of the pg_class entry for this index</td>
</tr>
<tr>
<td>indrelid oid (references pg_class.oid)</td>
<td>The OID of the pg_class entry for the table this index is for</td>
</tr>
<tr>
<td>indnatts int2</td>
<td>The total number of columns in the index (duplicates pg_class.relnatts); this number includes both key and included attributes</td>
</tr>
<tr>
<td>indnkeyatts int2</td>
<td>The number of key columns in the index, not counting any included columns, which are merely stored and do not participate in the index semantics</td>
</tr>
<tr>
<td>indisunique bool</td>
<td>If true, this is a unique index</td>
</tr>
<tr>
<td>indnullsnotdistinct bool</td>
<td>This value is only used for unique indexes. If false, this unique index will consider null values distinct (so the index can contain multiple null values in a column, the default PostgreSQL behavior). If it is true, it will consider null values to be equal (so the index can only contain one null value in a column).</td>
</tr>
<tr>
<td>indisprimary bool</td>
<td>If true, this index represents the primary key of the table (indisunique should always be true when this is true)</td>
</tr>
<tr>
<td>indisexclusion bool</td>
<td>If true, this index supports an exclusion constraint</td>
</tr>
<tr>
<td>Column Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>indimmediate bool</td>
<td>If true, the uniqueness check is enforced immediately on insertion (irrelevant if indisunique is not true)</td>
</tr>
<tr>
<td>indisclustered bool</td>
<td>If true, the table was last clustered on this index</td>
</tr>
<tr>
<td>indisvalid bool</td>
<td>If true, the index is currently valid for queries. False means the index is possibly incomplete: it must still be modified by INSERT/UPDATE operations, but it cannot safely be used for queries. If it is unique, the uniqueness property is not guaranteed true either.</td>
</tr>
<tr>
<td>indcheckxmin bool</td>
<td>If true, queries must not use the index until the xmin of this pg_index row is below their TransactionXmin event horizon, because the table may contain broken HOT chains with incompatible rows that they can see</td>
</tr>
<tr>
<td>indisready bool</td>
<td>If true, the index is currently ready for inserts. False means the index must be ignored by INSERT/UPDATE operations.</td>
</tr>
<tr>
<td>indislive bool</td>
<td>If false, the index is in process of being dropped, and should be ignored for all purposes (including HOT-safety decisions)</td>
</tr>
<tr>
<td>indisreplident bool</td>
<td>If true this index has been chosen as “replica identity” using ALTER TABLE ... REPLICA IDENTITY USING INDEX ...</td>
</tr>
<tr>
<td>indkey int2vector (references pg_attribute.attnum)</td>
<td>This is an array of indnatts values that indicate which table columns this index indexes. For example, a value of 1 3 would mean that the first and the third table columns make up the index entries. Key columns come before non-key (included) columns. A zero in this array indicates that the corresponding index attribute is an expression over the table columns, rather than a simple column reference.</td>
</tr>
<tr>
<td>indcollation oidvector (references pg_collation.oid)</td>
<td>For each column in the index key (indnkeyatts values), this contains the OID of the collation to use for the index, or zero if the column is not of a collatable data type.</td>
</tr>
<tr>
<td>indclass oidvector (references pg_opclass.oid)</td>
<td>For each column in the index key (indnkeyatts values), this contains the OID of the operator class to use. See pg_opclass for details.</td>
</tr>
<tr>
<td>indoption int2vector</td>
<td>This is an array of indnkeyatts values that store per-column flag bits. The meaning of the bits is defined by the index's access method.</td>
</tr>
<tr>
<td>indexprs pg_node_tree</td>
<td>Expression trees (in nodeToString() representation) for index attributes that are not simple column references. This is a list with one element for each zero entry in indkey. Null if all index attributes are simple references.</td>
</tr>
<tr>
<td>indpred pg_node_tree</td>
<td>Expression tree (in nodeToString() representation) for partial index predicate. Null if not a partial index.</td>
</tr>
</tbody>
</table>
The catalog `pg_inherits` records information about table and index inheritance hierarchies. There is one entry for each direct parent-child table or index relationship in the database. (Indirect inheritance can be determined by following chains of entries.)

**Table 53.27. pg_inherits Columns**

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inhrelid oid</td>
<td>The OID of the child table or index</td>
</tr>
<tr>
<td>inhparent oid</td>
<td>The OID of the parent table or index</td>
</tr>
<tr>
<td>inhseqno int4</td>
<td>If there is more than one direct parent for a child table (multiple inheritance), this number tells the order in which the inherited columns are to be arranged. The count starts at 1. Indexes cannot have multiple inheritance, since they can only inherit when using declarative partitioning.</td>
</tr>
<tr>
<td>inhdetachpending bool</td>
<td>true for a partition that is in the process of being detached; false otherwise.</td>
</tr>
</tbody>
</table>

53.28. **pg_init_prives**

The catalog `pg_init_prives` records information about the initial privileges of objects in the system. There is one entry for each object in the database which has a non-default (non-NULL) initial set of privileges.

Objects can have initial privileges either by having those privileges set when the system is initialized (by initdb) or when the object is created during a `CREATE EXTENSION` and the extension script sets initial privileges using the `GRANT` system. Note that the system will automatically handle recording of the privileges during the extension script and that extension authors need only use the `GRANT` and `REVOKE` statements in their script to have the privileges recorded. The `privtype` column indicates if the initial privilege was set by initdb or during a `CREATE EXTENSION` command.

Objects which have initial privileges set by initdb will have entries where `privtype` is 'i', while objects which have initial privileges set by `CREATE EXTENSION` will have entries where `privtype` is 'e'.

**Table 53.28. pg_init_prives Columns**

</tbody>
</table>

53.30. **pg_largeobject**

The catalog `pg_largeobject` holds the data making up “large objects”. A large object is identified by an OID assigned when it is created. Each large object is broken into segments or “pages” small enough to be conveniently stored as rows in `pg_largeobject`. The amount of data per page is defined to be `LOBLKSIZE` (which is currently `BLCKSZ/4`, or typically 2 kB).

Prior to PostgreSQL 9.0, there was no permission structure associated with large objects. As a result, `pg_largeobject` was publicly readable and could be used to obtain the OIDs (and contents) of all
large objects in the system. This is no longer the case; use \texttt{pg\_largeobject\_metadata} to obtain a list of large object OIDs.

Table 53.30. \texttt{pg\_largeobject} Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{loid} oid</td>
<td>Identifier of the large object that includes this page</td>
</tr>
<tr>
<td>\texttt{pageno} int4</td>
<td>Page number of this page within its large object (counting from zero)</td>
</tr>
<tr>
<td>\texttt{data} bytea</td>
<td>Actual data stored in the large object. This will never be more than \texttt{LOBLKSIZE} bytes and might be less.</td>
</tr>
</tbody>
</table>

Each row of \texttt{pg\_largeobject} holds data for one page of a large object, beginning at byte offset \((\texttt{pageno} \times \texttt{LOBLKSIZE})\) within the object. The implementation allows sparse storage: pages might be missing, and might be shorter than \texttt{LOBLKSIZE} bytes even if they are not the last page of the object. Missing regions within a large object read as zeroes.

53.31. \texttt{pg\_largeobject\_metadata}

The catalog \texttt{pg\_largeobject\_metadata} holds metadata associated with large objects. The actual large object data is stored in \texttt{pg\_largeobject}.

Table 53.31. \texttt{pg\_largeobject\_metadata} Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{oid} oid</td>

<td>Owner of the large object</td>
</tr>
<tr>
<td>\texttt{lomacl aclitem[]}</td>
<td>Access privileges; see Section 5.7 for details</td>
</tr>
</tbody>
</table>

53.32. \texttt{pg\_namespace}

The catalog \texttt{pg\_namespace} stores namespaces. A namespace is the structure underlying SQL schemas: each namespace can have a separate collection of relations, types, etc. without name conflicts.

Table 53.32. \texttt{pg\_namespace} Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>

<td>Owner of the namespace</td>
</tr>
<tr>
<td>nspacl aclitem[]</td>
<td>Access privileges; see Section 5.7 for details</td>
</tr>
</tbody>
</table>

#### 53.33. pg_opclass

The catalog **pg_opclass** defines index access method operator classes. Each operator class defines semantics for index columns of a particular data type and a particular index access method. An operator class essentially specifies that a particular operator family is applicable to a particular indexable column data type. The set of operators from the family that are actually usable with the indexed column are whichever ones accept the column's data type as their left-hand input.

Operator classes are described at length in Section 38.16.

**Table 53.33. pg_opclass Columns**

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>Row identifier</td>
</tr>
<tr>
<td>opcmethod oid</td>
<td>Index access method operator class is for</td>
</tr>
<tr>
<td>opcname name</td>
<td>Name of this operator class</td>
</tr>
<tr>
<td>opcnamespace oid</td>
<td>Namespace of this operator class</td>
</tr>
<tr>
<td>opcowner oid</td>
<td>Owner of the operator class</td>
</tr>
<tr>
<td>opcfamily oid</td>
<td>Operator family containing the operator class</td>
</tr>
<tr>
<td>opcintype oid</td>
<td>Data type that the operator class indexes</td>
</tr>
<tr>
<td>opcdefault bool</td>
<td>True if this operator class is the default for opcintype</td>
</tr>
<tr>
<td>opckeytype oid</td>
<td>Type of data stored in index, or zero if same as opcintype</td>
</tr>
</tbody>
</table>

An operator class's opcmethod must match the opfmethod of its containing operator family. Also, there must be no more than one pg_opclass row having opcdefault true for any given combination of opcmethod and opcintype.

#### 53.34. pg_operator

The catalog **pg_operator** stores information about operators. See CREATE OPERATOR and Section 38.14 for more information.
### Table 53.34. pg_operator Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid oid</td>
<td>Row identifier</td>
</tr>
<tr>
<td>oprname name</td>
<td>Name of the operator</td>
</tr>
<tr>
<td>oprnamespace oid</td>
<td>The OID of the namespace that contains this operator</td>
</tr>
<tr>
<td>oprowner oid</td>
<td>Owner of the operator</td>
</tr>
<tr>
<td>oprkind char</td>
<td>b = infix operator (&quot;both&quot;), or 1 = prefix operator (&quot;left&quot;)</td>
</tr>
<tr>
<td>oprcanmerge bool</td>
<td>This operator supports merge joins</td>
</tr>
<tr>
<td>oprcanhash bool</td>
<td>This operator supports hash joins</td>
</tr>
<tr>
<td>oprleft oid</td>
<td>Type of the left operand (zero for a prefix operator)</td>
</tr>
<tr>
<td>oprright oid</td>
<td>Type of the right operand</td>
</tr>
<tr>
<td>oprresult oid</td>
<td>Type of the result (zero for a not-yet-defined “shell” operator)</td>
</tr>
<tr>
<td>oprcom oid</td>
<td>Commutator of this operator (zero if none)</td>
</tr>
<tr>
<td>oprnegate oid</td>
<td>Negator of this operator (zero if none)</td>
</tr>
<tr>
<td>oprcode regproc</td>
<td>Function that implements this operator (zero for a not-yet-defined “shell” operator)</td>
</tr>
<tr>
<td>oprrest regproc</td>
<td>Restriction selectivity estimation function for this operator (zero if none)</td>
</tr>
<tr>
<td>oprjoin regproc</td>
<td>Join selectivity estimation function for this operator (zero if none)</td>
</tr>
</tbody>
</table>

53.35. pg_opfamily

The catalog pg_opfamily defines operator families. Each operator family is a collection of operators and associated support routines that implement the semantics specified for a particular index access method. Furthermore, the operators in a family are all “compatible”, in a way that is specified by the access method. The operator family concept allows cross-data-type operators to be used with indexes and to be reasoned about using knowledge of access method semantics.

Operator families are described at length in Section 38.16.
Table 53.35. pg_opfamily Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid oid</td>
<td>Row identifier</td>
</tr>
<tr>
<td>opfmethod oid (references pg_am.oid)</td>
<td>Index access method operator family is for</td>
</tr>
<tr>
<td>opfname name</td>
<td>Name of this operator family</td>
</tr>
<tr>
<td>opfnamespace oid (references pg_namespace.oid)</td>
<td>Namespace of this operator family</td>
</tr>
<tr>
<td>opfowner oid (references pg_authid.oid)</td>
<td>Owner of the operator family</td>
</tr>
</tbody>
</table>

The majority of the information defining an operator family is not in its pg_opfamily row, but in the associated rows in pg_amop, pg_amproc, and pg_opclass.

53.36. pg_parameter_acl

The catalog pg_parameter_acl records configuration parameters for which privileges have been granted to one or more roles. No entry is made for parameters that have default privileges.

Unlike most system catalogs, pg_parameter_acl is shared across all databases of a cluster: there is only one copy of pg_parameter_acl per cluster, not one per database.

Table 53.36. pg_parameter_acl Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid oid</td>
<td>Row identifier</td>
</tr>
<tr>
<td>parname text</td>
<td>The name of a configuration parameter for which privileges are granted</td>
</tr>
<tr>
<td>paracl aclitem[]</td>
<td>Access privileges; see Section 5.7 for details</td>
</tr>
</tbody>
</table>

53.37. pg_partitioned_table

The catalog pg_partitioned_table stores information about how tables are partitioned.

Table 53.37. pg_partitioned_table Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>partrelid oid (references pg_class.oid)</td>
<td>The OID of the pg_class entry for this partitioned table</td>
</tr>
<tr>
<td>partstrat char</td>
<td>Partitioning strategy; h = hash partitioned table, l = list partitioned table, r = range partitioned table</td>
</tr>
<tr>
<td>Column Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>partnatts int2</td>
<td>The number of columns in the partition key</td>
</tr>
<tr>
<td>partdefoid oid</td>
<td>The OID of the pg_class entry for the default partition of this partitioned table, or zero if this partitioned table does not have a default partition</td>
</tr>
<tr>
<td>partattrs int2vector</td>
<td>This is an array of partnatts values that indicate which table columns are part of the partition key. For example, a value of 1 3 would mean that the first and the third table columns make up the partition key. A zero in this array indicates that the corresponding partition key column is an expression, rather than a simple column reference.</td>
</tr>
<tr>
<td>partclass oidvector</td>
<td>For each column in the partition key, this contains the OID of the operator class to use. See pg_opclass for details.</td>
</tr>
<tr>
<td>partcollation oidvector</td>
<td>For each column in the partition key, this contains the OID of the collation to use for partitioning, or zero if the column is not of a collatable data type.</td>
</tr>
<tr>
<td>partexprs pg_node_tree</td>
<td>Expression trees (in nodeToString() representation) for partition key columns that are not simple column references. This is a list with one element for each zero entry in partattrs. Null if all partition key columns are simple references.</td>
</tr>
</tbody>
</table>

53.38. pg_policy

The catalog pg_policy stores row-level security policies for tables. A policy includes the kind of command that it applies to (possibly all commands), the roles that it applies to, the expression to be added as a security-barrier qualification to queries that include the table, and the expression to be added as a WITH CHECK option for queries that attempt to add new records to the table.

Table 53.38. pg_policy Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid oid</td>
<td>Row identifier</td>
</tr>
<tr>
<td>polname name</td>
<td>The name of the policy</td>
</tr>
<tr>
<td>polrelid oid</td>
<td>The table to which the policy applies</td>
</tr>
<tr>
<td>polcmd char</td>
<td>The command type to which the policy is applied: r for SELECT, a for INSERT, w for UPDATE, d for DELETE, or * for all</td>
</tr>
<tr>
<td>polpermissive bool</td>
<td>Is the policy permissive or restrictive?</td>
</tr>
<tr>
<td>polroles oid[]</td>
<td>The roles to which the policy is applied: zero means PUBLIC (and normally appears alone in the array)</td>
</tr>
<tr>
<td>Column Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>polqual pg_node_tree</td>
<td>The expression tree to be added to the security barrier qualifications for queries that use the table</td>
</tr>
<tr>
<td>polwithcheck pg_node_tree</td>
<td>The expression tree to be added to the WITH CHECK qualifications for queries that attempt to add rows to the table</td>
</tr>
</tbody>
</table>

**Note**

Policies stored in pg_policy are applied only when pg_class.relrowsecurity is set for their table.

**53.39. pg_proc**

The catalog pg_proc stores information about functions, procedures, aggregate functions, and window functions (collectively also known as routines). See CREATE FUNCTION, CREATE PROCEDURE, and Section 38.3 for more information.

If prokind indicates that the entry is for an aggregate function, there should be a matching row in pg_aggregate.

**Table 53.39. pg_proc Columns**

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid oid</td>
<td>Row identifier</td>
</tr>
<tr>
<td>proname name</td>
<td>Name of the function</td>
</tr>
<tr>
<td>pronamespace oid (references pg_namespace.oid)</td>
<td>The OID of the namespace that contains this function</td>
</tr>
<tr>
<td>proowner oid (references pg_authid.oid)</td>
<td>Owner of the function</td>
</tr>
<tr>
<td>prolang oid (references pg_language.oid)</td>
<td>Implementation language or call interface of this function</td>
</tr>
<tr>
<td>procost float4</td>
<td>Estimated execution cost (in units of cpu_operator_cost); if proretset, this is cost per row returned</td>
</tr>
<tr>
<td>prorows float4</td>
<td>Estimated number of result rows (zero if not proretset)</td>
</tr>
<tr>
<td>provariadic oid (references pg_type.oid)</td>
<td>Data type of the variadic array parameter's elements, or zero if the function does not have a variadic parameter</td>
</tr>
<tr>
<td>prosupport regproc (references pg_proc.oid)</td>
<td>Planner support function for this function (see Section 38.11), or zero if none</td>
</tr>
<tr>
<td><strong>Column Type</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>-----------------</td>
<td>----------------</td>
</tr>
<tr>
<td>prokind</td>
<td>char</td>
</tr>
<tr>
<td>f</td>
<td>for a normal function, p for a procedure, a for an aggregate function, or w for a window function</td>
</tr>
<tr>
<td>prosecdef</td>
<td>bool</td>
</tr>
<tr>
<td>Function is a security definer (i.e., a “setuid” function)</td>
<td></td>
</tr>
<tr>
<td>proleakproof</td>
<td>bool</td>
</tr>
<tr>
<td>The function has no side effects. No information about the arguments is conveyed except via the return value. Any function that might throw an error depending on the values of its arguments is not leak-proof.</td>
<td></td>
</tr>
<tr>
<td>proisstrict</td>
<td>bool</td>
</tr>
<tr>
<td>Function returns null if any call argument is null. In that case the function won't actually be called at all. Functions that are not “strict” must be prepared to handle null inputs.</td>
<td></td>
</tr>
<tr>
<td>proretset</td>
<td>bool</td>
</tr>
<tr>
<td>Function returns a set (i.e., multiple values of the specified data type)</td>
<td></td>
</tr>
<tr>
<td>provolatile</td>
<td>char</td>
</tr>
<tr>
<td>provolatile tells whether the function's result depends only on its input arguments, or is affected by outside factors. It is i for “immutable” functions, which always deliver the same result for the same inputs. It is s for “stable” functions, whose results (for fixed inputs) do not change within a scan. It is v for “volatile” functions, whose results might change at any time. (Use v also for functions with side-effects, so that calls to them cannot get optimized away.)</td>
<td></td>
</tr>
<tr>
<td>proparallel</td>
<td>char</td>
</tr>
<tr>
<td>proparallel tells whether the function can be safely run in parallel mode. It is s for functions which are safe to run in parallel mode without restriction. It is r for functions which can be run in parallel mode, but their execution is restricted to the parallel group leader; parallel worker processes cannot invoke these functions. It is u for functions which are unsafe in parallel mode; the presence of such a function forces a serial execution plan.</td>
<td></td>
</tr>
<tr>
<td>pronargs</td>
<td>int2</td>
</tr>
<tr>
<td>Number of input arguments</td>
<td></td>
</tr>
<tr>
<td>pronargdefaults</td>
<td>int2</td>
</tr>
<tr>
<td>Number of arguments that have defaults</td>
<td></td>
</tr>
<tr>
<td>prorettype</td>
<td>oid (references pg_type.oid)</td>
</tr>
<tr>
<td>Data type of the return value</td>
<td></td>
</tr>
<tr>
<td>proargtypes</td>
<td>oidvector (references pg_type.oid)</td>
</tr>
<tr>
<td>An array of the data types of the function arguments. This includes only input arguments (including INOUT and VARIADIC arguments), and thus represents the call signature of the function.</td>
<td></td>
</tr>
<tr>
<td>proallargtypes</td>
<td>oid[] (references pg_type.oid)</td>
</tr>
<tr>
<td>An array of the data types of the function arguments. This includes all arguments (including OUT and INOUT arguments); however, if all the arguments are IN arguments, this field will be null. Note that subscripting is 1-based, whereas for historical reasons proargtypes is subscripted from 0.</td>
<td></td>
</tr>
<tr>
<td>proargmodes</td>
<td>char[]</td>
</tr>
<tr>
<td>An array of the modes of the function arguments, encoded as i for IN arguments, o for OUT arguments, b for INOUT arguments, v for VARIADIC arguments, t for TABLE arguments.</td>
<td></td>
</tr>
</tbody>
</table>
System Catalogs

### Column Type

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proargnames text[]</td>
<td>An array of the names of the function arguments. Arguments without a name are set to empty strings in the array. If none of the arguments have a name, this field will be null. Note that subscripts correspond to positions of proallargtypes not proargtypes.</td>
</tr>
<tr>
<td>proargdefaults pg_node_tree</td>
<td>Expression trees (in nodeToString() representation) for default values. This is a list with proargdefaults elements, corresponding to the last ( N ) input arguments (i.e., the last ( N ) proargtypes positions). If none of the arguments have defaults, this field will be null.</td>
</tr>
<tr>
<td>protrftypes oid[] (references pg_type.oid)</td>
<td>An array of the argument/result data type(s) for which to apply transforms (from the function's TRANSFORM clause). Null if none.</td>
</tr>
<tr>
<td>prosrc text</td>
<td>This tells the function handler how to invoke the function. It might be the actual source code of the function for interpreted languages, a link symbol, a file name, or just about anything else, depending on the implementation language/call convention.</td>
</tr>
<tr>
<td>probin text</td>
<td>Additional information about how to invoke the function. Again, the interpretation is language-specific.</td>
</tr>
<tr>
<td>prosqlbody pg_node_tree</td>
<td>Pre-parsed SQL function body. This is used for SQL-language functions when the body is given in SQL-standard notation rather than as a string literal. It's null in other cases.</td>
</tr>
<tr>
<td>proconfig text[]</td>
<td>Function's local settings for run-time configuration variables</td>
</tr>
<tr>
<td>proacl aclitem[]</td>
<td>Access privileges; see Section 5.7 for details</td>
</tr>
</tbody>
</table>

For compiled functions, both built-in and dynamically loaded, prosrc contains the function's C-language name (link symbol). For SQL-language functions, prosrc contains the function's source text if that is specified as a string literal; but if the function body is specified in SQL-standard style, prosrc is unused (typically it's an empty string) and prosqlbody contains the pre-parsed definition. For all other currently-known language types, prosrc contains the function's source text. probin is null except for dynamically-loaded C functions, for which it gives the name of the shared library file containing the function.

### 53.40. pg_publication

The catalog pg_publication contains all publications created in the database. For more on publications see Section 31.1.

#### Table 53.40. pg_publication Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<tbody>
<tr>
<td>pubowner oid (references pg_authid.oid)</td>
<td>Owner of the publication</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>puballtables bool</td>
<td>If true, this publication automatically includes all tables in the database, including any that will be created in the future.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pubinsert bool</td>
<td>If true, INSERT operations are replicated for tables in the publication.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pubupdate bool</td>
<td>If true, UPDATE operations are replicated for tables in the publication.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pubdelete bool</td>
<td>If true, DELETE operations are replicated for tables in the publication.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pubtruncate bool</td>
<td>If true, TRUNCATE operations are replicated for tables in the publication.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pubviaroot bool</td>
<td>If true, operations on a leaf partition are replicated using the identity and schema of its top-most partitioned ancestor mentioned in the publication instead of its own.</td>
</tr>
</tbody>
</table>

#### 53.41. pg_publication_namespace

The catalog `pg_publication_namespace` contains the mapping between schemas and publications in the database. This is a many-to-many mapping.

**Table 53.41. pg_publication_namespace Columns**

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid oid</td>
<td>Row identifier</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pnpubid oid (references pg_publication.oid)</td>
<td>Reference to publication</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pnnspid oid (references pg_namespace.oid)</td>
<td>Reference to schema</td>
</tr>
</tbody>
</table>

#### 53.42. pg_publication_rel

The catalog `pg_publication_rel` contains the mapping between relations and publications in the database. This is a many-to-many mapping. See also Section 53.82 for a more user-friendly view of this information.

**Table 53.42. pg_publication_rel Columns**

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid oid</td>
<td></td>
</tr>
</tbody>
</table>
### System Catalogs

#### Column Type

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>prpubid oid</td>
<td>Reference to publication</td>
</tr>
<tr>
<td>prrelid oid</td>
<td>Reference to relation</td>
</tr>
<tr>
<td>prqual pg_node_tree</td>
<td>Expression tree (in nodeToString() representation) for the relation's publication qualifying condition.</td>
</tr>
<tr>
<td>prattrs int2vector</td>
<td>This is an array of values that indicates which table columns are part of the publication. For example, a value of 1 3 would mean that the first and the third table columns are published. A null value indicates that all columns are published.</td>
</tr>
</tbody>
</table>

#### 53.43. pg_range

The catalog `pg_range` stores information about range types. This is in addition to the types' entries in `pg_type`.

**Table 53.43. pg_range Columns**

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rngtypid oid</td>
<td>OID of the range type</td>
</tr>
<tr>
<td>rngsubtype oid</td>
<td>OID of the element type (subtype) of this range type</td>
</tr>
<tr>
<td>rngmultitypid oid</td>
<td>OID of the multirange type for this range type</td>
</tr>
<tr>
<td>rngcollation oid</td>
<td>OID of the collation used for range comparisons, or zero if none</td>
</tr>
<tr>
<td>rngsubopcid</td>
<td>OID of the subtype's operator class used for range comparisons</td>
</tr>
<tr>
<td>rngcanonical regproc</td>
<td>OID of the function to convert a range value into canonical form, or zero if none</td>
</tr>
<tr>
<td>rngsubdiff regproc</td>
<td>OID of the function to return the difference between two element values as double precision, or zero if none</td>
</tr>
</tbody>
</table>

`rngsubopcid` (plus `rngcollation`, if the element type is collatable) determines the sort ordering used by the range type. `rngcanonical` is used when the element type is discrete. `rngsubdiff` is optional but should be supplied to improve performance of GiST indexes on the range type.

#### 53.44. pg_replication_origin

The `pg_replication_origin` catalog contains all replication origins created. For more on replication origins see Chapter 50.
Unlike most system catalogs, `pg_replication_origin` is shared across all databases of a cluster: there is only one copy of `pg_replication_origin` per cluster, not one per database.

**Table 53.44. `pg_replication_origin` Columns**

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>roident</code> oid</td>
<td>A unique, cluster-wide identifier for the replication origin. Should never leave the system.</td>
</tr>
<tr>
<td><code>roname</code> text</td>
<td>The external, user defined, name of a replication origin.</td>
</tr>
</tbody>
</table>

**53.45. `pg_rewrite`**

The catalog `pg_rewrite` stores rewrite rules for tables and views.

**Table 53.45. `pg_rewrite` Columns**

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>oid</code> oid</td>
<td>Row identifier</td>
</tr>
<tr>
<td><code>rulename</code> name</td>
<td>Rule name</td>
</tr>
<tr>
<td><code>ev_class</code> oid (references <code>pg_class.oid</code>)</td>
<td>The table this rule is for</td>
</tr>
<tr>
<td><code>ev_type</code> char</td>
<td>Event type that the rule is for: 1 = SELECT, 2 = UPDATE, 3 = INSERT, 4 = DELETE</td>
</tr>
<tr>
<td><code>ev_enabled</code> char</td>
<td>Controls in which session_replication_role modes the rule fires. O = rule fires in “origin” and “local” modes, D = rule is disabled, R = rule fires in “replica” mode, A = rule fires always.</td>
</tr>
<tr>
<td><code>is_instead</code> bool</td>
<td>True if the rule is an INSTEAD rule</td>
</tr>
<tr>
<td><code>ev_qual</code> <code>pg_node_tree</code></td>
<td>Expression tree (in the form of a <code>nodeToString()</code> representation) for the rule's qualifying condition</td>
</tr>
<tr>
<td><code>ev_action</code> <code>pg_node_tree</code></td>
<td>Query tree (in the form of a <code>nodeToString()</code> representation) for the rule's action</td>
</tr>
</tbody>
</table>

**Note**

`pg_class.relhasrules` must be true if a table has any rules in this catalog.

**53.46. `pg_seclabel`**

The catalog `pg_seclabel` stores security labels on database objects. Security labels can be manipulated with the `SECURITY LABEL` command. For an easier way to view security labels, see Section 53.87.
See also `pg_shseclabel`, which performs a similar function for security labels of database objects that are shared across a database cluster.

### Table 53.46. `pg_seclabel` Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>objoid oid</code></td>
<td>(references any OID column) The OID of the object this security label pertains to</td>
</tr>
<tr>
<td><code>classoid oid</code></td>
<td>(references <code>pg_class.oid</code>) The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td><code>objsubid int4</code></td>
<td>For a security label on a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td><code>provider text</code></td>
<td>The label provider associated with this label.</td>
</tr>
<tr>
<td><code>label text</code></td>
<td>The security label applied to this object.</td>
</tr>
</tbody>
</table>

### 53.47. `pg_sequence`

The catalog `pg_sequence` contains information about sequences. Some of the information about sequences, such as the name and the schema, is in `pg_class`.

### Table 53.47. `pg_sequence` Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>seqrelid oid</code></td>
<td>(references <code>pg_class.oid</code>) The OID of the <code>pg_class</code> entry for this sequence</td>
</tr>
<tr>
<td><code>seqtypid oid</code></td>
<td>(references <code>pg_type.oid</code>) Data type of the sequence</td>
</tr>
<tr>
<td><code>seqstart int8</code></td>
<td>Start value of the sequence</td>
</tr>
<tr>
<td><code>seqincrement int8</code></td>
<td>Increment value of the sequence</td>
</tr>
<tr>
<td><code>seqmax int8</code></td>
<td>Maximum value of the sequence</td>
</tr>
<tr>
<td><code>seqmin int8</code></td>
<td>Minimum value of the sequence</td>
</tr>
<tr>
<td><code>seqcache int8</code></td>
<td>Cache size of the sequence</td>
</tr>
<tr>
<td><code>seqcycle bool</code></td>
<td>Whether the sequence cycles</td>
</tr>
</tbody>
</table>

### 53.48. `pg_shdepend`
The catalog `pg_shdepend` records the dependency relationships between database objects and shared objects, such as roles. This information allows PostgreSQL to ensure that those objects are unreferenced before attempting to delete them.

See also `pg_depend`, which performs a similar function for dependencies involving objects within a single database.

Unlike most system catalogs, `pg_shdepend` is shared across all databases of a cluster: there is only one copy of `pg_shdepend` per cluster, not one per database.

**Table 53.48. pg_shdepend Columns**

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbid oid (references pg_database.oid)</td>
<td>The OID of the database the dependent object is in, or zero for a shared object</td>
</tr>
<tr>
<td>classid oid (references pg_class.oid)</td>
<td>The OID of the system catalog the dependent object is in</td>
</tr>
<tr>
<td>objid oid (references any OID column)</td>
<td>The OID of the specific dependent object</td>
</tr>
<tr>
<td>objsubid int4</td>
<td>For a table column, this is the column number (the objid and classid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>refclassid oid (references pg_class.oid)</td>
<td>The OID of the system catalog the referenced object is in (must be a shared catalog)</td>
</tr>
<tr>
<td>refobjid oid (references any OID column)</td>
<td>The OID of the specific referenced object</td>
</tr>
<tr>
<td>deptype char</td>
<td>A code defining the specific semantics of this dependency relationship; see text</td>
</tr>
</tbody>
</table>

In all cases, a `pg_shdepend` entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by deptype:

**SHARED_DEPENDENCY_OWNER (o)**

The referenced object (which must be a role) is the owner of the dependent object.

**SHARED_DEPENDENCY_ACL (a)**

The referenced object (which must be a role) is mentioned in the ACL (access control list, i.e., privileges list) of the dependent object. (A `SHARED_DEPENDENCY_ACL` entry is not made for the owner of the object, since the owner will have a `SHARED_DEPENDENCY_OWNER` entry anyway.)

**SHARED_DEPENDENCY_POLICY (r)**

The referenced object (which must be a role) is mentioned as the target of a dependent policy object.

**SHARED_DEPENDENCY_TABLESPACE (t)**

The referenced object (which must be a tablespace) is mentioned as the tablespace for a relation that doesn't have storage.
Other dependency flavors might be needed in future. Note in particular that the current definition only supports roles and tablespaces as referenced objects.

As in the `pg_depend` catalog, most objects created during initdb are considered “pinned”. No entries are made in `pg_shdepend` that would have a pinned object as either referenced or dependent object.

### 53.49. `pg_shdescription`

The catalog `pg_shdescription` stores optional descriptions (comments) for shared database objects. Descriptions can be manipulated with the `COMMENT` command and viewed with psql's `\d` commands.

See also `pg_description`, which performs a similar function for descriptions involving objects within a single database.

Unlike most system catalogs, `pg_shdescription` is shared across all databases of a cluster: there is only one copy of `pg_shdescription` per cluster, not one per database.

#### Table 53.49. `pg_shdescription` Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>objoid oid</code></td>
<td>OID of the object this description pertains to</td>
</tr>
<tr>
<td><code>classoid oid</code></td>
<td>OID of the system catalog this object appears in</td>
</tr>
<tr>
<td><code>description</code></td>
<td>Arbitrary text that serves as the description of this object</td>
</tr>
</tbody>
</table>

### 53.50. `pg_shseclabel`

The catalog `pg_shseclabel` stores security labels on shared database objects. Security labels can be manipulated with the `SECURITY LABEL` command. For an easier way to view security labels, see Section 53.87.

See also `pg_seclabel`, which performs a similar function for security labels involving objects within a single database.

Unlike most system catalogs, `pg_shseclabel` is shared across all databases of a cluster: there is only one copy of `pg_shseclabel` per cluster, not one per database.

#### Table 53.50. `pg_shseclabel` Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>objoid oid</code></td>
<td>OID of the object this security label pertains to</td>
</tr>
<tr>
<td><code>classoid oid</code></td>
<td>OID of the system catalog this object appears in</td>
</tr>
<tr>
<td><code>provider</code></td>
<td>The label provider associated with this label.</td>
</tr>
</tbody>
</table>
System Catalogs

53.51. pg_statistic

The catalog pg_statistic stores statistical data about the contents of the database. Entries are created by ANALYZE and subsequently used by the query planner. Note that all the statistical data is inherently approximate, even assuming that it is up-to-date.

Normally there is one entry, with stainherit = false, for each table column that has been analyzed. If the table has inheritance children, a second entry with stainherit = true is also created. This row represents the column's statistics over the inheritance tree, i.e., statistics for the data you'd see with SELECT column FROM table*, whereas the stainherit = false row represents the results of SELECT column FROM ONLY table.

pg_statistic also stores statistical data about the values of index expressions. These are described as if they were actual data columns; in particular, starelid references the index. No entry is made for an ordinary non-expression index column, however, since it would be redundant with the entry for the underlying table column. Currently, entries for index expressions always have stainherit = false.

Since different kinds of statistics might be appropriate for different kinds of data, pg_statistic is designed not to assume very much about what sort of statistics it stores. Only extremely general statistics (such as nullness) are given dedicated columns in pg_statistic. Everything else is stored in “slots”, which are groups of associated columns whose content is identified by a code number in one of the slot’s columns. For more information see src/include/catalog/pg_statistic.h.

pg_statistic should not be readable by the public, since even statistical information about a table's contents might be considered sensitive. (Example: minimum and maximum values of a salary column might be quite interesting.) pg_stats is a publicly readable view on pg_statistic that only exposes information about those tables that are readable by the current user.

Table 53.51. pg_statistic Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>starelid oid</td>
<td>(references pg_class.oid) The table or index that the described column belongs to</td>
</tr>
<tr>
<td>staattnum int2</td>
<td>(references pg_attribute.attnum) The number of the described column</td>
</tr>
<tr>
<td>stainherit bool</td>
<td>If true, the stats include inheritance child columns, not just the values in the specified relation</td>
</tr>
<tr>
<td>stanullfrac float4</td>
<td>The fraction of the column's entries that are null</td>
</tr>
<tr>
<td>stawidth int4</td>
<td>The average stored width, in bytes, of nonnull entries</td>
</tr>
<tr>
<td>stadistinct float4</td>
<td>The number of distinct nonnull data values in the column. A value greater than zero is the actual number of distinct values. A value less than zero is the negative of a multiplier for</td>
</tr>
</tbody>
</table>
### System Catalogs

#### Column Type

<table>
<thead>
<tr>
<th>Description</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Column Type</td>
<td>Description</td>
</tr>
<tr>
<td></td>
<td>the number of rows in the table; for example, a column in which about 80% of the values are nonnull and each nonnull value appears about twice on average could be represented by <code>stadistinct = -0.4</code>. A zero value means the number of distinct values is unknown.</td>
</tr>
</tbody>
</table>

| `stakind` int2 | A code number indicating the kind of statistics stored in the \( M \)th “slot” of the `pg_statistic` row. |
| `staop` oid (references `pg_operator`.oid) | An operator used to derive the statistics stored in the \( M \)th “slot”. For example, a histogram slot would show the \(<\) operator that defines the sort order of the data. Zero if the statistics kind does not require an operator. |
| `stacoll` oid (references `pg_collation`.oid) | The collation used to derive the statistics stored in the \( M \)th “slot”. For example, a histogram slot for a collatable column would show the collation that defines the sort order of the data. Zero for noncollatable data. |
| `stanumbers` float4[] | Numerical statistics of the appropriate kind for the \( M \)th “slot”, or null if the slot kind does not involve numerical values |
| `stavalues` anyarray | Column data values of the appropriate kind for the \( M \)th “slot”, or null if the slot kind does not store any data values. Each array’s element values are actually of the specific column’s data type, or a related type such as an array’s element type, so there is no way to define these columns’ type more specifically than `anyarray`. |

#### 53.52. `pg_statistic_ext`

The catalog `pg_statistic_ext` holds definitions of extended planner statistics. Each row in this catalog corresponds to a `statistics object` created with `CREATE STATISTICS`.

*Table 53.52. `pg_statistic_ext` Columns*

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>oid</code> oid</td>
<td>Row identifier</td>
</tr>
<tr>
<td><code>stxrelid</code> oid (references <code>pg_class</code>.oid)</td>
<td>Table containing the columns described by this object</td>
</tr>
<tr>
<td><code>stxname</code> name</td>
<td>Name of the statistics object</td>
</tr>
<tr>
<td><code>stxnamespace</code> oid (references <code>pg_namespace</code>.oid)</td>
<td>The OID of the namespace that contains this statistics object</td>
</tr>
<tr>
<td><code>stxowner</code> oid (references <code>pg_authid</code>.oid)</td>
<td>Owner of the statistics object</td>
</tr>
<tr>
<td><code>stxstattarget</code> int4</td>
<td><code>stxstattarget</code> controls the level of detail of statistics accumulated for this statistics object by <code>ANALYZE</code>. A zero value indicates that no statistics should be collected. A negative value says to use the maximum of the statistics targets of the referenced columns, if set, or</td>
</tr>
</tbody>
</table>
The system default statistics target. Positive values of \texttt{stxstatattarget} determine the target number of “most common values” to collect.

\texttt{stxkeys int2vector (references pg_attribute.attnum)}

An array of attribute numbers, indicating which table columns are covered by this statistics object; for example a value of 1 3 would mean that the first and the third table columns are covered.

\texttt{stxkind char[]}  

An array containing codes for the enabled statistics kinds; valid values are: \texttt{d} for n-distinct statistics, \texttt{f} for functional dependency statistics, \texttt{m} for most common values (MCV) list statistics, and \texttt{e} for expression statistics.

\texttt{stxexprs pg_node_tree}

Expression trees (in \texttt{nodeToString()} representation) for statistics object attributes that are not simple column references. This is a list with one element per expression. Null if all statistics object attributes are simple references.

The \texttt{pg_statistic_ext} entry is filled in completely during \texttt{CREATE STATISTICS}, but the actual statistical values are not computed then. Subsequent \texttt{ANALYZE} commands compute the desired values and populate an entry in the \texttt{pg_statistic_ext_data} catalog.

### 53.53. \texttt{pg_statistic_ext_data}

The catalog \texttt{pg_statistic_ext_data} holds data for extended planner statistics defined in \texttt{pg_statistic_ext}. Each row in this catalog corresponds to a statistics object created with \texttt{CREATE STATISTICS}.

Normally there is one entry, with \texttt{stxdinherit = false}, for each statistics object that has been analyzed. If the table has inheritance children, a second entry with \texttt{stxdinherit = true} is also created. This row represents the statistics object over the inheritance tree, i.e., statistics for the data you’d see with \texttt{SELECT * FROM table*}, whereas the \texttt{stxdinherit = false} row represents the results of \texttt{SELECT * FROM ONLY table}.

Like \texttt{pg_statistic}, \texttt{pg_statistic_ext_data} should not be readable by the public, since the contents might be considered sensitive. (Example: most common combinations of values in columns might be quite interesting.) \texttt{pg_stats_ext} is a publicly readable view on \texttt{pg_statistic_ext_data} (after joining with \texttt{pg_statistic_ext}) that only exposes information about those tables and columns that are readable by the current user.

### Table 53.53. \texttt{pg_statistic_ext_data} Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{stxoid oid (references pg_statistic_ext.oid)}</td>
<td>Extended statistics object containing the definition for this data</td>
</tr>
<tr>
<td>\texttt{stxdinherit bool}</td>
<td>If true, the stats include inheritance child columns, not just the values in the specified relation</td>
</tr>
<tr>
<td>\texttt{stxdndistinct pg_ndistinct}</td>
<td>N-distinct counts, serialized as \texttt{pg_ndistinct} type</td>
</tr>
<tr>
<td>\texttt{stxddependencies pg_dependencies}</td>
<td>Functional dependency statistics, serialized as \texttt{pg_dependencies} type</td>
</tr>
</tbody>
</table>
### System Catalogs

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stxdmcv pg_mcv_list</td>
<td>MCV (most-common values) list statistics, serialized as pg_mcv_list type</td>
</tr>
<tr>
<td>stxexpr pg_statistic[]</td>
<td>Per-expression statistics, serialized as an array of pg_statistic type</td>
</tr>
</tbody>
</table>

### 53.54. **pg_subscription**

The catalog `pg_subscription` contains all existing logical replication subscriptions. For more information about logical replication see Chapter 31.

Unlike most system catalogs, `pg_subscription` is shared across all databases of a cluster: there is only one copy of `pg_subscription` per cluster, not one per database.

Access to the column `subconninfo` is revoked from normal users, because it could contain plain-text passwords.

#### Table 53.54. **pg_subscription** Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>Row identifier</td>
</tr>
<tr>
<td>subdbid oid (references pg_database.oid)</td>
<td>OID of the database that the subscription resides in</td>
</tr>
<tr>
<td>subskiplsn pg_lsn</td>
<td>Finish LSN of the transaction whose changes are to be skipped, if a valid LSN; otherwise 0/0.</td>
</tr>
<tr>
<td>subname name</td>
<td>Name of the subscription</td>
</tr>
<tr>
<td>subowner oid (references pg_authid.oid)</td>
<td>Owner of the subscription</td>
</tr>
<tr>
<td>subenabled bool</td>
<td>If true, the subscription is enabled and should be replicating</td>
</tr>
<tr>
<td>subbinary bool</td>
<td>If true, the subscription will request that the publisher send data in binary format</td>
</tr>
<tr>
<td>substream bool</td>
<td>If true, the subscription will allow streaming of in-progress transactions</td>
</tr>
<tr>
<td>subtwophase state char</td>
<td>State codes for two-phase mode: d = disabled, p = pending enablement, e = enabled</td>
</tr>
<tr>
<td>subdisableonerr bool</td>
<td>If true, the subscription will be disabled if one of its workers detects an error</td>
</tr>
<tr>
<td>subconninfo text</td>
<td>Connection string to the upstream database</td>
</tr>
<tr>
<td>subslotname name</td>
<td>Name of the replication slot in the upstream database (also used for the local replication origin name); null represents NONE</td>
</tr>
<tr>
<td>Column Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------</td>
</tr>
<tr>
<td>subsynccommit</td>
<td>text</td>
</tr>
<tr>
<td>subpublications</td>
<td>text[]</td>
</tr>
</tbody>
</table>

### 53.55. pg_subscription_rel

The catalog pg_subscription_rel contains the state for each replicated relation in each subscription. This is a many-to-many mapping.

This catalog only contains tables known to the subscription after running either CREATE SUBSCRIPTION or ALTER SUBSCRIPTION ... REFRESH PUBLICATION.

#### Table 53.55. pg_subscription_rel Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>srsubid</td>
<td>oid (references pg_subscription.oid)</td>
</tr>
<tr>
<td>srrelid</td>
<td>oid (references pg_class.oid)</td>
</tr>
<tr>
<td>srsubstate</td>
<td>char</td>
</tr>
<tr>
<td>srsublsn</td>
<td>pg_lsn</td>
</tr>
</tbody>
</table>

### 53.56. pg_tablespace

The catalog pg_tablespace stores information about the available tablespaces. Tables can be placed in particular tablespaces to aid administration of disk layout.

Unlike most system catalogs, pg_tablespace is shared across all databases of a cluster: there is only one copy of pg_tablespace per cluster, not one per database.

#### Table 53.56. pg_tablespace Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
</tr>
<tr>
<td>spcname</td>
<td>name</td>
</tr>
<tr>
<td>spcowner</td>
<td>oid (references pg_authid.oid)</td>
</tr>
<tr>
<td>Column Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>----------------------------------------------------------</td>
</tr>
<tr>
<td>spcacl aclitem[]</td>
<td>Access privileges; see Section 5.7 for details</td>
</tr>
<tr>
<td>spcoptions text[]</td>
<td>Tablespace-level options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

### 53.57. pg_transform

The catalog `pg_transform` stores information about transforms, which are a mechanism to adapt data types to procedural languages. See CREATE TRANSFORM for more information.

#### Table 53.57. pg_transform Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid oid</td>
<td>Row identifier</td>
</tr>
<tr>
<td>trftype oid (references pg_type.oid)</td>
<td>OID of the data type this transform is for</td>
</tr>
<tr>
<td>trflang oid (references pg_language.oid)</td>
<td>OID of the language this transform is for</td>
</tr>
<tr>
<td>trffromsql regproc (references pg_proc.oid)</td>
<td>The OID of the function to use when converting the data type for input to the procedural language (e.g., function parameters). Zero is stored if the default behavior should be used.</td>
</tr>
<tr>
<td>trftosql regproc (references pg_proc.oid)</td>
<td>The OID of the function to use when converting output from the procedural language (e.g., return values) to the data type. Zero is stored if the default behavior should be used.</td>
</tr>
</tbody>
</table>

### 53.58. pg_trigger

The catalog `pg_trigger` stores triggers on tables and views. See CREATE TRIGGER for more information.

#### Table 53.58. pg_trigger Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid oid</td>
<td>Row identifier</td>
</tr>
<tr>
<td>tgrelid oid (references pg_class.oid)</td>
<td>The table this trigger is on</td>
</tr>
<tr>
<td>tgparentid oid (references pg_trigger.oid)</td>
<td>Parent trigger that this trigger is cloned from (this happens when partitions are created or attached to a partitioned table); zero if not a clone</td>
</tr>
<tr>
<td>tgnname name</td>
<td>Trigger name (must be unique among triggers of same table)</td>
</tr>
<tr>
<td>Column Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------</td>
</tr>
<tr>
<td>tgfoid oid</td>
<td>oid (references pg_proc.oid) The function to be called</td>
</tr>
<tr>
<td>tgtype int2</td>
<td>Bit mask identifying trigger firing conditions</td>
</tr>
<tr>
<td>tgenabled char</td>
<td>Controls in which session replication role modes the trigger fires. O = trigger fires in “origin” and “local” modes, D = trigger is disabled, R = trigger fires in “replica” mode, A = trigger fires always.</td>
</tr>
<tr>
<td>tgisinternal bool</td>
<td>True if trigger is internally generated (usually, to enforce the constraint identified by tgconstraint)</td>
</tr>
<tr>
<td>tgconstrrelid oid</td>
<td>oid (references pg_class.oid) The table referenced by a referential integrity constraint (zero if trigger is not for a referential integrity constraint)</td>
</tr>
<tr>
<td>tgconstrindid oid</td>
<td>oid (references pg_class.oid) The index supporting a unique, primary key, referential integrity, or exclusion constraint (zero if trigger is not for one of these types of constraint)</td>
</tr>
<tr>
<td>tgconstraint oid</td>
<td>oid (references pg_constraint.oid) The pg_constraint entry associated with the trigger (zero if trigger is not for a constraint)</td>
</tr>
<tr>
<td>tgdeferrable bool</td>
<td>True if constraint trigger is deferrable</td>
</tr>
<tr>
<td>tginitdeferred bool</td>
<td>True if constraint trigger is initially deferred</td>
</tr>
<tr>
<td>tgnargs int2</td>
<td>Number of argument strings passed to trigger function</td>
</tr>
<tr>
<td>tgattr int2vector</td>
<td>(references pg_attribute.attnum) Column numbers, if trigger is column-specific; otherwise an empty array</td>
</tr>
<tr>
<td>tgargs bytea</td>
<td>Argument strings to pass to trigger, each NULL-terminated</td>
</tr>
<tr>
<td>tgqual pg_node_tree</td>
<td>Expression tree (in nodeToString() representation) for the trigger’s WHEN condition, or null if none</td>
</tr>
<tr>
<td>tgoldtable name</td>
<td>REFERENCING clause name for OLD_TABLE, or null if none</td>
</tr>
<tr>
<td>tgnewtable name</td>
<td>REFERENCING clause name for NEW_TABLE, or null if none</td>
</tr>
</tbody>
</table>

Currently, column-specific triggering is supported only for UPDATE events, and so tgattr is relevant only for that event type. tgtype might contain bits for other event types as well, but those are presumed to be table-wide regardless of what is in tgattr.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>When tgconstraint is nonzero, tgconstrrelid, tgconstrindid, tgdeferrable, and tginitdeferred are largely redundant with the referenced pg_constraint entry.</td>
</tr>
</tbody>
</table>
However, it is possible for a non-deferrable trigger to be associated with a deferrable constraint: foreign key constraints can have some deferrable and some non-deferrable triggers.

Note

pg_class.relhastriggers must be true if a relation has any triggers in this catalog.

53.59. pg_ts_config

The pg_ts_config catalog contains entries representing text search configurations. A configuration specifies a particular text search parser and a list of dictionaries to use for each of the parser's output token types. The parser is shown in the pg_ts_config entry, but the token-to-dictionary mapping is defined by subsidiary entries in pg_ts_config_map.

PostgreSQL's text search features are described at length in Chapter 12.

Table 53.59. pg_ts_config Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
</tr>
<tr>
<td>cfgname</td>
<td>name</td>
</tr>
<tr>
<td>cfgnamespace</td>
<td>oid (references pg_namespace.oid)</td>
</tr>
<tr>
<td>cfgowner</td>
<td>oid (references pg_authid.oid)</td>
</tr>
<tr>
<td>cfgparser</td>
<td>oid (references pg_ts_parser.oid)</td>
</tr>
</tbody>
</table>

53.60. pg_ts_config_map

The pg_ts_config_map catalog contains entries showing which text search dictionaries should be consulted, and in what order, for each output token type of each text search configuration's parser.

PostgreSQL's text search features are described at length in Chapter 12.

Table 53.60. pg_ts_config_map Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mapcfg</td>
<td>oid (references pg_ts_config.oid)</td>
</tr>
<tr>
<td>mapTokenType</td>
<td>int4</td>
</tr>
</tbody>
</table>
53.61. pg_ts_dict

The pg_ts_dict catalog contains entries defining text search dictionaries. A dictionary depends on a text search template, which specifies all the implementation functions needed; the dictionary itself provides values for the user-settable parameters supported by the template. This division of labor allows dictionaries to be created by unprivileged users. The parameters are specified by a text string dictinitoption, whose format and meaning vary depending on the template.

PostgreSQL’s text search features are described at length in Chapter 12.

Table 53.61. pg_ts_dict Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
</tr>
<tr>
<td>dictname</td>
<td>name</td>
</tr>
<tr>
<td>dictnamespace</td>
<td>oid (references pg_namespace.oid)</td>
</tr>
<tr>
<td>dictowner</td>
<td>oid (references pg_authid.oid)</td>
</tr>
<tr>
<td>dicttemplate</td>
<td>oid (references pg_ts_template.oid)</td>
</tr>
<tr>
<td>dictinitoption</td>
<td>text</td>
</tr>
</tbody>
</table>

53.62. pg_ts_parser

The pg_ts_parser catalog contains entries defining text search parsers. A parser is responsible for splitting input text into lexemes and assigning a token type to each lexeme. Since a parser must be implemented by C-language-level functions, creation of new parsers is restricted to database superusers.

PostgreSQL’s text search features are described at length in Chapter 12.

Table 53.62. pg_ts_parser Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
</tr>
</tbody>
</table>
The `pg_ts_template` catalog contains entries defining text search templates. A template is the implementation skeleton for a class of text search dictionaries. Since a template must be implemented by C-language-level functions, creation of new templates is restricted to database superusers.

PostgreSQL's text search features are described at length in Chapter 12.

**Table 53.63. pg_ts_template Columns**

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid oid</td>
<td>Row identifier</td>
</tr>
<tr>
<td>tmplname name</td>
<td>Text search template name</td>
</tr>
<tr>
<td>tmplnamespace oid (references pg_namespace.oid)</td>
<td>The OID of the namespace that contains this template</td>
</tr>
<tr>
<td>tmplinit regproc (references pg_proc.oid)</td>
<td>OID of the template's initialization function (zero if none)</td>
</tr>
<tr>
<td>tmpllexize regproc (references pg_proc.oid)</td>
<td>OID of the template's lexize function</td>
</tr>
</tbody>
</table>

The catalog `pg_type` stores information about data types. Base types and enum types (scalar types) are created with `CREATE TYPE`, and domains with `CREATE DOMAIN`. A composite type is automatically created for each table in the database, to represent the row structure of the table. It is also possible to create composite types with `CREATE TYPE AS`.

2382
### Table 53.64. pg_type Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid oid</td>
<td>Row identifier</td>
</tr>
<tr>
<td>typhname name</td>
<td>Data type name</td>
</tr>
<tr>
<td>typnamespace oid (references pg_namespace.oid)</td>
<td>The OID of the namespace that contains this type</td>
</tr>
<tr>
<td>typowner oid (references pg_authid.oid)</td>
<td>Owner of the type</td>
</tr>
<tr>
<td>typlen int2</td>
<td>For a fixed-size type, typlen is the number of bytes in the internal representation of the type. But for a variable-length type, typlen is negative. -1 indicates a &quot;varlena&quot; type (one that has a length word), -2 indicates a null-terminated C string.</td>
</tr>
<tr>
<td>typbyval bool</td>
<td>typbyval determines whether internal routines pass a value of this type by value or by reference. typbyval had better be false if typlen is not 1, 2, or 4 (or 8 on machines where Datum is 8 bytes). Variable-length types are always passed by reference. Note that typbyval can be false even if the length would allow pass-by-value.</td>
</tr>
<tr>
<td>typtype char</td>
<td>typtype is b for a base type, c for a composite type (e.g., a table's row type), d for a domain, e for an enum type, p for a pseudo-type, r for a range type, or m for a multirange type. See also typrelid and typbasetype.</td>
</tr>
<tr>
<td>typcategory char</td>
<td>typcategory is an arbitrary classification of data types that is used by the parser to determine which implicit casts should be “preferred”. See Table 53.65.</td>
</tr>
<tr>
<td>typispreferred bool</td>
<td>True if the type is a preferred cast target within its typcategory</td>
</tr>
<tr>
<td>typisdefined bool</td>
<td>True if the type is defined, false if this is a placeholder entry for a not-yet-defined type. When typisdefined is false, nothing except the type name, namespace, and OID can be relied on.</td>
</tr>
<tr>
<td>typdelim char</td>
<td>Character that separates two values of this type when parsing array input. Note that the delimiter is associated with the array element data type, not the array data type.</td>
</tr>
<tr>
<td>typrelid oid (references pg_class.oid)</td>
<td>If this is a composite type (see typtype), then this column points to the pg_class entry that defines the corresponding table. (For a free-standing composite type, the pg_class entry doesn't really represent a table, but it is needed anyway for the type's pg_attribute entries to link to.) Zero for non-composite types.</td>
</tr>
<tr>
<td>typsubscript regproc (references pg_proc.oid)</td>
<td>Subscripting handler function's OID, or zero if this type doesn't support subscripting. Types that are &quot;true&quot; array types have typsubscript = array_subscript_handler, but other types may have other handler functions to implement specialized subscripting behavior.</td>
</tr>
<tr>
<td>typelem oid (references pg_type.oid)</td>
<td></td>
</tr>
</tbody>
</table>
### Column Type Description

If `typelem` is not zero then it identifies another row in `pg_type`, defining the type yielded by subscripting. This should be zero if `typsubscript` is zero. However, it can be zero when `typsubscript` isn't zero, if the handler doesn't need `typelem` to determine the subscripting result type. Note that a `typelem` dependency is considered to imply physical containment of the element type in this type; so DDL changes on the element type might be restricted by the presence of this type.

<tr>
<td><code>typanalyze regproc</code></td>
<td>(references <code>pg_proc.oid</code>)</td>
</tr>
</tbody>
</table>

**typalign char**

`typalign` is the alignment required when storing a value of this type. It applies to storage on disk as well as most representations of the value inside PostgreSQL. When multiple values are stored consecutively, such as in the representation of a complete row on disk, padding is inserted before a datum of this type so that it begins on the specified boundary. The alignment reference is the beginning of the first datum in the sequence. Possible values are:

- `c` = char alignment, i.e., no alignment needed.
- `s` = short alignment (2 bytes on most machines).
- `i` = int alignment (4 bytes on most machines).
- `d` = double alignment (8 bytes on many machines, but by no means all).

**typstorage char**

`typstorage` tells for varlena types (those with `typlen = -1`) if the type is prepared for toasting and what the default strategy for attributes of this type should be. Possible values are:

- `p` (plain): Values must always be stored plain (non-varlena types always use this value).
- `e` (external): Values can be stored in a secondary “TOAST” relation (if relation has one, see `pg_class.reltoastrelid`).
- `m` (main): Values can be compressed and stored inline.
<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <code>x</code> (extended): Values can be compressed and/or moved to a secondary relation.</td>
</tr>
<tr>
<td></td>
<td><code>x</code> is the usual choice for toast-able types. Note that <code>m</code> values can also be moved out to secondary storage, but only as a last resort (<code>e</code> and <code>x</code> values are moved first).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>typnotnull bool</th>
<th>Represents a not-null constraint on a type. Used for domains only.</th>
</tr>
</thead>
<tbody>
<tr>
<td>typbasetype oid</td>
<td>(references pg_type.oid) If this is a domain (see typtype), then typbasetype identifies the type that this one is based on. Zero if this type is not a domain.</td>
</tr>
<tr>
<td>typtypmod int4</td>
<td>Domains use typtypmod to record the typmod to be applied to their base type (-1 if base type does not use a typmod). -1 if this type is not a domain.</td>
</tr>
<tr>
<td>typndims int4</td>
<td>typndims is the number of array dimensions for a domain over an array (that is, typbasetype is an array type). Zero for types other than domains over array types.</td>
</tr>
<tr>
<td>typcollation oid</td>
<td>(references pg_collation.oid) typcollation specifies the collation of the type. If the type does not support collations, this will be zero. A base type that supports collations will have a nonzero value here, typically DEFAULT_COLLATION_OID. A domain over a collatable type can have a collation OID different from its base type’s, if one was specified for the domain.</td>
</tr>
<tr>
<td>typdefaultbin pg_node_tree</td>
<td>If typdefaultbin is not null, it is the nodeToString() representation of a default expression for the type. This is only used for domains.</td>
</tr>
<tr>
<td>typdefault text</td>
<td>typdefault is null if the type has no associated default value. If typdefaultbin is not null, typdefault must contain a human-readable version of the default expression represented by typdefaultbin. If typdefaultbin is null and typdefault is not, then typdefault is the external representation of the type's default value, which can be fed to the type's input converter to produce a constant.</td>
</tr>
<tr>
<td>typacl aclitem[]</td>
<td>Access privileges; see Section 5.7 for details</td>
</tr>
</tbody>
</table>

**Note**

For fixed-width types used in system tables, it is critical that the size and alignment defined in pg_type agree with the way that the compiler will lay out the column in a structure representing a table row.

Table 53.65 lists the system-defined values of typcategory. Any future additions to this list will also be upper-case ASCII letters. All other ASCII characters are reserved for user-defined categories.

### Table 53.65. typcategory Codes

### 53.66. System Views

In addition to the system catalogs, PostgreSQL provides a number of built-in views. Some system views provide convenient access to some commonly used queries on the system catalogs. Other views provide access to internal server state.

The information schema (Chapter 37) provides an alternative set of views which overlap the functionality of the system views. Since the information schema is SQL-standard whereas the views described here are PostgreSQL-specific, it's usually better to use the information schema if it provides all the information you need.
Table 53.67 lists the system views described here. More detailed documentation of each view follows below. There are some additional views that provide access to accumulated statistics; they are described in Table 28.2.

Except where noted, all the views described here are read-only.

**Table 53.67. System Views**

<td>views</td>
</tr>
</tbody>
</table>

53.67. **pg_available_extensions**

The `pg_available_extensions` view lists the extensions that are available for installation. See also the `pg_extension` catalog, which shows the extensions currently installed.

Table 53.68. **pg_available_extensions** Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Extension name</td>
</tr>
<tr>
<td>default_version</td>
<td>Name of default version, or NULL if none is specified</td>
</tr>
<tr>
<td>installed_version</td>
<td>Currently installed version of the extension, or NULL if not installed</td>
</tr>
<tr>
<td>comment</td>
<td>Comment string from the extension's control file</td>
</tr>
</tbody>
</table>

The `pg_available_extensions` view is read-only.

53.68. **pg_available_extension_versions**

The `pg_available_extension_versions` view lists the specific extension versions that are available for installation. See also the `pg_extension` catalog, which shows the extensions currently installed.

Table 53.69. **pg_available_extension_versions** Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Extension name</td>
</tr>
<tr>
<td>version</td>
<td>Version name</td>
</tr>
<tr>
<td>installed bool</td>
<td>True if this version of this extension is currently installed</td>
</tr>
<tr>
<td>superuser bool</td>
<td>True if only superusers are allowed to install this extension (but see trusted)</td>
</tr>
<tr>
<td>trusted bool</td>
<td>True if the extension can be installed by non-superusers with appropriate privileges</td>
</tr>
<tr>
<td>relocatable bool</td>
<td></td>
</tr>
</tbody>
</table>
### System Catalogs

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>schema name</strong></td>
<td>Name of the schema that the extension must be installed into, or NULL if partially or fully relocatable</td>
</tr>
<tr>
<td><strong>requires name[]</strong></td>
<td>Names of prerequisite extensions, or NULL if none</td>
</tr>
<tr>
<td><strong>comment text</strong></td>
<td>Comment string from the extension’s control file</td>
</tr>
</tbody>
</table>

The `pg_available_extension_versions` view is read-only.

#### 53.69. `pg_backend_memory_contexts`

The view `pg_backend_memory_contexts` displays all the memory contexts of the server process attached to the current session.

`pg_backend_memory_contexts` contains one row for each memory context.

**Table 53.70. `pg_backend_memory_contexts` Columns**

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>name text</strong></td>
<td>Name of the memory context</td>
</tr>
<tr>
<td><strong>ident text</strong></td>
<td>Identification information of the memory context. This field is truncated at 1024 bytes</td>
</tr>
<tr>
<td><strong>parent text</strong></td>
<td>Name of the parent of this memory context</td>
</tr>
<tr>
<td><strong>level int4</strong></td>
<td>Distance from TopMemoryContext in context tree</td>
</tr>
<tr>
<td><strong>total_bytes int8</strong></td>
<td>Total bytes allocated for this memory context</td>
</tr>
<tr>
<td><strong>total_nblocks int8</strong></td>
<td>Total number of blocks allocated for this memory context</td>
</tr>
<tr>
<td><strong>free_bytes int8</strong></td>
<td>Free space in bytes</td>
</tr>
<tr>
<td><strong>free_chunks int8</strong></td>
<td>Total number of free chunks</td>
</tr>
<tr>
<td><strong>used_bytes int8</strong></td>
<td>Used space in bytes</td>
</tr>
</tbody>
</table>

By default, the `pg_backend_memory_contexts` view can be read only by superusers or roles with the privileges of the `pg_read_all_stats` role.

#### 53.70. `pg_config`

2389
The view `pg_config` describes the compile-time configuration parameters of the currently installed version of PostgreSQL. It is intended, for example, to be used by software packages that want to interface to PostgreSQL to facilitate finding the required header files and libraries. It provides the same basic information as the `pg_config` PostgreSQL client application.

By default, the `pg_config` view can be read only by superusers.

### Table 53.71. `pg_config` Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The parameter name</td>
</tr>
<tr>
<td>setting</td>
<td>The parameter value</td>
</tr>
</tbody>
</table>

### 53.71. `pg_cursors`

The `pg_cursors` view lists the cursors that are currently available. Cursors can be defined in several ways:

- via the `DECLARE` statement in SQL
- via the Bind message in the frontend/backend protocol, as described in Section 54.2.3
- via the Server Programming Interface (SPI), as described in Section 47.1

The `pg_cursors` view displays cursors created by any of these means. Cursors only exist for the duration of the transaction that defines them, unless they have been declared with `WITH HOLD`. Therefore non-holdable cursors are only present in the view until the end of their creating transaction.

**Note**

Cursors are used internally to implement some of the components of PostgreSQL, such as procedural languages. Therefore, the `pg_cursors` view might include cursors that have not been explicitly created by the user.

### Table 53.72. `pg_cursors` Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the cursor</td>
</tr>
<tr>
<td>statement</td>
<td>The verbatim query string submitted to declare this cursor</td>
</tr>
<tr>
<td>is_holdable</td>
<td><code>true</code> if the cursor is holdable (that is, it can be accessed after the transaction that declared the cursor has committed); <code>false</code> otherwise</td>
</tr>
<tr>
<td>is_binary</td>
<td><code>true</code> if the cursor is binary; <code>false</code> otherwise</td>
</tr>
</tbody>
</table>
System Catalogs

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sourcefile</td>
<td>Full path name of the configuration file</td>
</tr>
<tr>
<td>sourceline</td>
<td>Line number within the configuration file where the entry appears</td>
</tr>
<tr>
<td>seqno</td>
<td>Order in which the entries are processed (1..n)</td>
</tr>
<tr>
<td>name</td>
<td>Configuration parameter name</td>
</tr>
<tr>
<td>setting</td>
<td>Value to be assigned to the parameter</td>
</tr>
<tr>
<td>applied</td>
<td>True if the value can be applied successfully</td>
</tr>
<tr>
<td>error</td>
<td>If not null, an error message indicating why this entry could not be applied</td>
</tr>
</tbody>
</table>

The pg_cursors view is read-only.

53.72. pg_file_settings

The view pg_file_settings provides a summary of the contents of the server’s configuration file(s). A row appears in this view for each “name = value” entry appearing in the files, with annotations indicating whether the value could be applied successfully. Additional row(s) may appear for problems not linked to a “name = value” entry, such as syntax errors in the files.

This view is helpful for checking whether planned changes in the configuration files will work, or for diagnosing a previous failure. Note that this view reports on the current contents of the files, not on what was last applied by the server. (The pg_settings view is usually sufficient to determine that.)

By default, the pg_file_settings view can be read only by superusers.

Table 53.73. pg_file_settings Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sourcefile</td>
<td>Full path name of the configuration file</td>
</tr>
<tr>
<td>sourceline</td>
<td>Line number within the configuration file where the entry appears</td>
</tr>
<tr>
<td>seqno</td>
<td>Order in which the entries are processed (1..n)</td>
</tr>
<tr>
<td>name</td>
<td>Configuration parameter name</td>
</tr>
<tr>
<td>setting</td>
<td>Value to be assigned to the parameter</td>
</tr>
<tr>
<td>applied</td>
<td>True if the value can be applied successfully</td>
</tr>
<tr>
<td>error</td>
<td>If not null, an error message indicating why this entry could not be applied</td>
</tr>
</tbody>
</table>

If the configuration file contains syntax errors or invalid parameter names, the server will not attempt to apply any settings from it, and therefore all the applied fields will read as false. In such a case there will be one or more rows with non-null error fields indicating the problem(s). Otherwise, individual settings will be applied if possible. If an individual setting cannot be applied (e.g., invalid value, or the setting cannot be changed after server start) it will have an appropriate message in the error field. Another way that an entry might have applied = false is that it is overridden by a later entry for the same parameter name; this case is not considered an error so nothing appears in the error field.
See Section 20.1 for more information about the various ways to change run-time parameters.

## 53.73. pg_group

The view `pg_group` exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows the names and members of all roles that are marked as not `rolcanlogin`, which is an approximation to the set of roles that are being used as groups.

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>groname</code> name</td>
<td>Name of the group</td>
</tr>
<tr>
<td><code>grosysid oid</code></td>
<td>ID of this group</td>
</tr>
<tr>
<td><code>grolist oid[]</code></td>
<td>An array containing the IDs of the roles in this group</td>
</tr>
</tbody>
</table>

## 53.74. pg_hba_file_rules

The view `pg_hba_file_rules` provides a summary of the contents of the client authentication configuration file, `pg_hba.conf`. A row appears in this view for each non-empty, non-comment line in the file, with annotations indicating whether the rule could be applied successfully.

This view can be helpful for checking whether planned changes in the authentication configuration file will work, or for diagnosing a previous failure. Note that this view reports on the *current* contents of the file, not on what was last loaded by the server.

By default, the `pg_hba_file_rules` view can be read only by superusers.

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>line_number</code></td>
<td>Line number of this rule in <code>pg_hba.conf</code></td>
</tr>
<tr>
<td><code>type</code> text</td>
<td>Type of connection</td>
</tr>
<tr>
<td><code>database text[]</code></td>
<td>List of database name(s) to which this rule applies</td>
</tr>
<tr>
<td><code>user_name text[]</code></td>
<td>List of user and group name(s) to which this rule applies</td>
</tr>
<tr>
<td><code>address</code> text</td>
<td>Host name or IP address, or one of <code>all</code>, <code>samehost</code>, or <code>samenet</code>, or null for local connections</td>
</tr>
<tr>
<td><code>netmask text</code></td>
<td>IP address mask, or null if not applicable</td>
</tr>
</tbody>
</table>
### System Catalogs

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| `auth_method` | text
  | Authentication method                                   |
| `options`     | text[]
  | Options specified for authentication method, if any     |
| `error`       | text
  | If not null, an error message indicating why this line could not be processed |

Usually, a row reflecting an incorrect entry will have values for only the `line_number` and `error` fields.

See Chapter 21 for more information about client authentication configuration.

#### 53.75. pg_ident_file_mappings

The view `pg_ident_file_mappings` provides a summary of the contents of the client user name mapping configuration file, `pg_ident.conf`. A row appears in this view for each non-empty, non-comment line in the file, with annotations indicating whether the rule could be applied successfully.

This view can be helpful for checking whether planned changes in the authentication configuration file will work, or for diagnosing a previous failure. Note that this view reports on the current contents of the file, not on what was last loaded by the server.

By default, the `pg_ident_file_mappings` view can be read only by superusers.

### Table 53.76. pg_ident_file_mappings Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| `line_number`     | int4
  | Line number of this rule in `pg_ident.conf`                                 |
| `map_name`        | text
  | Name of the map                                                            |
| `sys_name`        | text
  | Detected user name of the client                                           |
| `pg_username`     | text
  | Requested PostgreSQL user name                                             |
| `error`           | text
  | If not NULL, an error message indicating why this line could not be processed |

Usually, a row reflecting an incorrect entry will have values for only the `line_number` and `error` fields.

See Chapter 21 for more information about client authentication configuration.

#### 53.76. pg_indexes

The view `pg_indexes` provides access to useful information about each index in the database.
### Table 53.77. pg_indexes Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname name</td>
<td>Name of schema containing table and index</td>
</tr>
<tr>
<td>tablename name</td>
<td>Name of table the index is for</td>
</tr>
<tr>
<td>indexname name</td>
<td>Name of index</td>
</tr>
<tr>
<td>tablespace name</td>
<td>Name of tablespace containing index (null if default for database)</td>
</tr>
<tr>
<td>indexdef text</td>
<td>Index definition (a reconstructed CREATE INDEX command)</td>
</tr>
</tbody>
</table>

### 53.77. pg_locks

The view `pg_locks` provides access to information about the locks held by active processes within the database server. See Chapter 13 for more discussion of locking.

`pg_locks` contains one row per active lockable object, requested lock mode, and relevant process. Thus, the same lockable object might appear many times, if multiple processes are holding or waiting for locks on it. However, an object that currently has no locks on it will not appear at all.

There are several distinct types of lockable objects: whole relations (e.g., tables), individual pages of relations, individual tuples of relations, transaction IDs (both virtual and permanent IDs), and general database objects (identified by class OID and object OID, in the same way as in `pg_description` or `pg_depend`). Also, the right to extend a relation is represented as a separate lockable object, as is the right to update `pg_database.datfrozenxid`. Also, “advisory” locks can be taken on numbers that have user-defined meanings.

### Table 53.78. pg_locks Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>locktype text</td>
<td>Type of the lockable object: relation, extend, frozenid, page, tuple, trans-</td>
</tr>
<tr>
<td></td>
<td>-actionid, virtualxid, spectoken, object, userlock, or advisory. (See also</td>
</tr>
<tr>
<td></td>
<td>Table 28.11.)</td>
</tr>
<tr>
<td>database oid</td>
<td>OID of the database in which the lock target exists, or zero if the target</td>
</tr>
<tr>
<td></td>
<td>is a shared object, or null if the target is a transaction ID</td>

<td>Tuple number targeted by the lock within the page, or null if the target</td>
</tr>
<tr>
<td></td>
<td>is not a tuple</td>
</tr>
<tr>
<td>Column Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>virtualxid text</td>
<td>Virtual ID of the transaction targeted by the lock, or null if the target is not a virtual transaction ID</td>
</tr>
<tr>
<td>transactionid xid</td>
<td>ID of the transaction targeted by the lock, or null if the target is not a transaction ID</td>
</tr>
<tr>
<td>classid oid (references pg_class.oid)</td>
<td>OID of the system catalog containing the lock target, or null if the target is not a general database object</td>
</tr>
<tr>
<td>objid oid (references any OID column)</td>
<td>OID of the lock target within its system catalog, or null if the target is not a general database object</td>
</tr>
<tr>
<td>objsubid int2</td>
<td>Column number targeted by the lock (the classid and objid refer to the table itself), or zero if the target is some other general database object, or null if the target is not a general database object</td>
</tr>
<tr>
<td>virtualtransaction text</td>
<td>Virtual ID of the transaction that is holding or awaiting this lock</td>
</tr>
<tr>
<td>pid int4</td>
<td>Process ID of the server process holding or awaiting this lock, or null if the lock is held by a prepared transaction</td>
</tr>
<tr>
<td>mode text</td>
<td>Name of the lock mode held or desired by this process (see Section 13.3.1 and Section 13.2.3)</td>
</tr>
<tr>
<td>granted bool</td>
<td>True if lock is held, false if lock is awaited</td>
</tr>
<tr>
<td>fastpath bool</td>
<td>True if lock was taken via fast path, false if taken via main lock table</td>
</tr>
<tr>
<td>waitstart timestamptz</td>
<td>Time when the server process started waiting for this lock, or null if the lock is held. Note that this can be null for a very short period of time after the wait started even though granted is false.</td>
</tr>
</tbody>
</table>

granted is true in a row representing a lock held by the indicated process. False indicates that this process is currently waiting to acquire this lock, which implies that at least one other process is holding or waiting for a conflicting lock mode on the same lockable object. The waiting process will sleep until the other lock is released (or a deadlock situation is detected). A single process can be waiting to acquire at most one lock at a time.

Throughout running a transaction, a server process holds an exclusive lock on the transaction's virtual transaction ID. If a permanent ID is assigned to the transaction (which normally happens only if the transaction changes the state of the database), it also holds an exclusive lock on the transaction's permanent transaction ID until it ends. When a process finds it necessary to wait specifically for another transaction to end, it does so by attempting to acquire share lock on the other transaction's ID (either virtual or permanent ID depending on the situation). That will succeed only when the other transaction terminates and releases its locks.

Although tuples are a lockable type of object, information about row-level locks is stored on disk, not in memory, and therefore row-level locks normally do not appear in this view. If a process is waiting for a
row-level lock, it will usually appear in the view as waiting for the permanent transaction ID of the current holder of that row lock.

Advisory locks can be acquired on keys consisting of either a single bigint value or two integer values. A bigint key is displayed with its high-order half in the classid column, its low-order half in the objid column, and objsubid equal to 1. The original bigint value can be reassembled with the expression (classid::bigint << 32) | objid::bigint. Integer keys are displayed with the first key in the classid column, the second key in the objid column, and objsubid equal to 2. The actual meaning of the keys is up to the user. Advisory locks are local to each database, so the database column is meaningful for an advisory lock.

pg_locks provides a global view of all locks in the database cluster, not only those relevant to the current database. Although its relation column can be joined against pg_class.oid to identify locked relations, this will only work correctly for relations in the current database (those for which the database column is either the current database's OID or zero).

The pid column can be joined to the pid column of the pg_stat_activity view to get more information on the session holding or awaiting each lock, for example

```sql
SELECT * FROM pg_locks pl LEFT JOIN pg_stat_activity psa
  ON pl.pid = psa.pid;
```

Also, if you are using prepared transactions, the virtualtransaction column can be joined to the transaction column of the pg_prepared_xacts view to get more information on prepared transactions that hold locks. (A prepared transaction can never be waiting for a lock, but it continues to hold the locks it acquired while running.) For example:

```sql
SELECT * FROM pg_locks pl LEFT JOIN pg_prepared_xacts ppx
  ON pl.virtualtransaction = '-1/' || ppx.transaction;
```

While it is possible to obtain information about which processes block which other processes by joining pg_locks against itself, this is very difficult to get right in detail. Such a query would have to encode knowledge about which lock modes conflict with which others. Worse, the pg_locks view does not expose information about which processes are ahead of which others in lock wait queues, nor information about which processes are parallel workers running on behalf of which other client sessions. It is better to use the pg_blocking_pids() function (see Table 9.69) to identify which process(es) a waiting process is blocked behind.

The pg_locks view displays data from both the regular lock manager and the predicate lock manager, which are separate systems; in addition, the regular lock manager subdivides its locks into regular and fast-path locks. This data is not guaranteed to be entirely consistent. When the view is queried, data on fast-path locks (with fastpath = true) is gathered from each backend one at a time, without freezing the state of the entire lock manager, so it is possible for locks to be taken or released while information is gathered. Note, however, that these locks are known not to conflict with any other lock currently in place. After all backends have been queried for fast-path locks, the remainder of the regular lock manager is locked as a unit, and a consistent snapshot of all remaining locks is collected as an atomic action. After unlocking the regular lock manager, the predicate lock manager is similarly locked and all predicate locks are collected as an atomic action. Thus, with the exception of fast-path locks, each lock manager will deliver a consistent set of results, but as we do not lock both lock managers simultaneously, it is possible for locks to be taken or released after we interrogate the regular lock manager and before we interrogate the predicate lock manager.

Locking the regular and/or predicate lock manager could have some impact on database performance if this view is very frequently accessed. The locks are held only for the minimum amount of time necessary to
obtain data from the lock managers, but this does not completely eliminate the possibility of a performance impact.

53.78. pg_matviews

The view pg_matviews provides access to useful information about each materialized view in the database.

Table 53.79. pg_matviews Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname name</td>
<td>Name of schema containing materialized view</td>
</tr>
<tr>
<td>matviewname name</td>
<td>Name of materialized view</td>
</tr>
<tr>
<td>matviewowner name</td>
<td>Name of materialized view's owner</td>
</tr>
<tr>
<td>tablespace name</td>
<td>Name of tablespace containing materialized view (null if default for database)</td>
</tr>
<tr>
<td>hasindexes bool</td>
<td>True if materialized view has (or recently had) any indexes</td>
</tr>
<tr>
<td>ispopulated bool</td>
<td>True if materialized view is currently populated</td>
</tr>
<tr>
<td>definition text</td>
<td>Materialized view definition (a reconstructed SELECT query)</td>
</tr>
</tbody>
</table>

53.79. pg_policies

The view pg_policies provides access to useful information about each row-level security policy in the database.

Table 53.80. pg_policies Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname name</td>
<td>Name of schema containing table policy is on</td>
</tr>
<tr>
<td>tablename name</td>
<td>Name of table policy is on</td>
</tr>
<tr>
<td>policyname name</td>
<td>Name of policy</td>
</tr>
<tr>
<td>permissive text</td>
<td>Is the policy permissive or restrictive?</td>
</tr>
<tr>
<td>roles name[]</td>
<td>The roles to which this policy applies</td>
</tr>
<tr>
<td>cmd text</td>
<td>The command type to which the policy is applied</td>
</tr>
</tbody>
</table>
System Catalogs

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>qual</td>
<td>The expression added to the security barrier qualifications for queries that this policy applies to</td>
</tr>
<tr>
<td>with_check</td>
<td>The expression added to the WITH CHECK qualifications for queries that attempt to add rows to this table</td>
</tr>
</tbody>
</table>

### 53.80. pg_prepared_statements

The `pg_prepared_statements` view displays all the prepared statements that are available in the current session. See `PREPARE` for more information about prepared statements.

`pg_prepared_statements` contains one row for each prepared statement. Rows are added to the view when a new prepared statement is created and removed when a prepared statement is released (for example, via the `DEALLOCATE` command).

#### Table 53.81. pg_prepared_statements Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The identifier of the prepared statement</td>
</tr>
<tr>
<td>statement</td>
<td>The query string submitted by the client to create this prepared statement. For prepared statements created via SQL, this is the <code>PREPARE</code> statement submitted by the client. For prepared statements created via the frontend/backend protocol, this is the text of the prepared statement itself.</td>
</tr>
<tr>
<td>prepare_time</td>
<td>The time at which the prepared statement was created</td>
</tr>
<tr>
<td>parameter_types</td>
<td>The expected parameter types for the prepared statement in the form of an array of <code>regtype</code>. The OID corresponding to an element of this array can be obtained by casting the <code>regtype</code> value to <code>oid</code>.</td>
</tr>
<tr>
<td>from_sql</td>
<td><code>true</code> if the prepared statement was created via the <code>PREPARE SQL</code> command; <code>false</code> if the statement was prepared via the frontend/backend protocol</td>
</tr>
<tr>
<td>generic_plans</td>
<td>Number of times generic plan was chosen</td>
</tr>
<tr>
<td>custom_plans</td>
<td>Number of times custom plan was chosen</td>
</tr>
</tbody>
</table>

The `pg_prepared_statements` view is read-only.

### 53.81. pg_prepared_xacts

The view `pg_prepared_xacts` displays information about transactions that are currently prepared for two-phase commit (see `PREPARE TRANSACTION` for details).
pg_prepared_xacts contains one row per prepared transaction. An entry is removed when the transaction is committed or rolled back.

Table 53.82. pg_prepared_xacts Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>transaction xid</td>
<td>Numeric transaction identifier of the prepared transaction</td>
</tr>
<tr>
<td>gid text</td>
<td>Global transaction identifier that was assigned to the transaction</td>
</tr>
<tr>
<td>prepared timestamptz</td>
<td>Time at which the transaction was prepared for commit</td>
</tr>
<tr>
<td>owner name (references pg_authid.rolname)</td>
<td>Name of the user that executed the transaction</td>
</tr>
<tr>
<td>database name (references pg_database.datname)</td>
<td>Name of the database in which the transaction was executed</td>
</tr>
</tbody>
</table>

When the pg_prepared_xacts view is accessed, the internal transaction manager data structures are momentarily locked, and a copy is made for the view to display. This ensures that the view produces a consistent set of results, while not blocking normal operations longer than necessary. Nonetheless there could be some impact on database performance if this view is frequently accessed.

53.82. pg_publication_tables

The view pg_publication_tables provides information about the mapping between publications and information of tables they contain. Unlike the underlying catalog pg_publication_rel, this view expands publications defined as FOR ALL TABLES and FOR ALL TABLES IN SCHEMA, so for such publications there will be a row for each eligible table.

Table 53.83. pg_publication_tables Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pubname name (references pg_publication.pubname)</td>
<td>Name of publication</td>
</tr>
<tr>
<td>schemaname name (references pg_namespace.nspname)</td>
<td>Name of schema containing table</td>
</tr>
<tr>
<td>tablename name (references pg_class.relname)</td>
<td>Name of table</td>
</tr>
<tr>
<td>attnames name[] (references pg_attribute.attname)</td>
<td>Names of table columns included in the publication. This contains all the columns of the table when the user didn't specify the column list for the table.</td>
</tr>
<tr>
<td>rowfilter text</td>
<td>Expression for the table's publication qualifying condition</td>
</tr>
</tbody>
</table>

53.83. pg_replication_origin_status

The pg_replication_origin_status view contains information about how far replay for a certain origin has progressed. For more on replication origins see Chapter 50.
Table 53.84. `pg_replication_origin_status` Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>local_id oid (references <code>pg_replication_origin.roident</code>)</td>
<td>internal node identifier</td>
</tr>
<tr>
<td>external_id text (references <code>pg_replication_origin.roname</code>)</td>
<td>external node identifier</td>
</tr>
<tr>
<td>remote_lsn <code>pg_lsn</code></td>
<td>The origin node's LSN up to which data has been replicated.</td>
</tr>
<tr>
<td>local_lsn <code>pg_lsn</code></td>
<td>This node's LSN at which remote_lsn has been replicated. Used to flush commit records before persisting data to disk when using asynchronous commits.</td>
</tr>
</tbody>
</table>

53.84. `pg_replication_slots`

The `pg_replication_slots` view provides a listing of all replication slots that currently exist on the database cluster, along with their current state.

For more on replication slots, see Section 27.2.6 and Chapter 49.

Table 53.85. `pg_replication_slots` Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>slot_name name</td>
<td>A unique, cluster-wide identifier for the replication slot</td>
</tr>
<tr>
<td>plugin name</td>
<td>The base name of the shared object containing the output plugin this logical slot is using, or null for physical slots.</td>
</tr>
<tr>
<td>slot_type text</td>
<td>The slot type: physical or logical</td>
</tr>
<tr>
<td>datoid oid (references <code>pg_database.oid</code>)</td>
<td>The OID of the database this slot is associated with, or null. Only logical slots have an associated database.</td>
</tr>
<tr>
<td>database name (references <code>pg_database.datname</code>)</td>
<td>The name of the database this slot is associated with, or null. Only logical slots have an associated database.</td>
</tr>
<tr>
<td>temporary bool</td>
<td>True if this is a temporary replication slot. Temporary slots are not saved to disk and are automatically dropped on error or when the session has finished.</td>
</tr>
<tr>
<td>active bool</td>
<td>True if this slot is currently actively being used</td>
</tr>
<tr>
<td>active_pid int4</td>
<td>The process ID of the session using this slot if the slot is currently actively being used. NULL if inactive.</td>
</tr>
<tr>
<td>xmin xid</td>
<td>The oldest transaction that this slot needs the database to retain. VACUUM cannot remove tuples deleted by any later transaction.</td>
</tr>
</tbody>
</table>
### System Catalogs

#### Column Type

**catalog_xmin xid**
The oldest transaction affecting the system catalogs that this slot needs the database to retain. VACUUM cannot remove catalog tuples deleted by any later transaction.

**restart_lsn pg_lsn**
The address (LSN) of oldest WAL which still might be required by the consumer of this slot and thus won't be automatically removed during checkpoints unless this LSN gets behind more than max_slot_wal_keep_size from the current LSN. NULL if the LSN of this slot has never been reserved.

**confirmed_flush_lsn pg_lsn**
The address (LSN) up to which the logical slot's consumer has confirmed receiving data. Data older than this is not available anymore. NULL for physical slots.

**wal_status text**
Availability of WAL files claimed by this slot. Possible values are:

- **reserved** means that the claimed files are within max_wal_size.
- **extended** means that max_wal_size is exceeded but the files are still retained, either by the replication slot or by wal_keep_size.
- **unreserved** means that the slot no longer retains the required WAL files and some of them are to be removed at the next checkpoint. This state can return to reserved or extended.
- **lost** means that some required WAL files have been removed and this slot is no longer usable.

The last two states are seen only when max_slot_wal_keep_size is non-negative. If restart_lsn is NULL, this field is null.

**safe_wal_size int8**
The number of bytes that can be written to WAL such that this slot is not in danger of getting in state "lost". It is NULL for lost slots, as well as if max_slot_wal_keep_size is -1.

**two_phase bool**
True if the slot is enabled for decoding prepared transactions. Always false for physical slots.

#### 53.85. pg_roles

The view pg_roles provides access to information about database roles. This is simply a publicly readable view of pg_authid that blanks out the password field.

#### Table 53.86. pg_roles Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rolname name</td>
<td>Role name</td>
</tr>
<tr>
<td>rolsuper bool</td>
<td>Role has superuser privileges</td>
</tr>
<tr>
<td>rolinherit bool</td>
<td></td>
</tr>
</tbody>
</table>
System Catalogs

### Column Type

<table>
<thead>
<tr>
<th>Description</th>
<th>Role automatically inherit privileges of roles it is a member of</th>
</tr>
</thead>
<tbody>
<tr>
<td>rolcreaterole bool</td>
<td>Role can create more roles</td>
</tr>
<tr>
<td>rolcreatedb bool</td>
<td>Role can create databases</td>
</tr>
<tr>
<td>roldblogin bool</td>
<td>Role can log in. That is, this role can be given as the initial session authorization identifier</td>
</tr>
<tr>
<td>roldbreplication bool</td>
<td>Role is a replication role. A replication role can initiate replication connections and create and drop replication slots.</td>
</tr>
<tr>
<td>roldbconnlimit int4</td>
<td>For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit.</td>
</tr>
<tr>
<td>roldbpASSWORD text</td>
<td>Not the password (always reads as *********)</td>
</tr>
<tr>
<td>roldbvaliduntil timestamptz</td>
<td>Password expiry time (only used for password authentication); null if no expiration</td>
</tr>
<tr>
<td>roldbbypassrls bool</td>
<td>Role bypasses every row-level security policy, see Section 5.8 for more information.</td>
</tr>
<tr>
<td>roldbconfig text[]</td>
<td>Role-specific defaults for run-time configuration variables</td>
</tr>
<tr>
<td>roldboid oid (references pg_authid.oid)</td>
<td>ID of role</td>
</tr>
</tbody>
</table>

### 53.86. pg_rules

The view pg_rules provides access to useful information about query rewrite rules.

#### Table 53.87. pg_rules Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname name</td>
<td>Name of schema containing table</td>
</tr>
<tr>
<td>tablename name</td>
<td>Name of table the rule is for</td>
</tr>
<tr>
<td>rulename name</td>
<td>Name of rule</td>
</tr>
<tr>
<td>definition text</td>
<td>Rule definition (a reconstructed creation command)</td>
</tr>
</tbody>
</table>

The pg_rules view excludes the ON SELECT rules of views and materialized views; those can be seen in pg_views and pg_matviews.

### 53.87. pg_seclabels

2402
The view pg_seclabels provides information about security labels. It is an easier-to-query version of the pg_seclabel catalog.

### Table 53.88. pg_seclabels Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid oid</td>
<td>The OID of the object this security label pertains to</td>
</tr>
<tr>
<td>classoid oid</td>
<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>objsubid int4</td>
<td>For a security label on a table column, this is the column number (the objoid and classoid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>objtype text</td>
<td>The type of object to which this label applies, as text.</td>
</tr>
<tr>
<td>objnamespace oid</td>
<td>The OID of the namespace for this object, if applicable; otherwise NULL.</td>
</tr>
<tr>
<td>objname text</td>
<td>The name of the object to which this label applies, as text.</td>
</tr>
<tr>
<td>provider text</td>
<td>The label provider associated with this label.</td>
</tr>
<tr>
<td>label text</td>
<td>The security label applied to this object.</td>
</tr>
</tbody>
</table>

53.88. pg_sequences

The view pg_sequences provides access to useful information about each sequence in the database.

### Table 53.89. pg_sequences Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname name name</td>
<td>Name of schema containing sequence</td>
</tr>
<tr>
<td>sequencename name name</td>
<td>Name of sequence</td>
</tr>
<tr>
<td>sequenceowner name name</td>
<td>Name of sequence's owner</td>
</tr>
<tr>
<td>data_type regtype</td>
<td>Data type of the sequence</td>
</tr>
<tr>
<td>start_value int8</td>
<td>Start value of the sequence</td>
</tr>
<tr>
<td>min_value int8</td>
<td>Minimum value of the sequence</td>
</tr>
<tr>
<td>max_value int8</td>
<td>Maximum value of the sequence</td>
</tr>
<tr>
<td>increment_by int8</td>
<td></td>
</tr>
</tbody>
</table>

2403
### System Catalogs

<table>
<thead>
<tr>
<th><strong>Column Type</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>cycle bool</td>
<td>Whether the sequence cycles</td>
</tr>
<tr>
<td>cache_size int8</td>
<td>Cache size of the sequence</td>
</tr>
<tr>
<td>last_value int8</td>
<td>The last sequence value written to disk. If caching is used, this value can be greater than the last value handed out from the sequence. Null if the sequence has not been read from yet. Also, if the current user does not have USAGE or SELECT privilege on the sequence, the value is null.</td>
</tr>
</tbody>
</table>

#### 53.89. pg_settings

The view **pg_settings** provides access to run-time parameters of the server. It is essentially an alternative interface to the **SHOW** and **SET** commands. It also provides access to some facts about each parameter that are not directly available from **SHOW**, such as minimum and maximum values.

**Table 53.90. pg_settings Columns**

<table>
<thead>
<tr>
<th><strong>Column Type</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>name text</td>
<td>Run-time configuration parameter name</td>
</tr>
<tr>
<td>setting text</td>
<td>Current value of the parameter</td>
</tr>
<tr>
<td>unit text</td>
<td>Implicit unit of the parameter</td>
</tr>
<tr>
<td>category text</td>
<td>Logical group of the parameter</td>
</tr>
<tr>
<td>short_desc text</td>
<td>A brief description of the parameter</td>
</tr>
<tr>
<td>extra_desc text</td>
<td>Additional, more detailed, description of the parameter</td>
</tr>
<tr>
<td>context text</td>
<td>Context required to set the parameter's value (see below)</td>
</tr>
<tr>
<td>vartype text</td>
<td>Parameter type (bool, enum, integer, real, or string)</td>
</tr>
<tr>
<td>source text</td>
<td>Source of the current parameter value</td>
</tr>
<tr>
<td>min_val text</td>
<td>Minimum allowed value of the parameter (null for non-numeric values)</td>
</tr>
<tr>
<td>max_val text</td>
<td>Maximum allowed value of the parameter (null for non-numeric values)</td>
</tr>
<tr>
<td>enumvals text[]</td>
<td>Allowed values of an enum parameter (null for non-enum values)</td>
</tr>
</tbody>
</table>
### System Catalogs

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>boot_val</td>
<td>Parameter value assumed at server startup if the parameter is not otherwise set</td>
</tr>
<tr>
<td>reset_val</td>
<td>Value that <code>RESET</code> would reset the parameter to in the current session</td>
</tr>
<tr>
<td>sourcefile</td>
<td>Configuration file the current value was set in (null for values set from sources other than configuration files, or when examined by a user who neither is a superuser nor has privileges of <code>pg_read_all_settings</code>); helpful when using <code>include</code> directives in configuration files</td>
</tr>
<tr>
<td>sourceline</td>
<td>Line number within the configuration file the current value was set at (null for values set from sources other than configuration files, or when examined by a user who neither is a superuser nor has privileges of <code>pg_read_all_settings</code>).</td>
</tr>
<tr>
<td>pending_restart</td>
<td><code>true</code> if the value has been changed in the configuration file but needs a restart; or <code>false</code> otherwise.</td>
</tr>
</tbody>
</table>

There are several possible values of `context`. In order of decreasing difficulty of changing the setting, they are:

- **internal**
  
  These settings cannot be changed directly; they reflect internally determined values. Some of them may be adjustable by rebuilding the server with different configuration options, or by changing options supplied to `initdb`.

- **postmaster**
  
  These settings can only be applied when the server starts, so any change requires restarting the server. Values for these settings are typically stored in the `postgresql.conf` file, or passed on the command line when starting the server. Of course, settings with any of the lower `context` types can also be set at server start time.

- **sighup**
  
  Changes to these settings can be made in `postgresql.conf` without restarting the server. Send a `SIGHUP` signal to the postmaster to cause it to re-read `postgresql.conf` and apply the changes. The postmaster will also forward the `SIGHUP` signal to its child processes so that they all pick up the new value.

- **superuser-backend**
  
  Changes to these settings can be made in `postgresql.conf` without restarting the server. They can also be set for a particular session in the connection request packet (for example, via libpq's `PGOPTIONS` environment variable), but only if the connecting user is a superuser or has been granted the appropriate `SET` privilege. However, these settings never change in a session after it is started. If you change them in `postgresql.conf`, send a `SIGHUP` signal to the postmaster to cause it to re-read `postgresql.conf`. The new values will only affect subsequently-launched sessions.

- **backend**
  
  Changes to these settings can be made in `postgresql.conf` without restarting the server. They can also be set for a particular session in the connection request packet (for example, via libpq's...
POPTIONS environment variable); any user can make such a change for their session. However, these settings never change in a session after it is started. If you change them in postgresql.conf, send a SIGHUP signal to the postmaster to cause it to re-read postgresql.conf. The new values will only affect subsequently-launched sessions.

**superuser**

These settings can be set from postgresql.conf, or within a session via the SET command; but only superusers and users with the appropriate SET privilege can change them via SET. Changes in postgresql.conf will affect existing sessions only if no session-local value has been established with SET.

**user**

These settings can be set from postgresql.conf, or within a session via the SET command. Any user is allowed to change their session-local value. Changes in postgresql.conf will affect existing sessions only if no session-local value has been established with SET.

See Section 20.1 for more information about the various ways to change these parameters.

This view does not display customized options until the extension module that defines them has been loaded.

This view cannot be inserted into or deleted from, but it can be updated. An UPDATE applied to a row of pg_settings is equivalent to executing the SET command on that named parameter. The change only affects the value used by the current session. If an UPDATE is issued within a transaction that is later aborted, the effects of the UPDATE command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another UPDATE or SET.

**53.90. pg_shadow**

The view pg_shadow exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows properties of all roles that are marked as rolcanlogin in pg_au-thid.

The name stems from the fact that this table should not be readable by the public since it contains passwords. pg_user is a publicly readable view on pg_shadow that blanks out the password field.

**Table 53.91. pg_shadow Columns**

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>usename</td>
<td>name (references pg_authid.rolname)</td>
</tr>

<td>text</td>
</tr>
<tr>
<td></td>
<td>Password (possibly encrypted); null if none. See pg_authid for details of how encrypted passwords are stored.</td>
</tr>
<tr>
<td>valuntil</td>
<td>timestamptz</td>
</tr>
<tr>
<td></td>
<td>Password expiry time (only used for password authentication)</td>
</tr>
<tr>
<td>useconfig</td>
<td>text[]</td>
</tr>
<tr>
<td></td>
<td>Session defaults for run-time configuration variables</td>
</tr>
</tbody>
</table>

53.91. pg_shmem_allocations

The pg_shmem_allocations view shows allocations made from the server's main shared memory segment. This includes both memory allocated by PostgreSQL itself and memory allocated by extensions using the mechanisms detailed in Section 38.10.10.

Note that this view does not include memory allocated using the dynamic shared memory infrastructure.

Table 53.92. pg_shmem_allocations Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
</tr>
<tr>
<td></td>
<td>The name of the shared memory allocation. NULL for unused memory and &lt;anonymous&gt; for anonymous allocations.</td>
</tr>
<tr>
<td>off</td>
<td>int8</td>
</tr>
<tr>
<td></td>
<td>The offset at which the allocation starts. NULL for anonymous allocations, since details related to them are not known.</td>
</tr>
<tr>
<td>size</td>
<td>int8</td>
</tr>
<tr>
<td></td>
<td>Size of the allocation</td>
</tr>
<tr>
<td>allocated_size</td>
<td>int8</td>
</tr>
<tr>
<td></td>
<td>Size of the allocation including padding. For anonymous allocations, no information about padding is available, so the size and allocated_size columns will always be equal. Padding is not meaningful for free memory, so the columns will be equal in that case also.</td>
</tr>
</tbody>
</table>

Anonymous allocations are allocations that have been made with ShmemAlloc() directly, rather than via ShmemInitStruct() or ShmemInitHash().

By default, the pg_shmem_allocations view can be read only by superusers or roles with privileges of the pg_read_all_stats role.

53.92. pg_stats

The view pg_stats provides access to the information stored in the pg_statistic catalog. This view allows access only to rows of pg_statistic that correspond to tables the user has permission to read, and therefore it is safe to allow public read access to this view.
pg_stats is also designed to present the information in a more readable format than the underlying catalog—at the cost that its schema must be extended whenever new slot types are defined for pg_statistic.

Table 53.93. pg_stats Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname name</td>
<td>Name of schema containing table</td>
</tr>
<tr>
<td>tablename name</td>
<td>Name of table</td>
</tr>
<tr>
<td>attname name</td>
<td>Name of column described by this row</td>
</tr>
<tr>
<td>inherited bool</td>
<td>If true, this row includes inheritance child columns, not just the values in the specified table</td>
</tr>
<tr>
<td>null_frac float4</td>
<td>Fraction of column entries that are null</td>
</tr>
<tr>
<td>avg_width int4</td>
<td>Average width in bytes of column's entries</td>
</tr>
<tr>
<td>n_distinct float4</td>
<td>If greater than zero, the estimated number of distinct values in the column. If less than zero, the negative of the number of distinct values divided by the number of rows. (The negated form is used when ANALYZE believes that the number of distinct values is likely to increase as the table grows; the positive form is used when the column seems to have a fixed number of possible values.) For example, -1 indicates a unique column in which the number of distinct values is the same as the number of rows.</td>
</tr>
<tr>
<td>most_common_vals anyarray</td>
<td>A list of the most common values in the column. (Null if no values seem to be more common than any others.)</td>
</tr>
<tr>
<td>most_common_freqs float4[]</td>
<td>A list of the frequencies of the most common values, i.e., number of occurrences of each divided by total number of rows. (Null when most_common_vals is.)</td>
</tr>
<tr>
<td>histogram_bounds anyarray</td>
<td>A list of values that divide the column's values into groups of approximately equal population. The values in most_common_vals, if present, are omitted from this histogram calculation. (This column is null if the column data type does not have a &lt; operator or if the most_common_vals list accounts for the entire population.)</td>
</tr>
<tr>
<td>correlation float4</td>
<td>Statistical correlation between physical row ordering and logical ordering of the column values. This ranges from -1 to +1. When the value is near -1 or +1, an index scan on the column will be estimated to be cheaper than when it is near zero, due to reduction of random access to the disk. (This column is null if the column data type does not have a &lt; operator.)</td>

The maximum number of entries in the array fields can be controlled on a column-by-column basis using the `ALTER TABLE SET STATISTICS` command, or globally by setting the `default_statistics_target` run-time parameter.

### 53.93. pg_stats_ext

The view `pg_stats_ext` provides access to information about each extended statistics object in the database, combining information stored in the `pg_statistic_ext` and `pg_statistic_ext_data` catalogs. This view allows access only to rows of `pg_statistic_ext` and `pg_statistic_ext_data` that correspond to tables the user has permission to read, and therefore it is safe to allow public read access to this view.

`pg_stats_ext` is also designed to present the information in a more readable format than the underlying catalogs — at the cost that its schema must be extended whenever new types of extended statistics are added to `pg_statistic_ext`.

#### Table 53.94. pg_stats_ext Columns

</table>

### 53.96. pg_timezone_abbrevs

The view `pg_timezone_abbrevs` provides a list of time zone abbreviations that are currently recognized by the datetime input routines. The contents of this view change when the `timezone_abbreviations` run-time parameter is modified.

#### Table 53.97. pg_timezone_abbrevs Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>abbrev</td>
<td>Time zone abbreviation</td>
</tr>
<tr>
<td>utc_offset</td>
<td>Offset from UTC (positive means east of Greenwich)</td>
</tr>
</tbody>
</table>
While most timezone abbreviations represent fixed offsets from UTC, there are some that have historically varied in value (see Section B.4 for more information). In such cases this view presents their current meaning.

53.97. **pg_timezone_names**

The view `pg_timezone_names` provides a list of time zone names that are recognized by `SET TIME-ZONE`, along with their associated abbreviations, UTC offsets, and daylight-savings status. (Technically, PostgreSQL does not use UTC because leap seconds are not handled.) Unlike the abbreviations shown in `pg_timezone_abbrevs`, many of these names imply a set of daylight-savings transition date rules. Therefore, the associated information changes across local DST boundaries. The displayed information is computed based on the current value of `CURRENT_TIMESTAMP`.

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Time zone name</td>
</tr>
<tr>
<td>abbrev</td>
<td>Time zone abbreviation</td>
</tr>
<tr>
<td>utc_offset</td>
<td>Offset from UTC (positive means east of Greenwich)</td>
</tr>
<tr>
<td>is_dst</td>
<td>True if currently observing daylight savings</td>
</tr>
</tbody>
</table>

53.98. **pg_user**

The view `pg_user` provides access to information about database users. This is simply a publicly readable view of `pg_shadow` that blanks out the password field.

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>usename</td>
<td>User name</td>
</tr>
<tr>
<td>usesysid</td>
<td>ID of this user</td>

<tr>
<td>usecreatedb</td>
<td>User can create databases</td>
</tr>
<tr>
<td>usesuper</td>
<td>User is a superuser</td>
</tr>
</tbody>
</table>

2413
<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>userrepl</td>
<td>bool</td>
</tr>
<tr>
<td></td>
<td>User can initiate streaming replication and put the system in and out of backup mode.</td>
</tr>
<tr>
<td>usebypassrls</td>
<td>bool</td>
</tr>
<tr>
<td></td>
<td>User bypasses every row-level security policy, see Section 5.8 for more information.</td>
</tr>
<tr>
<td>passwd</td>
<td>text</td>
</tr>
<tr>
<td></td>
<td>Not the password (always reads as *********)</td>
</tr>
<tr>
<td>valuntil</td>
<td>timestamptz</td>
</tr>
<tr>
<td></td>
<td>Password expiry time (only used for password authentication)</td>
</tr>
<tr>
<td>useconfig</td>
<td>text[]</td>
</tr>
<tr>
<td></td>
<td>Session defaults for run-time configuration variables</td>
</tr>
</tbody>
</table>

**53.99. pg_user_mappings**

The view `pg_user_mappings` provides access to information about user mappings. This is essentially a publicly readable view of `pg_user_mapping` that leaves out the options field if the user has no rights to use it.

**Table 53.100. pg_user_mappings Columns**

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>umid</td>
<td>oid (references pg_user_mapping.oid)</td>
</tr>
<tr>
<td></td>
<td>OID of the user mapping</td>
</tr>
<tr>
<td>srvid</td>
<td>oid (references pg_foreign_server.oid)</td>
</tr>
<tr>
<td></td>
<td>The OID of the foreign server that contains this mapping</td>
</tr>
<tr>
<td>srvname</td>
<td>name (references pg_foreign_server.srvname)</td>
</tr>
<tr>
<td></td>
<td>Name of the foreign server</td>
</tr>
<tr>
<td>umuser</td>
<td>oid (references pg_authid.oid)</td>
</tr>
<tr>
<td></td>
<td>OID of the local role being mapped, or zero if the user mapping is public</td>
</tr>
<tr>
<td>usename</td>
<td>Name of the local user to be mapped</td>
</tr>
<tr>
<td>umoptions</td>
<td>text[]</td>
</tr>
<tr>
<td></td>
<td>User mapping specific options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

To protect password information stored as a user mapping option, the `umoptions` column will read as null unless one of the following applies:

- current user is the user being mapped, and owns the server or holds USAGE privilege on it
- current user is the server owner and mapping is for PUBLIC
- current user is a superuser

**53.100. pg_views**

The view `pg_views` provides access to useful information about each view in the database.
### Table 53.101. pg_views Columns

</table>
Chapter 54. Frontend/Backend Protocol

PostgreSQL uses a message-based protocol for communication between frontends and backends (clients and servers). The protocol is supported over TCP/IP and also over Unix-domain sockets. Port number 5432 has been registered with IANA as the customary TCP port number for servers supporting this protocol, but in practice any non-privileged port number can be used.

This document describes version 3.0 of the protocol, implemented in PostgreSQL 7.4 and later. For descriptions of the earlier protocol versions, see previous releases of the PostgreSQL documentation. A single server can support multiple protocol versions. The initial startup-request message tells the server which protocol version the client is attempting to use. If the major version requested by the client is not supported by the server, the connection will be rejected (for example, this would occur if the client requested protocol version 4.0, which does not exist as of this writing). If the minor version requested by the client is not supported by the server (e.g., the client requests version 3.1, but the server supports only 3.0), the server may either reject the connection or may respond with a NegotiateProtocolVersion message containing the highest minor protocol version which it supports. The client may then choose either to continue with the connection using the specified protocol version or to abort the connection.

In order to serve multiple clients efficiently, the server launches a new “backend” process for each client. In the current implementation, a new child process is created immediately after an incoming connection is detected. This is transparent to the protocol, however. For purposes of the protocol, the terms “backend” and “server” are interchangeable; likewise “frontend” and “client” are interchangeable.

54.1. Overview

The protocol has separate phases for startup and normal operation. In the startup phase, the frontend opens a connection to the server and authenticates itself to the satisfaction of the server. (This might involve a single message, or multiple messages depending on the authentication method being used.) If all goes well, the server then sends status information to the frontend, and finally enters normal operation. Except for the initial startup-request message, this part of the protocol is driven by the server.

During normal operation, the frontend sends queries and other commands to the backend, and the backend sends back query results and other responses. There are a few cases (such as \texttt{NOTIFY}) wherein the backend will send unsolicited messages, but for the most part this portion of a session is driven by frontend requests.

Termination of the session is normally by frontend choice, but can be forced by the backend in certain cases. In any case, when the backend closes the connection, it will roll back any open (incomplete) transaction before exiting.

Within normal operation, SQL commands can be executed through either of two sub-protocols. In the “simple query” protocol, the frontend just sends a textual query string, which is parsed and immediately executed by the backend. In the “extended query” protocol, processing of queries is separated into multiple steps: parsing, binding of parameter values, and execution. This offers flexibility and performance benefits, at the cost of extra complexity.

Normal operation has additional sub-protocols for special operations such as \texttt{COPY}.

54.1.1. Messaging Overview

All communication is through a stream of messages. The first byte of a message identifies the message type, and the next four bytes specify the length of the rest of the message (this length count includes itself,
but not the message-type byte). The remaining contents of the message are determined by the message type. For historical reasons, the very first message sent by the client (the startup message) has no initial message-type byte.

To avoid losing synchronization with the message stream, both servers and clients typically read an entire message into a buffer (using the byte count) before attempting to process its contents. This allows easy recovery if an error is detected while processing the contents. In extreme situations (such as not having enough memory to buffer the message), the receiver can use the byte count to determine how much input to skip before it resumes reading messages.

Conversely, both servers and clients must take care never to send an incomplete message. This is commonly done by marshaling the entire message in a buffer before beginning to send it. If a communications failure occurs partway through sending or receiving a message, the only sensible response is to abandon the connection, since there is little hope of recovering message-boundary synchronization.

54.1.2. Extended Query Overview

In the extended-query protocol, execution of SQL commands is divided into multiple steps. The state retained between steps is represented by two types of objects: prepared statements and portals. A prepared statement represents the result of parsing and semantic analysis of a textual query string. A prepared statement is not in itself ready to execute, because it might lack specific values for parameters. A portal represents a ready-to-execute or already-partially-executed statement, with any missing parameter values filled in. (For SELECT statements, a portal is equivalent to an open cursor, but we choose to use a different term since cursors don't handle non-SELECT statements.)

The overall execution cycle consists of a parse step, which creates a prepared statement from a textual query string; a bind step, which creates a portal given a prepared statement and values for any needed parameters; and an execute step that runs a portal's query. In the case of a query that returns rows (SELECT, SHOW, etc.), the execute step can be told to fetch only a limited number of rows, so that multiple execute steps might be needed to complete the operation.

The backend can keep track of multiple prepared statements and portals (but note that these exist only within a session, and are never shared across sessions). Existing prepared statements and portals are referenced by names assigned when they were created. In addition, an “unnamed” prepared statement and portal exist. Although these behave largely the same as named objects, operations on them are optimized for the case of executing a query only once and then discarding it, whereas operations on named objects are optimized on the expectation of multiple uses.

54.1.3. Formats and Format Codes

Data of a particular data type might be transmitted in any of several different formats. As of PostgreSQL 7.4 the only supported formats are “text” and “binary”, but the protocol makes provision for future extensions. The desired format for any value is specified by a format code. Clients can specify a format code for each transmitted parameter value and for each column of a query result. Text has format code zero, binary has format code one, and all other format codes are reserved for future definition.

The text representation of values is whatever strings are produced and accepted by the input/output conversion functions for the particular data type. In the transmitted representation, there is no trailing null character; the frontend must add one to received values if it wants to process them as C strings. (The text format does not allow embedded nulls, by the way.)

Binary representations for integers use network byte order (most significant byte first). For other data types consult the documentation or source code to learn about the binary representation. Keep in mind that binary representations for complex data types might change across server versions; the text format is usually the more portable choice.
54.2. Message Flow

This section describes the message flow and the semantics of each message type. (Details of the exact representation of each message appear in Section 54.7.) There are several different sub-protocols depending on the state of the connection: start-up, query, function call, COPY, and termination. There are also special provisions for asynchronous operations (including notification responses and command cancellation), which can occur at any time after the start-up phase.

54.2.1. Start-up

To begin a session, a frontend opens a connection to the server and sends a startup message. This message includes the names of the user and of the database the user wants to connect to; it also identifies the particular protocol version to be used. (Optionally, the startup message can include additional settings for run-time parameters.) The server then uses this information and the contents of its configuration files (such as pg_hba.conf) to determine whether the connection is provisionally acceptable, and what additional authentication is required (if any).

The server then sends an appropriate authentication request message, to which the frontend must reply with an appropriate authentication response message (such as a password). For all authentication methods except GSSAPI, SSPI and SASL, there is at most one request and one response. In some methods, no response at all is needed from the frontend, and so no authentication request occurs. For GSSAPI, SSPI and SASL, multiple exchanges of packets may be needed to complete the authentication.

The authentication cycle ends with the server either rejecting the connection attempt (ErrorResponse), or sending AuthenticationOk.

The possible messages from the server in this phase are:

ErrorResponse

The connection attempt has been rejected. The server then immediately closes the connection.

AuthenticationOk

The authentication exchange is successfully completed.

AuthenticationKerberosV5

The frontend must now take part in a Kerberos V5 authentication dialog (not described here, part of the Kerberos specification) with the server. If this is successful, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. This is no longer supported.

AuthenticationCleartextPassword

The frontend must now send a PasswordMessage containing the password in clear-text form. If this is the correct password, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse.

AuthenticationMD5Password

The frontend must now send a PasswordMessage containing the password (with user name) encrypted via MD5, then encrypted again using the 4-byte random salt specified in the AuthenticationMD5Password message. If this is the correct password, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. The actual PasswordMessage can be comput-
ed in SQL as `concat('md5', md5(concat(md5(concat(password, username)), random-salt)))`. (Keep in mind the `md5()` function returns its result as a hex string.)

**AuthenticationSCMCredential**

This response is only possible for local Unix-domain connections on platforms that support SCM credential messages. The frontend must issue an SCM credential message and then send a single data byte. (The contents of the data byte are uninteresting; it’s only used to ensure that the server waits long enough to receive the credential message.) If the credential is acceptable, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. (This message type is only issued by pre-9.1 servers. It may eventually be removed from the protocol specification.)

**AuthenticationGSS**

The frontend must now initiate a GSSAPI negotiation. The frontend will send a GSSResponse message with the first part of the GSSAPI data stream in response to this. If further messages are needed, the server will respond with AuthenticationGSSContinue.

**AuthenticationSSPI**

The frontend must now initiate an SSPI negotiation. The frontend will send a GSSResponse with the first part of the SSPI data stream in response to this. If further messages are needed, the server will respond with AuthenticationGSSContinue.

**AuthenticationGSSContinue**

This message contains the response data from the previous step of GSSAPI or SSPI negotiation (AuthenticationGSS, AuthenticationSSPI or a previous AuthenticationGSSContinue). If the GSSAPI or SSPI data in this message indicates more data is needed to complete the authentication, the frontend must send that data as another GSSResponse message. If GSSAPI or SSPI authentication is completed by this message, the server will next send AuthenticationOk to indicate successful authentication or ErrorResponse to indicate failure.

**AuthenticationSASL**

The frontend must now initiate a SASL negotiation, using one of the SASL mechanisms listed in the message. The frontend will send a SASLInitialResponse with the name of the selected mechanism, and the first part of the SASL data stream in response to this. If further messages are needed, the server will respond with AuthenticationSASLContinue. See Section 54.3 for details.

**AuthenticationSASLContinue**

This message contains challenge data from the previous step of SASL negotiation (AuthenticationSASL, or a previous AuthenticationSASLContinue). The frontend must respond with a SASLResponse message.

**AuthenticationSASLFinal**

SASL authentication has completed with additional mechanism-specific data for the client. The server will next send AuthenticationOk to indicate successful authentication, or an ErrorResponse to indicate failure. This message is sent only if the SASL mechanism specifies additional data to be sent from server to client at completion.

**NegotiateProtocolVersion**

The server does not support the minor protocol version requested by the client, but does support an earlier version of the protocol; this message indicates the highest supported minor version. This
message will also be sent if the client requested unsupported protocol options (i.e., beginning with \_pq\_\_\_) in the startup packet. This message will be followed by an ErrorResponse or a message indicating the success or failure of authentication.

If the frontend does not support the authentication method requested by the server, then it should immediately close the connection.

After having received AuthenticationOk, the frontend must wait for further messages from the server. In this phase a backend process is being started, and the frontend is just an interested bystander. It is still possible for the startup attempt to fail (ErrorResponse) or the server to decline support for the requested minor protocol version (NegotiateProtocolVersion), but in the normal case the backend will send some ParameterStatus messages, BackendKeyData, and finally ReadyForQuery.

During this phase the backend will attempt to apply any additional run-time parameter settings that were given in the startup message. If successful, these values become session defaults. An error causes ErrorResponse and exit.

The possible messages from the backend in this phase are:

**BackendKeyData**

This message provides secret-key data that the frontend must save if it wants to be able to issue cancel requests later. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

**ParameterStatus**

This message informs the frontend about the current (initial) setting of backend parameters, such as client_encoding or DateStyle. The frontend can ignore this message, or record the settings for its future use; see Section 54.2.6 for more details. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

**ReadyForQuery**

Start-up is completed. The frontend can now issue commands.

**ErrorResponse**

Start-up failed. The connection is closed after sending this message.

**NoticeResponse**

A warning message has been issued. The frontend should display the message but continue listening for ReadyForQuery or ErrorResponse.

The ReadyForQuery message is the same one that the backend will issue after each command cycle. Depending on the coding needs of the frontend, it is reasonable to consider ReadyForQuery as starting a command cycle, or to consider ReadyForQuery as ending the start-up phase and each subsequent command cycle.

### 54.2.2. Simple Query

A simple query cycle is initiated by the frontend sending a Query message to the backend. The message includes an SQL command (or commands) expressed as a text string. The backend then sends one or more response messages depending on the contents of the query command string, and finally a ReadyForQuery
response message. ReadyForQuery informs the frontend that it can safely send a new command. (It is not actually necessary for the frontend to wait for ReadyForQuery before issuing another command, but the frontend must then take responsibility for figuring out what happens if the earlier command fails and already-issued later commands succeed.)

The possible response messages from the backend are:

**CommandComplete**
- An SQL command completed normally.

**CopyInResponse**
- The backend is ready to copy data from the frontend to a table; see Section 54.2.5.

**CopyOutResponse**
- The backend is ready to copy data from a table to the frontend; see Section 54.2.5.

**RowDescription**
- Indicates that rows are about to be returned in response to a SELECT, FETCH, etc. query. The contents of this message describe the column layout of the rows. This will be followed by a DataRow message for each row being returned to the frontend.

**DataRow**
- One of the set of rows returned by a SELECT, FETCH, etc. query.

**EmptyQueryResponse**
- An empty query string was recognized.

**ErrorResponse**
- An error has occurred.

**ReadyForQuery**
- Processing of the query string is complete. A separate message is sent to indicate this because the query string might contain multiple SQL commands. (CommandComplete marks the end of processing one SQL command, not the whole string.) ReadyForQuery will always be sent, whether processing terminates successfully or with an error.

**NoticeResponse**
- A warning message has been issued in relation to the query. Notices are in addition to other responses, i.e., the backend will continue processing the command.

The response to a SELECT query (or other queries that return row sets, such as EXPLAIN or SHOW) normally consists of RowDescription, zero or more DataRow messages, and then CommandComplete. COPY to or from the frontend invokes special protocol as described in Section 54.2.5. All other query types normally produce only a CommandComplete message.

Since a query string could contain several queries (separated by semicolons), there might be several such response sequences before the backend finishes processing the query string. ReadyForQuery is issued when the entire string has been processed and the backend is ready to accept a new query string.
If a completely empty (no contents other than whitespace) query string is received, the response is EmptyQueryResponse followed by ReadyForQuery.

In the event of an error, ErrorResponse is issued followed by ReadyForQuery. All further processing of the query string is aborted by ErrorResponse (even if more queries remained in it). Note that this might occur partway through the sequence of messages generated by an individual query.

In simple Query mode, the format of retrieved values is always text, except when the given command is a FETCH from a cursor declared with the BINARY option. In that case, the retrieved values are in binary format. The format codes given in the RowDescription message tell which format is being used.

A frontend must be prepared to accept ErrorResponse and NoticeResponse messages whenever it is expecting any other type of message. See also Section 54.2.6 concerning messages that the backend might generate due to outside events.

Recommended practice is to code frontends in a state-machine style that will accept any message type at any time that it could make sense, rather than wiring in assumptions about the exact sequence of messages.

### 54.2.2.1. Multiple Statements in a Simple Query

When a simple Query message contains more than one SQL statement (separated by semicolons), those statements are executed as a single transaction, unless explicit transaction control commands are included to force a different behavior. For example, if the message contains

```
INSERT INTO mytable VALUES(1);
SELECT 1/0;
INSERT INTO mytable VALUES(2);
```

then the divide-by-zero failure in the SELECT will force rollback of the first INSERT. Furthermore, because execution of the message is abandoned at the first error, the second INSERT is never attempted at all.

If instead the message contains

```
BEGIN;
INSERT INTO mytable VALUES(1);
COMMIT;
INSERT INTO mytable VALUES(2);
SELECT 1/0;
```

then the first INSERT is committed by the explicit COMMIT command. The second INSERT and the SELECT are still treated as a single transaction, so that the divide-by-zero failure will roll back the second INSERT, but not the first one.

This behavior is implemented by running the statements in a multi-statement Query message in an **implicit transaction block** unless there is some explicit transaction block for them to run in. The main difference between an implicit transaction block and a regular one is that an implicit block is closed automatically at the end of the Query message, either by an implicit commit if there was no error, or an implicit rollback if there was an error. This is similar to the implicit commit or rollback that happens for a statement executed by itself (when not in a transaction block).

If the session is already in a transaction block, as a result of a BEGIN in some previous message, then the Query message simply continues that transaction block, whether the message contains one statement or several. However, if the Query message contains a COMMIT or ROLLBACK closing the existing transaction block, then any following statements are executed in an implicit transaction block. Conversely, if a BEGIN
appears in a multi-statement Query message, then it starts a regular transaction block that will only be
terminated by an explicit COMMIT or ROLLBACK, whether that appears in this Query message or a later
one. If the BEGIN follows some statements that were executed as an implicit transaction block, those
statements are not immediately committed; in effect, they are retroactively included into the new regular
transaction block.

A COMMIT or ROLLBACK appearing in an implicit transaction block is executed as normal, closing the
implicit block; however, a warning will be issued since a COMMIT or ROLLBACK without a previous
BEGIN might represent a mistake. If more statements follow, a new implicit transaction block will be
started for them.

Savepoints are not allowed in an implicit transaction block, since they would conflict with the behavior
of automatically closing the block upon any error.

Remember that, regardless of any transaction control commands that may be present, execution of the
Query message stops at the first error. Thus for example given

BEGIN;
SELECT 1/0;
ROLLBACK;

in a single Query message, the session will be left inside a failed regular transaction block, since the
ROLLBACK is not reached after the divide-by-zero error. Another ROLLBACK will be needed to restore
the session to a usable state.

Another behavior of note is that initial lexical and syntactic analysis is done on the entire query string
before any of it is executed. Thus simple errors (such as a misspelled keyword) in later statements can
prevent execution of any of the statements. This is normally invisible to users since the statements would all
roll back anyway when done as an implicit transaction block. However, it can be visible when attempting
to do multiple transactions within a multi-statement Query. For instance, if a typo turned our previous
example into

BEGIN;
INSERT INTO mytable VALUES(1);
COMMIT;
INSERT INTO mytable VALUES(2);
SELECT 1/0;

then none of the statements would get run, resulting in the visible difference that the first INSERT is not
committed. Errors detected at semantic analysis or later, such as a misspelled table or column name, do
not have this effect.

54.2.3. Extended Query

The extended query protocol breaks down the above-described simple query protocol into multiple steps.
The results of preparatory steps can be re-used multiple times for improved efficiency. Furthermore, addi-
tional features are available, such as the possibility of supplying data values as separate parameters instead
of having to insert them directly into a query string.

In the extended protocol, the frontend first sends a Parse message, which contains a textual query string,
optionally some information about data types of parameter placeholders, and the name of a destination
prepared-statement object (an empty string selects the unnamed prepared statement). The response is either
ParseComplete or ErrorResponse. Parameter data types can be specified by OID; if not given, the parser
attempts to infer the data types in the same way as it would do for untyped literal string constants.
A parameter data type can be left unspecified by setting it to zero, or by making the array of parameter type OIDs shorter than the number of parameter symbols ($n$) used in the query string. Another special case is that a parameter's type can be specified as void (that is, the OID of the void pseudo-type). This is meant to allow parameter symbols to be used for function parameters that are actually OUT parameters. Ordinarily there is no context in which a void parameter could be used, but if such a parameter symbol appears in a function's parameter list, it is effectively ignored. For example, a function call such as `foo($1,$2,$3,$4)` could match a function with two IN and two OUT arguments, if `$3` and `$4` are specified as having type void.

The query string contained in a Parse message cannot include more than one SQL statement; else a syntax error is reported. This restriction does not exist in the simple-query protocol, but it does exist in the extended protocol, because allowing prepared statements or portals to contain multiple commands would complicate the protocol unduly.

If successfully created, a named prepared-statement object lasts till the end of the current session, unless explicitly destroyed. An unnamed prepared statement lasts only until the next Parse statement specifying the unnamed statement as destination is issued. (Note that a simple Query message also destroys the unnamed statement.) Named prepared statements must be explicitly closed before they can be redefined by another Parse message, but this is not required for the unnamed statement. Named prepared statements can also be created and accessed at the SQL command level, using `PREPARE` and `EXECUTE`.

Once a prepared statement exists, it can be readied for execution using a Bind message. The Bind message gives the name of the source prepared statement (empty string denotes the unnamed prepared statement), the name of the destination portal (empty string denotes the unnamed portal), and the values to use for any parameter placeholders present in the prepared statement. The supplied parameter set must match those needed by the prepared statement. (If you declared any void parameters in the Parse message, pass NULL values for them in the Bind message.) Bind also specifies the format to use for any data returned by the query; the format can be specified overall, or per-column. The response is either BindComplete or ErrorResponse.

The choice between text and binary output is determined by the format codes given in Bind, regardless of the SQL command involved. The `BINARY` attribute in cursor declarations is irrelevant when using extended query protocol.

Query planning typically occurs when the Bind message is processed. If the prepared statement has no parameters, or is executed repeatedly, the server might save the created plan and re-use it during subsequent Bind messages for the same prepared statement. However, it will do so only if it finds that a generic plan can be created that is not much less efficient than a plan that depends on the specific parameter values supplied. This happens transparently so far as the protocol is concerned.

If successfully created, a named portal object lasts till the end of the current transaction, unless explicitly destroyed. An unnamed portal is destroyed at the end of the transaction, or as soon as the next Bind statement specifying the unnamed portal as destination is issued. (Note that a simple Query message also destroys the unnamed portal.) Named portals must be explicitly closed before they can be redefined by
another Bind message, but this is not required for the unnamed portal. Named portals can also be created and accessed at the SQL command level, using DECLARE CURSOR and FETCH.

Once a portal exists, it can be executed using an Execute message. The Execute message specifies the portal name (empty string denotes the unnamed portal) and a maximum result-row count (zero meaning “fetch all rows”). The result-row count is only meaningful for portals containing commands that return row sets; in other cases the command is always executed to completion, and the row count is ignored. The possible responses to Execute are the same as those described above for queries issued via simple query protocol, except that Execute doesn't cause ReadyForQuery or RowDescription to be issued.

If Execute terminates before completing the execution of a portal (due to reaching a nonzero result-row count), it will send a PortalSuspended message; the appearance of this message tells the frontend that another Execute should be issued against the same portal to complete the operation. The CommandComplete message indicating completion of the source SQL command is not sent until the portal's execution is completed. Therefore, an Execute phase is always terminated by the appearance of exactly one of these messages: CommandComplete, EmptyQueryResponse (if the portal was created from an empty query string), ErrorResponse, or PortalSuspended.

At completion of each series of extended-query messages, the frontend should issue a Sync message. This parameterless message causes the backend to close the current transaction if it's not inside a BEGIN/COMMIT transaction block (“close” meaning to commit if no error, or roll back if error). Then a ReadyForQuery response is issued. The purpose of Sync is to provide a resynchronization point for error recovery. When an error is detected while processing any extended-query message, the backend issues ErrorResponse, then reads and discards messages until a Sync is reached, then issues ReadyForQuery and returns to normal message processing. (But note that no skipping occurs if an error is detected while processing Sync — this ensures that there is one and only one ReadyForQuery sent for each Sync.)

### Note

Sync does not cause a transaction block opened with BEGIN to be closed. It is possible to detect this situation since the ReadyForQuery message includes transaction status information.

In addition to these fundamental, required operations, there are several optional operations that can be used with extended-query protocol.

The Describe message (portal variant) specifies the name of an existing portal (or an empty string for the unnamed portal). The response is a RowDescription message describing the rows that will be returned by executing the portal; or a NoData message if the portal does not contain a query that will return rows; or ErrorResponse if there is no such portal.

The Describe message (statement variant) specifies the name of an existing prepared statement (or an empty string for the unnamed prepared statement). The response is a ParameterDescription message describing the parameters needed by the statement, followed by a RowDescription message describing the rows that will be returned when the statement is eventually executed (or a NoData message if the statement will not return rows). ErrorResponse is issued if there is no such prepared statement. Note that since Bind has not yet been issued, the formats to be used for returned columns are not yet known to the backend; the format code fields in the RowDescription message will be zeroes in this case.

### Tip

In most scenarios the frontend should issue one or the other variant of Describe before issuing Execute, to ensure that it knows how to interpret the results it will get back.
The Close message closes an existing prepared statement or portal and releases resources. It is not an error to issue Close against a nonexistent statement or portal name. The response is normally CloseComplete, but could be ErrorResponse if some difficulty is encountered while releasing resources. Note that closing a prepared statement implicitly closes any open portals that were constructed from that statement.

The Flush message does not cause any specific output to be generated, but forces the backend to deliver any data pending in its output buffers. A Flush must be sent after any extended-query command except Sync, if the frontend wishes to examine the results of that command before issuing more commands. Without Flush, messages returned by the backend will be combined into the minimum possible number of packets to minimize network overhead.

**Note**

The simple Query message is approximately equivalent to the series Parse, Bind, portal Describe, Execute, Close, Sync, using the unnamed prepared statement and portal objects and no parameters. One difference is that it will accept multiple SQL statements in the query string, automatically performing the bind/describe/execute sequence for each one in succession. Another difference is that it will not return ParseComplete, BindComplete, CloseComplete, or NoData messages.

### 54.2.4. Function Call

The Function Call sub-protocol allows the client to request a direct call of any function that exists in the database's `pg_proc` system catalog. The client must have execute permission for the function.

**Note**

The Function Call sub-protocol is a legacy feature that is probably best avoided in new code. Similar results can be accomplished by setting up a prepared statement that does `SELECT function($1, ...).` The Function Call cycle can then be replaced with Bind/Execute.

A Function Call cycle is initiated by the frontend sending a FunctionCall message to the backend. The backend then sends one or more response messages depending on the results of the function call, and finally a ReadyForQuery response message. ReadyForQuery informs the frontend that it can safely send a new query or function call.

The possible response messages from the backend are:

- ErrorResponse
  
  An error has occurred.

- FunctionCallResponse
  
  The function call was completed and returned the result given in the message. (Note that the Function Call protocol can only handle a single scalar result, not a row type or set of results.)

- ReadyForQuery
  
  Processing of the function call is complete. ReadyForQuery will always be sent, whether processing terminates successfully or with an error.
NoticeResponse

A warning message has been issued in relation to the function call. Notices are in addition to other responses, i.e., the backend will continue processing the command.

54.2.5. COPY Operations

The COPY command allows high-speed bulk data transfer to or from the server. Copy-in and copy-out operations each switch the connection into a distinct sub-protocol, which lasts until the operation is completed.

Copy-in mode (data transfer to the server) is initiated when the backend executes a COPY FROM STDIN SQL statement. The backend sends a CopyInResponse message to the frontend. The frontend should then send zero or more CopyData messages, forming a stream of input data. (The message boundaries are not required to have anything to do with row boundaries, although that is often a reasonable choice.) The frontend can terminate the copy-in mode by sending either a CopyDone message (allowing successful termination) or a CopyFail message (which will cause the COPY SQL statement to fail with an error). The backend then reverts to the command-processing mode it was in before the COPY started, which will be either simple or extended query protocol. It will next send either CommandComplete (if successful) or ErrorResponse (if not).

In the event of a backend-detected error during copy-in mode (including receipt of a CopyFail message), the backend will issue an ErrorResponse message. If the COPY command was issued via an extended-query message, the backend will now discard frontend messages until a Sync message is received, then it will issue ReadyForQuery and return to normal processing. If the COPY command was issued in a simple Query message, the rest of that message is discarded and ReadyForQuery is issued. In either case, any subsequent CopyData, CopyDone, or CopyFail messages issued by the frontend will simply be dropped.

The backend will ignore Flush and Sync messages received during copy-in mode. Receipt of any other non-copy message type constitutes an error that will abort the copy-in state as described above. (The exception for Flush and Sync is for the convenience of client libraries that always send Flush or Sync after an Execute message, without checking whether the command to be executed is a COPY FROM STDIN.)

Copy-out mode (data transfer from the server) is initiated when the backend executes a COPY TO STDOUT SQL statement. The backend sends a CopyOutResponse message to the frontend, followed by zero or more CopyData messages (always one per row), followed by CopyDone. The backend then reverts to the command-processing mode it was in before the COPY started, and sends CommandComplete. The frontend cannot abort the transfer (except by closing the connection or issuing a Cancel request), but it can discard unwanted CopyData and CopyDone messages.

In the event of a backend-detected error during copy-out mode, the backend will issue an ErrorResponse message and revert to normal processing. The frontend should treat receipt of ErrorResponse as terminating the copy-out mode.

It is possible for NoticeResponse and ParameterStatus messages to be interspersed between CopyData messages; frontends must handle these cases, and should be prepared for other asynchronous message types as well (see Section 54.2.6). Otherwise, any message type other than CopyData or CopyDone may be treated as terminating copy-out mode.

There is another Copy-related mode called copy-both, which allows high-speed bulk data transfer to and from the server. Copy-both mode is initiated when a backend in walsender mode executes a START_REPLICATION statement. The backend sends a CopyBothResponse message to the frontend. Both the backend and the frontend may then send CopyData messages until either end sends a CopyDone message. After the client sends a CopyDone message, the connection goes from copy-both mode to copy-out mode, and the client may not send any more CopyData messages. Similarly, when the server sends a CopyDone
FRONTEND/BACKEND PROTOCOL

message, the connection goes into copy-in mode, and the server may not send any more CopyData
messages. After both sides have sent a CopyDone message, the copy mode is terminated, and the backend
reverts to the command-processing mode. In the event of a backend-detected error during copy-both mode,
the backend will issue an ErrorResponse message, discard frontend messages until a Sync message is re-
ceived, and then issue ReadyForQuery and return to normal processing. The frontend should treat receipt
of ErrorResponse as terminating the copy in both directions; no CopyDone should be sent in this case. See
Section 54.4 for more information on the subprotocol transmitted over copy-both mode.

The CopyInResponse, CopyOutResponse and CopyBothResponse messages include fields that inform the
frontend of the number of columns per row and the format codes being used for each column. (As of the
present implementation, all columns in a given COPY operation will use the same format, but the message
design does not assume this.)

54.2.6. ASYNCHRONOUS OPERATIONS

There are several cases in which the backend will send messages that are not specifically prompted by the
frontend's command stream. Frontends must be prepared to deal with these messages at any time, even
when not engaged in a query. At minimum, one should check for these cases before beginning to read
a query response.

It is possible for NoticeResponse messages to be generated due to outside activity; for example, if the
database administrator commands a “fast” database shutdown, the backend will send a NoticeResponse
indicating this fact before closing the connection. Accordingly, frontends should always be prepared to
accept and display NoticeResponse messages, even when the connection is nominally idle.

ParameterStatus messages will be generated whenever the active value changes for any of the parameters
the backend believes the frontend should know about. Most commonly this occurs in response to a SET
SQL command executed by the frontend, and this case is effectively synchronous — but it is also possible
for parameter status changes to occur because the administrator changed a configuration file and then sent
the SIGHUP signal to the server. Also, if a SET command is rolled back, an appropriate ParameterStatus
message will be generated to report the current effective value.

At present there is a hard-wired set of parameters for which ParameterStatus will be generated: they are
server_version, server_encoding, client_encoding, application_name, de-
default_transaction_read_only, in_hot_standby, is_superuser, session_autho-
rization, DateStyle, IntervalStyle, TimeZone, integer_datetimes, and stan-

dard_conforming_strings. (server_encoding, TimeZone, and integer_datetimes
were not reported by releases before 8.0; standard_conforming_strings was not reported by re-
leases before 8.1; IntervalStyle was not reported by releases before 8.4; application_name was
not reported by releases before 9.0; default_transaction_read_only and in_hot_standby
were not reported by releases before 14.) Note that server_version, server_encoding and in-
teger_datetimes are pseudo-parameters that cannot change after startup. This set might change in
the future, or even become configurable. Accordingly, a frontend should simply ignore ParameterStatus
for parameters that it does not understand or care about.

If a frontend issues a LISTEN command, then the backend will send a NotificationResponse message (not
to be confused with NoticeResponse!) whenever a NOTIFY command is executed for the same channel
name.

Note

At present, NotificationResponse can only be sent outside a transaction, and thus it will not occur
in the middle of a command-response series, though it might occur just before ReadyForQuery. It
is unwise to design frontend logic that assumes that, however. Good practice is to be able to accept NotificationResponse at any point in the protocol.

54.2.7. Canceling Requests in Progress

During the processing of a query, the frontend might request cancellation of the query. The cancel request is not sent directly on the open connection to the backend for reasons of implementation efficiency: we don't want to have the backend constantly checking for new input from the frontend during query processing. Cancel requests should be relatively infrequent, so we make them slightly cumbersome in order to avoid a penalty in the normal case.

To issue a cancel request, the frontend opens a new connection to the server and sends a CancelRequest message, rather than the StartupMessage message that would ordinarily be sent across a new connection. The server will process this request and then close the connection. For security reasons, no direct reply is made to the cancel request message.

A CancelRequest message will be ignored unless it contains the same key data (PID and secret key) passed to the frontend during connection start-up. If the request matches the PID and secret key for a currently executing backend, the processing of the current query is aborted. (In the existing implementation, this is done by sending a special signal to the backend process that is processing the query.)

The cancellation signal might or might not have any effect — for example, if it arrives after the backend has finished processing the query, then it will have no effect. If the cancellation is effective, it results in the current command being terminated early with an error message.

The upshot of all this is that for reasons of both security and efficiency, the frontend has no direct way to tell whether a cancel request has succeeded. It must continue to wait for the backend to respond to the query. Issuing a cancel simply improves the odds that the current query will finish soon, and improves the odds that it will fail with an error message instead of succeeding.

Since the cancel request is sent across a new connection to the server and not across the regular frontend/backend communication link, it is possible for the cancel request to be issued by any process, not just the frontend whose query is to be canceled. This might provide additional flexibility when building multiple-process applications. It also introduces a security risk, in that unauthorized persons might try to cancel queries. The security risk is addressed by requiring a dynamically generated secret key to be supplied in cancel requests.

54.2.8. Termination

The normal, graceful termination procedure is that the frontend sends a Terminate message and immediately closes the connection. On receipt of this message, the backend closes the connection and terminates.

In rare cases (such as an administrator-commanded database shutdown) the backend might disconnect without any frontend request to do so. In such cases the backend will attempt to send an error or notice message giving the reason for the disconnection before it closes the connection.

Other termination scenarios arise from various failure cases, such as core dump at one end or the other, loss of the communications link, loss of message-boundary synchronization, etc. If either frontend or backend sees an unexpected closure of the connection, it should clean up and terminate. The frontend has the option of launching a new backend by recontacting the server if it doesn't want to terminate itself. Closing the connection is also advisable if an unrecognizable message type is received, since this probably indicates loss of message-boundary sync.
For either normal or abnormal termination, any open transaction is rolled back, not committed. One should note however that if a frontend disconnects while a non-SELECT query is being processed, the backend will probably finish the query before noticing the disconnection. If the query is outside any transaction block (BEGIN ... COMMIT sequence) then its results might be committed before the disconnection is recognized.

54.2.9. SSL Session Encryption

If PostgreSQL was built with SSL support, frontend/backend communications can be encrypted using SSL. This provides communication security in environments where attackers might be able to capture the session traffic. For more information on encrypting PostgreSQL sessions with SSL, see Section 19.9.

To initiate an SSL-encrypted connection, the frontend initially sends an SSLRequest message rather than a StartupMessage. The server then responds with a single byte containing S or N, indicating that it is willing or unwilling to perform SSL, respectively. The frontend might close the connection at this point if it is dissatisfied with the response. To continue after S, perform an SSL startup handshake (not described here, part of the SSL specification) with the server. If this is successful, continue with sending the usual StartupMessage. In this case the StartupMessage and all subsequent data will be SSL-encrypted. To continue after N, send the usual StartupMessage and proceed without encryption. (Alternatively, it is permissible to issue a GSSENCRequest message after an N response to try to use GSSAPI encryption instead of SSL.)

The frontend should also be prepared to handle an ErrorMessage response to SSLRequest from the server. This would only occur if the server predates the addition of SSL support to PostgreSQL. (Such servers are now very ancient, and likely do not exist in the wild anymore.) In this case the connection must be closed, but the frontend might choose to open a fresh connection and proceed without requesting SSL.

When SSL encryption can be performed, the server is expected to send only the single S byte and then wait for the frontend to initiate an SSL handshake. If additional bytes are available to read at this point, it likely means that a man-in-the-middle is attempting to perform a buffer-stuffing attack (CVE-2021-232221). Frontends should be coded either to read exactly one byte from the socket before turning the socket over to their SSL library, or to treat it as a protocol violation if they find they have read additional bytes.

An initial SSLRequest can also be used in a connection that is being opened to send a CancelRequest message.

While the protocol itself does not provide a way for the server to force SSL encryption, the administrator can configure the server to reject unencrypted sessions as a byproduct of authentication checking.

54.2.10. GSSAPI Session Encryption

If PostgreSQL was built with GSSAPI support, frontend/backend communications can be encrypted using GSSAPI. This provides communication security in environments where attackers might be able to capture the session traffic. For more information on encrypting PostgreSQL sessions with GSSAPI, see Section 19.10.

To initiate a GSSAPI-encrypted connection, the frontend initially sends a GSSENCRequest message rather than a StartupMessage. The server then responds with a single byte containing G or N, indicating that it is willing or unwilling to perform GSSAPI encryption, respectively. The frontend might close the connection at this point if it is dissatisfied with the response. To continue after G, using the GSSAPI C bindings as discussed in RFC 27442 or equivalent, perform a GSSAPI initialization by calling gss_init_sec_context() in a loop and sending the result to the server, starting with an empty input and then with each result

1 https://www.postgresql.org/support/security/CVE-2021-23222/
from the server, until it returns no output. When sending the results of `gss_init_sec_context()` to the server, prepend the length of the message as a four byte integer in network byte order. To continue after N, send the usual StartupMessage and proceed without encryption. (Alternatively, it is permissible to issue an SSLRequest message after an N response to try to use SSL encryption instead of GSSAPI.)

The frontend should also be prepared to handle an ErrorMessage response to GSSENCRequest from the server. This would only occur if the server predates the addition of GSSAPI encryption support to PostgreSQL. In this case the connection must be closed, but the frontend might choose to open a fresh connection and proceed without requesting GSSAPI encryption.

When GSSAPI encryption can be performed, the server is expected to send only the single G byte and then wait for the frontend to initiate a GSSAPI handshake. If additional bytes are available to read at this point, it likely means that a man-in-the-middle is attempting to perform a buffer-stuffing attack (CVE-2021-23222³). Frontends should be coded either to read exactly one byte from the socket before turning the socket over to their GSSAPI library, or to treat it as a protocol violation if they find they have read additional bytes.

An initial GSSENCRequest can also be used in a connection that is being opened to send a CancelRequest message.

Once GSSAPI encryption has been successfully established, use `gss_wrap()` to encrypt the usual StartupMessage and all subsequent data, prepending the length of the result from `gss_wrap()` as a four byte integer in network byte order to the actual encrypted payload. Note that the server will only accept encrypted packets from the client which are less than 16kB; `gss_wrap_size_limit()` should be used by the client to determine the size of the unencrypted message which will fit within this limit and larger messages should be broken up into multiple `gss_wrap()` calls. Typical segments are 8kB of unencrypted data, resulting in encrypted packets of slightly larger than 8kB but well within the 16kB maximum. The server can be expected to not send encrypted packets of larger than 16kB to the client.

While the protocol itself does not provide a way for the server to force GSSAPI encryption, the administrator can configure the server to reject unencrypted sessions as a byproduct of authentication checking.

### 54.3. SASL Authentication

SASL is a framework for authentication in connection-oriented protocols. At the moment, PostgreSQL implements two SASL authentication mechanisms, SCRAM-SHA-256 and SCRAM-SHA-256-PLUS. More might be added in the future. The below steps illustrate how SASL authentication is performed in general, while the next subsection gives more details on SCRAM-SHA-256 and SCRAM-SHA-256-PLUS.

**SASL Authentication Message Flow**

1. To begin a SASL authentication exchange, the server sends an AuthenticationSASL message. It includes a list of SASL authentication mechanisms that the server can accept, in the server’s preferred order.

2. The client selects one of the supported mechanisms from the list, and sends a SASLInitialResponse message to the server. The message includes the name of the selected mechanism, and an optional Initial Client Response, if the selected mechanism uses that.

3. One or more server-challenge and client-response message will follow. Each server-challenge is sent in an AuthenticationSASLContinue message, followed by a response from client in a SASLResponse message. The particulars of the messages are mechanism specific.

³ [https://www.postgresql.org/support/security/CVE-2021-23222/](https://www.postgresql.org/support/security/CVE-2021-23222/)
4. Finally, when the authentication exchange is completed successfully, the server sends an AuthenticationSASLFinal message, followed immediately by an AuthenticationOk message. The AuthenticationSASLFinal contains additional server-to-client data, whose content is particular to the selected authentication mechanism. If the authentication mechanism doesn't use additional data that's sent at completion, the AuthenticationSASLFinal message is not sent.

On error, the server can abort the authentication at any stage, and send an ErrorMessage.

54.3.1. SCRAM-SHA-256 Authentication

The implemented SASL mechanisms at the moment are SCRAM-SHA-256 and its variant with channel binding SCRAM-SHA-256-PLUS. They are described in detail in RFC 7677\(^4\) and RFC 5802\(^5\).

When SCRAM-SHA-256 is used in PostgreSQL, the server will ignore the user name that the client sends in the client-first-message. The user name that was already sent in the startup message is used instead. PostgreSQL supports multiple character encodings, while SCRAM dictates UTF-8 to be used for the user name, so it might be impossible to represent the PostgreSQL user name in UTF-8.

The SCRAM specification dictates that the password is also in UTF-8, and is processed with the SASLprep algorithm. PostgreSQL, however, does not require UTF-8 to be used for the password. When a user's password is set, it is processed with SASLprep as if it was in UTF-8, regardless of the actual encoding used. However, if it is not a legal UTF-8 byte sequence, or it contains UTF-8 byte sequences that are prohibited by the SASLprep algorithm, the raw password will be used without SASLprep processing, instead of throwing an error. This allows the password to be normalized when it is in UTF-8, but still allows a non-UTF-8 password to be used, and doesn't require the system to know which encoding the password is in.

Channel binding is supported in PostgreSQL builds with SSL support. The SASL mechanism name for SCRAM with channel binding is SCRAM-SHA-256-PLUS. The channel binding type used by PostgreSQL is tls-server-end-point.

In SCRAM without channel binding, the server chooses a random number that is transmitted to the client to be mixed with the user-supplied password in the transmitted password hash. While this prevents the password hash from being successfully retransmitted in a later session, it does not prevent a fake server between the real server and client from passing through the server's random value and successfully authenticating.

SCRAM with channel binding prevents such man-in-the-middle attacks by mixing the signature of the server's certificate into the transmitted password hash. While a fake server can retransmit the real server's certificate, it doesn't have access to the private key matching that certificate, and therefore cannot prove it is the owner, causing SSL connection failure.

Example

1. The server sends an AuthenticationSASL message. It includes a list of SASL authentication mechanisms that the server can accept. This will be SCRAM-SHA-256-PLUS and SCRAM-SHA-256 if the server is built with SSL support, or else just the latter.

2. The client responds by sending a SASLInitialResponse message, which indicates the chosen mechanism, SCRAM-SHA-256 or SCRAM-SHA-256-PLUS. (A client is free to choose either mechanism, but for better security it should choose the channel-binding variant if it can support it.) In the Initial Client response field, the message contains the SCRAM client-first-message. The client-first-message also contains the channel binding type chosen by the client.

---
\(^4\) https://tools.ietf.org/html/rfc7677
\(^5\) https://tools.ietf.org/html/rfc5802
3. Server sends an AuthenticationSASLContinue message, with a SCRAM server-first-message as the content.

4. Client sends a SASLResponse message, with SCRAM client-final-message as the content.

5. Server sends an AuthenticationSASLFinal message, with the SCRAM server-final-message, followed immediately by an AuthenticationOk message.

54.4. Streaming Replication Protocol

To initiate streaming replication, the frontend sends the replication parameter in the startup message. A Boolean value of true (or on, yes, 1) tells the backend to go into physical replication walsender mode, wherein a small set of replication commands, shown below, can be issued instead of SQL statements.

Passing database as the value for the replication parameter instructs the backend to go into logical replication walsender mode, connecting to the database specified in the dbname parameter. In logical replication walsender mode, the replication commands shown below as well as normal SQL commands can be issued.

In either physical replication or logical replication walsender mode, only the simple query protocol can be used.

For the purpose of testing replication commands, you can make a replication connection via psql or any other libpq-using tool with a connection string including the replication option, e.g.:

```sql
psql "dbname=postgres replication=database" -c "IDENTIFY_SYSTEM;"
```

However, it is often more useful to use pg_receivewal (for physical replication) or pg_recvlogical (for logical replication).

Replication commands are logged in the server log when log_replication_commands is enabled.

The commands accepted in replication mode are:

**IDENTIFY_SYSTEM**

Requests the server to identify itself. Server replies with a result set of a single row, containing four fields:

- **systemid (text)**
  - The unique system identifier identifying the cluster. This can be used to check that the base backup used to initialize the standby came from the same cluster.

- **timeline (int4)**
  - Current timeline ID. Also useful to check that the standby is consistent with the primary.

- **xlogpos (text)**
  - Current WAL flush location. Useful to get a known location in the write-ahead log where streaming can start.

- **dbname (text)**
  - Database connected to or null.
Show name

Requests the server to send the current setting of a run-time parameter. This is similar to the SQL command SHOW.

name

The name of a run-time parameter. Available parameters are documented in Chapter 20.

Timeline_history tli

Requests the server to send over the timeline history file for timeline tli. Server replies with a result set of a single row, containing two fields. While the fields are labeled as text, they effectively return raw bytes, with no encoding conversion:

filename (text)

File name of the timeline history file, e.g., 00000002.history.

content (text)

Contents of the timeline history file.

Create_replication_slot slot_name [ TEMPORARY ] [ PHYSICAL | LOGICAL ] [ ( option [ , ... ] ) ]

Create a physical or logical replication slot. See Section 27.2.6 for more about replication slots.

slot_name

The name of the slot to create. Must be a valid replication slot name (see Section 27.2.6.1).

output_plugin

The name of the output plugin used for logical decoding (see Section 49.6).

Temporal

Specify that this replication slot is a temporary one. Temporary slots are not saved to disk and are automatically dropped on error or when the session has finished.

The following options are supported:

Two_phase [ boolean ]

If true, this logical replication slot supports decoding of two-phase commit. With this option, commands related to two-phase commit such as PREPARE TRANSACTION, COMMIT PREPARED and ROLLBACK PREPARED are decoded and transmitted. The transaction will be decoded and transmitted at PREPARE TRANSACTION time. The default is false.

Reserve_wal [ boolean ]

If true, this physical replication slot reserves WAL immediately. Otherwise, WAL is only reserved upon connection from a streaming replication client. The default is false.

Snapshot ( 'export' | 'use' | 'nothing' )

Decides what to do with the snapshot created during logical slot initialization. 'export', which is the default, will export the snapshot for use in other sessions. This option can't be used inside
a transaction. 'use' will use the snapshot for the current transaction executing the command. This option must be used in a transaction, and CREATE_REPLICATION_SLOT must be the first command run in that transaction. Finally, 'nothing' will just use the snapshot for logical decoding as normal but won't do anything else with it.

In response to this command, the server will send a one-row result set containing the following fields:

```
slot_name (text)
```

The name of the newly-created replication slot.

```
consistent_point (text)
```

The WAL location at which the slot became consistent. This is the earliest location from which streaming can start on this replication slot.

```
snapshot_name (text)
```

The identifier of the snapshot exported by the command. The snapshot is valid until a new command is executed on this connection or the replication connection is closed. Null if the created slot is physical.

```
output_plugin (text)
```

The name of the output plugin used by the newly-created replication slot. Null if the created slot is physical.

```
CREATE_REPLICATION_SLOT slot_name [ TEMPORARY ] { PHYSICAL [ RESERVE_WAL ] | LOGICAL output_plugin [ EXPORT_SNAPSHOT | NOEXPORT_SNAPSHOT | USE_SNAPSHOT | TWO_PHASE ] }
```

For compatibility with older releases, this alternative syntax for the CREATE_REPLICATION_SLOT command is still supported.

```
READ_REPLICATION_SLOT slot_name
```

Read some information associated with a replication slot. Returns a tuple with NULL values if the replication slot does not exist. This command is currently only supported for physical replication slots.

In response to this command, the server will return a one-row result set, containing the following fields:

```
slot_type (text)
```

The replication slot's type, either physical or NULL.

```
restart_lsn (text)
```

The replication slot's restart_lsn.

```
restart_tli (int8)
```

The timeline ID associated with restart_lsn, following the current timeline history.

```
START_REPLICATION [ SLOT slot_name ] [ PHYSICAL ] XXX/XXX [ TIMELINE tli ]
```

Instructs server to start streaming WAL, starting at WAL location XXX/XXX. If TIMELINE option is specified, streaming starts on timeline tli; otherwise, the server's current timeline is selected. The
server can reply with an error, for example if the requested section of WAL has already been recycled. On success, the server responds with a CopyBothResponse message, and then starts to stream WAL to the frontend.

If a slot's name is provided via slot_name, it will be updated as replication progresses so that the server knows which WAL segments, and if hot_standby_feedback is on which transactions, are still needed by the standby.

If the client requests a timeline that's not the latest but is part of the history of the server, the server will stream all the WAL on that timeline starting from the requested start point up to the point where the server switched to another timeline. If the client requests streaming at exactly the end of an old timeline, the server skips COPY mode entirely.

After streaming all the WAL on a timeline that is not the latest one, the server will end streaming by exiting the COPY mode. When the client acknowledges this by also exiting COPY mode, the server sends a result set with one row and two columns, indicating the next timeline in this server's history. The first column is the next timeline's ID (type int8), and the second column is the WAL location where the switch happened (type text). Usually, the switch position is the end of the WAL that was streamed, but there are corner cases where the server can send some WAL from the old timeline that it has not itself replayed before promoting. Finally, the server sends two CommandComplete messages (one that ends the CopyData and the other ends the START_REPLICATION itself), and is ready to accept a new command.

WAL data is sent as a series of CopyData messages. (This allows other information to be intermixed; in particular the server can send an ErrorResponse message if it encounters a failure after beginning to stream.) The payload of each CopyData message from server to the client contains a message of one of the following formats:

XLogData (B)

Byte1('w')

Identifies the message as WAL data.

Int64

The starting point of the WAL data in this message.

Int64

The current end of WAL on the server.

Int64

The server's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte

A section of the WAL data stream.

A single WAL record is never split across two XLogData messages. When a WAL record crosses a WAL page boundary, and is therefore already split using continuation records, it can be split at the page boundary. In other words, the first main WAL record and its continuation records can be sent in different XLogData messages.
Primary keepalive message (B)

Byte1('k')
Identifies the message as a sender keepalive.

Int64
The current end of WAL on the server.

Int64
The server's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte1
I means that the client should reply to this message as soon as possible, to avoid a timeout disconnect. 0 otherwise.

The receiving process can send replies back to the sender at any time, using one of the following message formats (also in the payload of a CopyData message):

Standby status update (F)

Byte1('r')
Identifies the message as a receiver status update.

Int64
The location of the last WAL byte + 1 received and written to disk in the standby.

Int64
The location of the last WAL byte + 1 flushed to disk in the standby.

Int64
The location of the last WAL byte + 1 applied in the standby.

Int64
The client's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte1
If 1, the client requests the server to reply to this message immediately. This can be used to ping the server, to test if the connection is still healthy.

Hot standby feedback message (F)

Byte1('h')
Identifies the message as a hot standby feedback message.
Int64

The client's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Int32

The standby's current global xmin, excluding the catalog_xmin from any replication slots. If both this value and the following catalog_xmin are 0 this is treated as a notification that hot standby feedback will no longer be sent on this connection. Later non-zero messages may reinitiate the feedback mechanism.

Int32

The epoch of the global xmin xid on the standby.

Int32

The lowest catalog_xmin of any replication slots on the standby. Set to 0 if no catalog_xmin exists on the standby or if hot standby feedback is being disabled.

Int32

The epoch of the catalog_xmin xid on the standby.

```
START_REPLICATION SLOT slot_name LOGICAL XXX/XXX [ ( option_name [ option_value][, ...])]
```

Instructs server to start streaming WAL for logical replication, starting at either WAL location XXX/XXX or the slot's confirmed_flush_lsn (see Section 53.84), whichever is greater. This behavior makes it easier for clients to avoid updating their local LSN status when there is no data to process. However, starting at a different LSN than requested might not catch certain kinds of client errors; so the client may wish to check that confirmed_flush_lsn matches its expectations before issuing START_REPLICATION.

The server can reply with an error, for example if the slot does not exist. On success, the server responds with a CopyBothResponse message, and then starts to stream WAL to the frontend.

The messages inside the CopyBothResponse messages are of the same format documented for START_REPLICATION ... PHYSICAL, including two CommandComplete messages.

The output plugin associated with the selected slot is used to process the output for streaming.

```
SLOT slot_name
```

The name of the slot to stream changes from. This parameter is required, and must correspond to an existing logical replication slot created with CREATE_REPLICATION_SLOT in LOGICAL mode.

```
XXX/XXX
```

The WAL location to begin streaming at.

```
option_name
```

The name of an option passed to the slot's logical decoding plugin.
option_value

Optional value, in the form of a string constant, associated with the specified option.

DROP_REPLICATION_SLOT slot_name [ WAIT ]

Drops a replication slot, freeing any reserved server-side resources. If the slot is a logical slot that was created in a database other than the database the walsender is connected to, this command fails.

slot_name

The name of the slot to drop.

WAIT

This option causes the command to wait if the slot is active until it becomes inactive, instead of the default behavior of raising an error.

BASE_BACKUP [ ( option[,...] ) ]

Instructs the server to start streaming a base backup. The system will automatically be put in backup mode before the backup is started, and taken out of it when the backup is complete. The following options are accepted:

LABEL 'label'

Sets the label of the backup. If none is specified, a backup label of base backup will be used. The quoting rules for the label are the same as a standard SQL string with standard_conforming_strings turned on.

TARGET 'target'

Tells the server where to send the backup. If the target is client, which is the default, the backup data is sent to the client. If it is server, the backup data is written to the server at the pathname specified by the TARGET_DETAIL option. If it is blackhole, the backup data is not sent anywhere; it is simply discarded.

The server target requires superuser privilege or being granted the pg_write_server_files role.

TARGET_DETAIL 'detail'

Provides additional information about the backup target.

Currently, this option can only be used when the backup target is server. It specifies the server directory to which the backup should be written.

PROGRESS [ boolean ]

If set to true, request information required to generate a progress report. This will send back an approximate size in the header of each tablespace, which can be used to calculate how far along the stream is done. This is calculated by enumerating all the file sizes once before the transfer is even started, and might as such have a negative impact on the performance. In particular, it might take longer before the first data is streamed. Since the database files can change during the backup, the size is only approximate and might both grow and shrink between the time of approximation and the sending of the actual files. The default is false.
CHECKPOINT { 'fast' | 'spread' }

Sets the type of checkpoint to be performed at the beginning of the base backup. The default is spread.

WAL [ boolean ]

If set to true, include the necessary WAL segments in the backup. This will include all the files between start and stop backup in the pg_wal directory of the base directory tar file. The default is false.

WAIT [ boolean ]

If set to true, the backup will wait until the last required WAL segment has been archived, or emit a warning if log archiving is not enabled. If false, the backup will neither wait nor warn, leaving the client responsible for ensuring the required log is available. The default is true.

COMPRESSION 'method'

Instructs the server to compress the backup using the specified method. Currently, the supported methods are gzip, lz4, and zstd.

COMPRESSION_DETAIL detail

Specifies details for the chosen compression method. This should only be used in conjunction with the COMPRESSION option. If the value is an integer, it specifies the compression level. Otherwise, it should be a comma-separated list of items, each of the form keyword or keyword=value. Currently, the supported keywords are level and workers.

The level keyword sets the compression level. For gzip the compression level should be an integer between 1 and 9, for lz4 an integer between 1 and 12, and for zstd an integer between 1 and 22.

The workers keyword sets the number of threads that should be used for parallel compression. Parallel compression is supported only for zstd.

MAX_RATE rate

Limit (throttle) the maximum amount of data transferred from server to client per unit of time. The expected unit is kilobytes per second. If this option is specified, the value must either be equal to zero or it must fall within the range from 32 kB through 1 GB (inclusive). If zero is passed or the option is not specified, no restriction is imposed on the transfer.

TABLESPACE_MAP [ boolean ]

If true, include information about symbolic links present in the directory pg_tblspc in a file named tablespace_map. The tablespace map file includes each symbolic link name as it exists in the directory pg_tblspc/ and the full path of that symbolic link. The default is false.

VERIFY_CHECKSUMS [ boolean ]

If true, checksums are verified during a base backup if they are enabled. If false, this is skipped. The default is true.

MANIFEST manifest_option

When this option is specified with a value of yes or force-encode, a backup manifest is created and sent along with the backup. The manifest is a list of every file present in the backup with the exception of any WAL files that may be included. It also stores the size, last modification
time, and optionally a checksum for each file. A value of `force-encode` forces all filenames to be hex-encoded; otherwise, this type of encoding is performed only for files whose names are non-UTF8 octet sequences. `force-encode` is intended primarily for testing purposes, to be sure that clients which read the backup manifest can handle this case. For compatibility with previous releases, the default is `MANIFEST 'no'`.

**MANIFEST_CHECKSUMS checksum_algorithm**

Specifies the checksum algorithm that should be applied to each file included in the backup manifest. Currently, the available algorithms are `NONE`, `CRC32C`, `SHA224`, `SHA256`, `SHA384`, and `SHA512`. The default is `CRC32C`.

When the backup is started, the server will first send two ordinary result sets, followed by one or more `CopyOutResponse` results.

The first ordinary result set contains the starting position of the backup, in a single row with two columns. The first column contains the start position given in XLogRecPtr format, and the second column contains the corresponding timeline ID.

The second ordinary result set has one row for each tablespace. The fields in this row are:

- `spcoid(oid)`
  The OID of the tablespace, or null if it's the base directory.

- `spclocation(text)`
  The full path of the tablespace directory, or null if it's the base directory.

- `size(int8)`
  The approximate size of the tablespace, in kilobytes (1024 bytes), if progress report has been requested; otherwise it's null.

After the second regular result set, a `CopyOutResponse` will be sent. The payload of each `CopyData` message will contain a message in one of the following formats:

- **new archive (B)**
  Byte1('n')
  Identifies the message as indicating the start of a new archive. There will be one archive for the main data directory and one for each additional tablespace; each will use tar format (following the “ustar interchange format” specified in the POSIX 1003.1-2008 standard).

- **String**
  The file name for this archive.

- **String**
  For the main data directory, an empty string. For other tablespaces, the full path to the directory from which this archive was created.

- **manifest (B)**
  Byte1('m')
  Identifies the message as indicating the start of the backup manifest.
archive or manifest data (B)

Byte1('d')

Identifies the message as containing archive or manifest data.

Byte n

Data bytes.

progress report (B)

Byte1('p')

Identifies the message as a progress report.

Int64

The number of bytes from the current tablespace for which processing has been completed.

After the CopyOutResponse, or all such responses, have been sent, a final ordinary result set will be sent, containing the WAL end position of the backup, in the same format as the start position.

The tar archive for the data directory and each tablespace will contain all files in the directories, regardless of whether they are PostgreSQL files or other files added to the same directory. The only excluded files are:

- postmaster.pid
- postmaster.opts
- pg_internal.init (found in multiple directories)
- Various temporary files and directories created during the operation of the PostgreSQL server, such as any file or directory beginning with pgsql_tmp and temporary relations.
- Unlogged relations, except for the init fork which is required to recreate the (empty) unlogged relation on recovery.
- pg_wal, including subdirectories. If the backup is run with WAL files included, a synthesized version of pg_wal will be included, but it will only contain the files necessary for the backup to work, not the rest of the contents.
- pg_dynshmem, pg_notify, pg_replslot, pg_serial, pg_snapshots, pg_stat_tmp, and pg_subtrans are copied as empty directories (even if they are symbolic links).
- Files other than regular files and directories, such as symbolic links (other than for the directories listed above) and special device files, are skipped. (Symbolic links in pg_tblspc are maintained.)
- Owner, group, and file mode are set if the underlying file system on the server supports it.

54.5. Logical Streaming Replication Protocol

This section describes the logical replication protocol, which is the message flow started by the START_REPLICATION SLOT slot_name LOGICAL replication command.

The logical streaming replication protocol builds on the primitives of the physical streaming replication protocol.

54.5.1. Logical Streaming Replication Parameters

The logical replication START_REPLICATION command accepts following parameters:
Frontend/Backend Protocol

proto_version

Protocol version. Currently versions 1, 2, and 3 are supported.

Version 2 is supported only for server version 14 and above, and it allows streaming of large in-progress transactions.

Version 3 is supported only for server version 15 and above, and it allows streaming of two-phase commits.

publication_names

Comma separated list of publication names for which to subscribe (receive changes). The individual publication names are treated as standard objects names and can be quoted the same as needed.

54.5.2. Logical Replication Protocol Messages

The individual protocol messages are discussed in the following subsections. Individual messages are described in Section 54.9.

All top-level protocol messages begin with a message type byte. While represented in code as a character, this is a signed byte with no associated encoding.

Since the streaming replication protocol supplies a message length there is no need for top-level protocol messages to embed a length in their header.

54.5.3. Logical Replication Protocol Message Flow

With the exception of the START_REPLICATION command and the replay progress messages, all information flows only from the backend to the frontend.

The logical replication protocol sends individual transactions one by one. This means that all messages between a pair of Begin and Commit messages belong to the same transaction. Similarly, all messages between a pair of Begin Prepare and Prepare messages belong to the same transaction. It also sends changes of large in-progress transactions between a pair of Stream Start and Stream Stop messages. The last stream of such a transaction contains a Stream Commit or Stream Abort message.

Every sent transaction contains zero or more DML messages (Insert, Update, Delete). In case of a cascaded setup it can also contain Origin messages. The origin message indicates that the transaction originated on different replication node. Since a replication node in the scope of logical replication protocol can be pretty much anything, the only identifier is the origin name. It's downstream's responsibility to handle this as needed (if needed). The Origin message is always sent before any DML messages in the transaction.

Every DML message contains a relation OID, identifying the publisher's relation that was acted on. Before the first DML message for a given relation OID, a Relation message will be sent, describing the schema of that relation. Subsequently, a new Relation message will be sent if the relation's definition has changed since the last Relation message was sent for it. (The protocol assumes that the client is capable of remembering this metadata for as many relations as needed.)

Relation messages identify column types by their OIDs. In the case of a built-in type, it is assumed that the client can look up that type OID locally, so no additional data is needed. For a non-built-in type OID, a Type message will be sent before the Relation message, to provide the type name associated with that OID. Thus, a client that needs to specifically identify the types of relation columns should cache the contents of Type messages, and first consult that cache to see if the type OID is defined there. If not, look up the type OID locally.
54.6. Message Data Types

This section describes the base data types used in messages.

Int\(_n\) (\(i\))

An \(n\)-bit integer in network byte order (most significant byte first). If \(i\) is specified it is the exact value that will appear, otherwise the value is variable. Eg. Int16, Int32(42).

Int\(_n\)[\(k\)]

An array of \(k\) \(n\)-bit integers, each in network byte order. The array length \(k\) is always determined by an earlier field in the message. Eg. Int16[M].

String(\(s\))

A null-terminated string (C-style string). There is no specific length limitation on strings. If \(s\) is specified it is the exact value that will appear, otherwise the value is variable. Eg. String, String("user").

Note

*There is no predefined limit* on the length of a string that can be returned by the backend. Good coding strategy for a frontend is to use an expandable buffer so that anything that fits in memory can be accepted. If that's not feasible, read the full string and discard trailing characters that don't fit into your fixed-size buffer.

Byte\(_n\)(\(c\))

Exactly \(n\) bytes. If the field width \(n\) is not a constant, it is always determinable from an earlier field in the message. If \(c\) is specified it is the exact value. Eg. Byte2, Byte1(‘\n’).

54.7. Message Formats

This section describes the detailed format of each message. Each is marked to indicate that it can be sent by a frontend (F), a backend (B), or both (F & B). Notice that although each message includes a byte count at the beginning, the message format is defined so that the message end can be found without reference to the byte count. This aids validity checking. (The CopyData message is an exception, because it forms part of a data stream; the contents of any individual CopyData message cannot be interpretable on their own.)

AuthenticationOk (B)

Byte1(‘R’)

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(0)

Specifies that the authentication was successful.
AuthenticationKerberosV5 (B)
Byte1('R')
Identifies the message as an authentication request.
Int32(8)
Length of message contents in bytes, including self.
Int32(2)
Specifies that Kerberos V5 authentication is required.

AuthenticationCleartextPassword (B)
Byte1('R')
Identifies the message as an authentication request.
Int32(8)
Length of message contents in bytes, including self.
Int32(3)
Specifies that a clear-text password is required.

AuthenticationMD5Password (B)
Byte1('R')
Identifies the message as an authentication request.
Int32(12)
Length of message contents in bytes, including self.
Int32(5)
Specifies that an MD5-encrypted password is required.
Byte4
The salt to use when encrypting the password.

AuthenticationSCMCredential (B)
Byte1('R')
Identifies the message as an authentication request.
Int32(8)
Length of message contents in bytes, including self.
Int32(6)
Specifies that an SCM credentials message is required.
AuthenticationGSS (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(7)

Specifies that GSSAPI authentication is required.

AuthenticationGSSContinue (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(8)

Specifies that this message contains GSSAPI or SSPI data.

Byte

GSSAPI or SSPI authentication data.

AuthenticationSSPI (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(9)

Specifies that SSPI authentication is required.

AuthenticationSASL (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(10)

Specifies that SASL authentication is required.
The message body is a list of SASL authentication mechanisms, in the server's order of preference. A zero byte is required as terminator after the last authentication mechanism name. For each mechanism, there is the following:

String

Name of a SASL authentication mechanism.

AuthenticationSASLContinue (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(11)

Specifies that this message contains a SASL challenge.

Byte

SASL data, specific to the SASL mechanism being used.

AuthenticationSASLFinal (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(12)

Specifies that SASL authentication has completed.

Byte

SASL outcome "additional data", specific to the SASL mechanism being used.

BackendKeyData (B)

Byte1('K')

Identifies the message as cancellation key data. The frontend must save these values if it wishes to be able to issue CancelRequest messages later.

Int32(12)

Length of message contents in bytes, including self.

Int32

The process ID of this backend.
Int32

The secret key of this backend.

Bind (F)

Byte1('B')

Identifies the message as a Bind command.

Int32

Length of message contents in bytes, including self.

String

The name of the destination portal (an empty string selects the unnamed portal).

String

The name of the source prepared statement (an empty string selects the unnamed prepared statement).

Int16

The number of parameter format codes that follow (denoted \(C\) below). This can be zero to indicate that there are no parameters or that the parameters all use the default format (text); or one, in which case the specified format code is applied to all parameters; or it can equal the actual number of parameters.

Int16\[C\]

The parameter format codes. Each must presently be zero (text) or one (binary).

Int16

The number of parameter values that follow (possibly zero). This must match the number of parameters needed by the query.

Next, the following pair of fields appear for each parameter:

Int32

The length of the parameter value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL parameter value. No value bytes follow in the NULL case.

Byte\(n\)

The value of the parameter, in the format indicated by the associated format code. \(n\) is the above length.

After the last parameter, the following fields appear:

Int16

The number of result-column format codes that follow (denoted \(R\) below). This can be zero to indicate that there are no result columns or that the result columns should all use the default format (text); or one, in which case the specified format code is applied to all result columns (if any); or it can equal the actual number of result columns of the query.
Int16[R]

The result-column format codes. Each must presently be zero (text) or one (binary).

BindComplete (B)

Byte1('2')

Identifies the message as a Bind-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

CancelRequest (F)

Int32(16)

Length of message contents in bytes, including self.

Int32(80877102)

The cancel request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5678 in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

Int32

The process ID of the target backend.

Int32

The secret key for the target backend.

Close (F)

Byte1('C')

Identifies the message as a Close command.

Int32

Length of message contents in bytes, including self.

Byte1

'S' to close a prepared statement; or 'P' to close a portal.

String

The name of the prepared statement or portal to close (an empty string selects the unnamed prepared statement or portal).

CloseComplete (B)

Byte1('3')

Identifies the message as a Close-complete indicator.
Int32(4)
Length of message contents in bytes, including self.

CommandComplete (B)

Byte1('C')
Identifies the message as a command-completed response.

Int32
Length of message contents in bytes, including self.

String
The command tag. This is usually a single word that identifies which SQL command was completed.

For an INSERT command, the tag is INSERT oid rows, where rows is the number of rows inserted. oid used to be the object ID of the inserted row if rows was 1 and the target table had OIDs, but OIDs system columns are not supported anymore; therefore oid is always 0.

For a DELETE command, the tag is DELETE rows where rows is the number of rows deleted.

For an UPDATE command, the tag is UPDATE rows where rows is the number of rows updated.

For a SELECT or CREATE TABLE AS command, the tag is SELECT rows where rows is the number of rows retrieved.

For a MOVE command, the tag is MOVE rows where rows is the number of rows the cursor's position has been changed by.

For a FETCH command, the tag is FETCH rows where rows is the number of rows that have been retrieved from the cursor.

For a COPY command, the tag is COPY rows where rows is the number of rows copied. (Note: the row count appears only in PostgreSQL 8.2 and later.)

CopyData (F & B)

Byte1('d')
Identifies the message as COPY data.

Int32
Length of message contents in bytes, including self.

Byte n
Data that forms part of a COPY data stream. Messages sent from the backend will always correspond to single data rows, but messages sent by frontends might divide the data stream arbitrarily.

CopyDone (F & B)

Byte1('c')
Identifies the message as a COPY-complete indicator.
Int32(4)
Length of message contents in bytes, including self.

CopyFail (F)
Byte1('f')
Identifies the message as a COPY-failure indicator.

Int32
Length of message contents in bytes, including self.

String
An error message to report as the cause of failure.

CopyInResponse (B)
Byte1('G')
Identifies the message as a Start Copy In response. The frontend must now send copy-in data (if not prepared to do so, send a CopyFail message).

Int32
Length of message contents in bytes, including self.

Int8
0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc.). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16
The number of columns in the data to be copied (denoted N below).

Int16[N]
The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

CopyOutResponse (B)
Byte1('H')
Identifies the message as a Start Copy Out response. This message will be followed by copy-out data.

Int32
Length of message contents in bytes, including self.

Int8
0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc.). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.
Int16

The number of columns in the data to be copied (denoted \( N \) below).

\( Int16[N] \)

The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

**CopyBothResponse (B)**

Byte1('W')

Identifies the message as a Start Copy Both response. This message is used only for Streaming Replication.

Int32

Length of message contents in bytes, including self.

Int8

0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc.). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16

The number of columns in the data to be copied (denoted \( N \) below).

\( Int16[N] \)

The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

**DataRow (B)**

Byte1('D')

Identifies the message as a data row.

Int32

Length of message contents in bytes, including self.

Int16

The number of column values that follow (possibly zero).

Next, the following pair of fields appear for each column:

Int32

The length of the column value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL column value. No value bytes follow in the NULL case.

Byte\( n \)

The value of the column, in the format indicated by the associated format code. \( n \) is the above length.
Describe (F)

Byte1('D')

Identifies the message as a Describe command.

Int32
Length of message contents in bytes, including self.

Byte1
'S' to describe a prepared statement; or 'P' to describe a portal.

String
The name of the prepared statement or portal to describe (an empty string selects the unnamed prepared statement or portal).

EmptyQueryResponse (B)

Byte1('I')

Identifies the message as a response to an empty query string. (This substitutes for Command-Complete.)

Int32(4)
Length of message contents in bytes, including self.

ErrorResponse (B)

Byte1('E')

Identifies the message as an error.

Int32
Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:

Byte1
A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in Section 54.8. Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

String
The field value.

Execute (F)

Byte1('E')

Identifies the message as an Execute command.
Int32
Length of message contents in bytes, including self.

String
The name of the portal to execute (an empty string selects the unnamed portal).

Int32
Maximum number of rows to return, if portal contains a query that returns rows (ignored otherwise). Zero denotes “no limit”.

Flush (F)
Byte1('H')
Identifies the message as a Flush command.

Int32(4)
Length of message contents in bytes, including self.

FunctionCall (F)
Byte1('F')
Identifies the message as a function call.

Int32
Length of message contents in bytes, including self.

Int32
Specifies the object ID of the function to call.

Int16
The number of argument format codes that follow (denoted C below). This can be zero to indicate that there are no arguments or that the arguments all use the default format (text); or one, in which case the specified format code is applied to all arguments; or it can equal the actual number of arguments.

Int16[C]
The argument format codes. Each must presently be zero (text) or one (binary).

Int16
Specifies the number of arguments being supplied to the function.

Next, the following pair of fields appear for each argument:

Int32
The length of the argument value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL argument value. No value bytes follow in the NULL case.
Byte\(n\)

The value of the argument, in the format indicated by the associated format code. \(n\) is the above length.

After the last argument, the following field appears:

Int16

The format code for the function result. Must presently be zero (text) or one (binary).

**FunctionCallResponse (B)**

Byte1('V')

Identifies the message as a function call result.

Int32

Length of message contents in bytes, including self.

Int32

The length of the function result value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL function result. No value bytes follow in the NULL case.

Byte\(n\)

The value of the function result, in the format indicated by the associated format code. \(n\) is the above length.

**GSSENCRequest (F)**

Int32(8)

Length of message contents in bytes, including self.

Int32(80877104)

The GSSAPI Encryption request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5680 in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

**GSSResponse (F)**

Byte1('p')

Identifies the message as a GSSAPI or SSPI response. Note that this is also used for SASL and password response messages. The exact message type can be deduced from the context.

Int32

Length of message contents in bytes, including self.

Byte\(n\)

GSSAPI/SSPI specific message data.
NegotiateProtocolVersion (B)

Byte1('v')

Identifies the message as a protocol version negotiation message.

Int32

Length of message contents in bytes, including self.

Int32

Newest minor protocol version supported by the server for the major protocol version requested by the client.

Int32

Number of protocol options not recognized by the server.

Then, for protocol option not recognized by the server, there is the following:

String

The option name.

NoData (B)

Byte1('n')

Identifies the message as a no-data indicator.

Int32(4)

Length of message contents in bytes, including self.

NoticeResponse (B)

Byte1('N')

Identifies the message as a notice.

Int32

Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:

Byte1

A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in Section 54.8. Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

String

The field value.
NotificationResponse (B)

Byte1('A')
Identifies the message as a notification response.

Int32
Length of message contents in bytes, including self.

Int32
The process ID of the notifying backend process.

String
The name of the channel that the notify has been raised on.

String
The “payload” string passed from the notifying process.

ParameterDescription (B)

Byte1('t')
Identifies the message as a parameter description.

Int32
Length of message contents in bytes, including self.

Int16
The number of parameters used by the statement (can be zero).

Then, for each parameter, there is the following:

Int32
Specifies the object ID of the parameter data type.

ParameterStatus (B)

Byte1('S')
Identifies the message as a run-time parameter status report.

Int32
Length of message contents in bytes, including self.

String
The name of the run-time parameter being reported.

String
The current value of the parameter.
Parse (F)

Byte1('P')

Identifies the message as a Parse command.

Int32

Length of message contents in bytes, including self.

String

The name of the destination prepared statement (an empty string selects the unnamed prepared statement).

String

The query string to be parsed.

Int16

The number of parameter data types specified (can be zero). Note that this is not an indication of the number of parameters that might appear in the query string, only the number that the frontend wants to prespecify types for.

Then, for each parameter, there is the following:

Int32

Specifies the object ID of the parameter data type. Placing a zero here is equivalent to leaving the type unspecified.

ParseComplete (B)

Byte1('1')

Identifies the message as a Parse-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

PasswordMessage (F)

Byte1('p')

Identifies the message as a password response. Note that this is also used for GSSAPI, SSPI and SASL response messages. The exact message type can be deduced from the context.

Int32

Length of message contents in bytes, including self.

String

The password (encrypted, if requested).
PortalSuspended (B)

Byte1('s')

Identifies the message as a portal-suspended indicator. Note this only appears if an Execute message's row-count limit was reached.

Int32(4)

Length of message contents in bytes, including self.

Query (F)

Byte1('Q')

Identifies the message as a simple query.

Int32

Length of message contents in bytes, including self.

String

The query string itself.

ReadyForQuery (B)

Byte1('Z')

Identifies the message type. ReadyForQuery is sent whenever the backend is ready for a new query cycle.

Int32(5)

Length of message contents in bytes, including self.

Byte1

Current backend transaction status indicator. Possible values are 'I' if idle (not in a transaction block); 'T' if in a transaction block; or 'E' if in a failed transaction block (queries will be rejected until block is ended).

RowDescription (B)

Byte1('T')

Identifies the message as a row description.

Int32

Length of message contents in bytes, including self.

Int16

Specifies the number of fields in a row (can be zero).

Then, for each field, there is the following:
String

The field name.

Int32

If the field can be identified as a column of a specific table, the object ID of the table; otherwise zero.

Int16

If the field can be identified as a column of a specific table, the attribute number of the column; otherwise zero.

Int32

The object ID of the field's data type.

Int16

The data type size (see `pg_type.typlen`). Note that negative values denote variable-width types.

Int32

The type modifier (see `pg_attribute.atttypmod`). The meaning of the modifier is type-specific.

Int16

The format code being used for the field. Currently will be zero (text) or one (binary). In a RowDescription returned from the statement variant of Describe, the format code is not yet known and will always be zero.

SASLInitialResponse (F)

Byte1('p')

Identifies the message as an initial SASL response. Note that this is also used for GSSAPI, SSPI and password response messages. The exact message type is deduced from the context.

Int32

Length of message contents in bytes, including self.

String

Name of the SASL authentication mechanism that the client selected.

Int32

Length of SASL mechanism specific "Initial Client Response" that follows, or -1 if there is no Initial Response.

Byte

SASL mechanism specific "Initial Response".
SASLResponse (F)

Byte1('p')

Identifies the message as a SASL response. Note that this is also used for GSSAPI, SSPI and password response messages. The exact message type can be deduced from the context.

Int32

Length of message contents in bytes, including self.

Byte

SASL mechanism specific message data.

SSLRequest (F)

Int32(8)

Length of message contents in bytes, including self.

Int32(80877103)

The SSL request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5679 in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

StartupMessage (F)

Int32

Length of message contents in bytes, including self.

Int32(196608)

The protocol version number. The most significant 16 bits are the major version number (3 for the protocol described here). The least significant 16 bits are the minor version number (0 for the protocol described here).

The protocol version number is followed by one or more pairs of parameter name and value strings. A zero byte is required as a terminator after the last name/value pair. Parameters can appear in any order. user is required, others are optional. Each parameter is specified as:

String

The parameter name. Currently recognized names are:

user

The database user name to connect as. Required; there is no default.

database

The database to connect to. Defaults to the user name.

options

Command-line arguments for the backend. (This is deprecated in favor of setting individual run-time parameters.) Spaces within this string are considered to separate arguments, unless escaped with a backslash (\); write \ to represent a literal backslash.
replication

Used to connect in streaming replication mode, where a small set of replication commands can be issued instead of SQL statements. Value can be true, false, or database, and the default is false. See Section 54.4 for details.

In addition to the above, other parameters may be listed. Parameter names beginning with _pq_. are reserved for use as protocol extensions, while others are treated as run-time parameters to be set at backend start time. Such settings will be applied during backend start (after parsing the command-line arguments if any) and will act as session defaults.

String

The parameter value.

Sync (F)

Byte1('S')

Identifies the message as a Sync command.

Int32(4)

Length of message contents in bytes, including self.

Terminate (F)

Byte1('X')

Identifies the message as a termination.

Int32(4)

Length of message contents in bytes, including self.

54.8. Error and Notice Message Fields

This section describes the fields that can appear in ErrorResponse and NoticeResponse messages. Each field type has a single-byte identification token. Note that any given field type should appear at most once per message.

S

Severity: the field contents are ERROR, FATAL, or PANIC (in an error message), or WARNING, NOTICE, DEBUG, INFO, or LOG (in a notice message), or a localized translation of one of these. Always present.

V

Severity: the field contents are ERROR, FATAL, or PANIC (in an error message), or WARNING, NOTICE, DEBUG, INFO, or LOG (in a notice message). This is identical to the S field except that the contents are never localized. This is present only in messages generated by PostgreSQL versions 9.6 and later.

C

Code: the SQLSTATE code for the error (see Appendix A). Not localizable. Always present.
M

Message: the primary human-readable error message. This should be accurate but terse (typically one line). Always present.

D

Detail: an optional secondary error message carrying more detail about the problem. Might run to multiple lines.

H

Hint: an optional suggestion what to do about the problem. This is intended to differ from Detail in that it offers advice (potentially inappropriate) rather than hard facts. Might run to multiple lines.

P

Position: the field value is a decimal ASCII integer, indicating an error cursor position as an index into the original query string. The first character has index 1, and positions are measured in characters not bytes.

P

Internal position: this is defined the same as the P field, but it is used when the cursor position refers to an internally generated command rather than the one submitted by the client. The q field will always appear when this field appears.

q

Internal query: the text of a failed internally-generated command. This could be, for example, an SQL query issued by a PL/pgSQL function.

W

Where: an indication of the context in which the error occurred. Presently this includes a call stack traceback of active procedural language functions and internally-generated queries. The trace is one entry per line, most recent first.

s

Schema name: if the error was associated with a specific database object, the name of the schema containing that object, if any.

t

Table name: if the error was associated with a specific table, the name of the table. (Refer to the schema name field for the name of the table's schema.)

c

Column name: if the error was associated with a specific table column, the name of the column. (Refer to the schema and table name fields to identify the table.)

d

Data type name: if the error was associated with a specific data type, the name of the data type. (Refer to the schema name field for the name of the data type's schema.)
Constraint name: if the error was associated with a specific constraint, the name of the constraint. Refer to fields listed above for the associated table or domain. (For this purpose, indexes are treated as constraints, even if they weren't created with constraint syntax.)

File: the file name of the source-code location where the error was reported.

Line: the line number of the source-code location where the error was reported.

Routine: the name of the source-code routine reporting the error.

Note
The fields for schema name, table name, column name, data type name, and constraint name are supplied only for a limited number of error types; see Appendix A. Frontends should not assume that the presence of any of these fields guarantees the presence of another field. Core error sources observe the interrelationships noted above, but user-defined functions may use these fields in other ways. In the same vein, clients should not assume that these fields denote contemporary objects in the current database.

The client is responsible for formatting displayed information to meet its needs; in particular it should break long lines as needed. Newline characters appearing in the error message fields should be treated as paragraph breaks, not line breaks.

54.9. Logical Replication Message Formats

This section describes the detailed format of each logical replication message. These messages are either returned by the replication slot SQL interface or are sent by a walsender. In the case of a walsender, they are encapsulated inside replication protocol WAL messages as described in Section 54.4, and generally obey the same message flow as physical replication.

Begin

Byte1('B')

Identifies the message as a begin message.

Int64 (XLogRecPtr)

The final LSN of the transaction.

Int64 (TimestampTz)

Commit timestamp of the transaction. The value is in number of microseconds since PostgreSQL epoch (2000-01-01).
Int32 (TransactionId)
Xid of the transaction.

Message
Byte1('M')
Identifies the message as a logical decoding message.

Int32 (TransactionId)
Xid of the transaction (only present for streamed transactions). This field is available since protocol version 2.

Int8
Flags; Either 0 for no flags or 1 if the logical decoding message is transactional.

Int64 (XLogRecPtr)
The LSN of the logical decoding message.

String
The prefix of the logical decoding message.

Int32
Length of the content.

Byte
The content of the logical decoding message.

Commit
Byte1('C')
Identifies the message as a commit message.

Int8(0)
Flags; currently unused.

Int64 (XLogRecPtr)
The LSN of the commit.

Int64 (XLogRecPtr)
The end LSN of the transaction.

Int64 (TimestampTz)
Commit timestamp of the transaction. The value is in number of microseconds since PostgreSQL epoch (2000-01-01).
Origin
Byte1('O')
Identifies the message as an origin message.
Int64 (XLogRecPtr)
The LSN of the commit on the origin server.
String
Name of the origin.
Note that there can be multiple Origin messages inside a single transaction.

Relation
Byte1('R')
Identifies the message as a relation message.
Int32 (TransactionId)
Xid of the transaction (only present for streamed transactions). This field is available since protocol version 2.
Int32 (Oid)
OID of the relation.
String
Namespace (empty string for `pg_catalog`).
String
Relation name.
Int8
Replica identity setting for the relation (same as `relreplident` in `pg_class`).
Int16
Number of columns.

Next, the following message part appears for each column included in the publication (except generated columns):

Int8
Flags for the column. Currently can be either 0 for no flags or 1 which marks the column as part of the key.
String
Name of the column.
Frontend/Backend Protocol

Int32 (Oid)

OID of the column's data type.

Int32

Type modifier of the column (atttypmod).

Type

Byte1('Y')

Identifies the message as a type message.

Int32 (TransactionId)

Xid of the transaction (only present for streamed transactions). This field is available since protocol version 2.

Int32 (Oid)

OID of the data type.

String

Namespace (empty string for pg_catalog).

String

Name of the data type.

Insert

Byte1('I')

Identifies the message as an insert message.

Int32 (TransactionId)

Xid of the transaction (only present for streamed transactions). This field is available since protocol version 2.

Int32 (Oid)

OID of the relation corresponding to the ID in the relation message.

Byte1('N')

Identifies the following TupleData message as a new tuple.

TupleData

TupleData message part representing the contents of new tuple.

Update

Byte1('U')

Identifies the message as an update message.
Int32 (TransactionId)

Xid of the transaction (only present for streamed transactions). This field is available since protocol version 2.

Int32 (Oid)

OID of the relation corresponding to the ID in the relation message.

Byte1('K')

Identifies the following TupleData submessage as a key. This field is optional and is only present if the update changed data in any of the column(s) that are part of the REPLICA IDENTITY index.

Byte1('O')

Identifies the following TupleData submessage as an old tuple. This field is optional and is only present if the table in which the update happened has REPLICA IDENTITY set to FULL.

TupleData

TupleData message part representing the contents of the old tuple or primary key. Only present if the previous 'O' or 'K' part is present.

Byte1('N')

Identifies the following TupleData message as a new tuple.

TupleData

TupleData message part representing the contents of a new tuple.

The Update message may contain either a 'K' message part or an 'O' message part or neither of them, but never both of them.

Delete

Byte1('D')

Identifies the message as a delete message.

Int32 (TransactionId)

Xid of the transaction (only present for streamed transactions). This field is available since protocol version 2.

Int32 (Oid)

OID of the relation corresponding to the ID in the relation message.

Byte1('K')

Identifies the following TupleData submessage as a key. This field is present if the table in which the delete has happened uses an index as REPLICA IDENTITY.

Byte1('O')

Identifies the following TupleData message as an old tuple. This field is present if the table in which the delete happened has REPLICA IDENTITY set to FULL.
TupleData

TupleData message part representing the contents of the old tuple or primary key, depending on the previous field.

The Delete message may contain either a 'K' message part or an 'O' message part, but never both of them.

Truncate

Byte1('T')

Identifies the message as a truncate message.

Int32 (TransactionId)

Xid of the transaction (only present for streamed transactions). This field is available since protocol version 2.

Int32

Number of relations

Int8

Option bits for TRUNCATE: 1 for CASCADE, 2 for RESTART IDENTITY

Int32 (Oid)

OID of the relation corresponding to the ID in the relation message. This field is repeated for each relation.

The following messages (Stream Start, Stream Stop, Stream Commit, and Stream Abort) are available since protocol version 2.

Stream Start

Byte1('S')

Identifies the message as a stream start message.

Int32 (TransactionId)

Xid of the transaction.

Int8

A value of 1 indicates this is the first stream segment for this XID, 0 for any other stream segment.

Stream Stop

Byte1('E')

Identifies the message as a stream stop message.

Stream Commit

Byte1('c')

Identifies the message as a stream commit message.
Int32 (TransactionId)
  Xid of the transaction.

Int8(0)
  Flags; currently unused.

Int64 (XLogRecPtr)
  The LSN of the commit.

Int64 (XLogRecPtr)
  The end LSN of the transaction.

Int64 (TimestampTz)
  Commit timestamp of the transaction. The value is in number of microseconds since PostgreSQL epoch (2000-01-01).

Stream Abort

Byte1('A')
  Identifies the message as a stream abort message.

Int32 (TransactionId)
  Xid of the transaction.

Int32 (TransactionId)
  Xid of the subtransaction (will be same as xid of the transaction for top-level transactions).

The following messages (Begin Prepare, Prepare, Commit Prepared, Rollback Prepared, Stream Prepare) are available since protocol version 3.

Begin Prepare

Byte1('b')
  Identifies the message as the beginning of a two-phase transaction message.

Int64 (XLogRecPtr)
  The LSN of the prepare.

Int64 (XLogRecPtr)
  The end LSN of the prepared transaction.

Int64 (TimestampTz)
  Prepare timestamp of the transaction. The value is in number of microseconds since PostgreSQL epoch (2000-01-01).

Int32 (TransactionId)
  Xid of the transaction.
String

The user defined GID of the two-phase transaction.

Prepare

Byte1('P')

Identifies the message as a two-phase prepared transaction message.

Int8(0)

Flags; currently unused.

Int64 (XLogRecPtr)

The LSN of the prepare.

Int64 (XLogRecPtr)

The end LSN of the prepared transaction.

Int64 (TimestampTz)

Prepare timestamp of the transaction. The value is in number of microseconds since PostgreSQL epoch (2000-01-01).

Int32 (TransactionId)

Xid of the transaction.

String

The user defined GID of the two-phase transaction.

Commit Prepared

Byte1('K')

Identifies the message as the commit of a two-phase transaction message.

Int8(0)

Flags; currently unused.

Int64 (XLogRecPtr)

The LSN of the commit prepared.

Int64 (XLogRecPtr)

The end LSN of the commit prepared transaction.

Int64 (TimestampTz)

Commit timestamp of the transaction. The value is in number of microseconds since PostgreSQL epoch (2000-01-01).
Int32 (TransactionId)
   Xid of the transaction.

String
   The user defined GID of the two-phase transaction.

Rollback Prepared

Byte1('r')
   Identifies the message as the rollback of a two-phase transaction message.

Int8(0)
   Flags; currently unused.

Int64 (XLogRecPtr)
   The end LSN of the prepared transaction.

Int64 (XLogRecPtr)
   The end LSN of the rollback prepared transaction.

Int64 (TimestampTz)
   Prepare timestamp of the transaction. The value is in number of microseconds since PostgreSQL epoch (2000-01-01).

Int64 (TimestampTz)
   Rollback timestamp of the transaction. The value is in number of microseconds since PostgreSQL epoch (2000-01-01).

Int32 (TransactionId)
   Xid of the transaction.

String
   The user defined GID of the two-phase transaction.

Stream Prepare

Byte1('p')
   Identifies the message as a two-phase stream prepare message.

Int8(0)
   Flags; currently unused.

Int64 (XLogRecPtr)
   The LSN of the prepare.
Int64 (XLogRecPtr)

The end LSN of the prepare transaction.

Int64 (TimestampTz)

Prepare timestamp of the transaction. The value is in number of microseconds since PostgreSQL epoch (2000-01-01).

Int32 (TransactionId)

Xid of the transaction.

String

The user defined GID of the two-phase transaction.

The following message parts are shared by the above messages.

TupleData

Int16

Number of columns.

Next, one of the following submessages appears for each column (except generated columns):

Byte1('n')

Identifies the data as NULL value.

Or

Byte1('u')

Identifies unchanged TOASTed value (the actual value is not sent).

Or

Byte1('t')

Identifies the data as text formatted value.

Or

Byte1('b')

Identifies the data as binary formatted value.

Int32

Length of the column value.

Byte

The value of the column, either in binary or in text format. (As specified in the preceding format byte). $n$ is the above length.
54.10. Summary of Changes since Protocol 2.0

This section provides a quick checklist of changes, for the benefit of developers trying to update existing client libraries to protocol 3.0.

The initial startup packet uses a flexible list-of-strings format instead of a fixed format. Notice that session default values for run-time parameters can now be specified directly in the startup packet. (Actually, you could do that before using the options field, but given the limited width of options and the lack of any way to quote whitespace in the values, it wasn’t a very safe technique.)

All messages now have a length count immediately following the message type byte (except for startup packets, which have no type byte). Also note that PasswordMessage now has a type byte.

ErrorResponse and NoticeResponse (‘E’ and ‘N’) messages now contain multiple fields, from which the client code can assemble an error message of the desired level of verbosity. Note that individual fields will typically not end with a newline, whereas the single string sent in the older protocol always did.

The ReadyForQuery (‘Z’) message includes a transaction status indicator.

The distinction between BinaryRow and DataRow message types is gone; the single DataRow message type serves for returning data in all formats. Note that the layout of DataRow has changed to make it easier to parse. Also, the representation of binary values has changed: it is no longer directly tied to the server's internal representation.

There is a new “extended query” sub-protocol, which adds the frontend message types Parse, Bind, Execute, Describe, Close, Flush, and Sync, and the backend message types ParseComplete, BindComplete, PortalSuspended, ParameterDescription, NoData, and CloseComplete. Existing clients do not have to concern themselves with this sub-protocol, but making use of it might allow improvements in performance or functionality.

COPY data is now encapsulated into CopyData and CopyDone messages. There is a well-defined way to recover from errors during COPY. The special “\.” last line is not needed anymore, and is not sent during COPY OUT. (It is still recognized as a terminator during COPY IN, but its use is deprecated and will eventually be removed.) Binary COPY is supported. The CopyInResponse and CopyOutResponse messages include fields indicating the number of columns and the format of each column.

The layout of FunctionCall and FunctionCallResponse messages has changed. FunctionCall can now support passing NULL arguments to functions. It also can handle passing parameters and retrieving results in either text or binary format. There is no longer any reason to consider FunctionCall a potential security hole, since it does not offer direct access to internal server data representations.

The backend sends ParameterStatus (‘S’) messages during connection startup for all parameters it considers interesting to the client library. Subsequently, a ParameterStatus message is sent whenever the active value changes for any of these parameters.

The RowDescription (‘T’) message carries new table OID and column number fields for each column of the described row. It also shows the format code for each column.

The CursorResponse (‘P’) message is no longer generated by the backend.

The NotificationResponse (‘A’) message has an additional string field, which can carry a “payload” string passed from the NOTIFY event sender.

The EmptyQueryResponse (‘I’) message used to include an empty string parameter; this has been removed.
Chapter 55. PostgreSQL Coding Conventions

55.1. Formatting

Source code formatting uses 4 column tab spacing, with tabs preserved (i.e., tabs are not expanded to spaces). Each logical indentation level is one additional tab stop.

Layout rules (brace positioning, etc.) follow BSD conventions. In particular, curly braces for the controlled blocks of `if`, `while`, `switch`, etc. go on their own lines.

Limit line lengths so that the code is readable in an 80-column window. (This doesn't mean that you must never go past 80 columns. For instance, breaking a long error message string in arbitrary places just to keep the code within 80 columns is probably not a net gain in readability.)

To maintain a consistent coding style, do not use C++ style comments (`//` comments). `pgindent` will replace them with `/* . . . */`.

The preferred style for multi-line comment blocks is

```c
/*
 * comment text begins here
 * and continues here
 */
```

Note that comment blocks that begin in column 1 will be preserved as-is by `pgindent`, but it will re-flow indented comment blocks as though they were plain text. If you want to preserve the line breaks in an indented block, add dashes like this:

```c
/*-------
 * comment text begins here
 * and continues here
 *-------
 */
```

While submitted patches do not absolutely have to follow these formatting rules, it's a good idea to do so. Your code will get run through `pgindent` before the next release, so there's no point in making it look nice under some other set of formatting conventions. A good rule of thumb for patches is "make the new code look like the existing code around it".

The `src/tools/editors` directory contains sample settings files that can be used with the Emacs, xemacs or vim editors to help ensure that they format code according to these conventions.

If you'd like to run `pgindent` locally to help make your code match project style, see the `src/tools/pgindent` directory.

The text browsing tools `more` and `less` can be invoked as:

```
more -x4
```
55.2. Reporting Errors Within the Server

Error, warning, and log messages generated within the server code should be created using ereport, or its older cousin elog. The use of this function is complex enough to require some explanation.

There are two required elements for every message: a severity level (ranging from DEBUG to PANIC) and a primary message text. In addition there are optional elements, the most common of which is an error identifier code that follows the SQL spec's SQLSTATE conventions. ereport itself is just a shell macro that exists mainly for the syntactic convenience of making message generation look like a single function call in the C source code. The only parameter accepted directly by ereport is the severity level. The primary message text and any optional message elements are generated by calling auxiliary functions, such as errmsg, within the ereport call.

A typical call to ereport might look like this:

```c
ereport(ERROR,
    errcode(ERRCODE_DIVISION_BY_ZERO),
    errmsg("division by zero"));
```

This specifies error severity level ERROR (a run-of-the-mill error). The errcode call specifies the SQLSTATE error code using a macro defined in src/include/utils/errcodes.h. The errmsg call provides the primary message text.

You will also frequently see this older style, with an extra set of parentheses surrounding the auxiliary function calls:

```c
ereport(ERROR,
    (errcode(ERRCODE_DIVISION_BY_ZERO),
    errmsg("division by zero")));
```

The extra parentheses were required before PostgreSQL version 12, but are now optional.

Here is a more complex example:

```c
ereport(ERROR,
    errcode(ERRCODE_AMBIGUOUS_FUNCTION),
    errmsg("function %s is not unique",
        func_signature_string(funcname, nargs, NIL, actual_arg_types)),
    errhint("Unable to choose a best candidate function. "
        "You might need to add explicit typecasts.");
```

This illustrates the use of format codes to embed run-time values into a message text. Also, an optional “hint” message is provided. The auxiliary function calls can be written in any order, but conventionally errcode and errmsg appear first.

If the severity level is ERROR or higher, ereport aborts execution of the current query and does not return to the caller. If the severity level is lower than ERROR, ereport returns normally.
The available auxiliary routines for `ereport` are:

- **errcode(sqlerrcode)** specifies the SQLSTATE error identifier code for the condition. If this routine is not called, the error identifier defaults to **ERRCODE_INTERNAL_ERROR** when the error severity level is **ERROR** or higher, **ERRCODE_WARNING** when the error level is **WARNING**, otherwise (for **NOTICE** and below) **ERRCODE_SUCCESSFUL_COMPLETION**. While these defaults are often convenient, always think whether they are appropriate before omitting the `errcode()` call.

- **errmsg(const char *msg, ...)** specifies the primary error message text, and possibly runtime values to insert into it. Insertions are specified by `sprintf`-style format codes. In addition to the standard format codes accepted by `sprintf`, the format code `%m` can be used to insert the error message returned by `strerror` for the current value of `errno`.¹ `%m` does not require any corresponding entry in the parameter list for `errmsg`. Note that the message string will be run through `gettext` for possible localization before format codes are processed.

- **errmsg_internal(const char *msg, ...)** is the same as `errmsg`, except that the message string will not be translated nor included in the internationalization message dictionary. This should be used for “cannot happen” cases that are probably not worth expending translation effort on.

- **errmsg_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)** is like `errmsg`, but with support for various plural forms of the message. `fmt_singular` is the English singular format, `fmt_plural` is the English plural format, `n` is the integer value that determines which plural form is needed, and the remaining arguments are formatted according to the selected format string. For more information see Section 56.2.2.

- **errdetail(const char *msg, ...)** supplies an optional “detail” message; this is to be used when there is additional information that seems inappropriate to put in the primary message. The message string is processed in just the same way as for `errmsg`.

- **errdetail_internal(const char *msg, ...)** is the same as `errdetail`, except that the message string will not be translated nor included in the internationalization message dictionary. This should be used for detail messages that are not worth expending translation effort on, for instance because they are too technical to be useful to most users.

- **errdetail_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)** is like `errdetail`, but with support for various plural forms of the message. For more information see Section 56.2.2.

- **errdetail_log(const char *msg, ...)** is the same as `errdetail` except that this string goes only to the server log, never to the client. If both `errdetail` (or one of its equivalents above) and `errdetail_log` are used then one string goes to the client and the other to the log. This is useful for error details that are too security-sensitive or too bulky to include in the report sent to the client.

- **errdetail_log_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)** is like `errdetail_log`, but with support for various plural forms of the message. For more information see Section 56.2.2.

- **errhint(const char *msg, ...)** supplies an optional “hint” message; this is to be used when offering suggestions about how to fix the problem, as opposed to factual details about what went wrong. The message string is processed in just the same way as for `errmsg`.

- **errhint_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)** is like `errhint`, but with support for various plural forms of the message. For more information see Section 56.2.2.

¹ That is, the value that was current when the `ereport` call was reached; changes of `errno` within the auxiliary reporting routines will not affect it. That would not be true if you were to write `strerror(errno)` explicitly in `errmsg`'s parameter list; accordingly, do not do so.
• `errcontext(const char *msg, ...)` is not normally called directly from an `ereport` message site; rather it is used in `error_context_stack` callback functions to provide information about the context in which an error occurred, such as the current location in a PL function. The message string is processed in just the same way as for `errmsg`. Unlike the other auxiliary functions, this can be called more than once per `ereport` call; the successive strings thus supplied are concatenated with separating newlines.

• `errposition(int cursorpos)` specifies the textual location of an error within a query string. Currently it is only useful for errors detected in the lexical and syntactic analysis phases of query processing.

• `errtable(Relation rel)` specifies a relation whose name and schema name should be included as auxiliary fields in the error report.

• `errtablecol(Relation rel, int attnum)` specifies a column whose name, table name, and schema name should be included as auxiliary fields in the error report.

• `errtableconstraint(Relation rel, const char *conname)` specifies a table constraint whose name, table name, and schema name should be included as auxiliary fields in the error report. Indexes should be considered to be constraints for this purpose, whether or not they have an associated `pg_constraint` entry. Be careful to pass the underlying heap relation, not the index itself, as `rel`.

• `errdatatype(Oid datatypeOid)` specifies a data type whose name and schema name should be included as auxiliary fields in the error report.

• `errdomainconstraint(Oid datatypeOid, const char *conname)` specifies a domain constraint whose name, domain name, and schema name should be included as auxiliary fields in the error report.

• `errcode_for_file_access()` is a convenience function that selects an appropriate SQLSTATE error identifier for a failure in a file-access-related system call. It uses the saved `errno` to determine which error code to generate. Usually this should be used in combination with `%m` in the primary error message text.

• `errcode_for_socket_access()` is a convenience function that selects an appropriate SQLSTATE error identifier for a failure in a socket-related system call.

• `errhidestmt(bool hide_stmt)` can be called to specify suppression of the `STATEMENT:` portion of a message in the postmaster log. Generally this is appropriate if the message text includes the current statement already.

• `errhidecontext(bool hide_ctx)` can be called to specify suppression of the `CONTEXT:` portion of a message in the postmaster log. This should only be used for verbose debugging messages where the repeated inclusion of context would bloat the log too much.

---

**Note**

At most one of the functions `errtable`, `errtablecol`, `errtableconstraint`, `errdatatype`, or `errdomainconstraint` should be used in an `ereport` call. These functions exist to allow applications to extract the name of a database object associated with the error condition without having to examine the potentially-localized error message text. These functions should be used in error reports for which it's likely that applications would wish to have automatic error handling. As of PostgreSQL 9.3, complete coverage exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.
There is an older function `elog` that is still heavily used. An `elog` call:

```
elog(level, "format string", ...);
```
is exactly equivalent to:

```
erreport(level, errmsg_internal("format string", ...));
```
Notice that the SQLSTATE error code is always defaulted, and the message string is not subject to translation. Therefore, `elog` should be used only for internal errors and low-level debug logging. Any message that is likely to be of interest to ordinary users should go through `ereport`. Nonetheless, there are enough internal “cannot happen” error checks in the system that `elog` is still widely used; it is preferred for those messages for its notational simplicity.

Advice about writing good error messages can be found in Section 55.3.

### 55.3. Error Message Style Guide

This style guide is offered in the hope of maintaining a consistent, user-friendly style throughout all the messages generated by PostgreSQL.

#### What Goes Where

The primary message should be short, factual, and avoid reference to implementation details such as specific function names. “Short” means “should fit on one line under normal conditions”. Use a detail message if needed to keep the primary message short, or if you feel a need to mention implementation details such as the particular system call that failed. Both primary and detail messages should be factual. Use a hint message for suggestions about what to do to fix the problem, especially if the suggestion might not always be applicable.

For example, instead of:

```
IpcMemoryCreate: shmget(key=%d, size=%u, 0%o) failed: %m
```

(plus a long addendum that is basically a hint)

write:

```
Primary:    could not create shared memory segment: %m
Detail:     Failed syscall was shmget(key=%d, size=%u, 0%o).
Hint:       the addendum
```

Rationale: keeping the primary message short helps keep it to the point, and lets clients lay out screen space on the assumption that one line is enough for error messages. Detail and hint messages can be relegated to a verbose mode, or perhaps a pop-up error-details window. Also, details and hints would normally be suppressed from the server log to save space. Reference to implementation details is best avoided since users aren't expected to know the details.

#### Formatting

Don't put any specific assumptions about formatting into the message texts. Expect clients and the server log to wrap lines to fit their own needs. In long messages, newline characters (`\n`) can be used to indicate
suggested paragraph breaks. Don't end a message with a newline. Don't use tabs or other formatting characters. (In error context displays, newlines are automatically added to separate levels of context such as function calls.)

Rationale: Messages are not necessarily displayed on terminal-type displays. In GUI displays or browsers these formatting instructions are at best ignored.

Quotation Marks

English text should use double quotes when quoting is appropriate. Text in other languages should consistently use one kind of quotes that is consistent with publishing customs and computer output of other programs.

Rationale: The choice of double quotes over single quotes is somewhat arbitrary, but tends to be the preferred use. Some have suggested choosing the kind of quotes depending on the type of object according to SQL conventions (namely, strings single quoted, identifiers double quoted). But this is a language-internal technical issue that many users aren't even familiar with, it won't scale to other kinds of quoted terms, it doesn't translate to other languages, and it's pretty pointless, too.

Use of Quotes

Always use quotes to delimit file names, user-supplied identifiers, and other variables that might contain words. Do not use them to mark up variables that will not contain words (for example, operator names).

There are functions in the backend that will double-quote their own output as needed (for example, format_type_be()). Do not put additional quotes around the output of such functions.

Rationale: Objects can have names that create ambiguity when embedded in a message. Be consistent about denoting where a plugged-in name starts and ends. But don't clutter messages with unnecessary or duplicate quote marks.

Grammar and Punctuation

The rules are different for primary error messages and for detail/hint messages:

Primary error messages: Do not capitalize the first letter. Do not end a message with a period. Do not even think about ending a message with an exclamation point.

Detail and hint messages: Use complete sentences, and end each with a period. Capitalize the first word of sentences. Put two spaces after the period if another sentence follows (for English text; might be inappropriate in other languages).

Error context strings: Do not capitalize the first letter and do not end the string with a period. Context strings should normally not be complete sentences.

Rationale: Avoiding punctuation makes it easier for client applications to embed the message into a variety of grammatical contexts. Often, primary messages are not grammatically complete sentences anyway. (And if they're long enough to be more than one sentence, they should be split into primary and detail parts.) However, detail and hint messages are longer and might need to include multiple sentences. For consistency, they should follow complete-sentence style even when there's only one sentence.

Upper Case vs. Lower Case

Use lower case for message wording, including the first letter of a primary error message. Use upper case for SQL commands and key words if they appear in the message.
Avoid Passive Voice

Use the active voice. Use complete sentences when there is an acting subject (“A could not do B”). Use telegram style without subject if the subject would be the program itself; do not use “I” for the program.

Rationale: The program is not human. Don't pretend otherwise.

Present vs. Past Tense

Use past tense if an attempt to do something failed, but could perhaps succeed next time (perhaps after fixing some problem). Use present tense if the failure is certainly permanent.

There is a nontrivial semantic difference between sentences of the form:

could not open file "%s": %m

and:

cannot open file "%s"

The first one means that the attempt to open the file failed. The message should give a reason, such as “disk full” or “file doesn't exist”. The past tense is appropriate because next time the disk might not be full anymore or the file in question might exist.

The second form indicates that the functionality of opening the named file does not exist at all in the program, or that it's conceptually impossible. The present tense is appropriate because the condition will persist indefinitely.

Rationale: Granted, the average user will not be able to draw great conclusions merely from the tense of the message, but since the language provides us with a grammar we should use it correctly.

Type of the Object

When citing the name of an object, state what kind of object it is.

Rationale: Otherwise no one will know what “foo.bar.baz” refers to.

Brackets

Square brackets are only to be used (1) in command synopses to denote optional arguments, or (2) to denote an array subscript.

Rationale: Anything else does not correspond to widely-known customary usage and will confuse people.

Assembling Error Messages

When a message includes text that is generated elsewhere, embed it in this style:
could not open file %s: %m

Rationale: It would be difficult to account for all possible error codes to paste this into a single smooth sentence, so some sort of punctuation is needed. Putting the embedded text in parentheses has also been suggested, but it's unnatural if the embedded text is likely to be the most important part of the message, as is often the case.

Reasons for Errors

Messages should always state the reason why an error occurred. For example:

BAD: could not open file %s
BETTER: could not open file %s (I/O failure)

If no reason is known you better fix the code.

Function Names

Don't include the name of the reporting routine in the error text. We have other mechanisms for finding that out when needed, and for most users it's not helpful information. If the error text doesn't make as much sense without the function name, reword it.

BAD: pg_strtoint32: error in "z": cannot parse "z"
BETTER: invalid input syntax for type integer: "z"

Avoid mentioning called function names, either; instead say what the code was trying to do:

BAD: open() failed: %m
BETTER: could not open file %s: %m

If it really seems necessary, mention the system call in the detail message. (In some cases, providing the actual values passed to the system call might be appropriate information for the detail message.)

Rationale: Users don't know what all those functions do.

Tricky Words to Avoid

Unable. “Unable” is nearly the passive voice. Better use “cannot” or “could not”, as appropriate.

Bad. Error messages like “bad result” are really hard to interpret intelligently. It's better to write why the result is “bad”, e.g., “invalid format”.

Illegal. “Illegal” stands for a violation of the law, the rest is “invalid”. Better yet, say why it's invalid.

Unknown. Try to avoid “unknown”. Consider “error: unknown response”. If you don't know what the response is, how do you know it's erroneous? “Unrecognized” is often a better choice. Also, be sure to include the value being complained of.

BAD: unknown node type
BETTER: unrecognized node type: 42
Find vs. Exists. If the program uses a nontrivial algorithm to locate a resource (e.g., a path search) and that algorithm fails, it is fair to say that the program couldn't "find" the resource. If, on the other hand, the expected location of the resource is known but the program cannot access it there then say that the resource doesn't "exist". Using "find" in this case sounds weak and confuses the issue.

May vs. Can vs. Might. "May" suggests permission (e.g., "You may borrow my rake."), and has little use in documentation or error messages. "Can" suggests ability (e.g., "I can lift that log."), and "might" suggests possibility (e.g., "It might rain today."). Using the proper word clarifies meaning and assists translation.

Contractions. Avoid contractions, like "can't"; use "cannot" instead.

Non-negative. Avoid "non-negative" as it is ambiguous about whether it accepts zero. It's better to use "greater than zero" or "greater than or equal to zero".

Proper Spelling

Spell out words in full. For instance, avoid:

- spec
- stats
- parens
- auth
- xact

Rationale: This will improve consistency.

Localization

Keep in mind that error message texts need to be translated into other languages. Follow the guidelines in Section 56.2.2 to avoid making life difficult for translators.

55.4. Miscellaneous Coding Conventions

C Standard

Code in PostgreSQL should only rely on language features available in the C99 standard. That means a conforming C99 compiler has to be able to compile postgres, at least aside from a few platform dependent pieces.

A few features included in the C99 standard are, at this time, not permitted to be used in core PostgreSQL code. This currently includes variable length arrays, intermingled declarations and code, // comments, universal character names. Reasons for that include portability and historical practices.

Features from later revisions of the C standard or compiler specific features can be used, if a fallback is provided.

For example _Static_assert() and __builtin_constant_p are currently used, even though they are from newer revisions of the C standard and a GCC extension respectively. If not available we
respectively fall back to using a C99 compatible replacement that performs the same checks, but emits rather cryptic messages and do not use \texttt{\_\_builtin\_constant\_p}.

**Function-Like Macros and Inline Functions**

Both, macros with arguments and \texttt{static inline} functions, may be used. The latter are preferable if there are multiple-evaluation hazards when written as a macro, as e.g., the case with

\begin{verbatim}
#define Max(x, y)       ((x) > (y) ? (x) : (y))
\end{verbatim}

or when the macro would be very long. In other cases it's only possible to use macros, or at least easier. For example because expressions of various types need to be passed to the macro.

When the definition of an inline function references symbols (i.e., variables, functions) that are only available as part of the backend, the function may not be visible when included from frontend code.

\begin{verbatim}
#ifndef FRONTEND
static inline MemoryContext
MemoryContextSwitchTo(MemoryContext context)
{
    MemoryContext old = CurrentMemoryContext;
    CurrentMemoryContext = context;
    return old;
}
#endif /* FRONTEND */
\end{verbatim}

In this example \texttt{CurrentMemoryContext}, which is only available in the backend, is referenced and the function thus hidden with a \texttt{\#ifndef FRONTEND}. This rule exists because some compilers emit references to symbols contained in inline functions even if the function is not used.

**Writing Signal Handlers**

To be suitable to run inside a signal handler code has to be written very carefully. The fundamental problem is that, unless blocked, a signal handler can interrupt code at any time. If code inside the signal handler uses the same state as code outside chaos may ensue. As an example consider what happens if a signal handler tries to acquire a lock that's already held in the interrupted code.

Barring special arrangements code in signal handlers may only call async-signal safe functions (as defined in POSIX) and access variables of type \texttt{volatile sig_atomic\_t}. A few functions in \texttt{postgres} are also deemed signal safe, importantly \texttt{SetLatch()}.

In most cases signal handlers should do nothing more than note that a signal has arrived, and wake up code running outside of the handler using a latch. An example of such a handler is the following:

\begin{verbatim}
static void
handle_sighup(SIGNAL_ARGS)
{
    int         save_errno = errno;
    got_SIGHUP = true;
    SetLatch(MyLatch);
\end{verbatim}
errno = save_errno;
}

errno is saved and restored because SetLatch() might change it. If that were not done interrupted code that's currently inspecting errno might see the wrong value.

**Calling Function Pointers**

For clarity, it is preferred to explicitly dereference a function pointer when calling the pointed-to function if the pointer is a simple variable, for example:

```c
(*emit_log_hook) (edata);
```

(even though `emit_log_hook(edata)` would also work). When the function pointer is part of a structure, then the extra punctuation can and usually should be omitted, for example:

```c
paramInfo->paramFetch(paramInfo, paramId);
```
Chapter 56. Native Language Support

56.1. For the Translator

PostgreSQL programs (server and client) can issue their messages in your favorite language — if the messages have been translated. Creating and maintaining translated message sets needs the help of people who speak their own language well and want to contribute to the PostgreSQL effort. You do not have to be a programmer at all to do this. This section explains how to help.

56.1.1. Requirements

We won't judge your language skills — this section is about software tools. Theoretically, you only need a text editor. But this is only in the unlikely event that you do not want to try out your translated messages. When you configure your source tree, be sure to use the `--enable-nls` option. This will also check for the libintl library and the `msgfmt` program, which all end users will need anyway. To try out your work, follow the applicable portions of the installation instructions.

If you want to start a new translation effort or want to do a message catalog merge (described later), you will need the programs `xgettext` and `msgmerge`, respectively, in a GNU-compatible implementation. Later, we will try to arrange it so that if you use a packaged source distribution, you won't need `xgettext`. (If working from Git, you will still need it.) GNU Gettext 0.10.36 or later is currently recommended.

Your local gettext implementation should come with its own documentation. Some of that is probably duplicated in what follows, but for additional details you should look there.

56.1.2. Concepts

The pairs of original (English) messages and their (possibly) translated equivalents are kept in message catalogs, one for each program (although related programs can share a message catalog) and for each target language. There are two file formats for message catalogs: The first is the “PO” file (for Portable Object), which is a plain text file with special syntax that translators edit. The second is the “MO” file (for Machine Object), which is a binary file generated from the respective PO file and is used while the internationalized program is run. Translators do not deal with MO files; in fact hardly anyone does.

The extension of the message catalog file is no surprise either .po or .mo. The base name is either the name of the program it accompanies, or the language the file is for, depending on the situation. This is a bit confusing. Examples are `psql.po` (PO file for `psql`) or `fr.mo` (MO file in French).

The file format of the PO files is illustrated here:

```
# comment
msgid "original string"
msgstr "translated string"

msgid "more original"
msgstr "another translated"
"string can be broken up like this"
```
The msgid lines are extracted from the program source. (They need not be, but this is the most common way.) The msgstr lines are initially empty and are filled in with useful strings by the translator. The strings can contain C-style escape characters and can be continued across lines as illustrated. (The next line must start at the beginning of the line.)

The # character introduces a comment. If whitespace immediately follows the # character, then this is a comment maintained by the translator. There can also be automatic comments, which have a non-white-space character immediately following the #. These are maintained by the various tools that operate on the PO files and are intended to aid the translator.

#. automatic comment
#: filename.c:1023
#, flags, flags

The #. style comments are extracted from the source file where the message is used. Possibly the programmer has inserted information for the translator, such as about expected alignment. The #: comments indicate the exact locations where the message is used in the source. The translator need not look at the program source, but can if there is doubt about the correct translation. The #, comments contain flags that describe the message in some way. There are currently two flags: fuzzy is set if the message has possibly been outdated because of changes in the program source. The translator can then verify this and possibly remove the fuzzy flag. Note that fuzzy messages are not made available to the end user. The other flag is c-format, which indicates that the message is a printf-style format template. This means that the translation should also be a format string with the same number and type of placeholders. There are tools that can verify this, which key off the c-format flag.

### 56.1.3. Creating and Maintaining Message Catalogs

OK, so how does one create a “blank” message catalog? First, go into the directory that contains the program whose messages you want to translate. If there is a file nls.mk, then this program has been prepared for translation.

If there are already some .po files, then someone has already done some translation work. The files are named language.po, where language is the ISO 639-1 two-letter language code (in lower case), e.g., fr.po for French. If there is really a need for more than one translation effort per language then the files can also be named language_region.po where region is the ISO 3166-1 two-letter country code (in upper case), e.g., pt_BR.po for Portuguese in Brazil. If you find the language you wanted you can just start working on that file.

If you need to start a new translation effort, then first run the command:

```
make init-po
```

This will create a file programe.pot. (.pot to distinguish it from PO files that are “in production”. The T stands for “template”.) Copy this file to language.po and edit it. To make it known that the new language is available, also edit the file nls.mk and add the language (or language and country) code to the line that looks like:

---

AVAIL_LANGUAGES := de fr

(Other languages can appear, of course.)

As the underlying program or library changes, messages might be changed or added by the programmers. In this case you do not need to start from scratch. Instead, run the command:

```
maker update-po
```

which will create a new blank message catalog file (the pot file you started with) and will merge it with the existing PO files. If the merge algorithm is not sure about a particular message it marks it “fuzzy” as explained above. The new PO file is saved with a `.po.new` extension.

### 56.1.4. Editing the PO Files

The PO files can be edited with a regular text editor. The translator should only change the area between the quotes after the `msgstr` directive, add comments, and alter the fuzzy flag. There is (unsurprisingly) a PO mode for Emacs, which I find quite useful.

The PO files need not be completely filled in. The software will automatically fall back to the original string if no translation (or an empty translation) is available. It is no problem to submit incomplete translations for inclusions in the source tree; that gives room for other people to pick up your work. However, you are encouraged to give priority to removing fuzzy entries after doing a merge. Remember that fuzzy entries will not be installed; they only serve as reference for what might be the right translation.

Here are some things to keep in mind while editing the translations:

- Make sure that if the original ends with a newline, the translation does, too. Similarly for tabs, etc.

- If the original is a `printf` format string, the translation also needs to be. The translation also needs to have the same format specifiers in the same order. Sometimes the natural rules of the language make this impossible or at least awkward. In that case you can modify the format specifiers like this:

  ```
  msgstr "Die Datei %2$s hat %1$u Zeichen."
  ```

  Then the first placeholder will actually use the second argument from the list. The `digits$` needs to follow the `%` immediately, before any other format manipulators. (This feature really exists in the `printf` family of functions. You might not have heard of it before because there is little use for it outside of message internationalization.)

- If the original string contains a linguistic mistake, report that (or fix it yourself in the program source) and translate normally. The corrected string can be merged in when the program sources have been updated. If the original string contains a factual mistake, report that (or fix it yourself) and do not translate it. Instead, you can mark the string with a comment in the PO file.

- Maintain the style and tone of the original string. Specifically, messages that are not sentences (cannot open file `%s`) should probably not start with a capital letter (if your language distinguishes letter case) or end with a period (if your language uses punctuation marks). It might help to read Section 55.3.

- If you don't know what a message means, or if it is ambiguous, ask on the developers' mailing list. Chances are that English speaking end users might also not understand it or find it ambiguous, so it's best to improve the message.
56.2. For the Programmer

56.2.1. Mechanics

This section describes how to implement native language support in a program or library that is part of the PostgreSQL distribution. Currently, it only applies to C programs.

Adding NLS Support to a Program

1. Insert this code into the start-up sequence of the program:

```c
#ifdef ENABLE_NLS
#include <locale.h>
#endif
...

#ifdef ENABLE_NLS
setlocale(LC_ALL, "");
bindtextdomain("proname", LOCALEDIR);
textdomain("proname");
#endif
```

(The `proname` can actually be chosen freely.)

2. Wherever a message that is a candidate for translation is found, a call to `gettext()` needs to be inserted. E.g.:

```c
fprintf(stderr, "panic level %d\n", lvl);
```

would be changed to:

```c
fprintf(stderr, gettext("panic level %d\n"), lvl);
```

(`gettext` is defined as a no-op if NLS support is not configured.)

This tends to add a lot of clutter. One common shortcut is to use:

```c
#define _(x) gettext(x)
```

Another solution is feasible if the program does much of its communication through one or a few functions, such as `ereport()` in the backend. Then you make this function call `gettext` internally on all input strings.

3. Add a file `nls.mk` in the directory with the program sources. This file will be read as a makefile. The following variable assignments need to be made here:

```
CATALOG_NAME
```

The program name, as provided in the `textdomain()` call.
AVAIL_LANGUAGES

List of provided translations — initially empty.

GETTEXT_FILES

List of files that contain translatable strings, i.e., those marked with gettext or an alternative solution. Eventually, this will include nearly all source files of the program. If this list gets too long you can make the first “file” be a + and the second word be a file that contains one file name per line.

GETTEXT_TRIGGERS

The tools that generate message catalogs for the translators to work on need to know what function calls contain translatable strings. By default, only gettext() calls are known. If you used _ or other identifiers you need to list them here. If the translatable string is not the first argument, the item needs to be of the form func:2 (for the second argument). If you have a function that supports pluralized messages, the item should look like func:1,2 (identifying the singular and plural message arguments).

The build system will automatically take care of building and installing the message catalogs.

56.2.2. Message-Writing Guidelines

Here are some guidelines for writing messages that are easily translatable.

• Do not construct sentences at run-time, like:

  printf("Files were %s.\n", flag ? "copied" : "removed");

  The word order within the sentence might be different in other languages. Also, even if you remember to call gettext() on each fragment, the fragments might not translate well separately. It’s better to duplicate a little code so that each message to be translated is a coherent whole. Only numbers, file names, and such-like run-time variables should be inserted at run time into a message text.

• For similar reasons, this won’t work:

  printf("copied %d file%s", n, n!=1 ? "s" : ";

  because it assumes how the plural is formed. If you figured you could solve it like this:

  if (n==1)
    printf("copied 1 file");
  else
    printf("copied %d files", n);

  then be disappointed. Some languages have more than two forms, with some peculiar rules. It’s often best to design the message to avoid the issue altogether, for instance like this:

  printf("number of copied files: %d", n);
If you really want to construct a properly pluralized message, there is support for this, but it's a bit awkward. When generating a primary or detail error message in `ereport()`, you can write something like this:

```c
errmsg_plural("copied %d file",
             "copied %d files",
            n,
            n)
```

The first argument is the format string appropriate for English singular form, the second is the format string appropriate for English plural form, and the third is the integer control value that determines which plural form to use. Subsequent arguments are formatted per the format string as usual. (Normally, the pluralization control value will also be one of the values to be formatted, so it has to be written twice.) In English it only matters whether `n` is 1 or not 1, but in other languages there can be many different plural forms. The translator sees the two English forms as a group and has the opportunity to supply multiple substitute strings, with the appropriate one being selected based on the run-time value of `n`.

If you need to pluralize a message that isn't going directly to an `errmsg` or `errdetail` report, you have to use the underlying function `ngettext`. See the gettext documentation.

- If you want to communicate something to the translator, such as about how a message is intended to line up with other output, precede the occurrence of the string with a comment that starts with `translator`, e.g.:

  ```
  /* translator: This message is not what it seems to be. */
  ```

These comments are copied to the message catalog files so that the translators can see them.
Chapter 57. Writing a Procedural Language Handler

All calls to functions that are written in a language other than the current “version 1” interface for compiled languages (this includes functions in user-defined procedural languages and functions written in SQL) go through a call handler function for the specific language. It is the responsibility of the call handler to execute the function in a meaningful way, such as by interpreting the supplied source text. This chapter outlines how a new procedural language’s call handler can be written.

The call handler for a procedural language is a “normal” function that must be written in a compiled language such as C, using the version-1 interface, and registered with PostgreSQL as taking no arguments and returning the type language_handler. This special pseudo-type identifies the function as a call handler and prevents it from being called directly in SQL commands. For more details on C language calling conventions and dynamic loading, see Section 38.10.

The call handler is called in the same way as any other function: It receives a pointer to a FunctionCallInfoBaseData struct containing argument values and information about the called function, and it is expected to return a Datum result (and possibly set the isnull field of the FunctionCallInfoBaseData structure, if it wishes to return an SQL null result). The difference between a call handler and an ordinary callee function is that the flinfo->fn_oid field of the FunctionCallInfoBaseData structure will contain the OID of the actual function to be called, not of the call handler itself. The call handler must use this field to determine which function to execute. Also, the passed argument list has been set up according to the declaration of the target function, not of the call handler.

It’s up to the call handler to fetch the entry of the function from the pg_proc system catalog and to analyze the argument and return types of the called function. The AS clause from the CREATE FUNCTION command for the function will be found in the prosrc column of the pg_proc row. This is commonly source text in the procedural language, but in theory it could be something else, such as a path name to a file, or anything else that tells the call handler what to do in detail.

Often, the same function is called many times per SQL statement. A call handler can avoid repeated lookups of information about the called function by using the flinfo->fn_extra field. This will initially be NULL, but can be set by the call handler to point at information about the called function. On subsequent calls, if flinfo->fn_extra is already non-NULL then it can be used and the information lookup step skipped. The call handler must make sure that flinfo->fn_extra is made to point at memory that will live at least until the end of the current query, since an FmgrInfo data structure could be kept that long. One way to do this is to allocate the extra data in the memory context specified by flinfo->fn_mcxt; such data will normally have the same lifespan as the FmgrInfo itself. But the handler could also choose to use a longer-lived memory context so that it can cache function definition information across queries.

When a procedural-language function is invoked as a trigger, no arguments are passed in the usual way, but the FunctionCallInfoBaseData's context field points at a TriggerData structure, rather than being NULL as it is in a plain function call. A language handler should provide mechanisms for procedural-language functions to get at the trigger information.

A template for a procedural-language handler written as a C extension is provided in src/test/modules/plsample. This is a working sample demonstrating one way to create a procedural-language handler, process parameters, and return a value.

Although providing a call handler is sufficient to create a minimal procedural language, there are two other functions that can optionally be provided to make the language more convenient to use. These are a validator and an inline handler. A validator can be provided to allow language-specific checking to be
done during CREATE FUNCTION. An inline handler can be provided to allow the language to support anonymous code blocks executed via the DO command.

If a validator is provided by a procedural language, it must be declared as a function taking a single parameter of type `oid`. The validator's result is ignored, so it is customarily declared to return `void`. The validator will be called at the end of a `CREATE FUNCTION` command that has created or updated a function written in the procedural language. The passed-in OID is the OID of the function's `pg_proc` row. The validator must fetch this row in the usual way, and do whatever checking is appropriate. First, call `CheckFunctionValidatorAccess()` to diagnose explicit calls to the validator that the user could not achieve through `CREATE FUNCTION`. Typical checks then include verifying that the function's argument and result types are supported by the language, and that the function's body is syntactically correct in the language. If the validator finds the function to be okay, it should just return. If it finds an error, it should report that via the normal `ereport()` error reporting mechanism. Throwing an error will force a transaction rollback and thus prevent the incorrect function definition from being committed.

Validator functions should typically honor the `check_function_bodies` parameter: if it is turned off then any expensive or context-sensitive checking should be skipped. If the language provides for code execution at compilation time, the validator must suppress checks that would induce such execution. In particular, this parameter is turned off by `pg_dump` so that it can load procedural language functions without worrying about side effects or dependencies of the function bodies on other database objects. (Because of this requirement, the call handler should avoid assuming that the validator has fully checked the function. The point of having a validator is not to let the call handler omit checks, but to notify the user immediately if there are obvious errors in a `CREATE FUNCTION` command.) While the choice of exactly what to check is mostly left to the discretion of the validator function, note that the core `CREATE FUNCTION` code only executes SET clauses attached to a function when `check_function_bodies` is on. Therefore, checks whose results might be affected by GUC parameters definitely should be skipped when `check_function_bodies` is off, to avoid false failures when reloading a dump.

If an inline handler is provided by a procedural language, it must be declared as a function taking a single parameter of type `internal`. The inline handler's result is ignored, so it is customarily declared to return `void`. The inline handler will be called when a `DO` statement is executed specifying the procedural language. The parameter actually passed is a pointer to an `InlineCodeBlock` struct, which contains information about the `DO` statement's parameters, in particular the text of the anonymous code block to be executed. The inline handler should execute this code and return.

It's recommended that you wrap all these function declarations, as well as the `CREATE LANGUAGE` command itself, into an `extension` so that a simple `CREATE EXTENSION` command is sufficient to install the language. See Section 38.17 for information about writing extensions.

The procedural languages included in the standard distribution are good references when trying to write your own language handler. Look into the `src/pl` subdirectory of the source tree. The `CREATE LANGUAGE` reference page also has some useful details.
Chapter 58. Writing a Foreign Data Wrapper

All operations on a foreign table are handled through its foreign data wrapper, which consists of a set of functions that the core server calls. The foreign data wrapper is responsible for fetching data from the remote data source and returning it to the PostgreSQL executor. If updating foreign tables is to be supported, the wrapper must handle that, too. This chapter outlines how to write a new foreign data wrapper.

The foreign data wrappers included in the standard distribution are good references when trying to write your own. Look into the contrib subdirectory of the source tree. The CREATE FOREIGN DATA WRAPPER reference page also has some useful details.

Note

The SQL standard specifies an interface for writing foreign data wrappers. However, PostgreSQL does not implement that API, because the effort to accommodate it into PostgreSQL would be large, and the standard API hasn't gained wide adoption anyway.

58.1. Foreign Data Wrapper Functions

The FDW author needs to implement a handler function, and optionally a validator function. Both functions must be written in a compiled language such as C, using the version-1 interface. For details on C language calling conventions and dynamic loading, see Section 38.10.

The handler function simply returns a struct of function pointers to callback functions that will be called by the planner, executor, and various maintenance commands. Most of the effort in writing an FDW is in implementing these callback functions. The handler function must be registered with PostgreSQL as taking no arguments and returning the special pseudo-type fdw_handler. The callback functions are plain C functions and are not visible or callable at the SQL level. The callback functions are described in Section 58.2.

The validator function is responsible for validating options given in CREATE and ALTER commands for its foreign data wrapper, as well as foreign servers, user mappings, and foreign tables using the wrapper. The validator function must be registered as taking two arguments, a text array containing the options to be validated, and an OID representing the type of object the options are associated with (in the form of the OID of the system catalog the object would be stored in, either ForeignDataWrapperRelationId, ForeignServerRelationId, UserMappingRelationId, or ForeignTableRelationId). If no validator function is supplied, options are not checked at object creation time or object alteration time.

58.2. Foreign Data Wrapper Callback Routines

The FDW handler function returns a palloc'd FdwRoutine struct containing pointers to the callback functions described below. The scan-related functions are required, the rest are optional.

The FdwRoutine struct type is declared in src/include/foreign/fdwapi.h, which see for additional details.
58.2.1. FDW Routines for Scanning Foreign Tables

```c
void
GetForeignRelSize(PlannerInfo *root,
                   RelOptInfo *baserel,
                   Oid foreigntableid);
```

Obtain relation size estimates for a foreign table. This is called at the beginning of planning for a query
that scans a foreign table. root is the planner's global information about the query; baserel is the
planner's information about this table; and foreigntableid is the pg_class OID of the foreign
table. (foreigntableid could be obtained from the planner data structures, but it's passed explicitly
to save effort.)

This function should update baserel->rows to be the expected number of rows returned by the table
scan, after accounting for the filtering done by the restriction quals. The initial value of baserel->rows
is just a constant default estimate, which should be replaced if at all possible. The function may also choose
to update baserel->width if it can compute a better estimate of the average result row width. (The
initial value is based on column data types and on column average-width values measured by the last
ANALYZE.) Also, this function may update baserel->tuples if it can compute a better estimate of
the foreign table's total row count. (The initial value is from pg_class.reltuples which represents
the total row count seen by the last ANALYZE; it will be -1 if no ANALYZE has been done on this foreign
table.)

See Section 58.4 for additional information.

```c
void
GetForeignPaths(PlannerInfo *root,
                 RelOptInfo *baserel,
                 Oid foreigntableid);
```

Create possible access paths for a scan on a foreign table. This is called during query planning. The para-
meters are the same as for GetForeignRelSize, which has already been called.

This function must generate at least one access path (ForeignPath node) for a scan on the foreign table
and must call add_path to add each such path to baserel->pathlist. It's recommended to use
create_foreignscan_path to build the ForeignPath nodes. The function can generate multiple
access paths, e.g., a path which has valid pathkeys to represent a pre-sorted result. Each access path
must contain cost estimates, and can contain any FDW-private information that is needed to identify the
specific scan method intended.

See Section 58.4 for additional information.

```c
ForeignScan *
GetForeignPlan(PlannerInfo *root,
               RelOptInfo *baserel,
               Oid foreigntableid,
               ForeignPath *best_path,
               List *tlist,
               List *scan_clauses,
               Plan *outer_plan);
```

Create a ForeignScan plan node from the selected foreign access path. This is called at the end of
query planning. The parameters are as for GetForeignRelSize, plus the selected ForeignPath
Writing a Foreign Data Wrapper

(previously produced by `GetForeignPaths`, `GetForeignJoinPaths`, or `GetForeignUpperPaths`), the target list to be emitted by the plan node, the restriction clauses to be enforced by the plan node, and the outer subplan of the `ForeignScan`, which is used for rechecks performed by `RecheckForeignScan`. (If the path is for a join rather than a base relation, `foreignTableId` is `InvalidOid`.)

This function must create and return a `ForeignScan` plan node; it's recommended to use `make_foreignscan` to build the `ForeignScan` node.

See Section 58.4 for additional information.

```c
void
BeginForeignScan(ForeignScanState *node,
                 int eflags);
```

Begin executing a foreign scan. This is called during executor startup. It should perform any initialization needed before the scan can start, but not start executing the actual scan (that should be done upon the first call to `IterateForeignScan`). The `ForeignScanState` node has already been created, but its `fdw_state` field is still `NULL`. Information about the table to scan is accessible through the `ForeignScanState` node (in particular, from the underlying `ForeignScan` plan node, which contains any FDW-private information provided by `GetForeignPlan`). `eflags` contains flag bits describing the executor's operating mode for this plan node.

Note that when `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for `ExplainForeignScan` and `EndForeignScan`.

```c
TupleTableSlot *
IterateForeignScan(ForeignScanState *node);
```

Fetch one row from the foreign source, returning it in a tuple table slot (the node's `ScanTupleSlot` should be used for this purpose). Return `NULL` if no more rows are available. The tuple table slot infrastructure allows either a physical or virtual tuple to be returned; in most cases the latter choice is preferable from a performance standpoint. Note that this is called in a short-lived memory context that will be reset between invocations. Create a memory context in `BeginForeignScan` if you need longer-lived storage, or use the `es_query_cxt` of the node's `EState`.

The rows returned must match the `fdw_scan_tlist` target list if one was supplied, otherwise they must match the row type of the foreign table being scanned. If you choose to optimize away fetching columns that are not needed, you should insert nulls in those column positions, or else generate a `fdw_scan_tlist` list with those columns omitted.

Note that PostgreSQL's executor doesn't care whether the rows returned violate any constraints that were defined on the foreign table — but the planner does care, and may optimize queries incorrectly if there are rows visible in the foreign table that do not satisfy a declared constraint. If a constraint is violated when the user has declared that the constraint should hold true, it may be appropriate to raise an error (just as you would need to do in the case of a data type mismatch).

```c
void
ReScanForeignScan(ForeignScanState *node);
```

Restart the scan from the beginning. Note that any parameters the scan depends on may have changed value, so the new scan does not necessarily return exactly the same rows.
void
EndForeignScan(ForeignScanState *node);

End the scan and release resources. It is normally not important to release palloc’d memory, but for example
open files and connections to remote servers should be cleaned up.

58.2.2. FDW Routines for Scanning Foreign Joins

If an FDW supports performing foreign joins remotely (rather than by fetching both tables' data and doing
the join locally), it should provide this callback function:

void
GetForeignJoinPaths(PlannerInfo *root,
                    RelOptInfo *joinrel,
                    RelOptInfo *outerrel,
                    RelOptInfo *innerrel,
                    JoinType jointype,
                    JoinPathExtraData *extra);

Create possible access paths for a join of two (or more) foreign tables that all belong to the same
foreign server. This optional function is called during query planning. As with GetForeignPaths,
this function should generate ForeignPath path(s) for the supplied joinrel (use create_foreign_join_path to build them), and call add_path to add these paths to the set of paths considered
for the join. But unlike GetForeignPaths, it is not necessary that this function succeed in creating at
least one path, since paths involving local joining are always possible.

Note that this function will be invoked repeatedly for the same join relation, with different combinations
of inner and outer relations; it is the responsibility of the FDW to minimize duplicated work.

If a ForeignPath path is chosen for the join, it will represent the entire join process; paths generated
for the component tables and subsidiary joins will not be used. Subsequent processing of the join path
proceeds much as it does for a path scanning a single foreign table. One difference is that the scanrelid
of the resulting ForeignScan plan node should be set to zero, since there is no single relation that it
represents; instead, the fs_relids field of the ForeignScan node represents the set of relations that
were joined. (The latter field is set up automatically by the core planner code, and need not be filled by
the FDW.) Another difference is that, because the column list for a remote join cannot be found from
the system catalogs, the FDW must fill fdw_scan_tlist with an appropriate list of TargetEntry
nodes, representing the set of columns it will supply at run time in the tuples it returns.

See Section 58.4 for additional information.

58.2.3. FDW Routines for Planning Post-Scan/Join Processing

If an FDW supports performing remote post-scan/join processing, such as remote aggregation, it should
provide this callback function:

void
GetForeignUpperPaths(PlannerInfo *root,
                      UpperRelationKind stage,
                      RelOptInfo *input_rel,
                      RelOptInfo *output_rel,
void *extra);  

Create possible access paths for upper relation processing, which is the planner's term for all post-scan/join query processing, such as aggregation, window functions, sorting, and table updates. This optional function is called during query planning. Currently, it is called only if all base relation(s) involved in the query belong to the same FDW. This function should generate ForeignPath path(s) for any post-scan/join processing that the FDW knows how to perform remotely (use create_foreign_upper_path to build them), and call add_path to add these paths to the indicated upper relation. As with GetForeignJoinPaths, it is not necessary that this function succeed in creating any paths, since paths involving local processing are always possible.

The stage parameter identifies which post-scan/join step is currently being considered. output_rel is the upper relation that should receive paths representing computation of this step, and input_rel is the relation representing the input to this step. The extra parameter provides additional details, currently, it is set only for UPPERREL_PARTIAL_GROUP_AGG or UPPERREL_GROUP_AGG, in which case it points to a GroupPathExtraData structure; or for UPPERREL_FINAL, in which case it points to a FinalPathExtraData structure. (Note that ForeignPath paths added to output_rel would typically not have any direct dependency on paths of the input_rel, since their processing is expected to be done externally. However, examining paths previously generated for the previous processing step can be useful to avoid redundant planning work.)

See Section 58.4 for additional information.

58.2.4. FDW Routines for Updating Foreign Tables

If an FDW supports writable foreign tables, it should provide some or all of the following callback functions depending on the needs and capabilities of the FDW:

```c
void AddForeignUpdateTargets(PlannerInfo *root,
    Index rtindex,
    RangeTblEntry *target_rte,
    Relation target_relation);
```

UPDATE and DELETE operations are performed against rows previously fetched by the table-scanning functions. The FDW may need extra information, such as a row ID or the values of primary-key columns, to ensure that it can identify the exact row to update or delete. To support that, this function can add extra hidden, or “junk”, target columns to the list of columns that are to be retrieved from the foreign table during an UPDATE or DELETE.

To do that, construct a Var representing an extra value you need, and pass it to add_row_identity_var, along with a name for the junk column. (You can do this more than once if several columns are needed.) You must choose a distinct junk column name for each different Var you need, except that Vars that are identical except for the varno field can and should share a column name. The core system uses the junk column names tableoid for a table's tableoid column, ctid or ctidN for ctid, wholerow for a whole-row Var marked with vartype = RECORD, and wholerowN for a whole-row Var with vartype equal to the table's declared row type. Re-use these names when you can (the planner will combine duplicate requests for identical junk columns). If you need another kind of junk column besides these, it might be wise to choose a name prefixed with your extension name, to avoid conflicts against other FDWs.

If the AddForeignUpdateTargets pointer is set to NULL, no extra target expressions are added. (This will make it impossible to implement DELETE operations, though UPDATE may still be feasible if the FDW relies on an unchanging primary key to identify rows.)
Writing a Foreign Data Wrapper

List *
PlanForeignModify(PlannerInfo *root,
    ModifyTable *plan,
    Index resultRelation,
    int subplan_index);

Perform any additional planning actions needed for an insert, update, or delete on a foreign table. This function generates the FDW-private information that will be attached to the ModifyTable plan node that performs the update action. This private information must have the form of a List, and will be delivered to BeginForeignModify during the execution stage.

root is the planner’s global information about the query. plan is the ModifyTable plan node, which is complete except for the fdwPrivLists field. resultRelation identifies the target foreign table by its range table index. subplan_index identifies which target of the ModifyTable plan node this is, counting from zero; use this if you want to index into per-target-relation substructures of the plan node.

See Section 58.4 for additional information.

If the PlanForeignModify pointer is set to NULL, no additional plan-time actions are taken, and the fdw_private list delivered to BeginForeignModify will be NIL.

void
BeginForeignModify(ModifyTableState *mtstate,
    ResultRelInfo *rinfo,
    List *fdw_private,
    int subplan_index,
    int eflags);

Begin executing a foreign table modification operation. This routine is called during executor startup. It should perform any initialization needed prior to the actual table modifications. Subsequently, ExecForeignInsert/ExecForeignBatchInsert, ExecForeignUpdate or ExecForeignDelete will be called for tuple(s) to be inserted, updated, or deleted.

mtstate is the overall state of the ModifyTable plan node being executed; global data about the plan and execution state is available via this structure. rinfo is the ResultRelInfo struct describing the target foreign table. (The ri_FdwState field of ResultRelInfo is available for the FDW to store any private state it needs for this operation.) fdw_private contains the private data generated by PlanForeignModify, if any. subplan_index identifies which target of the ModifyTable plan node this is. eflags contains flag bits describing the executor’s operating mode for this plan node.

Note that when (eflags & EXEC_FLAG_EXPLAIN_ONLY) is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for ExplainForeignModify and EndForeignModify.

If the BeginForeignModify pointer is set to NULL, no action is taken during executor startup.

TupleTableSlot *
ExecForeignInsert(EState *estate,
    ResultRelInfo *rinfo,
    TupleTableSlot *slot,
    TupleTableSlot *planSlot);

Insert one tuple into the foreign table. estate is global execution state for the query. rinfo is the ResultRelInfo struct describing the target foreign table. slot contains the tuple to be inserted; it will
Writing a Foreign Data Wrapper

match the row-type definition of the foreign table. planSlot contains the tuple that was generated by the ModifyTable plan node's subplan; it differs from slot in possibly containing additional "junk" columns. (The planSlot is typically of little interest for INSERT cases, but is provided for completeness.)

The return value is either a slot containing the data that was actually inserted (this might differ from the data supplied, for example as a result of trigger actions), or NULL if no row was actually inserted (again, typically as a result of triggers). The passed-in slot can be re-used for this purpose.

The data in the returned slot is used only if the INSERT statement has a RETURNING clause or involves a view WITH CHECK OPTION; or if the foreign table has an AFTER ROW trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the RETURNING clause or WITH CHECK OPTION constraints. Regardless, some slot must be returned to indicate success, or the query's reported row count will be wrong.

If the ExecForeignInsert pointer is set to NULL, attempts to insert into the foreign table will fail with an error message.

Note that this function is also called when inserting routed tuples into a foreign-table partition or executing COPY FROM on a foreign table, in which case it is called in a different way than it is in the INSERT case. See the callback functions described below that allow the FDW to support that.

TupleTableSlot **
ExecForeignBatchInsert(EState *estate,
    ResultRelInfo *rinfo,
    TupleTableSlot **slots,
    TupleTableSlot **planSlots,
    int *numSlots);

Insert multiple tuples in bulk into the foreign table. The parameters are the same for ExecForeignInsert except slots and planSlots contain multiple tuples and *numSlots specifies the number of tuples in those arrays.

The return value is an array of slots containing the data that was actually inserted (this might differ from the data supplied, for example as a result of trigger actions.) The passed-in slots can be re-used for this purpose. The number of successfully inserted tuples is returned in *numSlots.

The data in the returned slot is used only if the INSERT statement involves a view WITH CHECK OPTION; or if the foreign table has an AFTER ROW trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the WITH CHECK OPTION constraints.

If the ExecForeignBatchInsert or GetForeignModifyBatchSize pointer is set to NULL, attempts to insert into the foreign table will use ExecForeignInsert. This function is not used if the INSERT has the RETURNING clause.

Note that this function is also called when inserting routed tuples into a foreign-table partition. See the callback functions described below that allow the FDW to support that.

int
GetForeignModifyBatchSize(ResultRelInfo *rinfo);

Report the maximum number of tuples that a single ExecForeignBatchInsert call can handle for the specified foreign table. The executor passes at most the given number of tuples to ExecForeign-
BatchInsert. rinfo is the ResultRelInfo struct describing the target foreign table. The FDW is expected to provide a foreign server and/or foreign table option for the user to set this value, or some hard-coded value.

If the ExecForeignBatchInsert or GetForeignModifyBatchSize pointer is set to NULL, attempts to insert into the foreign table will use ExecForeignInsert.

TupleTableSlot *
ExecForeignUpdate(EState *estate,
        ResultRelInfo *rinfo,
        TupleTableSlot *slot,
        TupleTableSlot *planSlot);

Update one tuple in the foreign table. estate is global execution state for the query. rinfo is the ResultRelInfo struct describing the target foreign table. slot contains the new data for the tuple; it will match the row-type definition of the foreign table. planSlot contains the tuple that was generated by the ModifyTable plan node's subplan. Unlike slot, this tuple contains only the new values for columns changed by the query, so do not rely on attribute numbers of the foreign table to index into planSlot. Also, planSlot typically contains additional “junk” columns. In particular, any junk columns that were requested by AddForeignUpdateTargets will be available from this slot.

The return value is either a slot containing the row as it was actually updated (this might differ from the data supplied, for example as a result of trigger actions), or NULL if no row was actually updated (again, typically as a result of triggers). The passed-in slot can be re-used for this purpose.

The data in the returned slot is used only if the UPDATE statement has a RETURNING clause or involves a view WITH CHECK OPTION; or if the foreign table has an AFTER ROW trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the RETURNING clause or WITH CHECK OPTION constraints. Regardless, some slot must be returned to indicate success, or the query's reported row count will be wrong.

If the ExecForeignUpdate pointer is set to NULL, attempts to update the foreign table will fail with an error message.

TupleTableSlot *
ExecForeignDelete(EState *estate,
        ResultRelInfo *rinfo,
        TupleTableSlot *slot,
        TupleTableSlot *planSlot);

Delete one tuple from the foreign table. estate is global execution state for the query. rinfo is the ResultRelInfo struct describing the target foreign table. slot contains nothing useful upon call, but can be used to hold the returned tuple. planSlot contains the tuple that was generated by the ModifyTable plan node's subplan; in particular, it will carry any junk columns that were requested by AddForeignUpdateTargets. The junk column(s) must be used to identify the tuple to be deleted.

The return value is either a slot containing the row that was deleted, or NULL if no row was deleted (typically as a result of triggers). The passed-in slot can be used to hold the tuple to be returned.

The data in the returned slot is used only if the DELETE query has a RETURNING clause or the foreign table has an AFTER ROW trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the RETURNING clause. Regardless, some slot must be returned to indicate success, or the query's reported row count will be wrong.
If the ExecForeignDelete pointer is set to NULL, attempts to delete from the foreign table will fail with an error message.

```c
void
EndForeignModify(EState *estate,
                   ResultRelInfo *rinfo);
```

End the table update and release resources. It is normally not important to release palloc'd memory, but for example open files and connections to remote servers should be cleaned up.

If the EndForeignModify pointer is set to NULL, no action is taken during executor shutdown.

Tuples inserted into a partitioned table by INSERT or COPY FROM are routed to partitions. If an FDW supports routable foreign-table partitions, it should also provide the following callback functions. These functions are also called when COPY FROM is executed on a foreign table.

```c
void
BeginForeignInsert(ModifyTableState *mtstate,
                    ResultRelInfo *rinfo);
```

Begin executing an insert operation on a foreign table. This routine is called right before the first tuple is inserted into the foreign table in both cases when it is the partition chosen for tuple routing and the target specified in a COPY FROM command. It should perform any initialization needed prior to the actual insertion. Subsequently, ExecForeignInsert or ExecForeignBatchInsert will be called for tuple(s) to be inserted into the foreign table.

*mtstate* is the overall state of the ModifyTable plan node being executed; global data about the plan and execution state is available via this structure. *rinfo* is the ResultRelInfo struct describing the target foreign table. (The ri_FdwState field of ResultRelInfo is available for the FDW to store any private state it needs for this operation.)

When this is called by a COPY FROM command, the plan-related global data in *mtstate* is not provided and the planSlot parameter of ExecForeignInsert subsequently called for each inserted tuple is NULL, whether the foreign table is the partition chosen for tuple routing or the target specified in the command.

If the BeginForeignInsert pointer is set to NULL, no action is taken for the initialization.

Note that if the FDW does not support routable foreign-table partitions and/or executing COPY FROM on foreign tables, this function or ExecForeignInsert/ExecForeignBatchInsert subsequently called must throw error as needed.

```c
void
EndForeignInsert(EState *estate,
                  ResultRelInfo *rinfo);
```

End the insert operation and release resources. It is normally not important to release palloc'd memory, but for example open files and connections to remote servers should be cleaned up.

If the EndForeignInsert pointer is set to NULL, no action is taken for the termination.

```c
int
IsForeignRelUpdatable(Relation rel);
```
Report which update operations the specified foreign table supports. The return value should be a bit mask of rule event numbers indicating which operations are supported by the foreign table, using the \texttt{CmdType} enumeration; that is, \((1 \ll \texttt{CMD\_UPDATE}) = 4\) for \texttt{UPDATE}, \((1 \ll \texttt{CMD\_INSERT}) = 8\) for \texttt{INSERT}, and \((1 \ll \texttt{CMD\_DELETE}) = 16\) for \texttt{DELETE}.

If the \textit{IsForeignRelUpdatable} pointer is set to \texttt{NULL}, foreign tables are assumed to be insertable, updatable, or deletable if the FDW provides \texttt{ExecForeignInsert}, \texttt{ExecForeignUpdate}, or \texttt{ExecForeignDelete} respectively. This function is only needed if the FDW supports some tables that are updatable and some that are not. (Even then, it's permissible to throw an error in the execution routine instead of checking in this function. However, this function is used to determine updatability for display in the \textit{information\_schema} views.)

Some inserts, updates, and deletes to foreign tables can be optimized by implementing an alternative set of interfaces. The ordinary interfaces for inserts, updates, and deletes fetch rows from the remote server and then modify those rows one at a time. In some cases, this row-by-row approach is necessary, but it can be inefficient. If it is possible for the foreign server to determine which rows should be modified without actually retrieving them, and if there are no local structures which would affect the operation (row-level local triggers, stored generated columns, or WITH CHECK OPTION constraints from parent views), then it is possible to arrange things so that the entire operation is performed on the remote server. The interfaces described below make this possible.

\begin{verbatim}
bool PlanDirectModify(PlannerInfo *root,
               ModifyTable *plan,
               Index resultRelation,
               int subplan_index);
\end{verbatim}

Decide whether it is safe to execute a direct modification on the remote server. If so, return \texttt{true} after performing planning actions needed for that. Otherwise, return \texttt{false}. This optional function is called during query planning. If this function succeeds, \texttt{BeginDirectModify}, \texttt{IterateDirectModify} and \texttt{EndDirectModify} will be called at the execution stage, instead. Otherwise, the table modification will be executed using the table-updating functions described above. The parameters are the same as for \texttt{PlanForeignModify}.

To execute the direct modification on the remote server, this function must rewrite the target subplan with a \texttt{ForeignScan} plan node that executes the direct modification on the remote server. The \texttt{operation} and \texttt{resultRelation} fields of the \texttt{ForeignScan} must be set appropriately. \texttt{operation} must be set to the \texttt{CmdType} enumeration corresponding to the statement kind (that is, \texttt{CMD\_UPDATE} for \texttt{UPDATE}, \texttt{CMD\_INSERT} for \texttt{INSERT}, and \texttt{CMD\_DELETE} for \texttt{DELETE}), and the \texttt{resultRelation} argument must be copied to the \texttt{resultRelation} field.

See Section 58.4 for additional information.

If the \texttt{PlanDirectModify} pointer is set to \texttt{NULL}, no attempts to execute a direct modification on the remote server are taken.

\begin{verbatim}
void BeginDirectModify(ForeignScanState *node,
               int eflags);
\end{verbatim}

Prepare to execute a direct modification on the remote server. This is called during executor startup. It should perform any initialization needed prior to the direct modification (that should be done upon the first call to \texttt{IterateDirectModify}). The \texttt{ForeignScanState} node has already been created, but its \texttt{fdw\_state} field is still \texttt{NULL}. Information about the table to modify is accessible through the For-
Writing a Foreign Data Wrapper

eignScanState node (in particular, from the underlying ForeignScan plan node, which contains any FDW-private information provided by PlanDirectModify). eflags contains flag bits describing the executor's operating mode for this plan node.

Note that when (eflags & EXEC_FLAG_EXPLAIN_ONLY) is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for ExplainDirectModify and EndDirectModify.

If the BeginDirectModify pointer is set to NULL, no attempts to execute a direct modification on the remote server are taken.

TupleTableSlot *
IterateDirectModify(ForeignScanState *node);

When the INSERT, UPDATE or DELETE query doesn't have a RETURNING clause, just return NULL after a direct modification on the remote server. When the query has the clause, fetch one result containing the data needed for the RETURNING calculation, returning it in a tuple table slot (the node's ScanTupleSlot should be used for this purpose). The data that was actually inserted, updated or deleted must be stored in node->resultRelInfo->ri_projectReturning->pi_exprContext->ecx-t_scantuple. Return NULL if no more rows are available. Note that this is called in a short-lived memory context that will be reset between invocations. Create a memory context in BeginDirectModify if you need longer-lived storage, or use the es_query_cxt of the node's EState.

The rows returned must match the fdw_scan_tlist target list if one was supplied, otherwise they must match the row type of the foreign table being updated. If you choose to optimize away fetching columns that are not needed for the RETURNING calculation, you should insert nulls in those column positions, or else generate a fdw_scan_tlist list with those columns omitted.

Whether the query has the clause or not, the query's reported row count must be incremented by the FDW itself. When the query doesn't have the clause, the FDW must also increment the row count for the ForeignScanState node in the EXPLAIN ANALYZE case.

If the IterateDirectModify pointer is set to NULL, no attempts to execute a direct modification on the remote server are taken.

void
EndDirectModify(ForeignScanState *node);

Clean up following a direct modification on the remote server. It is normally not important to release palloc'd memory, but for example open files and connections to the remote server should be cleaned up.

If the EndDirectModify pointer is set to NULL, no attempts to execute a direct modification on the remote server are taken.

58.2.5. FDW Routines for TRUNCATE

void
ExecForeignTruncate(List *rels,
DropBehavior behavior,
bool restart_seqs);

Truncate foreign tables. This function is called when TRUNCATE is executed on a foreign table. rels is a list of Relation data structures of foreign tables to truncate.
Writing a Foreign Data Wrapper

behavior is either DROP_RESTRICT or DROPCASCADE indicating that the RESTRICT or CASCADE option was requested in the original TRUNCATE command, respectively.

If restart_seq is true, the original TRUNCATE command requested the RESTART IDENTITY behavior, otherwise the CONTINUE IDENTITY behavior was requested.

Note that the ONLY options specified in the original TRUNCATE command are not passed to ExecForeignTruncate. This behavior is similar to the callback functions of SELECT, UPDATE and DELETE on a foreign table.

ExecForeignTruncate is invoked once per foreign server for which foreign tables are to be truncated. This means that all foreign tables included in rels must belong to the same server.

If the ExecForeignTruncate pointer is set to NULL, attempts to truncate foreign tables will fail with an error message.

### 58.2.6. FDW Routines for Row Locking

If an FDW wishes to support late row locking (as described in Section 58.5), it must provide the following callback functions:

```c
RowMarkType
GetForeignRowMarkType(RangeTblEntry *rte,
                      LockClauseStrength strength);
```

Report which row-marking option to use for a foreign table. `rte` is the RangeTblEntry node for the table and `strength` describes the lock strength requested by the relevant FOR UPDATE/SHARE clause, if any. The result must be a member of the RowMarkType enum type.

This function is called during query planning for each foreign table that appears in an UPDATE, DELETE, or SELECT FOR UPDATE/SHARE query and is not the target of UPDATE or DELETE.

If the GetForeignRowMarkType pointer is set to NULL, the ROW_MARK_COPY option is always used. (This implies that RefetchForeignRow will never be called, so it need not be provided either.)

See Section 58.5 for more information.

```c
void
RefetchForeignRow(EState *estate,
                   ExecRowMark *erm,
                   Datum rowid,
                   TupleTableSlot *slot,
                   bool *updated);
```

Re-fetch one tuple slot from the foreign table, after locking it if required. `estate` is global execution state for the query. `erm` is the ExecRowMark struct describing the target foreign table and the row lock type (if any) to acquire. `rowid` identifies the tuple to be fetched. `slot` contains nothing useful upon call, but can be used to hold the returned tuple. `updated` is an output parameter.

This function should store the tuple into the provided slot, or clear it if the row lock couldn't be obtained. The row lock type to acquire is defined by `erm->markType`, which is the value previously returned by GetForeignRowMarkType. (ROW_MARK_REFERENCE means to just re-fetch the tuple without acquiring any lock, and ROW_MARK_COPY will never be seen by this routine.)

2505
In addition, *updated should be set to true if what was fetched was an updated version of the tuple rather than the same version previously obtained. (If the FDW cannot be sure about this, always returning true is recommended.)

Note that by default, failure to acquire a row lock should result in raising an error; returning with an empty slot is only appropriate if the SKIP LOCKED option is specified by erm->waitPolicy.

The rowid is the ctid value previously read for the row to be re-fetched. Although the rowid value is passed as a Datum, it can currently only be a tid. The function API is chosen in hopes that it may be possible to allow other data types for row IDs in future.

If the RefetchForeignRow pointer is set to NULL, attempts to re-fetch rows will fail with an error message.

See Section 58.5 for more information.

```c
bool RecheckForeignScan(ForeignScanState *node,
                        TupleTableSlot *slot);
```

Recheck that a previously-returned tuple still matches the relevant scan and join qualifiers, and possibly provide a modified version of the tuple. For foreign data wrappers which do not perform join pushdown, it will typically be more convenient to set this to NULL and instead set fdw_recheck_quals appropriately. When outer joins are pushed down, however, it isn’t sufficient to reapply the checks relevant to all the base tables to the result tuple, even if all needed attributes are present, because failure to match some qualifier might result in some attributes going to NULL, rather than in no tuple being returned. RecheckForeignScan can recheck qualifiers and return true if they are still satisfied and false otherwise, but it can also store a replacement tuple into the supplied slot.

To implement join pushdown, a foreign data wrapper will typically construct an alternative local join plan which is used only for rechecks; this will become the outer subplan of the ForeignScan. When a recheck is required, this subplan can be executed and the resulting tuple can be stored in the slot. This plan need not be efficient since no base table will return more than one row; for example, it may implement all joins as nested loops. The function GetExistingLocalJoinPath may be used to search existing paths for a suitable local join path, which can be used as the alternative local join plan. GetExistingLocalJoinPath searches for an unparameterized path in the path list of the specified join relation. (If it does not find such a path, it returns NULL, in which case a foreign data wrapper may build the local path by itself or may choose not to create access paths for that join.)

### 58.2.7. FDW Routines for EXPLAIN

```c
void ExplainForeignScan(ForeignScanState *node,
                        ExplainState *es);
```

Print additional EXPLAIN output for a foreign table scan. This function can call ExplainPropertyText and related functions to add fields to the EXPLAIN output. The flag fields in es can be used to determine what to print, and the state of the ForeignScanState node can be inspected to provide runtime statistics in the EXPLAIN ANALYZE case.

If the ExplainForeignScan pointer is set to NULL, no additional information is printed during EXPLAIN.
void ExplainForeignModify(ModifyTableState *mtstate,  
    ResultRelInfo *rinfo,  
    List *fdw_private,  
    int subplan_index,  
    struct ExplainState *es);

Print additional EXPLAIN output for a foreign table update. This function can call ExplainPropertyText and related functions to add fields to the EXPLAIN output. The flag fields in es can be used to determine what to print, and the state of the ModifyTableState node can be inspected to provide run-time statistics in the EXPLAIN ANALYZE case. The first four arguments are the same as for BeginForeignModify.

If the ExplainForeignModify pointer is set to NULL, no additional information is printed during EXPLAIN.

void ExplainDirectModify(ForeignScanState *node,  
    ExplainState *es);

Print additional EXPLAIN output for a direct modification on the remote server. This function can call ExplainPropertyText and related functions to add fields to the EXPLAIN output. The flag fields in es can be used to determine what to print, and the state of the ForeignScanState node can be inspected to provide run-time statistics in the EXPLAIN ANALYZE case.

If the ExplainDirectModify pointer is set to NULL, no additional information is printed during EXPLAIN.

58.2.8. FDW Routines for ANALYZE

bool AnalyzeForeignTable(Relation relation,  
    AcquireSampleRowsFunc *func,  
    BlockNumber *totalpages);

This function is called when ANALYZE is executed on a foreign table. If the FDW can collect statistics for this foreign table, it should return true, and provide a pointer to a function that will collect sample rows from the table in func, plus the estimated size of the table in pages in totalpages. Otherwise, return false.

If the FDW does not support collecting statistics for any tables, the AnalyzeForeignTable pointer can be set to NULL.

If provided, the sample collection function must have the signature

int AcquireSampleRowsFunc(Relation relation,  
    int elevel,  
    HeapTuple *rows,  
    int targrows,  
    double *totalrows,  
    double *totaldeadrows);
A random sample of up to `targrows` rows should be collected from the table and stored into the caller-provided `rows` array. The actual number of rows collected must be returned. In addition, store estimates of the total numbers of live and dead rows in the table into the output parameters `totalrows` and `totaldeadrows`. (Set `totaldeadrows` to zero if the FDW does not have any concept of dead rows.)

**58.2.9. FDW Routines for IMPORT FOREIGN SCHEMA**

```c
List *
ImportForeignSchema(ImportForeignSchemaStmt *stmt, Oid serverOid);
```

Obtain a list of foreign table creation commands. This function is called when executing IMPORT FOREIGN SCHEMA, and is passed the parse tree for that statement, as well as the OID of the foreign server to use. It should return a list of C strings, each of which must contain a CREATE FOREIGN TABLE command. These strings will be parsed and executed by the core server.

Within the `ImportForeignSchemaStmt` struct, `remote_schema` is the name of the remote schema from which tables are to be imported. `list_type` identifies how to filter table names: FDW_IMPORT_SCHEMA_ALL means that all tables in the remote schema should be imported (in this case `table_list` is empty), FDW_IMPORT_SCHEMA_LIMIT_TO means to include only tables listed in `table_list`, and FDW_IMPORT_SCHEMA_EXCEPT means to exclude the tables listed in `table_list`. `options` is a list of options used for the import process. The meanings of the options are up to the FDW. For example, an FDW could use an option to define whether the `NOT NULL` attributes of columns should be imported. These options need not have anything to do with those supported by the FDW as database object options.

The FDW may ignore the `local_schema` field of the `ImportForeignSchemaStmt`, because the core server will automatically insert that name into the parsed CREATE FOREIGN TABLE commands.

The FDW does not have to concern itself with implementing the filtering specified by `list_type` and `table_list`, either, as the core server will automatically skip any returned commands for tables excluded according to those options. However, it's often useful to avoid the work of creating commands for excluded tables in the first place. The function `IsImportableForeignTable()` may be useful to test whether a given foreign-table name will pass the filter.

If the FDW does not support importing table definitions, the `ImportForeignSchema` pointer can be set to `NULL`.

**58.2.10. FDW Routines for Parallel Execution**

A `ForeignScan` node can, optionally, support parallel execution. A parallel `ForeignScan` will be executed in multiple processes and must return each row exactly once across all cooperating processes. To do this, processes can coordinate through fixed-size chunks of dynamic shared memory. This shared memory is not guaranteed to be mapped at the same address in every process, so it must not contain pointers. The following functions are all optional, but most are required if parallel execution is to be supported.

```c
bool
IsForeignScanParallelSafe(PlannerInfo *root, RelOptInfo *rel,
                          RangeTblEntry *rte);
```

Test whether a scan can be performed within a parallel worker. This function will only be called when the planner believes that a parallel plan might be possible, and should return true if it is safe for that scan to
run within a parallel worker. This will generally not be the case if the remote data source has transaction semantics, unless the worker's connection to the data can somehow be made to share the same transaction context as the leader.

If this function is not defined, it is assumed that the scan must take place within the parallel leader. Note that returning true does not mean that the scan itself can be done in parallel, only that the scan can be performed within a parallel worker. Therefore, it can be useful to define this method even when parallel execution is not supported.

```
Size
EstimateDSMForeignScan(ForeignScanState *node, ParallelContext *pcxt);
```

Estimate the amount of dynamic shared memory that will be required for parallel operation. This may be higher than the amount that will actually be used, but it must not be lower. The return value is in bytes. This function is optional, and can be omitted if not needed; but if it is omitted, the next three functions must be omitted as well, because no shared memory will be allocated for the FDW's use.

```
void
InitializeDSMForeignScan(ForeignScanState *node, ParallelContext *pcxt, void *coordinate);
```

Initialize the dynamic shared memory that will be required for parallel operation. coordinate points to a shared memory area of size equal to the return value of EstimateDSMForeignScan. This function is optional, and can be omitted if not needed.

```
void
ReInitializeDSMForeignScan(ForeignScanState *node, ParallelContext *pcxt, void *coordinate);
```

Re-initialize the dynamic shared memory required for parallel operation when the foreign-scan plan node is about to be re-scanned. This function is optional, and can be omitted if not needed. Recommended practice is that this function reset only shared state, while the ReScanForeignScan function resets only local state. Currently, this function will be called before ReScanForeignScan, but it's best not to rely on that ordering.

```
void
InitializeWorkerForeignScan(ForeignScanState *node, shm_toc *toc, void *coordinate);
```

Initialize a parallel worker's local state based on the shared state set up by the leader during InitializeDSMForeignScan. This function is optional, and can be omitted if not needed.

```
void
ShutdownForeignScan(ForeignScanState *node);
```

Release resources when it is anticipated the node will not be executed to completion. This is not called in all cases; sometimes, EndForeignScan may be called without this function having been called first. Since the DSM segment used by parallel query is destroyed just after this callback is invoked, foreign data wrappers that wish to take some action before the DSM segment goes away should implement this method.
58.2.11. FDW Routines for Asynchronous Execution

A ForeignScan node can, optionally, support asynchronous execution as described in src/backend/executor/README. The following functions are all optional, but are all required if asynchronous execution is to be supported.

```c
bool IsForeignPathAsyncCapable(ForeignPath *path);
```

Test whether a given ForeignPath path can scan the underlying foreign relation asynchronously. This function will only be called at the end of query planning when the given path is a direct child of an AppendPath path and when the planner believes that asynchronous execution improves performance, and should return true if the given path is able to scan the foreign relation asynchronously.

If this function is not defined, it is assumed that the given path scans the foreign relation using IterateForeignScan. (This implies that the callback functions described below will never be called, so they need not be provided either.)

```c
void ForeignAsyncRequest(AsyncRequest *areq);
```

Produce one tuple asynchronously from the ForeignScan node. areq is the AsyncRequest struct describing the ForeignScan node and the parent Append node that requested the tuple from it. This function should store the tuple into the slot specified by areq->result, and set areq->request_complete to true; or if it needs to wait on an event external to the core server such as network I/O, and cannot produce any tuple immediately, set the flag to false, and set areq->callback_pending to true for the ForeignScan node to get a callback from the callback functions described below. If no more tuples are available, set the slot to NULL or an empty slot, and the areq->request_complete flag to true. It’s recommended to use ExecAsyncRequestDone or ExecAsyncRequestPending to set the output parameters in the areq.

```c
void ForeignAsyncConfigureWait(AsyncRequest *areq);
```

Configure a file descriptor event for which the ForeignScan node wishes to wait. This function will only be called when the ForeignScan node has the areq->callback_pending flag set, and should add the event to the as_eventset of the parent Append node described by the areq. See the comments for ExecAsyncConfigureWait in src/backend/executor/execAsync.c for additional information. When the file descriptor event occurs, ForeignAsyncNotify will be called.

```c
void ForeignAsyncNotify(AsyncRequest *areq);
```

Process a relevant event that has occurred, then produce one tuple asynchronously from the ForeignScan node. This function should set the output parameters in the areq in the same way as ForeignAsyncRequest.

58.2.12. FDW Routines for Reparameterization of Paths

List *
ReparameterizeForeignPathByChild(PlannerInfo *root, List *fdw_private, RelOptInfo *child_rel);

This function is called while converting a path parameterized by the top-most parent of the given child relation child_rel to be parameterized by the child relation. The function is used to reparameterize any paths or translate any expression nodes saved in the given fdw_private member of a ForeignPath. The callback may use reparameterize_path_by_child, adjust_appendrelattrs or adjust_appendrelattrs_multilevel as required.

58.3. Foreign Data Wrapper Helper Functions

Several helper functions are exported from the core server so that authors of foreign data wrappers can get easy access to attributes of FDW-related objects, such as FDW options. To use any of these functions, you need to include the header file foreign/foreign.h in your source file. That header also defines the struct types that are returned by these functions.

ForeignDataWrapper *
GetForeignDataWrapperExtended(Oid fdwid, bits16 flags);

This function returns a ForeignDataWrapper object for the foreign-data wrapper with the given OID. A ForeignDataWrapper object contains properties of the FDW (see foreign/foreign.h for details). flags is a bitwise-or'd bit mask indicating an extra set of options. It can take the value FDW_MISSING_OK, in which case a NULL result is returned to the caller instead of an error for an undefined object.

ForeignDataWrapper *
GetForeignDataWrapper(Oid fdwid);

This function returns a ForeignDataWrapper object for the foreign-data wrapper with the given OID. A ForeignDataWrapper object contains properties of the FDW (see foreign/foreign.h for details).

ForeignServer *
GetForeignServerExtended(Oid serverid, bits16 flags);

This function returns a ForeignServer object for the foreign server with the given OID. A ForeignServer object contains properties of the server (see foreign/foreign.h for details). flags is a bitwise-or'd bit mask indicating an extra set of options. It can take the value FSV_MISSING_OK, in which case a NULL result is returned to the caller instead of an error for an undefined object.

ForeignServer *
GetForeignServer(Oid serverid);

This function returns a ForeignServer object for the foreign server with the given OID. A ForeignServer object contains properties of the server (see foreign/foreign.h for details).

UserMapping *
GetUserMapping(Oid userid, Oid serverid);

This function returns a UserMapping object for the user mapping of the given role on the given server. (If there is no mapping for the specific user, it will return the mapping for PUBLIC, or throw error if there

2511
is none.) A UserMapping object contains properties of the user mapping (see foreign/foreign.h for details).

ForeignTable *
GetForeignTable(Oid relid);

This function returns a ForeignTable object for the foreign table with the given OID. A ForeignTable object contains properties of the foreign table (see foreign/foreign.h for details).

List *
GetForeignColumnOptions(Oid relid, AttrNumber attnum);

This function returns the per-column FDW options for the column with the given foreign table OID and attribute number, in the form of a list of DefElem. NIL is returned if the column has no options.

Some object types have name-based lookup functions in addition to the OID-based ones:

ForeignDataWrapper *
GetForeignDataWrapperByName(const char *name, bool missing_ok);

This function returns a ForeignDataWrapper object for the foreign-data wrapper with the given name. If the wrapper is not found, return NULL if missing_ok is true, otherwise raise an error.

ForeignServer *
GetForeignServerByName(const char *name, bool missing_ok);

This function returns a ForeignServer object for the foreign server with the given name. If the server is not found, return NULL if missing_ok is true, otherwise raise an error.

58.4. Foreign Data Wrapper Query Planning

The FDW callback functions GetForeignRelSize, GetForeignPaths, GetForeignPlan, PlanForeignModify, GetForeignJoinPaths, GetForeignUpperPaths, and PlanDirectModify must fit into the workings of the PostgreSQL planner. Here are some notes about what they must do.

The information in root and baserel can be used to reduce the amount of information that has to be fetched from the foreign table (and therefore reduce the cost). baserel->baserestrictinfo is particularly interesting, as it contains restriction quals (WHERE clauses) that should be used to filter the rows to be fetched. (The FDW itself is not required to enforce these quals, as the core executor can check them instead.) baserel->reltarget->exprs can be used to determine which columns need to be fetched; but note that it only lists columns that have to be emitted by the ForeignScan plan node, not columns that are used in qual evaluation but not output by the query.

Various private fields are available for the FDW planning functions to keep information in. Generally, whatever you store in FDW private fields should be palloc'd, so that it will be reclaimed at the end of planning.

baserel->fdw_private is a void pointer that is available for FDW planning functions to store information relevant to the particular foreign table. The core planner does not touch it except to initialize it to NULL when the RelOptInfo node is created. It is useful for passing information forward from
GetForeignRelSize to GetForeignPaths and/or GetForeignPaths to GetForeignPlan, thereby avoiding recalculation.

GetForeignPaths can identify the meaning of different access paths by storing private information in the `fdw_private` field of `ForeignPath` nodes. `fdw_private` is declared as a List pointer, but could actually contain anything since the core planner does not touch it. However, best practice is to use a representation that's dumpable by `nodeToString`, for use with debugging support available in the backend.

GetForeignPlan can examine the `fdw_private` field of the selected `ForeignPath` node, and can generate `fdw_exprs` and `fdw_private` lists to be placed in the `ForeignScan` plan node, where they will be available at execution time. Both of these lists must be represented in a form that `copyObject` knows how to copy. The `fdw_private` list has no other restrictions and is not interpreted by the core backend in any way. The `fdw_exprs` list, if not NIL, is expected to contain expression trees that are intended to be executed at run time. These trees will undergo post-processing by the planner to make them fully executable.

In GetForeignPlan, generally the passed-in target list can be copied into the plan node as-is. The passed `scan_clauses` list contains the same clauses as `baserel->baserestrictinfo`, but may be re-ordered for better execution efficiency. In simple cases the FDW can just strip `RestrictInfo` nodes from the `scan_clauses` list (using `extract_actual_clauses`) and put all the clauses into the plan node's `qual` list, which means that all the clauses will be checked by the executor at run time. More complex FDWs may be able to check some of the clauses internally, in which case those clauses can be removed from the plan node's `qual` list so that the executor doesn't waste time rechecking them.

As an example, the FDW might identify some restriction clauses of the form `foreign_variable = sub_expression`, which it determines can be executed on the remote server given the locally-evaluated value of the `sub_expression`. The actual identification of such a clause should happen during GetForeignPaths, since it would affect the cost estimate for the path. The path's `fdw_private` field would probably include a pointer to the identified clause's `RestrictInfo` node. Then GetForeignPlan would remove that clause from `scan_clauses`, but add the `sub_expression` to `fdw_exprs` to ensure that it gets massaged into executable form. It would probably also put control information into the plan node's `fdw_private` field to tell the execution functions what to do at run time. The query transmitted to the remote server would involve something like `WHERE foreign_variable = $1`, with the parameter value obtained at run time from evaluation of the `fdw_exprs` expression tree.

Any clauses removed from the plan node's `qual` list must instead be added to `fdw_recheck_quals` or rechecked by `RecheckForeignScan` in order to ensure correct behavior at the READ COMMITTED isolation level. When a concurrent update occurs for some other table involved in the query, the executor may need to verify that all of the original `quals` are still satisfied for the tuple, possibly against a different set of parameter values. Using `fdw_recheck_quals` is typically easier than implementing checks inside `RecheckForeignScan`, but this method will be insufficient when outer joins have been pushed down, since the join tuples in that case might have some fields go to NULL without rejecting the tuple entirely.

Another `ForeignScan` field that can be filled by FDWs is `fdw_scan_tlist`, which describes the tuples returned by the FDW for this plan node. For simple foreign table scans this can be set to NIL, implying that the returned tuples have the row type declared for the foreign table. A non-NIL value must be a target list (list of TargetEntries) containing Vars and/or expressions representing the returned columns. This might be used, for example, to show that the FDW has omitted some columns that it noticed won't be needed for the query. Also, if the FDW can compute expressions used by the query more cheaply than can be done locally, it could add those expressions to `fdw_scan_tlist`. Note that join plans (created from paths made by GetForeignJoinPaths) must always supply `fdw_scan_tlist` to describe the set of columns they will return.

The FDW should always construct at least one path that depends only on the table's restriction clauses. In join queries, it might also choose to construct path(s) that depend on join clauses, for example for-
Writing a Foreign Data Wrapper

\[ \text{eign\_variable} = \text{local\_variable} \]. Such clauses will not be found in baserel->baserestrictinfo but must be sought in the relation's join lists. A path using such a clause is called a “parameterized path”. It must identify the other relations used in the selected join clause(s) with a suitable value of param_info; use get_baserel_parampathinfo to compute that value. In GetForeignPlan, the local_variable portion of the join clause would be added to fdw_exprs, and then at run time the case works the same as for an ordinary restriction clause.

If an FDW supports remote joins, GetForeignJoinPaths should produce ForeignPaths for potential remote joins in much the same way as GetForeignPaths works for base tables. Information about the intended join can be passed forward to GetForeignPlan in the same ways described above. However, baserestrictinfo is not relevant for join relations; instead, the relevant join clauses for a particular join are passed to GetForeignJoinPaths as a separate parameter (extra->restrictlist).

An FDW might additionally support direct execution of some plan actions that are above the level of scans and joins, such as grouping or aggregation. To offer such options, the FDW should generate paths and insert them into the appropriate upper relation. For example, a path representing remote aggregation should be inserted into the UPPERREL_GROUP_AGG relation, using add_path. This path will be compared on a cost basis with local aggregation performed by reading a simple scan path for the foreign relation (note that such a path must also be supplied, else there will be an error at plan time). If the remote-aggregation path wins, which it usually would, it will be converted into a plan in the usual way, by calling GetForeignPlan. The recommended place to generate such paths is in the GetForeignUpperPaths callback function, which is called for each upper relation (i.e., each post-scan/join processing step), if all the base relations of the query come from the same FDW.

PlanForeignModify and the other callbacks described in Section 58.2.4 are designed around the assumption that the foreign relation will be scanned in the usual way and then individual row updates will be driven by a local ModifyTable plan node. This approach is necessary for the general case where an update requires reading local tables as well as foreign tables. However, if the operation could be executed entirely by the foreign server, the FDW could generate a path representing that and insert it into the UPPERREL_FINAL upper relation, where it would compete against the ModifyTable approach. This approach could also be used to implement remote SELECT FOR UPDATE, rather than using the row locking callbacks described in Section 58.2.6. Keep in mind that a path inserted into UPPERREL_FINAL is responsible for implementing all behavior of the query.

When planning an UPDATE or DELETE, PlanForeignModify and PlanDirectModify can look up the RelOptInfo struct for the foreign table and make use of the baserel->fdw_private data previously created by the scan-planning functions. However, in INSERT the target table is not scanned so there is no RelOptInfo for it. The List returned by PlanForeignModify has the same restrictions as the fdw_private list of a ForeignScan plan node, that is it must contain only structures that copyObject knows how to copy.

INSERT with an ON CONFLICT clause does not support specifying the conflict target, as unique constraints or exclusion constraints on remote tables are not locally known. This in turn implies that ON CONFLICT DO UPDATE is not supported, since the specification is mandatory there.

58.5. Row Locking in Foreign Data Wrappers

If an FDW’s underlying storage mechanism has a concept of locking individual rows to prevent concurrent updates of those rows, it is usually worthwhile for the FDW to perform row-level locking with as close an approximation as practical to the semantics used in ordinary PostgreSQL tables. There are multiple considerations involved in this.

One key decision to be made is whether to perform early locking or late locking. In early locking, a row is locked when it is first retrieved from the underlying store, while in late locking, the row is locked only
when it is known that it needs to be locked. (The difference arises because some rows may be discarded by locally-checked restriction or join conditions.) Early locking is much simpler and avoids extra round trips to a remote store, but it can cause locking of rows that need not have been locked, resulting in reduced concurrency or even unexpected deadlocks. Also, late locking is only possible if the row to be locked can be uniquely re-identified later. Preferably the row identifier should identify a specific version of the row, as PostgreSQL TIDs do.

By default, PostgreSQL ignores locking considerations when interfacing to FDWs, but an FDW can perform early locking without any explicit support from the core code. The API functions described in Section 58.2.6, which were added in PostgreSQL 9.5, allow an FDW to use late locking if it wishes.

An additional consideration is that in READ COMMITTED isolation mode, PostgreSQL may need to re-check restriction and join conditions against an updated version of some target tuple. Rechecking join conditions requires re-obtaining copies of the non-target rows that were previously joined to the target tuple. When working with standard PostgreSQL tables, this is done by including the TIDs of the non-target tables in the column list projected through the join, and then re-fetching non-target rows when required. This approach keeps the join data set compact, but it requires inexpensive re-fetch capability, as well as a TID that can uniquely identify the row version to be re-fetched. By default, therefore, the approach used with foreign tables is to include a copy of the entire row fetched from a foreign table in the column list projected through the join. This puts no special demands on the FDW but can result in reduced performance of merge and hash joins. An FDW that is capable of meeting the re-fetch requirements can choose to do it the first way.

For an UPDATE or DELETE on a foreign table, it is recommended that the ForeignScan operation on the target table perform early locking on the rows that it fetches, perhaps via the equivalent of SELECT FOR UPDATE. An FDW can detect whether a table is an UPDATE/DELETE target at plan time by comparing its relid to root->parse->resultRelation, or at execution time by using ExecRelationIsTargetRelation(). An alternative possibility is to perform late locking within the ExecForeignUpdate or ExecForeignDelete callback, but no special support is provided for this.

For foreign tables that are specified to be locked by a SELECT FOR UPDATE/SHARE command, the ForeignScan operation can again perform early locking by fetching tuples with the equivalent of SELECT FOR UPDATE/SHARE. To perform late locking instead, provide the callback functions defined in Section 58.2.6. In GetForeignRowMarkType, select rowmark option ROW_MARK_EXCLUSIVE, ROW_MARK_NOKEYEXCLUSIVE, ROW_MARK_SHARE, or ROW_MARK_KEYSHARE depending on the requested lock strength. (The core code will act the same regardless of which of these four options you choose.) Elsewhere, you can detect whether a foreign table was specified to be locked by this type of command by using get_plan_rowmark at plan time, or ExecFindRowMark at execution time; you must check not only whether a non-null rowmark struct is returned, but that its strength field is not LCS_NONE.

Lastly, for foreign tables that are used in an UPDATE, DELETE or SELECT FOR UPDATE/SHARE command but are not specified to be row-locked, you can override the default choice to copy entire rows by having GetForeignRowMarkType select option ROW_MARK_REFERENCE when it sees lock strength LCS_NONE. This will cause RefetchForeignRow to be called with that value for markType; it should then re-fetch the row without acquiring any new lock. (If you have a GetForeignRowMarkType function but don't wish to re-fetch unlocked rows, select option ROW_MARK_COPY for LCS_NONE.)

See src/include/nodes/lockoptions.h, the comments for RowMarkType and PlanRowMark in src/include/nodes/plannodes.h, and the comments for ExecRowMark in src/include/nodes/execnodes.h for additional information.
Chapter 59. Writing a Table Sampling Method

PostgreSQL's implementation of the TABLESAMPLE clause supports custom table sampling methods, in addition to the BERNOULLI and SYSTEM methods that are required by the SQL standard. The sampling method determines which rows of the table will be selected when the TABLESAMPLE clause is used.

At the SQL level, a table sampling method is represented by a single SQL function, typically implemented in C, having the signature

```
method_name(internal) RETURNS tsm_handler
```

The name of the function is the same method name appearing in the TABLESAMPLE clause. The internal argument is a dummy (always having value zero) that simply serves to prevent this function from being called directly from an SQL command. The result of the function must be a palloc'd struct of type `TsmRoutine`, which contains pointers to support functions for the sampling method. These support functions are plain C functions and are not visible or callable at the SQL level. The support functions are described in Section 59.1.

In addition to function pointers, the `TsmRoutine` struct must provide these additional fields:

- `List *parameterTypes`
  
  This is an OID list containing the data type OIDs of the parameter(s) that will be accepted by the TABLESAMPLE clause when this sampling method is used. For example, for the built-in methods, this list contains a single item with value `FLOAT4OID`, which represents the sampling percentage. Custom sampling methods can have more or different parameters.

- `bool repeatable_across_queries`
  
  If true, the sampling method can deliver identical samples across successive queries, if the same parameters and REPEATABLE seed value are supplied each time and the table contents have not changed. When this is false, the REPEATABLE clause is not accepted for use with the sampling method.

- `bool repeatable_across_scans`
  
  If true, the sampling method can deliver identical samples across successive scans in the same query (assuming unchanging parameters, seed value, and snapshot). When this is false, the planner will not select plans that would require scanning the sampled table more than once, since that might result in inconsistent query output.

The `TsmRoutine` struct type is declared in `src/include/access/tsmapi.h`, which see for additional details.

The table sampling methods included in the standard distribution are good references when trying to write your own. Look into the `src/backend/access/tablesample` subdirectory of the source tree for the built-in sampling methods, and into the `contrib` subdirectory for add-on methods.
59.1. Sampling Method Support Functions

The TSM handler function returns a palloc'd TsmRoutine struct containing pointers to the support functions described below. Most of the functions are required, but some are optional, and those pointers can be NULL.

```c
void SampleScanGetSampleSize (PlannerInfo *root,
                                RelOptInfo *baserel,
                                List *paramexprs,
                                BlockNumber *pages,
                                double *tuples);
```

This function is called during planning. It must estimate the number of relation pages that will be read during a sample scan, and the number of tuples that will be selected by the scan. (For example, these might be determined by estimating the sampling fraction, and then multiplying the baserel->pages and baserel->tuples numbers by that, being sure to round the results to integral values.) The paramexprs list holds the expression(s) that are parameters to the TABLESAMPLE clause. It is recommended to use estimate_expression_value() to try to reduce these expressions to constants, if their values are needed for estimation purposes; but the function must provide size estimates even if they cannot be reduced, and it should not fail even if the values appear invalid (remember that they're only estimates of what the run-time values will be). The pages and tuples parameters are outputs.

```c
void InitSampleScan (SampleScanState *node,
                      int eflags);
```

Initialize for execution of a SampleScan plan node. This is called during executor startup. It should perform any initialization needed before processing can start. The SampleScanState node has already been created, but its tsm_state field is NULL. The InitSampleScan function can alloc whatever internal state data is needed by the sampling method, and store a pointer to it in node->tsm_state. Information about the table to scan is accessible through other fields of the SampleScanState node (but note that the node->ss.ss_currentScanDesc scan descriptor is not set up yet). eflags contains flag bits describing the executor's operating mode for this plan node.

When (eflags & EXEC_FLAG_EXPLAIN_ONLY) is true, the scan will not actually be performed, so this function should only do the minimum required to make the node state valid for EXPLAIN and EndSampleScan.

This function can be omitted (set the pointer to NULL), in which case BeginSampleScan must perform all initialization needed by the sampling method.

```c
void BeginSampleScan (SampleScanState *node,
                      Datum *params,
                      int nparams,
                      uint32 seed);
```

Begin execution of a sampling scan. This is called just before the first attempt to fetch a tuple, and may be called again if the scan needs to be restarted. Information about the table to scan is accessible through fields of the SampleScanState node (but note that the node->ss.ss_currentScanDesc scan
Writing a Table Sampling Method

descriptor is not set up yet). The params array, of length nparams, contains the values of the parameters supplied in the TABLESAMPLE clause. These will have the number and types specified in the sampling method's parameterTypes list, and have been checked to not be null. seed contains a seed to use for any random numbers generated within the sampling method; it is either a hash derived from the REPEATABLE value if one was given, or the result of random() if not.

This function may adjust the fields node->use_bulkread and node->use_pagemode. If node->use_bulkread is true, which it is by default, the scan will use a buffer access strategy that encourages recycling buffers after use. It might be reasonable to set this to false if the scan will visit only a small fraction of the table's pages. If node->use_pagemode is true, which it is by default, the scan will perform visibility checking in a single pass for all tuples on each visited page. It might be reasonable to set this to false if the scan will select only a small fraction of the tuples on each visited page. That will result in fewer tuple visibility checks being performed, though each one will be more expensive because it will require more locking.

If the sampling method is marked repeatable_across_scans, it must be able to select the same set of tuples during a rescan as it did originally, that is a fresh call of BeginSampleScan must lead to selecting the same tuples as before (if the TABLESAMPLE parameters and seed don't change).

BlockNumber
NextSampleBlock (SampleScanState *node, BlockNumber nblocks);

Returns the block number of the next page to be scanned, or InvalidBlockNumber if no pages remain to be scanned.

This function can be omitted (set the pointer to NULL), in which case the core code will perform a sequential scan of the entire relation. Such a scan can use synchronized scanning, so that the sampling method cannot assume that the relation pages are visited in the same order on each scan.

OffsetNumber
NextSampleTuple (SampleScanState *node, BlockNumber blockno, OffsetNumber maxoffset);

Returns the offset number of the next tuple to be sampled on the specified page, or InvalidOffsetNumber if no tuples remain to be sampled. maxoffset is the largest offset number in use on the page.

Note

NextSampleTuple is not explicitly told which of the offset numbers in the range 1 .. max-offset actually contain valid tuples. This is not normally a problem since the core code ignores requests to sample missing or invisible tuples; that should not result in any bias in the sample. However, if necessary, the function can use node->donetuples to examine how many of the tuples it returned were valid and visible.

Note

NextSampleTuple must not assume that blockno is the same page number returned by the most recent NextSampleBlock call. It was returned by some previous NextSampleBlock call, but the core code is allowed to call NextSampleBlock in advance of actually scanning
pages, so as to support prefetching. It is OK to assume that once sampling of a given page begins, successive NextSampleTuple calls all refer to the same page until InvalidOffsetNumber is returned.

```c
void EndSampleScan (SampleScanState *node);
```

End the scan and release resources. It is normally not important to release palloc'd memory, but any externally-visible resources should be cleaned up. This function can be omitted (set the pointer to NULL) in the common case where no such resources exist.
Chapter 60. Writing a Custom Scan Provider

PostgreSQL supports a set of experimental facilities which are intended to allow extension modules to add new scan types to the system. Unlike a foreign data wrapper, which is only responsible for knowing how to scan its own foreign tables, a custom scan provider can provide an alternative method of scanning any relation in the system. Typically, the motivation for writing a custom scan provider will be to allow the use of some optimization not supported by the core system, such as caching or some form of hardware acceleration. This chapter outlines how to write a new custom scan provider.

Implementing a new type of custom scan is a three-step process. First, during planning, it is necessary to generate access paths representing a scan using the proposed strategy. Second, if one of those access paths is selected by the planner as the optimal strategy for scanning a particular relation, the access path must be converted to a plan. Finally, it must be possible to execute the plan and generate the same results that would have been generated for any other access path targeting the same relation.

60.1. Creating Custom Scan Paths

A custom scan provider will typically add paths for a base relation by setting the following hook, which is called after the core code has generated all the access paths it can for the relation (except for Gather paths, which are made after this call so that they can use partial paths added by the hook):

```c
typedef void (*set_rel_pathlist_hook_type) (PlannerInfo *root,
                                          RelOptInfo *rel,
                                          Index rti,
                                          RangeTblEntry *rte);
extern PGDLLIMPORT set_rel_pathlist_hook_type set_rel_pathlist_hook;
```

Although this hook function can be used to examine, modify, or remove paths generated by the core system, a custom scan provider will typically confine itself to generating CustomPath objects and adding them to rel using add_path. The custom scan provider is responsible for initializing the CustomPath object, which is declared like this:

```c
typedef struct CustomPath
{
    Path      path;
    uint32    flags;
    List     *custom_paths;
    List     *custom_private;
    const CustomPathMethods *methods;
} CustomPath;
```

path must be initialized as for any other path, including the row-count estimate, start and total cost, and sort ordering provided by this path. flags is a bit mask, which specifies whether the scan provider can support certain optional capabilities. flags should include CUSTOMPATH_SUPPORT_BACKWARD_SCAN if the custom path can support a backward scan, CUSTOMPATH_SUPPORT_MARK_RESTORE if it can support mark and restore, and CUSTOMPATH_SUPPORT_PROJECTION if it can perform projections. (If CUSTOMPATH_SUPPORT_PROJECTION is not set, the scan node will only be asked to produce Vars of the scanned relation; while if that flag is set, the scan node must be able to evaluate scalar expressions over these Vars.) An optional custom_paths is a list of Path nodes used by this custom-path
node; these will be transformed into Plan nodes by planner. custom_private can be used to store the custom path's private data. Private data should be stored in a form that can be handled by nodeToString, so that debugging routines that attempt to print the custom path will work as designed. methods must point to a (usually statically allocated) object implementing the required custom path methods, of which there is currently only one.

A custom scan provider can also provide join paths. Just as for base relations, such a path must produce the same output as would normally be produced by the join it replaces. To do this, the join provider should set the following hook, and then within the hook function, create CustomPath path(s) for the join relation.

typedef void (*set_join_pathlist_hook_type) (PlannerInfo *root, RelOptInfo *joinrel, RelOptInfo *outerrel, RelOptInfo *innerrel, JoinType jointype, JoinPathExtraData *extra);

extern PGDLLIMPORT set_join_pathlist_hook_type set_join_pathlist_hook;

This hook will be invoked repeatedly for the same join relation, with different combinations of inner and outer relations; it is the responsibility of the hook to minimize duplicated work.

60.1.1. Custom Scan Path Callbacks

Plan *(*PlanCustomPath) (PlannerInfo *root, RelOptInfo *rel, CustomPath *best_path, List *tlist, List *clauses, List *custom_plans);

Convert a custom path to a finished plan. The return value will generally be a CustomScan object, which the callback must allocate and initialize. See Section 60.2 for more details.

60.2. Creating Custom Scan Plans

A custom scan is represented in a finished plan tree using the following structure:

typedef struct CustomScan
{
    Scan        scan;
    uint32      flags;
    List        *custom_plans;
    List        *custom_exprs;
    List        *custom_private;
    List        *custom_scan_tlist;
    Bitmapset   *custom_relids;
    const CustomScanMethods *methods;
} CustomScan;

scan must be initialized as for any other scan, including estimated costs, target lists, qualifications, and so on. flags is a bit mask with the same meaning as in CustomPath. custom_plans can be used
to store child Plan nodes. custom_exprs should be used to store expression trees that will need to be fixed up by setrefs.c and subselect.c, while custom_private should be used to store other private data that is only used by the custom scan provider itself. custom_scan_tlist can be NIL when scanning a base relation, indicating that the custom scan returns scan tuples that match the base relation’s row type. Otherwise it is a target list describing the actual scan tuples. custom_scan_tlist must be provided for joins, and could be provided for scans if the custom scan provider can compute some non-Var expressions. custom_relids is set by the core code to the set of relations (range table indexes) that this scan node handles; except when this scan is replacing a join, it will have only one member. methods must point to a (usually statically allocated) object implementing the required custom scan methods, which are further detailed below.

When a CustomScan scans a single relation, scan.scanrelid must be the range table index of the table to be scanned. When it replaces a join, scan.scanrelid should be zero.

Plan trees must be able to be duplicated using copyObject, so all the data stored within the “custom” fields must consist of nodes that that function can handle. Furthermore, custom scan providers cannot substitute a larger structure that embeds a CustomScan for the structure itself, as would be possible for a CustomPath or CustomScanState.

60.2.1. Custom Scan Plan Callbacks

Node *(*CreateCustomScanState) (CustomScan *cscan);

Allocate a CustomScanState for this CustomScan. The actual allocation will often be larger than required for an ordinary CustomScanState, because many providers will wish to embed that as the first field of a larger structure. The value returned must have the node tag and methods set appropriately, but other fields should be left as zeroes at this stage; after ExecInitCustomScan performs basic initialization, the BeginCustomScan callback will be invoked to give the custom scan provider a chance to do whatever else is needed.

60.3. Executing Custom Scans

When a CustomScan is executed, its execution state is represented by a CustomScanState, which is declared as follows:

typedef struct CustomScanState
{
    ScanState ss;
    uint32 flags;
    const CustomExecMethods *methods;
} CustomScanState;

ss is initialized as for any other scan state, except that if the scan is for a join rather than a base relation, ss.ss_currentRelation is left NULL. flags is a bit mask with the same meaning as in CustomPath and CustomScan. methods must point to a (usually statically allocated) object implementing the required custom scan state methods, which are further detailed below. Typically, a CustomScanState, which need not support copyObject, will actually be a larger structure embedding the above as its first member.

60.3.1. Custom Scan Execution Callbacks
void (*BeginCustomScan) (CustomScanState *node, 
    EState *estate, 
    int eflags);

Complete initialization of the supplied CustomScanState. Standard fields have been initialized by 
ExecInitCustomScan, but any private fields should be initialized here.

TupleTableSlot *((*ExecCustomScan) (CustomScanState *node));

Fetch the next scan tuple. If any tuples remain, it should fill ps_ResultTupleSlot with the next tuple 
in the current scan direction, and then return the tuple slot. If not, NULL or an empty slot should be returned.

void (*EndCustomScan) (CustomScanState *node);

Clean up any private data associated with the CustomScanState. This method is required, but it does 
not need to do anything if there is no associated data or it will be cleaned up automatically.

void (*ReScanCustomScan) (CustomScanState *node);

Rewind the current scan to the beginning and prepare to rescan the relation.

void (*MarkPosCustomScan) (CustomScanState *node);

Save the current scan position so that it can subsequently be restored by the RestrPosCustomScan 
callback. This callback is optional, and need only be supplied if the CUSTOMPATH_SUPPORT_MARK_RESTORE flag is set.

void (*RestrPosCustomScan) (CustomScanState *node);

Restore the previous scan position as saved by the MarkPosCustomScan callback. This callback is 
optional, and need only be supplied if the CUSTOMPATH_SUPPORT_MARK_RESTORE flag is set.

Size (*EstimateDSMCustomScan) (CustomScanState *node, 
    ParallelContext *pcxt);

Estimate the amount of dynamic shared memory that will be required for parallel operation. This may be 
higher than the amount that will actually be used, but it must not be lower. The return value is in bytes. This 
callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

void (*InitializeDSMCustomScan) (CustomScanState *node, 
    ParallelContext *pcxt, 
    void *coordinate);

Initialize the dynamic shared memory that will be required for parallel operation. coordinate points to 
a shared memory area of size equal to the return value of EstimateDSMCustomScan. This callback is 
optional, and need only be supplied if this custom scan provider supports parallel execution.

void (*ReInitializeDSMCustomScan) (CustomScanState *node, 
    ParallelContext *pcxt,
void *coordinate);

Re-initialize the dynamic shared memory required for parallel operation when the custom-scan plan node is about to be re-scanned. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution. Recommended practice is that this callback reset only shared state, while the ReScanCustomScan callback resets only local state. Currently, this callback will be called before ReScanCustomScan, but it's best not to rely on that ordering.

void (*InitializeWorkerCustomScan) (CustomScanState *node,
    shm_toc *toc,
    void *coordinate);

Initialize a parallel worker's local state based on the shared state set up by the leader during InitializeDSMCustomScan. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

void (*ShutdownCustomScan) (CustomScanState *node);

Release resources when it is anticipated the node will not be executed to completion. This is not called in all cases; sometimes, EndCustomScan may be called without this function having been called first. Since the DSM segment used by parallel query is destroyed just after this callback is invoked, custom scan providers that wish to take some action before the DSM segment goes away should implement this method.

void (*ExplainCustomScan) (CustomScanState *node,
    List *ancestors,
    ExplainState *es);

Output additional information for EXPLAIN of a custom-scan plan node. This callback is optional. Common data stored in the ScanState, such as the target list and scan relation, will be shown even without this callback, but the callback allows the display of additional, private state.
61.1. Query Handling as a Complex Optimization Problem

Among all relational operators the most difficult one to process and optimize is the join. The number of possible query plans grows exponentially with the number of joins in the query. Further optimization effort is caused by the support of a variety of join methods (e.g., nested loop, hash join, merge join in PostgreSQL) to process individual joins and a diversity of indexes (e.g., B-tree, hash, GiST and GIN in PostgreSQL) as access paths for relations.

The normal PostgreSQL query optimizer performs a near-exhaustive search over the space of alternative strategies. This algorithm, first introduced in IBM's System R database, produces a near-optimal join order, but can take an enormous amount of time and memory space when the number of joins in the query grows large. This makes the ordinary PostgreSQL query optimizer inappropriate for queries that join a large number of tables.

The Institute of Automatic Control at the University of Mining and Technology, in Freiberg, Germany, encountered some problems when it wanted to use PostgreSQL as the backend for a decision support knowledge based system for the maintenance of an electrical power grid. The DBMS needed to handle large join queries for the inference machine of the knowledge based system. The number of joins in these queries made using the normal query optimizer infeasible.

In the following we describe the implementation of a genetic algorithm to solve the join ordering problem in a manner that is efficient for queries involving large numbers of joins.

61.2. Genetic Algorithms

The genetic algorithm (GA) is a heuristic optimization method which operates through randomized search. The set of possible solutions for the optimization problem is considered as a population of individuals. The degree of adaptation of an individual to its environment is specified by its fitness.

The coordinates of an individual in the search space are represented by chromosomes, in essence a set of character strings. A gene is a subsection of a chromosome which encodes the value of a single parameter being optimized. Typical encodings for a gene could be binary or integer.

Through simulation of the evolutionary operations recombination, mutation, and selection new generations of search points are found that show a higher average fitness than their ancestors. Figure 61.1 illustrates these steps.
Figure 61.1. Structure of a Genetic Algorithm

According to the comp.ai.genetic FAQ it cannot be stressed too strongly that a GA is not a pure random search for a solution to a problem. A GA uses stochastic processes, but the result is distinctly non-random (better than random).

61.3. Genetic Query Optimization (GEQO) in PostgreSQL

The GEQO module approaches the query optimization problem as though it were the well-known traveling salesman problem (TSP). Possible query plans are encoded as integer strings. Each string represents the join order from one relation of the query to the next. For example, the join tree

```plaintext
\( / \backslash \) 2
\( / \backslash \) 3
```
is encoded by the integer string ‘4-1-3-2’, which means, first join relation ‘4’ and ‘1’, then ‘3’, and then ‘2’, where 1, 2, 3, 4 are relation IDs within the PostgreSQL optimizer.

Specific characteristics of the GEQO implementation in PostgreSQL are:

- Usage of a steady state GA (replacement of the least fit individuals in a population, not whole-generational replacement) allows fast convergence towards improved query plans. This is essential for query handling with reasonable time;
- Usage of edge recombination crossover which is especially suited to keep edge losses low for the solution of the TSP by means of a GA;
- Mutation as genetic operator is deprecated so that no repair mechanisms are needed to generate legal TSP tours.

Parts of the GEQO module are adapted from D. Whitley's Genitor algorithm.

The GEQO module allows the PostgreSQL query optimizer to support large join queries effectively through non-exhaustive search.

### 61.3.1. Generating Possible Plans with GEQO

The GEQO planning process uses the standard planner code to generate plans for scans of individual relations. Then join plans are developed using the genetic approach. As shown above, each candidate join plan is represented by a sequence in which to join the base relations. In the initial stage, the GEQO code simply generates some possible join sequences at random. For each join sequence considered, the standard planner code is invoked to estimate the cost of performing the query using that join sequence. (For each step of the join sequence, all three possible join strategies are considered; and all the initially-determined relation scan plans are available. The estimated cost is the cheapest of these possibilities.) Join sequences with lower estimated cost are considered “more fit” than those with higher cost. The genetic algorithm discards the least fit candidates. Then new candidates are generated by combining genes of more-fit candidates — that is, by using randomly-chosen portions of known low-cost join sequences to create new sequences for consideration. This process is repeated until a preset number of join sequences have been considered; then the best one found at any time during the search is used to generate the finished plan.

This process is inherently nondeterministic, because of the randomized choices made during both the initial population selection and subsequent “mutation” of the best candidates. To avoid surprising changes of the selected plan, each run of the GEQO algorithm restarts its random number generator with the current geqo_seed parameter setting. As long as geqo_seed and the other GEQO parameters are kept fixed, the same plan will be generated for a given query (and other planner inputs such as statistics). To experiment with different search paths, try changing geqo_seed.

### 61.3.2. Future Implementation Tasks for PostgreSQL GEQO

Work is still needed to improve the genetic algorithm parameter settings. In file src/backend/optimizer/geqo/geqo_main.c, routines gimme_pool_size and gimme_number_generations, we have to find a compromise for the parameter settings to satisfy two competing demands:

- Optimality of the query plan
- Computing time

In the current implementation, the fitness of each candidate join sequence is estimated by running the standard planner's join selection and cost estimation code from scratch. To the extent that different candidates
use similar sub-sequences of joins, a great deal of work will be repeated. This could be made significantly faster by retaining cost estimates for sub-joins. The problem is to avoid expending unreasonable amounts of memory on retaining that state.

At a more basic level, it is not clear that solving query optimization with a GA algorithm designed for TSP is appropriate. In the TSP case, the cost associated with any substring (partial tour) is independent of the rest of the tour, but this is certainly not true for query optimization. Thus it is questionable whether edge recombination crossover is the most effective mutation procedure.

Chapter 62. Table Access Method Interface Definition

This chapter explains the interface between the core PostgreSQL system and table access methods, which manage the storage for tables. The core system knows little about these access methods beyond what is specified here, so it is possible to develop entirely new access method types by writing add-on code.

Each table access method is described by a row in the pg_am system catalog. The pg_am entry specifies a name and a handler function for the table access method. These entries can be created and deleted using the CREATE ACCESS METHOD and DROP ACCESS METHOD SQL commands.

A table access method handler function must be declared to accept a single argument of type `internal` and to return the pseudo-type `table_am_handler`. The argument is a dummy value that simply serves to prevent handler functions from being called directly from SQL commands. The result of the function must be a pointer to a struct of type `TableAmRoutine`, which contains everything that the core code needs to know to make use of the table access method. The return value needs to be of server lifetime, which is typically achieved by defining it as a `static const` variable in global scope. The `TableAmRoutine` struct, also called the access method’s API struct, defines the behavior of the access method using callbacks. These callbacks are pointers to plain C functions and are not visible or callable at the SQL level. All the callbacks and their behavior is defined in the `TableAmRoutine` structure (with comments inside the struct defining the requirements for callbacks). Most callbacks have wrapper functions, which are documented from the point of view of a user (rather than an implementor) of the table access method. For details, please refer to the `src/include/access/tableam.h` file.

To implement an access method, an implementor will typically need to implement an AM-specific type of tuple table slot (see `src/include/executor/tuptable.h`), which allows code outside the access method to hold references to tuples of the AM, and to access the columns of the tuple.

Currently, the way an AM actually stores data is fairly unconstrained. For example, it’s possible, but not required, to use postgres’ shared buffer cache. In case it is used, it likely makes sense to use PostgreSQL’s standard page layout as described in Section 72.6.

One fairly large constraint of the table access method API is that, currently, if the AM wants to support modifications and/or indexes, it is necessary for each tuple to have a tuple identifier (TID) consisting of a block number and an item number (see also Section 72.6). It is not strictly necessary that the sub-parts of TIDs have the same meaning they e.g., have for `heap`, but if bitmap scan support is desired (it is optional), the block number needs to provide locality.

For crash safety, an AM can use postgres’ WAL, or a custom implementation. If WAL is chosen, either Generic WAL Records can be used, or a new type of WAL records can be implemented. Generic WAL Records are easy, but imply higher WAL volume. Implementation of a new type of WAL record currently requires modifications to core code (specifically, `src/include/access/rmgrlist.h`).

To implement transactional support in a manner that allows different table access methods be accessed within a single transaction, it is likely necessary to closely integrate with the machinery in `src/backend/access/transam/xlog.c`.

Any developer of a new table access method can refer to the existing `heap` implementation present in `src/backend/access/heap/heapam_handler.c` for details of its implementation.

Chapter 63. Index Access Method Interface Definition

This chapter defines the interface between the core PostgreSQL system and index access methods, which manage individual index types. The core system knows nothing about indexes beyond what is specified here, so it is possible to develop entirely new index types by writing add-on code.

All indexes in PostgreSQL are what are known technically as secondary indexes; that is, the index is physically separate from the table file that it describes. Each index is stored as its own physical relation and so is described by an entry in the pg_class catalog. The contents of an index are entirely under the control of its index access method. In practice, all index access methods divide indexes into standard-size pages so that they can use the regular storage manager and buffer manager to access the index contents. (All the existing index access methods furthermore use the standard page layout described in Section 72.6, and most use the same format for index tuple headers; but these decisions are not forced on an access method.)

An index is effectively a mapping from some data key values to tuple identifiers, or TIDs, of row versions (tuples) in the index's parent table. A TID consists of a block number and an item number within that block (see Section 72.6). This is sufficient information to fetch a particular row version from the table. Indexes are not directly aware that under MVCC, there might be multiple extant versions of the same logical row; to an index, each tuple is an independent object that needs its own index entry. Thus, an update of a row always creates all-new index entries for the row, even if the key values did not change. (HOT tuples are an exception to this statement; but indexes do not deal with those, either.) Index entries for dead tuples are reclaimed (by vacuuming) when the dead tuples themselves are reclaimed.

63.1. Basic API Structure for Indexes

Each index access method is described by a row in the pg_am system catalog. The pg_am entry specifies a name and a handler function for the index access method. These entries can be created and deleted using the CREATE ACCESS METHOD and DROP ACCESS METHOD SQL commands.

An index access method handler function must be declared to accept a single argument of type internal and to return the pseudo-type index_am_handler. The argument is a dummy value that simply serves to prevent handler functions from being called directly from SQL commands. The result of the function must be a palloc'd struct of type IndexAmRoutine, which contains everything that the core code needs to know to make use of the index access method. The IndexAmRoutine struct, also called the access method's API struct, includes fields specifying assorted fixed properties of the access method, such as whether it can support multicolumn indexes. More importantly, it contains pointers to support functions for the access method, which do all of the real work to access indexes. These support functions are plain C functions and are not visible or callable at the SQL level. The support functions are described in Section 63.2.

The structure IndexAmRoutine is defined thus:

```c
typedef struct IndexAmRoutine
{
    NodeTag     type;

    /*
     * Total number of strategies (operators) by which we can
     * traverse/search
```
Index Access Method
Interface Definition

* this AM. Zero if AM does not have a fixed set of strategy assignments. */
uint16 amstrategies;
/* total number of support functions that this AM uses */
uint16 amsupport;
/* opclass options support function number or 0 */
uint16 amoptspoprocnun;
/* does AM support ORDER BY indexed column's value? */
bool amcanorder;
/* does AM support ORDER BY result of an operator on indexed column? */
bool amcanorderbyop;
/* does AM support backward scanning? */
bool amcanbackward;
/* does AM support UNIQUE indexes? */
bool amcanunique;
/* does AM support multi-column indexes? */
bool amcanmulticol;
/* does AM require scans to have a constraint on the first index column? */
bool amoptionalkey;
/* does AM handle ScalarArrayOpExpr quals? */
bool amsearcharray;
/* does AM handle IS NULL/IS NOT NULL quals? */
bool amsearchnulls;
/* can index storage data type differ from column data type? */
bool amstorage;
/* can an index of this type be clustered on? */
bool amclusterable;
/* does AM handle predicate locks? */
bool ampredlocks;
/* does AM support parallel scan? */
bool amcanparallel;
/* does AM support columns included with clause INCLUDE? */
bool amcaninclude;
/* does AM use maintenance_work_mem? */
bool amusemaintenanceworkmem;
/* OR of parallel vacuum flags */
uint8 amparallelvacuumoptions;
/* type of data stored in index, or InvalidOid if variable */
Oid amkeytype;

/* interface functions */
ambuild_function ambuild;
ambuildempty_function ambuildempty;
aminsert_function aminsert;
ambulkdelete_function ambulkdelete;
amvacuumcleanup_function amvacuumcleanup;
amcanreturn_function amcanreturn; /* can be NULL */
amcostestimate_function amcostestimate;
amoptions_function amoptions;
amproperty_function amproperty; /* can be NULL */
ambuildphasename_function ambuildphasename; /* can be NULL */
To be useful, an index access method must also have one or more operator families and operator classes defined in `pg_opfamily`, `pg_opclass`, `pg_amop`, and `pg_amproc`. These entries allow the planner to determine what kinds of query qualifications can be used with indexes of this access method. Operator families and classes are described in Section 38.16, which is prerequisite material for reading this chapter.

An individual index is defined by a `pg_class` entry that describes it as a physical relation, plus a `pg_index` entry that shows the logical content of the index — that is, the set of index columns it has and the semantics of those columns, as captured by the associated operator classes. The index columns (key values) can be either simple columns of the underlying table or expressions over the table rows. The index access method normally has no interest in where the index key values come from (it is always handed precomputed key values) but it will be very interested in the operator class information in `pg_index`. Both of these catalog entries can be accessed as part of the Relation data structure that is passed to all operations on the index.

Some of the flag fields of `IndexAmRoutine` have nonobvious implications. The requirements of `amcanunique` are discussed in Section 63.5. The `amcanmulticol` flag asserts that the access method supports multi-key-column indexes, while `amoptionalkey` asserts that it allows scans where no indexable restriction clause is given for the first index column. When `amcanmulticol` is false, `amoptionalkey` essentially says whether the access method supports full-index scans without any restriction clause. Access methods that support multiple index columns must support scans that omit restrictions on any or all of the columns after the first; however they are permitted to require some restriction to appear for the first index column, and this is signaled by setting `amoptionalkey` false. One reason that an index AM might set `amoptionalkey` false is if it doesn't index null values. Since most indexable operators are strict and hence cannot return true for null inputs, it is at first sight attractive to not store index entries for null values: they could never be returned by an index scan anyway. However, this argument fails when an index scan has no restriction clause for a given index column. In practice this means that indexes that have `amoptionalkey` true must index nulls, since the planner might decide to use such an index with no scan keys at all. A related restriction is that an index access method that supports multiple index columns must support indexing null values in columns after the first, because the planner will assume the index can be used for queries that do not restrict these columns. For example, consider an index on \((a,b)\) and a query with `WHERE a = 4`. The system will assume the index can be used to scan for rows with \(a = 4\), which is wrong if the index omits rows where \(b\) is null. It is, however, OK to omit rows where the first indexed column is null. An index access method that does index nulls may also set `amsearchnulls`, indicating that it supports \(\text{IS NULL}\) and \(\text{IS NOT NULL}\) clauses as search conditions.

The `amcaninclude` flag indicates whether the access method supports “included” columns, that is it can store (without processing) additional columns beyond the key column(s). The requirements of the

```c
amvalidate_function amvalidate;
amadjustmembers_function amadjustmembers; /* can be NULL */
ambeginscan_function ambeginscan;
amrescan_function amrescan;
amgettuple_function amgettuple; /* can be NULL */
amgetbitmap_function amgetbitmap; /* can be NULL */
amendscan_function amendscan;
ammarkpos_function ammarkpos; /* can be NULL */
amrestrpos_function amrestrpos; /* can be NULL */

/* interface functions to support parallel index scans */
amestimateparallelscan_function amestimateparallelscan; /* can be NULL */
aminitparallelscan_function aminitparallelscan; /* can be NULL */
amparallelrescan_function amparallelrescan; /* can be NULL */
} IndexAmRoutine;
```
preceding paragraph apply only to the key columns. In particular, the combination of \texttt{amcanmulticol=false} and \texttt{amcaninclude=true} is sensible: it means that there can only be one key column, but there can also be included column(s). Also, included columns must be allowed to be null, independently of \texttt{amoptionalky}.

\section*{63.2. Index Access Method Functions}

The index construction and maintenance functions that an index access method must provide in \texttt{Index-AmRoutine} are:

\begin{verbatim}
IndexBuildResult *
ambuild (Relation heapRelation,
        Relation indexRelation,
        IndexInfo *indexInfo);

void
ambuildempty (Relation indexRelation);

bool
aminsert (Relation indexRelation,
          Datum *values,
          bool *isnull,
          ItemPointer heap_tid,
          Relation heapRelation,
          IndexUniqueCheck checkUnique,
          bool indexUnchanged,
          IndexInfo *indexInfo);
\end{verbatim}

Build a new index. The index relation has been physically created, but is empty. It must be filled in with whatever fixed data the access method requires, plus entries for all tuples already existing in the table. Ordinarily the \texttt{ambuild} function will call \texttt{table_index_build_scan()} to scan the table for existing tuples and compute the keys that need to be inserted into the index. The function must return a \texttt{palloc'd} struct containing statistics about the new index.

\begin{verbatim}
void
ambuildempty (Relation indexRelation);
\end{verbatim}

Build an empty index, and write it to the initialization fork (\texttt{INIT_FORKNUM}) of the given relation. This method is called only for unlogged indexes; the empty index written to the initialization fork will be copied over the main relation fork on each server restart.

\begin{verbatim}
bool
aminsert (Relation indexRelation,
           Datum *values,
           bool *isnull,
           ItemPointer heap_tid,
           Relation heapRelation,
           IndexUniqueCheck checkUnique,
           bool indexUnchanged,
           IndexInfo *indexInfo);
\end{verbatim}

Insert a new tuple into an existing index. The \texttt{values} and \texttt{isnull} arrays give the key values to be indexed, and \texttt{heap_tid} is the TID to be indexed. If the access method supports unique indexes (its \texttt{amcanunique} flag is true) then \texttt{checkUnique} indicates the type of uniqueness check to perform. This varies depending on whether the unique constraint is deferrable; see Section 63.5 for details. Normally the access method only needs the \texttt{heapRelation} parameter when performing uniqueness checking (since then it will have to look into the heap to verify tuple liveness).

The \texttt{indexUnchanged} Boolean value gives a hint about the nature of the tuple to be indexed. When it is true, the tuple is a duplicate of some existing tuple in the index. The new tuple is a logically unchanged successor MVCC tuple version. This happens when an \texttt{UPDATE} takes place that does not modify any columns covered by the index, but nevertheless requires a new version in the index. The index AM may use this hint to decide to apply bottom-up index deletion in parts of the index where many versions of
the same logical row accumulate. Note that updating a non-key column does not affect the value of indexUnchanged.

The function’s Boolean result value is significant only when checkUnique is UNIQUE_CHECK_PARTIAL. In this case a true result means the new entry is known unique, whereas false means it might be non-unique (and a deferred uniqueness check must be scheduled). For other cases a constant false result is recommended.

Some indexes might not index all tuples. If the tuple is not to be indexed, aminsert should just return without doing anything.

If the index AM wishes to cache data across successive index insertions within an SQL statement, it can allocate space in indexInfo->ii_Context and store a pointer to the data in indexInfo->ii_AmCache (which will be NULL initially).

```c
IndexBulkDeleteResult *
ambulkdelete (IndexVacuumInfo *info,
            IndexBulkDeleteResult *stats,
            IndexBulkDeleteCallback callback,
            void *callback_state);
```

Delete tuple(s) from the index. This is a “bulk delete” operation that is intended to be implemented by scanning the whole index and checking each entry to see if it should be deleted. The passed-in callback function must be called, in the style callback(TID, callback_state) returns bool, to determine whether any particular index entry, as identified by its referenced TID, is to be deleted. Must return either NULL or a palloc'd struct containing statistics about the effects of the deletion operation. It is OK to return NULL if no information needs to be passed on to amvacuumcleanup.

Because of limited maintenance_work_mem, ambulkdelete might need to be called more than once when many tuples are to be deleted. The stats argument is the result of the previous call for this index (it is NULL for the first call within a VACUUM operation). This allows the AM to accumulate statistics across the whole operation. Typically, ambulkdelete will modify and return the same struct if the passed stats is not null.

```c
IndexBulkDeleteResult *
amvacuumcleanup (IndexVacuumInfo *info,
                 IndexBulkDeleteResult *stats);
```

Clean up after a VACUUM operation (zero or more ambulkdelete calls). This does not have to do anything beyond returning index statistics, but it might perform bulk cleanup such as reclaiming empty index pages. stats is whatever the last ambulkdelete call returned, or NULL if ambulkdelete was not called because no tuples needed to be deleted. If the result is not NULL it must be a palloc’d struct. The statistics it contains will be used to update pg_class, and will be reported by VACUUM if VERBOSE is given. It is OK to return NULL if the index was not changed at all during the VACUUM operation, but otherwise correct stats should be returned.

amvacuumcleanup will also be called at completion of an ANALYZE operation. In this case stats is always NULL and any return value will be ignored. This case can be distinguished by checking info->analyze_only. It is recommended that the access method do nothing except post-insert cleanup in such a call, and that only in an autovacuum worker process.
amcanreturn (Relation indexRelation, int attno);

Check whether the index can support *index-only scans* on the given column, by returning the column's original indexed value. The attribute number is 1-based, i.e., the first column's attno is 1. Returns true if supported, else false. This function should always return true for included columns (if those are supported), since there's little point in an included column that can't be retrieved. If the access method does not support index-only scans at all, the amcanreturn field in its IndexAmRoutine struct can be set to NULL.

void
amcostestimate (PlannerInfo *root,
    IndexPath *path,
    double loop_count,
    Cost *indexStartupCost,
    Cost *indexTotalCost,
    Selectivity *indexSelectivity,
    double *indexCorrelation,
    double *indexPages);

Estimate the costs of an index scan. This function is described fully in Section 63.6, below.

bytea *
amoptions (ArrayType *reloptions,
    bool validate);

Parse and validate the reloptions array for an index. This is called only when a non-null reloptions array exists for the index. *reloptions* is a text array containing entries of the form name=value. The function should construct a bytea value, which will be copied into the rd_options field of the index's relcache entry. The data contents of the bytea value are open for the access method to define; most of the standard access methods use struct StdRdOptions. When validate is true, the function should report a suitable error message if any of the options are unrecognized or have invalid values; when validate is false, invalid entries should be silently ignored. (validate is false when loading options already stored in pg_catalog; an invalid entry could only be found if the access method has changed its rules for options, and in that case ignoring obsolete entries is appropriate.) It is OK to return NULL if default behavior is wanted.

bool
amproperty (Oid index_oid, int attno,
    IndexAMProperty prop, const char *propname,
    bool *res, bool *isnull);

The amproperty method allows index access methods to override the default behavior of pg_index_column_has_property and related functions. If the access method does not have any special behavior for index property inquiries, the amproperty field in its IndexAmRoutine struct can be set to NULL. Otherwise, the amproperty method will be called with index_oid and attno both zero for pg_indexam_has_property calls, or with index_oid valid and attno zero for pg_index_has_property calls, or with index_oid valid and attno greater than zero for pg_index_column_has_property calls. prop is an enum value identifying the property being tested, while propname is the original property name string. If the core code does not recognize the property name then prop is AMPROP_UNKNOWN. Access methods can define custom property names by checking propname for a match (use pg_strcasecmp to match, for consistency with the core code); for names known to the core code, it's better to inspect prop. If the amproperty method returns true then it has determined the property test result: it must set *res to the Boolean value to return, or set *isnull
Index Access Method
Interface Definition

to true to return a NULL. (Both of the referenced variables are initialized to false before the call.)
If the amproperty method returns false then the core code will proceed with its normal logic for
determining the property test result.

Access methods that support ordering operators should implement AMPROP_DISTANCE_ORDERABLE
property testing, as the core code does not know how to do that and will return NULL. It may also be
advantageous to implement AMPROP_RETURNABLE testing, if that can be done more cheaply than by
opening the index and calling amcanreturn, which is the core code’s default behavior. The default
behavior should be satisfactory for all other standard properties.

char *
ambuildphasename (int64 phasenum);

Return the textual name of the given build phase number. The phase numbers are those reported during an
index build via the pgstat_progress_update_param interface. The phase names are then exposed
in the pg_stat_progress_create_index view.

bool
amvalidate (Oid opclassoid);

Validate the catalog entries for the specified operator class, so far as the access method can reasonably do
that. For example, this might include testing that all required support functions are provided. The amval-
validate function must return false if the opclass is invalid. Problems should be reported with ereport
messages, typically at INFO level.

void
amadjustmembers (Oid opfamilyoid,
Oid opclassoid,
List *operators,
List *functions);

Validate proposed new operator and function members of an operator family, so far as the access method
can reasonably do that, and set their dependency types if the default is not satisfactory. This is called during
CREATE OPERATOR CLASS and during ALTER OPERATOR FAMILY ADD; in the latter case op-
classoid is InvalidOid. The List arguments are lists of OpFamilyMember structs, as defined
in amapi.h. Tests done by this function will typically be a subset of those performed by amvalidate,
since amadjustmembers cannot assume that it is seeing a complete set of members. For example, it
would be reasonable to check the signature of a support function, but not to check whether all required
support functions are provided. Any problems can be reported by throwing an error. The dependency-re-
lated fields of the OpFamilyMember structs are initialized by the core code to create hard dependencies
on the opclass if this is CREATE OPERATOR CLASS, or soft dependencies on the opfamily if this is
ALTER OPERATOR FAMILY ADD. amadjustmembers can adjust these fields if some other behavior
is more appropriate. For example, GIN, GiST, and SP-GiST always set operator members to have soft de-
pendencies on the opfamily, since the connection between an operator and an opclass is relatively weak in
these index types; so it is reasonable to allow operator members to be added and removed freely. Optional
support functions are typically also given soft dependencies, so that they can be removed if necessary.

The purpose of an index, of course, is to support scans for tuples matching an indexable WHERE con-
tion, often called a qualifier or scan key. The semantics of index scanning are described more fully in
Section 63.3, below. An index access method can support “plain” index scans, “bitmap” index scans, or
both. The scan-related functions that an index access method must or may provide are:
Index Scan Desc

`ambeginscan` (Relation `indexRelation`,
  int `nkeys`,
  int `norderbys`);

Prepare for an index scan. The `nkeys` and `norderbys` parameters indicate the number of quals and ordering operators that will be used in the scan; these may be useful for space allocation purposes. Note that the actual values of the scan keys aren't provided yet. The result must be a `palloc'd` struct. For implementation reasons the index access method must create this struct by calling `RelationGetIndexScan()`. In most cases `ambegin`scan does little beyond making that call and perhaps acquiring locks; the interesting parts of index-scan startup are in `amrescan`.

`void` `amrescan` (IndexScanDesc `scan`,
  ScanKey `keys`,
  int `nkeys`,
  ScanKey `orderbys`,
  int `norderbys`);

Start or restart an index scan, possibly with new scan keys. (To restart using previously-passed keys, NULL is passed for `keys` and/or `orderbys`.) Note that it is not allowed for the number of keys or order-by operators to be larger than what was passed to `ambegin`scan. In practice the restart feature is used when a new outer tuple is selected by a nested-loop join and so a new key comparison value is needed, but the scan key structure remains the same.

`bool` `amgettuple` (IndexScanDesc `scan`,
  ScanDirection `direction`);

Fetch the next tuple in the given scan, moving in the given direction (forward or backward in the index). Returns true if a tuple was obtained, false if no matching tuples remain. In the true case the tuple TID is stored into the `scan` structure. Note that “success” means only that the index contains an entry that matches the scan keys, not that the tuple necessarily still exists in the heap or will pass the caller's snapshot test. On success, `amgettuple` must also set `scan->xs_recheck` to true or false. False means it is certain that the index entry matches the scan keys. True means this is not certain, and the conditions represented by the scan keys must be rechecked against the heap tuple after fetching it. This provision supports “lossy” index operators. Note that rechecking will extend only to the scan conditions; a partial index predicate (if any) is never rechecked by `amgettuple` callers.

If the index supports index-only scans (i.e., `amcanreturn` returns true for any of its columns), then on success the AM must also check `scan->xs_want_itup`, and if that is true it must return the originally indexed data for the index entry. Columns for which `amcanreturn` returns false can be returned as nulls. The data can be returned in the form of an `IndexTuple` pointer stored at `scan->xs_itup`, with tuple descriptor `scan->xs_itupdesc`; or in the form of a `HeapTuple` pointer stored at `scan->xs_hitup`, with tuple descriptor `scan->xs_hitupdesc`. (The latter format should be used when reconstructing data that might possibly not fit into an `IndexTuple`.) In either case, management of the data referenced by the pointer is the access method's responsibility. The data must remain good at least until the next `amgettuple`, `amrescan`, or `amendscan` call for the scan.

The `amgettuple` function need only be provided if the access method supports “plain” index scans. If it doesn't, the `amgettuple` field in its `IndexAmRoutine` struct must be set to NULL.
int64
amgetbitmap (IndexScanDesc scan, TIDBitmap *tbm);

Fetch all tuples in the given scan and add them to the caller-supplied TIDBitmap (that is, OR the set of tuple IDs into whatever set is already in the bitmap). The number of tuples fetched is returned (this might be just an approximate count, for instance some AMs do not detect duplicates). While inserting tuple IDs into the bitmap, amgetbitmap can indicate that rechecking of the scan conditions is required for specific tuple IDs. This is analogous to the xs_recheck output parameter of amgettuple. Note: in the current implementation, support for this feature is conflated with support for lossy storage of the bitmap itself, and therefore callers recheck both the scan conditions and the partial index predicate (if any) for recheckable tuples. That might not always be true, however. amgetbitmap and amgettuple cannot be used in the same index scan; there are other restrictions too when using amgetbitmap, as explained in Section 63.3.

The amgetbitmap function need only be provided if the access method supports “bitmap” index scans. If it doesn't, the amgetbitmap field in its IndexAmRoutine struct must be set to NULL.

void
amendscan (IndexScanDesc scan);

End a scan and release resources. The scan struct itself should not be freed, but any locks or pins taken internally by the access method must be released, as well as any other memory allocated by ambegin-scan and other scan-related functions.

void
ammarkpos (IndexScanDesc scan);

Mark current scan position. The access method need only support one remembered scan position per scan.

The ammarkpos function need only be provided if the access method supports ordered scans. If it doesn't, the ammarkpos field in its IndexAmRoutine struct may be set to NULL.

void
amrestrpos (IndexScanDesc scan);

Restore the scan to the most recently marked position.

The amrestrpos function need only be provided if the access method supports ordered scans. If it doesn't, the amrestrpos field in its IndexAmRoutine struct may be set to NULL.

In addition to supporting ordinary index scans, some types of index may wish to support parallel index scans, which allow multiple backends to cooperate in performing an index scan. The index access method should arrange things so that each cooperating process returns a subset of the tuples that would be performed by an ordinary, non-parallel index scan, but in such a way that the union of those subsets is equal to the set of tuples that would be returned by an ordinary, non-parallel index scan. Furthermore, while there need not be any global ordering of tuples returned by a parallel scan, the ordering of that subset of tuples returned within each cooperating backend must match the requested ordering. The following functions may be implemented to support parallel index scans:

Size
amestimateparallelsscan (void);
Estimate and return the number of bytes of dynamic shared memory which the access method will be needed to perform a parallel scan. (This number is in addition to, not in lieu of, the amount of space needed for AM-independent data in ParallelIndexScanDescData.)

It is not necessary to implement this function for access methods which do not support parallel scans or for which the number of additional bytes of storage required is zero.

```c
void aminitparallelscan (void *target);
```

This function will be called to initialize dynamic shared memory at the beginning of a parallel scan. `target` will point to at least the number of bytes previously returned by `amestimateparallelscan`, and this function may use that amount of space to store whatever data it wishes.

It is not necessary to implement this function for access methods which do not support parallel scans or in cases where the shared memory space required needs no initialization.

```c
void amparallelrescan (IndexScanDesc scan);
```

This function, if implemented, will be called when a parallel index scan must be restarted. It should reset any shared state set up by `aminitparallelscan` such that the scan will be restarted from the beginning.

### 63.3. Index Scanning

In an index scan, the index access method is responsible for regurgitating the TIDs of all the tuples it has been told about that match the `scan keys`. The access method is **not** involved in actually fetching those tuples from the index's parent table, nor in determining whether they pass the scan's visibility test or other conditions.

A scan key is the internal representation of a `WHERE` clause of the form `index_key operator constant`, where the index key is one of the columns of the index and the operator is one of the members of the index column. An index scan has zero or more scan keys, which are implicitly ANDed — the returned tuples are expected to satisfy all the indicated conditions.

The access method can report that the index is *lossy*, or requires rechecks, for a particular query. This implies that the index scan will return all the entries that pass the scan key, plus possibly additional entries that do not. The core system's index-scan machinery will then apply the index conditions again to the heap tuple to verify whether or not it really should be selected. If the recheck option is not specified, the index scan must return exactly the set of matching entries.

Note that it is entirely up to the access method to ensure that it correctly finds all and only the entries passing all the given scan keys. Also, the core system will simply hand off all the `WHERE` clauses that match the index keys and operator families, without any semantic analysis to determine whether they are redundant or contradictory. As an example, given `WHERE x > 4 AND x > 14` where `x` is a b-tree indexed column, it is left to the b-tree index access method to realize that the first scan key is redundant and can be discarded. The extent of preprocessing needed during index-scan machinery will then apply the index conditions again to the heap tuple to verify whether or not it really should be selected. If the recheck option is not specified, the index scan must return exactly the set of matching entries.

Some access methods return index entries in a well-defined order, others do not. There are actually two different ways that an access method can support sorted output:
Index Access Method

Interface Definition

- Access methods that always return entries in the natural ordering of their data (such as btree) should set `amcanorder` to true. Currently, such access methods must use btree-compatible strategy numbers for their equality and ordering operators.

- Access methods that support ordering operators should set `amcanorderbyop` to true. This indicates that the index is capable of returning entries in an order satisfying `ORDER BY index_key operator constant`. Scan modifiers of that form can be passed to `amrescan` as described previously.

The `amgettuple` function has a `direction` argument, which can be either `ForwardScanDirection` (the normal case) or `BackwardScanDirection`. If the first call after `amrescan` specifies `BackwardScanDirection`, then the set of matching index entries is to be scanned back-to-front rather than in the normal front-to-back direction, so `amgettuple` must return the last matching tuple in the index, rather than the first one as it normally would. (This will only occur for access methods that set `amcanorder` to true.) After the first call, `amgettuple` must be prepared to advance the scan in either direction from the most recently returned entry. (But if `amcanbackward` is false, all subsequent calls will have the same direction as the first one.)

Access methods that support ordered scans must support “marking” a position in a scan and later returning to the marked position. The same position might be restored multiple times. However, only one position need be remembered per scan; a new `ammarkpos` call overrides the previously marked position. An access method that does not support ordered scans need not provide `ammarkpos` and `amrestrpos` functions in `IndexAmRoutine`; set those pointers to NULL instead.

Both the scan position and the mark position (if any) must be maintained consistently in the face of concurrent insertions or deletions in the index. It is OK if a freshly-inserted entry is not returned by a scan that would have found the entry if it had existed when the scan started, or for the scan to return such an entry upon rescanning or backing up even though it had not been returned the first time through. Similarly, a concurrent delete might or might not be reflected in the results of a scan. What is important is that insertions or deletions not cause the scan to miss or multiply return entries that were not themselves being inserted or deleted.

If the index stores the original indexed data values (and not some lossy representation of them), it is useful to support index-only scans, in which the index returns the actual data not just the TID of the heap tuple. This will only avoid I/O if the visibility map shows that the TID is on an all-visible page; else the heap tuple must be visited anyway to check MVCC visibility. But that is no concern of the access method’s.

Instead of using `amgettuple`, an index scan can be done with `amgetbitmap` to fetch all tuples in one call. This can be noticeably more efficient than `amgettuple` because it allows avoiding lock/unlock cycles within the access method. In principle `amgetbitmap` should have the same effects as repeated `amgettuple` calls, but we impose several restrictions to simplify matters. First of all, `amgetbitmap` returns all tuples at once and marking or restoring scan positions isn't supported. Secondly, the tuples are returned in a bitmap which doesn't have any specific ordering, which is why `amgetbitmap` doesn't take a `direction` argument. (Ordering operators will never be supplied for such a scan, either.) Also, there is no provision for index-only scans with `amgetbitmap`, since there is no way to return the contents of index tuples. Finally, `amgetbitmap` does not guarantee any locking of the returned tuples, with implications spelled out in Section 63.4.

Note that it is permitted for an access method to implement only `amgetbitmap` and not `amgettuple`, or vice versa, if its internal implementation is unsuited to one API or the other.

### 63.4. Index Locking Considerations

Index access methods must handle concurrent updates of the index by multiple processes. The core PostgreSQL system obtains `AccessShareLock` on the index during an index scan, and `RowExclusive-
Lock when updating the index (including plain VACUUM). Since these lock types do not conflict, the access method is responsible for handling any fine-grained locking it might need. An ACCESS EXCLUSIVE lock on the index as a whole will be taken only during index creation, destruction, or REINDEX (SHARE UPDATE EXCLUSIVE is taken instead with CONCURRENTLY).

Building an index type that supports concurrent updates usually requires extensive and subtle analysis of the required behavior. For the b-tree and hash index types, you can read about the design decisions involved in `src/backend/access/nbtree/README` and `src/backend/access/hash/README`.

Aside from the index's own internal consistency requirements, concurrent updates create issues about consistency between the parent table (the heap) and the index. Because PostgreSQL separates accesses and updates of the heap from those of the index, there are windows in which the index might be inconsistent with the heap. We handle this problem with the following rules:

- A new heap entry is made before making its index entries. (Therefore a concurrent index scan is likely to fail to see the heap entry. This is okay because the index reader would be uninterested in an uncommitted row anyway. But see Section 63.5.)

- When a heap entry is to be deleted (by VACUUM), all its index entries must be removed first.

- An index scan must maintain a pin on the index page holding the item last returned by `amgettuplereg` and `ambulkdelete` cannot delete entries from pages that are pinned by other backends. The need for this rule is explained below.

Without the third rule, it is possible for an index reader to see an index entry just before it is removed by VACUUM, and then to arrive at the corresponding heap entry after that was removed by VACUUM. This creates no serious problems if that item number is still unused when the reader reaches it, since an empty item slot will be ignored by `heap_fetch()`. But what if a third backend has already re-used the item slot for something else? When using an MVCC-compliant snapshot, there is no problem because the new occupant of the slot is certain to be too new to pass the snapshot test. However, with a non-MVCC-compliant snapshot (such as `SnapshotAny`), it would be possible to accept and return a row that does not in fact match the scan keys. We could defend against this scenario by requiring the scan keys to be rechecked against the heap row in all cases, but that is too expensive. Instead, we use a pin on an index page as a proxy to indicate that the reader might still be “in flight” from the index entry to the matching heap entry. Making `ambulkdelete` block on such a pin ensures that VACUUM cannot delete the heap entry before the reader is done with it. This solution costs little in run time, and adds blocking overhead only in the rare cases where there actually is a conflict.

This solution requires that index scans be “synchronous”: we have to fetch each heap tuple immediately after scanning the corresponding index entry. This is expensive for a number of reasons. An “asynchronous” scan in which we collect many TIDs from the index, and only visit the heap tuples sometime later, requires much less index locking overhead and can allow a more efficient heap access pattern. Per the above analysis, we must use the synchronous approach for non-MVCC-compliant snapshots, but an asynchronous scan is workable for a query using an MVCC snapshot.

In an `amgetbitmap` index scan, the access method does not keep an index pin on any of the returned tuples. Therefore it is only safe to use such scans with MVCC-compliant snapshots.

When the `ampredlocks` flag is not set, any scan using that index access method within a serializable transaction will acquire a nonblocking predicate lock on the full index. This will generate a read-write conflict with the insert of any tuple into that index by a concurrent serializable transaction. If certain patterns of read-write conflicts are detected among a set of concurrent serializable transactions, one of those transactions may be canceled to protect data integrity. When the flag is set, it indicates that the index access method implements finer-grained predicate locking, which will tend to reduce the frequency of such transaction cancellations.
63.5. Index Uniqueness Checks

PostgreSQL enforces SQL uniqueness constraints using *unique indexes*, which are indexes that disallow multiple entries with identical keys. An access method that supports this feature sets `amcanunique` true. (At present, only b-tree supports it.) Columns listed in the `INCLUDE` clause are not considered when enforcing uniqueness.

Because of MVCC, it is always necessary to allow duplicate entries to exist physically in an index: the entries might refer to successive versions of a single logical row. The behavior we actually want to enforce is that no MVCC snapshot could include two rows with equal index keys. This breaks down into the following cases that must be checked when inserting a new row into a unique index:

- If a conflicting valid row has been deleted by the current transaction, it’s okay. (In particular, since an UPDATE always deletes the old row version before inserting the new version, this will allow an UPDATE on a row without changing the key.)

- If a conflicting row has been inserted by an as-yet-uncommitted transaction, the would-be inserter must wait to see if that transaction commits. If it rolls back then there is no conflict. If it commits without deleting the conflicting row again, there is a uniqueness violation. (In practice we just wait for the other transaction to end and then redo the visibility check in toto.)

- Similarly, if a conflicting valid row has been deleted by an as-yet-uncommitted transaction, the would-be inserter must wait for that transaction to commit or abort, and then repeat the test.

Furthermore, immediately before reporting a uniqueness violation according to the above rules, the access method must recheck the liveness of the row being inserted. If it is committed dead then no violation should be reported. (This case cannot occur during the ordinary scenario of inserting a row that’s just been created by the current transaction. It can happen during `CREATE UNIQUE INDEX CONCURRENTLY`, however.)

We require the index access method to apply these tests itself, which means that it must reach into the heap to check the commit status of any row that is shown to have a duplicate key according to the index contents. This is without a doubt ugly and non-modular, but it saves redundant work: if we did a separate probe then the index lookup for a conflicting row would be essentially repeated while finding the place to insert the new row’s index entry. What’s more, there is no obvious way to avoid race conditions unless the conflict check is an integral part of insertion of the new index entry.

If the unique constraint is deferrable, there is additional complexity: we need to be able to insert an index entry for a new row, but defer any uniqueness-violation error until end of statement or even later. To avoid unnecessary repeat searches of the index, the index access method should do a preliminary uniqueness check during the initial insertion. If this shows that there is definitely no conflicting live tuple, we are done. Otherwise, we schedule a recheck to occur when it is time to enforce the constraint. If, at the time of the recheck, both the inserted tuple and some other tuple with the same key are live, then the error must be reported. (Note that for this purpose, “live” actually means “any tuple in the index entry’s HOT chain is live”.) To implement this, the `aminsert` function is passed a `checkUnique` parameter having one of the following values:

- `UNIQUE_CHECK_NO` indicates that no uniqueness checking should be done (this is not a unique index).
- `UNIQUE_CHECK_YES` indicates that this is a non-deferrable unique index, and the uniqueness check must be done immediately, as described above.
- `UNIQUE_CHECK_PARTIAL` indicates that the unique constraint is deferrable. PostgreSQL will use this mode to insert each row’s index entry. The access method must allow duplicate entries into the index, and report any potential duplicates by returning false from `aminsert`. For each row for which false is returned, a deferred recheck will be scheduled.
The access method must identify any rows which might violate the unique constraint, but it is not an error for it to report false positives. This allows the check to be done without waiting for other transactions to finish; conflicts reported here are not treated as errors and will be rechecked later, by which time they may no longer be conflicts.

- **UNIQUE_CHECK_EXISTING** indicates that this is a deferred recheck of a row that was reported as a potential uniqueness violation. Although this is implemented by calling `aminsert`, the access method must not insert a new index entry in this case. The index entry is already present. Rather, the access method must check to see if there is another live index entry. If so, and if the target row is also still live, report error.

It is recommended that in a **UNIQUE_CHECK_EXISTING** call, the access method further verify that the target row actually does have an existing entry in the index, and report error if not. This is a good idea because the index tuple values passed to `aminsert` will have been recomputed. If the index definition involves functions that are not really immutable, we might be checking the wrong area of the index. Checking that the target row is found in the recheck verifies that we are scanning for the same tuple values as were used in the original insertion.

### 63.6. Index Cost Estimation Functions

The `amcostestimate` function is given information describing a possible index scan, including lists of WHERE and ORDER BY clauses that have been determined to be usable with the index. It must return estimates of the cost of accessing the index and the selectivity of the WHERE clauses (that is, the fraction of parent-table rows that will be retrieved during the index scan). For simple cases, nearly all the work of the cost estimator can be done by calling standard routines in the optimizer; the point of having an `amcostestimate` function is to allow index access methods to provide index-type-specific knowledge, in case it is possible to improve on the standard estimates.

Each `amcostestimate` function must have the signature:

```c
void amcostestimate (PlannerInfo *root,
    IndexPath *path,
    double loop_count,
    Cost *indexStartupCost,
    Cost *indexTotalCost,
    Selectivity *indexSelectivity,
    double *indexCorrelation,
    double *indexPages);
```

The first three parameters are inputs:

- **root**
  
  The planner's information about the query being processed.

- **path**
  
  The index access path being considered. All fields except cost and selectivity values are valid.

- **loop_count**
  
  The number of repetitions of the index scan that should be factored into the cost estimates. This will typically be greater than one when considering a parameterized scan for use in the inside of a nestloop.
join. Note that the cost estimates should still be for just one scan; a larger `loop_count` means that it may be appropriate to allow for some caching effects across multiple scans.

The last five parameters are pass-by-reference outputs:

* `indexStartupCost`
  
  Set to cost of index start-up processing

* `indexTotalCost`
  
  Set to total cost of index processing

* `indexSelectivity`
  
  Set to index selectivity

* `indexCorrelation`
  
  Set to correlation coefficient between index scan order and underlying table's order

* `indexPages`
  
  Set to number of index leaf pages

Note that cost estimate functions must be written in C, not in SQL or any available procedural language, because they must access internal data structures of the planner/optimizer.

The index access costs should be computed using the parameters used by `src/backend/optimizer/path/costsize.c`: a sequential disk block fetch has cost `seq_page_cost`, a nonsequential fetch has cost `random_page_cost`, and the cost of processing one index row should usually be taken as `cpu_index_tuple_cost`. In addition, an appropriate multiple of `cpu_operator_cost` should be charged for any comparison operators invoked during index processing (especially evaluation of the indexquals themselves).

The access costs should include all disk and CPU costs associated with scanning the index itself, but not the costs of retrieving or processing the parent-table rows that are identified by the index.

The “start-up cost” is the part of the total scan cost that must be expended before we can begin to fetch the first row. For most indexes this can be taken as zero, but an index type with a high start-up cost might want to set it nonzero.

The `indexSelectivity` should be set to the estimated fraction of the parent table rows that will be retrieved during the index scan. In the case of a lossy query, this will typically be higher than the fraction of rows that actually pass the given qual conditions.

The `indexCorrelation` should be set to the correlation (ranging between -1.0 and 1.0) between the index order and the table order. This is used to adjust the estimate for the cost of fetching rows from the parent table.

The `indexPages` should be set to the number of leaf pages. This is used to estimate the number of workers for parallel index scan.

When `loop_count` is greater than one, the returned numbers should be averages expected for any one scan of the index.

**Cost Estimation**

A typical cost estimator will proceed as follows:
1. Estimate and return the fraction of parent-table rows that will be visited based on the given qual conditions. In the absence of any index-type-specific knowledge, use the standard optimizer function `clauselist_selectivity()`:

```c
*indexSelectivity = clauselist_selectivity(root, path->indexquals, 
    path->indexinfo->relid, 
    JOIN_INNER, NULL);
```

2. Estimate the number of index rows that will be visited during the scan. For many index types this is the same as `indexSelectivity` times the number of rows in the index, but it might be more. (Note that the index's size in pages and rows is available from the `path->indexinfo` struct.)

3. Estimate the number of index pages that will be retrieved during the scan. This might be just `indexSelectivity` times the index's size in pages.

4. Compute the index access cost. A generic estimator might do this:

```c
/*
 * Our generic assumption is that the index pages will be read
 * sequentially, so they cost seq_page_cost each, not
 * random_page_cost.
 * Also, we charge for evaluation of the indexquals at each index
 * row.
 * All the costs are assumed to be paid incrementally during the
 * scan.
 */

    cost_qual_eval(&index_qual_cost, path->indexquals, root);
    *indexStartupCost = index_qual_cost.startup;
    *indexTotalCost = seq_page_cost * numIndexPages +
            (cpu_index_tuple_cost + index_qual_cost.per_tuple) *
            numIndexTuples;
```

However, the above does not account for amortization of index reads across repeated index scans.

5. Estimate the index correlation. For a simple ordered index on a single field, this can be retrieved from `pg_statistic`. If the correlation is not known, the conservative estimate is zero (no correlation).

Examples of cost estimator functions can be found in `src/backend/utils/adt/selfuncs.c`.

Chapter 64. Generic WAL Records

Although all built-in WAL-logged modules have their own types of WAL records, there is also a generic WAL record type, which describes changes to pages in a generic way. This is useful for extensions that provide custom access methods.

In comparison with Custom WAL Resource Managers, Generic WAL is simpler for an extension to implement and does not require the extension library to be loaded in order to apply the records.

Note

Generic WAL records are ignored during Logical Decoding. If logical decoding is required for your extension, consider a Custom WAL Resource Manager.

The API for constructing generic WAL records is defined in access/generic_xlog.h and implemented in access/transam/generic_xlog.c.

To perform a WAL-logged data update using the generic WAL record facility, follow these steps:

1. state = GenericXLogStart(relation) — start construction of a generic WAL record for the given relation.

2. page = GenericXLogRegisterBuffer(state, buffer, flags) — register a buffer to be modified within the current generic WAL record. This function returns a pointer to a temporary copy of the buffer’s page, where modifications should be made. (Do not modify the buffer’s contents directly.) The third argument is a bit mask of flags applicable to the operation. Currently the only such flag is GENERIC_XLOG_FULL_IMAGE, which indicates that a full-page image rather than a delta update should be included in the WAL record. Typically this flag would be set if the page is new or has been rewritten completely. GenericXLogRegisterBuffer can be repeated if the WAL-logged action needs to modify multiple pages.

3. Apply modifications to the page images obtained in the previous step.

4. GenericXLogFinish(state) — apply the changes to the buffers and emit the generic WAL record.

WAL record construction can be canceled between any of the above steps by calling GenericXLogAbort(state). This will discard all changes to the page image copies.

Please note the following points when using the generic WAL record facility:

• No direct modifications of buffers are allowed! All modifications must be done in copies acquired from GenericXLogRegisterBuffer(). In other words, code that makes generic WAL records should never call BufferGetPage() for itself. However, it remains the caller’s responsibility to pin/unpin and lock/unlock the buffers at appropriate times. Exclusive lock must be held on each target buffer from before GenericXLogRegisterBuffer() until after GenericXLogFinish().

• Registrations of buffers (step 2) and modifications of page images (step 3) can be mixed freely, i.e., both steps may be repeated in any sequence. Keep in mind that buffers should be registered in the same order in which locks are to be obtained on them during replay.

• The maximum number of buffers that can be registered for a generic WAL record is MAX GENERIC_XLOG_PAGES. An error will be thrown if this limit is exceeded.
Generic WAL Records

- Generic WAL assumes that the pages to be modified have standard layout, and in particular that there is no useful data between `pd_lower` and `pd_upper`.

- Since you are modifying copies of buffer pages, `GenericXLogStart()` does not start a critical section. Thus, you can safely do memory allocation, error throwing, etc. between `GenericXLogStart()` and `GenericXLogFinish()`. The only actual critical section is present inside `GenericXLogFinish()`. There is no need to worry about calling `GenericXLogAbort()` during an error exit, either.

- `GenericXLogFinish()` takes care of marking buffers dirty and setting their LSNs. You do not need to do this explicitly.

- For unlogged relations, everything works the same except that no actual WAL record is emitted. Thus, you typically do not need to do any explicit checks for unlogged relations.

- The generic WAL redo function will acquire exclusive locks to buffers in the same order as they were registered. After redoing all changes, the locks will be released in the same order.

- If `GENERIC_XLOG_FULL_IMAGE` is not specified for a registered buffer, the generic WAL record contains a delta between the old and the new page images. This delta is based on byte-by-byte comparison. This is not very compact for the case of moving data within a page, and might be improved in the future.
Chapter 65. Custom WAL Resource Managers

This chapter explains the interface between the core PostgreSQL system and custom WAL resource managers, which enable extensions to integrate directly with the WAL.

An extension, especially a Table Access Method or Index Access Method, may need to use WAL for recovery, replication, and/or Logical Decoding. Custom resource managers are a more flexible alternative to Generic WAL (which does not support logical decoding), but more complex for an extension to implement.

To create a new custom WAL resource manager, first define an RmgrData structure with implementations for the resource manager methods. Refer to src/backend/access/transam/README and src/include/access/xlog_internal.h in the PostgreSQL source.

```
/*
 * Method table for resource managers.
 *
 * This struct must be kept in sync with the PG_RMGR definition in
 * rmgr.c.
 *
 * rm_identify must return a name for the record based on xl_info
 * (without
 * reference to the rmid). For example, XLOG_BTREE_VACUUM would be
 * "VACUUM". rm_desc can then be called to obtain additional detail
 * for the
 * record, if available (e.g. the last block).
 *
 * rm_mask takes as input a page modified by the resource manager and
 * masks
 * out bits that shouldn't be flagged by wal_consistency_checking.
 *
 * RmgrTable[] is indexed by RmgrId values (see rmgrlist.h). If
 * rm_name is
 * NULL, the corresponding RmgrTable entry is considered invalid.
 */
typedef struct RmgrData
{
    const char *rm_name;
    void (*rm_redo) (XLogReaderState *record);
    void (*rm_desc) (StringInfo buf, XLogReaderState *record);
    const char *(*rm_identify) (uint8 info);
    void (*rm_startup) (void);
    void (*rm_cleanup) (void);
    void (*rm_mask) (char *pagedata, BlockNumber blkno);
    void (*rm_decode) (struct LogicalDecodingContext *ctx,
                       struct XLogRecordBuffer *buf);
} RmgrData;
```

Then, register your new resource manager.
/ * Register a new custom WAL resource manager. 
 * Resource manager IDs must be globally unique across all extensions. Refer 
 * to https://wiki.postgresql.org/wiki/CustomWALResourceManager to reserve a 
 * unique RmgrId for your extension, to avoid conflicts with other extension 
 * developers. During development, use RM_EXPERIMENTAL_ID to avoid needlessly 
 * reserving a new ID. 
 */
extern void RegisterCustomRmgr(RmgrId rmid, RmgrData *rmgr);

RegisterCustomRmgr must be called from the extension module's _PG_init function. While developing a new extension, use RM_EXPERIMENTAL_ID for rmid. When you ready to release the extension to users, reserve a new resource manager ID at the Custom WAL Resource Manager1 page.

Place the extension module implementing the custom resource manager in shared_preload_libraries so that it will be loaded early during PostgreSQL startup.

**Note**

The extension must remain in shared_preload_libraries as long as any custom WAL records may exist in the system. Otherwise PostgreSQL will not be able to apply or decode the custom WAL records, which may prevent the server from starting.

Chapter 66. B-Tree Indexes

66.1. Introduction

PostgreSQL includes an implementation of the standard btree (multi-way balanced tree) index data structure. Any data type that can be sorted into a well-defined linear order can be indexed by a btree index. The only limitation is that an index entry cannot exceed approximately one-third of a page (after TOAST compression, if applicable).

Because each btree operator class imposes a sort order on its data type, btree operator classes (or, really, operator families) have come to be used as PostgreSQL’s general representation and understanding of sorting semantics. Therefore, they’ve acquired some features that go beyond what would be needed just to support btree indexes, and parts of the system that are quite distant from the btree AM make use of them.

66.2. Behavior of B-Tree Operator Classes

As shown in Table 38.3, a btree operator class must provide five comparison operators, <, <=, =, => and >. One might expect that <> should also be part of the operator class, but it is not, because it would almost never be useful to use a <> WHERE clause in an index search. (For some purposes, the planner treats <> as associated with a btree operator class; but it finds that operator via the = operator's negator link, rather than from pg_amop.)

When several data types share near-identical sorting semantics, their operator classes can be grouped into an operator family. Doing so is advantageous because it allows the planner to make deductions about cross-type comparisons. Each operator class within the family should contain the single-type operators (and associated support functions) for its input data type, while cross-type comparison operators and support functions are “loose” in the family. It is recommendable that a complete set of cross-type operators be included in the family, thus ensuring that the planner can represent any comparison conditions that it deduces from transitivity.

There are some basic assumptions that a btree operator family must satisfy:

- An = operator must be an equivalence relation; that is, for all non-null values A, B, C of the data type:
  - A = A is true (reflexive law)
  - if A = B, then B = A (symmetric law)
  - if A = B and B = C, then A = C (transitive law)

- A < operator must be a strong ordering relation; that is, for all non-null values A, B, C:
  - A < A is false (irreflexive law)
  - if A < B and B < C, then A < C (transitive law)

- Furthermore, the ordering is total; that is, for all non-null values A, B:
  - exactly one of A < B, A = B, and B < A is true (trichotomy law)
  (The trichotomy law justifies the definition of the comparison support function, of course.)

The other three operators are defined in terms of = and < in the obvious way, and must act consistently with them.
For an operator family supporting multiple data types, the above laws must hold when A, B, C are taken from any data types in the family. The transitive laws are the trickiest to ensure, as in cross-type situations they represent statements that the behaviors of two or three different operators are consistent. As an example, it would not work to put float8 and numeric into the same operator family, at least not with the current semantics that numeric values are converted to float8 for comparison to a float8. Because of the limited accuracy of float8, this means there are distinct numeric values that will compare equal to the same float8 value, and thus the transitive law would fail.

Another requirement for a multiple-data-type family is that any implicit or binary-coercion casts that are defined between data types included in the operator family must not change the associated sort ordering.

It should be fairly clear why a btree index requires these laws to hold within a single data type: without them there is no ordering to arrange the keys with. Also, index searches using a comparison key of a different data type require comparisons to behave sanely across two data types. The extensions to three or more data types within a family are not strictly required by the btree index mechanism itself, but the planner relies on them for optimization purposes.

### 66.3. B-Tree Support Functions

As shown in Table 38.9, btree defines one required and four optional support functions. The five user-defined methods are:

**order**

For each combination of data types that a btree operator family provides comparison operators for, it must provide a comparison support function, registered in pg_amproc with support function number 1 and amproclefttype/amprocrighttype equal to the left and right data types for the comparison (i.e., the same data types that the matching operators are registered with in pg_amop). The comparison function must take two non-null values A and B and return an int32 value that is \(<\), \(=\), or \(>\) when \(A < B\), \(A = B\), or \(A > B\), respectively. A null result is disallowed: all values of the data type must be comparable. See src/backend/access/nbtree/nbtcompare.c for examples.

If the compared values are of a collatable data type, the appropriate collation OID will be passed to the comparison support function, using the standard PG_GET_COLLATION() mechanism.

**sortsupport**

Optionally, a btree operator family may provide sort support function(s), registered under support function number 2. These functions allow implementing comparisons for sorting purposes in a more efficient way than naively calling the comparison support function. The APIs involved in this are defined in src/include/utils/sortsupport.h.

**in_range**

Optionally, a btree operator family may provide in_range support function(s), registered under support function number 3. These are not used during btree index operations; rather, they extend the semantics of the operator family so that it can support window clauses containing the RANGE offset PRECEDING and RANGE offset FOLLOWING frame bound types (see Section 4.2.8). Fundamentally, the extra information provided is how to add or subtract an offset value in a way that is compatible with the family’s data ordering.

An in_range function must have the signature

```
in_range(val type1, base type1, offset type2, sub bool, less bool) returns bool
```
val and base must be of the same type, which is one of the types supported by the operator family (i.e., a type for which it provides an ordering). However, offset could be of a different type, which might be one otherwise unsupported by the family. An example is that the built-in time_ops family provides an in_range function that has offset of type interval. A family can provide in_range functions for any of its supported types and one or more offset types. Each in_range function should be entered in pg_amproc with amproclfttype equal to type1 and amprocrghttype equal to type2.

The essential semantics of an in_range function depend on the two Boolean flag parameters. It should add or subtract base and offset, then compare val to the result, as follows:

- if !sub and !less, return val >= (base + offset)
- if !sub and less, return val <= (base + offset)
- if sub and !less, return val >= (base - offset)
- if sub and less, return val <= (base - offset)

Before doing so, the function should check the sign of offset: if it is less than zero, raise error ERRCODE_INVALID_PRECEDING_OR_FOLLOWING_SIZE (22013) with error text like “invalid preceding or following size in window function”. (This is required by the SQL standard, although nonstandard operator families might perhaps choose to ignore this restriction, since there seems to be little semantic necessity for it.) This requirement is delegated to the in_range function so that the core code needn’t understand what “less than zero” means for a particular data type.

An additional expectation is that in_range functions should, if practical, avoid throwing an error if base + offset or base - offset would overflow. The correct comparison result can be determined even if that value would be out of the data type’s range. Note that if the data type includes concepts such as “infinity” or “NaN”, extra care may be needed to ensure that in_range’s results agree with the normal sort order of the operator family.

The results of the in_range function must be consistent with the sort ordering imposed by the operator family. To be precise, given any fixed values of offset and sub, then:

- If in_range with less = true is true for some val1 and base, it must be true for every val2 <= val1 with the same base.
- If in_range with less = true is false for some val1 and base, it must be false for every val2 >= val1 with the same base.
- If in_range with less = true is true for some val and base1, it must be true for every base2 >= base1 with the same val.
- If in_range with less = true is false for some val and base1, it must be false for every base2 <= base1 with the same val.

Analogous statements with inverted conditions hold when less = false.

If the type being ordered (type1) is collatable, the appropriate collation OID will be passed to the in_range function, using the standard PG_GET_COLLATION() mechanism.

in_range functions need not handle NULL inputs, and typically will be marked strict.

equalimage

Optionally, a btree operator family may provide equalimage (“equality implies image equality”) support functions, registered under support function number 4. These functions allow the core code
B-Tree Indexes

to determine when it is safe to apply the btree deduplication optimization. Currently, **equalimage** functions are only called when building or rebuilding an index.

An **equalimage** function must have the signature

**equalimage**(opcintype oid) returns bool

The return value is static information about an operator class and collation. Returning **true** indicates that the **order** function for the operator class is guaranteed to only return 0 ("arguments are equal") when its A and B arguments are also interchangeable without any loss of semantic information. Not registering an **equalimage** function or returning **false** indicates that this condition cannot be assumed to hold.

The **opcintype** argument is the **pg_type.oid** of the data type that the operator class indexes. This is a convenience that allows reuse of the same underlying **equalimage** function across operator classes. If **opcintype** is a collatable data type, the appropriate collation OID will be passed to the **equalimage** function, using the standard **PG_GET_COLLATION()** mechanism.

As far as the operator class is concerned, returning **true** indicates that deduplication is safe (or safe for the collation whose OID was passed to its **equalimage** function). However, the core code will only deem deduplication safe for an index when **every** indexed column uses an operator class that registers an **equalimage** function, and each function actually returns **true** when called.

Image equality is *almost* the same condition as simple bitwise equality. There is one subtle difference: When indexing a varlena data type, the on-disk representation of two image equal datums may not be bitwise equal due to inconsistent application of TOAST compression on input. Formally, when an operator class's **equalimage** function returns **true**, it is safe to assume that the **datum_image_eq()** C function will always agree with the operator class's **order** function (provided that the same collation OID is passed to both the **equalimage** and **order** functions).

The core code is fundamentally unable to deduce anything about the “equality implies image equality” status of an operator class within a multiple-data-type family based on details from other operator classes in the same family. Also, it is not sensible for an operator family to register a cross-type **equalimage** function, and attempting to do so will result in an error. This is because “equality implies image equality” status does not just depend on sorting/equality semantics, which are more or less defined at the operator family level. In general, the semantics that one particular data type implements must be considered separately.

The convention followed by the operator classes included with the core PostgreSQL distribution is to register a stock, generic **equalimage** function. Most operator classes register **btequalimage()**, which indicates that deduplication is safe unconditionally. Operator classes for collatable data types such as **text** register **btvarstrequalimage()**, which indicates that deduplication is safe with deterministic collations. Best practice for third-party extensions is to register their own custom function to retain control.

**options**

Optionally, a B-tree operator family may provide **options** ("operator class specific options") support functions, registered under support function number 5. These functions define a set of user-visible parameters that control operator class behavior.

An **options** support function must have the signature
options(relopts local_relopts *) returns void

The function is passed a pointer to a local_relopts struct, which needs to be filled with a set of
operator class specific options. The options can be accessed from other support functions using the
PG_HAS_OPCLASS_OPTIONS() and PG_GET_OPCLASS_OPTIONS() macros.

Currently, no B-Tree operator class has an options support function. B-tree doesn't allow flexible
representation of keys like GiST, SP-GiST, GIN and BRIN do. So, options probably doesn't have
much application in the current B-tree index access method. Nevertheless, this support function was
added to B-tree for uniformity, and will probably find uses during further evolution of B-tree in Post-
greSQL.

66.4. Implementation

This section covers B-Tree index implementation details that may be of use to advanced users. See src/
backend/access/nbtree/README in the source distribution for a much more detailed, internals-foc-
cused description of the B-Tree implementation.

66.4.1. B-Tree Structure

PostgreSQL B-Tree indexes are multi-level tree structures, where each level of the tree can be used as a
doubly-linked list of pages. A single metapage is stored in a fixed position at the start of the first segment
file of the index. All other pages are either leaf pages or internal pages. Leaf pages are the pages on the
lowest level of the tree. All other levels consist of internal pages. Each leaf page contains tuples that point
to table rows. Each internal page contains tuples that point to the next level down in the tree. Typically,
over 99% of all pages are leaf pages. Both internal pages and leaf pages use the standard page format
described in Section 72.6.

New leaf pages are added to a B-Tree index when an existing leaf page cannot fit an incoming tuple. A
page split operation makes room for items that originally belonged on the overflowing page by moving a
portion of the items to a new page. Page splits must also insert a new downlink to the new page in the parent
page, which may cause the parent to split in turn. Page splits “cascade upwards” in a recursive fashion.
When the root page finally cannot fit a new downlink, a root page split operation takes place. This adds a
new level to the tree structure by creating a new root page that is one level above the original root page.

66.4.2. Bottom-up Index Deletion

B-Tree indexes are not directly aware that under MVCC, there might be multiple extant versions of the
same logical table row; to an index, each tuple is an independent object that needs its own index entry.
“Version churn” tuples may sometimes accumulate and adversely affect query latency and throughput.
This typically occurs with UPDATE-heavy workloads where most individual updates cannot apply the HOT
optimization. Changing the value of only one column covered by one index during an UPDATE always
necessitates a new set of index tuples — one for each and every index on the table. Note in particular that
this includes indexes that were not “logically modified” by the UPDATE. All indexes will need a successor
physical index tuple that points to the latest version in the table. Each new tuple within each index will
generally need to coexist with the original “updated” tuple for a short period of time (typically until shortly
after the UPDATE transaction commits).

B-Tree indexes incrementally delete version churn index tuples by performing bottom-up index deletion
passes. Each deletion pass is triggered in reaction to an anticipated “version churn page split”. This only
happens with indexes that are not logically modified by UPDATE statements, where concentrated build
up of obsolete versions in particular pages would occur otherwise. A page split will usually be avoided,
though it's possible that certain implementation-level heuristics will fail to identify and delete even one
garbage index tuple (in which case a page split or deduplication pass resolves the issue of an incoming new tuple not fitting on a leaf page). The worst-case number of versions that any index scan must traverse (for any single logical row) is an important contributor to overall system responsiveness and throughput. A bottom-up index deletion pass targets suspected garbage tuples in a single leaf page based on qualitative distinctions involving logical rows and versions. This contrasts with the “top-down” index cleanup performed by autovacuum workers, which is triggered when certain quantitative table-level thresholds are exceeded (see Section 25.1.6).

**Note**

Not all deletion operations that are performed within B-Tree indexes are bottom-up deletion operations. There is a distinct category of index tuple deletion: *simple index tuple deletion*. This is a deferred maintenance operation that deletes index tuples that are known to be safe to delete (those whose item identifier’s LP_DEAD bit is already set). Like bottom-up index deletion, simple index deletion takes place at the point that a page split is anticipated as a way of avoiding the split.

Simple deletion is opportunistic in the sense that it can only take place when recent index scans set the LP_DEAD bits of affected items in passing. Prior to PostgreSQL 14, the only category of B-Tree deletion was simple deletion. The main differences between it and bottom-up deletion are that only the former is opportunistically driven by the activity of passing index scans, while only the latter specifically targets version churn from *UPDATEs* that do not logically modify indexed columns.

Bottom-up index deletion performs the vast majority of all garbage index tuple cleanup for particular indexes with certain workloads. This is expected with any B-Tree index that is subject to significant version churn from *UPDATEs* that rarely or never logically modify the columns that the index covers. The average and worst-case number of versions per logical row can be kept low purely through targeted incremental deletion passes. It’s quite possible that the on-disk size of certain indexes will never increase by even one single page/block despite constant version churn from *UPDATEs*. Even then, an exhaustive “clean sweep” by a *VACUUM* operation (typically run in an autovacuum worker process) will eventually be required as a part of collective cleanup of the table and each of its indexes.

Unlike *VACUUM*, bottom-up index deletion does not provide any strong guarantees about how old the oldest garbage index tuple may be. No index can be permitted to retain “floating garbage” index tuples that became dead prior to a conservative cutoff point shared by the table and all of its indexes collectively. This fundamental table-level invariant makes it safe to recycle table TIDs. This is how it is possible for distinct logical rows to reuse the same table TID over time (though this can never happen with two logical rows whose lifetimes span the same *VACUUM* cycle).

### 66.4.3. Deduplication

A duplicate is a leaf page tuple (a tuple that points to a table row) where all indexed key columns have values that match corresponding column values from at least one other leaf page tuple in the same index. Duplicate tuples are quite common in practice. B-Tree indexes can use a special, space-efficient representation for duplicates when an optional technique is enabled: *deduplication*.

Deduplication works by periodically merging groups of duplicate tuples together, forming a single *posting list* tuple for each group. The column key value(s) only appear once in this representation. This is followed by a sorted array of TIDs that point to rows in the table. This significantly reduces the storage size of indexes where each value (or each distinct combination of column values) appears several times on average. The latency of queries can be reduced significantly. Overall query throughput may increase significantly. The overhead of routine index vacuuming may also be reduced significantly.
B-Tree Indexes

Note

B-Tree deduplication is just as effective with “duplicates” that contain a NULL value, even though NULL values are never equal to each other according to the = member of any B-Tree operator class. As far as any part of the implementation that understands the on-disk B-Tree structure is concerned, NULL is just another value from the domain of indexed values.

The deduplication process occurs lazily, when a new item is inserted that cannot fit on an existing leaf page, though only when index tuple deletion could not free sufficient space for the new item (typically deletion is briefly considered and then skipped over). Unlike GIN posting list tuples, B-Tree posting list tuples do not need to expand every time a new duplicate is inserted: they are merely an alternative physical representation of the original logical contents of the leaf page. This design prioritizes consistent performance with mixed read-write workloads. Most client applications will at least see a moderate performance benefit from using deduplication. Deduplication is enabled by default.

CREATE INDEX and REINDEX apply deduplication to create posting list tuples, though the strategy they use is slightly different. Each group of duplicate ordinary tuples encountered in the sorted input taken from the table is merged into a posting list tuple before being added to the current pending leaf page. Individual posting list tuples are packed with as many TIDs as possible. Leaf pages are written out in the usual way, without any separate deduplication pass. This strategy is well-suited to CREATE INDEX and REINDEX because they are once-off batch operations.

Write-heavy workloads that don’t benefit from deduplication due to having few or no duplicate values in indexes will incur a small, fixed performance penalty (unless deduplication is explicitly disabled). The deduplicate_items storage parameter can be used to disable deduplication within individual indexes. There is never any performance penalty with read-only workloads, since reading posting list tuples is at least as efficient as reading the standard tuple representation. Disabling deduplication isn’t usually helpful.

It is sometimes possible for unique indexes (as well as unique constraints) to use deduplication. This allows leaf pages to temporarily “absorb” extra version churn duplicates. Deduplication in unique indexes augments bottom-up index deletion, especially in cases where a long-running transaction holds a snapshot that blocks garbage collection. The goal is to buy time for the bottom-up index deletion strategy to become effective again. Delaying page splits until a single long-running transaction naturally goes away can allow a bottom-up deletion pass to succeed where an earlier deletion pass failed.

Tip

A special heuristic is applied to determine whether a deduplication pass in a unique index should take place. It can often skip straight to splitting a leaf page, avoiding a performance penalty from wasting cycles on unhelpful deduplication passes. If you’re concerned about the overhead of deduplication, consider setting deduplicate_items = off selectively. Leaving deduplication enabled in unique indexes has little downside.

Deduplication cannot be used in all cases due to implementation-level restrictions. Deduplication safety is determined when CREATE INDEX or REINDEX is run.

Note that deduplication is deemed unsafe and cannot be used in the following cases involving semantically significant differences among equal datums:

- text, varchar, and char cannot use deduplication when a nondeterministic collation is used. Case and accent differences must be preserved among equal datums.
• `numeric` cannot use deduplication. Numeric display scale must be preserved among equal datums.

• `jsonb` cannot use deduplication, since the `jsonb` B-Tree operator class uses `numeric` internally.

• `float4` and `float8` cannot use deduplication. These types have distinct representations for \(-0\) and 0, which are nevertheless considered equal. This difference must be preserved.

There is one further implementation-level restriction that may be lifted in a future version of PostgreSQL:

• Container types (such as composite types, arrays, or range types) cannot use deduplication.

There is one further implementation-level restriction that applies regardless of the operator class or collation used:

• `INCLUDE` indexes can never use deduplication.
Chapter 67. GiST Indexes

67.1. Introduction

GiST stands for Generalized Search Tree. It is a balanced, tree-structured access method, that acts as a base template in which to implement arbitrary indexing schemes. B-trees, R-trees and many other indexing schemes can be implemented in GiST.

One advantage of GiST is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from the University of California at Berkeley's GiST Indexing Project web site¹ and Marcel Kornacker's thesis, Access Methods for Next-Generation Database Systems². The GiST implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their web site³.

67.2. Built-in Operator Classes

The core PostgreSQL distribution includes the GiST operator classes shown in Table 67.1. (Some of the optional modules described in Appendix F provide additional GiST operator classes.)

For historical reasons, the `inet_ops` operator class is not the default class for types `inet` and `cidr`. To use it, mention the class name in `CREATE INDEX`, for example:

```sql
CREATE INDEX ON my_table USING GIST (my_inet_column inet_ops);
```

### 67.3. Extensibility

Traditionally, implementing a new index access method meant a lot of difficult work. It was necessary to understand the inner workings of the database, such as the lock manager and Write-Ahead Log. The GiST interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GiST layer itself takes care of concurrency, logging and searching the tree structure.

This extensibility should not be confused with the extensibility of the other standard search trees in terms of the data they can handle. For example, PostgreSQL supports extensible B-trees and hash indexes. That means that you can use PostgreSQL to build a B-tree or hash over any data type you want. But B-trees only support range predicates (\(<\), \(\leq\), \(\geq\), \(\approx\)), and hash indexes only support equality queries.

So if you index, say, an image collection with a PostgreSQL B-tree, you can only issue queries such as “is imagex equal to imagey”, “is imagex less than imagey” and “is imagex greater than imagey”. Depending on how you define “equals”, “less than” and “greater than” in this context, this could be useful. However, by using a GiST based index, you could create ways to ask domain-specific questions, perhaps “find all images of horses” or “find all over-exposed images”.

All it takes to get a GiST access method up and running is to implement several user-defined methods, which define the behavior of keys in the tree. Of course these methods have to be pretty fancy to support fancy queries, but for all the standard queries (B-trees, R-trees, etc.) they’re relatively straightforward. In short, GiST combines extensibility along with generality, code reuse, and a clean interface.

There are five methods that an index operator class for GiST must provide, and six that are optional. Correctness of the index is ensured by proper implementation of the `same`, `consistent` and `union` methods, while efficiency (size and speed) of the index will depend on the `penalty` and `picksplit`
methods. Two optional methods are `compress` and `decompress`, which allow an index to have internal tree data of a different type than the data it indexes. The leaves are to be of the indexed data type, while the other tree nodes can be of any C struct (but you still have to follow PostgreSQL data type rules here, see about `varlena` for variable sized data). If the tree's internal data type exists at the SQL level, the `STORAGE` option of the `CREATE OPERATOR CLASS` command can be used. The optional eighth method is `distance`, which is needed if the operator class wishes to support ordered scans (nearest-neighbor searches). The optional ninth method `fetch` is needed if the operator class wishes to support index-only scans, except when the `compress` method is omitted. The optional tenth method `options` is needed if the operator class has user-specified parameters. The optional eleventh method `sortsupport` is used to speed up building a GiST index.

consistent

Given an index entry $p$ and a query value $q$, this function determines whether the index entry is “consistent” with the query; that is, could the predicate “`indexed_column indexable_operator q`” be true for any row represented by the index entry? For a leaf index entry this is equivalent to testing the indexable condition, while for an internal tree node this determines whether it is necessary to scan the subtree of the index represented by the tree node. When the result is `true`, a `recheck` flag must also be returned. This indicates whether the predicate is certainly true or only possibly true. If `recheck = false` then the index has tested the predicate condition exactly, whereas if `recheck = true` the row is only a candidate match. In that case the system will automatically evaluate the `indexable_operator` against the actual row value to see if it is really a match. This convention allows GiST to support both lossless and lossy index structures.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_consistent(internal, data_type, smallint, oid, internal) 
RETURNS bool 
AS 'MODULE_PATHNAME' 
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_consistent);

Datum
my_consistent(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    data_type *query = PG_GETARG_DATA_TYPE_P(1);
    StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
    /* Oid subtype = PG_GETARG_OID(3); */
    bool       *recheck = (bool *) PG_GETARG_POINTER(4);
    data_type *key = DatumGetDataType(entry->key);
    bool     retval;

    /*
    * determine return value as a function of strategy, key and query.
    *
    * Use GIST_LEAF(entry) to know where you're called in the index tree,
    */
```
GiST Indexes

* which comes handy when supporting the = operator for example (you could
  * check for non empty union() in non-leaf nodes and equality in leaf
  * nodes).

*recheck = true;       /* or false if check is exact */

PG_RETURN_BOOL(retval);
}

Here, key is an element in the index and query the value being looked up in the index. The StrategyNumber parameter indicates which operator of your operator class is being applied — it matches one of the operator numbers in the CREATE OPERATOR CLASS command.

Depending on which operators you have included in the class, the data type of query could vary with the operator, since it will be whatever type is on the right-hand side of the operator, which might be different from the indexed data type appearing on the left-hand side. (The above code skeleton assumes that only one type is possible; if not, fetching the query argument value would have to depend on the operator.) It is recommended that the SQL declaration of the consistent function use the opclass's indexed data type for the query argument, even though the actual type might be something else depending on the operator.

union

This method consolidates information in the tree. Given a set of entries, this function generates a new index entry that represents all the given entries.

The SQL declaration of the function must look like this:

CREATE OR REPLACE FUNCTION my_union(internal, internal)
RETURNS storage_type
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

And the matching code in the C module could then follow this skeleton:

PG_FUNCTION_INFO_V1(my_union);

Datum
my_union(PG_FUNCTION_ARGS)
{
  GistEntryVector *entryvec = (GistEntryVector *)
PG_GETARG_POINTER(0);
  GISTENTRY  *ent = entryvec->vector;
  data_type  *out,
               *tmp,
               *old;
  int         numranges,
              i = 0;

numranges = entryvec->n;
GiST Indexes

tmp = DatumGetDataType(ent[0].key);
out = tmp;

if (numranges == 1)
{
    out = data_type_deep_copy(tmp);
    PG_RETURN_DATA_TYPE_P(out);
}

for (i = 1; i < numranges; i++)
{
    old = out;
    tmp = DatumGetDataType(ent[i].key);
    out = my_union_implementation(out, tmp);
}

PG_RETURN_DATA_TYPE_P(out);

As you can see, in this skeleton we're dealing with a data type where union(X, Y, Z) = union(union(X, Y), Z). It's easy enough to support data types where this is not the case, by implementing the proper union algorithm in this GiST support method.

The result of the union function must be a value of the index's storage type, whatever that is (it might or might not be different from the indexed column's type). The union function should return a pointer to newly palloc()ed memory. You can't just return the input value as-is, even if there is no type change.

As shown above, the union function's first internal argument is actually a GistEntryVector pointer. The second argument is a pointer to an integer variable, which can be ignored. (It used to be required that the union function store the size of its result value into that variable, but this is no longer necessary.)

compress

Converts a data item into a format suitable for physical storage in an index page. If the compress method is omitted, data items are stored in the index without modification.

The SQL declaration of the function must look like this:

CREATE OR REPLACE FUNCTION my_compress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

And the matching code in the C module could then follow this skeleton:

PG_FUNCTION_INFO_V1(my_compress);

Datum
my_compress(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
GiST Indexes

GISTENTRY *retval;

if (entry->leafkey)
{
    /* replace entry->key with a compressed version */
    compressed_data_type *compressed_data =
        palloc(sizeof(compressed_data_type));

    /* fill *compressed_data from entry->key ... */
    retval = palloc(sizeof(GISTENTRY));
    gistentryinit(*retval, PointerGetDatum(compressed_data),
        entry->rel, entry->page, entry->offset,
        FALSE);
}
else
{
    /* typically we needn't do anything with non-leaf entries */
    retval = entry;
}

PG_RETURN_POINTER(retval);

You have to adapt compressed_data_type to the specific type you're converting to in order to compress your leaf nodes, of course.

decompress

Converts the stored representation of a data item into a format that can be manipulated by the other GiST methods in the operator class. If the decompress method is omitted, it is assumed that the other GiST methods can work directly on the stored data format. (decompress is not necessarily the reverse of the compress method; in particular, if compress is lossy then it's impossible for decompress to exactly reconstruct the original data. decompress is not necessarily equivalent to fetch, either, since the other GiST methods might not require full reconstruction of the data.)

The SQL declaration of the function must look like this:

CREATE OR REPLACE FUNCTION my_decompress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

And the matching code in the C module could then follow this skeleton:

PG_FUNCTION_INFO_V1(my_decompress);

Datum
my_decompress(PG_FUNCTION_ARGS)
{
    PG_RETURN_POINTER(PG_GETARG_POINTER(0));
}
The above skeleton is suitable for the case where no decompression is needed. (But, of course, omitting the method altogether is even easier, and is recommended in such cases.)

penalty

Returns a value indicating the “cost” of inserting the new entry into a particular branch of the tree. Items will be inserted down the path of least penalty in the tree. Values returned by penalty should be non-negative. If a negative value is returned, it will be treated as zero.

The SQL declaration of the function must look like this:

CREATE OR REPLACE FUNCTION my_penalty(internal, internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT; -- in some cases penalty functions need not be strict

And the matching code in the C module could then follow this skeleton:

Datum
my_penalty(PG_FUNCTION_ARGS)
{
    GISTENTRY *origentry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *newentry = (GISTENTRY *) PG_GETARG_POINTER(1);
    float *penalty = (float *) PG_GETARG_POINTER(2);
    data_type *orig = DatumGetDataType(origentry->key);
    data_type *new = DatumGetDataType(newentry->key);

    *penalty = my_penalty_implementation(orig, new);
    PG_RETURN_POINTER(penalty);
}

For historical reasons, the penalty function doesn't just return a float result; instead it has to store the value at the location indicated by the third argument. The return value per se is ignored, though it's conventional to pass back the address of that argument.

The penalty function is crucial to good performance of the index. It'll get used at insertion time to determine which branch to follow when choosing where to add the new entry in the tree. At query time, the more balanced the index, the quicker the lookup.

picksplit

When an index page split is necessary, this function decides which entries on the page are to stay on the old page, and which are to move to the new page.

The SQL declaration of the function must look like this:

CREATE OR REPLACE FUNCTION my_picksplit(internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
And the matching code in the C module could then follow this skeleton:

```c
PG_FUNCTION_INFO_V1(my_picksplit);

Datum
my_picksplit(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
    GIST_SPLITVEC *v = (GIST_SPLITVEC *) PG_GETARG_POINTER(1);
    OffsetNumber maxoff = entryvec->n - 1;
    GISTENTRY *ent = entryvec->vector;
    int i,
        nbytes;
    OffsetNumber *left,
        *right;
    data_type *tmp_union;
    data_type *unionL;
    data_type *unionR;
    GISTENTRY **raw_entryvec;
    maxoff = entryvec->n - 1;
    nbytes = (maxoff + 1) * sizeof(OffsetNumber);
    v->spl_left = (OffsetNumber *) palloc(nbytes);
    left = v->spl_left;
    v->spl_nleft = 0;
    v->spl_right = (OffsetNumber *) palloc(nbytes);
    right = v->spl_right;
    v->spl_nright = 0;
    unionL = NULL;
    unionR = NULL;

    /* Initialize the raw entry vector. */
    raw_entryvec = (GISTENTRY **) malloc(entryvec->n * sizeof(void *));
    for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
        raw_entryvec[i] = &(entryvec->vector[i]);
    for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
    {
        int real_index = raw_entryvec[i] - entryvec->vector;
        tmp_union = DatumGetDataType(entryvec->vector[real_index].key);
        Assert(tmp_union != NULL);
    }
}
```

2567
GiST Indexes

* Choose where to put the index entries and update unionL and unionR
  * accordingly. Append the entries to either v->spl_left or v->spl_right, and care about the counters.
  */

if (my_choice_is_left(unionL, curl, unionR, curr))
{
  if (unionL == NULL)
    unionL = tmp_union;
  else
    unionL = my_union_implementation(unionL, tmp_union);

  *left = real_index;
  ++left;
  ++(v->spl_nleft);
}
else
{
  /*
    * Same on the right
    */
}

v->spl_ldatum = DataTypeGetDatum(unionL);
  v->spl_rdatum = DataTypeGetDatum(unionR);
    PG_RETURN_POINTER(v);
}

Notice that the picksplit function's result is delivered by modifying the passed-in v structure. The return value per se is ignored, though it's conventional to pass back the address of v.

Like penalty, the picksplit function is crucial to good performance of the index. Designing suitable penalty and picksplit implementations is where the challenge of implementing well-performing GiST indexes lies.

same

Returns true if two index entries are identical, false otherwise. (An “index entry” is a value of the index's storage type, not necessarily the original indexed column's type.)

The SQL declaration of the function must look like this:

CREATE OR REPLACE FUNCTION my_same(storage_type, storage_type, internal)
  RETURNS internal
    AS 'MODULE_PATHNAME'
    LANGUAGE C STRICT;

And the matching code in the C module could then follow this skeleton:
GiST Indexes

```
PG_FUNCTION_INFO_V1(my_same);

Datum
my_same(PG_FUNCTION_ARGS)
{
    prefix_range *v1 = PG_GETARG_PREFIX_RANGE_P(0);
    prefix_range *v2 = PG_GETARG_PREFIX_RANGE_P(1);
    bool       *result = (bool *) PG_GETARG_POINTER(2);

    *result = my_eq(v1, v2);
    PG_RETURN_POINTER(result);
}
```

For historical reasons, the `same` function doesn't just return a Boolean result; instead it has to store the flag at the location indicated by the third argument. The return value per se is ignored, though it's conventional to pass back the address of that argument.

distance

Given an index entry `p` and a query value `q`, this function determines the index entry's “distance” from the query value. This function must be supplied if the operator class contains any ordering operators. A query using the ordering operator will be implemented by returning index entries with the smallest “distance” values first, so the results must be consistent with the operator's semantics. For a leaf index entry the result just represents the distance to the index entry; for an internal tree node, the result must be the smallest distance that any child entry could have.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_distance(internal, data_type,
    smallint, oid, internal)
RETURNS float8
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_distance);

Datum
my_distance(PG_FUNCTION_ARGS)
{
    GISTENTRY  *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    data_type  *query = PG_GETARG_DATA_TYPE_P(1);
    StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
    /* Oid subtype = PG_GETARG_OID(3); */
    /* bool *recheck = (bool *) PG_GETARG_POINTER(4); */
    data_type  *key = DatumGetDataType(entry->key);
    double      retval;

    /*
        * determine return value as a function of strategy, key and
        query.
        */
```
The arguments to the distance function are identical to the arguments of the consistent function.

Some approximation is allowed when determining the distance, so long as the result is never greater than the entry's actual distance. Thus, for example, distance to a bounding box is usually sufficient in geometric applications. For an internal tree node, the distance returned must not be greater than the distance to any of the child nodes. If the returned distance is not exact, the function must set *recheck to true. (This is not necessary for internal tree nodes; for them, the calculation is always assumed to be inexact.) In this case the executor will calculate the accurate distance after fetching the tuple from the heap, and reorder the tuples if necessary.

If the distance function returns *recheck = true for any leaf node, the original ordering operator's return type must be float8 or float4, and the distance function's result values must be comparable to those of the original ordering operator, since the executor will sort using both distance function results and recalculated ordering-operator results. Otherwise, the distance function's result values can be any finite float8 values, so long as the relative order of the result values matches the order returned by the ordering operator. (Infinity and minus infinity are used internally to handle cases such as nulls, so it is not recommended that distance functions return these values.)

fetch

Converts the compressed index representation of a data item into the original data type, for index-only scans. The returned data must be an exact, non-lossy copy of the originally indexed value.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_fetch(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The argument is a pointer to a GISTENTRY struct. On entry, its key field contains a non-NULL leaf datum in compressed form. The return value is another GISTENTRY struct, whose key field contains the same datum in its original, uncompressed form. If the opclass's compress function does nothing for leaf entries, the fetch method can return the argument as-is. Or, if the opclass does not have a compress function, the fetch method can be omitted as well, since it would necessarily be a no-op.

The matching code in the C module could then follow this skeleton:

```
Datum
my_fetch(PG_FUNCTION_ARGS)
{
    GISTENTRY  *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    input_data_type *in = DatumGetPointer(entry->key);
    fetched_data_type *fetched_data;
    GISTENTRY  *retval;

    retval = palloc(sizeof(GISTENTRY));
    ```
fetched_data = palloc(sizeof(fetched_data_type));

/*
 * Convert 'fetched_data' into the a Datum of the original
datatype.
*/

/* fill *retval from fetched_data. */
gistentryinit(*retval, PointerGetDatum(converted_datum),
    entry->rel, entry->page, entry->offset, FALSE);

PG_RETURN_POINTER(retval);
}

If the compress method is lossy for leaf entries, the operator class cannot support index-only scans,
and must not define a fetch function.

options

Allows definition of user-visible parameters that control operator class behavior.

The SQL declaration of the function must look like this:

CREATE OR REPLACE FUNCTION my_options(internal)
RETURNS void
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

The function is passed a pointer to a local_relopts struct, which needs to be filled with a set of
operator class specific options. The options can be accessed from other support functions using the
PG_HAS_OPCLASS_OPTIONS() and PG_GET_OPCLASS_OPTIONS() macros.

An example implementation of my_options() and parameters use from other support functions are
given below:

typedef enum MyEnumType
{
    MY_ENUM_ON,
    MY_ENUM_OFF,
    MY_ENUM_AUTO
} MyEnumType;

typedef struct
{
    int32   vl_len_;   /* varlena header (do not touch directly!) */
    int     int_param; /* integer parameter */
    double  real_param; /* real parameter */
    MyEnumType enum_param; /* enum parameter */
    int     str_param;  /* string parameter */
} MyOptionsStruct;

/* String representation of enum values */
GiST Indexes

static relopt_enum_elt_def myEnumValues[] =
{
    {"on", MY_ENUM_ON},
    {"off", MY_ENUM_OFF},
    {"auto", MY_ENUM_AUTO},
    {(const char *) NULL} /* list terminator */
};

static char *str_param_default = "default";

/*
 * Sample validator: checks that string is not longer than 8 bytes.
 */
static void
validate_my_string_relopt(const char *value)
{
    if (strlen(value) > 8)
        ereport(ERROR,
            (errcode(ERRCODE_INVALID_PARAMETER_VALUE),
            errmsg("str_param must be at most 8 bytes"));
}

/*
 * Sample filler: switches characters to lower case.
 */
static Size
fill_my_string_relopt(const char *value, void *ptr)
{
    char   *tmp = str_tolower(value, strlen(value),
        DEFAULT_COLLATION_OID);
    int     len = strlen(tmp);

    if (ptr)
        strcpy((char *) ptr, tmp);

    pfree(tmp);
    return len + 1;
}

PG_FUNCTION_INFO_V1(my_options);

Datum
my_options(PG_FUNCTION_ARGS)
{
    local_relopts *relopts = (local_relopts *)
    PG_GETARG_POINTER(0);

    init_local_reloptions(relopts, sizeof(MyOptionsStruct));
    add_local_int_reloption(relopts, "int_param", "integer parameter",
        100, 0, 1000000,
        offsetof(MyOptionsStruct, int_param));
    add_local_real_reloption(relopts, "real_param", "real parameter",
        2572, 0, 10000000,
        offsetof(MyOptionsStruct, real_param));

offsetof(MyOptionsStruct,
str_param));

PG_RETURN_VOID();
}

PG_FUNCTION_INFO_V1(my_compress);

Datum
my_compress(PG_FUNCTION_ARGS)
{
    int     int_param = 100;
    double  real_param = 1.0;
    MyEnumType enum_param = MY_ENUM_ON;
    char   *str_param = str_param_default;
    
    /*
      * Normally, when opclass contains 'options' method, then options are always
      * passed to support functions. However, if you add 'options' method to
      * existing opclass, previously defined indexes have no options, so the
      * check is required.
      */
    if (PG_HAS_OPCLASS_OPTIONS())
    {
        MyOptionsStruct *options = (MyOptionsStruct *)
PG_GET_OPCLASS_OPTIONS();

        int_param = options->int_param;
        real_param = options->real_param;
        enum_param = options->enum_param;
        str_param = GET_STRING_RELOPTION(options, str_param);
    }
    
    /* the rest implementation of support function */
}
GiST Indexes

Since the representation of the key in GiST is flexible, it may depend on user-specified parameters. For instance, the length of key signature may be specified. See \texttt{gtsvector\_options()} for example.

\textbf{sortsupport}

Returns a comparator function to sort data in a way that preserves locality. It is used by \texttt{CREATE INDEX} and \texttt{REINDEX} commands. The quality of the created index depends on how well the sort order determined by the comparator function preserves locality of the inputs.

The \texttt{sortsupport} method is optional. If it is not provided, \texttt{CREATE INDEX} builds the index by inserting each tuple to the tree using the \texttt{penalty} and \texttt{picksplit} functions, which is much slower.

The SQL declaration of the function must look like this:

\begin{verbatim}
CREATE OR REPLACE FUNCTION my_sortsupport(internal)
RETURNS void
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
\end{verbatim}

The argument is a pointer to a \texttt{SortSupport} struct. At a minimum, the function must fill in its comparator field. The comparator takes three arguments: two Datums to compare, and a pointer to the \texttt{SortSupport} struct. The Datums are the two indexed values in the format that they are stored in the index; that is, in the format returned by the \texttt{compress} method. The full API is defined in \texttt{src/include/utils/sortsupport.h}.

The matching code in the C module could then follow this skeleton:

\begin{verbatim}
PG_FUNCTION_INFO_V1(my_sortsupport);

static int
my_fastcmp(Datum x, Datum y, SortSupport ssup)
{
    /* establish order between x and y by computing some sorting value z */

    int z1 = ComputeSpatialCode(x);
    int z2 = ComputeSpatialCode(y);

    return z1 == z2 ? 0 : z1 > z2 ? 1 : -1;
}

Datum
my_sortsupport(PG_FUNCTION_ARGS)
{
    SortSupport ssup = (SortSupport) PG_GETARG_POINTER(0);

    ssup->comparator = my_fastcmp;
    PG_RETURN_VOID();
}
\end{verbatim}

All the GiST support methods are normally called in short-lived memory contexts; that is, \texttt{CurrentMemoryContext} will get reset after each tuple is processed. It is therefore not very important to worry about \texttt{pfree\_ing} everything you \texttt{palloc}. However, in some cases it's useful for a support method to cache data across repeated calls. To do that, allocate the longer-lived data in \texttt{fcinfo->flinfo->fn\_mcxt},

2574
and keep a pointer to it in fcinfo->flinfo->fn_extra. Such data will survive for the life of the index operation (e.g., a single GiST index scan, index build, or index tuple insertion). Be careful to pfree the previous value when replacing a fn_extra value, or the leak will accumulate for the duration of the operation.

67.4. Implementation

67.4.1. GiST Index Build Methods

The simplest way to build a GiST index is just to insert all the entries, one by one. This tends to be slow for large indexes, because if the index tuples are scattered across the index and the index is large enough to not fit in cache, a lot of random I/O will be needed. PostgreSQL supports two alternative methods for initial build of a GiST index: sorted and buffered modes.

The sorted method is only available if each of the opclasses used by the index provides a sortsupport function, as described in Section 67.3. If they do, this method is usually the best, so it is used by default.

The buffered method works by not inserting tuples directly into the index right away. It can dramatically reduce the amount of random I/O needed for non-ordered data sets. For well-ordered data sets the benefit is smaller or non-existent, because only a small number of pages receive new tuples at a time, and those pages fit in cache even if the index as a whole does not.

The buffered method needs to call the penalty function more often than the simple method does, which consumes some extra CPU resources. Also, the buffers need temporary disk space, up to the size of the resulting index. Buffering can also influence the quality of the resulting index, in both positive and negative directions. That influence depends on various factors, like the distribution of the input data and the operator class implementation.

If sorting is not possible, then by default a GiST index build switches to the buffering method when the index size reaches effective_cache_size. Buffering can be manually forced or prevented by the buffering parameter to the CREATE INDEX command. The default behavior is good for most cases, but turning buffering off might speed up the build somewhat if the input data is ordered.

67.5. Examples

The PostgreSQL source distribution includes several examples of index methods implemented using GiST. The core system currently provides text search support (indexing for tsvector and tsquery) as well as R-Tree equivalent functionality for some of the built-in geometric data types (see src/backend/access/gist/gistproc.c). The following contrib modules also contain GiST operator classes:

btree_gist
  B-tree equivalent functionality for several data types
cube
  Indexing for multidimensional cubes
hstore
  Module for storing (key, value) pairs
intarray
  RD-Tree for one-dimensional array of int4 values
GiST Indexes

ltree
   Indexing for tree-like structures

pg_trgm
   Text similarity using trigram matching

seg
   Indexing for “float ranges”
Chapter 68. SP-GiST Indexes

68.1. Introduction

SP-GiST is an abbreviation for space-partitioned GiST. SP-GiST supports partitioned search trees, which facilitate development of a wide range of different non-balanced data structures, such as quad-trees, k-d trees, and radix trees (tries). The common feature of these structures is that they repeatedly divide the search space into partitions that need not be of equal size. Searches that are well matched to the partitioning rule can be very fast.

These popular data structures were originally developed for in-memory usage. In main memory, they are usually designed as a set of dynamically allocated nodes linked by pointers. This is not suitable for direct storing on disk, since these chains of pointers can be rather long which would require too many disk accesses. In contrast, disk-based data structures should have a high fanout to minimize I/O. The challenge addressed by SP-GiST is to map search tree nodes to disk pages in such a way that a search need access only a few disk pages, even if it traverses many nodes.

Like GiST, SP-GiST is meant to allow the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from Purdue University’s SP-GiST Indexing Project web site\(^1\). The SP-GiST implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their web site\(^2\).

68.2. Built-in Operator Classes

The core PostgreSQL distribution includes the SP-GiST operator classes shown in Table 68.1.

Table 68.1. Built-in SP-GiST Operator Classes

Of the two operator classes for type `point`, `quad_point_ops` is the default. `kd_point_ops` supports the same operators but uses a different index data structure that may offer better performance in some applications.

The `quad_point_ops`, `kd_point_ops` and `poly_ops` operator classes support the `<->` ordering operator, which enables the k-nearest neighbor (k-NN) search over indexed point or polygon data sets.

### 68.3. Extensibility

SP-GiST offers an interface with a high level of abstraction, requiring the access method developer to implement only methods specific to a given data type. The SP-GiST core is responsible for efficient disk mapping and searching the tree structure. It also takes care of concurrency and logging considerations.

Leaf tuples of an SP-GiST tree usually contain values of the same data type as the indexed column, although it is also possible for them to contain lossy representations of the indexed column. Leaf tuples stored at the root level will directly represent the original indexed data value, but leaf tuples at lower levels might contain only a partial value, such as a suffix. In that case the operator class support functions must be able to reconstruct the original value using information accumulated from the inner tuples that are passed through to reach the leaf level.

When an SP-GiST index is created with `INCLUDE` columns, the values of those columns are also stored in leaf tuples. The `INCLUDE` columns are of no concern to the SP-GiST operator class, so they are not discussed further here.

Inner tuples are more complex, since they are branching points in the search tree. Each inner tuple contains a set of one or more `nodes`, which represent groups of similar leaf values. A node contains a downlink that leads either to another, lower-level inner tuple, or to a short list of leaf tuples that all lie on the same index page. Each node normally has a `label` that describes it; for example, in a radix tree the node label could be the next character of the string value. (Alternatively, an operator class can omit the node labels,
if it works with a fixed set of nodes for all inner tuples; see Section 68.4.2.) Optionally, an inner tuple can have a *prefix* value that describes all its members. In a radix tree this could be the common prefix of the represented strings. The prefix value is not necessarily really a prefix, but can be any data needed by the operator class; for example, in a quad-tree it can store the central point that the four quadrants are measured with respect to. A quad-tree inner tuple would then also contain four nodes corresponding to the quadrants around this central point.

Some tree algorithms require knowledge of level (or depth) of the current tuple, so the SP-GiST core provides the possibility for operator classes to manage level counting while descending the tree. There is also support for incrementally reconstructing the represented value when that is needed, and for passing down additional data (called *traverse values*) during a tree descent.

**Note**

The SP-GiST core code takes care of null entries. Although SP-GiST indexes do store entries for nulls in indexed columns, this is hidden from the index operator class code: no null index entries or search conditions will ever be passed to the operator class methods. (It is assumed that SP-GiST operators are strict and so cannot succeed for null values.) Null values are therefore not discussed further here.

There are five user-defined methods that an index operator class for SP-GiST must provide, and two are optional. All five mandatory methods follow the convention of accepting two *internal* arguments, the first of which is a pointer to a C struct containing input values for the support method, while the second argument is a pointer to a C struct where output values must be placed. Four of the mandatory methods just return *void*, since all their results appear in the output struct; but *leaf_consistent* returns a *boolean* result. The methods must not modify any fields of their input structs. In all cases, the output struct is initialized to zeroes before calling the user-defined method. The optional sixth method *compress* accepts a *datum* to be indexed as the only argument and returns a value suitable for physical storage in a leaf tuple. The optional seventh method *options* accepts an *internal* pointer to a C struct, where opclass-specific parameters should be placed, and returns *void*.

The five mandatory user-defined methods are:

- **config**
  Returns static information about the index implementation, including the data type OIDs of the prefix and node label data types.

  The SQL declaration of the function must look like this:

  ```sql
  CREATE FUNCTION my_config(internal, internal) RETURNS void ...
  ```

  The first argument is a pointer to a *spgConfigIn* C struct, containing input data for the function. The second argument is a pointer to a *spgConfigOut* C struct, which the function must fill with result data.

  ```c
  typedef struct spgConfigIn
  {
      Oid attType;        /* Data type to be indexed */
  } spgConfigIn;

  typedef struct spgConfigOut
  {
  ```

  2580
attType is passed in order to support polymorphic index operator classes; for ordinary fixed-data-type operator classes, it will always have the same value and so can be ignored.

For operator classes that do not use prefixes, prefixType can be set to VOIDOID. Likewise, for operator classes that do not use node labels, labelType can be set to VOIDOID. canReturnData should be set true if the operator class is capable of reconstructing the originally-supplied index value. longValuesOK should be set true only when the attType is of variable length and the operator class is capable of segmenting long values by repeated suffixing (see Section 68.4.1).

leafType should match the index storage type defined by the operator class's opckeytype catalog entry. (Note that opckeytype can be zero, implying the storage type is the same as the operator class's input type, which is the most common situation.) For reasons of backward compatibility, the config method can set leafType to some other value, and that value will be used; but this is deprecated since the index contents are then incorrectly identified in the catalogs. Also, it's permissible to leave leafType uninitialized (zero); that is interpreted as meaning the index storage type derived from opckeytype.

When attType and leafType are different, the optional method compress must be provided. Method compress is responsible for transformation of datums to be indexed from attType to leafType.

choose

Chooses a method for inserting a new value into an inner tuple.

The SQL declaration of the function must look like this:

CREATE FUNCTION my_choose(internal, internal) RETURNS void ...

The first argument is a pointer to a spgChooseIn C struct, containing input data for the function. The second argument is a pointer to a spgChooseOut C struct, which the function must fill with result data.

typedef struct spgChooseIn
{
  Datum       datum;          /* original datum to be indexed */
  Datum       leafDatum;      /* current datum to be stored at
leaf */
  int         level;          /* current level (counting from
zero) */
  /* Data from current inner tuple */
  bool        allTheSame;     /* tuple is marked all-the-same? */
} spgChooseOut;
bool hasPrefix; /* tuple has a prefix? */
Datum prefixDatum; /* if so, the prefix value */
int nNodes; /* number of nodes in the inner tuple */
Datum *nodeLabels; /* node label values (NULL if none) */
} spgChooseIn;

typedef enum spgChooseResultType
{
    spgMatchNode = 1, /* descend into existing node */
    spgAddNode, /* add a node to the inner tuple */
    spgSplitTuple /* split inner tuple (change its prefix) */
} spgChooseResultType;

typedef struct spgChooseOut
{
    spgChooseResultType resultType; /* action code, see above */
    union
    {  /* results for spgMatchNode */
        struct
        {
            int nodeN; /* descend to this node (index from 0) */
            int levelAdd; /* increment level by this much */
            Datum restDatum; /* new leaf datum */
        } matchNode;
    }
    struct /* results for spgAddNode */
    {  /* results for spgAddNode */
        Datum nodeLabel; /* new node's label */
        int nodeN; /* where to insert it (index from 0) */
    } addNode;
    struct /* results for spgSplitTuple */
    {  /* Info to form new upper-level inner tuple with one child tuple */
        bool prefixHasPrefix; /* tuple should have a prefix? */
        Datum prefixPrefixDatum; /* if so, its value */
        int prefixNNodes; /* number of nodes */
        Datum *prefixNodeLabels; /* their labels (or NULL for * no labels) */
        int childNodeN; /* which node gets child tuple */
    }
    /* Info to form new lower-level inner tuple with all old nodes */
    bool postfixHasPrefix; /* tuple should have a prefix? */
Datum postfixPrefixDatum; /* if so, its value */
} splitTuple;
} result;
} spgChooseOut;

datum is the original datum of spgConfigIn.attType type that was to be inserted into the index.
leafDatum is a value of spgConfigOut.leafType type, which is initially a result of method
compress applied to datum when method compress is provided, or the same value as datum
otherwise. leafDatum can change at lower levels of the tree if the choose or picksplit methods
change it. When the insertion search reaches a leaf page, the current value of leafDatum is what
will be stored in the newly created leaf tuple. level is the current inner tuple's level, starting at zero
for the root level. allTheSame is true if the current inner tuple is marked as containing multiple
equivalent nodes (see Section 68.4.3). hasPrefix is true if the current inner tuple contains a prefix;
if so, prefixDatum is its value. nNodes is the number of child nodes contained in the inner tuple,
and nodeLabels is an array of their label values, or NULL if there are no labels.

The choose function can determine either that the new value matches one of the existing child nodes,
or that a new child node must be added, or that the new value is inconsistent with the tuple prefix and
so the inner tuple must be split to create a less restrictive prefix.

If the new value matches one of the existing child nodes, set resultType to spgMatchNode. Set
nodeN to the index (from zero) of that node in the node array. Set levelAdd to the increment in
level caused by descending through that node, or leave it as zero if the operator class does not use
levels. Set restDatum to equal leafDatum if the operator class does not modify datums from one
level to the next, or otherwise set it to the modified value to be used as leafDatum at the next level.

If a new child node must be added, set resultType to spgAddNode. Set nodeLabel to the label
to be used for the new node, and set nodeN to the index (from zero) at which to insert the node in
the node array. After the node has been added, the choose function will be called again with the
modified inner tuple; that call should result in an spgMatchNode result.

If the new value is inconsistent with the tuple prefix, set resultType to spgSplitTuple. This
action moves all the existing nodes into a new lower-level inner tuple, and replaces the existing inner
tuple with a tuple having a single downlink pointing to the new lower-level inner tuple. Set prefix-
HasPrefix to indicate whether the new upper tuple should have a prefix, and if so set prefix-
PrefixDatum to the prefix value. This new prefix value must be sufficiently less restrictive than the
original to accept the new value to be indexed. Set prefixNNodes to the number of nodes needed
in the new tuple, and set prefixNodeLabels to a palloc'd array holding their labels, or to NULL
if node labels are not required. Note that the total size of the new upper tuple must be no more than the
total size of the tuple it is replacing; this constrains the lengths of the new prefix and new labels. Set
childNodeN to the index (from zero) of the node that will downlink to the new lower-level inner
tuple. Set postfixHasPrefix to indicate whether the new lower-level inner tuple should have
a prefix, and if so set postfixPrefixDatum to the prefix value. The combination of these two
prefixes and the downlink node's label (if any) must have the same meaning as the original prefix,
because there is no opportunity to alter the node labels that are moved to the new lower-level tuple, nor
to change any child index entries. After the node has been split, the choose function will be called
again with the replacement inner tuple. That call may return an spgAddNode result, if no suitable
node was created by the spgSplitTuple action. Eventually choose must return spgMatchN-
ode to allow the insertion to descend to the next level.

picksplit

Decides how to create a new inner tuple over a set of leaf tuples.

The SQL declaration of the function must look like this:
CREATE FUNCTION my_picksplit(internal, internal) RETURNS void ...

The first argument is a pointer to a spgPickSplitIn C struct, containing input data for the function. The second argument is a pointer to a spgPickSplitOut C struct, which the function must fill with result data.

typedef struct spgPickSplitIn
{
    int nTuples;        /* number of leaf tuples */
    Datum *datums;      /* their datums (array of length nTuples) */
    int level;          /* current level (counting from zero) */
} spgPickSplitIn;

typedef struct spgPickSplitOut
{
    bool hasPrefix;      /* new inner tuple should have a prefix? */
    Datum prefixDatum;   /* if so, its value */
    int nNodes;          /* number of nodes for new inner tuple */
    Datum *nodeLabels;   /* their labels (or NULL for no labels) */
    int *mapTuplesToNodes; /* node index for each leaf tuple */
    Datum *leafTupleDatums; /* datum to store in each new leaf tuple */
} spgPickSplitOut;

nTuples is the number of leaf tuples provided. datums is an array of their datum values of spg-ConfigOut.leafType type. level is the current level that all the leaf tuples share, which will become the level of the new inner tuple.

Set hasPrefix to indicate whether the new inner tuple should have a prefix, and if so set prefixDatum to the prefix value. Set nNodes to indicate the number of nodes that the new inner tuple will contain, and set nodeLabels to an array of their label values, or to NULL if node labels are not required. Set mapTuplesToNodes to an array that gives the index (from zero) of the node that each leaf tuple should be assigned to. Set leafTupleDatums to an array of the values to be stored in the new leaf tuples (these will be the same as the input datums if the operator class does not modify datums from one level to the next). Note that the picksplit function is responsible for palloc'ing the nodeLabels, mapTuplesToNodes and leafTupleDatums arrays.

If more than one leaf tuple is supplied, it is expected that the picksplit function will classify them into more than one node; otherwise it is not possible to split the leaf tuples across multiple pages, which is the ultimate purpose of this operation. Therefore, if the picksplit function ends up placing all the leaf tuples in the same node, the core SP-GiST code will override that decision and generate an inner tuple in which the leaf tuples are assigned at random to several identically-labeled nodes. Such a tuple is marked allTheSame to signify that this has happened. The choose and inner_consistent functions must take suitable care with such inner tuples. See Section 68.4.3 for more information.
picksplit can be applied to a single leaf tuple only in the case that the \texttt{config} function set \texttt{longValuesOK} to true and a larger-than-a-page input value has been supplied. In this case the point of the operation is to strip off a prefix and produce a new, shorter leaf datum value. The call will be repeated until a leaf datum short enough to fit on a page has been produced. See Section 68.4.1 for more information.

\texttt{inner\_consistent}

Returns set of nodes (branches) to follow during tree search.

The SQL declaration of the function must look like this:

\begin{verbatim}
CREATE FUNCTION my_inner_consistent(internal, internal) RETURNS void ...
\end{verbatim}

The first argument is a pointer to a \texttt{spgInnerConsistentIn C struct}, containing input data for the function. The second argument is a pointer to a \texttt{spgInnerConsistentOut C struct}, which the function must fill with result data.

\begin{verbatim}
typedef struct spgInnerConsistentIn {
    ScanKey     scankeys;       /* array of operators and
        comparison values */
    ScanKey     orderbys;       /* array of ordering operators and
        comparison values */
    int         nkeys;          /* length of scankeys array */
    int         norderbys;      /* length of orderbys array */
    Datum       reconstructedValue;     /* value reconstructed at
        parent */
    void       *traversalValue; /* opclass-specific traverse value */
    MemoryContext traversalMemoryContext;   /* put new traverse
        values here */
    int         level;          /* current level (counting from
        zero) */
    bool        returnData;     /* original data must be returned? */
    ...  
} spgInnerConsistentIn;

typedef struct spgInnerConsistentOut {
    ...  
} spgInnerConsistentOut;
\end{verbatim}
int nNodes; /* number of child nodes to be visited */
int *nodeNumbers; /* their indexes in the node array */
int *levelAdds; /* increment level by this much for each */
Datum *reconstructedValues; /* associated reconstructed values */
void **traversalValues; /* opclass-specific traverse values */
double **distances; /* associated distances */
}

spgInnerConsistentOut;

The array scankeys, of length nkeys, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them are interesting. (Note that nkeys = 0 implies that all index entries satisfy the query.) Usually the consistent function only cares about the sk_strategy and sk_argument fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check sk_flags to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. The array orderbys, of length norderbys, describes ordering operators (if any) in the same manner. reconstructedValue is the value reconstructed for the parent tuple; it is (Datum) 0 at the root level or if the inner_consistent function did not provide a value at the parent level. traversalValue is a pointer to any traverse data passed down from the previous call of inner_consistent on the parent index tuple, or NULL at the root level. traversalMemoryContext is the memory context in which to store output traverse values (see below). level is the current inner tuple's level, starting at zero for the root level. returnData is true if reconstructed data is required for this query; this will only be so if the config function asserted canReturnData. allTheSame is true if the current inner tuple is marked “all-the-same”; in this case all the nodes have the same label (if any) and so either all or none of them match the query (see Section 68.4.3). hasPrefix is true if the current inner tuple contains a prefix; if so, prefixDatum is its value. nNodes is the number of child nodes contained in the inner tuple, and nodeLabels is an array of their label values, or NULL if the nodes do not have labels.

nNodes must be set to the number of child nodes that need to be visited by the search, and nodeNumbers must be set to an array of their indexes. If the operator class keeps track of levels, set levelAdds to an array of the level increments required when descending to each node to be visited. (Often these increments will be the same for all the nodes, but that’s not necessarily so, so an array is used.) If value reconstruction is needed, set reconstructedValues to an array of the values reconstructed for each child node to be visited; otherwise, leave reconstructedValues as NULL. The reconstructed values are assumed to be of type spgConfigOut.leafType. (However, since the core system will do nothing with them except possibly copy them, it is sufficient for them to have the same typlen and typbyval properties as leafType.) If ordered search is performed, set distances to an array of distance values according to orderbys array (nodes with lowest distances will be processed first). Leave it NULL otherwise. If it is desired to pass down additional out-of-band information (“traverse values”) to lower levels of the tree search, set traversalValues to an array of the appropriate traverse values, one for each child node to be visited; otherwise, leave traversalValues as NULL. Note that the inner_consistent function is responsible for palloc'ing the nodeNumbers, levelAdds, distances, reconstructedValues, and traversalValues arrays in the current memory context. However, any output traverse values pointed to by the traversalValues array should be allocated in traversalMemoryContext. Each traverse value must be a single palloc'd chunk.

leaf_consistent

Returns true if a leaf tuple satisfies a query.
The SQL declaration of the function must look like this:

```sql
CREATE FUNCTION my_leaf_consistent(internal, internal) RETURNS bool ...
```

The first argument is a pointer to a `spgLeafConsistentIn` C struct, containing input data for the function. The second argument is a pointer to a `spgLeafConsistentOut` C struct, which the function must fill with result data.

```c
typedef struct spgLeafConsistentIn
{
    ScanKey scankeys;       /* array of operators and
    comparison values */
    ScanKey orderbys;       /* array of ordering operators and
    comparison * values */
    int nkeys;          /* length of scankeys array */
    int norderbys;      /* length of orderbys array */
    Datum reconstructedValue;     /* value reconstructed at
    parent */
    void *traversalValue; /* opclass-specific traverse value */
    int level;          /* current level (counting from
    zero) */
    bool returnData;     /* original data must be returned? */
    Datum leafDatum;      /* datum in leaf tuple */
} spgLeafConsistentIn;

typedef struct spgLeafConsistentOut
{
    Datum leafValue;        /* reconstructed original data, if any */
    bool rechecked;          /* set true if operator must be
    rechecked */
    bool recheckDistances;   /* set true if distances must be
    rechecked */
    double *distances;        /* associated distances */
} spgLeafConsistentOut;
```

The array `scankeys`, of length `nkeys`, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them satisfy the query. (Note that `nkeys` = 0 implies that all index entries satisfy the query.) Usually the consistent function only cares about the `sk_strategy` and `sk_argument` fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check `sk_flags` to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. The array `orderbys`, of length `norderbys`, describes the ordering operators in the same manner. `reconstructedValue` is the value reconstructed for the parent tuple; it is (Datum) 0 at the root level or if the inner consistent function did not provide a value at the parent level. `traversalValue` is a pointer to any traverse data passed down from the previous call of `inner_consistent` on the parent index tuple, or NULL at the root level. `level` is the current leaf tuple's level,
starting at zero for the root level. returnData is true if reconstructed data is required for this query; this will only be so if the config function asserted canReturnData. leafDatum is the key value of spgConfigOut.leafType stored in the current leaf tuple.

The function must return true if the leaf tuple matches the query, or false if not. In the true case, if returnData is true then leafValue must be set to the value (of type spgConfigIn.attType) originally supplied to be indexed for this leaf tuple. Also, recheck may be set to true if the match is uncertain and so the operator(s) must be re-applied to the actual heap tuple to verify the match. If ordered search is performed, set distances to an array of distance values according to orderbys array. Leave it NULL otherwise. If at least one of returned distances is not exact, set recheckDistances to true. In this case, the executor will calculate the exact distances after fetching the tuple from the heap, and will reorder the tuples if needed.

The optional user-defined methods are:

Datum compress(Datum in)

Converts a data item into a format suitable for physical storage in a leaf tuple of the index. It accepts a value of type spgConfigIn.attType and returns a value of type spgConfigOut.leafType. The output value must not contain an out-of-line TOAST pointer.

Note: the compress method is only applied to values to be stored. The consistent methods receive query scankeys unchanged, without transformation using compress.

options

Defines a set of user-visible parameters that control operator class behavior.

The SQL declaration of the function must look like this:

CREATE OR REPLACE FUNCTION my_options(internal)
RETURNS void
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

The function is passed a pointer to a local_relopts struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the PG_HAS_OPCLASS_OPTIONS() and PG_GET_OPCLASS_OPTIONS() macros.

Since the representation of the key in SP-GiST is flexible, it may depend on user-specified parameters.

All the SP-GiST support methods are normally called in a short-lived memory context; that is, Current-MemoryContext will be reset after processing of each tuple. It is therefore not very important to worry about freeing everything you malloc. (The config method is an exception: it should try to avoid leaking memory. But usually the config method need do nothing but assign constants into the passed parameter struct.)

If the indexed column is of a collatable data type, the index collation will be passed to all the support methods, using the standard PG_GET_COLLATION() mechanism.

### 68.4. Implementation

This section covers implementation details and other tricks that are useful for implementers of SP-GiST operator classes to know.
68.4.1. SP-GiST Limits

Individual leaf tuples and inner tuples must fit on a single index page (8kB by default). Therefore, when indexing values of variable-length data types, long values can only be supported by methods such as radix trees, in which each level of the tree includes a prefix that is short enough to fit on a page, and the final leaf level includes a suffix also short enough to fit on a page. The operator class should set $longValuesOK$ to true only if it is prepared to arrange for this to happen. Otherwise, the SP-GiST core will reject any request to index a value that is too large to fit on an index page.

Likewise, it is the operator class's responsibility that inner tuples do not grow too large to fit on an index page; this limits the number of child nodes that can be used in one inner tuple, as well as the maximum size of a prefix value.

Another limitation is that when an inner tuple's node points to a set of leaf tuples, those tuples must all be in the same index page. (This is a design decision to reduce seeking and save space in the links that chain such tuples together.) If the set of leaf tuples grows too large for a page, a split is performed and an intermediate inner tuple is inserted. For this to fix the problem, the new inner tuple must divide the set of leaf values into more than one node group. If the operator class's $picksplit$ function fails to do that, the SP-GiST core resorts to extraordinary measures described in Section 68.4.3.

When $longValuesOK$ is true, it is expected that successive levels of the SP-GiST tree will absorb more and more information into the prefixes and node labels of the inner tuples, making the required leaf datum smaller and smaller, so that eventually it will fit on a page. To prevent bugs in operator classes from causing infinite insertion loops, the SP-GiST core will raise an error if the leaf datum does not become any smaller within ten cycles of $choose$ method calls.

68.4.2. SP-GiST Without Node Labels

Some tree algorithms use a fixed set of nodes for each inner tuple; for example, in a quad-tree there are always exactly four nodes corresponding to the four quadrants around the inner tuple's centroid point. In such a case the code typically works with the nodes by number, and there is no need for explicit node labels. To suppress node labels (and thereby save some space), the $picksplit$ function can return NULL for the $nodeLabels$ array, and likewise the $choose$ function can return NULL for the $prefixNodeLabels$ array during a $spgSplitTuple$ action. This will in turn result in $nodeLabels$ being NULL during subsequent calls to $choose$ and $inner_consistent$. In principle, node labels could be used for some inner tuples and omitted for others in the same index.

When working with an inner tuple having unlabeled nodes, it is an error for $choose$ to return $spgAddNode$, since the set of nodes is supposed to be fixed in such cases.

68.4.3. “All-the-Same” Inner Tuples

The SP-GiST core can override the results of the operator class's $picksplit$ function when $picksplit$ fails to divide the supplied leaf values into at least two node categories. When this happens, the new inner tuple is created with multiple nodes that each have the same label (if any) that $picksplit$ gave to the one node it did use, and the leaf values are divided at random among these equivalent nodes. The $allTheSame$ flag is set on the inner tuple to warn the $choose$ and $inner_consistent$ functions that the tuple does not have the node set that they might otherwise expect.

When dealing with an $allTheSame$ tuple, a $choose$ result of $spgMatchNode$ is interpreted to mean that the new value can be assigned to any of the equivalent nodes; the core code will ignore the supplied $nodeN$ value and descend into one of the nodes at random (so as to keep the tree balanced). It is an error for $choose$ to return $spgAddNode$, since that would make the nodes not all equivalent; the $spgSplitTuple$ action must be used if the value to be inserted doesn't match the existing nodes.
When dealing with an allTheSame tuple, the inner_consistent function should return either all or none of the nodes as targets for continuing the index search, since they are all equivalent. This may or may not require any special-case code, depending on how much the inner_consistent function normally assumes about the meaning of the nodes.

68.5. Examples

The PostgreSQL source distribution includes several examples of index operator classes for SP-GiST, as described in Table 68.1. Look into src/backend/access/spgist/ and src/backend/utils/adt/ to see the code.
Chapter 69. GIN Indexes

69.1. Introduction

GIN stands for Generalized Inverted Index. GIN is designed for handling cases where the items to be indexed are composite values, and the queries to be handled by the index need to search for element values that appear within the composite items. For example, the items could be documents, and the queries could be searches for documents containing specific words.

We use the word *item* to refer to a composite value that is to be indexed, and the word *key* to refer to an element value. GIN always stores and searches for keys, not item values per se.

A GIN index stores a set of (key, posting list) pairs, where a *posting list* is a set of row IDs in which the key occurs. The same row ID can appear in multiple posting lists, since an item can contain more than one key. Each key value is stored only once, so a GIN index is very compact for cases where the same key appears many times.

GIN is generalized in the sense that the GIN access method code does not need to know the specific operations that it accelerates. Instead, it uses custom strategies defined for particular data types. The strategy defines how keys are extracted from indexed items and query conditions, and how to determine whether a row that contains some of the key values in a query actually satisfies the query.

One advantage of GIN is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert. This is much the same advantage as using GiST.

The GIN implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov. There is more information about GIN on their website.

69.2. Built-in Operator Classes

The core PostgreSQL distribution includes the GIN operator classes shown in Table 69.1. (Some of the optional modules described in Appendix F provide additional GIN operator classes.)

Of the two operator classes for type jsonb, jsonb_ops is the default. jsonb_path_ops supports fewer operators but offers better performance for those operators. See Section 8.14.4 for details.

69.3. Extensibility

The GIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GIN layer itself takes care of concurrency, logging and searching the tree structure.

All it takes to get a GIN access method working is to implement a few user-defined methods, which define the behavior of keys in the tree and the relationships between keys, indexed items, and indexable queries. In short, GIN combines extensibility with generality, code reuse, and a clean interface.

There are two methods that an operator class for GIN must provide:

\[
\text{Datum *extractValue(Datum itemValue, int32 *nkeys, bool **nullFlags)}
\]

Returns a palloc'd array of keys given an item to be indexed. The number of returned keys must be stored into *nkeys. If any of the keys can be null, also palloc an array of *nkeys bool fields, store its address at *nullFlags, and set these null flags as needed. *nullFlags can be left NULL (its initial value) if all keys are non-null. The return value can be NULL if the item contains no keys.

\[
\text{Datum *extractQuery(Datum query, int32 *nkeys, StrategyNumber n, bool **pmatch, Pointer **extra_data, bool **nullFlags, int32 *searchMode)}
\]

Returns a palloc'd array of keys given a value to be queried; that is, query is the value on the right-hand side of an indexable operator whose left-hand side is the indexed column. n is the strategy number of the operator within the operator class (see Section 38.16.2). Often, extractQuery will need to consult n to determine the data type of query and the method it should use to extract key values. The number of returned keys must be stored into *nkeys. If any of the keys can be null, also palloc an array of *nkeys bool fields, store its address at *nullFlags, and set these null flags as needed. *nullFlags can be left NULL (its initial value) if all keys are non-null. The return value can be NULL if the query contains no keys.

searchMode is an output argument that allows extractQuery to specify details about how the search will be done. If *searchMode is set to GIN_SEARCH_MODE_DEFAULT (which is the value it is initialized to before call), only items that match at least one of the returned keys are considered candidate matches. If *searchMode is set to GIN_SEARCH_MODE_INCLUDE_EMPTY, then in addition to items containing at least one matching key, items that contain no keys at all are considered candidate matches. (This mode is useful for implementing is-subset-of operators, for example.) If *searchMode is set to GIN_SEARCH_MODE_ALL, then all non-null items in the index are considered candidate matches, whether they match any of the returned keys or not. (This mode is much slower than the other two choices, since it requires scanning essentially the entire index, but it may be necessary to implement corner cases correctly. An operator that needs this mode in most cases is probably not a good candidate for a GIN operator class.) The symbols to use for setting this mode are defined in access/gin.h.
pmatch is an output argument for use when partial match is supported. To use it, extractQuery
must allocate an array of *nkeys bools and store its address at *pmatch. Each element of the
array should be set to true if the corresponding key requires partial match, false if not. If *pmatch is
set to NULL then GIN assumes partial match is not required. The variable is initialized to NULL before
call, so this argument can simply be ignored by operator classes that do not support partial match.

extra_data is an output argument that allows extractQuery to pass additional data to the
consistent and comparePartial methods. To use it, extractQuery must allocate an array
of *nkeys pointers and store its address at *extra_data, then store whatever it wants to into the
individual pointers. The variable is initialized to NULL before call, so this argument can simply be
ignored by operator classes that do not require extra data. If *extra_data is set, the whole array is
passed to the consistent method, and the appropriate element to the comparePartial method.

An operator class must also provide a function to check if an indexed item matches the query. It comes
in two flavors, a Boolean consistent function, and a ternary triConsistent function. triConsistent
covers the functionality of both, so providing triConsistent alone is sufficient. However,
if the Boolean variant is significantly cheaper to calculate, it can be advantageous to provide both. If only
the Boolean variant is provided, some optimizations that depend on refuting index items before fetching
all the keys are disabled.

bool consistent(bool check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], bool *recheck, Datum queryKeys[], bool nullFlags[])

Returns true if an indexed item satisfies the query operator with strategy number n (or might satisfy
it, if the recheck indication is returned). This function does not have direct access to the indexed
item's value, since GIN does not store items explicitly. Rather, what is available is knowledge about
which key values extracted from the query appear in a given indexed item. The check array has
length nkeys, which is the same as the number of keys previously returned by extractQuery
for this query datum. Each element of the check array is true if the indexed item contains the
corresponding query key, i.e., if (check[i] == true) the i-th key of the extractQuery result array is
present in the indexed item. The original query datum is passed in case the consistent method
needs to consult it, and so are the queryKeys[] and nullFlags[] arrays previously returned
by extractQuery. extra_data is the extra-data array returned by extractQuery, or NULL
if none.

When extractQuery returns a null key in queryKeys[], the corresponding check[] element
is true if the indexed item contains a null key; that is, the semantics of check[] are like IS NOT
DISTINCT FROM. The consistent function can examine the corresponding nullFlags[]
element if it needs to tell the difference between a regular value match and a null match.

On success, *recheck should be set to true if the heap tuple needs to be rechecked against the query
operator, or false if the index test is exact. That is, a false return value guarantees that the heap tuple
does not match the query; a true return value with *recheck set to false guarantees that the heap
tuple does match the query; and a true return value with *recheck set to true means that the heap
tuple might match the query, so it needs to be fetched and rechecked by evaluating the query operator
directly against the originally indexed item.

GinTernaryValue triConsistent(GinTernaryValue check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], Datum queryKeys[], bool nullFlags[])

triConsistent is similar to consistent, but instead of Booleans in the check vector, there
are three possible values for each key: GIN_TRUE, GIN_FALSE and GIN_MAYBE. GIN_FALSE
and GIN_TRUE have the same meaning as regular Boolean values, while GIN_MAYBE means that
the presence of that key is not known. When GIN_MAYBE values are present, the function should only return GIN_TRUE if the item certainly matches whether or not the index item contains the corresponding query keys. Likewise, the function must return GIN_FALSE only if the item certainly does not match, whether or not it contains the GIN_MAYBE keys. If the result depends on the GIN_MAYBE entries, i.e., the match cannot be confirmed or refuted based on the known query keys, the function must return GIN_MAYBE.

When there are no GIN_MAYBE values in the check vector, a GIN_MAYBE return value is the equivalent of setting the recheck flag in the Boolean consistent function.

In addition, GIN must have a way to sort the key values stored in the index. The operator class can define the sort ordering by specifying a comparison method:

```c
int compare(Datum a, Datum b)
```

Compares two keys (not indexed items!) and returns an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second. Null keys are never passed to this function.

Alternatively, if the operator class does not provide a `compare` method, GIN will look up the default btree operator class for the index key data type, and use its comparison function. It is recommended to specify the comparison function in a GIN operator class that is meant for just one data type, as looking up the btree operator class costs a few cycles. However, polymorphic GIN operator classes (such as `array_ops`) typically cannot specify a single comparison function.

An operator class for GIN can optionally supply the following methods:

```c
int comparePartial(Datum partial_key, Datum key, StrategyNumber n, Pointer extra_data)
```

Compare a partial-match query key to an index key. Returns an integer whose sign indicates the result: less than zero means the index key does not match the query, but the index scan should continue; zero means that the index key does match the query; greater than zero indicates that the index scan should stop because no more matches are possible. The strategy number `n` of the operator that generated the partial match query is provided, in case its semantics are needed to determine when to end the scan. Also, `extra_data` is the corresponding element of the extra-data array made by `extractQuery`, or NULL if none. Null keys are never passed to this function.

```c
void options(local_relopts *relopts)
```

Defines a set of user-visible parameters that control operator class behavior.

The `options` function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Since both key extraction of indexed values and representation of the key in GIN are flexible, they may depend on user-specified parameters.

To support “partial match” queries, an operator class must provide the `comparePartial` method, and its `extractQuery` method must set the `pmatch` parameter when a partial-match query is encountered. See Section 69.4.2 for details.

The actual data types of the various `Datum` values mentioned above vary depending on the operator class. The item values passed to `extractValue` are always of the operator class's input type, and all key values must be of the class's `STORAGE` type. The type of the query argument passed to `extractQuery`,
consistent and triConsistent is whatever is the right-hand input type of the class member operator identified by the strategy number. This need not be the same as the indexed type, so long as key values of the correct type can be extracted from it. However, it is recommended that the SQL declarations of these three support functions use the opclass’s indexed data type for the query argument, even though the actual type might be something else depending on the operator.

69.4. Implementation

Internally, a GIN index contains a B-tree index constructed over keys, where each key is an element of one or more indexed items (a member of an array, for example) and where each tuple in a leaf page contains either a pointer to a B-tree of heap pointers (a “posting tree”), or a simple list of heap pointers (a “posting list”) when the list is small enough to fit into a single index tuple along with the key value. Figure 69.1 illustrates these components of a GIN index.

As of PostgreSQL 9.1, null key values can be included in the index. Also, placeholder nulls are included in the index for indexed items that are null or contain no keys according to extractValue. This allows searches that should find empty items to do so.

Multicolumn GIN indexes are implemented by building a single B-tree over composite values (column number, key value). The key values for different columns can be of different types.

Figure 69.1. GIN Internals

69.4.1. GIN Fast Update Technique

Updating a GIN index tends to be slow because of the intrinsic nature of inverted indexes: inserting or updating one heap row can cause many inserts into the index (one for each key extracted from the indexed item). GIN is capable of postponing much of this work by inserting new tuples into a temporary, unsorted list of pending entries. When the table is vacuumed or autoanalyzed, or when gin_clean_pending_list function is called, or if the pending list becomes larger than gin_pending_list_limit, the entries are moved to the main GIN data structure using the same bulk insert techniques used during initial index creation. This greatly improves GIN index update speed, even counting the additional vacuum overhead. Moreover the overhead work can be done by a background process instead of in foreground query processing.
The main disadvantage of this approach is that searches must scan the list of pending entries in addition to searching the regular index, and so a large list of pending entries will slow searches significantly. Another disadvantage is that, while most updates are fast, an update that causes the pending list to become “too large” will incur an immediate cleanup cycle and thus be much slower than other updates. Proper use of autovacuum can minimize both of these problems.

If consistent response time is more important than update speed, use of pending entries can be disabled by turning off the `fastupdate` storage parameter for a GIN index. See CREATE INDEX for details.

### 69.4.2. Partial Match Algorithm

GIN can support “partial match” queries, in which the query does not determine an exact match for one or more keys, but the possible matches fall within a reasonably narrow range of key values (within the key sorting order determined by the `compare` support method). The `extractQuery` method, instead of returning a key value to be matched exactly, returns a key value that is the lower bound of the range to be searched, and sets the `pmatch` flag true. The key range is then scanned using the `comparePartial` method. `comparePartial` must return zero for a matching index key, less than zero for a non-match that is still within the range to be searched, or greater than zero if the index key is past the range that could match.

### 69.5. GIN Tips and Tricks

**Create vs. insert**

Insertion into a GIN index can be slow due to the likelihood of many keys being inserted for each item. So, for bulk insertions into a table it is advisable to drop the GIN index and recreate it after finishing bulk insertion.

When `fastupdate` is enabled for GIN (see Section 69.4.1 for details), the penalty is less than when it is not. But for very large updates it may still be best to drop and recreate the index.

**maintenance_work_mem**

Build time for a GIN index is very sensitive to the `maintenance_work_mem` setting; it doesn't pay to skimp on work memory during index creation.

**gin_pending_list_limit**

During a series of insertions into an existing GIN index that has `fastupdate` enabled, the system will clean up the pending-entry list whenever the list grows larger than `gin_pending_list_limit`. To avoid fluctuations in observed response time, it's desirable to have pending-list cleanup occur in the background (i.e., via autovacuum). Foreground cleanup operations can be avoided by increasing `gin_pending_list_limit` or making autovacuum more aggressive. However, enlarging the threshold of the cleanup operation means that if a foreground cleanup does occur, it will take even longer.

`gin_pending_list_limit` can be overridden for individual GIN indexes by changing storage parameters, which allows each GIN index to have its own cleanup threshold. For example, it's possible to increase the threshold only for the GIN index which can be updated heavily, and decrease it otherwise.

**gin_fuzzy_search_limit**

The primary goal of developing GIN indexes was to create support for highly scalable full-text search in PostgreSQL, and there are often situations when a full-text search returns a very large set of results.
Moreover, this often happens when the query contains very frequent words, so that the large result set is not even useful. Since reading many tuples from the disk and sorting them could take a lot of time, this is unacceptable for production. (Note that the index search itself is very fast.)

To facilitate controlled execution of such queries, GIN has a configurable soft upper limit on the number of rows returned: the `gin_fuzzy_search_limit` configuration parameter. It is set to 0 (meaning no limit) by default. If a non-zero limit is set, then the returned set is a subset of the whole result set, chosen at random.

“Soft” means that the actual number of returned results could differ somewhat from the specified limit, depending on the query and the quality of the system’s random number generator.

From experience, values in the thousands (e.g., 5000 — 20000) work well.

## 69.6. Limitations

GIN assumes that indexable operators are strict. This means that `extractValue` will not be called at all on a null item value (instead, a placeholder index entry is created automatically), and `extractQuery` will not be called on a null query value either (instead, the query is presumed to be unsatisfiable). Note however that null key values contained within a non-null composite item or query value are supported.

## 69.7. Examples

The core PostgreSQL distribution includes the GIN operator classes previously shown in Table 69.1. The following `contrib` modules also contain GIN operator classes:

- `btree_gin`
  - B-tree equivalent functionality for several data types
- `hstore`
  - Module for storing (key, value) pairs
- `intarray`
  - Enhanced support for `int[]`
- `pg_trgm`
  - Text similarity using trigram matching
Chapter 70. BRIN Indexes

70.1. Introduction

BRIN stands for Block Range Index. BRIN is designed for handling very large tables in which certain columns have some natural correlation with their physical location within the table. A block range is a group of pages that are physically adjacent in the table; for each block range, some summary info is stored by the index. For example, a table storing a store's sale orders might have a date column on which each order was placed, and most of the time the entries for earlier orders will appear earlier in the table as well; a table storing a ZIP code column might have all codes for a city grouped together naturally.

BRIN indexes can satisfy queries via regular bitmap index scans, and will return all tuples in all pages within each range if the summary info stored by the index is consistent with the query conditions. The query executor is in charge of rechecking these tuples and discarding those that do not match the query conditions — in other words, these indexes are lossy. Because a BRIN index is very small, scanning the index adds little overhead compared to a sequential scan, but may avoid scanning large parts of the table that are known not to contain matching tuples.

The specific data that a BRIN index will store, as well as the specific queries that the index will be able to satisfy, depend on the operator class selected for each column of the index. Data types having a linear sort order can have operator classes that store the minimum and maximum value within each block range, for instance; geometrical types might store the bounding box for all the objects in the block range.

The size of the block range is determined at index creation time by the pages_per_range storage parameter. The number of index entries will be equal to the size of the relation in pages divided by the selected value for pages_per_range. Therefore, the smaller the number, the larger the index becomes (because of the need to store more index entries), but at the same time the summary data stored can be more precise and more data blocks can be skipped during an index scan.

70.1.1. Index Maintenance

At the time of creation, all existing heap pages are scanned and a summary index tuple is created for each range, including the possibly-incomplete range at the end. As new pages are filled with data, page ranges that are already summarized will cause the summary information to be updated with data from the new tuples. When a new page is created that does not fall within the last summarized range, that range does not automatically acquire a summary tuple; those tuples remain unsummarized until a summarization run is invoked later, creating initial summaries. This process can be invoked manually using the brin_summarize_range(regclass, bigint) or brin_summarize_new_values(regclass) functions; automatically when VACUUM processes the table; or by automatic summarization executed by autovacuum, as insertions occur. (This last trigger is disabled by default and can be enabled with the autosummarize parameter.) Conversely, a range can be de-summarized using the brin_desummarize_range(regclass, bigint) function, which is useful when the index tuple is no longer a very good representation because the existing values have changed.

When autosummarization is enabled, each time a page range is filled a request is sent to autovacuum for it to execute a targeted summarization for that range, to be fulfilled at the end of the next worker run on the same database. If the request queue is full, the request is not recorded and a message is sent to the server log:

LOG: request for BRIN range summarization for index "brin_wi_idx" page 128 was not recorded

When this happens, the range will be summarized normally during the next regular vacuum of the table.
70.2. Built-in Operator Classes

The core PostgreSQL distribution includes the BRIN operator classes shown in Table 70.1.

The `minmax` operator classes store the minimum and the maximum values appearing in the indexed column within the range. The `inclusion` operator classes store a value which includes the values in the indexed column within the range. The `bloom` operator classes build a Bloom filter for all values in the range. The `minmax-multi` operator classes store multiple minimum and maximum values, representing values appearing in the indexed column within the range.

### 70.2.1. Operator Class Parameters

Some of the built-in operator classes allow specifying parameters affecting behavior of the operator class. Each operator class has its own set of allowed parameters. Only the `bloom` and `minmax-multi` operator classes allow specifying parameters:

- **bloom operator classes** accept these parameters:
  
  - `n_distinct_per_range`

  Defines the estimated number of distinct non-null values in the block range, used by BRIN bloom indexes for sizing of the Bloom filter. It behaves similarly to `n_distinct` option for `ALTER TABLE`. When set to a positive value, each block range is assumed to contain this number of distinct non-null values. When set to a negative value, which must be greater than or equal to -1, the number of distinct non-null values is assumed to grow linearly with the maximum possible number of tuples in the block range (about 290 rows per block). The default value is -0.1, and the minimum number of distinct non-null values is 16.
false_positive_rate

Defines the desired false positive rate used by BRIN bloom indexes for sizing of the Bloom filter. The values must be between 0.0001 and 0.25. The default value is 0.01, which is 1% false positive rate.

minmax-multi operator classes accept these parameters:

values_per_range

Defines the maximum number of values stored by BRIN minmax indexes to summarize a block range. Each value may represent either a point, or a boundary of an interval. Values must be between 8 and 256, and the default value is 32.

70.3. Extensibility

The BRIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The BRIN layer itself takes care of concurrency, logging and searching the index structure.

All it takes to get a BRIN access method working is to implement a few user-defined methods, which define the behavior of summary values stored in the index and the way they interact with scan keys. In short, BRIN combines extensibility with generality, code reuse, and a clean interface.

There are four methods that an operator class for BRIN must provide:

BrinOpcInfo *opcInfo(Oid type_oid)

Returns internal information about the indexed columns' summary data. The return value must point to a palloc'd BrinOpcInfo, which has this definition:

typedef struct BrinOpcInfo
{
    /* Number of columns stored in an index column of this opclass */
    uint16    oi_nstored;

    /* Opaque pointer for the opclass' private use */
    void      *oi_opaque;

    /* Type cache entries of the stored columns */
    TypeCacheEntry *oi_typcache[FLEXIBLE_ARRAY_MEMBER];
} BrinOpcInfo;

BrinOpcInfo.oi_opaque can be used by the operator class routines to pass information between support functions during an index scan.

bool consistent(BrinDesc *bdesc, BrinValues *column, ScanKey *keys, int nkeys)

Returns whether all the ScanKey entries are consistent with the given indexed values for a range. The attribute number to use is passed as part of the scan key. Multiple scan keys for the same attribute may be passed at once; the number of entries is determined by the nkeys parameter.
bool consistent(BrinDesc *bdesc, BrinValues *column, ScanKey key)

Returns whether the ScanKey is consistent with the given indexed values for a range. The attribute number to use is passed as part of the scan key. This is an older backward-compatible variant of the consistent function.

bool addValue(BrinDesc *bdesc, BrinValues *column, Datum newval, bool isnull)

Given an index tuple and an indexed value, modifies the indicated attribute of the tuple so that it additionally represents the new value. If any modification was done to the tuple, true is returned.

bool unionTuples(BrinDesc *bdesc, BrinValues *a, BrinValues *b)

Consolidates two index tuples. Given two index tuples, modifies the indicated attribute of the first of them so that it represents both tuples. The second tuple is not modified.

An operator class for BRIN can optionally specify the following method:

void options(local_relopts *relopts)

Defines a set of user-visible parameters that control operator class behavior.

The options function is passed a pointer to a local_relopts struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the PG_HAS_OPCLASS_OPTIONS() and PG_GET_OPCLASS_OPTIONS() macros.

Since both key extraction of indexed values and representation of the key in BRIN are flexible, they may depend on user-specified parameters.

The core distribution includes support for four types of operator classes: minmax, minmax-multi, inclusion and bloom. Operator class definitions using them are shipped for in-core data types as appropriate. Additional operator classes can be defined by the user for other data types using equivalent definitions, without having to write any source code; appropriate catalog entries being declared is enough. Note that assumptions about the semantics of operator strategies are embedded in the support functions' source code.

Operator classes that implement completely different semantics are also possible, provided implementations of the four main support functions described above are written. Note that backwards compatibility across major releases is not guaranteed: for example, additional support functions might be required in later releases.

To write an operator class for a data type that implements a totally ordered set, it is possible to use the minmax support functions alongside the corresponding operators, as shown in Table 70.2. All operator class members (functions and operators) are mandatory.

Table 70.2. Function and Support Numbers for Minmax Operator Classes

</tr>
</tbody>
</table>
To write an operator class for a complex data type which has values included within another type, it's possible to use the inclusion support functions alongside the corresponding operators, as shown in Table 70.3. It requires only a single additional function, which can be written in any language. More functions can be defined for additional functionality. All operators are optional. Some operators require other operators, as shown as dependencies on the table.

<td>Operator Strategy 1</td>
</tr>
</tbody>
</table>

Support function numbers 1 through 10 are reserved for the BRIN internal functions, so the SQL level functions start with number 11. Support function number 11 is the main function required to build the index. It should accept two arguments with the same data type as the operator class, and return the union of them. The inclusion operator class can store union values with different data types if it is defined with the STORAGE parameter. The return value of the union function should match the STORAGE data type.

Support function numbers 12 and 14 are provided to support irregularities of built-in data types. Function number 12 is used to support network addresses from different families which are not mergeable. Function number 14 is used to support empty ranges. Function number 13 is an optional but recommended one, which allows the new value to be checked before it is passed to the union function. As the BRIN framework can shortcut some operations when the union is not changed, using this function can improve index performance.

To write an operator class for a data type that implements only an equality operator and supports hashing, it is possible to use the bloom support procedures alongside the corresponding operators, as shown in Table 70.4. All operator class members (procedures and operators) are mandatory.

### Table 70.4. Procedure and Support Numbers for Bloom Operator Classes

<table>
<thead>
<tr>
<th>Operator class member</th>
<th>Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Support Procedure 1</td>
<td>internal function brin_bloom_opcinfo()</td>
</tr>
<tr>
<td>Support Procedure 2</td>
<td>internal function brin_bloom_add_value()</td>
</tr>
<tr>
<td>Support Procedure 3</td>
<td>internal function brin_bloom_consistent()</td>
</tr>
<tr>
<td>Support Procedure 4</td>
<td>internal function brin_bloom_union()</td>
</tr>
<tr>
<td>Support Procedure 11</td>
<td>function to compute hash of an element</td>
</tr>
<tr>
<td>Operator Strategy 1</td>
<td>operator equal-to</td>
</tr>
</tbody>
</table>

Support procedure numbers 1-10 are reserved for the BRIN internal functions, so the SQL level functions start with number 11. Support function number 11 is the main function required to build the index. It should accept one argument with the same data type as the operator class, and return a hash of the value.

The minmax-multi operator class is also intended for data types implementing a totally ordered set, and may be seen as a simple extension of the minmax operator class. While minmax operator class summarizes values from each block range into a single contiguous interval, minmax-multi allows summarization into multiple smaller intervals to improve handling of outlier values. It is possible to use the minmax-multi support procedures alongside the corresponding operators, as shown in Table 70.5. All operator class members (procedures and operators) are mandatory.

### Table 70.5. Procedure and Support Numbers for minmax-multi Operator Classes

<table>
<thead>
<tr>
<th>Operator class member</th>
<th>Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Support Procedure 1</td>
<td>internal function brin_minmax_multi_opcinfo()</td>
</tr>
</tbody>
</table>
Both minmax and inclusion operator classes support cross-data-type operators, though with these the dependencies become more complicated. The minmax operator class requires a full set of operators to be defined with both arguments having the same data type. It allows additional data types to be supported by defining extra sets of operators. Inclusion operator class operator strategies are dependent on another operator strategy as shown in Table 70.3, or the same operator strategy as themselves. They require the dependency operator to be defined with the STORAGE data type as the left-hand-side argument and the other supported data type to be the right-hand-side argument of the supported operator. See float4_minmax_ops as an example of minmax, and box_inclusion_ops as an example of inclusion.
Chapter 71. Hash Indexes

71.1. Overview

PostgreSQL includes an implementation of persistent on-disk hash indexes, which are fully crash recoverable. Any data type can be indexed by a hash index, including data types that do not have a well-defined linear ordering. Hash indexes store only the hash value of the data being indexed, thus there are no restrictions on the size of the data column being indexed.

Hash indexes support only single-column indexes and do not allow uniqueness checking.

Hash indexes support only the \( = \) operator, so WHERE clauses that specify range operations will not be able to take advantage of hash indexes.

Each hash index tuple stores just the 4-byte hash value, not the actual column value. As a result, hash indexes may be much smaller than B-trees when indexing longer data items such as UUIDs, URLs, etc. The absence of the column value also makes all hash index scans lossy. Hash indexes may take part in bitmap index scans and backward scans.

Hash indexes are best optimized for SELECT and UPDATE-heavy workloads that use equality scans on larger tables. In a B-tree index, searches must descend through the tree until the leaf page is found. In tables with millions of rows, this descent can increase access time to data. The equivalent of a leaf page in a hash index is referred to as a bucket page. In contrast, a hash index allows accessing the bucket pages directly, thereby potentially reducing index access time in larger tables. This reduction in "logical I/O" becomes even more pronounced on indexes/data larger than shared_buffers/RAM.

Hash indexes have been designed to cope with uneven distributions of hash values. Direct access to the bucket pages works well if the hash values are evenly distributed. When inserts mean that the bucket page becomes full, additional overflow pages are chained to that specific bucket page, locally expanding the storage for index tuples that match that hash value. When scanning a hash bucket during queries, we need to scan through all of the overflow pages. Thus an unbalanced hash index might actually be worse than a B-tree in terms of number of block accesses required, for some data.

As a result of the overflow cases, we can say that hash indexes are most suitable for unique, nearly unique data or data with a low number of rows per hash bucket. One possible way to avoid problems is to exclude highly non-unique values from the index using a partial index condition, but this may not be suitable in many cases.

Like B-Trees, hash indexes perform simple index tuple deletion. This is a deferred maintenance operation that deletes index tuples that are known to be safe to delete (those whose item identifier's LP_DEAD bit is already set). If an insert finds no space is available on a page we try to avoid creating a new overflow page by attempting to remove dead index tuples. Removal cannot occur if the page is pinned at that time. Deletion of dead index pointers also occurs during VACUUM.

If it can, VACUUM will also try to squeeze the index tuples onto as few overflow pages as possible, minimizing the overflow chain. If an overflow page becomes empty, overflow pages can be recycled for reuse in other buckets, though we never return them to the operating system. There is currently no provision to shrink a hash index, other than by rebuilding it with REINDEX. There is no provision for reducing the number of buckets, either.

Hash indexes may expand the number of bucket pages as the number of rows indexed grows. The hash key-to-bucket-number mapping is chosen so that the index can be incrementally expanded. When a new bucket is to be added to the index, exactly one existing bucket will need to be "split", with some of its tuples being transferred to the new bucket according to the updated key-to-bucket-number mapping.
The expansion occurs in the foreground, which could increase execution time for user inserts. Thus, hash indexes may not be suitable for tables with rapidly increasing number of rows.

### 71.2. Implementation

There are four kinds of pages in a hash index: the meta page (page zero), which contains statically allocated control information; primary bucket pages; overflow pages; and bitmap pages, which keep track of overflow pages that have been freed and are available for re-use. For addressing purposes, bitmap pages are regarded as a subset of the overflow pages.

Both scanning the index and inserting tuples require locating the bucket where a given tuple ought to be located. To do this, we need the bucket count, highmask, and lowmask from the metapage; however, it's undesirable for performance reasons to have to have to lock and pin the metapage for every such operation. Instead, we retain a cached copy of the metapage in each backend's relcache entry. This will produce the correct bucket mapping as long as the target bucket hasn't been split since the last cache refresh.

Primary bucket pages and overflow pages are allocated independently since any given index might need more or fewer overflow pages relative to its number of buckets. The hash code uses an interesting set of addressing rules to support a variable number of overflow pages while not having to move primary bucket pages around after they are created.

Each row in the table indexed is represented by a single index tuple in the hash index. Hash index tuples are stored in bucket pages, and if they exist, overflow pages. We speed up searches by keeping the index entries in any one index page sorted by hash code, thus allowing binary search to be used within an index page. Note however that there is *no* assumption about the relative ordering of hash codes across different index pages of a bucket.

The bucket splitting algorithms to expand the hash index are too complex to be worthy of mention here, though are described in more detail in `src/backend/access/hash/README`. The split algorithm is crash safe and can be restarted if not completed successfully.
Chapter 72. Database Physical Storage

This chapter provides an overview of the physical storage format used by PostgreSQL databases.

72.1. Database File Layout

This section describes the storage format at the level of files and directories.

Traditionally, the configuration and data files used by a database cluster are stored together within the cluster’s data directory, commonly referred to as PGDATA (after the name of the environment variable that can be used to define it). A common location for PGDATA is /var/lib/pgsql/data. Multiple clusters, managed by different server instances, can exist on the same machine.

The PGDATA directory contains several subdirectories and control files, as shown in Table 72.1. In addition to these required items, the cluster configuration files postgresql.conf, pg_hba.conf, and pg_ident.conf are traditionally stored in PGDATA, although it is possible to place them elsewhere.

Table 72.1. Contents of PGDATA

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PG_VERSION</td>
<td>A file containing the major version number of PostgreSQL</td>
</tr>
<tr>
<td>base</td>
<td>Subdirectory containing per-database subdirectories</td>
</tr>
<tr>
<td>current_logfiles</td>
<td>File recording the log file(s) currently written to by the logging collector</td>
</tr>
<tr>
<td>global</td>
<td>Subdirectory containing cluster-wide tables, such as pg_database</td>

<td>Subdirectory containing exported snapshots</td>
</tr>
<tr>
<td>pg_stat</td>
<td>Subdirectory containing permanent files for the statistics subsystem</td>
</tr>
<tr>
<td>pg_stat_tmp</td>
<td>Subdirectory containing temporary files for the statistics subsystem</td>
</tr>
</tbody>
</table>
For each database in the cluster there is a subdirectory within $PGDATA/base$, named after the database's OID in $pg\_database$. This subdirectory is the default location for the database's files; in particular, its system catalogs are stored there.

Note that the following sections describe the behavior of the builtin heap table access method, and the builtin index access methods. Due to the extensible nature of PostgreSQL, other access methods might work differently.

Each table and index is stored in a separate file. For ordinary relations, these files are named after the table or index's filenode number, which can be found in $pg\_class.relfilenode$. But for temporary relations, the file name is of the form $tBBB\_FFF$, where $BBB$ is the backend ID of the backend which created the file, and $FFF$ is the filenode number. In either case, in addition to the main file (aka main fork), each table and index has a free space map (see Section 72.3), which stores information about free space available in the relation. The free space map is stored in a file named with the filenode number plus the suffix $_fsm$. Tables also have a visibility map, stored in a fork with the suffix $_vm$, to track which pages are known to have no dead tuples. The visibility map is described further in Section 72.4. Unlogged tables and indexes have a third fork, known as the initialization fork, which is stored in a fork with the suffix $_init$ (see Section 72.5).

### Caution

Note that while a table's filenode often matches its OID, this is not necessarily the case; some operations, like TRUNCATE, REINDEX, CLUSTER and some forms of ALTER TABLE, can change the filenode while preserving the OID. Avoid assuming that filenode and table OID are the same. Also, for certain system catalogs including $pg\_class$ itself, $pg\_class.relfilenode$ contains zero. The actual filenode number of these catalogs is stored in a lower-level data structure, and can be obtained using the $pg\_relation\_filenode$() function.
When a table or index exceeds 1 GB, it is divided into gigabyte-sized segments. The first segment's file name is the same as the filenode; subsequent segments are named filenode.1, filenode.2, etc. This arrangement avoids problems on platforms that have file size limitations. (Actually, 1 GB is just the default segment size. The segment size can be adjusted using the configuration option --with-segsize when building PostgreSQL.) In principle, free space map and visibility map forks could require multiple segments as well, though this is unlikely to happen in practice.

A table that has columns with potentially large entries will have an associated TOAST table, which is used for out-of-line storage of field values that are too large to keep in the table rows proper. pg_class.reltoastrelid links from a table to its TOAST table, if any. See Section 72.2 for more information.

The contents of tables and indexes are discussed further in Section 72.6.

Tablespaces make the scenario more complicated. Each user-defined tablespace has a symbolic link inside the PGDATA/pg_tblspc directory, which points to the physical tablespace directory (i.e., the location specified in the tablespace's CREATE TABLESPACE command). This symbolic link is named after the tablespace's OID. Inside the physical tablespace directory there is a subdirectory with a name that depends on the PostgreSQL server version, such as PG_9.0_201008051. (The reason for using this subdirectory is so that successive versions of the database can use the same CREATE TABLESPACE location value without conflicts.) Within the version-specific subdirectory, there is a subdirectory for each database that has elements in the tablespace, named after the database's OID. Tables and indexes are stored within that directory, using the filenode naming scheme. The pg_default tablespace is not accessed through pg_tblspc, but corresponds to PGDATA/base. Similarly, the pg_global tablespace is not accessed through pg_tblspc, but corresponds to PGDATA/global.

The pg_relation_filepath() function shows the entire path (relative to PGDATA) of any relation. It is often useful as a substitute for remembering many of the above rules. But keep in mind that this function just gives the name of the first segment of the main fork of the relation — you may need to append a segment number and/or _fsm, _vm, or _init to find all the files associated with the relation.

Temporary files (for operations such as sorting more data than can fit in memory) are created within PGDATA/base/pgsql_tmp, or within a pgsql_tmp subdirectory of a tablespace directory if a tablespace other than pg_default is specified for them. The name of a temporary file has the form pgsql_tmpPPP.NNN, where PPP is the PID of the owning backend and NNN distinguishes different temporary files of that backend.

### 72.2. TOAST

This section provides an overview of TOAST (The Oversized-Attribute Storage Technique).

PostgreSQL uses a fixed page size (commonly 8 kB), and does not allow tuples to span multiple pages. Therefore, it is not possible to store very large field values directly. To overcome this limitation, large field values are compressed and/or broken up into multiple physical rows. This happens transparently to the user, with only small impact on most of the backend code. The technique is affectionately known as TOAST (or “the best thing since sliced bread”). The TOAST infrastructure is also used to improve handling of large data values in-memory.

Only certain data types support TOAST — there is no need to impose the overhead on data types that cannot produce large field values. To support TOAST, a data type must have a variable-length (varlena) representation, in which, ordinarily, the first four-byte word of any stored value contains the total length of the value in bytes (including itself). TOAST does not constrain the rest of the data type's representation. The special representations collectively called TOASTed values work by modifying or reinterpreting this initial length word. Therefore, the C-level functions supporting a TOAST-able data type must be careful about how they handle potentially TOASTed input values: an input might not actually consist of a four-byte length word and contents until after it's been detoasted. (This is normally done by invoking
PG_DETOAST_DATUM before doing anything with an input value, but in some cases more efficient approaches are possible. See Section 38.13.1 for more detail.)

TOAST usurps two bits of the varlena length word (the high-order bits on big-endian machines, the low-order bits on little-endian machines), thereby limiting the logical size of any value of a TOAST-able data type to 1 GB ($2^{30}$ - 1 bytes). When both bits are zero, the value is an ordinary un-TOASTed value of the data type, and the remaining bits of the length word give the total datum size (including length word) in bytes. When the highest-order or lowest-order bit is set, the value has only a single-byte header instead of the normal four-byte header, and the remaining bits of that byte give the total datum size (including length byte) in bytes. This alternative supports space-efficient storage of values shorter than 127 bytes, while still allowing the data type to grow to 1 GB at need. Values with single-byte headers aren't aligned on any particular boundary, whereas values with four-byte headers are aligned on at least a four-byte boundary; this omission of alignment padding provides additional space savings that is significant compared to short values. As a special case, if the remaining bits of a single-byte header are all zero (which would be impossible for a self-inclusive length), the value is a pointer to out-of-line data, with several possible alternatives as described below. The type and size of such a TOAST pointer are determined by a code stored in the second byte of the datum. Lastly, when the highest-order or lowest-order bit is clear but the adjacent bit is set, the content of the datum has been compressed and must be decompressed before use. In this case the remaining bits of the four-byte length word give the total size of the compressed datum, not the original data. Note that compression is also possible for out-of-line data but the varlena header does not tell whether it has occurred — the content of the TOAST pointer tells that, instead.

The compression technique used for either in-line or out-of-line compressed data can be selected for each column by setting the COMPRESSION column option in CREATE TABLE or ALTER TABLE. The default for columns with no explicit setting is to consult the default_toast_compression parameter at the time data is inserted.

As mentioned, there are multiple types of TOAST pointer datums. The oldest and most common type is a pointer to out-of-line data stored in a TOAST table that is separate from, but associated with, the table containing the TOAST pointer datum itself. These on-disk pointer datums are created by the TOAST management code (in access/common/toast_internals.c) when a tuple to be stored on disk is too large to be stored as-is. Further details appear in Section 72.2.1. Alternatively, a TOAST pointer datum can contain a pointer to out-of-line data that appears elsewhere in memory. Such datums are necessarily short-lived, and will never appear on-disk, but they are very useful for avoiding copying and redundant processing of large data values. Further details appear in Section 72.2.2.

### 72.2.1. Out-of-Line, On-Disk TOAST Storage

If any of the columns of a table are TOAST-able, the table will have an associated TOAST table, whose OID is stored in the table's pg_class.reltoastrelid entry. On-disk TOASTed values are kept in the TOAST table, as described in more detail below.

Out-of-line values are divided (after compression if used) into chunks of at most TOAST_MAX CHUNK SIZE bytes (by default this value is chosen so that four chunk rows will fit on a page, making it about 2000 bytes). Each chunk is stored as a separate row in the TOAST table belonging to the owning table. Every TOAST table has the columns chunk_id (an OID identifying the particular TOASTed value), chunk_seq (a sequence number for the chunk within its value), and chunk_data (the actual data of the chunk). A unique index on chunk_id and chunk_seq provides fast retrieval of the values. A pointer datum representing an out-of-line on-disk TOASTed value therefore needs to store the OID of the TOAST table in which to look and the OID of the specific value (its chunk_id). For convenience, pointer datums also store the logical datum size (original uncompressed data length), physical stored size (different if compression was applied), and the compression method used, if any. Allowing for the varlena header bytes, the total size of an on-disk TOAST pointer datum is therefore 18 bytes regardless of the actual size of the represented value.
The TOAST management code is triggered only when a row value to be stored in a table is wider than \( TOAST\_TUPLE\_THRESHOLD \) bytes (normally 2 kB). The TOAST code will compress and/or move field values out-of-line until the row value is shorter than \( TOAST\_TUPLE\_TARGET \) bytes (also normally 2 kB, adjustable) or no more gains can be had. During an UPDATE operation, values of unchanged fields are normally preserved as-is; so an UPDATE of a row with out-of-line values incurs no TOAST costs if none of the out-of-line values change.

The TOAST management code recognizes four different strategies for storing TOAST-able columns on disk:

- **PLAIN** prevents either compression or out-of-line storage; furthermore it disables use of single-byte headers for varlena types. This is the only possible strategy for columns of non-TOAST-able data types.

- **EXTENDED** allows both compression and out-of-line storage. This is the default for most TOAST-able data types. Compression will be attempted first, then out-of-line storage if the row is still too big.

- **EXTERNAL** allows out-of-line storage but not compression. Use of EXTERNAL will make substring operations on wide text and bytea columns faster (at the penalty of increased storage space) because these operations are optimized to fetch only the required parts of the out-of-line value when it is not compressed.

- **MAIN** allows compression but not out-of-line storage. (Actually, out-of-line storage will still be performed for such columns, but only as a last resort when there is no other way to make the row small enough to fit on a page.)

Each TOAST-able data type specifies a default strategy for columns of that data type, but the strategy for a given table column can be altered with `ALTER TABLE ... SET STORAGE`.

\( TOAST\_TUPLE\_TARGET \) can be adjusted for each table using `ALTER TABLE ... SET (toast_tuple_target = N)`

This scheme has a number of advantages compared to a more straightforward approach such as allowing row values to span pages. Assuming that queries are usually qualified by comparisons against relatively small key values, most of the work of the executor will be done using the main row entry. The big values of TOASTed attributes will only be pulled out (if selected at all) at the time the result set is sent to the client. Thus, the main table is much smaller and more of its rows fit in the shared buffer cache than would be the case without any out-of-line storage. Sort sets shrink also, and sorts will more often be done entirely in memory. A little test showed that a table containing typical HTML pages and their URLs was stored in about half of the raw data size including the TOAST table, and that the main table contained only about 10% of the entire data (the URLs and some small HTML pages). There was no run time difference compared to an un-TOASTed comparison table, in which all the HTML pages were cut down to 7 kB to fit.

### 72.2.2. Out-of-Line, In-Memory TOAST Storage

TOAST pointers can point to data that is not on disk, but is elsewhere in the memory of the current server process. Such pointers obviously cannot be long-lived, but they are nonetheless useful. There are currently two sub-cases: pointers to *indirect* data and pointers to *expanded* data.

Indirect TOAST pointers simply point at a non-indirect varlena value stored somewhere in memory. This case was originally created merely as a proof of concept, but it is currently used during logical decoding to avoid possibly having to create physical tuples exceeding 1 GB (as pulling all out-of-line field values into the tuple might do). The case is of limited use since the creator of the pointer datum is entirely responsible that the referenced data survives for as long as the pointer could exist, and there is no infrastructure to help with this.
Expanded TOAST pointers are useful for complex data types whose on-disk representation is not especially suited for computational purposes. As an example, the standard varlena representation of a PostgreSQL array includes dimensionality information, a nulls bitmap if there are any null elements, then the values of all the elements in order. When the element type itself is variable-length, the only way to find the $n$th element is to scan through all the preceding elements. This representation is appropriate for on-disk storage because of its compactness, but for computations with the array it's much nicer to have an “expanded” or “deconstructed” representation in which all the element starting locations have been identified. The TOAST pointer mechanism supports this need by allowing a pass-by-reference Datum to point to either a standard varlena value (the on-disk representation) or a TOAST pointer that points to an expanded representation somewhere in memory. The details of this expanded representation are up to the data type, though it must have a standard header and meet the other API requirements given in `src/include/utils/expandeddatum.h`. C-level functions working with the data type can choose to handle either representation. Functions that do not know about the expanded representation, but simply apply `PG_DETOAST_DATUM` to their inputs, will automatically receive the traditional varlena representation; so support for an expanded representation can be introduced incrementally, one function at a time.

TOAST pointers to expanded values are further broken down into read-write and read-only pointers. The pointed-to representation is the same either way, but a function that receives a read-write pointer is allowed to modify the referenced value in-place, whereas one that receives a read-only pointer must not; it must first create a copy if it wants to make a modified version of the value. This distinction and some associated conventions make it possible to avoid unnecessary copying of expanded values during query execution.

For all types of in-memory TOAST pointer, the TOAST management code ensures that no such pointer datum can accidentally get stored on disk. In-memory TOAST pointers are automatically expanded to normal in-line varlena values before storage — and then possibly converted to on-disk TOAST pointers, if the containing tuple would otherwise be too big.

### 72.3. Free Space Map

Each heap and index relation, except for hash indexes, has a Free Space Map (FSM) to keep track of available space in the relation. It's stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a `_fsm` suffix. For example, if the filenode of a relation is 12345, the FSM is stored in a file called `12345_fsm`, in the same directory as the main relation file.

The Free Space Map is organized as a tree of FSM pages. The bottom level FSM pages store the free space available on each heap (or index) page, using one byte to represent each such page. The upper levels aggregate information from the lower levels.

Within each FSM page is a binary tree, stored in an array with one byte per node. Each leaf node represents a heap page, or a lower level FSM page. In each non-leaf node, the higher of its children’s values is stored. The maximum value in the leaf nodes is therefore stored at the root.

See `src/backend/storage/freespace/README` for more details on how the FSM is structured, and how it's updated and searched. The `pg_freespacemap` module can be used to examine the information stored in free space maps.

### 72.4. Visibility Map

Each heap relation has a Visibility Map (VM) to keep track of which pages contain only tuples that are known to be visible to all active transactions; it also keeps track of which pages contain only frozen tuples. It's stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a `_vm` suffix. For example, if the filenode of a relation is 12345, the VM is stored in a file called `12345_vm`, in the same directory as the main relation file. Note that indexes do not have VMs.
The visibility map stores two bits per heap page. The first bit, if set, indicates that the page is all-visible, or in other words that the page does not contain any tuples that need to be vacuumed. This information can also be used by index-only scans to answer queries using only the index tuple. The second bit, if set, means that all tuples on the page have been frozen. That means that even an anti-wraparound vacuum need not revisit the page.

The map is conservative in the sense that we make sure that whenever a bit is set, we know the condition is true, but if a bit is not set, it might or might not be true. Visibility map bits are only set by vacuum, but are cleared by any data-modifying operations on a page.

The pg_visibility module can be used to examine the information stored in the visibility map.

### 72.5. The Initialization Fork

Each unlogged table, and each index on an unlogged table, has an initialization fork. The initialization fork is an empty table or index of the appropriate type. When an unlogged table must be reset to empty due to a crash, the initialization fork is copied over the main fork, and any other forks are erased (they will be recreated automatically as needed).

### 72.6. Database Page Layout

This section provides an overview of the page format used within PostgreSQL tables and indexes. Sequences and TOAST tables are formatted just like a regular table.

In the following explanation, a byte is assumed to contain 8 bits. In addition, the term item refers to an individual data value that is stored on a page. In a table, an item is a row; in an index, an item is an index entry.

Every table and index is stored as an array of pages of a fixed size (usually 8 kB, although a different page size can be selected when compiling the server). In a table, all the pages are logically equivalent, so a particular item (row) can be stored in any page. In indexes, the first page is generally reserved as a metapage holding control information, and there can be different types of pages within the index, depending on the index access method.

Table 72.2 shows the overall layout of a page. There are five parts to each page.

#### Table 72.2. Overall Page Layout

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PageHeaderData</td>
<td>24 bytes long. Contains general information about the page, including free space pointers.</td>
</tr>
<tr>
<td>ItemIdData</td>
<td>Array of item identifiers pointing to the actual items. Each entry is an (offset,length) pair. 4 bytes per item.</td>
</tr>
<tr>
<td>Free space</td>
<td>The unallocated space. New item identifiers are allocated from the start of this area, new items from the end.</td>
</tr>
<tr>
<td>Items</td>
<td>The actual items themselves.</td>
</tr>
<tr>
<td>Special space</td>
<td>Index access method specific data. Different methods store different data. Empty in ordinary tables.</td>
</tr>
</tbody>
</table>

1 Actually, use of this page format is not required for either table or index access methods. The heap table access method always uses this format. All the existing index methods also use the basic format, but the data kept on index metapages usually doesn't follow the item layout rules.
The first 24 bytes of each page consists of a page header (PageHeaderData). Its format is detailed in Table 72.3. The first field tracks the most recent WAL entry related to this page. The second field contains the page checksum if data checksums are enabled. Next is a 2-byte field containing flag bits. This is followed by three 2-byte integer fields (pd_lower, pd_upper, and pd_special). These contain byte offsets from the page start to the start of unallocated space, to the end of unallocated space, and to the start of the special space. The next 2 bytes of the page header, pd_pagesize_version, store both the page size and a version indicator. Beginning with PostgreSQL 8.3 the version number is 4; PostgreSQL 8.1 and 8.2 used version number 3; PostgreSQL 8.0 used version number 2; PostgreSQL 7.3 and 7.4 used version number 1; prior releases used version number 0. (The basic page layout and header format has not changed in most of these versions, but the layout of heap row headers has.) The page size is basically only present as a cross-check; there is no support for having more than one page size in an installation. The last field is a hint that shows whether pruning the page is likely to be profitable: it tracks the oldest un-pruned XMAX on the page.

Table 72.3. PageHeaderData Layout

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Length</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pd_lsn</td>
<td>PageXLogRecPtr</td>
<td>8 bytes</td>
<td>LSN: next byte after last byte of WAL record for last change to this page</td>
</tr>
<tr>
<td>pd_checksum</td>
<td>uint16</td>
<td>2 bytes</td>
<td>Page checksum</td>
</tr>
<tr>

<td>uint16</td>
<td>2 bytes</td>
<td>Flag bits</td>
</tr>
<tr>
<td>pd_lower</td>
<td>LocationIndex</td>
<td>2 bytes</td>
<td>Offset to start of free space</td>
</tr>
<tr>
<td>pd_upper</td>
<td>LocationIndex</td>
<td>2 bytes</td>
<td>Offset to end of free space</td>
</tr>
<tr>
<td>pd_special</td>
<td>LocationIndex</td>
<td>2 bytes</td>
<td>Offset to start of special space</td>
</tr>
<tr>
<td>pd_pagesize_version</td>
<td>uint16</td>
<td>2 bytes</td>
<td>Page size and layout version number information</td>
</tr>
<tr>
<td>pd_prune_xid</td>
<td>TransactionId</td>
<td>4 bytes</td>
<td>Oldest unpruned XMAX on page, or zero if none</td>
</tr>
</tbody>
</table>

All the details can be found in src/include/storage/bufpage.h.

Following the page header are item identifiers (ItemIdData), each requiring four bytes. An item identifier contains a byte-offset to the start of an item, its length in bytes, and a few attribute bits which affect its interpretation. New item identifiers are allocated as needed from the beginning of the unallocated space. The number of item identifiers present can be determined by looking at pd_lower, which is increased to allocate a new identifier. Because an item identifier is never moved until it is freed, its index can be used on a long-term basis to reference an item, even when the item itself is moved around on the page to compact free space. In fact, every pointer to an item (ItemPointer, also known as CTID) created by PostgreSQL consists of a page number and the index of an item identifier.

The items themselves are stored in space allocated backwards from the end of unallocated space. The exact structure varies depending on what the table is to contain. Tables and sequences both use a structure named HeapTupleHeaderData, described below.

The final section is the “special section” which can contain anything the access method wishes to store. For example, b-tree indexes store links to the page’s left and right siblings, as well as some other data
relevant to the index structure. Ordinary tables do not use a special section at all (indicated by setting `pd_special` to equal the page size).

Figure 72.1 illustrates how these parts are laid out in a page.

</table>
```

### 72.6.1. Table Row Layout

All table rows are structured in the same way. There is a fixed-size header (occupying 23 bytes on most machines), followed by an optional null bitmap, an optional object ID field, and the user data. The header is detailed in Table 72.4. The actual user data (columns of the row) begins at the offset indicated by `t_hoff`, which must always be a multiple of the MAXALIGN distance for the platform. The null bitmap is only present if the `HEAP_HASNULL` bit is set in `t_infomask`. If it is present it begins just after the fixed header and occupies enough bytes to have one bit per data column (that is, the number of bits that equals the attribute count in `t_infomask2`). In this list of bits, a 1 bit indicates not-null, a 0 bit is a null. When the bitmap is not present, all columns are assumed not-null. The object ID is only present if the `HEAP_HASOID_OLD` bit is set in `t_infomask`. If present, it appears just before the `t_hoff` boundary. Any padding needed to make `t_hoff` a MAXALIGN multiple will appear between the null bitmap and the object ID. (This in turn ensures that the object ID is suitably aligned.)

**Table 72.4. HeapTupleHeaderData Layout**

<table>
<thead>
<tr>
<th>Field</th>

<td>2 bytes</td>
<td>various flag bits</td>
</tr>
<tr>
<td>t_hoff</td>
<td>uint8</td>
<td>1 byte</td>
<td>offset to user data</td>
</tr>
</tbody>
</table>
All the details can be found in `src/include/access/htup_details.h`.

Interpreting the actual data can only be done with information obtained from other tables, mostly `pg_attribute`. The key values needed to identify field locations are `attlen` and `attalign`. There is no way to directly get a particular attribute, except when there are only fixed width fields and no null values. All this trickery is wrapped up in the functions `heap_getattr`, `fastgetattr` and `heap_getsysattr`.

To read the data you need to examine each attribute in turn. First check whether the field is NULL according to the null bitmap. If it is, go to the next. Then make sure you have the right alignment. If the field is a fixed width field, then all the bytes are simply placed. If it's a variable length field (`attlen = -1`) then it's a bit more complicated. All variable-length data types share the common header structure `struct varlena`, which includes the total length of the stored value and some flag bits. Depending on the flags, the data can be either inline or in a TOAST table; it might be compressed, too (see Section 72.2).
Chapter 73. System Catalog Declarations and Initial Contents

PostgreSQL uses many different system catalogs to keep track of the existence and properties of database objects, such as tables and functions. Physically there is no difference between a system catalog and a plain user table, but the backend C code knows the structure and properties of each catalog, and can manipulate it directly at a low level. Thus, for example, it is inadvisable to attempt to alter the structure of a catalog on-the-fly; that would break assumptions built into the C code about how rows of the catalog are laid out. But the structure of the catalogs can change between major versions.

The structures of the catalogs are declared in specially formatted C header files in the `src/include/catalog/` directory of the source tree. For each catalog there is a header file named after the catalog (e.g., `pg_class.h` for `pg_class`), which defines the set of columns the catalog has, as well as some other basic properties such as its OID.

Many of the catalogs have initial data that must be loaded into them during the “bootstrap” phase of initdb, to bring the system up to a point where it is capable of executing SQL commands. (For example, `pg_class.h` must contain an entry for itself, as well as one for each other system catalog and index.) This initial data is kept in editable form in data files that are also stored in the `src/include/catalog/` directory. For example, `pg_proc.dat` describes all the initial rows that must be inserted into the `pg_proc` catalog.

To create the catalog files and load this initial data into them, a backend running in bootstrap mode reads a BKI (Backend Interface) file containing commands and initial data. The `postgres.bki` file used in this mode is prepared from the aforementioned header and data files, while building a PostgreSQL distribution, by a Perl script named `genbki.pl`. Although it's specific to a particular PostgreSQL release, `postgres.bki` is platform-independent and is installed in the `share` subdirectory of the installation tree.

`genbki.pl` also produces a derived header file for each catalog, for example `pg_class_d.h` for the `pg_class` catalog. This file contains automatically-generated macro definitions, and may contain other macros, enum declarations, and so on that can be useful for client C code that reads a particular catalog.

Most PostgreSQL developers don't need to be directly concerned with the BKI file, but almost any non-trivial feature addition in the backend will require modifying the catalog header files and/or initial data files. The rest of this chapter gives some information about that, and for completeness describes the BKI file format.

73.1. System Catalog Declaration Rules

The key part of a catalog header file is a C structure definition describing the layout of each row of the catalog. This begins with a `CATALOG` macro, which so far as the C compiler is concerned is just shorthand for `typedef struct FormData_catalogname`. Each field in the struct gives rise to a catalog column. Fields can be annotated using the BKI property macros described in `genbki.h`, for example to define a default value for a field or mark it as nullable or not nullable. The `CATALOG` line can also be annotated, with some other BKI property macros described in `genbki.h`, to define other properties of the catalog as a whole, such as whether it is a shared relation.

The system catalog cache code (and most catalog-munging code in general) assumes that the fixed-length portions of all system catalog tuples are in fact present, because it maps this C struct declaration onto them. Thus, all variable-length fields and nullable fields must be placed at the end, and they cannot be
System Catalog Declarations and Initial Contents

accessed as struct fields. For example, if you tried to set `pg_type.typrelid` to be NULL, it would fail when some piece of code tried to reference `typetup->typrelid` (or worse, `typetup->typelem`, because that follows `typrelid`). This would result in random errors or even segmentation violations.

As a partial guard against this type of error, variable-length or nullable fields should not be made directly visible to the C compiler. This is accomplished by wrapping them in `#ifdef CATALOG_VARLEN ... #endif` (where `CATALOG_VARLEN` is a symbol that is never defined). This prevents C code from carelessly trying to access fields that might not be there or might be at some other offset. As an independent guard against creating incorrect rows, we require all columns that should be non-nullable to be marked so in `pg_attribute`. The bootstrap code will automatically mark catalog columns as NOT NULL if they are fixed-width and are not preceded by any nullable or variable-width column. Where this rule is inadequate, you can force correct marking by using `BKI_FORCE_NOT_NULL` and `BKI_FORCE_NULL` annotations as needed.

Frontend code should not include any `pg_xxx.h` catalog header file, as these files may contain C code that won't compile outside the backend. (Typically, that happens because these files also contain declarations for functions in `src/backend/catalog/files`.) Instead, frontend code may include the corresponding generated `pg_xxx_d.h` header, which will contain OID #defines and any other data that might be of use on the client side. If you want macros or other code in a catalog header to be visible to frontend code, write `#ifdef EXPOSE_TO_CLIENT_CODE ... #endif` around that section to instruct `genbki.pl` to copy that section to the `pg_xxx_d.h` header.

A few of the catalogs are so fundamental that they can’t even be created by the BKI `create` command that’s used for most catalogs, because that command needs to write information into these catalogs to describe the new catalog. These are called bootstrap catalogs, and defining one takes a lot of extra work: you have to manually prepare appropriate entries for them in the pre-loaded contents of `pg_class` and `pg_type`, and those entries will need to be updated for subsequent changes to the catalog’s structure. (Bootstrap catalogs also need pre-loaded entries in `pg_attribute`, but fortunately `genbki.pl` handles that chore nowadays.) Avoid making new catalogs be bootstrap catalogs if at all possible.

### 73.2. System Catalog Initial Data

Each catalog that has any manually-created initial data (some do not) has a corresponding `.dat` file that contains its initial data in an editable format.

#### 73.2.1. Data File Format

Each `.dat` file contains Perl data structure literals that are simply eval’d to produce an in-memory data structure consisting of an array of hash references, one per catalog row. A slightly modified excerpt from `pg_database.dat` will demonstrate the key features:

```perl
[
    # A comment could appear here.
    { oid => '1', oid_symbol => 'Template1DbOid',
      descr => 'database\'s default template',
      datname => 'template1', encoding => 'ENCODING',
      datlocprovider => 'LOCALE_PROVIDER', datistemplate => 't',
      datallowconn => 't', datconnlimit => '-1', datfrozenxid => '0',
      datminmxid => '1', dattablespace => 'pg_default', datcollate =>
      'LC_COLLATE',
      datctype => 'LC_CTYPE', daticulocale => 'ICU_LOCALE', datacl =>
      '_null_' },
```
Points to note:

- The overall file layout is: open square bracket, one or more sets of curly braces each of which represents a catalog row, close square bracket. Write a comma after each closing curly brace.

- Within each catalog row, write comma-separated `key => value` pairs. The allowed `keys` are the names of the catalog's columns, plus the metadata keys `oid`, `oid_symbol`, `array_type_oid`, and `descr`. (The use of `oid` and `oid_symbol` is described in Section 73.2.2 below, while `array_type_oid` is described in Section 73.2.4. `descr` supplies a description string for the object, which will be inserted into `pg_description` or `pg_shdescription` as appropriate.) While the metadata keys are optional, the catalog's defined columns must all be provided, except when the catalog's `.h` file specifies a default value for the column. (In the example above, the `datdba` field has been omitted because `pg_database.h` supplies a suitable default value for it.)

- All values must be single-quoted. Escape single quotes used within a value with a backslash. Backslashes meant as data can, but need not, be doubled; this follows Perl's rules for simple quoted literals. Note that backslashes appearing as data will be treated as escapes by the bootstrap scanner, according to the same rules as for escape string constants (see Section 4.1.2.2); for example `\t` converts to a tab character. If you actually want a backslash in the final value, you will need to write four of them: Perl strips two, leaving `\\` for the bootstrap scanner to see.

- Null values are represented by `_null_`. (Note that there is no way to create a value that is just that string.)

- Comments are preceded by `#`, and must be on their own lines.

- Field values that are OIDs of other catalog entries should be represented by symbolic names rather than actual numeric OIDs. (In the example above, `dattablespace` contains such a reference.) This is described in Section 73.2.3 below.

- Since hashes are unordered data structures, field order and line layout aren't semantically significant. However, to maintain a consistent appearance, we set a few rules that are applied by the formatting script `reformat_dat_file.pl`:
  
  - Within each pair of curly braces, the metadata fields `oid`, `oid_symbol`, `array_type_oid`, and `descr` (if present) come first, in that order, then the catalog's own fields appear in their defined order.
  
  - Newlines are inserted between fields as needed to limit line length to 80 characters, if possible. A newline is also inserted between the metadata fields and the regular fields.
  
  - If the catalog's `.h` file specifies a default value for a column, and a data entry has that same value, `reformat_dat_file.pl` will omit it from the data file. This keeps the data representation compact.

  - `reformat_dat_file.pl` preserves blank lines and comment lines as-is. It's recommended to run `reformat_dat_file.pl` before submitting catalog data patches. For convenience, you can simply change to `src/include/catalog/` and run `make reformat-datatype-files`.

  - If you want to add a new method of making the data representation smaller, you must implement it in `reformat_dat_file.pl` and also teach `Catalog::ParseData()` how to expand the data back into the full representation.
73.2.2. OID Assignment

A catalog row appearing in the initial data can be given a manually-assigned OID by writing an `oid => nnnn` metadata field. Furthermore, if an OID is assigned, a C macro for that OID can be created by writing an `oid_symbol => name` metadata field.

Pre-loaded catalog rows must have preassigned OIDs if there are OID references to them in other pre-loaded rows. A preassigned OID is also needed if the row’s OID must be referenced from C code. If neither case applies, the `oid` metadata field can be omitted, in which case the bootstrap code assigns an OID automatically. In practice we usually preassign OIDs for all or none of the pre-loaded rows in a given catalog, even if only some of them are actually cross-referenced.

Writing the actual numeric value of any OID in C code is considered very bad form; always use a macro, instead. Direct references to `pg_proc` OIDs are common enough that there’s a special mechanism to create the necessary macros automatically; see `src/backend/utils/Gen_fmgrtab.pl`. Similarly — but, for historical reasons, not done the same way — there’s an automatic method for creating macros for `pg_type` OIDs. `oid_symbol` entries are therefore not necessary in those two catalogs. Likewise, macros for the `pg_class` OIDs of system catalogs and indexes are set up automatically. For all other system catalogs, you have to manually specify any macros you need via `oid_symbol` entries.

To find an available OID for a new pre-loaded row, run the script `src/include/catalog/unused_oids`. It prints inclusive ranges of unused OIDs (e.g., the output line `45-900` means OIDs 45 through 900 have not been allocated yet). Currently, OIDs 1–9999 are reserved for manual assignment; the `unused_oids` script simply looks through the catalog headers and `.dat` files to see which ones do not appear. You can also use the `duplicate_oids` script to check for mistakes. (`genbki.pl` will assign OIDs for any rows that didn’t get one hand-assigned to them, and it will also detect duplicate OIDs at compile time.)

When choosing OIDs for a patch that is not expected to be committed immediately, best practice is to use a group of more-or-less consecutive OIDs starting with some random choice in the range 8000—9999. This minimizes the risk of OID collisions with other patches being developed concurrently. To keep the 8000—9999 range free for development purposes, after a patch has been committed to the master git repository its OIDs should be renumbered into available space below that range. Typically, this will be done near the end of each development cycle, moving all OIDs consumed by patches committed in that cycle at the same time. The script `renumber_oids.pl` can be used for this purpose. If an uncommitted patch is found to have OID conflicts with some recently-committed patch, `renumber_oids.pl` may also be useful for recovering from that situation.

Because of this convention of possibly renumbering OIDs assigned by patches, the OIDs assigned by a patch should not be considered stable until the patch has been included in an official release. We do not change manually-assigned object OIDs once released, however, as that would create assorted compatibility problems.

If `genbki.pl` needs to assign an OID to a catalog entry that does not have a manually-assigned OID, it will use a value in the range 10000—11999. The server's OID counter is set to 10000 at the start of a bootstrap run, so that any objects created on-the-fly during bootstrap processing also receive OIDs in this range. (The usual OID assignment mechanism takes care of preventing any conflicts.)

Objects with OIDs below `FirstUnpinnedObjectId` (12000) are considered “pinned”, preventing them from being deleted. (There are a small number of exceptions, which are hard-wired into `IsPinnedObject()`.) `initdb` forces the OID counter up to `FirstUnpinnedObjectId` as soon as it's ready to create unpinned objects. Thus objects created during the later phases of `initdb`, such as objects created while running the `information_schema.sql` script, will not be pinned, while all objects known to `genbki.pl` will be.
OIDs assigned during normal database operation are constrained to be 16384 or higher. This ensures that the range 10000—16383 is free for OIDs assigned automatically by `genbki.pl` or during initdb. These automatically-assigned OIDs are not considered stable, and may change from one installation to another.

### 73.2.3. OID Reference Lookup

In principle, cross-references from one initial catalog row to another could be written just by writing the preassigned OID of the referenced row in the referencing field. However, that is against project policy, because it is error-prone, hard to read, and subject to breakage if a newly-assigned OID is renumbered. Therefore `genbki.pl` provides mechanisms to write symbolic references instead. The rules are as follows:

- Use of symbolic references is enabled in a particular catalog column by attaching `BKI_LOOKUP(lookuprule)` to the column's definition, where `lookuprule` is the name of the referenced catalog, e.g., `pg_proc`. `BKI_LOOKUP` can be attached to columns of type `Oid`, `regproc`, `oidvector`, or `Oid[]`; in the latter two cases it implies performing a lookup on each element of the array.

- It's also permissible to attach `BKI_LOOKUP(encoding)` to integer columns to reference character set encodings, which are not currently represented as catalog OIDs, but have a set of values known to `genbki.pl`.

- In some catalog columns, it's allowed for entries to be zero instead of a valid reference. If this is allowed, write `BKI_LOOKUP_OPT` instead of `BKI_LOOKUP`. Then you can write 0 for an entry. (If the column is declared `regproc`, you can optionally write - instead of 0.) Except for this special case, all entries in a `BKI_LOOKUP` column must be symbolic references. `genbki.pl` will warn about unrecognized names.

- Most kinds of catalog objects are simply referenced by their names. Note that type names must exactly match the referenced `pg_type` entry's `typname`; you do not get to use any aliases such as `integer` for `int4`.

- A function can be represented by its `proname`, if that is unique among the `pg_proc.dat` entries (this works like `regproc` input). Otherwise, write it as `proname(argtypename,argtypename,...)`, like `regprocedure`. The argument type names must be spelled exactly as they are in the `pg_proc.dat` entry's `proargtypes` field. Do not insert any spaces.

- Operators are represented by `oprname(lefttype,righttype)`, writing the type names exactly as they appear in the `pg_operator.dat` entry's `oprleft` and `oprright` fields. (Write 0 for the omitted operand of a unary operator.)

- The names of opclasses and opfamilies are only unique within an access method, so they are represented by `access_method_name/object_name`.

- In none of these cases is there any provision for schema-qualification; all objects created during bootstrap are expected to be in the `pg_catalog` schema.

`genbki.pl` resolves all symbolic references while it runs, and puts simple numeric OIDs into the emitted BKI file. There is therefore no need for the bootstrap backend to deal with symbolic references.

It's desirable to mark OID reference columns with `BKI_LOOKUP` or `BKI_LOOKUP_OPT` even if the catalog has no initial data that requires lookup. This allows `genbki.pl` to record the foreign key relationships that exist in the system catalogs. That information is used in the regression tests to check for incorrect entries. See also the macros `DECLARE_FOREIGN_KEY`, `DECLARE_FOREIGN_KEY_OPT`, `DECLARE_FOREIGN_KEY_OPT`,
E_ARRAY_FOREIGN_KEY, and DECLARE_ARRAY_FOREIGN_KEY_OPT, which are used to declare foreign key relationships that are too complex for BKI_LOOKUP (typically, multi-column foreign keys).

73.2.4. Automatic Creation of Array Types

Most scalar data types should have a corresponding array type (that is, a standard varlena array type whose element type is the scalar type, and which is referenced by the typarray field of the scalar type's pg_type entry). genbki.pl is able to generate the pg_type entry for the array type automatically in most cases.

To use this facility, just write an array_type_oid => nnnn metadata field in the scalar type's pg_type entry, specifying the OID to use for the array type. You may then omit the typarray field, since it will be filled automatically with that OID.

The generated array type's name is the scalar type's name with an underscore prepended. The array entry's other fields are filled from BKI_ARRAY_DEFAULT(value) annotations in pg_type.h, or if there isn't one, copied from the scalar type. (There's also a special case for typalign.) Then the typelem and typarray fields of the two entries are set to cross-reference each other.

73.2.5. Recipes for Editing Data Files

Here are some suggestions about the easiest ways to perform common tasks when updating catalog data files.

**Add a new column with a default to a catalog:** Add the column to the header file with a BKI_DEFAULT(value) annotation. The data file need only be adjusted by adding the field in existing rows where a non-default value is needed.

**Add a default value to an existing column that doesn't have one:** Add a BKI_DEFAULT annotation to the header file, then run make reformat-dat-files to remove now-redundant field entries.

**Remove a column, whether it has a default or not:** Remove the column from the header, then run make reformat-dat-files to remove now-useless field entries.

**Change or remove an existing default value:** You cannot simply change the header file, since that will cause the current data to be interpreted incorrectly. First run make expand-dat-files to rewrite the data files with all default values inserted explicitly, then change or remove the BKI_DEFAULT annotation, then run make reformat-dat-files to remove superfluous fields again.

**Ad-hoc bulk editing:** reformat_dat_file.pl can be adapted to perform many kinds of bulk changes. Look for its block comments showing where one-off code can be inserted. In the following example, we are going to consolidate two Boolean fields in pg_proc into a char field:

1. Add the new column, with a default, to pg_proc.h:

   ```
   +    /* see PROKIND_ categories below */
   +    char        prokind BKI_DEFAULT(f);
   ```

2. Create a new script based on reformat_dat_file.pl to insert appropriate values on-the-fly:

   ```
   # At this point we have the full row in memory as a
   ```
3. Run the new script:

   $ cd src/include/catalog
   $ perl rewrite_dat_with_prokind.pl pg_proc.dat

   At this point pg_proc.dat has all three columns, prokind, proisagg, and proiswindow, though they will appear only in rows where they have non-default values.

4. Remove the old columns from pg_proc.h:

   - /* is it an aggregate? */
   - bool proisagg BKI_DEFAULT(f);
   - /* is it a window function? */
   - bool proiswindow BKI_DEFAULT(f);

5. Finally, run make reformat-dat-files to remove the useless old entries from pg_proc.dat.

For further examples of scripts used for bulk editing, see convert_oid2name.pl and remove_pg_type_oid_symbols.pl attached to this message: https://www.postgresql.org/message-id/CAJVSVGVX8gXnPm+Xa=DxR7kFYprcQ1tNcCT5D003ShfnM6jehA@mail.gmail.com

73.3. BKI File Format

This section describes how the PostgreSQL backend interprets BKI files. This description will be easier to understand if the postgres.bki file is at hand as an example.

BKI input consists of a sequence of commands. Commands are made up of a number of tokens, depending on the syntax of the command. Tokens are usually separated by whitespace, but need not be if there is no ambiguity. There is no special command separator; the next token that syntactically cannot belong to the preceding command starts a new one. (Usually you would put a new command on a new line, for clarity.) Tokens can be certain key words, special characters (parentheses, commas, etc.), identifiers, numbers, or single-quoted strings. Everything is case sensitive.

Lines starting with # are ignored.
73.4. BKI Commands

create tablename tableoid [bootstrap] [shared_relation] [rowtype_oid oid] (name1 = typel [FORCE NOT NULL | FORCE NULL ] [, name2 = type2 [FORCE NOT NULL | FORCE NULL ] , ...])

Create a table named tablename, and having the OID tableoid, with the columns given in parentheses.

The following column types are supported directly by bootstrap.c: bool, bytea, char (1 byte), name, int2, int4, regproc, regclass, regtype, text, oid, tid, xid, cid, int2vector, oidvector, _int4 (array), _text (array), _oid (array), _char (array), _aclitem (array). Although it is possible to create tables containing columns of other types, this cannot be done until after pg_type has been created and filled with appropriate entries. (That effectively means that only these column types can be used in bootstrap catalogs, but non-bootstrap catalogs can contain any built-in type.)

When bootstrap is specified, the table will only be created on disk; nothing is entered into pg_class, pg_attribute, etc. for it. Thus the table will not be accessible by ordinary SQL operations until such entries are made the hard way (with insert commands). This option is used for creating pg_class etc. themselves.

The table is created as shared if shared_relation is specified. The table's row type OID (pg_type OID) can optionally be specified via the rowtype_oid clause; if not specified, an OID is automatically generated for it. (The rowtype_oid clause is useless if bootstrap is specified, but it can be provided anyway for documentation.)

open tablename

Open the table named tablename for insertion of data. Any currently open table is closed.

close tablename

Close the open table. The name of the table must be given as a cross-check.

insert ([oid_value] value1 value2 ...)

Insert a new row into the open table using value1, value2, etc., for its column values.

NULL values can be specified using the special keyword _null_. Values that do not look like identifiers or digit strings must be single-quoted. (To include a single quote in a value, write it twice. Escape-string-style backslash escapes are allowed in the string, too.)

declare[unique]index indexname indexoid on tablename using amname ( opclass1 name1 [, ...])

Create an index named indexname, having OID indexoid, on the table named tablename, using the amname access method. The fields to index are called name1, name2 etc., and the operator classes to use are opclass1, opclass2 etc., respectively. The index file is created and appropriate catalog entries are made for it, but the index contents are not initialized by this command.

declare toast toast_tableoid toast_indexoid on tablename

Create a TOAST table for the table named tablename. The TOAST table is assigned OID toast_tableoid and its index is assigned OID toast_indexoid. As with declare index, filling of the index is postponed.
Fill in the indices that have previously been declared.

73.5. Structure of the Bootstrap BKI File

The `open` command cannot be used until the tables it uses exist and have entries for the table that is to be opened. (These minimum tables are `pg_class`, `pg_attribute`, `pg_proc`, and `pg_type`.) To allow those tables themselves to be filled, `create` with the `bootstrap` option implicitly opens the created table for data insertion.

Also, the `declare index` and `declare toast` commands cannot be used until the system catalogs they need have been created and filled in.

Thus, the structure of the `postgres.bki` file has to be:

1. `create bootstrap` one of the critical tables
2. `insert` data describing at least the critical tables
3. `close`
4. Repeat for the other critical tables.
5. `create (without bootstrap)` a noncritical table
6. `open`
7. `insert` desired data
8. `close`
9. Repeat for the other noncritical tables.
10. Define indexes and toast tables.
11. `build indices`

There are doubtless other, undocumented ordering dependencies.

73.6. BKI Example

The following sequence of commands will create the table `test_table` with OID 420, having three columns `oid`, `cola` and `colb` of type `oid`, `int4` and `text`, respectively, and insert two rows into the table:

```sql
create test_table 420 (oid = oid, cola = int4, colb = text)
open test_table
insert ( 421 1 'value 1' )
insert ( 422 2 _null_ )
close test_table
```
Chapter 74. How the Planner Uses Statistics

This chapter builds on the material covered in Section 14.1 and Section 14.2 to show some additional details about how the planner uses the system statistics to estimate the number of rows each part of a query might return. This is a significant part of the planning process, providing much of the raw material for cost calculation.

The intent of this chapter is not to document the code in detail, but to present an overview of how it works. This will perhaps ease the learning curve for someone who subsequently wishes to read the code.

74.1. Row Estimation Examples

The examples shown below use tables in the PostgreSQL regression test database. The outputs shown are taken from version 8.3. The behavior of earlier (or later) versions might vary. Note also that since ANALYZE uses random sampling while producing statistics, the results will change slightly after any new ANALYZE.

Let's start with a very simple query:

```
EXPLAIN SELECT * FROM tenk1;
```

```
QUERY PLAN
-------------------------------------------------------------
Seq Scan on tenk1  (cost=0.00..458.00 rows=10000 width=244)
```

How the planner determines the cardinality of tenk1 is covered in Section 14.2, but is repeated here for completeness. The number of pages and rows is looked up in pg_class:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 'tenk1';
```

| relpages | reltuples |
|----------+-----------|
| 358      | 10000     |

These numbers are current as of the last VACUUM or ANALYZE on the table. The planner then fetches the actual current number of pages in the table (this is a cheap operation, not requiring a table scan). If that is different from relpages then reltuples is scaled accordingly to arrive at a current number-of-rows estimate. In the example above, the value of relpages is up-to-date so the rows estimate is the same as reltuples.

Let's move on to an example with a range condition in its WHERE clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000;
```

```
QUERY PLAN
-------------------------------------------------------------------------------
2633
```
How the Planner Uses Statistics

Bitmap Heap Scan on tenk1  (cost=24.06..394.64 rows=1007 width=244)
   Recheck Cond: (unique1 < 1000)
   ->  Bitmap Index Scan on tenk1_unique1  (cost=0.00..23.80 rows=1007
       width=0)
       Index Cond: (unique1 < 1000)

The planner examines the WHERE clause condition and looks up the selectivity function for the operator < in \texttt{pg\_operator}. This is held in the column \texttt{oprrest}, and the entry in this case is \texttt{scalarltsel}. The \texttt{scalarltsel} function retrieves the histogram for \texttt{unique1} from \texttt{pg\_statistic}. For manual queries it is more convenient to look in the simpler \texttt{pg\_stats} view:

\begin{verbatim}
SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='unique1';
\end{verbatim}

\begin{verbatim}
histogram_bounds
------------------------------------------------------
{0,993,1997,3050,4040,5036,5957,7057,8029,9016,9995}
\end{verbatim}

Next the fraction of the histogram occupied by "< 1000" is worked out. This is the selectivity. The histogram divides the range into equal frequency buckets, so all we have to do is locate the bucket that our value is in and count part of it and all of the ones before. The value 1000 is clearly in the second bucket (993–1997). Assuming a linear distribution of values inside each bucket, we can calculate the selectivity as:

\begin{verbatim}
selectivity = (1 + (1000 - bucket[2].min)/(bucket[2].max - bucket[2].min))/num_buckets
= (1 + (1000 - 993)/(1997 - 993))/10
= 0.100697
\end{verbatim}

that is, one whole bucket plus a linear fraction of the second, divided by the number of buckets. The estimated number of rows can now be calculated as the product of the selectivity and the cardinality of \texttt{tenk1}:

\begin{verbatim}
rows = rel_cardinality * selectivity
= 10000 * 0.100697
= 1007  (rounding off)
\end{verbatim}

Next let's consider an example with an equality condition in its \texttt{WHERE} clause:

\begin{verbatim}
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'CRAAAA';
\end{verbatim}

\begin{verbatim}
QUERY PLAN
---------------------------------------------------------
Seq Scan on tenk1  (cost=0.00..483.00 rows=30 width=244)
   Filter: (stringu1 = 'CRAAAA'::name)
\end{verbatim}

Again the planner examines the \texttt{WHERE} clause condition and looks up the selectivity function for =, which is \texttt{eqsel}. For equality estimation the histogram is not useful; instead the list of most common values (MCVs) is used to determine the selectivity. Let's have a look at the MCVs, with some additional columns that will be useful later:
How the Planner Uses Statistics

```sql
SELECT null_frac, n_distinct, most_common_vals, most_common_freqs FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';
```

| null_frac | 0 |
| n_distinct | 676 |
| most_common_vals | {EJAAAA,BBAAAA,CRAAAA,FCAAAA,FEAAAA,GSAAAA,JOAAAA,MCAAAA,NAAAAA,WGAAAA} |
| most_common_freqs | {0.00333333,0.003,0.003,0.003,0.003,0.003,0.003,0.003,0.003,0.003} |

Since CRAAAA appears in the list of MCVs, the selectivity is merely the corresponding entry in the list of most common frequencies (MCFs):

```sql
selectivity = mcf[3]
= 0.003
```

As before, the estimated number of rows is just the product of this with the cardinality of tenk1:

```sql
rows = 10000 * 0.003
= 30
```

Now consider the same query, but with a constant that is not in the MCV list:

```sql
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'xxx';
```

```
QUERY PLAN
----------------------------------------------------------
Seq Scan on tenk1  (cost=0.00..483.00 rows=15 width=244)
  Filter: (stringu1 = 'xxx'::name)
```

This is quite a different problem: how to estimate the selectivity when the value is not in the MCV list. The approach is to use the fact that the value is not in the list, combined with the knowledge of the frequencies for all of the MCVs:

```sql
selectivity = (1 - sum(mvf))/(num_distinct - num_mcv)
= (1 - (0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003))/(676 - 10)
= 0.0014559
```

That is, add up all the frequencies for the MCVs and subtract them from one, then divide by the number of other distinct values. This amounts to assuming that the fraction of the column that is not any of the MCVs is evenly distributed among all the other distinct values. Notice that there are no null values so we don’t have to worry about those (otherwise we’d subtract the null fraction from the numerator as well). The estimated number of rows is then calculated as usual:

```sql
rows = 10000 * 0.0014559
= 15  (rounding off)
```
The previous example with \texttt{unique1 < 1000} was an oversimplification of what \texttt{scalarlt} really does; now that we have seen an example of the use of MCVs, we can fill in some more detail. The example was correct as far as it went, because since \texttt{unique1} is a unique column it has no MCVs (obviously, no value is any more common than any other value). For a non-unique column, there will normally be both a histogram and an MCV list, and the histogram does not include the portion of the column population represented by the MCVs. We do things this way because it allows more precise estimation. In this situation \texttt{scalarlt} directly applies the condition (e.g., \texttt{“< 1000”}) to each value of the MCV list, and adds up the frequencies of the MCVs for which the condition is true. This gives an exact estimate of the selectivity within the portion of the table that is MCVs. The histogram is then used in the same way as above to estimate the selectivity in the portion of the table that is not MCVs, and then the two numbers are combined to estimate the overall selectivity. For example, consider

\begin{verbatim}
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 < 'IAAAAA';

QUERY PLAN
------------------------------------------------------------
Seq Scan on tenk1  (cost=0.00..483.00 rows=3077 width=244)
  Filter: (stringu1 < 'IAAAAA'::name)

We already saw the MCV information for stringu1, and here is its histogram:

SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';

<table>
<thead>
<tr>
<th>histogram_bounds</th>
</tr>
</thead>
<tbody>
<tr>
<td>{AAAAAA, CQAAAA, FRAAAA, IBAAAA, KRAAAA, NFAAAA, PSAAAA, SGAAAA, VAAAAA, XLAAAA, ZZAAAA}</td>
</tr>
</tbody>
</table>

Checking the MCV list, we find that the condition \texttt{stringu1 < 'IAAAAA'} is satisfied by the first six entries and not the last four, so the selectivity within the MCV part of the population is

\[
\text{selectivity} = \text{sum(relevant mvfs)} \\
= \frac{1}{30} + \frac{1}{30} + \frac{1}{30} + \frac{1}{30} + \frac{1}{30} + \frac{1}{30} \\
= 0.01833333
\]

Summing all the MCFs also tells us that the total fraction of the population represented by MCVs is 0.03033333, and therefore the fraction represented by the histogram is 0.96966667 (again, there are no nulls, else we’d have to exclude them here). We can see that the value \texttt{IAAAAA} falls nearly at the end of the third histogram bucket. Using some rather cheesy assumptions about the frequency of different characters, the planner arrives at the estimate 0.298387 for the portion of the histogram population that is less than \texttt{IAAAAA}. We then combine the estimates for the MCV and non-MCV populations:

\[
\text{selectivity} = \text{mcv_selectivity} + \text{histogram_selectivity} \times \text{histogram_fraction} \\
= 0.01833333 + 0.298387 \times 0.96966667 \\
= 0.307669
\]

\[
\text{rows} = 10000 \times 0.307669 \\
= 3077  \text{ (rounding off)}
\]
\end{verbatim}
In this particular example, the correction from the MCV list is fairly small, because the column distribution is actually quite flat (the statistics showing these particular values as being more common than others are mostly due to sampling error). In a more typical case where some values are significantly more common than others, this complicated process gives a useful improvement in accuracy because the selectivity for the most common values is found exactly.

Now let's consider a case with more than one condition in the WHERE clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000 AND stringul = 'xxx';
```

**QUERY PLAN**

```
 BERMAP Heap Scan on tenk1 (cost=23.80..396.91 rows=1 width=244)
  Recheck Cond: (unique1 < 1000)
  Filter: (stringul = 'xxx':::name)
    -> Bitmap Index Scan on tenk1_unique1 (cost=0.00..23.80 rows=1007 width=0)
      Index Cond: (unique1 < 1000)
```

The planner assumes that the two conditions are independent, so that the individual selectivities of the clauses can be multiplied together:

```
selectivity = selectivity(unique1 < 1000) * selectivity(stringul = 'xxx')
  = 0.100697 * 0.0014559
  = 0.0001466
rows        = 10000 * 0.0001466
  = 1  (rounding off)
```

Notice that the number of rows estimated to be returned from the bitmap index scan reflects only the condition used with the index; this is important since it affects the cost estimate for the subsequent heap fetches.

Finally we will examine a query that involves a join:

```
EXPLAIN SELECT * FROM tenk1 t1, tenk2 t2
WHERE t1.unique1 < 50 AND t1.unique2 = t2.unique2;
```

**QUERY PLAN**

```
 Nested Loop (cost=4.64..456.23 rows=50 width=488)
   -> Bitmap Heap Scan on tenk1 t1 (cost=4.64..142.17 rows=50 width=244)
     Recheck Cond: (unique1 < 50)
     -> Bitmap Index Scan on tenk1_unique1 (cost=0.00..4.63 rows=50 width=0)
       Index Cond: (unique1 < 50)
     -> Index Scan using tenk2_unique2 on tenk2 t2 (cost=0.00..6.27 rows=1 width=244)
       Index Cond: (unique2 = t1.unique2)
```

2637
The restriction on `tenk1, unique1 < 50`, is evaluated before the nested-loop join. This is handled analogously to the previous range example. This time the value 50 falls into the first bucket of the `unique1` histogram:

\[
\text{selectivity} = \frac{(0 + (50 - \text{bucket}[1].\text{min})/(\text{bucket}[1].\text{max} - \text{bucket}[1].\text{min}))}{\text{num_buckets}}
\]
\[
= \frac{(0 + (50 - 0))/(993 - 0))}{10}
\]
\[
= 0.005035
\]
\[
\text{rows} = 10000 \times 0.005035
\]
\[
= 50 \text{ (rounding off)}
\]

The restriction for the join is `t2.unique2 = t1.unique2`. The operator is just our familiar `=`, however the selectivity function is obtained from the `oprjoin` column of `pg_operator`, and is `eqjoinsel`. `eqjoinsel` looks up the statistical information for both `tenk2` and `tenk1`:

```sql
SELECT tablename, null_frac, n_distinct, most_common_vals FROM pg_stats
WHERE tablename IN ('tenk1', 'tenk2') AND attname='unique2';
```

<table>
<thead>
<tr>
<th>tablename</th>
<th>null_frac</th>
<th>n_distinct</th>
<th>most_common_vals</th>
</tr>
</thead>
<tbody>
<tr>
<td>tenk1</td>
<td>0</td>
<td>-1</td>
<td></td>
</tr>
<tr>
<td>tenk2</td>
<td>0</td>
<td>-1</td>
<td></td>
</tr>
</tbody>
</table>
```

In this case there is no MCV information for `unique2` because all the values appear to be unique, so we use an algorithm that relies only on the number of distinct values for both relations together with their null fractions:

\[
\text{selectivity} = (1 - \text{null_frac1}) \times (1 - \text{null_frac2}) \times \min(1/\text{num_distinct1}, 1/\text{num_distinct2})
\]
\[
= (1 - 0) \times (1 - 0) / \max(10000, 10000)
\]
\[
= 0.0001
\]

This is, subtract the null fraction from one for each of the relations, and divide by the maximum of the numbers of distinct values. The number of rows that the join is likely to emit is calculated as the cardinality of the Cartesian product of the two inputs, multiplied by the selectivity:

\[
\text{rows} = (\text{outer_cardinality} \times \text{inner_cardinality}) \times \text{selectivity}
\]
\[
= (50 \times 10000) \times 0.0001
\]
\[
= 50
\]

Had there been MCV lists for the two columns, `eqjoinsel` would have used direct comparison of the MCV lists to determine the join selectivity within the part of the column populations represented by the MCVs. The estimate for the remainder of the populations follows the same approach shown here.

Notice that we showed `inner_cardinality` as 10000, that is, the unmodified size of `tenk2`. It might appear from inspection of the `EXPLAIN` output that the estimate of join rows comes from `50 \times 1`, that is, the number of outer rows times the estimated number of rows obtained by each inner index scan on `tenk2`. But this is not the case: the join relation size is estimated before any particular join plan has been considered. If everything is working well then the two ways of estimating the join size will produce about the same answer, but due to round-off error and other factors they sometimes diverge significantly.
For those interested in further details, estimation of the size of a table (before any WHERE clauses) is done in src/backend/optimizer/util/plancat.c. The generic logic for clause selectivities is in src/backend/optimizer/path/clausesel.c. The operator-specific selectivity functions are mostly found in src/backend/utils/adt/selfuncs.c.

### 74.2. Multivariate Statistics Examples

#### 74.2.1. Functional Dependencies

Multivariate correlation can be demonstrated with a very simple data set — a table with two columns, both containing the same values:

```
CREATE TABLE t (a INT, b INT);
INSERT INTO t SELECT i % 100, i % 100 FROM generate_series(1, 10000) s(i);
ANALYZE t;
```

As explained in Section 14.2, the planner can determine cardinality of `t` using the number of pages and rows obtained from `pg_class`:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 't';
```

<table>
<thead>
<tr>
<th>relpages</th>
<th>reltuples</th>
</tr>
</thead>
<tbody>
<tr>
<td>45</td>
<td>10000</td>
</tr>
</tbody>
</table>

The data distribution is very simple; there are only 100 distinct values in each column, uniformly distributed.

The following example shows the result of estimating a WHERE condition on the `a` column:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1;
```

```
QUERY PLAN
-------------------------------------------------------------------
-----------
Seq Scan on t  (cost=0.00..170.00 rows=100 width=8) (actual rows=100
loops=1)
  Filter: (a = 1)
  Rows Removed by Filter: 9900
```

The planner examines the condition and determines the selectivity of this clause to be 1%. By comparing this estimate and the actual number of rows, we see that the estimate is very accurate (in fact exact, as the table is very small). Changing the WHERE condition to use the `b` column, an identical plan is generated. But observe what happens if we apply the same condition on both columns, combining them with AND:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 1;
```

```
QUERY PLAN
---------
Seq Scan on t  (cost=0.00..195.00 rows=1 width=8) (actual rows=100
loops=1)
```

2639
How the Planner Uses Statistics

Filter: ((a = 1) AND (b = 1))
Rows Removed by Filter: 9900

The planner estimates the selectivity for each condition individually, arriving at the same 1% estimates as above. Then it assumes that the conditions are independent, and so it multiplies their selectivities, producing a final selectivity estimate of just 0.01%. This is a significant underestimate, as the actual number of rows matching the conditions (100) is two orders of magnitude higher.

This problem can be fixed by creating a statistics object that directs ANALYZE to calculate functional-dependency multivariate statistics on the two columns:

CREATE STATISTICS stts (dependencies) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 1;

QUERY PLAN
-------------------------------------------------------------------
------------
Seq Scan on t  (cost=0.00..195.00 rows=100 width=8) (actual rows=100
loops=1)
Filter: ((a = 1) AND (b = 1))
Rows Removed by Filter: 9900

74.2.2. Multivariate N-Distinct Counts

A similar problem occurs with estimation of the cardinality of sets of multiple columns, such as the number of groups that would be generated by a GROUP BY clause. When GROUP BY lists a single column, the n-distinct estimate (which is visible as the estimated number of rows returned by the HashAggregate node) is very accurate:

EXPLAIN (ANALYZE, TIMING OFF) SELECT COUNT(*) FROM t GROUP BY a;
QUERY PLAN
-------------------------------------------------------------------
----------------------
HashAggregate  (cost=195.00..196.00 rows=100 width=12) (actual rows=100
loops=1)
  Group Key: a
    ->  Seq Scan on t  (cost=0.00..145.00 rows=10000 width=4) (actual
rows=10000 loops=1)

But without multivariate statistics, the estimate for the number of groups in a query with two columns in GROUP BY, as in the following example, is off by an order of magnitude:

EXPLAIN (ANALYZE, TIMING OFF) SELECT COUNT(*) FROM t GROUP BY a, b;
QUERY PLAN
-------------------------------------------------------------------
-------------------------
HashAggregate  (cost=220.00..230.00 rows=1000 width=16) (actual rows=1000
loops=1)
  Group Key: a, b
    ->  Seq Scan on t  (cost=0.00..145.00 rows=10000 width=8) (actual
rows=10000 loops=1)
By redefining the statistics object to include n-distinct counts for the two columns, the estimate is much improved:

```
DROP STATISTICS stts;
CREATE STATISTICS stts (dependencies, ndistinct) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF) SELECT COUNT(*) FROM t GROUP BY a, b;
```

```
Query Plan

---------------------------------------------------------------------------------
| HashAggregate | (cost=220.00..221.00 rows=100 width=16) (actual rows=100 loops=1) |
| Group Key: | a, b |
| -> Seq Scan on t | (cost=0.00..145.00 rows=10000 width=8) (actual rows=10000 loops=1) |
```

### 74.2.3. MCV Lists

As explained in Section 74.2.1, functional dependencies are very cheap and efficient type of statistics, but their main limitation is their global nature (only tracking dependencies at the column level, not between individual column values).

This section introduces multivariate variant of MCV (most-common values) lists, a straightforward extension of the per-column statistics described in Section 74.1. These statistics address the limitation by storing individual values, but it is naturally more expensive, both in terms of building the statistics in `ANALYZE`, storage and planning time.

Let's look at the query from Section 74.2.1 again, but this time with a MCV list created on the same set of columns (be sure to drop the functional dependencies, to make sure the planner uses the newly created statistics).

```
DROP STATISTICS stts;
CREATE STATISTICS stts2 (mcv) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 1;
```

```
Query Plan

---------------------------------------------------------------------------------
| Seq Scan on t | (cost=0.00..195.00 rows=100 width=8) (actual rows=100 loops=1) |
| Filter: | ((a = 1) AND (b = 1)) |
| Rows Removed by Filter: | 9900 |
```

The estimate is as accurate as with the functional dependencies, mostly thanks to the table being fairly small and having a simple distribution with a low number of distinct values. Before looking at the second query, which was not handled by functional dependencies particularly well, let's inspect the MCV list a bit.

Inspecting the MCV list is possible using `pg_mcv_list_items` set-returning function.

```
SELECT m.* FROM pg_statistic_ext join pg_statistic_ext_data on (oid = stxoid),
          pg_mcv_list_items(stxdmcv) m WHERE stxname = 'stts2';
```
How the Planner Uses Statistics

<table>
<thead>
<tr>
<th>index</th>
<th>values</th>
<th>nulls</th>
<th>frequency</th>
<th>base_frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(0, 0)</td>
<td>{f,f}</td>
<td>0.01</td>
<td>0.0001</td>
</tr>
<tr>
<td>1</td>
<td>(1, 1)</td>
<td>{f,f}</td>
<td>0.01</td>
<td>0.0001</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>49</td>
<td>(49, 49)</td>
<td>{f,f}</td>
<td>0.01</td>
<td>0.0001</td>
</tr>
<tr>
<td>50</td>
<td>(50, 50)</td>
<td>{f,f}</td>
<td>0.01</td>
<td>0.0001</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>97</td>
<td>(97, 97)</td>
<td>{f,f}</td>
<td>0.01</td>
<td>0.0001</td>
</tr>
<tr>
<td>98</td>
<td>(98, 98)</td>
<td>{f,f}</td>
<td>0.01</td>
<td>0.0001</td>
</tr>
<tr>
<td>99</td>
<td>(99, 99)</td>
<td>{f,f}</td>
<td>0.01</td>
<td>0.0001</td>
</tr>
</tbody>
</table>

This confirms there are 100 distinct combinations in the two columns, and all of them are about equally likely (1% frequency for each one). The base frequency is the frequency computed from per-column statistics, as if there were no multi-column statistics. Had there been any null values in either of the columns, this would be identified in the nulls column.

When estimating the selectivity, the planner applies all the conditions on items in the MCV list, and then sums the frequencies of the matching ones. See `mcv_clauselist_selectivity` in `src/backend/statistics/mcv.c` for details.

Compared to functional dependencies, MCV lists have two major advantages. Firstly, the list stores actual values, making it possible to decide which combinations are compatible.

EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 10;

QUERY PLAN

```
Seq Scan on t  (cost=0.00..195.00 rows=1 width=8) (actual rows=0 loops=1)
  Filter: ((a = 1) AND (b = 10))
  Rows Removed by Filter: 10000
```

Secondly, MCV lists handle a wider range of clause types, not just equality clauses like functional dependencies. For example, consider the following range query for the same table:

EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a <= 49 AND b > 49;

QUERY PLAN

```
Seq Scan on t  (cost=0.00..195.00 rows=1 width=8) (actual rows=0 loops=1)
  Filter: ((a <= 49) AND (b > 49))
  Rows Removed by Filter: 10000
```

74.3. Planner Statistics and Security

Access to the table `pg_statistic` is restricted to superusers, so that ordinary users cannot learn about the contents of the tables of other users from it. Some selectivity estimation functions will use a user-provided operator (either the operator appearing in the query or a related operator) to analyze the stored
statistics. For example, in order to determine whether a stored most common value is applicable, the selectivity estimator will have to run the appropriate = operator to compare the constant in the query to the stored value. Thus the data in \texttt{pg\_statistic} is potentially passed to user-defined operators. An appropriately crafted operator can intentionally leak the passed operands (for example, by logging them or writing them to a different table), or accidentally leak them by showing their values in error messages, in either case possibly exposing data from \texttt{pg\_statistic} to a user who should not be able to see it.

In order to prevent this, the following applies to all built-in selectivity estimation functions. When planning a query, in order to be able to use stored statistics, the current user must either have \texttt{SELECT} privilege on the table or the involved columns, or the operator used must be \texttt{LEAKPROOF} (more accurately, the function that the operator is based on). If not, then the selectivity estimator will behave as if no statistics are available, and the planner will proceed with default or fall-back assumptions.

If a user does not have the required privilege on the table or columns, then in many cases the query will ultimately receive a permission-denied error, in which case this mechanism is invisible in practice. But if the user is reading from a security-barrier view, then the planner might wish to check the statistics of an underlying table that is otherwise inaccessible to the user. In that case, the operator should be leak-proof or the statistics will not be used. There is no direct feedback about that, except that the plan might be suboptimal. If one suspects that this is the case, one could try running the query as a more privileged user, to see if a different plan results.

This restriction applies only to cases where the planner would need to execute a user-defined operator on one or more values from \texttt{pg\_statistic}. Thus the planner is permitted to use generic statistical information, such as the fraction of null values or the number of distinct values in a column, regardless of access privileges.

Selectivity estimation functions contained in third-party extensions that potentially operate on statistics with user-defined operators should follow the same security rules. Consult the PostgreSQL source code for guidance.
Chapter 75. Backup Manifest Format

The backup manifest generated by pg_basebackup is primarily intended to permit the backup to be verified using pg_verifybackup. However, it is also possible for other tools to read the backup manifest file and use the information contained therein for their own purposes. To that end, this chapter describes the format of the backup manifest file.

A backup manifest is a JSON document encoded as UTF-8. (Although in general JSON documents are required to be Unicode, PostgreSQL permits the json and jsonb data types to be used with any supported server encoding. There is no similar exception for backup manifests.) The JSON document is always an object; the keys that are present in this object are described in the next section.

75.1. Backup Manifest Top-level Object

The backup manifest JSON document contains the following keys.

**PostgreSQL-Backup-Manifest-Version**

The associated value is always the integer 1.

**Files**

The associated value is always a list of objects, each describing one file that is present in the backup. No entries are present in this list for the WAL files that are needed in order to use the backup, or for the backup manifest itself. The structure of each object in the list is described in Section 75.2.

**WAL-Ranges**

The associated value is always a list of objects, each describing a range of WAL records that must be readable from a particular timeline in order to make use of the backup. The structure of these objects is further described in Section 75.3.

**Manifest-Checksum**

This key is always present on the last line of the backup manifest file. The associated value is a SHA256 checksum of all the preceding lines. We use a fixed checksum method here to make it possible for clients to do incremental parsing of the manifest. While a SHA256 checksum is significantly more expensive than a CRC32C checksum, the manifest should normally be small enough that the extra computation won’t matter very much.

75.2. Backup Manifest File Object

The object which describes a single file contains either a **Path** key or an **Encoded-Path** key. Normally, the **Path** key will be present. The associated string value is the path of the file relative to the root of the backup directory. Files located in a user-defined tablesapce will have paths whose first two components are pg_tblspc and the OID of the tablespace. If the path is not a string that is legal in UTF-8, or if the user requests that encoded paths be used for all files, then the **Encoded-Path** key will be present instead. This stores the same data, but it is encoded as a string of hexadecimal digits. Each pair of hexadecimal digits in the string represents a single octet.

The following two keys are always present:

**Size**

The expected size of this file, as an integer.
Last-Modified

The last modification time of the file as reported by the server at the time of the backup. Unlike the other fields stored in the backup, this field is not used by pg_verifybackup. It is included only for informational purposes.

If the backup was taken with file checksums enabled, the following keys will be present:

Checksum-Algorithm

The checksum algorithm used to compute a checksum for this file. Currently, this will be the same for every file in the backup manifest, but this may change in future releases. At present, the supported checksum algorithms are CRC32C, SHA224, SHA256, SHA384, and SHA512.

Checksum

The checksum computed for this file, stored as a series of hexadecimal characters, two for each byte of the checksum.

75.3. Backup Manifest WAL Range Object

The object which describes a WAL range always has three keys:

Timeline

The timeline for this range of WAL records, as an integer.

Start-LSN

The LSN at which replay must begin on the indicated timeline in order to make use of this backup. The LSN is stored in the format normally used by PostgreSQL; that is, it is a string consisting of two strings of hexadecimal characters, each with a length of between 1 and 8, separated by a slash.

End-LSN

The earliest LSN at which replay on the indicated timeline may end when making use of this backup. This is stored in the same format as Start-LSN.

Ordinarily, there will be only a single WAL range. However, if a backup is taken from a standby which switches timelines during the backup due to an upstream promotion, it is possible for multiple ranges to be present, each with a different timeline. There will never be multiple WAL ranges present for the same timeline.

Appendix A. PostgreSQL Error Codes

All messages emitted by the PostgreSQL server are assigned five-character error codes that follow the SQL standard’s conventions for “SQLSTATE” codes. Applications that need to know which error condition has occurred should usually test the error code, rather than looking at the textual error message. The error codes are less likely to change across PostgreSQL releases, and also are not subject to change due to localization of error messages. Note that some, but not all, of the error codes produced by PostgreSQL are defined by the SQL standard; some additional error codes for conditions not defined by the standard have been invented or borrowed from other databases.

According to the standard, the first two characters of an error code denote a class of errors, while the last three characters indicate a specific condition within that class. Thus, an application that does not recognize the specific error code might still be able to infer what to do from the error class.

Table A.1 lists all the error codes defined in PostgreSQL 15beta2. (Some are not actually used at present, but are defined by the SQL standard.) The error classes are also shown. For each error class there is a “standard” error code having the last three characters 000. This code is used only for error conditions that fall within the class but do not have any more-specific code assigned.

The symbol shown in the column “Condition Name” is the condition name to use in PL/pgSQL. Condition names can be written in either upper or lower case. (Note that PL/pgSQL does not recognize warning, as opposed to error, condition names; those are classes 00, 01, and 02.)

For some types of errors, the server reports the name of a database object (a table, table column, data type, or constraint) associated with the error; for example, the name of the unique constraint that caused a unique_violation error. Such names are supplied in separate fields of the error report message so that applications need not try to extract them from the possibly-localized human-readable text of the message. As of PostgreSQL 9.3, complete coverage for this feature exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

Appendix B. Date/Time Support

PostgreSQL uses an internal heuristic parser for all date/time input support. Dates and times are input as strings, and are broken up into distinct fields with a preliminary determination of what kind of information can be in the field. Each field is interpreted and either assigned a numeric value, ignored, or rejected. The parser contains internal lookup tables for all textual fields, including months, days of the week, and time zones.

This appendix includes information on the content of these lookup tables and describes the steps used by the parser to decode dates and times.

B.1. Date/Time Input Interpretation

Date/time input strings are decoded using the following procedure.

1. Break the input string into tokens and categorize each token as a string, time, time zone, or number.
   a. If the numeric token contains a colon (:), this is a time string. Include all subsequent digits and colons.
   b. If the numeric token contains a dash (-), slash (/), or two or more dots (.), this is a date string which might have a text month. If a date token has already been seen, it is instead interpreted as a time zone name (e.g., America/New_York).
   c. If the token is numeric only, then it is either a single field or an ISO 8601 concatenated date (e.g., 19990113 for January 13, 1999) or time (e.g., 141516 for 14:15:16).
   d. If the token starts with a plus (+) or minus (−), then it is either a numeric time zone or a special field.
2. If the token is an alphabetic string, match up with possible strings:
   a. See if the token matches any known time zone abbreviation. These abbreviations are supplied by the configuration file described in Section B.4.
   b. If not found, search an internal table to match the token as either a special string (e.g., today), day (e.g., Thursday), month (e.g., January), or noise word (e.g., at, on).
   c. If still not found, throw an error.
3. When the token is a number or number field:
   a. If there are eight or six digits, and if no other date fields have been previously read, then interpret as a “concatenated date” (e.g., 19990118 or 990118). The interpretation is YYYYMMDD or YYMMDD.
   b. If the token is three digits and a year has already been read, then interpret as day of year.
   c. If four or six digits and a year has already been read, then interpret as a time (HHMM or HHMMSS).
   d. If three or more digits and no date fields have yet been found, interpret as a year (this forces yy-mm-dd ordering of the remaining date fields).
   e. Otherwise the date field ordering is assumed to follow the DateStyle setting: mm-dd-yy, dd-mm-yy, or yy-mm-dd. Throw an error if a month or day field is found to be out of range.
4. If BC has been specified, negate the year and add one for internal storage. (There is no year zero in the Gregorian calendar, so numerically 1 BC becomes year zero.)

5. If BC was not specified, and if the year field was two digits in length, then adjust the year to four digits. If the field is less than 70, then add 2000, otherwise add 1900.

**Tip**

Gregorian years AD 1–99 can be entered by using 4 digits with leading zeros (e.g., 0099 is AD 99).

### B.2. Handling of Invalid or Ambiguous Timestamps

Ordinarily, if a date/time string is syntactically valid but contains out-of-range field values, an error will be thrown. For example, input specifying the 31st of February will be rejected.

During a daylight-savings-time transition, it is possible for a seemingly valid timestamp string to represent a nonexistent or ambiguous timestamp. Such cases are not rejected; the ambiguity is resolved by determining which UTC offset to apply. For example, supposing that the TimeZone parameter is set to America/New_York, consider

```sql
=> SELECT '2018-03-11 02:30'::timestamptz;
        timestamptz
------------------------
2018-03-11 03:30:00-04
(1 row)
```

Because that day was a spring-forward transition date in that time zone, there was no civil time instant 2:30AM; clocks jumped forward from 2AM EST to 3AM EDT. PostgreSQL interprets the given time as if it were standard time (UTC-5), which then renders as 3:30AM EDT (UTC-4).

Conversely, consider the behavior during a fall-back transition:

```sql
=> SELECT '2018-11-04 01:30'::timestamptz;
        timestamptz
------------------------
2018-11-04 01:30:00-05
(1 row)
```

On that date, there were two possible interpretations of 1:30AM; there was 1:30AM EDT, and then an hour later after clocks jumped back from 2AM EDT to 1AM EST, there was 1:30AM EST. Again, PostgreSQL interprets the given time as if it were standard time (UTC-5). We can force the other interpretation by specifying daylight-savings time:

```sql
=> SELECT '2018-11-04 01:30 EDT'::timestamptz;
        timestamptz
------------------------
2018-11-04 01:30:00-04
(1 row)
```
The precise rule that is applied in such cases is that an invalid timestamp that appears to fall within a jump-forward daylight savings transition is assigned the UTC offset that prevailed in the time zone just before the transition, while an ambiguous timestamp that could fall on either side of a jump-back transition is assigned the UTC offset that prevailed just after the transition. In most time zones this is equivalent to saying that “the standard-time interpretation is preferred when in doubt”.

In all cases, the UTC offset associated with a timestamp can be specified explicitly, using either a numeric UTC offset or a time zone abbreviation that corresponds to a fixed UTC offset. The rule just given applies only when it is necessary to infer a UTC offset for a time zone in which the offset varies.

### B.3. Date/Time Key Words

Table B.1 shows the tokens that are recognized as names of months.

B.4. Date/Time Configuration Files

Since timezone abbreviations are not well standardized, PostgreSQL provides a means to customize the set of abbreviations accepted by the server. The timezone_abbreviations run-time parameter determines the active set of abbreviations. While this parameter can be altered by any database user, the possible values for it are under the control of the database administrator — they are in fact names of configuration files stored in .../share/timezonesets/ of the installation directory. By adding or altering files in that directory, the administrator can set local policy for timezone abbreviations.

timezone_abbreviations can be set to any file name found in .../share/timezonesets/, if the file's name is entirely alphabetic. (The prohibition against non-alphabetic characters in timezone_abbreviations prevents reading files outside the intended directory, as well as reading editor backup files and other extraneous files.)

A timezone abbreviation file can contain blank lines and comments beginning with #. Non-comment lines must have one of these formats:

```
zone_abbreviation offset
zone_abbreviation offset D
zone_abbreviation time_zone_name
@INCLUDE file_name
@OVERRIDE
```

A `zone_abbreviation` is just the abbreviation being defined. An `offset` is an integer giving the equivalent offset in seconds from UTC, positive being east from Greenwich and negative being west. For example, -18000 would be five hours west of Greenwich, or North American east coast standard time. `D` indicates that the `zone` name represents local daylight-savings time rather than standard time.

Alternatively, a `time_zone_name` can be given, referencing a zone name defined in the IANA timezone database. The zone's definition is consulted to see whether the abbreviation is or has been in use in that zone, and if so, the appropriate meaning is used — that is, the meaning that was currently in use at the timestamp whose value is being determined, or the meaning in use immediately before that if it wasn't current at that time, or the oldest meaning if it was used only after that time. This behavior is essential for dealing with abbreviations whose meaning has historically varied. It is also allowed to define an abbreviation in terms of a zone name in which that abbreviation does not appear; then using the abbreviation is just equivalent to writing out the zone name.
Tip

Using a simple integer offset is preferred when defining an abbreviation whose offset from UTC has never changed, as such abbreviations are much cheaper to process than those that require consulting a time zone definition.

The @INCLUDE syntax allows inclusion of another file in the .../share/timezonesets/ directory. Inclusion can be nested, to a limited depth.

The @OVERRIDE syntax indicates that subsequent entries in the file can override previous entries (typically, entries obtained from included files). Without this, conflicting definitions of the same timezone abbreviation are considered an error.

In an unmodified installation, the file Default contains all the non-conflicting time zone abbreviations for most of the world. Additional files Australia and India are provided for those regions: these files first include the Default file and then add or modify abbreviations as needed.

For reference purposes, a standard installation also contains files Africa.txt, America.txt, etc., containing information about every time zone abbreviation known to be in use according to the IANA timezone database. The zone name definitions found in these files can be copied and pasted into a custom configuration file as needed. Note that these files cannot be directly referenced as timezone_abbreviations settings, because of the dot embedded in their names.

Note

If an error occurs while reading the time zone abbreviation set, no new value is applied and the old set is kept. If the error occurs while starting the database, startup fails.

Caution

Time zone abbreviations defined in the configuration file override non-timezone meanings built into PostgreSQL. For example, the Australia configuration file defines SAT (for South Australian Standard Time). When this file is active, SAT will not be recognized as an abbreviation for Saturday.

Caution

If you modify files in .../share/timezonesets/, it is up to you to make backups — a normal database dump will not include this directory.

B.5. POSIX Time Zone Specifications

PostgreSQL can accept time zone specifications that are written according to the POSIX standard's rules for the TZ environment variable. POSIX time zone specifications are inadequate to deal with the complexity of real-world time zone history, but there are sometimes reasons to use them.
A POSIX time zone specification has the form

\[ \text{STD} \quad \text{offset} \quad [\quad \text{DST} \quad [\quad \text{dstoffset} \quad ] \quad [\quad ,\quad \text{rule} \quad ] \quad ] \]

(For readability, we show spaces between the fields, but spaces should not be used in practice.) The fields are:

- \textit{STD} is the zone abbreviation to be used for standard time.
- \textit{offset} is the zone's standard-time offset from UTC.
- \textit{DST} is the zone abbreviation to be used for daylight-savings time. If this field and the following ones are omitted, the zone uses a fixed UTC offset with no daylight-savings rule.
- \textit{dstoffset} is the daylight-savings offset from UTC. This field is typically omitted, since it defaults to one hour less than the standard-time offset, which is usually the right thing.
- \textit{rule} defines the rule for when daylight savings is in effect, as described below.

In this syntax, a zone abbreviation can be a string of letters, such as \texttt{EST}, or an arbitrary string surrounded by angle brackets, such as \texttt{<UTC-05>}. Note that the zone abbreviations given here are only used for output, and even then only in some timestamp output formats. The zone abbreviations recognized in timestamp input are determined as explained in Section B.4.

The offset fields specify the hours, and optionally minutes and seconds, difference from UTC. They have the format \texttt{hh:mm:ss} optionally with a leading sign (+ or -). The positive sign is used for zones west of Greenwich. (Note that this is the opposite of the ISO-8601 sign convention used elsewhere in PostgreSQL.) \texttt{hh} can have one or two digits; \texttt{mm} and \texttt{ss} (if used) must have two.

The daylight-savings transition \textit{rule} has the format

\[ \text{dstdate} \quad [\quad /\quad \text{dsttime} \quad ]\quad ,\quad \text{stddate} \quad [\quad /\quad \text{stdtime} \quad ] \]

(As before, spaces should not be included in practice.) The \texttt{dstdate} and \texttt{dsttime} fields define when daylight-savings time starts, while \texttt{stddate} and \texttt{stdtime} define when standard time starts. (In some cases, notably in zones south of the equator, the former might be later in the year than the latter.) The date fields have one of these formats:

\texttt{n}

A plain integer denotes a day of the year, counting from zero to 364, or to 365 in leap years.

\texttt{Jn}

In this form, \texttt{n} counts from 1 to 365, and February 29 is not counted even if it is present. (Thus, a transition occurring on February 29 could not be specified this way. However, days after February have the same numbers whether it's a leap year or not, so that this form is usually more useful than the plain-integer form for transitions on fixed dates.)

\texttt{Mm.n.d}

This form specifies a transition that always happens during the same month and on the same day of the week. \texttt{m} identifies the month, from 1 to 12. \texttt{n} specifies the \texttt{n}'th occurrence of the weekday identified by \texttt{d}. \texttt{n} is a number between 1 and 4, or 5 meaning the last occurrence of that weekday in the month (which could be the fourth or the fifth). \texttt{d} is a number between 0 and 6, with 0 indicating Sunday. For example, \texttt{M3.2.0} means “the second Sunday in March”.

2667
Note

The M format is sufficient to describe many common daylight-savings transition laws. But note that none of these variants can deal with daylight-savings law changes, so in practice the historical data stored for named time zones (in the IANA time zone database) is necessary to interpret past time stamps correctly.

The time fields in a transition rule have the same format as the offset fields described previously, except that they cannot contain signs. They define the current local time at which the change to the other time occurs. If omitted, they default to 02:00:00.

If a daylight-savings abbreviation is given but the transition rule field is omitted, the fallback behavior is to use the rule M3.2.0, M11.1.0, which corresponds to USA practice as of 2020 (that is, spring forward on the second Sunday of March, fall back on the first Sunday of November, both transitions occurring at 2AM prevailing time). Note that this rule does not give correct USA transition dates for years before 2007.

As an example, CET-1CEST, M3.5.0, M10.5.0/3 describes current (as of 2020) timekeeping practice in Paris. This specification says that standard time has the abbreviation CET and is one hour ahead (east) of UTC; daylight savings time has the abbreviation CEST and is implicitly two hours ahead of UTC; daylight savings time begins on the last Sunday in March at 2AM CET and ends on the last Sunday in October at 3AM CEST.

The four timezone names EST5EDT, CST6CDT, MST7MDT, and PST8PDT look like they are POSIX zone specifications. However, they actually are treated as named time zones because (for historical reasons) there are files by those names in the IANA time zone database. The practical implication of this is that these zone names will produce valid historical USA daylight-savings transitions, even when a plain POSIX specification would not.

One should be wary that it is easy to misspell a POSIX-style time zone specification, since there is no check on the reasonableness of the zone abbreviation(s). For example, SET TIMEZONE TO FOOBAR0 will work, leaving the system effectively using a rather peculiar abbreviation for UTC.

B.6. History of Units

The SQL standard states that “Within the definition of a ‘datetime literal’, the ‘datetime values’ are constrained by the natural rules for dates and times according to the Gregorian calendar”. PostgreSQL follows the SQL standard’s lead by counting dates exclusively in the Gregorian calendar, even for years before that calendar was in use. This rule is known as the proleptic Gregorian calendar.

The Julian calendar was introduced by Julius Caesar in 45 BC. It was in common use in the Western world until the year 1582, when countries started changing to the Gregorian calendar. In the Julian calendar, the tropical year is approximated as 365 1/4 days = 365.25 days. This gives an error of about 1 day in 128 years.

The accumulating calendar error prompted Pope Gregory XIII to reform the calendar in accordance with instructions from the Council of Trent. In the Gregorian calendar, the tropical year is approximated as 365 + 97 / 400 days = 365.2425 days. Thus it takes approximately 3300 years for the tropical year to shift one day with respect to the Gregorian calendar.

The approximation 365+97/400 is achieved by having 97 leap years every 400 years, using the following rules:

Every year divisible by 4 is a leap year.
However, every year divisible by 100 is not a leap year. However, every year divisible by 400 is a leap year after all.

So, 1700, 1800, 1900, 2100, and 2200 are not leap years. But 1600, 2000, and 2400 are leap years. By contrast, in the older Julian calendar all years divisible by 4 are leap years.

The papal bull of February 1582 decreed that 10 days should be dropped from October 1582 so that 15 October should follow immediately after 4 October. This was observed in Italy, Poland, Portugal, and Spain. Other Catholic countries followed shortly after, but Protestant countries were reluctant to change, and the Greek Orthodox countries didn't change until the start of the 20th century. The reform was observed by Great Britain and its dominions (including what is now the USA) in 1752. Thus 2 September 1752 was followed by 14 September 1752. This is why Unix systems that have the \texttt{cal} program produce the following:

\begin{verbatim}
$ cal 9 1752
   September 1752
   S M Tu W Th F S
   1 2 14 15 16
   17 18 19 20 21 22 23
   24 25 26 27 28 29 30
\end{verbatim}

But, of course, this calendar is only valid for Great Britain and dominions, not other places. Since it would be difficult and confusing to try to track the actual calendars that were in use in various places at various times, PostgreSQL does not try, but rather follows the Gregorian calendar rules for all dates, even though this method is not historically accurate.

Different calendars have been developed in various parts of the world, many predating the Gregorian system. For example, the beginnings of the Chinese calendar can be traced back to the 14th century BC. Legend has it that the Emperor Huangdi invented that calendar in 2637 BC. The People's Republic of China uses the Gregorian calendar for civil purposes. The Chinese calendar is used for determining festivals.

\section*{B.7. Julian Dates}

The \textit{Julian Date} system is a method for numbering days. It is unrelated to the Julian calendar, though it is confusingly named similarly to that calendar. The Julian Date system was invented by the French scholar Joseph Justus Scaliger (1540–1609) and probably takes its name from Scaliger's father, the Italian scholar Julius Caesar Scaliger (1484–1558).

In the Julian Date system, each day has a sequential number, starting from JD 0 (which is sometimes called \textit{the} Julian Date). JD 0 corresponds to 1 January 4713 BC in the Julian calendar, or 24 November 4714 BC in the Gregorian calendar. Julian Date counting is most often used by astronomers for labeling their nightly observations, and therefore a date runs from noon UTC to the next noon UTC, rather than from midnight to midnight: JD 0 designates the 24 hours from noon UTC on 24 November 4714 BC to noon UTC on 25 November 4714 BC.

Although PostgreSQL supports Julian Date notation for input and output of dates (and also uses Julian dates for some internal datetime calculations), it does not observe the nicety of having dates run from noon to noon. PostgreSQL treats a Julian Date as running from local midnight to local midnight, the same as a normal date.

This definition does, however, provide a way to obtain the astronomical definition when you need it: do the arithmetic in time zone UTC+12. For example,
=> SELECT extract(julian from '2021-06-23 7:00:00-04':::timestamptz at time zone 'UTC+12');
  extract
-----------------------------
  2459388.95833333333333333333
(1 row)
=> SELECT extract(julian from '2021-06-23 8:00:00-04':::timestamptz at time zone 'UTC+12');
  extract
-----------------------------
  2459389.0000000000000000000000000000000000
(1 row)
=> SELECT extract(julian from date '2021-06-23');
  extract
--------
  2459389
(1 row)
Appendix C. SQL Key Words

Table C.1 lists all tokens that are key words in the SQL standard and in PostgreSQL 15beta2. Background information can be found in Section 4.1.1. (For space reasons, only the latest two versions of the SQL standard, and SQL-92 for historical comparison, are included. The differences between those and the other intermediate standard versions are small.)

SQL distinguishes between reserved and non-reserved key words. According to the standard, reserved key words are the only real key words; they are never allowed as identifiers. Non-reserved key words only have a special meaning in particular contexts and can be used as identifiers in other contexts. Most non-reserved key words are actually the names of built-in tables and functions specified by SQL. The concept of non-reserved key words essentially only exists to declare that some predefined meaning is attached to a word in some contexts.

In the PostgreSQL parser, life is a bit more complicated. There are several different classes of tokens ranging from those that can never be used as an identifier to those that have absolutely no special status in the parser, but are considered ordinary identifiers. (The latter is usually the case for functions specified by SQL.) Even reserved key words are not completely reserved in PostgreSQL, but can be used as column labels (for example, SELECT 55 AS CHECK, even though CHECK is a reserved key word).

In Table C.1 in the column for PostgreSQL we classify as “non-reserved” those key words that are explicitly known to the parser but are allowed as column or table names. Some key words that are otherwise non-reserved cannot be used as function or data type names and are marked accordingly. (Most of these words represent built-in functions or data types with special syntax. The function or type is still available but it cannot be redefined by the user.) Labeled “reserved” are those tokens that are not allowed as column or table names. Some reserved key words are allowable as names for functions or data types; this is also shown in the table. If not so marked, a reserved key word is only allowed as a column label. A blank entry in this column means that the word is treated as an ordinary identifier by PostgreSQL.

Furthermore, while most key words can be used as “bare” column labels without writing AS before them (as described in Section 7.3.2), there are a few that require a leading AS to avoid ambiguity. These are marked in the table as “requires AS”.

As a general rule, if you get spurious parser errors for commands that use any of the listed key words as an identifier, you should try quoting the identifier to see if the problem goes away.

It is important to understand before studying Table C.1 that the fact that a key word is not reserved in PostgreSQL does not mean that the feature related to the word is not implemented. Conversely, the presence of a key word does not indicate the existence of a feature.

Appendix D. SQL Conformance

This section attempts to outline to what extent PostgreSQL conforms to the current SQL standard. The following information is not a full statement of conformance, but it presents the main topics in as much detail as is both reasonable and useful for users.

The formal name of the SQL standard is ISO/IEC 9075 “Database Language SQL”. A revised version of the standard is released from time to time; the most recent update appearing in 2016. The 2016 version is referred to as ISO/IEC 9075:2016, or simply as SQL:2016. The versions prior to that were SQL:2011, SQL:2008, SQL:2006, SQL:2003, SQL:1999, and SQL-92. Each version replaces the previous one, so claims of conformance to earlier versions have no official merit. PostgreSQL development aims for conformance with the latest official version of the standard where such conformance does not contradict traditional features or common sense. Many of the features required by the SQL standard are supported, though sometimes with slightly differing syntax or function. Further moves towards conformance can be expected over time.

SQL-92 defined three feature sets for conformance: Entry, Intermediate, and Full. Most database management systems claiming SQL standard conformance were conforming at only the Entry level, since the entire set of features in the Intermediate and Full levels was either too voluminous or in conflict with legacy behaviors.

Starting with SQL:1999, the SQL standard defines a large set of individual features rather than the ineffectively broad three levels found in SQL-92. A large subset of these features represents the “Core” features, which every conforming SQL implementation must supply. The rest of the features are purely optional.

The standard versions beginning with SQL:2003 are also split into a number of parts. Each is known by a shorthand name. Note that these parts are not consecutively numbered.

• ISO/IEC 9075-1 Framework (SQL/Framework)
• ISO/IEC 9075-2 Foundation (SQL/Foundation)
• ISO/IEC 9075-3 Call Level Interface (SQL/CLI)
• ISO/IEC 9075-4 Persistent Stored Modules (SQL/PSM)
• ISO/IEC 9075-9 Management of External Data (SQL/MED)
• ISO/IEC 9075-10 Object Language Bindings (SQL/OLB)
• ISO/IEC 9075-11 Information and Definition Schemas (SQL/Schemata)
• ISO/IEC 9075-13 Routines and Types using the Java Language (SQL/JRT)
• ISO/IEC 9075-14 XML-related specifications (SQL/XML)
• ISO/IEC 9075-15 Multi-dimensional arrays (SQL/MDA)
SQL Conformance

The PostgreSQL core covers parts 1, 2, 9, 11, and 14. Part 3 is covered by the ODBC driver, and part 13 is covered by the PL/Java plug-in, but exact conformance is currently not being verified for these components. There are currently no implementations of parts 4, 10, and 15 for PostgreSQL.

PostgreSQL supports most of the major features of SQL:2016. Out of 177 mandatory features required for full Core conformance, PostgreSQL conforms to at least 170. In addition, there is a long list of supported optional features. It might be worth noting that at the time of writing, no current version of any database management system claims full conformance to Core SQL:2016.

In the following two sections, we provide a list of those features that PostgreSQL supports, followed by a list of the features defined in SQL:2016 which are not yet supported in PostgreSQL. Both of these lists are approximate: There might be minor details that are nonconforming for a feature that is listed as supported, and large parts of an unsupported feature might in fact be implemented. The main body of the documentation always contains the most accurate information about what does and does not work.

Note

Feature codes containing a hyphen are subfeatures. Therefore, if a particular subfeature is not supported, the main feature is listed as unsupported even if some other subfeatures are supported.

D.1. Supported Features

### D.2. Unsupported Features

The following features defined in SQL:2016 are not implemented in this release of PostgreSQL. In a few cases, equivalent functionality is available.

D.3. XML Limits and Conformance to SQL/XML

Significant revisions to the XML-related specifications in ISO/IEC 9075-14 (SQL/XML) were introduced with SQL:2006. PostgreSQL’s implementation of the XML data type and related functions largely follows the earlier 2003 edition, with some borrowing from later editions. In particular:

- Where the current standard provides a family of XML data types to hold “document” or “content” in untyped or XML Schema-typed variants, and a type `XML(SEQUENCE)` to hold arbitrary pieces of XML content, PostgreSQL provides the single `xml` type, which can hold “document” or “content”. There is no equivalent of the standard’s “sequence” type.
• PostgreSQL provides two functions introduced in SQL:2006, but in variants that use the XPath 1.0 language, rather than XML Query as specified for them in the standard.

This section presents some of the resulting differences you may encounter.

D.3.1. Queries Are Restricted to XPath 1.0

The PostgreSQL-specific functions `xpath()` and `xpath_exists()` query XML documents using the XPath language. PostgreSQL also provides XPath-only variants of the standard functions `XMLEXISTS` and `XMLTABLE`, which officially use the XQuery language. For all of these functions, PostgreSQL relies on the libxml2 library, which provides only XPath 1.0.

There is a strong connection between the XQuery language and XPath versions 2.0 and later: any expression that is syntactically valid and executes successfully in both produces the same result (with a minor exception for expressions containing numeric character references or predefined entity references, which XQuery replaces with the corresponding character while XPath leaves them alone). But there is no such connection between these languages and XPath 1.0; it was an earlier language and differs in many respects.

There are two categories of limitation to keep in mind: the restriction from XQuery to XPath for the functions specified in the SQL standard, and the restriction of XPath to version 1.0 for both the standard and the PostgreSQL-specific functions.

D.3.1.1. Restriction of XQuery to XPath

Features of XQuery beyond those of XPath include:

• XQuery expressions can construct and return new XML nodes, in addition to all possible XPath values. XPath can create and return values of the atomic types (numbers, strings, and so on) but can only return XML nodes that were already present in documents supplied as input to the expression.

• XQuery has control constructs for iteration, sorting, and grouping.

• XQuery allows declaration and use of local functions.

Recent XPath versions begin to offer capabilities overlapping with these (such as functional-style `for-each` and `sort`, anonymous functions, and `parse-xml` to create a node from a string), but such features were not available before XPath 3.0.

D.3.1.2. Restriction of XPath to 1.0

For developers familiar with XQuery and XPath 2.0 or later, XPath 1.0 presents a number of differences to contend with:

• The fundamental type of an XQuery/XPath expression, the `sequence`, which can contain XML nodes, atomic values, or both, does not exist in XPath 1.0. A 1.0 expression can only produce a node-set (containing zero or more XML nodes), or a single atomic value.

• Unlike an XQuery/XPath sequence, which can contain any desired items in any desired order, an XPath 1.0 node-set has no guaranteed order and, like any set, does not allow multiple appearances of the same item.
The libxml2 library does seem to always return node-sets to PostgreSQL with their members in the same relative order they had in the input document. Its documentation does not commit to this behavior, and an XPath 1.0 expression cannot control it.

- While XQuery/XPath provides all of the types defined in XML Schema and many operators and functions over those types, XPath 1.0 has only node-sets and the three atomic types boolean, double, and string.

- XPath 1.0 has no conditional operator. An XQuery/XPath expression such as if ( hat ) then hat/@size else "no hat" has no XPath 1.0 equivalent.

- XPath 1.0 has no ordering comparison operator for strings. Both "cat" < "dog" and "cat" > "dog" are false, because each is a numeric comparison of two NaNs. In contrast, = and != do compare the strings as strings.

- XPath 1.0 blurs the distinction between value comparisons and general comparisons as XQuery/XPath define them. Both sale/@hatsize = 7 and sale/@customer = "alice" are existentially quantified comparisons, true if there is any sale with the given value for the attribute, but sale/@taxable = false() is a value comparison to the effective boolean value of a whole node-set. It is true only if no sale has a taxable attribute at all.

- In the XQuery/XPath data model, a document node can have either document form (i.e., exactly one top-level element, with only comments and processing instructions outside of it) or content form (with those constraints relaxed). Its equivalent in XPath 1.0, the root node, can only be in document form. This is part of the reason an xml value passed as the context item to any PostgreSQL XPath-based function must be in document form.

The differences highlighted here are not all of them. In XQuery and the 2.0 and later versions of XPath, there is an XPath 1.0 compatibility mode, and the W3C lists of function library changes1 and language changes2 applied in that mode offer a more complete (but still not exhaustive) account of the differences. The compatibility mode cannot make the later languages exactly equivalent to XPath 1.0.

### D.3.1.3. Mappings between SQL and XML Data Types and Values

In SQL:2006 and later, both directions of conversion between standard SQL data types and the XML Schema types are specified precisely. However, the rules are expressed using the types and semantics of XQuery/XPath, and have no direct application to the different data model of XPath 1.0.

When PostgreSQL maps SQL data values to XML (as in xmlelement), or XML to SQL (as in the output columns of xmltable), except for a few cases treated specially, PostgreSQL simply assumes that the XML data type's XPath 1.0 string form will be valid as the text-input form of the SQL datatype, and conversely. This rule has the virtue of simplicity while producing, for many data types, results similar to the mappings specified in the standard.

Where interoperability with other systems is a concern, for some data types, it may be necessary to use data type formatting functions (such as those in Section 9.8) explicitly to produce the standard mappings.

1 [https://www.w3.org/TR/2010/REC-xpath-functions-20101214/#xpath1-compatibility](https://www.w3.org/TR/2010/REC-xpath-functions-20101214/#xpath1-compatibility)
2 [https://www.w3.org/TR/xpath20/#id-backwards-compatibility](https://www.w3.org/TR/xpath20/#id-backwards-compatibility)
D.3.2. Incidental Limits of the Implementation

This section concerns limits that are not inherent in the libxml2 library, but apply to the current implementation in PostgreSQL.

D.3.2.1. Only **BY VALUE** Passing Mechanism Is Supported

The SQL standard defines two *passing mechanisms* that apply when passing an XML argument from SQL to an XML function or receiving a result: **BY REF**, in which a particular XML value retains its node identity, and **BY VALUE**, in which the content of the XML is passed but node identity is not preserved. A mechanism can be specified before a list of parameters, as the default mechanism for all of them, or after any parameter, to override the default.

To illustrate the difference, if $x$ is an XML value, these two queries in an SQL:2006 environment would produce true and false, respectively:

SELECT XMLQUERY('$a is $b' PASSING BY REF $x AS a, $x AS b NULL ON EMPTY);
SELECT XMLQUERY('$a is $b' PASSING BY VALUE $x AS a, $x AS b NULL ON EMPTY);

PostgreSQL will accept **BY VALUE** or **BY REF** in an XMLEXISTS or XMLTABLE construct, but it ignores them. The xml data type holds a character-string serialized representation, so there is no node identity to preserve, and passing is always effectively **BY VALUE**.

D.3.2.2. Cannot Pass Named Parameters to Queries

The XPath-based functions support passing one parameter to serve as the XPath expression's context item, but do not support passing additional values to be available to the expression as named parameters.

D.3.2.3. No XML (SEQUENCE) Type

The PostgreSQL xml data type can only hold a value in DOCUMENT or CONTENT form. An XQuery/XPath expression context item must be a single XML node or atomic value, but XPath 1.0 further restricts it to be only an XML node, and has no node type allowing CONTENT. The upshot is that a well-formed DOCUMENT is the only form of XML value that PostgreSQL can supply as an XPath context item.
Appendix E. Release Notes

The release notes contain the significant changes in each PostgreSQL release, with major features and migration issues listed at the top. The release notes do not contain changes that affect only a few users or changes that are internal and therefore not user-visible. For example, the optimizer is improved in almost every release, but the improvements are usually observed by users as simply faster queries.

A complete list of changes for each release can be obtained by viewing the Git logs for each release. The `pgsql-committers` email list\(^1\) records all source code changes as well. There is also a web interface\(^2\) that shows changes to specific files.

The name appearing next to each item represents the major developer for that item. Of course all changes involve community discussion and patch review, so each item is truly a community effort.

E.1. Release 15

Release date: AS OF 2022-06-11

E.1.1. Overview

PostgreSQL 15 contains many new features and enhancements, including:

- 

The above items and other new features of PostgreSQL 15 are explained in more detail in the sections below.

E.1.2. Migration to Version 15

A dump/restore using `pg_dumpall` or use of `pg_upgrade` or logical replication is required for those wishing to migrate data from any previous release. See Section 19.6 for general information on migrating to new major releases.

Version 15 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- Remove `PUBLIC` creation permission on the public schema (Noah Misch)

  This is a change in the default for newly-created databases in existing clusters and for new clusters; `USAGE` permissions on the public schema has not been changed. Databases restored from previous Postgres releases will be restored with their current permissions. Users wishing to have the old permissions on new objects will need to grant `CREATE` permission for `PUBLIC` on the public schema; this change can be made on `template1` to cause all new databases to have these permissions. `template1` permissions for `pg_dumpall` and `pg_upgrade`?

- Change the owner of the public schema to `pg_database_owner` (Noah Misch)

  Previously it was the literal user name of the database owner. Databases restored from previous Postgres releases will be restored with their current owner specification.

---

1 https://www.postgresql.org/list/pgsql-committers/
2 https://git.postgresql.org/gitweb/?p=postgresql.git;a=summary
• Remove long-deprecated exclusive backup mode (David Steele, Nathan Bossart)

If the database server stops abruptly while in this mode, the server could fail to start. The non-exclusive backup mode requires a continuous database connection during the backup. Functions `pg_start_backup()`/`pg_stop_backup()` have been renamed to `pg_backup_start()`/`pg_backup_stop()`, and the functions `pg_backup_start_time()` and `pg_is_in_backup()` have been removed.

• Increase `hash_mem_multiplier` default to 2.0 (Peter Geoghegan)

This allows query hash operations to use double the amount of work_mem memory as other operations.

• Remove server-side language `plpython2u` and generic Python language `plpythonu` (Andres Freund)

• Mark the `interval` output function as stable, not immutable, since it depends on `IntervalStyle` (Tom Lane)

This will cause the creation of indexes relying on the text output of `interval` values to fail.

• Generate an error if `array_to_tsvector()` is passed an empty array element (Jean-Christophe Arnu)

This is prohibited because lexemes should never be empty. Users of previous Postgres releases should verify that no empty lexemes are stored because they can lead to dump/restore failures and inconsistent results.

• Generate an error when `chr()` is supplied with a negative argument (Peter Eisentraut)

• Prevent Unicode zero-length identifiers, e.g., U"" (Peter Eisentraut)

Non-Unicode zero-length identifiers were already prevented.

• Remove `pg_dump`'s `--no-synchronized-snapshots` option since all supported server versions support synchronized snapshots (Tom Lane)

• Prevent `CREATE OR REPLACE VIEW` from changing the collation of an output column (Tom Lane)

• Prevent numeric literals from having non-numeric trailing characters (Peter Eisentraut)

Previously literals like `123abc` would be interpreted as `123` and `abc`.

• Adjust JSON numeric literal processing to match the SQL/JSON-standard (Peter Eisentraut)

This accepts numeric formats like `.1` and `1.`, and disallows trailing junk after numeric literals, like `1.type()`.

• Improve consistency of interval parsing with trailing periods (Tom Lane)

Some platforms disallowed trailing periods.

• When specifying fractional interval values in units greater than months, round to the nearest month (Bruce Momjian)

For example, report `1.99 years` as `2 years`, not `1 year 11 months`.

• Detect integer overflow in interval justification functions (Joe Koshakow)
Specifically, functions `justify_interval()`, `justify_hours()`, and `justify_days()` are affected.

- Remove the default ADMIN OPTION privilege a login role has on its own role membership (Robert Haas)
  Previously, login roles could add/remove members of its own role, even without ADMIN OPTION privilege.

- Allow logical replication to run as the owner of the subscription (Mark Dilger)
  Because row-level security policies are not checked, only superusers, roles with bypassrls, and table owners can replicate into tables with row-level security policies.

- Prevent UPDATE and DELETE logical replication operations on tables where the subscription owner does not have SELECT permission on the table (Jeff Davis)
  UPDATE and DELETE perform SELECT, so require the subscription owner to have table SELECT permission.

- When EXPLAIN references the temporary object schema, refer to it as pg_temp (Amul Sul)
  Previously the actual schema name was used.

- Modify SPI's `SPI_commit()` and `SPI_commit_and_chain()` to automatically start a new transaction at completion (Peter Eisentraut, Tom Lane)

  BACKPATCHED?

- Fix `pg_statio_all_tables` to sum values for the rare case of TOAST tables with multiple indexes (Andrei Zubkov)
  Previously such cases would have one row for each index.

- Disallow setting of server variables matching the prefixes of installed extension (Florin Irion, Tom Lane)
  This also deletes any matching server variables during extension load.

- Remove unnecessary server variable `stats_temp_directory` (Andres Freund, Kyotaro Horiguchi)

- Improve the algorithm used to compute `random()` (Fabien Coelho)
  This will cause `random()` to differ from what was emitted by prior versions for the same seed values.

- Reduce casting of constants in `postgres_fdw` queries (Dian Fay)
  If column types were mismatched between local and remote databases, such casting could cause errors.

- Remove xml2’s function `xml_is_well_formed()` (Tom Lane)
  This function has been implemented in the core backend since Postgres 9.1.

- Allow custom scan providers to indicate if they support projections (Sven Klemm)
  The default is now that custom scan providers can’t support projections, so they need to be updated for this release.
E.1.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 15 and the previous major release.

E.1.3.1. Server

• Record and check the collation of each database (Peter Eisentraut)

  This is designed to detect collation mismatches to avoid data corruption. Function pg_database_collation_actual_version() reports the underlying operating system collation version, and ALTER DATABASE ... REFRESH sets the database to match the operating system collation version. DETAILS?

• Allow ICU collations to be set as the default for clusters and databases (Peter Eisentraut)

  Previously, ICU collations could only be specified in CREATE COLLATION and used with the COLLATE clause.

• Add system view pg_ident_file_mappings to report pg_ident.conf information (Julien Rouhaud)

E.1.3.1.1. Partitioning

• Improve planning time for queries referencing partitioned tables (David Rowley)

  Specifically this helps if only a small number of the many partitions are relevant.

• Allow ordered scans of partitions to avoid sorting in more cases (David Rowley)

  Previously, a partitioned table with a DEFAULT partition or a LIST partition containing multiple values could not be used for ordered partition scans. Now they can be used if these partitions are pruned.

• Improve foreign key behavior of updates on partitioned tables that move rows between partitions (Amit Langote)

  Previously, such updates ran delete actions on the source partition and insert actions on the target partition. PostgreSQL will now run update actions on the referenced partition root.

• Allow CLUSTER on partitioned tables (Justin Pryzby)

• Fix ALTER TRIGGER RENAME on partitioned tables to properly rename triggers an all partitions (Arne Roland, Álvaro Herrera)

  Also prohibit cloned triggers from being renamed.

E.1.3.1.2. Indexes

• Enable system and TOAST btree indexes to efficiently store duplicates (Peter Geoghegan)

  Previously de-duplication was disabled for these types of indexes.

• Improve lookup performance of GiST indexes built using sorting (Aliaksandr Kalenik, Sergei Shoulbakov, Andrey Borodin)

• Prevent changes to columns only indexed by BRIN indexes from disabling HOT updates (Josef Simanek)
• Allow unique constraints and indexes to treat NULL values as not distinct (Peter Eisentraut)

Previously NULL values were always indexed as distinct values, but this can now be changed by creating constraints and indexes using UNIQUE NULLS NOT DISTINCT.

• Allow ^@ and starts_with() to use btree indexes if using a C collation (Tom Lane)

Previously these could only use SP-GiST indexes.

E.1.3.1.3. Optimizer

• Allow extended statistics to record statistics for a parent with all its children (Tomas Vondra, Justin Pryzby)

Regular statistics already tracked parent and parent/all-children statistics separately.

• Allow GROUP BY sorting to optimize column order (Dmitry Dolgov, Teodor Sigaev, Tomas Vondra)

This optimization can be disabled using the server variable enable_group_by_reordering.

• Add server variable recursive_worktable_factor to allow the user to specify the expected recursive query worktable size (Simon Riggs)

WHAT IS A WORKTABLE? NOT DEFINED.

E.1.3.1.4. General Performance

• Allow hash lookup for NOT IN clauses with many constants (David Rowley, James Coleman)

Previously the code always sequentially scanned the list of values.

• Improve validation of UTF-8 text (even if only ASCII) by processing 16 bytes at a time (John Naylor, Heikki Linnakangas)

This will improve text-heavy operations like COPY FROM.

• Improve performance for sorts that exceed work_mem (Heikki Linnakangas)

Specifically, switch to a batch sorting algorithm that uses more output streams internally.

• Improve performance and reduce memory consumption of in-memory sorts (Ronan Dunklau, David Rowley, Thomas Munro, John Naylor)

• Allow WAL full page writes to use LZ4 and Zstandard compression (Andrey Borodin, Justin Pryzby)

This is controlled by the wal_compression server setting.

• Add direct I/O support to macOS (Thomas Munro)

This only works if max_wal_senders=0 and wal_level=minimal, and only for WAL.

• Allow vacuum to be more aggressive in setting the oldest frozenxid (Peter Geoghegan)

• Allow a query referencing multiple foreign tables to perform parallel foreign table scans in more cases (Andrey Lepikhov, Etsuro Fujita)

• Improve the performance of window functions that use row_number(), rank(), and count() (David Rowley)
- Improve the performance of spinlocks on high-core-count ARM64 systems (Geoffrey Blake)

**E.1.3.1.5. Monitoring**

- Enable default logging of checkpoints and slow autovacuum operations (Bharath Rupireddy)
  
  Specifically, this changes the default of log_checkpoints to on and log_autovacuum_min_duration to 10 minutes. This will cause idle servers to generate log output, which might cause problems on resource-constrained servers with insufficient log file removal. The defaults should be changed in such cases.

- Generate periodic log message during slow server starts (Nitin Jadhav, Robert Haas)
  
  Messages report the cause of the delay. The time interval for notification is controlled by the new server variable log_startup_progress_interval.

- Store server-level statistics in shared memory (Kyotaro Horiguchi, Andres Freund, Melanie Plageman)
  
  Previously this was updated via UDP packets, stored in the file system, and read by sessions. There is no longer a statistics collector process.

- Add additional information to VACUUM VERBOSE and autovacuum logging messages (Peter Geoghegan)

- Add EXPLAIN (BUFFERS) output for temporary file block I/O (Masahiko Sawada)

- Allow log output in JSON format (Sehrope Sarkuni, Michael Paquier)
  
  The new setting is log_destination=jsonlog.

- Allow pg_stat_reset_single_table_counters() to reset the counters of relations shared across all databases (B Sadhu, Prasad Patro)

- Add wait events for local shell commands (Fujii Masao)
  
  Specifically the new wait events are related to commands archive_command, archive_cleanup_command, restore_command and recovery_end_command.

**E.1.3.1.6. Privileges**

- Allow view access to be controlled by privileges of the view user (Christoph Heiss)
  
  Previously, view access could only be based on the view owner.

- Allow members of the pg_write_server_files predefined role to perform server-side base backups (Dagfinn Ilmari Mannsåker)
  
  Previously only the superusers could perform such backups.

- Allow GRANT to assign permission to change server variables via SET and ALTER SYSTEM (Mark Dilger)
  
  New function has_parameter_privilege() reports on this privilege.

- Add predefined role pg_checkpointer that allows members to run CHECKPOINT (Jeff Davis)
  
  Previously checkpoints could only be run by superusers.
• Allow members of the `pg_read_all_stats` predefined role to access the views `pg_backend_memory_contexts` and `pg_shmem_allocations` (Bharath Rupireddy)

  Previously these views could only be accessed by superusers.

• Allow `GRANT` to assign permissions on `pg_log_backend_memory_contexts()` (Jeff Davis)

  Previously this function could only be run by superusers.

### E.1.3.1.7. Server Configuration

• Add server variable `shared_memory_size` to report the size of allocated shared memory (Nathan Bossart)

• Add server variable `shared_memory_size_in_huge_pages` to report the number of huge memory pages required (Nathan Bossart)

  This is only supported on Linux.

• Allow `postgres -C` to properly report runtime-computed values (Nathan Bossart)

  Previously runtime-computed values `data_checksums`, `wal_segment_size`, and `data_directory_mode` would report values that would not be accurate on the running server. However, this does not work on a running server.

### E.1.3.2. Streaming Replication and Recovery

• Add support for LZ4 and Zstandard compression of server-side base backups (Jeevan Ladhe, Robert Haas)

• Run checkpointer and bgwriter during crash recovery (Thomas Munro)

• Allow WAL processing to pre-fetch needed file contents (Thomas Munro)

  This is controlled by the server variable `recovery_prefetch`.

• Add server variable `archive_library` to specify the library to be called for archiving (Nathan Bossart)

  Previously only shell commands could be called to perform archiving.

• No longer require `IDENTIFY_SYSTEM` to be run before `START_REPLICATION` (Jeff Davis)

### E.1.3.2.1. Logical Replication

• Allow publication of all tables in a schema (Vignesh C, Hou Zhijie, Amit Kapila)

  For example, this syntax is now supported: `CREATE PUBLICATION pub1 FOR ALL TABLES IN SCHEMA s1,s2; ALTER PUBLICATION` supports a similar syntax. Tables added to the listed schemas in the future will also be replicated.

• Allow publication content to be filtered using a `WHERE` clause (Hou Zhijie, Euler Taveira, Peter Smith, Ajin Cherian, Tomas Vondra, Amit Kapila)

• Allow publications to be restricted to specific columns (Tomas Vondra, Álvaro Herrera, Rahila Syed)

• Allow skipping of transactions on a subscriber using `ALTER SUBSCRIPTION ... SKIP` (Masahiko Sawada)
• Add support for prepared transactions to built-in logical replication (Peter Smith, Ajin Cherian, Amit Kapila, Nikhil Sontakke, Stas Kelvich)

• Add two-phase information to the logical replication stream (Ajin Cherian)

  The new `CREATE_REPLICATION_SLOT` option is called `TWO_PHASE`. `pg_recvlogical` now supports a new `--two-phase` option during slot creation.

• Prevent logical replication of empty transactions (Ajin Cherian, Hou Zhijie, Euler Taveira)

  Previously, write transactions would send empty transactions to subscribers if subscribed tables were not modified.

• Add SQL functions to monitor the directory contents of logical replication slots (Bharath Rupireddy)

  Specifically, the functions are `pg_lslogicalsnapdir()`, `pg_lslogicalmapdir()`, and `pg_lsreplslotdir()`. They can be run by members of the predefined `pg_monitor` role.

• Allow subscribers to stop logical replication application on error (Osumi Takamichi, Mark Dilger)

  This is enabled with the subscriber option `disable_on_error` and avoids possible infinite error loops during stream application.

• Adjust subscriber server variables to match the publisher so datetime and float8 values are interpreted consistently (Japin Li)

  Some publishers might be relying on inconsistent behavior.

• Add system view `pg_stat_subscription_stats` to report on subscriber activity (Masahiko Sawada)

  New function `pg_stat_reset_subscription_stats()` allows the resetting of subscriber statistics.

• Remove incorrect duplicate partitions in system view `pg_publication_tables` (Hou Zhijie)

E.1.3.3. SELECT, INSERT

• Allow `SELECT DISTINCT` to be parallelized (David Rowley)

E.1.3.4. Utility Commands

• Add SQL `MERGE` command to adjust one table to match another (Simon Riggs, Pavan Deolasee, Álvaro Herrera, Amit Langote)

  This is similar to `INSERT ... ON CONFLICT` but more batch-oriented.

• Add support for `HEADER` option in `COPY` text format (Rémi Lapeyre)

  The new option causes the column names to be output, and optionally verified on input.

• Add new default WAL-logged method for database creation (Dilip Kumar)

  This avoids the need for checkpoints during database creation; the old method is still available.

• Allow `CREATE DATABASE` to set the database OID (Shruthi KC, Antonin Houska)
• Prevent DROP DATABASE, DROP TABLESPACE, and ALTER DATABASE SET TABLESPACE from occasionally failing during concurrent use on Windows (Thomas Munro)

• Allow foreign key ON DELETE SET actions to affect only specified columns (Paul Martinez)
  Previously, all of the columns in the foreign key were always affected.

• Allow ALTER TABLE to modify a table's ACCESS METHOD (Justin Pryzby, Jeff Davis)

• Properly call object access hooks when ALTER TABLE causes table rewrites (Michael Paquier)

E.1.3.5. Data Types

• Allow numeric scale to be negative or greater than precision (Dean Rasheed, Tom Lane)
  This allows rounding of values to the left of the decimal point, e.g., '1234'::numeric(4, -2) returns 1200.

• Improve overflow detection when casting values to interval (Joe Koshakow)

• Allow the creation of unlogged sequences (Peter Eisentraut)

• Update the display width information of modern Unicode characters, like emojis (Jacob Champion)
  Also update from Unicode 5.0 to 14.0.0. There is now an automated way to keep Postgres updated with Unicode releases.

E.1.3.6. Functions

• Add multirange input to range_agg() (Paul Jungwirth)

• Add MIN() and MAX() aggregates for the xid8 data type (Ken Kato)

• Add regular expression functions for compatibility with other relational systems (Gilles Darold, Tom Lane)
  Specifically, the new functions are regexp_count(), regexp_instr(), regexp_like(), and regexp_substr(). Some new optional arguments were also added to regexp_replace().

• Add the ability to compute the distance between polygons (Tom Lane)

• Add to_char() format codes of, tzh, and tzm format codes (Nitin Jadhav)
  The upper-case versions of these were already supported.

• Improve the optimization of timetz_zone() by stabilizing its value at transaction start (Aleksander Alekseev, Tom Lane)

  HOW IS THIS USED?

• Allow tsvector_delete_arr() and tsvector_setweight_by_filter() to accept empty array elements (Jean-Christophe Arnu)
  These lexemes are not stored so the acceptance of empty array elements is not a problem. NOT DOCUMENTED, USER API?

• Add support for petabyte units to pg_size_pretty() and pg_size_bytes() (David Christensen)

2730
• Change `pg_event_trigger_ddl_commands()` to output references to non-local temporary schemas using the actual schema name (Tom Lane)

Previously this function referred to temporary schemas as `pg_temp`.

**E.1.3.6.1. JSON**

• Add SQL/JSON-standard JSON constructors (Nikita Glukhov)

The construction functions are `json()`, `json_scalar()`, and `json_serialize()`, `json_array()`, `json_arrayagg()`, `json_object()`, and `json_objectagg()`. They have a few functional advantages over the existing JSON functions.

• Add SQL/JSON query functions `json_exists()`, `json_query()`, and `json_value()` (Nikita Glukhov)

• Add JSON predicates to test JSON/JSONB values (Nikita Glukhov)

  The clauses are `IS JSON [ VALUE | ARRAY | OBJECT | SCALAR | [WITH | WITHOUT ] UNIQUE KEYS ]`.

• Add function `JSON_TABLE()` to cause JSON data to be treated as a table (Nikita Glukhov)

**E.1.3.7. PL/pgSQL**

• Fix enforcement of PL/pgSQL variable `CONSTANT` markings (Tom Lane)

Previously, a variable used as a CALL output parameter or refcursor `OPEN` variable would not enforce `CONSTANT`.

**E.1.3.8. libpq**

• Allow IP address matching against a server certificate's Subject Alternative Name (Jacob Champion)

• Allow `PQsslAttribute()` to report the SSL library type without requiring a libpq connection (Jacob Champion)

• Change query cancellations sent by the client to use the same TCP settings as normal client connections (Jelte Fennema)

  This allows configured TCP timeouts to apply to query cancel connections.

• Prevent libpq event callback failures from forcing an error result (Tom Lane)

**E.1.3.9. Client Applications**

• On Unix platforms, have client applications like `psql` check `HOME` environment variable for the user's home directory before checking the operating system definition (Anders Kaseorg)

**E.1.3.9.1. psql**

• Improve performance of `psql`'s `\copy` command (Heikki Linnakangas)

• Add `psql` command `\getenv` to assign the value of an environment variable to a `psql` variable (Tom Lane)

• Add `+' option to `psql`'s `\lo_list/\dl` to show object privileges (Pavel Luzanov)
• Add psql \dconfig to report server variables (Mark Dilger, Tom Lane)
  This is similar to the server-side SHOW command but can process patterns.

• Add pager option for psql's \watch command (Pavel Stehule, Thomas Munro)
  This is only supported on Unix, and is controlled by $PSQL\_WATCH\_PAGER$.

• Have psql send intra-query double-hyphen comments to the server (Tom Lane, Greg Nancarrow)
  Previously such comments were removed from the query before being sent. Double-hyphen comments
  that are before query text are not sent, and are not recorded as separate psql history entries.

• Adjust psql's readline meta-# to insert a double-hyphen comment marker (Tom Lane)
  Previously an unhelpful pound marker was inserted.

• Have psql output all results if multiple queries are passed to the server at once (Fabien Coelho)
  This can be disabled by setting SHOW\_ALL\_RESULTS.

• Improve psql's tab completion (Shinya Kato, Dagfinn Ilmari Mannsåker, Peter Smith, Koyu Tanigawa,
  Ken Kato, David Fetters, Haiying Tang, Peter Eisenraut, Álvaro Herrera, Tom Lane, Masahiko Sawada)

• Limit support of psql to servers running PostgreSQL 9.2 and later (Tom Lane)

E.1.3.10. Server Applications

• Add new pg_basebackup option --target to control the base backup location (Robert Haas)
  New output options are server to write the backup locally and blackhole to discard the backup
  (for testing).

• Allow pg_basebackup to use LZ4 and Zstandard compression on server-side base backup files (Dipesh
  Pandit, Jeevan Ladhe)

• Allow pg_basebackup's --compress option to control the compression method and options (Michael
  Paquier, Robert Haas)
  New options include server-gzip (gzip on the server), client-gzip (same as gzip).

• Allow pg_basebackup to compress on the server side and decompress on the client side before storage
  (Dipesh Pandit)
  This is accomplished by specifying compression on the server side and plain output format.

• Add the LZ4 compression method to pg_receivewal (Georgios Kokolatos)
  This is enabled via --compress=lz4 and requires binaries to be built using --with-lz4.

• Add additional capabilities to pg_receivewal's --compress option (Georgios Kokolatos)

• Improve pg_receivewal's ability to restart at the proper WAL location (Ronan Dunklau)
  Previously, pg_receivewal would start based on the WAL file stored in the local archive directory, or
  at the sending server's current WAL flush location. With this change, if the sending server is running
  Postgres 15 or later, the local archive directory is empty, and a replication slot is specified, the replication
  slot's restart point will be used.
• Add pg_rewind option --config-file to simplify use when server configuration files are stored outside the data directory (Gunnar Bluth)

• Allow pgbench to retry after serialization and deadlock failures (Yugo Nagata, Marina Polyakova)

E.1.3.10.1. pg_dump

• Have pg_dump dump public schema ownership changes and security labels (Noah Misch)

  It also dumps public schema comments.

• Improve performance of dumping databases with many objects (Tom Lane)

  This will also improve the performance of pg_upgrade.

• Improve the parallel pg_dump performance of TOAST tables (Tom Lane)

• Add dump/restore option --no-table-access-method to force restore to only use the default table access method (Justin Pryzby)

• Limit support of pg_dump and pg_dumpall to servers running PostgreSQL 9.2 and later (Tom Lane)

E.1.3.10.2. pg_upgrade

• Disable default status reporting during pg_upgrade operation if the output is not a terminal (Andres Freund)

  The status reporting output can be enabled for non-tty usage by using --verbose.

• Have pg_upgrade report all databases with invalid connection settings (Jeevan Ladhe)

  Previously only the first database with an invalid connection setting was reported.

• Store pg_upgrade temporary files in a new cluster subdirectory called pg_upgrade_output.d (Justin Pryzby)

  Previously temporary files were stored in the current directory.

• Have pg_upgrade preserve relfilenodes, tablespace, and database OIDs between old and new clusters (Shruthi KC, Antonin Houska)

• Add a --no-sync option to pg_upgrade (Michael Paquier)

  This useful only for testing.

• Limit support of pg_upgrade to old servers running PostgreSQL 9.2 and later (Tom Lane)

E.1.3.10.3. pg_waldump

• Allow pg_waldump to be filtered by relation file node, block number, fork number, and full page images (David Christensen, Thomas Munro)

• Have pg_waldump report statistics before an interrupted exit (Bharath Rupireddy)

  For example, issuing a control-C in a terminal running pg_waldump --stats --follow will report the current statistics before exiting. This does not work on Windows.

• Improve descriptions of some transaction WAL records reported by pg_waldump (Masahiko Sawada, Michael Paquier)
• Allow pg_waldump to dump information about multiple resource managers (Heikki Linnakangas)

This is enabled by specifying the --rmgr option multiple times.

E.1.3.11. Documentation

• Add documentation for pg_encoding_to_char() and pg_char_to_encoding() (Ian Lawrence Barwick)

• Document the ^@ starts-with operator (Tom Lane)

E.1.3.12. Source Code

• Add support for continuous integration testing using cirrus-ci (Andres Freund, Thomas Munro, Melanie Plageman)

• Add configure option --with-zstd to enable Zstandard builds (Jeevan Ladhe, Robert Haas, Michael Paquier)

• Add module field which can be customized for non-community PostgreSQL distributions (Peter Eisen- 

traut)

A module field mismatch would generate an error.

• Create a new pg_type.typcategory value for "char" (Tom Lane)

Some internal-use-only types have also been assigned this column.

• Add new protocol message TARGET to specify a new COPY method to be for base backups (Robert Haas)

Modify pg_basebackup to use this method.

• Add new protocol message COMPRESSION and COMPRESSION_DETAIL to specify the compression 

method and options (Robert Haas)

• Remove server support for old BASE_BACKUP command syntax and base backup protocol (Robert Haas)

• Add support for extensions to set custom backup targets (Robert Haas)

• Allow extensions to define their own WAL resource managers (Jeff Davis)

• Add function pg_settings_get_flags() to get the flags of server-side variables (Justin Pryzby)

• Add server variable allow_in_place_tablespaces for tablespace testing (Thomas Munro)

• Export all server variables on Windows using PGDLLIMPORT (Robert Haas)

Previously only specific variables where exported.

• Require OpenSSL to build pgcrypto binaries (Peter Eisentraut)

• Disallow building with Python 2 (Andres Freund)

• Adjust configure to require Perl version 5.8.3 or later (Dagfinn Ilmari Mannsåker)
E.1.3.13. Additional Modules

- Add new module pg_walinspect (Bharath Rupireddy)
  This gives SQL-level output similar to pg_waldump.
- Add module basic_archive to perform archiving via a library (Nathan Bossart)
- Add module basebackup_to_shell as a custom backup target (Robert Haas) contrib module.
- Add pg_stat_statements output for temporary file block I/O (Masahiko Sawada)
- Add JIT counters to pg_stat_statements (Magnus Hagander)
- Allow amcheck to check sequences (Mark Dilger)
- Improve amcheck sanity checks for TOAST tables (Mark Dilger)
- Allow btree_gist indexes on boolean columns (Emre Hasegeli)
  These can be used for exclusion constraints.
- Indicate the permissive/enforcing state in sepgsql log messages (Dave Page)
- Fix pageinspect's page_header() to handle 32 kilobyte page sizes (Quan Zongliang)
  Previously improper negative values could be returned in certain cases.

E.1.3.13.1. postgres_fdw

- Allow postgres_fdw to push down CASE expressions (Alexander Pyhalov)
- Add server variable postgres_fdw.application_name to control the application name of postgres_fdw connections (Hayato Kuroda)
  Previously the remote application_name could only be set on the remote server or via postgres_fdw connection specification. postgres_fdw.application_name also supports escape sequences for customization.
- Allow parallel commit on postgres_fdw servers (Etsuro Fujita)
  This is enabled with the CREATE SERVER option parallel_commit when using postgres_fdw.

E.1.4. Acknowledgments

The following individuals (in alphabetical order) have contributed to this release as patch authors, committers, reviewers, testers, or reporters of issues.

E.2. Prior Releases

Release notes for prior release branches can be found at https://www.postgresql.org/docs/release/
Appendix F. Additional Supplied Modules

This appendix and the next one contain information regarding the modules that can be found in the contrib directory of the PostgreSQL distribution. These include porting tools, analysis utilities, and plug-in features that are not part of the core PostgreSQL system, mainly because they address a limited audience or are too experimental to be part of the main source tree. This does not preclude their usefulness.

This appendix covers extensions and other server plug-in modules found in contrib. Appendix G covers utility programs.

When building from the source distribution, these components are not built automatically, unless you build the "world" target (see Step 2). You can build and install all of them by running:

```
make
make install
```

in the contrib directory of a configured source tree; or to build and install just one selected module, do the same in that module's subdirectory. Many of the modules have regression tests, which can be executed by running:

```
make check
```

before installation or

```
make installcheck
```

once you have a PostgreSQL server running.

If you are using a pre-packaged version of PostgreSQL, these modules are typically made available as a separate subpackage, such as postgresql-contrib.

Many modules supply new user-defined functions, operators, or types. To make use of one of these modules, after you have installed the code you need to register the new SQL objects in the database system. This is done by executing a CREATE EXTENSION command. In a fresh database, you can simply do

```
CREATE EXTENSION module_name;
```

This command registers the new SQL objects in the current database only, so you need to run it in each database that you want the module's facilities to be available in. Alternatively, run it in database template1 so that the extension will be copied into subsequently-created databases by default.

For all these modules, CREATE EXTENSION must be run by a database superuser, unless the module is considered “trusted”, in which case it can be run by any user who has CREATE privilege on the current database. Modules that are trusted are identified as such in the sections that follow. Generally, trusted modules are ones that cannot provide access to outside-the-database functionality.

Many modules allow you to install their objects in a schema of your choice. To do that, add SCHEMA schema_name to the CREATE EXTENSION command. By default, the objects will be placed in your current creation target schema, which in turn defaults to public.
Note, however, that some of these modules are not “extensions” in this sense, but are loaded into the server in some other way, for instance by way of shared_preload_libraries. See the documentation of each module for details.

### F.1. adminpack

adminpack provides a number of support functions which pgAdmin and other administration and management tools can use to provide additional functionality, such as remote management of server log files. Use of all these functions is only allowed to the superuser by default but may be allowed to other users by using the `GRANT` command.

The functions shown in Table F.1 provide write access to files on the machine hosting the server. (See also the functions in Table 9.101, which provide read-only access.) Only files within the database cluster directory can be accessed, unless the user is a superuser or given privileges of one of the pg_read_server_files, or pg_write_server_files roles, as appropriate for the function, but either a relative or absolute path is allowable.

**Table F.1. adminpack Functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pg_catalog.pg_file_write(filename text, data text, append boolean) → bigint</code></td>
<td>Writes, or appends to, a text file.</td>
</tr>
<tr>
<td><code>pg_catalog.pg_file_sync(filename text) → void</code></td>
<td>Flushes a file or directory to disk.</td>
</tr>
<tr>
<td><code>pg_catalog.pg_file_rename(oldname text, newname text [archivename text]) → boolean</code></td>
<td>Renames a file.</td>
</tr>
<tr>
<td><code>pg_catalog.pg_file_unlink(filename text) → boolean</code></td>
<td>Removes a file.</td>
</tr>
<tr>
<td><code>pg_catalog.pg_logdir_ls() → setof record</code></td>
<td>Lists the log files in the log_directory directory.</td>
</tr>
</tbody>
</table>

**pg_file_write** writes the specified `data` into the file named by `filename`. If `append` is false, the file must not already exist. If `append` is true, the file can already exist, and will be appended to if so. Returns the number of bytes written.

**pg_file_sync** fsyncs the specified file or directory named by `filename`. An error is thrown on failure (e.g., the specified file is not present). Note that data_sync_retry has no effect on this function, and therefore a PANIC-level error will not be raised even on failure to flush database files.

**pg_file_rename** renames a file. If `archivename` is omitted or NULL, it simply renames `oldname` to `newname` (which must not already exist). If `archivename` is provided, it first renames `newname` to `archivename` (which must not already exist), and then renames `oldname` to `newname`. In event of failure of the second rename step, it will try to rename `archivename` back to `newname` before reporting
the error. Returns true on success, false if the source file(s) are not present or not writable; other cases throw errors.

pg_file_unlink removes the specified file. Returns true on success, false if the specified file is not present or the unlink() call fails; other cases throw errors.

pg_logdir_ls returns the start timestamps and path names of all the log files in the log_directory directory. The log_filename parameter must have its default setting (postgresql-%Y-%m-%d_%H%M%S.log) to use this function.

F.2. amcheck

The amcheck module provides functions that allow you to verify the logical consistency of the structure of relations.

The B-Tree checking functions verify various invariants in the structure of the representation of particular relations. The correctness of the access method functions behind index scans and other important operations relies on these invariants always holding. For example, certain functions verify, among other things, that all B-Tree pages have items in “logical” order (e.g., for B-Tree indexes on text, index tuples should be in collated lexical order). If that particular invariant somehow fails to hold, we can expect binary searches on the affected page to incorrectly guide index scans, resulting in wrong answers to SQL queries. If the structure appears to be valid, no error is raised.

Verification is performed using the same procedures as those used by index scans themselves, which may be user-defined operator class code. For example, B-Tree index verification relies on comparisons made with one or more B-Tree support function 1 routines. See Section 38.16.3 for details of operator class support functions.

Unlike the B-Tree checking functions which report corruption by raising errors, the heap checking function verify_heapam checks a table and attempts to return a set of rows, one row per corruption detected. Despite this, if facilities that verify_heapam relies upon are themselves corrupted, the function may be unable to continue and may instead raise an error.

Permission to execute amcheck functions may be granted to non-superusers, but before granting such permissions careful consideration should be given to data security and privacy concerns. Although the corruption reports generated by these functions do not focus on the contents of the corrupted data so much as on the structure of that data and the nature of the corruptions found, an attacker who gains permission to execute these functions, particularly if the attacker can also induce corruption, might be able to infer something of the data itself from such messages.

F.2.1. Functions

bt_index_check(index regclass, heapallindexed boolean) returns void

bt_index_check tests that its target, a B-Tree index, respects a variety of invariants. Example usage:

test=# SELECT bt_index_check(index => c.oid, heapallindexed =>
   i.indisunique),
   c.relname,
   c.relpages
FROM pg_index i
JOIN pg_opclass op ON i.indclass[0] = op.oid
JOIN pg_am am ON op.opcmethod = am.oid
JOIN pg_class c ON i.indexrelid = c.oid
JOIN pg_namespace n ON c.relnamespace = n.oid
WHERE am.amname = 'btree' AND n.nspname = 'pg_catalog'
-- Don't check temp tables, which may be from another session:
AND c.relpersistence != 't'
-- Function may throw an error when this is omitted:
AND c.relkind = 'i' AND i.indisready AND i.indisvalid
ORDER BY c.relpages DESC LIMIT 10;

<table>
<thead>
<tr>
<th>relname</th>
<th>relpages</th>
</tr>
</thead>
<tbody>
<tr>
<td>pg_depend_reference_index</td>
<td>43</td>
</tr>
<tr>
<td>pg_depend_depender_index</td>
<td>40</td>
</tr>
<tr>
<td>pg_proc_proname_args_nsp_index</td>
<td>31</td>
</tr>
<tr>
<td>pg_description_o_c_o_index</td>
<td>21</td>
</tr>
<tr>
<td>pg_attribute_relid_attnam_index</td>
<td>14</td>
</tr>
<tr>
<td>pg_proc_oid_index</td>
<td>10</td>
</tr>
<tr>
<td>pg_attribute_relid_attnum_index</td>
<td>9</td>
</tr>
<tr>
<td>pg_amproc_fam_proc_index</td>
<td>5</td>
</tr>
<tr>
<td>pg_amop_opr_fam_index</td>
<td>5</td>
</tr>
<tr>
<td>pg_amop_fam_strat_index</td>
<td>5</td>
</tr>
</tbody>
</table>

(10 rows)

This example shows a session that performs verification of the 10 largest catalog indexes in the database “test”. Verification of the presence of heap tuples as index tuples is requested for the subset that are unique indexes. Since no error is raised, all indexes tested appear to be logically consistent. Naturally, this query could easily be changed to call `bt_index_check` for every index in the database where verification is supported.

`bt_index_check` acquires an `AccessShareLock` on the target index and the heap relation it belongs to. This lock mode is the same lock mode acquired on relations by simple `SELECT` statements. `bt_index_check` does not verify invariants that span child/parent relationships, but will verify the presence of all heap tuples as index tuples within the index when `heapallindexed` is true. When a routine, lightweight test for corruption is required in a live production environment, using `bt_index_check` often provides the best trade-off between thoroughness of verification and limiting the impact on application performance and availability.

`bt_index_parent_check(index regclass, heapallindexed boolean, rootdescend boolean) returns void`

`bt_index_parent_check` tests that its target, a B-Tree index, respects a variety of invariants. Optionally, when the `heapallindexed` argument is true, the function verifies the presence of all heap tuples that should be found within the index. When the optional `rootdescend` argument is true, verification re-finds tuples on the leaf level by performing a new search from the root page for each tuple. The checks that can be performed by `bt_index_parent_check` are a superset of the checks that can be performed by `bt_index_check`. `bt_index_parent_check` can be thought of as a more thorough variant of `bt_index_check`; unlike `bt_index_check`, `bt_index_parent_check` also checks invariants that span parent/child relationships, including checking that there are no missing downlinks in the index structure. `bt_index_parent_check` follows the general convention of raising an error if it finds a logical inconsistency or other problem.

A `ShareLock` is required on the target index by `bt_index_parent_check` (a `ShareLock` is also acquired on the heap relation). These locks prevent concurrent data modification from `INSERT`, `UPDATE`, and `DELETE` commands. The locks also prevent the underlying relation from being con-
currently processed by VACUUM, as well as all other utility commands. Note that the function holds locks only while running, not for the entire transaction.

bt_index_parent_check's additional verification is more likely to detect various pathological cases. These cases may involve an incorrectly implemented B-Tree operator class used by the index that is checked, or, hypothetically, undiscovered bugs in the underlying B-Tree index access method code. Note that bt_index_parent_check cannot be used when hot standby mode is enabled (i.e., on read-only physical replicas), unlike bt_index_check.

Tip

bt_index_check and bt_index_parent_check both output log messages about the verification process at DEBUG1 and DEBUG2 severity levels. These messages provide detailed information about the verification process that may be of interest to PostgreSQL developers. Advanced users may also find this information helpful, since it provides additional context should verification actually detect an inconsistency. Running:

```
SET client_min_messages = DEBUG1;
```

in an interactive psql session before running a verification query will display messages about the progress of verification with a manageable level of detail.

```
verify_heapam(relation regclass, on_error_stop boolean, check_toast boolean, skip text, startblock bigint, endblock bigint, blkno OUT bigint, offnum OUT integer, attnum OUT integer, msg OUT text) returns setof record
```

Checks a table, sequence, or materialized view for structural corruption, where pages in the relation contain data that is invalidly formatted, and for logical corruption, where pages are structurally valid but inconsistent with the rest of the database cluster.

The following optional arguments are recognized:

on_error_stop

If true, corruption checking stops at the end of the first block in which any corruptions are found. Defaults to false.

check_toast

If true, toasted values are checked against the target relation's TOAST table.

This option is known to be slow. Also, if the toast table or its index is corrupt, checking it against toast values could conceivably crash the server, although in many cases this would just produce an error.

Defaults to false.

skip

If not none, corruption checking skips blocks that are marked as all-visible or all-frozen, as specified. Valid options are all-visible, all-frozen and none.
Defaults to `none`.

**startblock**

If specified, corruption checking begins at the specified block, skipping all previous blocks. It is an error to specify a `startblock` outside the range of blocks in the target table.

By default, checking begins at the first block.

**endblock**

If specified, corruption checking ends at the specified block, skipping all remaining blocks. It is an error to specify an `endblock` outside the range of blocks in the target table.

By default, all blocks are checked.

For each corruption detected, `verify_heapam` returns a row with the following columns:

- **blkno**
  The number of the block containing the corrupt page.

- **offnum**
  The OffsetNumber of the corrupt tuple.

- **attnum**
  The attribute number of the corrupt column in the tuple, if the corruption is specific to a column and not the tuple as a whole.

- **msg**
  A message describing the problem detected.

### F.2.2. Optional `heapallindexed` Verification

When the `heapallindexed` argument to B-Tree verification functions is `true`, an additional phase of verification is performed against the table associated with the target index relation. This consists of a “dummy” `CREATE INDEX` operation, which checks for the presence of all hypothetical new index tuples against a temporary, in-memory summarizing structure (this is built when needed during the basic first phase of verification). The summarizing structure “fingerprints” every tuple found within the target index. The high level principle behind `heapallindexed` verification is that a new index that is equivalent to the existing, target index must only have entries that can be found in the existing structure.

The additional `heapallindexed` phase adds significant overhead: verification will typically take several times longer. However, there is no change to the relation-level locks acquired when `heapallindexed` verification is performed.

The summarizing structure is bound in size by `maintenance_work_mem`. In order to ensure that there is no more than a 2% probability of failure to detect an inconsistency for each heap tuple that should be represented in the index, approximately 2 bytes of memory are needed per tuple. As less memory is made available per tuple, the probability of missing an inconsistency slowly increases. This approach limits the overhead of verification significantly, while only slightly reducing the probability of detecting a problem,
especially for installations where verification is treated as a routine maintenance task. Any single absent or malformed tuple has a new opportunity to be detected with each new verification attempt.

F.2.3. Using amcheck Effectively

amcheck can be effective at detecting various types of failure modes that data checksums will fail to catch. These include:

- Structural inconsistencies caused by incorrect operator class implementations.

  This includes issues caused by the comparison rules of operating system collations changing. Comparisons of datums of a collatable type like `text` must be immutable (just as all comparisons used for B-Tree index scans must be immutable), which implies that operating system collation rules must never change. Though rare, updates to operating system collation rules can cause these issues. More commonly, an inconsistency in the collation order between a primary server and a standby server is implicated, possibly because the major operating system version in use is inconsistent. Such inconsistencies will generally only arise on standby servers, and so can generally only be detected on standby servers.

If a problem like this arises, it may not affect each individual index that is ordered using an affected collation, simply because indexed values might happen to have the same absolute ordering regardless of the behavioral inconsistency. See Section 24.1 and Section 24.2 for further details about how PostgreSQL uses operating system locales and collations.

- Structural inconsistencies between indexes and the heap relations that are indexed (when `heapallindexed` verification is performed).

  There is no cross-checking of indexes against their heap relation during normal operation. Symptoms of heap corruption can be subtle.

- Corruption caused by hypothetical undiscovered bugs in the underlying PostgreSQL access method code, sort code, or transaction management code.

  Automatic verification of the structural integrity of indexes plays a role in the general testing of new or proposed PostgreSQL features that could plausibly allow a logical inconsistency to be introduced. Verification of table structure and associated visibility and transaction status information plays a similar role. One obvious testing strategy is to call `amcheck` functions continuously when running the standard regression tests. See Section 33.1 for details on running the tests.

- File system or storage subsystem faults where checksums happen to simply not be enabled.

  Note that `amcheck` examines a page as represented in some shared memory buffer at the time of verification if there is only a shared buffer hit when accessing the block. Consequently, `amcheck` does not necessarily examine data read from the file system at the time of verification. Note that when checksums are enabled, `amcheck` may raise an error due to a checksum failure when a corrupt block is read into a buffer.

- Corruption caused by faulty RAM, or the broader memory subsystem.

  PostgreSQL does not protect against correctable memory errors and it is assumed you will operate using RAM that uses industry standard Error Correcting Codes (ECC) or better protection. However, ECC memory is typically only immune to single-bit errors, and should not be assumed to provide absolute protection against failures that result in memory corruption.

  When `heapallindexed` verification is performed, there is generally a greatly increased chance of detecting single-bit errors, since strict binary equality is tested, and the indexed attributes within the heap are tested.
Additional Supplied Modules

Structural corruption can happen due to faulty storage hardware, or relation files being overwritten or modified by unrelated software. This kind of corruption can also be detected with data page checksums.

Relation pages which are correctly formatted, internally consistent, and correct relative to their own internal checksums may still contain logical corruption. As such, this kind of corruption cannot be detected with checksums. Examples include toasted values in the main table which lack a corresponding entry in the toast table, and tuples in the main table with a Transaction ID that is older than the oldest valid Transaction ID in the database or cluster.

Multiple causes of logical corruption have been observed in production systems, including bugs in the PostgreSQL server software, faulty and ill-conceived backup and restore tools, and user error.

Corrupt relations are most concerning in live production environments, precisely the same environments where high risk activities are least welcome. For this reason, verify_heapam has been designed to diagnose corruption without undue risk. It cannot guard against all causes of backend crashes, as even executing the calling query could be unsafe on a badly corrupted system. Access to catalog tables is performed and could be problematic if the catalogs themselves are corrupted.

In general, amcheck can only prove the presence of corruption; it cannot prove its absence.

F.2.4. Repairing Corruption

No error concerning corruption raised by amcheck should ever be a false positive. amcheck raises errors in the event of conditions that, by definition, should never happen, and so careful analysis of amcheck errors is often required.

There is no general method of repairing problems that amcheck detects. An explanation for the root cause of an invariant violation should be sought. pageinspect may play a useful role in diagnosing corruption that amcheck detects. A REINDEX may not be effective in repairing corruption.

F.3. auth_delay

auth_delay causes the server to pause briefly before reporting authentication failure, to make brute-force attacks on database passwords more difficult. Note that it does nothing to prevent denial-of-service attacks, and may even exacerbate them, since processes that are waiting before reporting authentication failure will still consume connection slots.

In order to function, this module must be loaded via shared_preload_libraries in postgresql.conf.

F.3.1. Configuration Parameters

auth_delay.milliseconds (integer)

The number of milliseconds to wait before reporting an authentication failure. The default is 0.

These parameters must be set in postgresql.conf. Typical usage might be:

# postgresql.conf
shared_preload_libraries = 'auth_delay'
auth_delay.milliseconds = '500'
F.3.2. Author

KaiGai Kohei <kaigai@ak.jp.nec.com>

F.4. auto_explain

The auto_explain module provides a means for logging execution plans of slow statements automatically, without having to run EXPLAIN by hand. This is especially helpful for tracking down un-optimized queries in large applications.

The module provides no SQL-accessible functions. To use it, simply load it into the server. You can load it into an individual session:

LOAD 'auto_explain';

(You must be superuser to do that.) More typical usage is to preload it into some or all sessions by including auto_explain in session_preload_libraries or shared_preload_libraries in postgresql.conf. Then you can track unexpectedly slow queries no matter when they happen. Of course there is a price in overhead for that.

F.4.1. Configuration Parameters

There are several configuration parameters that control the behavior of auto_explain. Note that the default behavior is to do nothing, so you must set at least auto_explain.log_min_duration if you want any results.

auto_explain.log_min_duration (integer)

auto_explain.log_min_duration is the minimum statement execution time, in milliseconds, that will cause the statement’s plan to be logged. Setting this to 0 logs all plans. -1 (the default) disables logging of plans. For example, if you set it to 250ms then all statements that run 250ms or longer will be logged. Only superusers can change this setting.

auto_explain.log_analyze (boolean)

auto_explain.log_analyze causes EXPLAIN ANALYZE output, rather than just EXPLAIN output, to be printed when an execution plan is logged. This parameter is off by default. Only superusers can change this setting.

Note

When this parameter is on, per-plan-node timing occurs for all statements executed, whether or not they run long enough to actually get logged. This can have an extremely negative impact on performance. Turning off auto_explain.log_timing ameliorates the performance cost, at the price of obtaining less information.

auto_explain.log_buffers (boolean)

auto_explain.log_buffers controls whether buffer usage statistics are printed when an execution plan is logged; it's equivalent to the BUFFERS option of EXPLAIN. This parameter has no
**Additional Supplied Modules**

effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_wal (boolean)`

`auto_explain.log_wal` controls whether WAL usage statistics are printed when an execution plan is logged; it's equivalent to the `WAL` option of `EXPLAIN`. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_timing (boolean)`

`auto_explain.log_timing` controls whether per-node timing information is printed when an execution plan is logged; it's equivalent to the `TIMING` option of `EXPLAIN`. The overhead of repeatedly reading the system clock can slow down queries significantly on some systems, so it may be useful to set this parameter to off when only actual row counts, and not exact times, are needed. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is on by default. Only superusers can change this setting.

`auto_explain.log_triggers (boolean)`

`auto_explain.log_triggers` causes trigger execution statistics to be included when an execution plan is logged. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_verbose (boolean)`

`auto_explain.log_verbose` controls whether verbose details are printed when an execution plan is logged; it's equivalent to the `VERBOSE` option of `EXPLAIN`. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_settings (boolean)`

`auto_explain.log_settings` controls whether information about modified configuration options is printed when an execution plan is logged. Only options affecting query planning with value different from the built-in default value are included in the output. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_format (enum)`

`auto_explain.log_format` selects the `EXPLAIN` output format to be used. The allowed values are `text`, `xml`, `json`, and `yaml`. The default is `text`. Only superusers can change this setting.

`auto_explain.log_level (enum)`

`auto_explain.log_level` selects the log level at which `auto_explain` will log the query plan. Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `INFO`, `NOTICE`, `WARNING`, and `LOG`. The default is `LOG`. Only superusers can change this setting.

`auto_explain.log_nested_statements (boolean)`

`auto_explain.log_nested_statements` causes nested statements (statements executed inside a function) to be considered for logging. When it is off, only top-level query plans are logged. This parameter is off by default. Only superusers can change this setting.
auto_explain.sample_rate(real)

auto_explain.sample_rate causes auto_explain to only explain a fraction of the statements in each session. The default is 1, meaning explain all the queries. In case of nested statements, either all will be explained or none. Only superusers can change this setting.

In ordinary usage, these parameters are set in postgresql.conf, although superusers can alter them on-the-fly within their own sessions. Typical usage might be:

```
# postgresql.conf
session_preload_libraries = 'auto_explain'
auto_explain.log_min_duration = '3s'
```

**F.4.2. Example**

```
postgres=# LOAD 'auto_explain';
postgres=# SET auto_explain.log_min_duration = 0;
postgres=# SET auto_explain.log_analyze = true;
postgres=# SELECT count(*)
    FROM pg_class, pg_index
    WHERE oid = indrelid AND indisunique;
```

This might produce log output such as:

```
LOG: duration: 3.651 ms  plan:  Query Text: SELECT count(*)
    FROM pg_class, pg_index
    WHERE oid = indrelid AND indisunique;
  Aggregate (cost=16.79..16.80 rows=1 width=0) (actual
time=3.626..3.627 rows=1 loops=1)
    -> Hash Join (cost=4.17..16.55 rows=92 width=0) (actual
time=3.349..3.594 rows=92 loops=1)
        Hash Cond: (pg_class.oid = pg_index.indrelid)
    -> Seq Scan on pg_class (cost=0.00..9.55 rows=255 width=4)
          (actual time=0.016..0.140 rows=255 loops=1)
    -> Hash (cost=3.02..3.02 rows=92 width=4) (actual
time=3.238..3.238 rows=92 loops=1)
        Buckets: 1024  Batches: 1  Memory Usage: 4kB
          -> Seq Scan on pg_index (cost=0.00..3.02 rows=92
            width=4) (actual time=0.008..3.187 rows=92 loops=1)
            Filter: indisunique
```

**F.4.3. Author**

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>

**F.5. basebackup_to_shell**

basebackup_to_shell adds a custom basebackup target called shell. This makes it possible to run pg_basebackup --target=shell or, depending on how this module is configured, pg_base-
backup --target=shell:DETAIL_STRING, and cause a server command chosen by the server administrator to be executed for each tar archive generated by the backup process. The command will receive the contents of the archive via standard input.

This module is primarily intended as an example of how to create a new backup targets via an extension module, but in some scenarios it may be useful for its own sake. In order to function, this module must be loaded via shared_preload_libraries or local_preload_libraries.

F.5.1. Configuration Parameters

basebackup_to_shell.command (string)

The command which the server should execute for each archive generated by the backup process. If %f occurs in the command string, it will be replaced by the name of the archive (e.g. base.tar). If %d occurs in the command string, it will be replaced by the target detail provided by the user. A target detail is required if %d is used in the command string, and prohibited otherwise. For security reasons, it may contain only alphanumeric characters. If %occurs in the command string, it will be replaced by a single %. If % occurs in the command string followed by any other character or at the end of the string, an error occurs.

basebackup_to_shell.required_role (string)

The role required in order to make use of the shell backup target. If this is not set, any replication user may make use of the shell backup target.

F.5.2. Author

Robert Haas <rhaas@postgresql.org>

F.6. basic_archive

basic_archive is an example of an archive module. This module copies completed WAL segment files to the specified directory. This may not be especially useful, but it can serve as a starting point for developing your own archive module. For more information about archive modules, see Chapter 51.

In order to function, this module must be loaded via archive_library, and archive_mode must be enabled.

F.6.1. Configuration Parameters

basic_archive.archive_directory (string)

The directory where the server should copy WAL segment files. This directory must already exist. The default is an empty string, which effectively halts WAL archiving, but if archive_mode is enabled, the server will accumulate WAL segment files in the expectation that a value will soon be provided.

These parameters must be set in postgresql.conf. Typical usage might be:

```
# postgresql.conf
archive_mode = 'on'
archive_library = 'basic_archive'
basic_archive.archive_directory = '/path/to/archive/directory'
```
F.6.2. Notes

Server crashes may leave temporary files with the prefix `archtemp` in the archive directory. It is recommended to delete such files before restarting the server after a crash. It is safe to remove such files while the server is running as long as they are unrelated to any archiving still in progress, but users should use extra caution when doing so.

F.6.3. Author

Nathan Bossart

F.7. bloom

`bloom` provides an index access method based on Bloom filters\(^1\).

A Bloom filter is a space-efficient data structure that is used to test whether an element is a member of a set. In the case of an index access method, it allows fast exclusion of non-matching tuples via signatures whose size is determined at index creation.

A signature is a lossy representation of the indexed attribute(s), and as such is prone to reporting false positives; that is, it may be reported that an element is in the set, when it is not. So index search results must always be rechecked using the actual attribute values from the heap entry. Larger signatures reduce the odds of a false positive and thus reduce the number of useless heap visits, but of course also make the index larger and hence slower to scan.

This type of index is most useful when a table has many attributes and queries test arbitrary combinations of them. A traditional btree index is faster than a bloom index, but it can require many btree indexes to support all possible queries where one needs only a single bloom index. Note however that bloom indexes only support equality queries, whereas btree indexes can also perform inequality and range searches.

F.7.1. Parameters

A `bloom` index accepts the following parameters in its `WITH` clause:

- **length**
  
  Length of each signature (index entry) in bits. It is rounded up to the nearest multiple of 16. The default is 80 bits and the maximum is 4096.

- **col1 — col32**
  
  Number of bits generated for each index column. Each parameter's name refers to the number of the index column that it controls. The default is 2 bits and the maximum is 4095. Parameters for index columns not actually used are ignored.

F.7.2. Examples

This is an example of creating a bloom index:

```
CREATE INDEX bloomidx ON tbloom USING bloom (i1,i2,i3)
  WITH (length=80, col1=2, col2=2, col3=4);
```

\(^1\) https://en.wikipedia.org/wiki/Bloom_filter
The index is created with a signature length of 80 bits, with attributes i1 and i2 mapped to 2 bits, and attribute i3 mapped to 4 bits. We could have omitted the length, col1, and col2 specifications since those have the default values.

Here is a more complete example of bloom index definition and usage, as well as a comparison with equivalent btree indexes. The bloom index is considerably smaller than the btree index, and can perform better.

```sql
=# CREATE TABLE tbloom AS
   SELECT
     (random() * 1000000)::int as i1,
     (random() * 1000000)::int as i2,
     (random() * 1000000)::int as i3,
     (random() * 1000000)::int as i4,
     (random() * 1000000)::int as i5,
     (random() * 1000000)::int as i6
   FROM
generate_series(1,1000000);
SELECT 10000000

A sequential scan over this large table takes a long time:

```sql
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
```

QUERY PLAN

```
-------------------------------------------------------------------
Seq Scan on tbloom  (cost=0.00..2137.14 rows=3 width=24) (actual
time=16.971..16.971 rows=0 loops=1)
Filter: ((i2 = 898732) AND (i5 = 123451))
Rows Removed by Filter: 100000
Planning Time: 0.346 ms
Execution Time: 16.988 ms
(5 rows)
```

Even with the btree index defined the result will still be a sequential scan:

```sql
=# CREATE INDEX btreeidx ON tbloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('btreeidx'));
  pg_size_pretty
   -------
    3976 kB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
```

QUERY PLAN

```
-------------------------------------------------------------------
Seq Scan on tbloom  (cost=0.00..2137.00 rows=2 width=24) (actual
time=12.805..12.805 rows=0 loops=1)
Filter: ((i2 = 898732) AND (i5 = 123451))
```

2749
Rows Removed by Filter: 100000
Planning Time: 0.138 ms
Execution Time: 12.817 ms
(5 rows)

Having the bloom index defined on the table is better than btree in handling this type of search:

```sql
=# CREATE INDEX bloomidx ON tbloom USING bloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('bloomidx'));
pg_size_pretty
----------------
1584 kB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
QUERY PLAN
-------------------------------------------------------------------
--------------------------------------------------
Bitmap Heap Scan on tbloom  (cost=1792.00..1799.69 rows=2 width=24)  
(actual time=0.388..0.388 rows=0 loops=1)
  Recheck Cond: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Index Recheck: 29
  Heap Blocks: exact=28
->  Bitmap Index Scan on bloomidx  (cost=0.00..1792.00 rows=2 width=0)  
  (actual time=0.356..0.356 rows=29 loops=1)
    Index Cond: ((i2 = 898732) AND (i5 = 123451))
Planning Time: 0.099 ms
Execution Time: 0.408 ms
(8 rows)
```

Now, the main problem with the btree search is that btree is inefficient when the search conditions do not constrain the leading index column(s). A better strategy for btree is to create a separate index on each column. Then the planner will choose something like this:

```sql
=# CREATE INDEX btreeidx1 ON tbloom (i1);
CREATE INDEX
=# CREATE INDEX btreeidx2 ON tbloom (i2);
CREATE INDEX
=# CREATE INDEX btreeidx3 ON tbloom (i3);
CREATE INDEX
=# CREATE INDEX btreeidx4 ON tbloom (i4);
CREATE INDEX
=# CREATE INDEX btreeidx5 ON tbloom (i5);
CREATE INDEX
=# CREATE INDEX btreeidx6 ON tbloom (i6);
CREATE INDEX
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
QUERY PLAN
-------------------------------------------------------------------
--------------------------------------------------------
2750
```
Although this query runs much faster than with either of the single indexes, we pay a penalty in index size. Each of the single-column btree indexes occupies 2 MB, so the total space needed is 12 MB, eight times the space used by the bloom index.

**F.7.3. Operator Class Interface**

An operator class for bloom indexes requires only a hash function for the indexed data type and an equality operator for searching. This example shows the operator class definition for the `text` data type:

```sql
CREATE OPERATOR CLASS text_ops
DEFAULT FOR TYPE text USING bloom AS
  OPERATOR 1  =(text, text),
  FUNCTION 1  hashtext(text);
```

**F.7.4. Limitations**

- Only operator classes for `int4` and `text` are included with the module.
- Only the `=` operator is supported for search. But it is possible to add support for arrays with union and intersection operations in the future.
- `bloom` access method doesn't support UNIQUE indexes.
- `bloom` access method doesn't support searching for NULL values.

**F.7.5. Authors**

Teodor Sigaev <teodor@postgrespro.ru>, Postgres Professional, Moscow, Russia

Alexander Korotkov <a.korotkov@postgrespro.ru>, Postgres Professional, Moscow, Russia

Oleg Bartunov <obartunov@postgrespro.ru>, Postgres Professional, Moscow, Russia

**F.8. btree_gin**

`btree_gin` provides sample GIN operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with time zone`, `timestamp`
Additional Supplied Modules

without time zone, time with time zone, time without time zone, date, interval, oid, money, "char", varchar, text, bytea, bit, varbit, macaddr, macaddr8, inet, cidr, uuid, name, bool, bpchar, and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they are useful for GIN testing and as a base for developing other GIN operator classes. Also, for queries that test both a GIN-indexable column and a B-tree-indexable column, it might be more efficient to create a multicolumn GIN index that uses one of these operator classes than to create two separate indexes that would have to be combined via bitmap ANDing.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

### F.8.1. Example Usage

```sql
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIN (a);
-- query
SELECT * FROM test WHERE a < 10;
```

### F.8.2. Authors

Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See http://www.sai.msu.su/~megera/oddmuse/index.cgi/Gin for additional information.

### F.9. btree_gist

btree_gist provides GiST index operator classes that implement B-tree equivalent behavior for the data types int2, int4, int8, float4, float8, numeric, timestamp with time zone, timestamp without time zone, time with time zone, time without time zone, date, interval, oid, money, char, varchar, text, bytea, bit, varbit, macaddr, macaddr8, inet, cidr, uuid, bool and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they provide some other features that are not available with a B-tree index, as described below. Also, these operator classes are useful when a multicolumn GiST index is needed, wherein some of the columns are of data types that are only indexable with GiST but other columns are just simple data types. Lastly, these operator classes are useful for GiST testing and as a base for developing other GiST operator classes.

In addition to the typical B-tree search operators, btree_gist also provides index support for <> (“not equals”). This may be useful in combination with an exclusion constraint, as described below.

Also, for data types for which there is a natural distance metric, btree_gist defines a distance operator <->, and provides GiST index support for nearest-neighbor searches using this operator. Distance operators are provided for int2, int4, int8, float4, float8, timestamp with time zone, timestamp without time zone, time with time zone, time without time zone, date, interval, oid, and money.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.
F.9.1. Example Usage

Simple example using btree_gist instead of btree:

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIST (a);
-- query
SELECT * FROM test WHERE a < 10;
-- nearest-neighbor search: find the ten entries closest to "42"
SELECT *, a <-> 42 AS dist FROM test ORDER BY a <-> 42 LIMIT 10;
```

Use an exclusion constraint to enforce the rule that a cage at a zoo can contain only one kind of animal:

```
=> CREATE TABLE zoo (
    cage   INTEGER,
    animal TEXT,
    EXCLUDE USING GIST (cage WITH =, animal WITH <>)
);

F.9.2. Authors

Teodor Sigaev (<teodor@stack.net>), Oleg Bartunov (<oleg@sai.msu.su>), Janko Richter (<jankorichter@yahoo.de>), and Paul Jungwirth (<pj@illuminatedcomputing.com>). See http://www.sai.msu.su/~megera/postgres/gist/ for additional information.

F.10. citext

The citext module provides a case-insensitive character string type, citext. Essentially, it internally calls lower when comparing values. Otherwise, it behaves almost exactly like text.

Tip

Consider using nondeterministic collations (see Section 24.2.2.4) instead of this module. They can be used for case-insensitive comparisons, accent-insensitive comparisons, and other combinations, and they handle more Unicode special cases correctly.
Additional Supplied Modules

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.10.1. Rationale

The standard approach to doing case-insensitive matches in PostgreSQL has been to use the lower function when comparing values, for example

```
SELECT * FROM tab WHERE lower(col) = LOWER(?);
```

This works reasonably well, but has a number of drawbacks:

- It makes your SQL statements verbose, and you always have to remember to use lower on both the column and the query value.
- It won't use an index, unless you create a functional index using lower.
- If you declare a column as UNIQUE or PRIMARY KEY, the implicitly generated index is case-sensitive. So it's useless for case-insensitive searches, and it won't enforce uniqueness case-insensitively.

The citext data type allows you to eliminate calls to lower in SQL queries, and allows a primary key to be case-insensitive. citext is locale-aware, just like text, which means that the matching of upper case and lower case characters is dependent on the rules of the database's LC_CTYPE setting. Again, this behavior is identical to the use of lower in queries. But because it's done transparently by the data type, you don't have to remember to do anything special in your queries.

F.10.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE users (  
nick CITEXT PRIMARY KEY,  
pass TEXT NOT NULL
);

INSERT INTO users VALUES ( 'larry', sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'Tom',   sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'Damian', sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'NEAL',   sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'Bjørn',  sha256(random()::text::bytea) );

SELECT * FROM users WHERE nick = 'Larry';
```

The SELECT statement will return one tuple, even though the nick column was set to larry and the query was for Larry.

F.10.3. String Comparison Behavior

citext performs comparisons by converting each string to lower case (as though lower were called) and then comparing the results normally. Thus, for example, two strings are considered equal if lower would produce identical results for them.

2754
In order to emulate a case-insensitive collation as closely as possible, there are `citext`-specific versions of a number of string-processing operators and functions. So, for example, the regular expression operators `~` and `~*` exhibit the same behavior when applied to `citext`: they both match case-insensitively. The same is true for `!~` and `!~*`, as well as for the `LIKE` operators `~~` and `~~*`, and `!~~` and `!~~*`. If you'd like to match case-sensitively, you can cast the operator's arguments to `text`.

Similarly, all of the following functions perform matching case-insensitively if their arguments are `citext`:

- `regexp_match()`
- `regexp_matches()`
- `regexp_replace()`
- `regexp_split_to_array()`
- `regexp_split_to_table()`
- `replace()`
- `split_part()`
- `strpos()`
- `translate()`

For the `regexp` functions, if you want to match case-sensitively, you can specify the “c” flag to force a case-sensitive match. Otherwise, you must cast to `text` before using one of these functions if you want case-sensitive behavior.

### F.10.4. Limitations

- `citext`'s case-folding behavior depends on the `LC_CTYPE` setting of your database. How it compares values is therefore determined when the database is created. It is not truly case-insensitive in the terms defined by the Unicode standard. Effectively, what this means is that, as long as you're happy with your collation, you should be happy with `citext`'s comparisons. But if you have data in different languages stored in your database, users of one language may find their query results are not as expected if the collation is for another language.

- As of PostgreSQL 9.1, you can attach a `COLLATE` specification to `citext` columns or data values. Currently, `citext` operators will honor a non-default `COLLATE` specification while comparing case-folded strings, but the initial folding to lower case is always done according to the database's `LC_CTYPE` setting (that is, as though `COLLATE "default"` were given). This may be changed in a future release so that both steps follow the input `COLLATE` specification.

- `citext` is not as efficient as `text` because the operator functions and the B-tree comparison functions must make copies of the data and convert it to lower case for comparisons. Also, only `text` can support B-Tree deduplication. However, `citext` is slightly more efficient than using `lower` to get case-insensitive matching.

- `citext` doesn't help much if you need data to compare case-sensitively in some contexts and case-insensitively in other contexts. The standard answer is to use the `text` type and manually use the `lower` function when you need to compare case-insensitively; this works all right if case-insensitive comparison is needed only infrequently. If you need case-insensitive behavior most of the time and case-sensitive infrequently, consider storing the data as `citext` and explicitly casting the column to...
text when you want case-sensitive comparison. In either situation, you will need two indexes if you want both types of searches to be fast.

- The schema containing the citext operators must be in the current search_path (typically public); if it is not, the normal case-sensitive text operators will be invoked instead.

- The approach of lower-casing strings for comparison does not handle some Unicode special cases correctly, for example when one upper-case letter has two lower-case letter equivalents. Unicode distinguishes between case mapping and case folding for this reason. Use nondeterministic collations instead of citext to handle that correctly.

**F.10.5. Author**

David E. Wheeler <david@kineticode.com>

Inspired by the original citext module by Donald Fraser.

**F.11. cube**

This module implements a data type cube for representing multidimensional cubes.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

**F.11.1. Syntax**

Table F.2 shows the valid external representations for the cube type. x, y, etc. denote floating-point numbers.

<table>
<thead>
<tr>
<th>External Syntax</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>A one-dimensional point (or, zero-length one-dimensional interval)</td>
</tr>
<tr>
<td>(x)</td>
<td>Same as above</td>
</tr>
<tr>
<td>x1, x2,..., xn</td>
<td>A point in n-dimensional space, represented internally as a zero-volume cube</td>
</tr>
<tr>
<td>(x1, x2,..., xn)</td>
<td>Same as above</td>
</tr>
<tr>
<td>(x), (y)</td>
<td>A one-dimensional interval starting at x and ending at y or vice versa; the order does not matter</td>
</tr>
<tr>
<td>[(x), (y)]</td>
<td>Same as above</td>
</tr>
<tr>
<td>(x1, ..., xn), (y1, ..., yn)</td>
<td>An n-dimensional cube represented by a pair of its diagonally opposite corners</td>
</tr>
<tr>
<td>[(x1, ..., xn), (y1, ..., yn)]</td>
<td>Same as above</td>
</tr>
</tbody>
</table>

It does not matter which order the opposite corners of a cube are entered in. The cube functions automatically swap values if needed to create a uniform “lower left — upper right” internal representation. When the corners coincide, cube stores only one corner along with an “is point” flag to avoid wasting space.

White space is ignored on input, so [(x), (y)] is the same as [(x), (y)].
F.11.2. Precision

Values are stored internally as 64-bit floating point numbers. This means that numbers with more than about 16 significant digits will be truncated.

F.11.3. Usage

Table F.3 shows the specialized operators provided for type `cube`.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cube &amp;&amp; cube</code></td>
<td><code>-&gt; boolean</code> Do the cubes overlap?</td>
</tr>
<tr>
<td><code>cube @&gt; cube</code></td>
<td><code>-&gt; boolean</code> Does the first cube contain the second?</td>
</tr>
<tr>
<td><code>cube &lt;@ cube</code></td>
<td><code>-&gt; boolean</code> Is the first cube contained in the second?</td>
</tr>
<tr>
<td><code>cube -&gt; integer</code></td>
<td><code>-&gt; float8</code> Extracts the n-th coordinate of the cube (counting from 1).</td>
</tr>
<tr>
<td><code>cube ~-&gt; integer</code></td>
<td><code>-&gt; float8</code> Extracts the n-th coordinate of the cube, counting in the following way: n = 2 * k - 1 means lower bound of k-th dimension, n = 2 * k means upper bound of k-th dimension. Negative n denotes the inverse value of the corresponding positive coordinate. This operator is designed for KNN-GiST support.</td>
</tr>
<tr>
<td><code>cube &lt;-&gt; cube</code></td>
<td><code>-&gt; float8</code> Computes the Euclidean distance between the two cubes.</td>
</tr>
<tr>
<td><code>cube &lt;# cube</code></td>
<td><code>-&gt; float8</code> Computes the taxicab (L-1 metric) distance between the two cubes.</td>
</tr>
<tr>
<td><code>cube &lt;=&gt; cube</code></td>
<td><code>-&gt; float8</code> Computes the Chebyshev (L-inf metric) distance between the two cubes.</td>
</tr>
</tbody>
</table>

In addition to the above operators, the usual comparison operators shown in Table 9.1 are available for type `cube`. These operators first compare the first coordinates, and if those are equal, compare the second coordinates, etc. They exist mainly to support the b-tree index operator class for `cube`, which can be useful for example if you would like a UNIQUE constraint on a `cube` column. Otherwise, this ordering is not of much practical use.

The `cube` module also provides a GiST index operator class for `cube` values. A `cube` GiST index can be used to search for values using the `=`, `&&`, `@>`, and `<@` operators in `WHERE` clauses.

In addition, a `cube` GiST index can be used to find nearest neighbors using the metric operators `<>`, `<#`, and `<=>` in `ORDER BY` clauses. For example, the nearest neighbor of the 3-D point (0.5, 0.5, 0.5) could be found efficiently with:

```sql
SELECT c FROM test ORDER BY c <-> cube(array[0.5,0.5,0.5]) LIMIT 1;
```
The `~>` operator can also be used in this way to efficiently retrieve the first few values sorted by a selected coordinate. For example, to get the first few cubes ordered by the first coordinate (lower left corner) ascending one could use the following query:

```
SELECT c FROM test ORDER BY c ~> 1 LIMIT 5;
```

And to get 2-D cubes ordered by the first coordinate of the upper right corner descending:

```
SELECT c FROM test ORDER BY c ~> 3 DESC LIMIT 5;
```

Table F.4 shows the available functions.

**Table F.4. Cube Functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cube(float8) → cube</td>
<td></td>
</tr>
<tr>
<td>Makes a one dimensional cube with both coordinates the same.</td>
<td></td>
</tr>
<tr>
<td>cube(1) → (1)</td>
<td></td>
</tr>
</tbody>
</table>

| cube(float8, float8) → cube |
| Makes a one dimensional cube. |
| cube(1, 2) → (1), (2) |

| cube(float8[]) → cube |
| Makes a zero-volume cube using the coordinates defined by the array. |
| cube(ARRAY[1,2,3]) → (1, 2, 3) |

| cube(float8[], float8[]) → cube |
| Makes a cube with upper right and lower left coordinates as defined by the two arrays, which must be of the same length. |
| cube(ARRAY[1,2], ARRAY[3,4]) → (1, 2), (3, 4) |

| cube(cube, float8) → cube |
| Makes a new cube by adding a dimension on to an existing cube, with the same values for both endpoints of the new coordinate. This is useful for building cubes piece by piece from calculated values. |
| cube('(1,2),(3,4)':'cube, 5) → (1, 2, 5), (3, 4, 5) |

| cube(cube, float8, float8) → cube |
| Makes a new cube by adding a dimension on to an existing cube. This is useful for building cubes piece by piece from calculated values. |
| cube('(1,2),(3,4)':'cube, 5, 6) → (1, 2, 5), (3, 4, 6) |

| cube_dim(cube) → integer |
| Returns the number of dimensions of the cube. |
| cube_dim('(1,2),(3,4)') → 2 |

| cube_ll_coord(cube, integer) → float8 |
| Returns the n-th coordinate value for the lower left corner of the cube. |
### Function Description Example(s)

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Example(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>cube_ll_coord</td>
<td>Returns the ( n )-th coordinate value for the lower left corner of the cube.</td>
<td><code>cube_ll_coord('(1,2),(3,4)', 2) \rightarrow 2</code></td>
</tr>
<tr>
<td>cube_ur_coord</td>
<td></td>
<td><code>cube_ur_coord('(1,2),(3,4)', 2) \rightarrow 4</code></td>
</tr>
<tr>
<td>cube_is_point</td>
<td>Returns true if the cube is a point, that is, the two defining corners are the same.</td>
<td><code>cube_is_point(cube(1,1)) \rightarrow t</code></td>
</tr>
<tr>
<td>cube_distance</td>
<td>Returns the distance between two cubes. If both cubes are points, this is the normal distance function.</td>
<td><code>cube_distance('(1,2)', '(3,4)') \rightarrow 2.8284271247461903</code></td>
</tr>
</tbody>
</table>
| cube_subset                     | Makes a new cube from an existing cube, using a list of dimension indexes from an array. Can be used to extract the endpoints of a single dimension, or to drop dimensions, or to reorder them as desired. | `cube_subset(cube('(1,3,5),(6,7,8)'), ARRAY[2]) \rightarrow (3),(7)`  
|                                |                                                                               | `cube_subset(cube('(1,3,5),(6,7,8)'), ARRAY[3,2,1,1]) \rightarrow (5, 3, 1, 1),(8, 7, 6, 6)` |
| cube_union                      | Produces the union of two cubes.                                             | `cube_union('(1,2)', '(3,4)') \rightarrow (1, 2),(3, 4)` |
| cube_inter                      | Produces the intersection of two cubes.                                      | `cube_inter('(1,2)', '(3,4)') \rightarrow (3, 4),(1, 2)` |
| cube_enlarge                    | Increases the size of the cube by the specified radius \( r \) in at least \( n \) dimensions. If the radius is negative the cube is shrunk instead. All defined dimensions are changed by the radius \( r \). Lower-left coordinates are decreased by \( r \) and upper-right coordinates are increased by \( r \). If a lower-left coordinate is increased to more than the corresponding upper-right coordinate (this can only happen when \( r < 0 \)) than both coordinates are set to their average. If \( n \) is greater than the number of defined dimensions and the cube is being enlarged \( (r > 0) \), then extra dimensions are added to make \( n \) altogether; 0 is used as the initial value for the extra coordinates. This function is useful for creating bounding boxes around a point for searching for nearby points. | `cube_enlarge('(1,2),(3,4)', 0.5, 3) \rightarrow (0.5, 1.5, -0.5),(3.5, 4.5, 0.5)` |

### F.11.4. Defaults

I believe this union:
Additional Supplied Modules

```
select cube_union('(0,5,2),(2,3,1)', '0');
cube_union
-------------------
(0, 0, 0),(2, 5, 2)
(1 row)
```
do not contradict common sense, neither does the intersection

```
select cube_inter('(0,-1),(1,1)', '(-2),(2)');
cube_inter
-------------
(0, 0),(1, 0)
(1 row)
```

In all binary operations on differently-dimensioned cubes, I assume the lower-dimensional one to be a Cartesian projection, i.e., having zeroes in place of coordinates omitted in the string representation. The above examples are equivalent to:

```
cube_union('(0,5,2),(2,3,1)','(0,0,0),(0,0,0)');
cube_inter('(0,-1),(1,1)','(-2,0),(2,0)');
```
The following containment predicate uses the point syntax, while in fact the second argument is internally represented by a box. This syntax makes it unnecessary to define a separate point type and functions for (box,point) predicates.

```
select cube_contains('(0,0),(1,1)', '0.5,0.5');
cube_contains
------------
t
(1 row)
```

F.11.5. Notes

For examples of usage, see the regression test sql/cube.sql.

To make it harder for people to break things, there is a limit of 100 on the number of dimensions of cubes. This is set in cubedata.h if you need something bigger.

F.11.6. Credits

Original author: Gene Selkov. Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (https://dsf.berkeley.edu/jmh/) for elucidating the gist of the GiST (http://gist.cs.berkeley.edu/), and to his former student Andy Dong for his example written for Illustra. I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

Minor updates to this package were made by Bruno Wolff III <bruno@wolff.to> in August/September of 2002. These include changing the precision from single precision to double precision and adding some new functions.
Additional updates were made by Joshua Reich <josh@root.net> in July 2006. These include
\texttt{cube(float8[], float8[])} and cleaning up the code to use the V1 call protocol instead of the
deprecated V0 protocol.

\section*{F.12. \texttt{dblink}}

\texttt{dblink} is a module that supports connections to other PostgreSQL databases from within a database session.

See also \texttt{postgres_fdw}, which provides roughly the same functionality using a more modern and stan-
dards-compliant infrastructure.
**dblink_connect**

*dblink_connect* — opens a persistent connection to a remote database

### Synopsis

```
 punishable_sections (text connstr) returns text
 punishable_sections (text connname, text connstr) returns text
```

### Description

*dblink_connect()* establishes a connection to a remote PostgreSQL database. The server and database to be contacted are identified through a standard libpq connection string. Optionally, a name can be assigned to the connection. Multiple named connections can be open at once, but only one unnamed connection is permitted at a time. The connection will persist until closed or until the database session is ended.

The connection string may also be the name of an existing foreign server. It is recommended to use the foreign-data wrapper *dblink_fdw* when defining the foreign server. See the example below, as well as *CREATE SERVER* and *CREATE USER MAPPING*.

### Arguments

- **connname**
  
  The name to use for this connection; if omitted, an unnamed connection is opened, replacing any existing unnamed connection.

- **connstr**
  
  libpq-style connection info string, for example `hostaddr=127.0.0.1 port=5432 dbname=mydb user=postgres password=mypasswd options=-csearch_path=`. For details see Section 34.1.1. Alternatively, the name of a foreign server.

### Return Value

Returns status, which is always *OK* (since any error causes the function to throw an error instead of returning).

### Notes

If untrusted users have access to a database that has not adopted a secure schema usage pattern, begin each session by removing publicly-writable schemas from *search_path*. One could, for example, add `options=-csearch_path= to *connstr*. This consideration is not specific to *dblink*; it applies to every interface for executing arbitrary SQL commands.

Only superusers may use *dblink_connect* to create non-password-authenticated connections. If non-superusers need this capability, use *dblink_connect_u* instead.

It is unwise to choose connection names that contain equal signs, as this opens a risk of confusion with connection info strings in other *dblink* functions.

### Examples
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
  dblink_connect
--------------------
   OK
  (1 row)

SELECT dblink_connect('myconn', 'dbname=postgres options=-csearch_path=');
  dblink_connect
--------------------
   OK
  (1 row)

-- FOREIGN DATA WRAPPER functionality
-- Note: local connection must require password authentication for
   this to work properly
-- Otherwise, you will receive the following error from
  dblink_connect():
--   ERROR: password is required
--   DETAIL: Non-superuser cannot connect if the server does not
  request a password.
--   HINT: Target server's authentication method must be changed.

CREATE SERVER fdtest FOREIGN DATA WRAPPER dblink_fdw OPTIONS (hostaddr '127.0.0.1', dbname 'contrib_regression');

CREATE USER regress_dblink_user WITH PASSWORD 'secret';
CREATE USER MAPPING FOR regress_dblink_user SERVER fdtest OPTIONS (user 'regress_dblink_user', password 'secret');
GRANT USAGE ON FOREIGN SERVER fdtest TO regress_dblink_user;
GRANT SELECT ON TABLE foo TO regress_dblink_user;

\set ORIGINAL_USER :USER
\c - regress_dblink_user
SELECT dblink_connect('myconn', 'fdtest');
  dblink_connect
--------------------
   OK
  (1 row)

SELECT * FROM dblink('myconn', 'SELECT * FROM foo') AS t(a int, b text, c text[]);
 a | b |       c
----+---+---------------
 0 | a | {a0,b0,c0}
 1 | b | {a1,b1,c1}
 2 | c | {a2,b2,c2}
 3 | d | {a3,b3,c3}
 4 | e | {a4,b4,c4}
 5 | f | {a5,b5,c5}
 6 | g | {a6,b6,c6}
 7 | h | {a7,b7,c7}
 8 | i | {a8,b8,c8}
 9 | j | {a9,b9,c9}
<table>
<thead>
<tr>
<th>10</th>
<th>k</th>
<th>{a10,b10,c10}</th>
</tr>
</thead>
</table>

(11 rows)

```
\c - :ORIGINAL_USER
REVOKE USAGE ON FOREIGN SERVER fdtest FROM regress_dblink_user;
REVOKE SELECT ON TABLE foo FROM regress_dblink_user;
DROP USER MAPPING FOR regress_dblink_user SERVER fdtest;
DROP USER regress_dblink_user;
DROP SERVER fdtest;
```
**dbname_connect_u**

dbname_connect_u — opens a persistent connection to a remote database, insecurely

**Synopsis**

```
dbfunc_connect_u(text connstr) returns text
dbname_connect_u(text connname, text connstr) returns text
```

**Description**

dbname_connect_u() is identical to dbname_connect(), except that it will allow non-superusers to connect using any authentication method.

If the remote server selects an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur, because the session will appear to have originated from the user as which the local PostgreSQL server runs. Also, even if the remote server does demand a password, it is possible for the password to be supplied from the server environment, such as a ~/.pgpass file belonging to the server's user. This opens not only a risk of impersonation, but the possibility of exposing a password to an untrustworthy remote server. Therefore, dbname_connect_u() is initially installed with all privileges revoked from PUBLIC, making it un-callable except by superusers. In some situations it may be appropriate to grant EXECUTE permission for dbname_connect_u() to specific users who are considered trustworthy, but this should be done with care. It is also recommended that any ~/.pgpass file belonging to the server's user not contain any records specifying a wildcard host name.

For further details see dbname_connect().
**dblink_disconnect**

dblink_disconnect — closes a persistent connection to a remote database

**Synopsis**

```c
dblink_disconnect() returns text
dblink_disconnect(text connname) returns text
```

**Description**

dblink_disconnect () closes a connection previously opened by dblink_connect (). The form with no arguments closes an unnamed connection.

**Arguments**

*connname*

The name of a named connection to be closed.

**Return Value**

Returns status, which is always OK (since any error causes the function to throw an error instead of returning).

**Examples**

```sql
SELECT dblink_disconnect();
  dblink_disconnect
-------------------
   OK
(1 row)

SELECT dblink_disconnect('myconn');
  dblink_disconnect
-------------------
   OK
(1 row)
```
**dblink**

`dblink` — executes a query in a remote database

## Synopsis

```
dblink(text connname, text sql [, bool fail_on_error]) returns setof record
dblink(text connstr, text sql [, bool fail_on_error]) returns setof record
dblink(text sql [, bool fail_on_error]) returns setof record
```

## Description

`dblink` executes a query (usually a `SELECT`, but it can be any SQL statement that returns rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

## Arguments

**connname**

Name of the connection to use; omit this parameter to use the unnamed connection.

**connstr**

A connection info string, as previously described for `dblink_connect`.

**sql**

The SQL query that you wish to execute in the remote database, for example `select * from foo`.

**fail_on_error**

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

## Return Value

The function returns the row(s) produced by the query. Since `dblink` can be used with any query, it is declared to return `record`, rather than specifying any particular set of columns. This means that you must specify the expected set of columns in the calling query — otherwise PostgreSQL would not know what to expect. Here is an example:

```
SELECT *
FROM dblink('dbname=myDb options=-csearch_path=',
```
The “alias” part of the FROM clause must specify the column names and types that the function will return. (Specifying column names in an alias is actually standard SQL syntax, but specifying column types is a PostgreSQL extension.) This allows the system to understand what * should expand to, and what proname in the WHERE clause refers to, in advance of trying to execute the function. At run time, an error will be thrown if the actual query result from the remote database does not have the same number of columns shown in the FROM clause. The column names need not match, however, and dblink does not insist on exact type matches either. It will succeed so long as the returned data strings are valid input for the column type declared in the FROM clause.

**Notes**

A convenient way to use dblink with predetermined queries is to create a view. This allows the column type information to be buried in the view, instead of having to spell it out in every query. For example,

```sql
CREATE VIEW myremote_pg_proc AS
  SELECT *
  FROM dblink('dbname=postgres options=-csearch_path=','
                 select proname, prosrc from pg_proc')
           AS t1(proname name, prosrc text);

SELECT * FROM myremote_pg_proc WHERE proname LIKE 'bytea%';
```

**Examples**

```sql
SELECT * FROM dblink('dbname=postgres options=-csearch_path=','
                      select proname, prosrc from pg_proc')
            AS t1(proname name, prosrc text) WHERE proname LIKE 'bytea%';

```
**dblink_exec**

*dblink_exec* — executes a command in a remote database

### Synopsis

```sql
dblink_exec(text connname, text sql [, bool fail_on_error]) returns text
dblink_exec(text connstr, text sql [, bool fail_on_error]) returns text
dblink_exec(text sql [, bool fail_on_error]) returns text
```

### Description

*dblink_exec* executes a command (that is, any SQL statement that doesn't return rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

### Arguments

- **connname**
  
  Name of the connection to use; omit this parameter to use the unnamed connection.

- **connstr**
  
  A connection info string, as previously described for `dblink_connect`.

- **sql**
  
  The SQL command that you wish to execute in the remote database, for example `insert into foo values(0, 'a', "{'a0","b0","c0'}")`.

- **fail_on_error**
  
  If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

### Return Value

Returns status, either the command's status string or `ERROR`.

### Examples

```sql
SELECT dblink_connect('dbname=dblink_test_standby');
dblink_connect
```
Additional Supplied Modules

-----------------
OK
(1 row)

SELECT dblink_exec('insert into foo values(21, ''z'', ''{"a0","b0","c0"}"'););
  dblink_exec
-----------------
INSERT 943366 1
(1 row)

SELECT dblink_connect('myconn', 'dbname=regression');
  dblink_connect
-----------------
OK
(1 row)

SELECT dblink_exec('myconn', 'insert into foo values(21, ''z'', ''{"a0","b0","c0"}"'););
  dblink_exec
-----------------
INSERT 6432584 1
(1 row)

SELECT dblink_exec('myconn', 'insert into pg_class values (''foo'')',false);
  dblink_exec
-----------------
OK
(1 row)

SELECT dblink_exec('myconn', 'insert into pg_class values (''foo'')',false);
  dblink_exec
-----------------
ERROR
(1 row)
**dblink_open**

dblink_open — opens a cursor in a remote database

**Synopsis**

dblink_open(text cursorname, text sql [, bool fail_on_error]) returns text
dblink_open(text connname, text cursorname, text sql [, bool fail_on_error]) returns text

**Description**

dblink_open() opens a cursor in a remote database. The cursor can subsequently be manipulated with dblink_fetch() and dblink_close().

**Arguments**

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*cursorname*

The name to assign to this cursor.

*sql*

The SELECT statement that you wish to execute in the remote database, for example select * from pg_class.

*fail_on_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to ERROR.

**Return Value**

Returns status, either OK or ERROR.

**Notes**

Since a cursor can only persist within a transaction, dblink_open starts an explicit transaction block (BEGIN) on the remote side, if the remote side was not already within a transaction. This transaction will be closed again when the matching dblink_close is executed. Note that if you use dblink_exec to change data between dblink_open and dblink_close, and then an error occurs or you use dblink_disconnect before dblink_close, your change will be lost because the transaction will be aborted.

**Examples**
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
  dblink_connect
-------------
OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
  dblink_open
------------
OK
(1 row)
**dblink_fetch**

$dblink_fetch$ — returns rows from an open cursor in a remote database

**Synopsis**

```sql
$dblink_fetch(text cursorname, int howmany [, bool fail_on_error]) returns setof record
$dblink_fetch(text connname, text cursorname, int howmany [, bool fail_on_error]) returns setof record
```

**Description**

$dblink_fetch$ fetches rows from a cursor previously established by $dblink_open$.

**Arguments**

- **connname**
  
  Name of the connection to use; omit this parameter to use the unnamed connection.

- **cursorname**
  
  The name of the cursor to fetch from.

- **howmany**
  
  The maximum number of rows to retrieve. The next $howmany$ rows are fetched, starting at the current cursor position, moving forward. Once the cursor has reached its end, no more rows are produced.

- **fail_on_error**
  
  If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

**Return Value**

The function returns the row(s) fetched from the cursor. To use this function, you will need to specify the expected set of columns, as previously discussed for $dblink$.

**Notes**

On a mismatch between the number of return columns specified in the $FROM$ clause, and the actual number of columns returned by the remote cursor, an error will be thrown. In this event, the remote cursor is still advanced by as many rows as it would have been if the error had not occurred. The same is true for any other error occurring in the local query after the remote $FETCH$ has been done.

**Examples**

2774
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
  dblink_connect
----------------
  OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc where
  proname like ''bytea%''');
  dblink_open
----------------
  OK
(1 row)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
  funcname  |  source
-----------|-----------
 byteacat   |  byteacat
 byteacmp   |  byteacmp
 byteaeq    |  byteaeq
 byteage    |  byteage
 byteagt    |  byteagt
(5 rows)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
  funcname  |  source
-----------|-----------
 byteain   |  byteain
 byteale   |  byteale
 bytealike |  bytealike
 bytealt   |  bytealt
 byteane   |  byteane
(5 rows)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
  funcname  |  source
-----------|-----------
 byteanlike |  byteanlike
 byteaout   |  byteaout
(2 rows)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
  funcname  |  source
-----------|-----------
(0 rows)
### dblink_close

**Synopsis**

`dblink_close(text cursorname [, bool fail_on_error]) returns text`

`dblink_close(text connname, text cursorname [, bool fail_on_error]) returns text`

**Description**

`dblink_close` closes a cursor previously opened with `dblink_open`.

**Arguments**

- `connname`
  
  Name of the connection to use; omit this parameter to use the unnamed connection.

- `cursorname`
  
  The name of the cursor to close.

- `fail_on_error`
  
  If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

**Return Value**

Returns status, either `OK` or `ERROR`.

**Notes**

If `dblink_open` started an explicit transaction block, and this is the last remaining open cursor in this connection, `dblink_close` will issue the matching `COMMIT`.

**Examples**

```sql
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
  dblink_connect
----------------
          OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
  dblink_open
-------------
```

2776
SELECT dblink_close('foo');
 dblink_close
----------
 OK
(1 row)

**dblink_get_connections**

`dblink_get_connections` — returns the names of all open named dblink connections

**Synopsis**

```
dblink_get_connections() returns text[]
```

**Description**

`dblink_get_connections` returns an array of the names of all open named dblink connections.

**Return Value**

Returns a text array of connection names, or NULL if none.

**Examples**

```
SELECT dblink_get_connections();
```
**dblink_error_message**

dblink_error_message — gets last error message on the named connection

**Synopsis**

dblink_error_message(text connname) returns text

**Description**

dblink_error_message fetches the most recent remote error message for a given connection.

**Arguments**

`connname`

Name of the connection to use.

**Return Value**

Returns last error message, or OK if there has been no error in this connection.

**Notes**

When asynchronous queries are initiated by dblink_send_query, the error message associated with the connection might not get updated until the server's response message is consumed. This typically means that dblink_is_busy or dblink_get_result should be called prior to dblink_error_message, so that any error generated by the asynchronous query will be visible.

**Examples**

```sql
SELECT dblink_error_message('dtest1');
```
dblink_send_query

  dblink_send_query — sends an async query to a remote database

Synopsis

  dblink_send_query(text connname, text sql) returns int

Description

  dblink_send_query sends a query to be executed asynchronously, that is, without immediately wait-
ing for the result. There must not be an async query already in progress on the connection.

  After successfully dispatching an async query, completion status can be checked with
dblink_is_busy, and the results are ultimately collected with dblink_get_result. It is also pos-
sible to attempt to cancel an active async query using dblink_cancel_query.

Arguments

  connname

    Name of the connection to use.

  sql

    The SQL statement that you wish to execute in the remote database, for example select * from
pg_class.

Return Value

  Returns 1 if the query was successfully dispatched, 0 otherwise.

Examples

  SELECT dblink_send_query('dtest1', 'SELECT * FROM foo WHERE f1 < 3');
**dblink_is_busy**

`dblink_is_busy` — checks if connection is busy with an async query

**Synopsis**

```
dblink_is_busy(text connname) returns int
```

**Description**

`dblink_is_busy` tests whether an async query is in progress.

**Arguments**

`connname`

Name of the connection to check.

**Return Value**

Returns 1 if connection is busy, 0 if it is not busy. If this function returns 0, it is guaranteed that `dblink_get_result` will not block.

**Examples**

```
SELECT dblink_is_busy('dtest1');
```
**dblink_get_notify**

**dblink_get_notify — retrieve async notifications on a connection**

**Synopsis**

```sql
dblink_get_notify() returns setof (notify_name text, be_pid int, extra text)
dblink_get_notify(text connname) returns setof (notify_name text, be_pid int, extra text)
```

**Description**

`dblink_get_notify` retrieves notifications on either the unnamed connection, or on a named connection if specified. To receive notifications via `dblink`, `LISTEN` must first be issued, using `dblink_exec`. For details see `LISTEN` and `NOTIFY`.

**Arguments**

`connname`

The name of a named connection to get notifications on.

**Return Value**

Returns `setof (notify_name text, be_pid int, extra text)`, or an empty set if none.

**Examples**

```sql
SELECT dblink_exec('LISTEN virtual');
  dblink_exec
  ------------
  LISTEN
  (1 row)

SELECT * FROM dblink_get_notify();
  notify_name | be_pid | extra
  -----------------------------
  (0 rows)

NOTIFY virtual;
NOTIFY

SELECT * FROM dblink_get_notify();
  notify_name | be_pid | extra
  -----------------------------
  virtual     | 1229 |
  (1 row)
```
**dblink_get_result**

`dblink_get_result` — gets an async query result

### Synopsis

```c
dblink_get_result(text connname [, bool fail_on_error]) returns setof record
```

### Description

`dblink_get_result` collects the results of an asynchronous query previously sent with `dblink_send_query`. If the query is not already completed, `dblink_get_result` will wait until it is.

### Arguments

**connname**

Name of the connection to use.

**fail_on_error**

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

### Return Value

For an async query (that is, an SQL statement returning rows), the function returns the row(s) produced by the query. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

For an async command (that is, an SQL statement not returning rows), the function returns a single row with a single text column containing the command's status string. It is still necessary to specify that the result will have a single text column in the calling `FROM` clause.

### Notes

This function *must* be called if `dblink_send_query` returned 1. It must be called once for each query sent, and one additional time to obtain an empty set result, before the connection can be used again.

When using `dblink_send_query` and `dblink_get_result`, `dblink` fetches the entire remote query result before returning any of it to the local query processor. If the query returns a large number of rows, this can result in transient memory bloat in the local session. It may be better to open such a query as a cursor with `dblink_open` and then fetch a manageable number of rows at a time. Alternatively, use plain `dblink()`, which avoids memory bloat by spooling large result sets to disk.

### Examples
contrib_regression=# SELECT dblink_connect('dtest1',
'dbname=contrib_regression');
dblink_connect
--------------
OK
(1 row)
contrib_regression=# SELECT * FROM
contrib_regression=# dblink_send_query('dtest1', 'select * from foo
where f1 < 3') AS t1;
t1
----
1
(1 row)
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS
t1(f1 int, f2 text, f3 text[]);
f1 | f2 |     f3

----+----+------------
 0 | a  | {a0,b0,c0}
 1 | b  | {a1,b1,c1}
 2 | c  | {a2,b2,c2}
(3 rows)
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS
t1(f1 int, f2 text, f3 text[]);
f1 | f2 |      f3
----+----+---------------
 7 | h  | {a7,b7,c7}
 8 | i  | {a8,b8,c8}
 9 | j  | {a9,b9,c9}

2784
10 | k  | {a10,b10,c10}
   (4 rows)

contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text, f3 text[]);
f1  | f2   | f3
----+------+----
(0 rows)
Additional Supplied Modules

**dblink_cancel_query**

*dblink_cancel_query* — cancels any active query on the named connection

**Synopsis**

```
dblink_cancel_query(text connname) returns text
```

**Description**

*dblink_cancel_query* attempts to cancel any query that is in progress on the named connection. Note that this is not certain to succeed (since, for example, the remote query might already have finished). A cancel request simply improves the odds that the query will fail soon. You must still complete the normal query protocol, for example by calling *dblink_get_result*.

**Arguments**

`connname`

Name of the connection to use.

**Return Value**

Returns *OK* if the cancel request has been sent, or the text of an error message on failure.

**Examples**

```
SELECT dblink_cancel_query('dtest1');
```
**dblink_get_pkey**

dblink_get_pkey — returns the positions and field names of a relation's primary key fields

**Synopsis**

dblink_get_pkey(text relname) returns setof dblink_pkey_results

**Description**

dblink_get_pkey provides information about the primary key of a relation in the local database. This is sometimes useful in generating queries to be sent to remote databases.

**Arguments**

* relname

  Name of a local relation, for example *foo* or *myschema.mytab*. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

**Return Value**

Returns one row for each primary key field, or no rows if the relation has no primary key. The result row type is defined as

```
CREATE TYPE dblink_pkey_results AS (position int, colname text);
```

The *position* column simply runs from 1 to \( N \); it is the number of the field within the primary key, not the number within the table's columns.

**Examples**

```
CREATE TABLE foobar (  
  f1 int,  
  f2 int,  
  f3 int,  
  PRIMARY KEY (f1, f2, f3)  
);  
CREATE TABLE

SELECT * FROM dblink_get_pkey('foobar');  
position | colname  
----------+---------  
1 | f1  
2 | f2  
3 | f3
(3 rows)
```
**dblink_build_sql_insert**

dblink_build_sql_insert — builds an INSERT statement using a local tuple, replacing the primary key field values with alternative supplied values

**Synopsis**

dblink_build_sql_insert(text relname,
    int2vector primary_key_attnums,
    integer num_primary_key_atts,
    text[] src_pk_att_vals_array,
    text[] tgt_pk_att_vals_array) returns text

**Description**

dblink_build_sql_insert can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds an SQL INSERT command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.)

**Arguments**

* relname
  Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

* primary_key_attnums
  Attribute numbers (1-based) of the primary key fields, for example `1 2`.

* num_primary_key_atts
  The number of primary key fields.

* src_pk_att_vals_array
  Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

* tgt_pk_att_vals_array
  Values of the primary key fields to be placed in the resulting INSERT command. Each field is represented in text form.

**Return Value**

Returns the requested SQL statement as text.

**Notes**

As of PostgreSQL 9.0, the attribute numbers in `primary_key_attnums` are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous
versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

**Examples**

```sql
SELECT dblink_build_sql_insert('foo', '1 2', 2, '{"1", "a"}', '{"1", "b""a"}')
```

```
<table>
<thead>
<tr>
<th>dblink_build_sql_insert</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
</tbody>
</table>

```sql
INSERT INTO foo(f1,f2,f3) VALUES('1','b''a','1')
```

(1 row)
dblink_build_sql_delete

dblink_build_sql_delete — builds a DELETE statement using supplied values for primary key field values

Synopsis

dblink_build_sql_delete(text relname,
                    int2vector primary_key_attnums,
                    integer num_primary_key_atts,
                    text[] tgt_pk_att_vals_array) returns text

Description

dblink_build_sql_delete can be useful in doing selective replication of a local table to a remote database. It builds an SQL DELETE command that will delete the row with the given primary key values.

Arguments

rename

Name of a local relation, for example foo or myschema.mytab. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

primary_key_attnums

Attribute numbers (1-based) of the primary key fields, for example 1 2.

num_primary_key_atts

The number of primary key fields.

tgt_pk_att_vals_array

Values of the primary key fields to be used in the resulting DELETE command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in primary_key_attnums are interpreted as logical column numbers, corresponding to the column's position in SELECT * FROM relname. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples
SELECT dblink_build_sql_delete('"MyFoo"', '1 2', 2, '{"1", "b"}');
-----------------------------
DELETE FROM "MyFoo" WHERE f1='1' AND f2='b'
(1 row)
**dblink_build_sql_update**

`dblink_build_sql_update` — builds an `UPDATE` statement using a local tuple, replacing the primary key field values with alternative supplied values

**Synopsis**

```sql
dblink_build_sql_update(text relname,
                        int2vector primary_key_attnums,
                        integer num_primary_key_atts,
                        text[] src_pk_att_vals_array,
                        text[] tgt_pk_att_vals_array) returns text
```

**Description**

`dblink_build_sql_update` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds an SQL `UPDATE` command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.) The `UPDATE` command always assigns all fields of the row — the main difference between this and `dblink_build_sql_insert` is that it's assumed that the target row already exists in the remote table.

**Arguments**

*relname*

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

*primary_key_attnums*

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

*num_primary_key_atts*

The number of primary key fields.

*src_pk_att_vals_array*

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

*tgt_pk_att_vals_array*

Values of the primary key fields to be placed in the resulting `UPDATE` command. Each field is represented in text form.

**Return Value**

Returns the requested SQL statement as text.
Notes

As of PostgreSQL 9.0, the attribute numbers in primary_key_attnums are interpreted as logical column numbers, corresponding to the column's position in SELECT * FROM relname. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

SELECT dblink_build_sql_update('foo', '1 2', 2, '{"1", "a"}', '{"1", "b"}');

<table>
<thead>
<tr>
<th>dblink_build_sql_update</th>
</tr>
</thead>
<tbody>
<tr>
<td>UPDATE foo SET f1='1', f2='b', f3='1' WHERE f1='1' AND f2='b'</td>
</tr>
<tr>
<td>(1 row)</td>
</tr>
</tbody>
</table>

F.13. dict_int

dict_int is an example of an add-on dictionary template for full-text search. The motivation for this example dictionary is to control the indexing of integers (signed and unsigned), allowing such numbers to be indexed while preventing excessive growth in the number of unique words, which greatly affects the performance of searching.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.13.1. Configuration

The dictionary accepts three options:

• The maxlen parameter specifies the maximum number of digits allowed in an integer word. The default value is 6.

• The rejectlong parameter specifies whether an overlength integer should be truncated or ignored. If rejectlong is false (the default), the dictionary returns the first maxlen digits of the integer. If rejectlong is true, the dictionary treats an overlength integer as a stop word, so that it will not be indexed. Note that this also means that such an integer cannot be searched for.

• The absval parameter specifies whether leading “+” or “−” signs should be removed from integer words. The default is false. When true, the sign is removed before maxlen is applied.

F.13.2. Usage

Installing the dict_int extension creates a text search template intdict_template and a dictionary intdict based on it, with the default parameters. You can alter the parameters, for example

mydb# ALTER TEXT SEARCH DICTIONARY intdict (MAXLEN = 4, REJECTLONG = true);
ALTER TEXT SEARCH DICTIONARY

or create new dictionaries based on the template.
To test the dictionary, you can try

```sql
mydb# select ts_lexize('intdict', '12345678');
  ts_lexize
---------
(123456)
```

but real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
    ALTER MAPPING FOR int, uint WITH intdict;
```

### F.14. dict_xsyn

dict_xsyn (Extended Synonym Dictionary) is an example of an add-on dictionary template for full-text search. This dictionary type replaces words with groups of their synonyms, and so makes it possible to search for a word using any of its synonyms.

#### F.14.1. Configuration

A dict_xsyn dictionary accepts the following options:

- `matchorig` controls whether the original word is accepted by the dictionary. Default is `true`.
- `matchsynonyms` controls whether the synonyms are accepted by the dictionary. Default is `false`.
- `keeporig` controls whether the original word is included in the dictionary's output. Default is `true`.
- `keepsynonyms` controls whether the synonyms are included in the dictionary's output. Default is `true`.
- `rules` is the base name of the file containing the list of synonyms. This file must be stored in `$SHAREDIR/tsearch_data/` (where `$SHAREDIR` means the PostgreSQL installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `rules` parameter).

The rules file has the following format:

- Each line represents a group of synonyms for a single word, which is given first on the line. Synonyms are separated by whitespace, thus:

  ```
  word syn1 syn2 syn3
  ```

- The sharp (#) sign is a comment delimiter. It may appear at any position in a line. The rest of the line will be skipped.

Look at `xsyn_sample.rules`, which is installed in `$SHAREDIR/tsearch_data/`, for an example.

#### F.14.2. Usage

Installing the dict_xsyn extension creates a text search template `xsyn_template` and a dictionary `xsyn` based on it, with default parameters. You can alter the parameters, for example
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules',
KEEPORIG=false);
ALTER TEXT SEARCH DICTIONARY

or create new dictionaries based on the template.

To test the dictionary, you can try

mydb=# SELECT ts_lexize('xsyn', 'word');
   ts_lexize
------------
{syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules',
KEEPORIG=true);
ALTER TEXT SEARCH DICTIONARY

mydb=# SELECT ts_lexize('xsyn', 'word');
   ts_lexize
------------
{word,syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules',
KEEPORIG=false, MATCHSYNONYMS=true);
ALTER TEXT SEARCH DICTIONARY

mydb=# SELECT ts_lexize('xsyn', 'syn1');
   ts_lexize
------------
{syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules',
KEEPORIG=true, MATCHORIG=false, KEEPSYNONYMS=false);
ALTER TEXT SEARCH DICTIONARY

mydb=# SELECT ts_lexize('xsyn', 'syn1');
   ts_lexize
------------
{word}

Real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:

ALTER TEXT SEARCH CONFIGURATION english
   ALTER MAPPING FOR word, asciiword WITH xsyn, english_stem;

F.15. earthdistance

The earthdistance module provides two different approaches to calculating great circle distances on the surface of the Earth. The one described first depends on the cube module. The second one is based on the built-in point data type, using longitude and latitude for the coordinates.
In this module, the Earth is assumed to be perfectly spherical. (If that's too inaccurate for you, you might want to look at the PostGIS\(^1\) project.)

The `cube` module must be installed before `earthdistance` can be installed (although you can use the `CASCADE` option of `CREATE EXTENSION` to install both in one command).

---

**Caution**

It is strongly recommended that `earthdistance` and `cube` be installed in the same schema, and that that schema be one for which `CREATE` privilege has not been and will not be granted to any untrusted users. Otherwise there are installation-time security hazards if `earthdistance`'s schema contains objects defined by a hostile user. Furthermore, when using `earthdistance`'s functions after installation, the entire search path should contain only trusted schemas.

---

**F.15.1. Cube-Based Earth Distances**

Data is stored in cubes that are points (both corners are the same) using 3 coordinates representing the x, y, and z distance from the center of the Earth. A domain `earth` over type `cube` is provided, which includes constraint checks that the value meets these restrictions and is reasonably close to the actual surface of the Earth.

The radius of the Earth is obtained from the `earth()` function. It is given in meters. But by changing this one function you can change the module to use some other units, or to use a different value of the radius that you feel is more appropriate.

This package has applications to astronomical databases as well. Astronomers will probably want to change `earth()` to return a radius of \(180/\pi()\) so that distances are in degrees.

Functions are provided to support input in latitude and longitude (in degrees), to support output of latitude and longitude, to calculate the great circle distance between two points and to easily specify a bounding box usable for index searches.

The provided functions are shown in Table F.5.

**Table F.5. Cube-Based Earthdistance Functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>earth() \rightarrow float8</code></td>
<td>Returns the assumed radius of the Earth.</td>
</tr>
<tr>
<td><code>sec_to_gc(float8) \rightarrow float8</code></td>
<td>Converts the normal straight line (secant) distance between two points on the surface of the Earth to the great circle distance between them.</td>
</tr>
<tr>
<td><code>gc_to_sec(float8) \rightarrow float8</code></td>
<td>Converts the great circle distance between two points on the surface of the Earth to the normal straight line (secant) distance between them.</td>
</tr>
<tr>
<td><code>ll_to_earth(float8, float8) \rightarrow earth</code></td>
<td>Returns the location of a point on the surface of the Earth given its latitude (argument 1) and longitude (argument 2) in degrees.</td>
</tr>
</tbody>
</table>

---

1 https://postgis.net/
### Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>latitude(earth) → float8</code></td>
<td>Returns the latitude in degrees of a point on the surface of the Earth.</td>
</tr>
<tr>
<td><code>longitude(earth) → float8</code></td>
<td>Returns the longitude in degrees of a point on the surface of the Earth.</td>
</tr>
<tr>
<td><code>earth_distance(earth, earth) → float8</code></td>
<td>Returns the great circle distance between two points on the surface of the Earth.</td>
</tr>
<tr>
<td><code>earth_box(earth, float8) → cube</code></td>
<td>Returns a box suitable for an indexed search using the cube @&gt; operator for points within a given great circle distance of a location. Some points in this box are further than the specified great circle distance from the location, so a second check using <code>earth_distance</code> should be included in the query.</td>
</tr>
</tbody>
</table>

#### F.15.2. Point-Based Earth Distances

The second part of the module relies on representing Earth locations as values of type `point`, in which the first component is taken to represent longitude in degrees, and the second component is taken to represent latitude in degrees. Points are taken as (longitude, latitude) and not vice versa because longitude is closer to the intuitive idea of x-axis and latitude to y-axis.

A single operator is provided, shown in Table F.6.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>point &lt;@&gt; point → float8</code></td>
<td>Computes the distance in statute miles between two points on the Earth's surface.</td>
</tr>
</tbody>
</table>

Note that unlike the `cube`-based part of the module, units are hardwired here: changing the `earth()` function will not affect the results of this operator.

One disadvantage of the longitude/latitude representation is that you need to be careful about the edge conditions near the poles and near +/- 180 degrees of longitude. The `cube`-based representation avoids these discontinuities.

#### F.16. `file_fdw`

The `file_fdw` module provides the foreign-data wrapper `file_fdw`, which can be used to access data files in the server's file system, or to execute programs on the server and read their output. The data file or program output must be in a format that can be read by `COPY FROM`; see `COPY` for details. Access to data files is currently read-only.

A foreign table created using this wrapper can have the following options:

- **filename**
  - Specifies the file to be read. Relative paths are relative to the data directory. Either `filename` or `program` must be specified, but not both.
program

Specifies the command to be executed. The standard output of this command will be read as though COPY FROM PROGRAM were used. Either program or filename must be specified, but not both.

format

Specifies the data format, the same as COPY’s FORMAT option.

header

Specifies whether the data has a header line, the same as COPY’s HEADER option.

delimiter

Specifies the data delimiter character, the same as COPY’s DELIMITER option.

quote

Specifies the data quote character, the same as COPY’s QUOTE option.

escape

Specifies the data escape character, the same as COPY’s ESCAPE option.

null

Specifies the data null string, the same as COPY’s NULL option.

encoding

Specifies the data encoding, the same as COPY’s ENCODING option.

Note that while COPY allows options such as HEADER to be specified without a corresponding value, the foreign table option syntax requires a value to be present in all cases. To activate COPY options typically written without a value, you can pass the value TRUE, since all such options are Booleans.

A column of a foreign table created using this wrapper can have the following options:

force_not_null

This is a Boolean option. If true, it specifies that values of the column should not be matched against the null string (that is, the table-level null option). This has the same effect as listing the column in COPY’s FORCE_NOT_NULL option.

force_null

This is a Boolean option. If true, it specifies that values of the column which match the null string are returned as NULL even if the value is quoted. Without this option, only unquoted values matching the null string are returned as NULL. This has the same effect as listing the column in COPY’s FORCE_NULL option.

COPY’s FORCE_QUOTE option is currently not supported by file_fdw.

These options can only be specified for a foreign table or its columns, not in the options of the file_fdw foreign-data wrapper, nor in the options of a server or user mapping using the wrapper.
Changing table-level options requires being a superuser or having the privileges of the role pg_read_server_files (to use a filename) or the role pg_execute_server_program (to use a program), for security reasons: only certain users should be able to control which file is read or which program is run. In principle regular users could be allowed to change the other options, but that’s not supported at present.

When specifying the program option, keep in mind that the option string is executed by the shell. If you need to pass any arguments to the command that come from an untrusted source, you must be careful to strip or escape any characters that might have special meaning to the shell. For security reasons, it is best to use a fixed command string, or at least avoid passing any user input in it.

For a foreign table using file_fdw, EXPLAIN shows the name of the file to be read or program to be run. For a file, unless COSTS OFF is specified, the file size (in bytes) is shown as well.

**Example F.1. Create a Foreign Table for PostgreSQL CSV Logs**

One of the obvious uses for file_fdw is to make the PostgreSQL activity log available as a table for querying. To do this, first you must be logging to a CSV file, which here we will call pglog.csv. First, install file_fdw as an extension:

```
CREATE EXTENSION file_fdw;
```

Then create a foreign server:

```
CREATE SERVER pglog FOREIGN DATA WRAPPER file_fdw;
```

Now you are ready to create the foreign data table. Using the CREATE FOREIGN TABLE command, you will need to define the columns for the table, the CSV file name, and its format:

```
CREATE FOREIGN TABLE pglog (  
    log_time timestamp(3) with time zone,  
    user_name text,  
    database_name text,  
    process_id integer,  
    connection_from text,  
    session_id text,  
    session_line_num bigint,  
    command_tag text,  
    session_start_time timestamp with time zone,  
    virtual_transaction_id text,  
    transaction_id bigint,  
    error_severity text,  
    sql_state_code text,  
    message text,  
    detail text,  
    hint text,  
    internal_query text,  
    internal_query_pos integer,  
    context text,  
    query text,  
    query_pos integer,
```
location text,
application_name text,
backend_type text,
leader_pid integer,
query_id bigint
) SERVER pglog
OPTIONS ( filename 'log/pglog.csv', format 'csv' );

That’s it — now you can query your log directly. In production, of course, you would need to define some way to deal with log rotation.

F.17. fuzzystrmatch

The fuzzystrmatch module provides several functions to determine similarities and distance between strings.

Caution

At present, the soundex, metaphone, dmetaphone, and dmetaphone_alt functions do not work well with multibyte encodings (such as UTF-8).

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.17.1. Soundex

The Soundex system is a method of matching similar-sounding names by converting them to the same code. It was initially used by the United States Census in 1880, 1900, and 1910. Note that Soundex is not very useful for non-English names.

The fuzzystrmatch module provides two functions for working with Soundex codes:

soundex(text) returns text
difference(text, text) returns int

The soundex function converts a string to its Soundex code. The difference function converts two strings to their Soundex codes and then reports the number of matching code positions. Since Soundex codes have four characters, the result ranges from zero to four, with zero being no match and four being an exact match. (Thus, the function is misnamed — similarity would have been a better name.)

Here are some usage examples:

SELECT soundex('hello world!');

SELECT soundex('Anne'), soundex('Ann'), difference('Anne', 'Ann');
SELECT soundex('Anne'), soundex('Andrew'), difference('Anne', 'Andrew');
SELECT soundex('Anne'), soundex('Margaret'), difference('Anne', 'Margaret');

CREATE TABLE s (nm text);

INSERT INTO s VALUES ('john');
INSERT INTO s VALUES ('joan');
INSERT INTO s VALUES ('wobbly');
INSERT INTO s VALUES ('jack');

SELECT * FROM s WHERE soundex(nm) = soundex('john');

SELECT * FROM s WHERE difference(s.nm, 'john') > 2;

**F.17.2. Levenshtein**

This function calculates the Levenshtein distance between two strings:

```sql
levenshtein(text source, text target, int ins_cost, int del_cost, int sub_cost) returns int
levenshtein(text source, text target) returns int
levenshtein_less_equal(text source, text target, int ins_cost, int del_cost, int sub_cost, int max_d) returns int
levenshtein_less_equal(text source, text target, int max_d) returns int
```

Both source and target can be any non-null string, with a maximum of 255 characters. The cost parameters specify how much to charge for a character insertion, deletion, or substitution, respectively. You can omit the cost parameters, as in the second version of the function; in that case they all default to 1.

`levenshtein_less_equal` is an accelerated version of the Levenshtein function for use when only small distances are of interest. If the actual distance is less than or equal to `max_d`, then `levenshtein_less_equal` returns the correct distance; otherwise it returns some value greater than `max_d`. If `max_d` is negative then the behavior is the same as `levenshtein`.

Examples:

```sql
test=# SELECT levenshtein('GUMBO', 'GAMBOL');
levenshtein
---------
  2
(1 row)

test=# SELECT levenshtein('GUMBO', 'GAMBOL', 2, 1, 1);
levenshtein
---------
  3
(1 row)

test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 2);
levenshtein_less_equal
----------------------
  2801
(1 row)
```
F.17.3. Metaphone

Metaphone, like Soundex, is based on the idea of constructing a representative code for an input string. Two strings are then deemed similar if they have the same codes.

This function calculates the metaphone code of an input string:

\[
\text{metaphone}(\text{text source}, \text{int max_output_length}) \text{ returns text}
\]

source has to be a non-null string with a maximum of 255 characters. max_output_length sets the maximum length of the output metaphone code; if longer, the output is truncated to this length.

Example:

```
test=# SELECT metaphone('GUMBO', 4);
metaphone
----------
KM
(1 row)
```

F.17.4. Double Metaphone

The Double Metaphone system computes two “sounds like” strings for a given input string — a “primary” and an “alternate”. In most cases they are the same, but for non-English names especially they can be a bit different, depending on pronunciation. These functions compute the primary and alternate codes:

\[
\text{dmetaphone}(\text{text source}) \text{ returns text}
\]
\[
\text{dmetaphone\_alt}(\text{text source}) \text{ returns text}
\]

There is no length limit on the input strings.

Example:

```
test=# SELECT dmetaphone('gumbo');
dmetaphone
----------
KMP
```
F.18. hstore

This module implements the hstore data type for storing sets of key/value pairs within a single PostgreSQL value. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data. Keys and values are simply text strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.18.1. hstore External Representation

The text representation of an hstore, used for input and output, includes zero or more key => value pairs separated by commas. Some examples:

```
  k => v
  foo => bar, baz => whatever
  "1-a" => "anything at all"
```

The order of the pairs is not significant (and may not be reproduced on output). Whitespace between pairs or around the => sign is ignored. Double-quote keys and values that include whitespace, commas, =s or >s. To include a double quote or a backslash in a key or value, escape it with a backslash.

Each key in an hstore is unique. If you declare an hstore with duplicate keys, only one will be stored in the hstore and there is no guarantee as to which will be kept:

```
SELECT 'a=>1,a=>2'::hstore;
  hstore
  -------
    "a"=>"1"
```

A value (but not a key) can be an SQL NULL. For example:

```
key => NULL
```

The NULL keyword is case-insensitive. Double-quote the NULL to treat it as the ordinary string “NULL”.

---

**Note**

Keep in mind that the hstore text format, when used for input, applies before any required quoting or escaping. If you are passing an hstore literal via a parameter, then no additional processing is needed. But if you're passing it as a quoted literal constant, then any single-quote characters and (depending on the setting of the standard_conforming_strings configuration parameter) backslash characters need to be escaped correctly. See Section 4.1.2.1 for more on the handling of string constants.

On output, double quotes always surround keys and values, even when it's not strictly necessary.
### F.18.2. hstore Operators and Functions

The operators provided by the `hstore` module are shown in Table F.7, the functions in Table F.8.

#### Table F.7. hstore Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>hstore -&gt; text</code></td>
<td>Returns value associated with given key, or NULL if not present.</td>
<td><code>'a=&gt;x, b=&gt;y'::hstore -&gt; 'a' -&gt; x</code></td>
</tr>
<tr>
<td><code>hstore -&gt; text[]</code></td>
<td>Returns values associated with given keys, or NULL if not present.</td>
<td><code>'a=&gt;x, b=&gt;y, c=&gt;z'::hstore -&gt; ARRAY['c','a']</code></td>
</tr>
<tr>
<td>`hstore</td>
<td></td>
<td>hstore`</td>
</tr>
<tr>
<td><code>hstore ? text</code></td>
<td>Does <code>hstore</code> contain key?</td>
<td><code>'a=&gt;1'::hstore ? 'a' -&gt; t</code></td>
</tr>
<tr>
<td><code>hstore ?&amp; text[]</code></td>
<td>Does <code>hstore</code> contain all the specified keys?</td>
<td><code>'a=&gt;1,b=&gt;2'::hstore ?&amp; ARRAY['a','b']</code></td>
</tr>
<tr>
<td>`hstore ?</td>
<td>text[]`</td>
<td>Does <code>hstore</code> contain any of the specified keys?</td>
</tr>
<tr>
<td><code>hstore @&gt; hstore</code></td>
<td>Does left operand contain right?</td>
<td><code>'a=&gt;b, b=&gt;1, c=&gt;NULL'::hstore @&gt; 'b=&gt;1' -&gt; t</code></td>
</tr>
<tr>
<td><code>hstore &lt;= hstore</code></td>
<td>Is left operand contained in right?</td>
<td><code>'a=&gt;c'::hstore &lt;= 'a=&gt;b, b=&gt;1, c=&gt;NULL' -&gt; f</code></td>
</tr>
<tr>
<td><code>hstore - text</code></td>
<td>Deletes key from left operand.</td>
<td><code>'a=&gt;1, b=&gt;2, c=&gt;3'::hstore - 'b':text -&gt; 'a' =&gt; &quot;1&quot;, 'c' =&gt; &quot;3&quot;</code></td>
</tr>
<tr>
<td><code>hstore - text[]</code></td>
<td>Deletes keys from left operand.</td>
<td><code>'a=&gt;1, b=&gt;2, c=&gt;3'::hstore - ARRAY['a','b']</code></td>
</tr>
<tr>
<td><code>hstore - hstore</code></td>
<td>Deletes pairs from left operand that match pairs in the right operand.</td>
<td></td>
</tr>
<tr>
<td>Operator</td>
<td>Description</td>
<td>Example(s)</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
<td>------------</td>
</tr>
<tr>
<td><code>a=&gt;1, b=&gt;2, c=&gt;3</code>:hstore - <code>a=&gt;4, b=&gt;2</code>:hstore → &quot;a&quot;=&gt;&quot;1&quot;, &quot;c&quot;=&gt;&quot;3&quot;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

`anyelement` #= `hstore` → `anyelement`

Replaces fields in the left operand (which must be a composite type) with matching values from `hstore`.

ROW(1,3) #= 'f1=>11':hstore → (11,3)

`% hstore` → `text[]`

Converts `hstore` to an array of alternating keys and values.

`% 'a'=>foo, b=>bar':hstore` → `{a,foo,b,bar}`

`%# hstore` → `text[]`

Converts `hstore` to a two-dimensional key/value array.

`%# 'a'=>foo, b=>bar':hstore` → `{{a,foo},{b,bar}}`

Table F.8. `hstore` Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Example(s)</th>
</tr>
</thead>
</table>
| `hstore(record)` → `hstore` | Constructs an `hstore` from a record or row. | `hstore(ROW(1,2))` → "f1"=>"1", "f2"=>"2"

`hstore(text[])` → `hstore`

Constructs an `hstore` from an array, which may be either a key/value array, or a two-dimensional array.

`hstore(ARRAY['a','1','b','2'])` → "a"=>"1", "b"=>"2"

`hstore(ARRAY['c','3'],['d','4'])` → "c"=>"3", "d"=>"4"

`hstore(text[],text[])` → `hstore`

Constructs an `hstore` from separate key and value arrays.

`hstore(ARRAY['a','b'], ARRAY['1','2'])` → "a"=>"1", "b"=>"2"

`hstore(text,text)` → `hstore`

Makes a single-item `hstore`.

`hstore('a', 'b')` → "a"=>"b"

`akeys(hstore)` → `text[]`

Extracts an `hstore`'s keys as an array.

`akeys('a=>1,b=>2')` → `{a,b}

`skeys(hstore)` → `setof text`

Extracts an `hstore`'s keys as a set.

`skeys('a=>1,b=>2')` →

<td>Does hstore contain key?</td>
<td><code>exist('a=&gt;1', 'a') → t</code></td>
</tr>
<tr>
<td><code>defined(hstore, text) → boolean</code></td>
<td>Does hstore contain a non-NULL value for key?</td>
<td><code>defined('a=&gt;NULL', 'a') → f</code></td>
</tr>
<tr>
<td><code>delete(hstore, text) → hstore</code></td>
<td>Deletes pair with matching key.</td>
<td><code>delete('a=&gt;1,b=&gt;2', 'b') → &quot;a&quot;=&gt;&quot;1&quot;</code></td>
</tr>
<tr>
<td><code>delete(hstore, text[]) → hstore</code></td>
<td>Deletes pairs with matching keys.</td>
<td><code>delete('a=&gt;1,b=&gt;2,c=&gt;3', ARRAY['a','b']) → &quot;c&quot;=&gt;&quot;3&quot;</code></td>
</tr>
<tr>
<td><code>delete(hstore, hstore) → hstore</code></td>
<td>Deletes pairs matching those in the second argument.</td>
<td><code>delete('a=&gt;1,b=&gt;2', 'a=&gt;4,b=&gt;2':hstore) → &quot;a&quot;=&gt;&quot;1&quot;</code></td>
</tr>
<tr>
<td><code>populate_record(anyelement, hstore) → anyelement</code></td>
<td>Replaces fields in the left operand (which must be a composite type) with matching values from hstore.</td>
<td><code>populate_record(ROW(1,2), 'f1=&gt;42':hstore) → (42,2)</code></td>
</tr>
</tbody>
</table>

In addition to these operators and functions, values of the `hstore` type can be subscripted, allowing them to act like associative arrays. Only a single subscript of type `text` can be specified; it is interpreted as a key and the corresponding value is fetched or stored. For example,
CREATE TABLE mytable (h hstore);
INSERT INTO mytable VALUES ('a=>b, c=>d');
SELECT h['a'] FROM mytable;

--

b
(1 row)

UPDATE mytable SET h['c'] = 'new';
SELECT h FROM mytable;

----------------------
"a"=>"b", "c"=>"new"
(1 row)

A subscripted fetch returns NULL if the subscript is NULL or that key does not exist in the hstore. (Thus, a subscripted fetch is not greatly different from the => operator.) A subscripted update fails if the subscript is NULL; otherwise, it replaces the value for that key, adding an entry to the hstore if the key does not already exist.

F.18.3. Indexes

hstore has GiST and GIN index support for the @>, ?, ?& and ?| operators. For example:

CREATE INDEX hidx ON testhstore USING GIST (h);
CREATE INDEX hidx ON testhstore USING GIN (h);

gist_hstore_ops GiST opclass approximates a set of key/value pairs as a bitmap signature. Its optional integer parameter siglen determines the signature length in bytes. The default length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

CREATE INDEX hidx ON testhstore USING GIST (h
gist_hstore_ops(siglen=32));

hstore also supports btree or hash indexes for the = operator. This allows hstore columns to be declared UNIQUE, or to be used in GROUP BY, ORDER BY or DISTINCT expressions. The sort ordering for hstore values is not particularly useful, but these indexes may be useful for equivalence lookups. Create indexes for = comparisons as follows:

CREATE INDEX hidx ON testhstore USING BTREE (h);
CREATE INDEX hidx ON testhstore USING HASH (h);

F.18.4. Examples

Add a key, or update an existing key with a new value:
UPDATE tab SET h['c'] = '3';

Another way to do the same thing is:

UPDATE tab SET h = h || hstore('c', '3');

If multiple keys are to be added or changed in one operation, the concatenation approach is more efficient than subscripting:

UPDATE tab SET h = h || hstore(array['q', 'w'], array['11', '12']);

Delete a key:

UPDATE tab SET h = delete(h, 'k1');

Convert a record to an hstore:

CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');

SELECT hstore(t) FROM test AS t;

-----------------------------
| "col1"=>"123", "col2"=>"foo", "col3"=>"bar" |
(1 row)

Convert an hstore to a predefined record type:

CREATE TABLE test (col1 integer, col2 text, col3 text);

SELECT * FROM populate_record(null::test, "col1"=>"456", "col2"=>"zzz");

col1 | col2 | col3
---+-----+-----+
456 | zzz  |     
(1 row)

Modify an existing record using the values from an hstore:

CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');

SELECT (r).* FROM (SELECT t #= "col3"=>"baz" AS r FROM test t) s;

col1 | col2 | col3
---+-----+-----+
123 | foo  | baz  
(1 row)
F.18.5. Statistics

The hstore type, because of its intrinsic liberality, could contain a lot of different keys. Checking for valid keys is the task of the application. The following examples demonstrate several techniques for checking keys and obtaining statistics.

Simple example:

```
SELECT * FROM each('aaa=>bq, b=>NULL, ""=>1');
```

Using a table:

```
CREATE TABLE stat AS SELECT (each(h)).key, (each(h)).value FROM testhstore;
```

Online statistics:

```
SELECT key, count(*) FROM
(SELECT (each(h)).key FROM testhstore) AS stat
GROUP BY key
ORDER BY count DESC, key;
```

```
key    | count
-----------+-------
line      |   883
query     |   207
pos       |   203
node      |   202
space     |   197
status    |   195
public    |   194
title     |   190
org       |   189
```

F.18.6. Compatibility

As of PostgreSQL 9.0, hstore uses a different internal representation than previous versions. This presents no obstacle for dump/restore upgrades since the text representation (used in the dump) is unchanged.

In the event of a binary upgrade, upward compatibility is maintained by having the new code recognize old-format data. This will entail a slight performance penalty when processing data that has not yet been modified by the new code. It is possible to force an upgrade of all values in a table column by doing an UPDATE statement as follows:

```
UPDATE tablename SET hstorecol = hstorecol || '';
```

Another way to do it is:

```
ALTER TABLE tablename ALTER hstorecol TYPE hstore USING hstorecol || '';
```
The `ALTER TABLE` method requires an `ACCESS EXCLUSIVE` lock on the table, but does not result in bloating the table with old row versions.

### F.18.7. Transforms

Additional extensions are available that implement transforms for the `hstore` type for the languages PL/Perl and PL/Python. The extensions for PL/Perl are called `hstore_plperl` and `hstore_plperlu`, for trusted and untrusted PL/Perl. If you install these transforms and specify them when creating a function, `hstore` values are mapped to Perl hashes. The extension for PL/Python is called `hstore_plpython3u`. If you use it, `hstore` values are mapped to Python dictionaries.

**Caution**

It is strongly recommended that the transform extensions be installed in the same schema as `hstore`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

### F.18.8. Authors

Oleg Bartunov <oleg@sai.msu.su>, Moscow, Moscow University, Russia

Teodor Sigaev <teodor@sigaev.ru>, Moscow, Delta-Soft Ltd., Russia

Additional enhancements by Andrew Gierth <andrew@taol1.riddles.org.uk>, United Kingdom

### F.19. intagg

The `intagg` module provides an integer aggregator and an enumerator. `intagg` is now obsolete, because there are built-in functions that provide a superset of its capabilities. However, the module is still provided as a compatibility wrapper around the built-in functions.

#### F.19.1. Functions

The aggregator is an aggregate function `int_array_aggregate(integer)` that produces an integer array containing exactly the integers it is fed. This is a wrapper around `array_agg`, which does the same thing for any array type.

The enumerator is a function `int_array_enum(integer[])` that returns `setof integer`. It is essentially the reverse operation of the aggregator: given an array of integers, expand it into a set of rows. This is a wrapper around `unnest`, which does the same thing for any array type.

#### F.19.2. Sample Uses

Many database systems have the notion of a one to many table. Such a table usually sits between two indexed tables, for example:

```
CREATE TABLE left (id INT PRIMARY KEY, ...);
CREATE TABLE right (id INT PRIMARY KEY, ...);
```
CREATE TABLE one_to_many(left INT REFERENCES left, right INT REFERENCES right);

It is typically used like this:

```sql
SELECT right.* from right JOIN one_to_many ON (right.id = one_to_many.right)
    WHERE one_to_many.left = item;
```

This will return all the items in the right hand table for an entry in the left hand table. This is a very common construct in SQL.

Now, this methodology can be cumbersome with a very large number of entries in the `one_to_many` table. Often, a join like this would result in an index scan and a fetch for each right hand entry in the table for a particular left hand entry. If you have a very dynamic system, there is not much you can do. However, if you have some data which is fairly static, you can create a summary table with the aggregator.

```sql
CREATE TABLE summary AS
    SELECT left, int_array_aggregate(right) AS right
    FROM one_to_many
    GROUP BY left;
```

This will create a table with one row per left item, and an array of right items. Now this is pretty useless without some way of using the array; that's why there is an array enumerator. You can do

```sql
SELECT left, int_array_enum(right) FROM summary WHERE left = item;
```

The above query using `int_array_enum` produces the same results as

```sql
SELECT left, right FROM one_to_many WHERE left = item;
```

The difference is that the query against the summary table has to get only one row from the table, whereas the direct query against `one_to_many` must index scan and fetch a row for each entry.

On one system, an `EXPLAIN` showed a query with a cost of 8488 was reduced to a cost of 329. The original query was a join involving the `one_to_many` table, which was replaced by:

```sql
SELECT right, count(right) FROM
    ( SELECT left, int_array_enum(right) AS right
        FROM summary JOIN (SELECT left FROM left_table WHERE left = item) AS lefts
        ON (summary.left = lefts.left)
    ) AS list
GROUP BY right
ORDER BY count DESC;
```

### F.20. intarray

The `intarray` module provides a number of useful functions and operators for manipulating null-free arrays of integers. There is also support for indexed searches using some of the operators.
All of these operations will throw an error if a supplied array contains any NULL elements.

Many of these operations are only sensible for one-dimensional arrays. Although they will accept input arrays of more dimensions, the data is treated as though it were a linear array in storage order.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

### F.20.1. intarray Functions and Operators

The functions provided by the intarray module are shown in Table F.9, the operators in Table F.10.

#### Table F.9. intarray Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Example(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>icount (integer[]) → integer</td>
<td>Returns the number of elements in the array.</td>
<td>icount ('{1,2,3}'::integer[]) → 3</td>
</tr>
<tr>
<td>sort (integer[], dir text) → integer[]</td>
<td>Sorts the array in either ascending or descending order. dir must be asc or desc.</td>
<td>sort ('{1,3,2}'::integer[], 'desc') → {3,2,1}</td>
</tr>
<tr>
<td>sort (integer[]) → integer[]</td>
<td></td>
<td>sort('array[11,77,44]') → {11,44,77}</td>
</tr>
<tr>
<td>sort_asc (integer[]) → integer[]</td>
<td>Sorts in ascending order.</td>
<td>sort_asc('array[11,77,44]') → {11,44,77}</td>
</tr>
<tr>
<td>sort_desc (integer[]) → integer[]</td>
<td>Sorts in descending order.</td>
<td>sort_desc('array[11,77,44]') → {77,44,11}</td>
</tr>
<tr>
<td>uniq (integer[]) → integer[]</td>
<td>Removes adjacent duplicates. Often used with sort to remove all duplicates.</td>
<td>uniq('array[11,2,3,1,1]') → {1,2,3,1}</td>
</tr>
<tr>
<td>idx (integer[], item integer) → integer</td>
<td>Returns index of the first array element matching item, or 0 if no match.</td>
<td>idx('array[11,22,33,22,11]', 22) → 2</td>
</tr>
<tr>
<td>subarray (integer[], start integer, len integer) → integer[]</td>
<td>Extacts the portion of the array starting at position start, with len elements.</td>
<td>subarray('array[1,2,3,2,1]::integer[]', 2, 3) → {2,3,2}</td>
</tr>
<tr>
<td>subarray (integer[], start integer) → integer[]</td>
<td>Extacts the portion of the array starting at position start.</td>
<td>subarray('array[1,2,3,2,1]::integer[]', 2) → {2,3,2,1}</td>
</tr>
<tr>
<td>intset (integer) → integer[]</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
## Additional Supplied Modules

### Table F.10. `intarray` Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>integer[] &amp;&amp; integer[] → boolean</code></td>
<td>Do arrays overlap (have at least one element in common)?</td>
</tr>
<tr>
<td><code>integer[] @&gt; integer[] → boolean</code></td>
<td>Does left array contain right array?</td>
</tr>
<tr>
<td><code>integer[] &lt;@ integer[] → boolean</code></td>
<td>Is left array contained in right array?</td>
</tr>
<tr>
<td><code># integer[] → integer</code></td>
<td>Returns the number of elements in the array.</td>
</tr>
<tr>
<td><code>integer[] # integer → integer</code></td>
<td>Returns index of the first array element matching the right argument, or 0 if no match. (Same as <code>idx</code> function.)</td>
</tr>
<tr>
<td><code>integer[] + integer → integer[]</code></td>
<td>Adds element to end of array.</td>
</tr>
<tr>
<td><code>integer[] + integer[] → integer[]</code></td>
<td>Concatenates the arrays.</td>
</tr>
<tr>
<td><code>integer[] - integer → integer[]</code></td>
<td>Removes entries matching the right argument from the array.</td>
</tr>
<tr>
<td><code>integer[] - integer[] → integer[]</code></td>
<td>Removes elements of the right array from the left array.</td>
</tr>
<tr>
<td>`integer[]</td>
<td>integer → integer[]`</td>
</tr>
<tr>
<td>`integer[]</td>
<td>integer[] → integer[]`</td>
</tr>
<tr>
<td><code>integer[] &amp; integer[] → integer[]</code></td>
<td>Computes the intersection of the arguments.</td>
</tr>
<tr>
<td><code>integer[] @@ query_int → boolean</code></td>
<td>Does array satisfy query? (see below)</td>
</tr>
<tr>
<td><code>query_int ~~ integer[] → boolean</code></td>
<td>Does array satisfy query? (commutator of <code>@@</code>)</td>
</tr>
</tbody>
</table>

The operators `&&`, `@>` and `<@` are equivalent to PostgreSQL's built-in operators of the same names, except that they work only on integer arrays that do not contain nulls, while the built-in operators work for any array type. This restriction makes them faster than the built-in operators in many cases.
The @@ and ~~~ operators test whether an array satisfies a *query*, which is expressed as a value of a specialized data type *query_int*. A *query* consists of integer values that are checked against the elements of the array, possibly combined using the operators & (AND), | (OR), and ! (NOT). Parentheses can be used as needed. For example, the query 1 & (2 | 3) matches arrays that contain 1 and also contain either 2 or 3.

### F.20.2. Index Support

`intarray` provides index support for the &&, @>, and @@ operators, as well as regular array equality.

Two parameterized GiST index operator classes are provided: `gist__int_ops` (used by default) is suitable for small- to medium-size data sets, while `gist__intbig_ops` uses a larger signature and is more suitable for indexing large data sets (i.e., columns containing a large number of distinct array values). The implementation uses an RD-tree data structure with built-in lossy compression.

`gist__int_ops` approximates an integer set as an array of integer ranges. Its optional integer parameter `numranges` determines the maximum number of ranges in one index key. The default value of `numranges` is 100. Valid values are between 1 and 253. Using larger arrays as GiST index keys leads to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

`gist__intbig_ops` approximates an integer set as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

There is also a non-default GIN operator class `gin__int_ops`, which supports these operators as well as <@.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

### F.20.3. Example

```
-- a message can be in one or more "sections"
CREATE TABLE message (mid INT PRIMARY KEY, sections INT[], ...);

-- create specialized index with signature length of 32 bytes
CREATE INDEX message_rdtree_idx ON message USING GIST (sections gist__intbig_ops (siglen = 32));

-- select messages in section 1 OR 2 - OVERLAP operator
SELECT message.mid FROM message WHERE message.sections && '{1,2}';

-- select messages in sections 1 AND 2 - CONTAINS operator
SELECT message.mid FROM message WHERE message.sections @> '{1,2}';

-- the same, using QUERY operator
SELECT message.mid FROM message WHERE message.sections @@ '1&2'::query_int;
```

### F.20.4. Benchmark

The source directory `contrib/intarray/bench` contains a benchmark test suite, which can be run against an installed PostgreSQL server. (It also requires `DBD::Pg` to be installed.) To run:
The bench.pl script has numerous options, which are displayed when it is run without any arguments.

F.20.5. Authors

All work was done by Teodor Sigaev (<teodor@sigaev.ru>) and Oleg Bartunov (<oleg@sai.msu.su>). See http://www.sai.msu.su/~megera/postgres/gist/ for additional information. Andrey Oktyabrski did a great work on adding new functions and operations.

F.21. isn

The isn module provides data types for the following international product numbering standards: EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials). Numbers are validated on input according to a hard-coded list of prefixes; this list of prefixes is also used to hyphenate numbers on output. Since new prefixes are assigned from time to time, the list of prefixes may be out of date. It is hoped that a future version of this module will obtain the prefix list from one or more tables that can be easily updated by users as needed; however, at present, the list can only be updated by modifying the source code and recompiling. Alternatively, prefix validation and hyphenation support may be dropped from a future version of this module.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.21.1. Data Types

Table F.11 shows the data types provided by the isn module.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAN13</td>
<td>European Article Numbers, always displayed in the EAN13 display format</td>
</tr>
<tr>
<td>ISBN13</td>
<td>International Standard Book Numbers to be displayed in the new EAN13 display format</td>
</tr>
<tr>
<td>ISMN13</td>
<td>International Standard Music Numbers to be displayed in the new EAN13 display format</td>
</tr>
<tr>
<td>ISSN13</td>
<td>International Standard Serial Numbers to be displayed in the new EAN13 display format</td>
</tr>
<tr>
<td>ISBN</td>
<td>International Standard Book Numbers to be displayed in the old short display format</td>
</tr>
<tr>
<td>ISMN</td>
<td>International Standard Music Numbers to be displayed in the old short display format</td>
</tr>
<tr>
<td>ISSN</td>
<td>International Standard Serial Numbers to be displayed in the old short display format</td>
</tr>
</tbody>
</table>
### Data Type Description

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UPC</td>
<td>Universal Product Codes</td>
</tr>
</tbody>
</table>

Some notes:

1. ISBN13, ISMN13, ISSN13 numbers are all EAN13 numbers.
2. EAN13 numbers aren't always ISBN13, ISMN13 or ISSN13 (some are).
3. Some ISBN13 numbers can be displayed as ISBN.
4. Some ISMN13 numbers can be displayed as ISMN.
5. Some ISSN13 numbers can be displayed as ISSN.
6. UPC numbers are a subset of the EAN13 numbers (they are basically EAN13 without the first 0 digit).
7. All UPC, ISBN, ISMN and ISSN numbers can be represented as EAN13 numbers.

Internally, all these types use the same representation (a 64-bit integer), and all are interchangeable. Multiple types are provided to control display formatting and to permit tighter validity checking of input that is supposed to denote one particular type of number.

The ISBN, ISMN, and ISSN types will display the short version of the number (ISxN 10) whenever it's possible, and will show ISxN 13 format for numbers that do not fit in the short version. The EAN13, ISBN13, ISMN13 and ISSN13 types will always display the long version of the ISxN (EAN13).

### F.21.2. Casts

The isn module provides the following pairs of type casts:

- ISBN13 <-> EAN13
- ISMN13 <-> EAN13
- ISSN13 <-> EAN13
- ISBN <-> EAN13
- ISMN <-> EAN13
- ISSN <-> EAN13
- UPC <-> EAN13
- ISMN <-> ISMN13
- ISSN <-> ISSN13

When casting from EAN13 to another type, there is a run-time check that the value is within the domain of the other type, and an error is thrown if not. The other casts are simply relabelings that will always succeed.

### F.21.3. Functions and Operators

The isn module provides the standard comparison operators, plus B-tree and hash indexing support for all these data types. In addition there are several specialized functions; shown in Table F.12. In this table, isn means any one of the module's data types.
Table F.12. isn Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>isn_weak(boolean) → boolean</td>
<td>Sets the weak input mode, and returns new setting.</td>
</tr>
<tr>
<td>isn_weak() → boolean</td>
<td>Returns the current status of the weak mode.</td>
</tr>
<tr>
<td>make_valid(isn) → isn</td>
<td>Validates an invalid number (clears the invalid flag).</td>
</tr>
<tr>
<td>is_valid(isn) → boolean</td>
<td>Checks for the presence of the invalid flag.</td>
</tr>
</tbody>
</table>

Weak mode is used to be able to insert invalid data into a table. Invalid means the check digit is wrong, not that there are missing numbers.

Why would you want to use the weak mode? Well, it could be that you have a huge collection of ISBN numbers, and that there are so many of them that for weird reasons some have the wrong check digit (perhaps the numbers were scanned from a printed list and the OCR got the numbers wrong, perhaps the numbers were manually captured... who knows). Anyway, the point is you might want to clean the mess up, but you still want to be able to have all the numbers in your database and maybe use an external tool to locate the invalid numbers in the database so you can verify the information and validate it more easily; so for example you'd want to select all the invalid numbers in the table.

When you insert invalid numbers in a table using the weak mode, the number will be inserted with the corrected check digit, but it will be displayed with an exclamation mark (!) at the end, for example 0-11-000322-5!. This invalid marker can be checked with the is_valid function and cleared with the make_valid function.

You can also force the insertion of invalid numbers even when not in the weak mode, by appending the ! character at the end of the number.

Another special feature is that during input, you can write ? in place of the check digit, and the correct check digit will be inserted automatically.

F.21.4. Examples

```sql
--Using the types directly:
SELECT isbn('978-0-393-04002-9');
SELECT isbn13('0901690546');
SELECT issn('1436-4522');

--Casting types:
-- note that you can only cast from ean13 to another type when the
-- number would be valid in the realm of the target type;
-- thus, the following will NOT work: select
   isbn(ean13('0220356483481'));
-- but these will:
SELECT upc(ean13('0220356483481'));
SELECT ean13(upc('220356483481'));
```

2818
Additional Supplied Modules

--Create a table with a single column to hold ISBN numbers:
CREATE TABLE test (id isbn);
INSERT INTO test VALUES('9780393040029');

--Automatically calculate check digits (observe the '?'):
INSERT INTO test VALUES('220500896?');
INSERT INTO test VALUES('978055215372?');

SELECT issn('3251231?');
SELECT ismn('979047213542?');

--Using the weak mode:
SELECT isn_weak(true);
INSERT INTO test VALUES('978-0-11-000533-4');
INSERT INTO test VALUES('9780141219307');
INSERT INTO test VALUES('2-205-00876-X');
SELECT isn_weak(false);

SELECT id FROM test WHERE NOT is_valid(id);
UPDATE test SET id = make_valid(id) WHERE id = '2-205-00876-X!';

SELECT * FROM test;
SELECT isbn13(id) FROM test;

F.21.5. Bibliography

The information to implement this module was collected from several sites, including:

- https://www.isbn-international.org/
- https://www.issn.org/
- https://www.ismn-international.org/
- https://www.wikipedia.org/

The prefixes used for hyphenation were also compiled from:

- https://www.gs1.org/standards/id-keys
- https://www.isbn-international.org/content/isbn-users-manual
- https://www.ismn-international.org/ranges.html

Care was taken during the creation of the algorithms and they were meticulously verified against the suggested algorithms in the official ISBN, ISMN, ISSN User Manuals.

F.21.6. Author

Germán Méndez Bravo (Kronuz), 2004–2006

This module was inspired by Garrett A. Wollman's isbn_issn code.
F.22. lo

The lo module provides support for managing Large Objects (also called LOs or BLOBs). This includes a data type lo and a trigger lo_manage.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.22.1. Rationale

One of the problems with the JDBC driver (and this affects the ODBC driver also), is that the specification assumes that references to BLOBs (Binary Large Objects) are stored within a table, and if that entry is changed, the associated BLOB is deleted from the database.

As PostgreSQL stands, this doesn't occur. Large objects are treated as objects in their own right; a table entry can reference a large object by OID, but there can be multiple table entries referencing the same large object OID, so the system doesn't delete the large object just because you change or remove one such entry.

Now this is fine for PostgreSQL-specific applications, but standard code using JDBC or ODBC won't delete the objects, resulting in orphan objects — objects that are not referenced by anything, and simply occupy disk space.

The lo module allows fixing this by attaching a trigger to tables that contain LO reference columns. The trigger essentially just does a lo_unlink whenever you delete or modify a value referencing a large object. When you use this trigger, you are assuming that there is only one database reference to any large object that is referenced in a trigger-controlled column!

The module also provides a data type lo, which is really just a domain over the oid type. This is useful for differentiating database columns that hold large object references from those that are OIDs of other things. You don't have to use the lo type to use the trigger, but it may be convenient to use it to keep track of which columns in your database represent large objects that you are managing with the trigger. It is also rumored that the ODBC driver gets confused if you don't use lo for BLOB columns.

F.22.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE image (title text, raster lo);

CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON image
    FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
```

For each column that will contain unique references to large objects, create a BEFORE UPDATE OR DELETE trigger, and give the column name as the sole trigger argument. You can also restrict the trigger to only execute on updates to the column by using BEFORE UPDATE OF column_name. If you need multiple lo columns in the same table, create a separate trigger for each one, remembering to give a different name to each trigger on the same table.

F.22.3. Limitations

- Dropping a table will still orphan any objects it contains, as the trigger is not executed. You can avoid this by preceding the DROP TABLE with DELETE FROM table.
TRUNCATE has the same hazard.

If you already have, or suspect you have, orphaned large objects, see the vacuumlo module to help you clean them up. It's a good idea to run vacuumlo occasionally as a back-stop to the lo_manage trigger.

- Some frontends may create their own tables, and will not create the associated trigger(s). Also, users may not remember (or know) to create the triggers.

F.22.4. Author

Peter Mount <peter@retep.org.uk>

F.23. ltree

This module implements a data type ltree for representing labels of data stored in a hierarchical tree-like structure. Extensive facilities for searching through label trees are provided.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.23.1. Definitions

A label is a sequence of alphanumeric characters and underscores (for example, in C locale the characters A-Za-z0-9_ are allowed). Labels must be less than 256 characters long.

Examples: 42, Personal_Services

A label path is a sequence of zero or more labels separated by dots, for example L1.L2.L3, representing a path from the root of a hierarchical tree to a particular node. The length of a label path cannot exceed 65535 labels.

Example: Top.Countries.Europe.Russia

The ltree module provides several data types:

- ltree stores a label path.

- lquery represents a regular-expression-like pattern for matching ltree values. A simple word matches that label within a path. A star symbol (*) matches zero or more labels. These can be joined with dots to form a pattern that must match the whole label path. For example:

  foo
  *.foo.*   Match the exact label path foo
  *.foo    Match any label path containing the label foo

Both star symbols and simple words can be quantified to restrict how many labels they can match:

  *(n)     Match exactly n labels
  *(n,}    Match at least n labels
  *(n,m)   Match at least n but not more than m labels
  *(,m}    Match at most m labels — same as *(0,m)
Additional Supplied Modules

foo\{n,m\}  Match at least \(n\) but not more than \(m\) occurrences of foo
foo\{,\}    Match any number of occurrences of foo, including zero

In the absence of any explicit quantifier, the default for a star symbol is to match any number of labels
(that is, \(\{,\}\)) while the default for a non-star item is to match exactly once (that is, \(\{1\}\)).

There are several modifiers that can be put at the end of a non-star \(lquery\) item to make it match more
than just the exact match:

@  Match case-insensitively, for example a@ matches A
*
matches foobar
%
Match initial underscore-separated words

The behavior of % is a bit complicated. It tries to match words rather than the entire label. For example
foo_bar% matches foo_bar_baz but not foo_barbaz. If combined with *, prefix matching applies to each word separately, for example foo_bar%* matches fool_bar2_baz but not fool_br2_baz.

Also, you can write several possibly-modified non-star items separated with | (OR) to match any of
those items, and you can put ! (NOT) at the start of a non-star group to match any label that doesn't
match any of the alternatives. A quantifier, if any, goes at the end of the group; it means some number
of matches for the group as a whole (that is, some number of labels matching or not matching any of
the alternatives).

Here's an annotated example of \(lquery\):

\[
Top.*\{0,2\}.sport*@.!football|tennis\{1,\}.Russ*|Spain
\]

This query will match any label path that:

a. begins with the label \(Top\)
b. and next has zero to two labels before
c. a label beginning with the case-insensitive prefix \(sport\)
d. then has one or more labels, none of which match \(football\) nor \(tennis\)
e. and then ends with a label beginning with \(Russ\) or exactly matching \(Spain\).

• \(ltxtquery\) represents a full-text-search-like pattern for matching \(ltree\) values. An \(ltxtquery\)
value contains words, possibly with the modifiers @, *, % at the end; the modifiers have the same mean-
ings as in \(lquery\). Words can be combined with & (AND), | (OR), ! (NOT), and parentheses. The key
difference from \(lquery\) is that \(ltxtquery\) matches words without regard to their position in the
label path.

Here's an example \(ltxtquery\):

Europe & Russia*@ & !Transportation

This will match paths that contain the label Europe and any label beginning with Russia (case-
sensitive), but not paths containing the label Transportation. The location of these words within
the path is not important. Also, when % is used, the word can be matched to any underscore-separated word within a label, regardless of position.

Note: ltxtquery allows whitespace between symbols, but ltree and lquery do not.

**F.23.2. Operators and Functions**

Type ltree has the usual comparison operators =, <>, <, >, <=, >=. Comparison sorts in the order of a tree traversal, with the children of a node sorted by label text. In addition, the specialized operators shown in Table F.13 are available.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ltree @&gt; ltree → boolean</td>
<td>Is left argument an ancestor of right (or equal)?</td>
</tr>
<tr>

<td>Does ltree match lquery?</td>
</tr>
<tr>
<td>ltree ? lquery[] → boolean</td>
<td>Does ltree match any lquery in array?</td>
</tr>
<tr>
<td>ltree[] @&gt; ltree → boolean</td>
<td>Does array contain an ancestor of ltree?</td>
</tr>
<tr>
<td>ltree &lt;@ ltree[] → boolean</td>
<td>Does array contain an ancestor of ltree?</td>
</tr>
<tr>
<td>ltree[] &lt;@ ltree → boolean</td>
<td>Does array contain a descendant of ltree?</td>
</tr>
<tr>
<td>ltree[] @&gt; ltree[] → boolean</td>
<td>Does array contain a descendant of ltree?</td>
</tr>
<tr>
<td>ltree[] ~ lquery → boolean</td>
<td>Does array contain any path matching lquery?</td>
</tr>
<tr>
<td>lquery[] ? ltree[] → boolean</td>
<td>Does array contain any path matching lquery?</td>
</tr>
<tr>
<td>lquery[] ? ltree[] → boolean</td>
<td>Does array contain any path matching lquery?</td>
</tr>
</tbody>
</table>
### Additional Supplied Modules

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\text{lquery} , \text{array} , \text{contain} , \text{any} , \text{path} , \text{matching} , \text{any} , \text{lquery}$?</td>
<td>Does $\text{lquery}$ array contain any path matching any $\text{lquery}$?</td>
</tr>
<tr>
<td>$\text{lquery} @ \text{ltxtquery} \rightarrow \text{boolean}$</td>
<td>$\text{ltree}[] , @ \text{ltxtquery} \rightarrow \text{boolean}$ Does array contain any path matching $\text{ltxtquery}$?</td>
</tr>
<tr>
<td>$\text{lquery} ?@&gt; \text{ltree} \rightarrow \text{ltree}$</td>
<td>Returns first array entry that is an ancestor of $\text{ltree}$, or NULL if none.</td>
</tr>
<tr>
<td>$\text{lquery} ?&lt;@ \text{ltree} \rightarrow \text{ltree}$</td>
<td>Returns first array entry that is a descendant of $\text{ltree}$, or NULL if none.</td>
</tr>
<tr>
<td>$\text{lquery} ?~ \text{lquery} \rightarrow \text{ltree}$</td>
<td>Returns first array entry that matches $\text{lquery}$, or NULL if none.</td>
</tr>
<tr>
<td>$\text{lquery} ?@ \text{ltxtquery} \rightarrow \text{ltree}$</td>
<td>Returns first array entry that matches $\text{ltxtquery}$, or NULL if none.</td>
</tr>
</tbody>
</table>

The operators $\langle@, @>, @$ and $\sim$ have analogues $\wedge@, \wedge@>, \wedge@, \sim$, which are the same except they do not use indexes. These are useful only for testing purposes.

The available functions are shown in Table F.14.

### Table F.14. ltree Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Example(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>subltree ($\text{ltree}, \text{start integer}, \text{end integer} ) \rightarrow \text{ltree}$</td>
<td>Returns subpath of $\text{ltree}$ from position $\text{start}$ to position $\text{end}-1$ (counting from 0).</td>
<td>$\text{subltree('Top.Child1.Child2', 1, 2)} \rightarrow \text{Child1}$</td>
</tr>
<tr>
<td>subpath ($\text{ltree}, \text{offset integer}, \text{len integer} ) \rightarrow \text{ltree}$</td>
<td>Returns subpath of $\text{ltree}$ starting at position $\text{offset}$, with length $\text{len}$. If $\text{offset}$ is negative, subpath starts that far from the end of the path. If $\text{len}$ is negative, leaves that many labels off the end of the path.</td>
<td>$\text{subpath('Top.Child1.Child2', 0, 2)} \rightarrow \text{Top.Child1}$</td>
</tr>
<tr>
<td>subpath ($\text{ltree}, \text{offset integer} ) \rightarrow \text{ltree}$</td>
<td>Returns subpath of $\text{ltree}$ starting at position $\text{offset}$, extending to end of path. If $\text{offset}$ is negative, subpath starts that far from the end of the path.</td>
<td>$\text{subpath('Top.Child1.Child2', 1)} \rightarrow \text{Child1.Child2}$</td>
</tr>
<tr>
<td>nlevel ($\text{ltree}$) $\rightarrow$ integer</td>
<td>Returns number of labels in path.</td>
<td>$\text{nlevel('Top.Child1.Child2')} \rightarrow 3$</td>
</tr>
<tr>
<td>index ($\text{a ltree}, \text{b ltree} ) \rightarrow$ integer</td>
<td>Returns position of first occurrence of $\text{b}$ in $\text{a}$, or -1 if not found.</td>
<td>$\text{index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6')} \rightarrow 6$</td>
</tr>
<tr>
<td>index ($\text{a ltree}, \text{b ltree}, \text{offset integer} ) \rightarrow$ integer</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

2824
### Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Example(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>text2ltree(text) → ltree</td>
<td>Casts text to ltree.</td>

<td>lca('1.2.3', '1.2.3.4.5.6') → 1.2</td>
</tr>
<tr>
<td>lca(ltree[]) → ltree</td>
<td>Computes longest common ancestor of paths in array.</td>
<td>lca(array['1.2.3':ltree,'1.2.3.4']) → 1.2</td>
</tr>
</tbody>
</table>

#### F.23.3. Indexes

`ltree` supports several types of indexes that can speed up the indicated operators:

- **B-tree index over `ltree`: `<, <=, =, >, >=**

- **GiST index over `ltree` (gist_ltree_ops opclass): `<, <=, =, >, @>, , @>, , ~, ?**

  `gist_ltree_ops` GiST opclass approximates a set of path labels as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 8 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

  Example of creating such an index with the default signature length of 8 bytes:

  ```sql
  CREATE INDEX path_gist_idx ON test USING GIST (path);
  ```

  Example of creating such an index with a signature length of 100 bytes:

  ```sql
  CREATE INDEX path_gist_idx ON test USING GIST (path
gist_ltree_ops(siglen=100));
  ```

- **GiST index over `ltree[]` (gist__ltree_ops opclass): `ltree[] <@ ltree, ltree @> ltree[], @, ~, ?**

  `gist__ltree_ops` GiST opclass works similarly to `gist_ltree_ops` and also takes signature length as a parameter. The default value of `siglen` in `gist__ltree_ops` is 28 bytes.

  Example of creating such an index with the default signature length of 28 bytes:
CREATE INDEX path_gist_idx ON test USING GIST (array_path);

Example of creating such an index with a signature length of 100 bytes:

```sql
CREATE INDEX path_gist_idx ON test USING GIST (array_path
gist__ltree_ops(siglen=100));
```

Note: This index type is lossy.

### F.23.4. Example

This example uses the following data (also available in file `contrib/ltree/ltreetest.sql` in the source distribution):

```sql
CREATE TABLE test (path ltree);
INSERT INTO test VALUES ('Top');
INSERT INTO test VALUES ('Top.Science');
INSERT INTO test VALUES ('Top.Science.Astronomy');
INSERT INTO test VALUES ('Top.Science.Astronomy.Astrophysics');
INSERT INTO test VALUES ('Top.Science.Astronomy.Cosmology');
INSERT INTO test VALUES ('Top.Hobbies');
INSERT INTO test VALUES ('Top.Hobbies.Amateurs_Astronomy');
INSERT INTO test VALUES ('Top.Collections');
INSERT INTO test VALUES ('Top.Collections.Pictures');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Astronauts');
CREATE INDEX path_gist_idx ON test USING GIST (path);
CREATE INDEX path_idx ON test USING BTREE (path);
```

Now, we have a table `test` populated with data describing the hierarchy shown below:

```
Top
  /  |  \  
Science Hobbies Collections
  /  |  \  
Astronomy Amateurs_Astronomy Pictures
  /  \  
Astrophysics Cosmology Astronomy
  /  \  
  \  Galaxies Stars Astronauts
```

We can do inheritance:

```sql
ltreetest=> SELECT path FROM test WHERE path @ 'Top.Science';
```

```
path
-----------------------
Top.Science
```

2826
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
(4 rows)

Here are some examples of path matching:

```
lreetest=> SELECT path FROM test WHERE path ~ '*.Astronomy.*';
   path
   -----------------------------------------------
     Top.Science.Astronomy
     Top.Science.Astronomy.Astrophysics
     Top.Collections.Pictures.Astronomy
   (7 rows)
```

```
lreetest=> SELECT path FROM test WHERE path ~ '*.!pictures@.Astronomy.*';
   path
   ------------------------------------
     Top.Science.Astronomy
     Top.Science.Astronomy.Astrophysics
   (3 rows)
```

Here are some examples of full text search:

```
lreetest=> SELECT path FROM test WHERE path @ 'Astro*% & !pictures@';
   path
   ----------------------------------------
     Top.Science.Astronomy
     Top.Science.Astronomy.Astrophysics
     Top.Hobbies.Amateurs_Astronomy
   (4 rows)
```

```
lreetest=> SELECT path FROM test WHERE path @ 'Astro* & !pictures@';
   path
   ----------------------------------------
     Top.Science.Astronomy
     Top.Science.Astronomy.Astrophysics
   (3 rows)
```

Path construction using functions:

```
lreetest=> SELECT subpath(path,0,2)||'Space'||subpath(path,2) FROM test WHERE path <@ 'Top.Science.Astronomy';
   ?column?
```

2827
We could simplify this by creating an SQL function that inserts a label at a specified position in a path:

```sql
CREATE FUNCTION ins_label(ltree, int, text) RETURNS ltree
AS 'select subpath($1,0,$2) || $3 || subpath($1,$2);'
LANGUAGE SQL IMMUTABLE;
```

```sql
ltreetest=> SELECT ins_label(path,2,'Space') FROM test WHERE path <@ 'Top.Science.Astronomy';
```

---

**F.23.5. Transforms**

The `ltree_plpython3u` extension implements transforms for the `ltree` type for PL/Python. If installed and specified when creating a function, `ltree` values are mapped to Python lists. (The reverse is currently not supported, however.)

**Caution**

It is strongly recommended that the transform extension be installed in the same schema as `ltree`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

**F.23.6. Authors**

All work was done by Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See http://www.sai.msu.su/~megera/postgres/gist/ for additional information. Authors would like to thank Eugeny Rodichev for helpful discussions. Comments and bug reports are welcome.

**F.24. old_snapshot**

The `old_snapshot` module allows inspection of the server state that is used to implement `old_snapshot_threshold`.

**F.24.1. Functions**

```sql
pg_old_snapshot_time_mapping(array_offset OUT int4, end_timestamp OUT timestamptz, newest_xmin OUT xid) returns setof record
```

Returns all of the entries in the server's timestamp to XID mapping. Each entry represents the newest xmin of any snapshot taken in the corresponding minute.
F.25. pageinspect

The `pageinspect` module provides functions that allow you to inspect the contents of database pages at a low level, which is useful for debugging purposes. All of these functions may be used only by superusers.

F.25.1. General Functions

`get_raw_page` reads the specified block of the named relation and returns a copy as a bytea value. This allows a single time-consistent copy of the block to be obtained. `fork` should be 'main' for the main data fork, 'fsm' for the free space map, 'vm' for the visibility map, or 'init' for the initialization fork.

A shorthand version of `get_raw_page`, for reading from the main fork. Equivalent to `get_raw_page` with `fork = 'main'`.

`page_header` shows fields that are common to all PostgreSQL heap and index pages. A page image obtained with `get_raw_page` should be passed as argument. For example:

```
SELECT * FROM page_header(get_raw_page('pg_class', 0));
```

The returned columns correspond to the fields in the `PageHeaderData` struct. See `src/include/storage/bufpage.h` for details.

The `checksum` field is the checksum stored in the page, which might be incorrect if the page is somehow corrupted. If data checksums are not enabled for this instance, then the value stored is meaningless.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
SELECT page_checksum(get_raw_page('pg_class', 0), 0);
```

Note that the checksum depends on the block number, so matching block numbers should be passed (except when doing esoteric debugging).
The checksum computed with this function can be compared with the `checksum` result field of the function `page_header`. If data checksums are enabled for this instance, then the two values should be equal.

```sql
fsm_page_contents(page bytea) returns text
```

`fsm_page_contents` shows the internal node structure of an FSM page. For example:

```sql
test=# SELECT fsm_page_contents(get_raw_page('pg_class', 'fsm', 0));
```

The output is a multiline string, with one line per node in the binary tree within the page. Only those nodes that are not zero are printed. The so-called "next" pointer, which points to the next slot to be returned from the page, is also printed.

See `src/backend/storage/freespace/README` for more information on the structure of an FSM page.

F.25.2. Heap Functions

```sql
heap_page_items(page bytea) returns setof record
```

`heap_page_items` shows all line pointers on a heap page. For those line pointers that are in use, tuple headers as well as tuple raw data are also shown. All tuples are shown, whether or not the tuples were visible to an MVCC snapshot at the time the raw page was copied.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```sql
test=# SELECT * FROM heap_page_items(get_raw_page('pg_class', 0));
```

See `src/include/storage/itemid.h` and `src/include/access/htup_details.h` for explanations of the fields returned.

The `heap_tuple_infomask_flags` function can be used to unpack the flag bits of `t_info_mask` and `t_infomask2` for heap tuples.

```sql
tuple_data_split(rel_oid oid, t_data bytea, t_infomask integer, t_infomask2 integer, t_bits text [, do_detoast bool]) returns bytea[]
```

`tuple_data_split` splits tuple data into attributes in the same way as backend internals.

```sql
test=# SELECT tuple_data_split('pg_class'::regclass, t_data, t_infomask, t_infomask2, t_bits) FROM heap_page_items(get_raw_page('pg_class', 0));
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

If `do_detoast` is true, attributes will be detoasted as needed. Default value is false.

```sql
heap_page_item_attrs(page bytea, rel_oid regclass [, do_detoast bool]) returns setof record
```

`heap_page_item_attrs` is equivalent to `heap_page_items` except that it returns tuple raw data as an array of attributes that can optionally be detoasted by `do_detoast` which is false by default.
A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_item_attrs(get_raw_page('pg_class', 0), 'pg_class'::regclass);
```

`heap_tuple_infomask_flags(t_infomask integer, t_infomask2 integer) returns record`

`heap_tuple_infomask_flags` decodes the `t_infomask` and `t_infomask2` returned by `heap_page_items` into a human-readable set of arrays made of flag names, with one column for all the flags and one column for combined flags. For example:

```
test=# SELECT t_ctid, raw_flags, combined_flags
    FROM heap_page_items(get_raw_page('pg_class', 0)),
    LATERAL heap_tuple_infomask_flags(t_infomask, t_infomask2)
    WHERE t_infomask IS NOT NULL OR t_infomask2 IS NOT NULL;
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

Combined flags are displayed for source-level macros that take into account the value of more than one raw bit, such as `HEAP_XMIN_FROZEN`.

See `src/include/access/htup_details.h` for explanations of the flag names returned.

### F.25.3. B-Tree Functions

`bt_metap(relname text) returns record`

`bt_metap` returns information about a B-tree index's metapage. For example:

```
test=# SELECT * FROM bt_metap('pg_cast_oid_index');
- [ RECORD 1 ]---------------------
magic      | 340322
version    | 4
root       | 1
level      | 0
fastroot   | 1
fastlevel  | 0
last_cleanup_num_delpages | 0
last_cleanup_num_tuples   | 230
allequalimage | f
```

`bt_page_stats(relname text, blkno bigint) returns record`

`bt_page_stats` returns summary information about single pages of B-tree indexes. For example:

```
test=# SELECT * FROM bt_page_stats('pg_cast_oid_index', 1);
- [ RECORD 1 ]---------
```

2831
bt_page_items returns detailed information about all of the items on a B-tree index page. For example:

```sql
test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, tids[0:2] AS some_tids
FROM bt_page_items('tenk2_hundred', 5);
```

<table>
<thead>
<tr>
<th>itemoffset</th>
<th>ctid</th>
<th>itemlen</th>
<th>nulls</th>
<th>vars</th>
<th>data</th>
<th>dead</th>
<th>htid</th>
<th>some_tids</th>
</tr>
</thead>

</table>

(13 rows)

This is a B-tree leaf page. All tuples that point to the table happen to be posting list tuples (all of which store a total of 100 6 byte TIDs). There is also a “high key” tuple at itemoffset number 1. ctid
is used to store encoded information about each tuple in this example, though leaf page tuples often store a heap TID directly in the ctid field instead. tids is the list of TIDs stored as a posting list.

In an internal page (not shown), the block number part of ctid is a "downlink", which is a block number of another page in the index itself. The offset part (the second number) of ctid stores encoded information about the tuple, such as the number of columns present (suffix truncation may have removed unneeded suffix columns). Truncated columns are treated as having the value "minus infinity".

htid shows a heap TID for the tuple, regardless of the underlying tuple representation. This value may match ctid, or may be decoded from the alternative representations used by posting list tuples and tuples from internal pages. Tuples in internal pages usually have the implementation level heap TID column truncated away, which is represented as a NULL htid value.

Note that the first item on any non-rightmost page (any page with a non-zero value in the btpe_next field) is the page's "high key", meaning its data serves as an upper bound on all items appearing on the page, while its ctid field does not point to another block. Also, on internal pages, the first real data item (the first item that is not a high key) reliably has every column truncated away, leaving no actual value in its data field. Such an item does have a valid downlink in its ctid field, however.

For more details about the structure of B-tree indexes, see Section 66.4.1. For more details about deduplication and posting lists, see Section 66.4.3.

bt_page_items (page bytea) returns setof record

It is also possible to pass a page to bt_page_items as a bytea value. A page image obtained with get_raw_page should be passed as argument. So the last example could also be rewritten like this:

test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, tids[0:2] AS some_tids
FROM bt_page_items(get_raw_page('tenk2_hundred', 5));

| itemoffset | ctid    | itemlen | nulls | vars |          data | dead | htid  | some_tids  |
|------------+---------+---------+-------+------|----------|------+--------+-----------|
| 1          | (16,1)  | 16      | f     | f    | 30 00 00 00 00| 1    |        |            |
| 2          | (16,8292)| 616     | f     | f    | 24 00 00 00 00| 2    | (1,6)  | "(1,6)","(10,22)" |
| 3          | (16,8292)| 616     | f     | f    | 25 00 00 00 00| 3    | (1,18) | "(1,18)","(4,22)" |
| 4          | (16,8292)| 616     | f     | f    | 26 00 00 00 00| 4    | (1,18) | "(1,18)","(4,22)" |
| 5          | (16,8292)| 616     | f     | f    | 27 00 00 00 00| 5    | (1,2)  | "(1,2)","(1,19)" |
| 6          | (16,8292)| 616     | f     | f    | 28 00 00 00 00| 6    | (2,24) | "(2,24)","(4,11)" |
| 7          | (16,8292)| 616     | f     | f    | 29 00 00 00 00| 7    | (2,24) | "(2,24)","(4,11)" |
| 8          | (16,8292)| 616     | f     | f    | 2a 00 00 00 00| 8    | (2,17) | "(2,17)","(11,2)" |
| 9          | (16,8292)| 616     | f     | f    | 2b 00 00 00 00| 9    | (0,25) | "(0,25)","(3,20)" |
| 10         | (16,8292)| 616     | f     | f    | 2c 00 00 00 00| 10   | (0,10) | "(0,10)","(0,14)" |
| 11         | (16,8292)| 616     | f     | f    |            | 11   | (1,3)  | "(1,3)","(3,9)"   |
F.25.4. BRIN Functions

**brin_page_type**(page bytea) returns text

`brin_page_type` returns the page type of the given BRIN index page, or throws an error if the page is not a valid BRIN page. For example:

```sql
TEST=# SELECT brin_page_type(get_raw_page('brinidx', 0));

<table>
<thead>
<tr>
<th>brin_page_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>meta</td>
</tr>
</tbody>
</table>
```

**brin_metapage_info**(page bytea) returns record

`brin_metapage_info` returns assorted information about a BRIN index metapage. For example:

```sql
TEST=# SELECT * FROM brin_metapage_info(get_raw_page('brinidx', 0));

<table>
<thead>
<tr>
<th>magic</th>
<th>version</th>
<th>pagesperrange</th>
<th>lastrevmappage</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xA8109CFA</td>
<td>1</td>
<td>4</td>
<td>2</td>
</tr>
</tbody>
</table>
```

**brin_revmap_data**(page bytea) returns setof tid

`brin_revmap_data` returns the list of tuple identifiers in a BRIN index range map page. For example:

```sql
TEST=# SELECT * FROM brin_revmap_data(get_raw_page('brinidx', 2))

<table>
<thead>
<tr>
<th>pages</th>
</tr>
</thead>
<tbody>
<tr>
<td>(6,137)</td>
</tr>
<tr>
<td>(6,138)</td>
</tr>
<tr>
<td>(6,139)</td>
</tr>
<tr>
<td>(6,140)</td>
</tr>
<tr>
<td>(6,141)</td>
</tr>
</tbody>
</table>
```

**brin_page_items**(page bytea, index oid) returns setof record

`brin_page_items` returns the data stored in the BRIN data page. For example:

```sql
TEST=# SELECT * FROM brin_page_items(get_raw_page('brinidx', 5), 'brinidx')
```
ORDER BY blknum, attnum LIMIT 6;

<table>
<thead>
<tr>
<th>itemoffset</th>
<th>blknum</th>
<th>attnum</th>
<th>allnulls</th>
<th>hasnulls</th>
<th>placeholder</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>{1 .. 88}</td>
<td>137</td>
<td>0</td>
<td>1</td>
<td>t</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td></td>
<td>137</td>
<td>0</td>
<td>2</td>
<td>f</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td></td>
<td>138</td>
<td>4</td>
<td>1</td>
<td>t</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td></td>
<td>138</td>
<td>4</td>
<td>2</td>
<td>f</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td></td>
<td>139</td>
<td>8</td>
<td>1</td>
<td>t</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td></td>
<td>139</td>
<td>8</td>
<td>2</td>
<td>f</td>
<td>f</td>
<td>f</td>
</tr>
</tbody>
</table>

The returned columns correspond to the fields in the BrinMemTuple and BrinValues structs. See src/include/access/brin_tuple.h for details.

**F.25.5. GIN Functions**

**gin_metapage_info(page bytea) returns record**

 gin_metapage_info returns information about a GIN index metapage. For example:

```sql
test=# SELECT * FROM gin_metapage_info(get_raw_page('gin_index', 0));
- [ RECORD 1 ]-------
pending_head | 4294967295
pending_tail  | 4294967295
tail_free_size| 0
n_pending_pages| 0
n_pending_tuples| 0
n_total_pages | 7
n_entry_pages | 6
n_data_pages  | 0
n_entries     | 693
version       | 2
```

**gin_page_opaque_info(page bytea) returns record**

 gin_page_opaque_info returns information about a GIN index opaque area, like the page type. For example:

```sql
test=# SELECT * FROM gin_page_opaque_info(get_raw_page('gin_index', 2));
rightlink | maxoff | flags
----------+--------+------------------------
5         | 0      | {data,leaf,compressed} (1 row)
```

**gin_leafpage_items(page bytea) returns setof record**

 gin_leafpage_items returns information about the data stored in a GIN leaf page. For example:
### F.25.6. GiST Functions

**gist_page_opaque_info(page bytea) returns record**

`gist_page_opaque_info` returns information from a GiST index page's opaque area, such as the NSN, rightlink and page type. For example:

```sql
test=# SELECT * FROM gist_page_opaque_info(get_raw_page('test_gist_idx', 2));

<table>
<thead>
<tr>
<th>lsn</th>
<th>nsn</th>
<th>rightlink</th>
<th>flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>0/1</td>
<td>0/0</td>
<td>1</td>
<td>{leaf}</td>
</tr>
</tbody>
</table>

(1 row)
```

**gist_page_items(page bytea, index_oid regclass) returns setof record**

`gist_page_items` returns information about the data stored in a page of a GiST index. For example:

```sql
test=# SELECT * FROM gist_page_items(get_raw_page('test_gist_idx', 0), 'test_gist_idx');

<table>
<thead>
<tr>
<th>itemoffset</th>
<th>ctid</th>
<th>itemlen</th>
<th>dead</th>
<th>keys</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>(1,65535)</td>
<td>40</td>
<td>f</td>
<td>(p)=((166,166))</td>
</tr>
<tr>
<td>2</td>
<td>(2,65535)</td>
<td>40</td>
<td>f</td>
<td>(p)=((332,332))</td>
</tr>
<tr>
<td>3</td>
<td>(3,65535)</td>
<td>40</td>
<td>f</td>
<td>(p)=((498,498))</td>
</tr>
<tr>
<td>4</td>
<td>(4,65535)</td>
<td>40</td>
<td>f</td>
<td>(p)=((664,664))</td>
</tr>
<tr>
<td>5</td>
<td>(5,65535)</td>
<td>40</td>
<td>f</td>
<td>(p)=((830,830))</td>
</tr>
<tr>
<td>6</td>
<td>(6,65535)</td>
<td>40</td>
<td>f</td>
<td>(p)=((996,996))</td>
</tr>
<tr>
<td>7</td>
<td>(7,65535)</td>
<td>40</td>
<td>f</td>
<td>(p)=((1000,1000))</td>
</tr>
</tbody>
</table>

(7 rows)
```
gist_page_items_bytea(page bytea) returns setof record

Same as gist_page_items, but returns the key data as a raw bytea blob. Since it does not attempt to decode the key, it does not need to know which index is involved. For example:

test=# SELECT * FROM gist_page_items_bytea(get_raw_page('test_gist_idx', 0));

<table>
<thead>
<tr>
<th>itemoffset</th>
<th>ctid</th>
<th>itemlen</th>
<th>dead</th>
<th>key_data</th>
</tr>
</thead>
<tbody>
<tr>
<td>+-----------------------------------------</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>(1,65535)</td>
<td>40</td>
<td>f</td>
<td>00000100ffff28000000000000c064400000000f03f000000000000f03f</td>
</tr>
<tr>
<td>2</td>
<td>(2,65535)</td>
<td>40</td>
<td>f</td>
<td>00000200ffff28000000000000c074400000000e064400000000000e06440</td>
</tr>
<tr>
<td>3</td>
<td>(3,65535)</td>
<td>40</td>
<td>f</td>
<td>00000300ffff280000000000000207f4000000000d07440000000000d07440</td>
</tr>
<tr>
<td>4</td>
<td>(4,65535)</td>
<td>40</td>
<td>f</td>
<td>00000400ffff28000000000000c0844000000000c0844000000000c88440</td>
</tr>
<tr>
<td>5</td>
<td>(5,65535)</td>
<td>40</td>
<td>f</td>
<td>00000500ffff280000000000000f089400000000f089400000000c88440</td>
</tr>
<tr>
<td>6</td>
<td>(6,65535)</td>
<td>40</td>

</tr>
</tbody>
</table>

(7 rows)

F.25.7. Hash Functions

hash_page_type(page bytea) returns text

hash_page_type returns page type of the given HASH index page. For example:

test=# SELECT hash_page_type(get_raw_page('con_hash_index', 0));

<table>
<thead>
<tr>
<th>hash_page_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>metapage</td>
</tr>
</tbody>
</table>

hash_page_stats(page bytea) returns setof record

hash_page_stats returns information about a bucket or overflow page of a HASH index. For example:
Additional Supplied Modules

```
test=# SELECT * FROM hash_page_stats(get_raw_page('con_hash_index', 1));
- [ RECORD 1 ]-----------------------
 live_items | 407
 dead_items | 0
 page_size  | 8192
 free_size  | 8
 hasho_prevblkno | 4096
 hasho_nextblkno | 8474
 hasho_bucket | 0
 hasho_flag  | 66
 hasho_page_id | 65408

hash_page_items(page bytea) returns setof record

hash_page_items returns information about the data stored in a bucket or overflow page of a HASH index page. For example:

```
test=# SELECT * FROM hash_page_items(get_raw_page('con_hash_index', 1)) LIMIT 5;
itemoffset |   ctid    |    data
------------+-----------+------------
 1 | (899,77)  | 1053474816
 2 | (897,29)  | 1053474816
 3 | (894,207) | 1053474816
 4 | (892,159) | 1053474816
 5 | (890,111) | 1053474816
```

hash_bitmap_info(index oid, blkno bigint) returns record

hash_bitmap_info shows the status of a bit in the bitmap page for a particular overflow page of HASH index. For example:

```
test=# SELECT * FROM hash_bitmap_info('con_hash_index', 2052);
bitmapblkno | bitmapbit | bitstatus
-------------+-----------+-----------
  65 |         3 | t
```

hash_metapage_info(page bytea) returns record

hash_metapage_info returns information stored in the meta page of a HASH index. For example:

```
test=# SELECT magic, version, ntuples, ffactor, bsize, bmsize, bmshift,
test-#     maxbucket, highmask, lowmask, ovflpoint, firstfree,
test-#     nmaps, procid,
test-#     regexp_replace(spares::text, '(,0)*}', '}') as spares,
test-#     regexp_replace(mapp::text, '(,0)*}', '}') as mapp
test-# FROM hash_metapage_info(get_raw_page('con_hash_index', 0));
- [ RECORD 1 ]------------------------------------------
 magic | 105121344
```

2838
version | 4
ntuples | 500500
ffactor | 40
bsize   | 8152
bmsize  | 4096
bmshift | 15
maxbucket | 12512
highmask | 16383
lowmask  | 8191
ovflpoint | 28
firstfree | 1204
nmaps   | 1
procid  | 450
spares  | {0,0,0,0,0,0,1,1,1,1,1,1,1,3,4,4,4,45,55,58,59,508,567,628,704,1193,1202,1204}
mapp    | {65}

F.26. passwordcheck

The passwordcheck module checks users' passwords whenever they are set with CREATE ROLE or ALTER ROLE. If a password is considered too weak, it will be rejected and the command will terminate with an error.

To enable this module, add '$libdir/passwordcheck' to shared_preload_libraries in postgresql.conf, then restart the server.

You can adapt this module to your needs by changing the source code. For example, you can use CrackLib\(^2\) to check passwords — this only requires uncommenting two lines in the Makefile and rebuilding the module. (We cannot include CrackLib by default for license reasons.) Without CrackLib, the module enforces a few simple rules for password strength, which you can modify or extend as you see fit.

<table>
<thead>
<tr>
<th>Caution</th>
</tr>
</thead>
<tbody>
<tr>
<td>To prevent unencrypted passwords from being sent across the network, written to the server log or otherwise stolen by a database administrator, PostgreSQL allows the user to supply pre-encrypted passwords. Many client programs make use of this functionality and encrypt the password before sending it to the server.</td>
</tr>
<tr>
<td>This limits the usefulness of the passwordcheck module, because in that case it can only try to guess the password. For this reason, passwordcheck is not recommended if your security requirements are high. It is more secure to use an external authentication method such as GSSAPI (see Chapter 21) than to rely on passwords within the database.</td>
</tr>
<tr>
<td>Alternatively, you could modify passwordcheck to reject pre-encrypted passwords, but forcing users to set their passwords in clear text carries its own security risks.</td>
</tr>
</tbody>
</table>

F.27. pg_buffercache

The pg_buffercache module provides a means for examining what's happening in the shared buffer cache in real time.

\(^2\)https://github.com/cracklib/cracklib
The module provides a C function `pg_buffercache_pages` that returns a set of records, plus a view `pg_buffercache` that wraps the function for convenient use.

By default, use is restricted to superusers and roles with privileges of the `pg_monitor` role. Access may be granted to others using `GRANT`.

F.27.1. The pg_buffercache View

The definitions of the columns exposed by the view are shown in Table F.15.

Table F.15. pg_buffercache Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bufferid integer</td>
<td>ID, in the range 1..shared_buffers</td>
</tr>
<tr>
<td>relfilenode oid</td>
<td>Filenode number of the relation</td>
</tr>
<tr>
<td>reltablespace oid</td>
<td>Tablespace OID of the relation</td>
</tr>
<tr>
<td>reldatabase oid</td>
<td>Database OID of the relation</td>
</tr>
<tr>
<td>relforknumber</td>
<td>Fork number within the relation; see common/relpath.h</td>
</tr>
<tr>
<td>relblocknumber</td>
<td>Page number within the relation</td>
</tr>
<tr>
<td>isdirty boolean</td>
<td>Is the page dirty?</td>
</tr>
<tr>
<td>usagecount smallint</td>
<td>Clock-sweep access count</td>
</tr>
<tr>
<td>pinning_backends integer</td>
<td>Number of backends pinning this buffer</td>
</tr>
</tbody>
</table>

There is one row for each buffer in the shared cache. Unused buffers are shown with all fields null except `bufferid`. Shared system catalogs are shown as belonging to database zero.

Because the cache is shared by all the databases, there will normally be pages from relations not belonging to the current database. This means that there may not be matching join rows in `pg_class` for some rows, or that there could even be incorrect joins. If you are trying to join against `pg_class`, it's a good idea to restrict the join to rows having `reldatabase` equal to the current database's OID or zero.

Since buffer manager locks are not taken to copy the buffer state data that the view will display, accessing `pg_buffercache` view has less impact on normal buffer activity but it doesn't provide a consistent set of results across all buffers. However, we ensure that the information of each buffer is self-consistent.

F.27.2. Sample Output

```
regression=# SELECT n.nspname, c.relname, count(*) AS buffers
```
FROM pg_buffercache b JOIN pg_class c
ON b.relfilenode = pg_relation_filenode(c.oid) AND
  b.reldatabase IN (0, (SELECT oid FROM pg_database
    WHERE datname = current_database()))
JOIN pg_namespace n ON n.oid = c.relnamespace
GROUP BY n.nspname, c.relname
ORDER BY 3 DESC
LIMIT 10;

Mark Kirkwood <markir@paradise.net.nz>

Design suggestions: Neil Conway <neilc@samurai.com>

Debugging advice: Tom Lane <tgl@sss.pgh.pa.us>

F.28. pgcrypto

The pgcrypto module provides cryptographic functions for PostgreSQL.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

pgcrypto requires OpenSSL and won’t be installed if OpenSSL support was not selected when PostgreSQL was built.

F.28.1. General Hashing Functions

F.28.1.1. digest ()

digest(data text, type text) returns bytea
digest(data bytea, type text) returns bytea

Computes a binary hash of the given data. type is the algorithm to use. Standard algorithms are md5, sha1, sha224, sha256, sha384 and sha512. Moreover, any digest algorithm OpenSSL supports is automatically picked up.
If you want the digest as a hexadecimal string, use `encode()` on the result. For example:

```sql
CREATE OR REPLACE FUNCTION sha1(bytea) returns text AS $$
SELECT encode(digest($1, 'sha1'), 'hex')$$ LANGUAGE SQL STRICT IMmutABLE;
```

**F.28.1.2. hmac()**

```sql
hmac(data text, key text, type text) returns bytea
hmac(data bytea, key bytea, type text) returns bytea
```

Calculates hashed MAC for `data` with key `key`. `type` is the same as in `digest()`.

This is similar to `digest()` but the hash can only be recalculated knowing the key. This prevents the scenario of someone altering data and also changing the hash to match.

If the key is larger than the hash block size it will first be hashed and the result will be used as key.

**F.28.2. Password Hashing Functions**

The functions `crypt()` and `gen_salt()` are specifically designed for hashing passwords. `crypt()` does the hashing and `gen_salt()` prepares algorithm parameters for it.

The algorithms in `crypt()` differ from the usual MD5 or SHA1 hashing algorithms in the following respects:

1. They are slow. As the amount of data is so small, this is the only way to make brute-forcing passwords hard.
2. They use a random value, called the `salt`, so that users having the same password will have different encrypted passwords. This is also an additional defense against reversing the algorithm.
3. They include the algorithm type in the result, so passwords hashed with different algorithms can co-exist.
4. Some of them are adaptive — that means when computers get faster, you can tune the algorithm to be slower, without introducing incompatibility with existing passwords.

Table F.16 lists the algorithms supported by the `crypt()` function.

**Table F.16. Supported Algorithms for crypt()**

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Max Password Length</th>
<th>Adaptive?</th>
<th>Salt Bits</th>
<th>Output Length</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bf</td>
<td>72</td>
<td>yes</td>
<td>128</td>
<td>60</td>
<td>Blowfish-based, variant 2a</td>
</tr>
<tr>
<td>md5</td>
<td>unlimited</td>
<td>no</td>
<td>48</td>

</tr>
<tr>
<td>des</td>
<td>8</td>
<td>no</td>
<td>12</td>
<td>13</td>
<td>Original UNIX crypt</td>
</tr>
</tbody>
</table>
F.28.2.1. `crypt()`

`crypt(password text, salt text) returns text`

Calculates a crypt(3)-style hash of `password`. When storing a new password, you need to use `gen_salt()` to generate a new `salt` value. To check a password, pass the stored hash value as `salt`, and test whether the result matches the stored value.

Example of setting a new password:

```
UPDATE ... SET pswhash = crypt('new password', gen_salt('md5'));
```

Example of authentication:

```
SELECT (pswhash = crypt('entered password', pswhash)) AS pswmatch
FROM ...;
```

This returns `true` if the entered password is correct.

F.28.2.2. `gen_salt()`

`gen_salt(type text [, iter_count integer ]) returns text`

Generates a new random salt string for use in `crypt()`. The salt string also tells `crypt()` which algorithm to use.

The `type` parameter specifies the hashing algorithm. The accepted types are: `des`, `xdes`, `md5` and `bf`.

The `iter_count` parameter lets the user specify the iteration count, for algorithms that have one. The higher the count, the more time it takes to hash the password and therefore the more time to break it. Although with too high a count the time to calculate a hash may be several years — which is somewhat impractical. If the `iter_count` parameter is omitted, the default iteration count is used. Allowed values for `iter_count` depend on the algorithm and are shown in Table F.17.

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Default</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>xdes</td>
<td>725</td>
<td>1</td>
<td>16777215</td>
</tr>
<tr>
<td>bf</td>
<td>6</td>
<td>4</td>
<td>31</td>
</tr>
</tbody>
</table>

For `xdes` there is an additional limitation that the iteration count must be an odd number.

To pick an appropriate iteration count, consider that the original DES crypt was designed to have the speed of 4 hashes per second on the hardware of that time. Slower than 4 hashes per second would probably dampen usability. Faster than 100 hashes per second is probably too fast.

Table F.18 gives an overview of the relative slowness of different hashing algorithms. The table shows how much time it would take to try all combinations of characters in an 8-character password, assuming that the password contains either only lower case letters, or upper- and lower-case letters and numbers. In the `crypt-bf` entries, the number after a slash is the `iter_count` parameter of `gen_salt`.

</tbody>
</table>

Notes:

- The machine used is an Intel Mobile Core i3.
- crypt-des and crypt-md5 algorithm numbers are taken from John the Ripper v1.6.38 -test output.
- md5 hash numbers are from mdcrack 1.2.
- sha1 numbers are from lcrack-20031130-beta.
- crypt-bf numbers are taken using a simple program that loops over 1000 8-character passwords. That way I can show the speed with different numbers of iterations. For reference, john -test shows 13506 loops/sec for crypt-bf/5. (The very small difference in results is in accordance with the fact that the crypt-bf implementation in pgcrypto is the same one used in John the Ripper.)

Note that “try all combinations” is not a realistic exercise. Usually password cracking is done with the help of dictionaries, which contain both regular words and various mutations of them. So, even somewhat word-like passwords could be cracked much faster than the above numbers suggest, while a 6-character non-word-like password may escape cracking. Or not.

F.28.3. PGP Encryption Functions

The functions here implement the encryption part of the OpenPGP (RFC 4880) standard. Supported are both symmetric-key and public-key encryption.

An encrypted PGP message consists of 2 parts, or packets:

- Packet containing a session key — either symmetric-key or public-key encrypted.
- Packet containing data encrypted with the session key.

When encrypting with a symmetric key (i.e., a password):

1. The given password is hashed using a String2Key (S2K) algorithm. This is rather similar to crypt() algorithms — purposefully slow and with random salt — but it produces a full-length binary key.

2. If a separate session key is requested, a new random key will be generated. Otherwise the S2K key will be used directly as the session key.

---

3. If the S2K key is to be used directly, then only S2K settings will be put into the session key packet. Otherwise the session key will be encrypted with the S2K key and put into the session key packet.

When encrypting with a public key:

1. A new random session key is generated.
2. It is encrypted using the public key and put into the session key packet.

In either case the data to be encrypted is processed as follows:

1. Optional data-manipulation: compression, conversion to UTF-8, and/or conversion of line-endings.
2. The data is prefixed with a block of random bytes. This is equivalent to using a random IV.
3. A SHA1 hash of the random prefix and data is appended.
4. All this is encrypted with the session key and placed in the data packet.

**F.28.3.1. pgp_sym_encrypt ()**

```c
pgp_sym_encrypt(data text, psw text [, options text ]) returns bytea
pgp_sym_encrypt_bytea(data bytea, psw text [, options text ]) returns bytea
```

Encrypt `data` with a symmetric PGP key `psw`. The `options` parameter can contain option settings, as described below.

**F.28.3.2. pgp_sym_decrypt ()**

```c
pgp_sym_decrypt(msg bytea, psw text [, options text ]) returns text
pgp_sym_decrypt_bytea(msg bytea, psw text [, options text ]) returns bytea
```

Decrypt a symmetric-key-encrypted PGP message.

Decrypting `bytea` data with `pgp_sym_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_sym_decrypt_bytea` is fine.

The `options` parameter can contain option settings, as described below.

**F.28.3.3. pgp_pub_encrypt ()**

```c
pgp_pub_encrypt(data text, key bytea [, options text ]) returns bytea
pgp_pub_encrypt_bytea(data bytea, key bytea [, options text ]) returns bytea
```

Encrypt `data` with a public PGP key `key`. Giving this function a secret key will produce an error.

The `options` parameter can contain option settings, as described below.

**F.28.3.4. pgp_pub_decrypt ()**
pgp_pub_decrypt(msg bytea, key bytea [, psw text [, options text ]])
returns text

pgp_pub_decrypt_bytea(msg bytea, key bytea [, psw text [, options text ]]) returns bytea

Decrypt a public-key-encrypted message. key must be the secret key corresponding to the public key that was used to encrypt. If the secret key is password-protected, you must give the password in psw. If there is no password, but you want to specify options, you need to give an empty password.

Decrypting bytea data with pgp_pub_decrypt is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with pgp_pub_decrypt_bytea is fine.

The options parameter can contain option settings, as described below.

F.28.3.5. pgp_key_id()

pgp_key_id(bytea) returns text

pgp_key_id extracts the key ID of a PGP public or secret key. Or it gives the key ID that was used for encrypting the data, if given an encrypted message.

It can return 2 special key IDs:

- **SYMKEY**
  The message is encrypted with a symmetric key.

- **ANYKEY**
  The message is public-key encrypted, but the key ID has been removed. That means you will need to try all your secret keys on it to see which one decrypts it. pgcrypto itself does not produce such messages.

Note that different keys may have the same ID. This is rare but a normal event. The client application should then try to decrypt with each one, to see which fits — like handling ANYKEY.

F.28.3.6. armor(), dearmor()

armor(data bytea [, keys text[], values text[]]) returns text
dearmarmor(data text) returns bytea

These functions wrap/unwrap binary data into PGP ASCII-armor format, which is basically Base64 with CRC and additional formatting.

If the keys and values arrays are specified, an armor header is added to the armored format for each key/value pair. Both arrays must be single-dimensional, and they must be of the same length. The keys and values cannot contain any non-ASCII characters.

F.28.3.7. pgp_armor_headers

pgp_armor_headers(data text, key out text, value out text) returns setof record
pgp_armor_headers() extracts the armor headers from data. The return value is a set of rows with two columns, key and value. If the keys or values contain any non-ASCII characters, they are treated as UTF-8.

F.28.3.8. Options for PGP Functions

Options are named to be similar to GnuPG. An option's value should be given after an equal sign; separate options from each other with commas. For example:

```
pgp_sym_encrypt(data, psw, 'compress-algo=1, cipher-algo=aes256')
```

All of the options except convert-crlf apply only to encrypt functions. Decrypt functions get the parameters from the PGP data.

The most interesting options are probably compress-algo and unicode-mode. The rest should have reasonable defaults.

F.28.3.8.1. cipher-algo

Which cipher algorithm to use.

Values: bf, aes128, aes192, aes256, 3des, cast5
Default: aes128
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.28.3.8.2. compress-algo

Which compression algorithm to use. Only available if PostgreSQL was built with zlib.

Values:
- 0 - no compression
- 1 - ZIP compression
- 2 - ZLIB compression (= ZIP plus meta-data and block CRCs)
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.28.3.8.3. compress-level

How much to compress. Higher levels compress smaller but are slower. 0 disables compression.

Values: 0, 1-9
Default: 6
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.28.3.8.4. convert-crlf

Whether to convert \n into \r\n when encrypting and \r\n to \n when decrypting. RFC 4880 specifies that text data should be stored using \r\n line-feeds. Use this to get fully RFC-compliant behavior.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt, pgp_sym_decrypt, pgp_pub_decrypt
F.28.3.8.5. disable-mdc

Do not protect data with SHA-1. The only good reason to use this option is to achieve compatibility with ancient PGP products, predating the addition of SHA-1 protected packets to RFC 4880. Recent gnupg.org and pgp.com software supports it fine.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.28.3.8.6. sess-key

Use separate session key. Public-key encryption always uses a separate session key; this option is for symmetric-key encryption, which by default uses the S2K key directly.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt

F.28.3.8.7. s2k-mode

Which S2K algorithm to use.

Values:
  0 - Without salt. Dangerous!
  1 - With salt but with fixed iteration count.
  3 - Variable iteration count.
Default: 3
Applies to: pgp_sym_encrypt

F.28.3.8.8. s2k-count

The number of iterations of the S2K algorithm to use. It must be a value between 1024 and 6501712, inclusive.

Default: A random value between 65536 and 253952
Applies to: pgp_sym_encrypt, only with s2k-mode=3

F.28.3.8.9. s2k-digest-algo

Which digest algorithm to use in S2K calculation.

Values: md5, sha1
Default: sha1
Applies to: pgp_sym_encrypt

F.28.3.8.10. s2k-cipher-algo

Which cipher to use for encrypting separate session key.
Values: bf, aes, aes128, aes192, aes256
Default: use cipher-algo
Applies to: pgp_sym_encrypt

F.28.3.8.11. unicode-mode

Whether to convert textual data from database internal encoding to UTF-8 and back. If your database already is UTF-8, no conversion will be done, but the message will be tagged as UTF-8. Without this option it will not be.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.28.3.9. Generating PGP Keys with GnuPG

To generate a new key:

```
gpg --gen-key
```

The preferred key type is “DSA and Elgamal”.

For RSA encryption you must create either DSA or RSA sign-only key as master and then add an RSA encryption subkey with `gpg --edit-key`.

To list keys:

```
gpg --list-secret-keys
```

To export a public key in ASCII-armor format:

```
gpg -a --export KEYID > public.key
```

To export a secret key in ASCII-armor format:

```
gpg -a --export-secret-keys KEYID > secret.key
```

You need to use `dearmor()` on these keys before giving them to the PGP functions. Or if you can handle binary data, you can drop `-a` from the command.

For more details see `man gpg`, The GNU Privacy Handbook\(^4\) and other documentation on https://www.gnupg.org/.

F.28.3.10. Limitations of PGP Code

- No support for signing. That also means that it is not checked whether the encryption subkey belongs to the master key.
- No support for encryption key as master key. As such practice is generally discouraged, this should not be a problem.

• No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with \texttt{pgcrypto}, but create new ones, as the usage scenario is rather different.

\section*{F.28.4. Raw Encryption Functions}

These functions only run a cipher over data; they don't have any advanced features of PGP encryption. Therefore they have some major problems:

1. They use user key directly as cipher key.
2. They don't provide any integrity checking, to see if the encrypted data was modified.
3. They expect that users manage all encryption parameters themselves, even IV.
4. They don't handle text.

So, with the introduction of PGP encryption, usage of raw encryption functions is discouraged.

\begin{verbatim}
encrypt (data bytea, key bytea, type text) returns bytea
decrypt (data bytea, key bytea, type text) returns bytea
derpy
encrypt_iv (data bytea, key bytea, iv bytea, type text) returns bytea
decrypt_iv (data bytea, key bytea, iv bytea, type text) returns bytea
\end{verbatim}

Encrypt/decrypt data using the cipher method specified by \texttt{type}. The syntax of the \texttt{type} string is:

\begin{verbatim}
algorithm [ - mode ] [ /pad: padding ]
\end{verbatim}

where \texttt{algorithm} is one of:

\begin{itemize}
  \item \texttt{bf} — Blowfish
  \item \texttt{aes} — AES (Rijndael-128, -192 or -256)
\end{itemize}

and \texttt{mode} is one of:

\begin{itemize}
  \item \texttt{cbc} — next block depends on previous (default)
  \item \texttt{ecb} — each block is encrypted separately (for testing only)
\end{itemize}

and \texttt{padding} is one of:

\begin{itemize}
  \item \texttt{pkcs} — data may be any length (default)
  \item \texttt{none} — data must be multiple of cipher block size
\end{itemize}

So, for example, these are equivalent:

\begin{verbatim}
encrypt (data, 'fooz', 'bf')
encrypt (data, 'fooz', 'bf-cbc/pad:pkcs')
\end{verbatim}

In \texttt{encrypt\_iv} and \texttt{decrypt\_iv}, the \texttt{iv} parameter is the initial value for the CBC mode; it is ignored for ECB. It is clipped or padded with zeroes if not exactly block size. It defaults to all zeroes in the functions without this parameter.
F.28.5. Random-Data Functions

```
gen_random_bytes(count integer) returns bytea
```

Returns `count` cryptographically strong random bytes. At most 1024 bytes can be extracted at a time. This is to avoid draining the randomness generator pool.

```
gen_random_uuid() returns uuid
```

Returns a version 4 (random) UUID. (Obsolete, this function is now also included in core PostgreSQL.)

F.28.6. Notes

F.28.6.1. Configuration

`pgcrypto` configures itself according to the findings of the main PostgreSQL `configure` script. The options that affect it are `--with-zlib` and `--with-ssl=openssl`.
When compiled with zlib, PGP encryption functions are able to compress data before encrypting.
`pgcrypto` requires OpenSSL. Otherwise, it will not be built or installed.
When compiled against OpenSSL 3.0.0 and later versions, the legacy provider must be activated in the `openssl.cnf` configuration file in order to use older ciphers like DES or Blowfish.

F.28.6.2. NULL Handling

As is standard in SQL, all functions return NULL, if any of the arguments are NULL. This may create security risks on careless usage.

F.28.6.3. Security Limitations

All `pgcrypto` functions run inside the database server. That means that all the data and passwords move between `pgcrypto` and client applications in clear text. Thus you must:

1. Connect locally or use SSL connections.
2. Trust both system and database administrator.

If you cannot, then better do crypto inside client application.

The implementation does not resist side-channel attacksº. For example, the time required for a `pgcrypto` decryption function to complete varies among ciphertexts of a given size.

F.28.6.4. Useful Reading

  The GNU Privacy Handbook.

</tr>
</tbody>
</table>

F.29. pg_freespacemap

The pg_freespacemap module provides a means for examining the free space map (FSM). It provides a function called pg_freespace, or two overloaded functions, to be precise. The functions show the value recorded in the free space map for a given page, or for all pages in the relation.
By default use is restricted to superusers and roles with privileges of the `pg_stat_scan_tables` role. Access may be granted to others using `GRANT`.

**F.29.1. Functions**

`pg_freespace(rel regclass IN, blkno bigint IN) returns int2`

Returns the amount of free space on the page of the relation, specified by `blkno`, according to the FSM.

`pg_freespace(rel regclass IN, blkno OUT bigint, avail OUT int2)`

Displays the amount of free space on each page of the relation, according to the FSM. A set of `(blkno bigint, avail int2)` tuples is returned, one tuple for each page in the relation.

The values stored in the free space map are not exact. They're rounded to precision of 1/256th of `BLCKSZ` (32 bytes with default `BLCKSZ`), and they're not kept fully up-to-date as tuples are inserted and updated.

For indexes, what is tracked is entirely-unused pages, rather than free space within pages. Therefore, the values are not meaningful, just whether a page is full or empty.

**F.29.2. Sample Output**

```
postgres=# SELECT * FROM pg_freespace('foo');
   blkno |   avail
----------+--------
         0 |      0
         1 |      0
         2 |     32
         3 |     704
         4 |     704
         5 |     704
         6 |    1216
         7 |     704
         8 |     704
         9 |     704
        10 |     704
        11 |     704
        12 |     704
        13 |     704
        14 |     704
        15 |     704
        16 |     704

```

F.29.3. Author

Original version by Mark Kirkwood <markir@paradise.net.nz>. Rewritten in version 8.4 to suit new FSM implementation by Heikki Linnakangas <heikki@enterprisedb.com>

F.30. pg_prewarm

The pg_prewarm module provides a convenient way to load relation data into either the operating system buffer cache or the PostgreSQL buffer cache. Prewarming can be performed manually using the pg_prewarm function, or can be performed automatically by including pg_prewarm in shared_preload_libraries. In the latter case, the system will run a background worker which periodically records the contents of shared buffers in a file called autoprewarm.blocks and will, using 2 background workers, reload those same blocks after a restart.

F.30.1. Functions

pg_prewarm(regclass, mode text default 'buffer', fork text default 'main',
    first_block int8 default null,
    last_block int8 default null) RETURNS int8

The first argument is the relation to be prewarmed. The second argument is the prewarming method to be used, as further discussed below; the third is the relation fork to be prewarmed, usually main. The fourth argument is the first block number to prewarm (NULL is accepted as a synonym for zero). The fifth argument is the last block number to prewarm (NULL means prewarm through the last block in the relation). The return value is the number of blocks prewarmed.

There are three available prewarming methods. prefetch issues asynchronous prefetch requests to the operating system, if this is supported, or throws an error otherwise. read reads the requested range of blocks; unlike prefetch, this is synchronous and supported on all platforms and builds, but may be slower. buffer reads the requested range of blocks into the database buffer cache.

Note that with any of these methods, attempting to prewarm more blocks than can be cached — by the OS when using prefetch or read, or by PostgreSQL when using buffer — will likely result in lower-numbered blocks being evicted as higher numbered blocks are read in. Prewarmed data also enjoys no special protection from cache evictions, so it is possible that other system activity may evict the newly prewarmed blocks shortly after they are read; conversely, prewarming may also evict other data from cache. For these reasons, prewarming is typically most useful at startup, when caches are largely empty.

autoprewarm_start_worker() RETURNS void

Launch the main autoprewarm worker. This will normally happen automatically, but is useful if automatic prewarm was not configured at server startup time and you wish to start up the worker at a later time.

autoprewarm_dump_now() RETURNS int8

Update autoprewarm.blocks immediately. This may be useful if the autoprewarm worker is not running but you anticipate running it after the next restart. The return value is the number of records written to autoprewarm.blocks.
F.30.2. Configuration Parameters

pg_prewarm.autoprewarm (boolean)

Controls whether the server should run the autoprewarm worker. This is on by default. This parameter can only be set at server start.

pg_prewarm.autoprewarm_interval (integer)

This is the interval between updates to autoprewarm.blocks. The default is 300 seconds. If set to 0, the file will not be dumped at regular intervals, but only when the server is shut down.

F.30.3. Author

Robert Haas <rhaas@postgresql.org>

F.31. pgrowlocks

The pgrowlocks module provides a function to show row locking information for a specified table.

By default use is restricted to superusers, roles with privileges of the pg_stat_scan_tables role, and users with SELECT permissions on the table.

F.31.1. Overview

pgrowlocks(text) returns setof record

The parameter is the name of a table. The result is a set of records, with one row for each locked row within the table. The output columns are shown in Table F.19.

Table F.19. pgrowlocks Output Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>locked_row</td>
<td>tid</td>
<td>Tuple ID (TID) of locked row</td>
</tr>
<tr>
<td>locker</td>
<td>xid</td>
<td>Transaction ID of locker, or multixact ID if multitransaction</td>
</tr>
<tr>
<td>multi</td>
<td>boolean</td>
<td>True if locker is a multitransaction</td>
</tr>
<tr>
<td>xids</td>
<td>xid[]</td>
<td>Transaction IDs of lockers (more than one if multitransaction)</td>
</tr>
<tr>
<td>modes</td>
<td>text[]</td>
<td>Lock mode of lockers (more than one if multitransaction), an array of Key Share, Share, For No Key Update, No Key Update, For Update, Update.</td>
</tr>
<tr>
<td>pids</td>
<td>integer[]</td>
<td>Process IDs of locking backends (more than one if multitransac-</td>
</tr>
</tbody>
</table>

pgrowlocks takes AccessShareLock for the target table and reads each row one by one to collect the row locking information. This is not very speedy for a large table. Note that:
1. If an `ACCESS EXCLUSIVE` lock is taken on the table, `pgrowlocks` will be blocked.

2. `pgrowlocks` is not guaranteed to produce a self-consistent snapshot. It is possible that a new row lock is taken, or an old lock is freed, during its execution.

`pgrowlocks` does not show the contents of locked rows. If you want to take a look at the row contents at the same time, you could do something like this:

```
SELECT * FROM accounts AS a, pgrowlocks('accounts') AS p
WHERE p.locked_row = a.ctid;
```

Be aware however that such a query will be very inefficient.

### F.31.2. Sample Output

```
=# SELECT * FROM pgrowlocks('t1');

locked_row | locker | multi | xids  | modes          | pids
------------|--------|-------|-------|----------------|--------
(0,1)       | 609    | f     | {609} | {"For Share"} | {3161} |
(0,2)       | 609    | f     | {609} | {"For Share"} | {3161} |
(0,3)       | 607    | f     | {607} | {"For Update"} | {3107} |
(0,4)       | 607    | f     | {607} | {"For Update"} | {3107} |
(4 rows)
```

Tatsuo Ishii

### F.32. `pg_stat_statements`

The `pg_stat_statements` module provides a means for tracking planning and execution statistics of all SQL statements executed by a server.

The module must be loaded by adding `pg_stat_statements` to `shared_preload_libraries` in `postgresql.conf`, because it requires additional shared memory. This means that a server restart is needed to add or remove the module. In addition, query identifier calculation must be enabled in order for the module to be active, which is done automatically if `compute_query_id` is set to `auto` or `on`, or any third-party module that calculates query identifiers is loaded.

When `pg_stat_statements` is active, it tracks statistics across all databases of the server. To access and manipulate these statistics, the module provides views `pg_stat_statements` and `pg_stat_statements_info`, and the utility functions `pg_stat_statements_reset` and `pg_stat_statements`. These are not available globally but can be enabled for a specific database with `CREATE EXTENSION pg_stat_statements`.

#### F.32.1. The `pg_stat_statements` View

The statistics gathered by the module are made available via a view named `pg_stat_statements`. This view contains one row for each distinct combination of database ID, user ID, query ID and whether it's a top-level statement or not (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in Table F.20.
### Table F.20. `pg_stat_statements` Columns

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>userid oid (references pg_authid.oid)</td>
<td>OID of user who executed the statement</td>
</tr>
<tr>
<td>dbid oid (references pg_database.oid)</td>
<td>OID of database in which the statement was executed</td>
</tr>
<tr>
<td>toplevel bool</td>
<td>True if the query was executed as a top-level statement (always true if <code>pg_stat_statements.track</code> is set to top)</td>

For security reasons, only superusers and roles with privileges of the `pg_read_all_stats` role are allowed to see the SQL text and `queryid` of queries executed by other users. Other users can see the statistics, however, if the view has been installed in their database.

Plannable queries (that is, `SELECT`, `INSERT`, `UPDATE`, and `DELETE`) are combined into a single `pg_stat_statements` entry whenever they have identical query structures according to an internal hash calculation. Typically, two queries will be considered the same for this purpose if they are semantically equivalent except for the values of literal constants appearing in the query. Utility commands (that is, all other commands) are compared strictly on the basis of their textual query strings, however.

#### Note

The following details about constant replacement and `queryid` only apply when `compute_query_id` is enabled. If you use an external module instead to compute `queryid`, you should refer to its documentation for details.

When a constant's value has been ignored for purposes of matching the query to other queries, the constant is replaced by a parameter symbol, such as `$1`, in the `pg_stat_statements` display. The rest of the query text is that of the first query that had the particular `queryid` hash value associated with the `pg_stat_statements` entry.

In some cases, queries with visibly different texts might get merged into a single `pg_stat_statements` entry. Normally this will happen only for semantically equivalent queries, but there is a small chance of hash collisions causing unrelated queries to be merged into one entry. (This cannot happen for queries belonging to different users or databases, however.)

Since the `queryid` hash value is computed on the post-parse-analysis representation of the queries, the opposite is also possible: queries with identical texts might appear as separate entries, if they have different meanings as a result of factors such as different `search_path` settings.

Consumers of `pg_stat_statements` may wish to use `queryid` (perhaps in combination with `dbid` and `userid`) as a more stable and reliable identifier for each entry than its query text. However, it is important to understand that there are only limited guarantees around the stability of the `queryid` hash value. Since the identifier is derived from the post-parse-analysis tree, its value is a function of, among other things, the internal object identifiers appearing in this representation. This has some counterintuitive implications. For example, `pg_stat_statements` will consider two apparently-identical queries to be distinct, if they reference a table that was dropped and recreated between the executions of the two queries.
The hashing process is also sensitive to differences in machine architecture and other facets of the platform. Furthermore, it is not safe to assume that queryid will be stable across major versions of PostgreSQL.

As a rule of thumb, queryid values can be assumed to be stable and comparable only so long as the underlying server version and catalog metadata details stay exactly the same. Two servers participating in replication based on physical WAL replay can be expected to have identical queryid values for the same query. However, logical replication schemes do not promise to keep replicas identical in all relevant details, so queryid will not be a useful identifier for accumulating costs across a set of logical replicas. If in doubt, direct testing is recommended.

The parameter symbols used to replace constants in representative query texts start from the next number after the highest $n$ parameter in the original query text, or $1$ if there was none. It's worth noting that in some cases there may be hidden parameter symbols that affect this numbering. For example, PL/pgSQL uses hidden parameter symbols to insert values of function local variables into queries, so that a PL/pgSQL statement like \texttt{SELECT i + 1 INTO j} would have representative text like \texttt{SELECT i + $2$}.

The representative query texts are kept in an external disk file, and do not consume shared memory. Therefore, even very lengthy query texts can be stored successfully. However, if many long query texts are accumulated, the external file might grow unmanageably large. As a recovery method if that happens, \texttt{pg_stat_statements} may choose to discard the query texts, whereupon all existing entries in the \texttt{pg_stat_statements} view will show null query fields, though the statistics associated with each queryid are preserved. If this happens, consider reducing \texttt{pg_stat_statements.max} to prevent recurrences.

plans and calls aren't always expected to match because planning and execution statistics are updated at their respective end phase, and only for successful operations. For example, if a statement is successfully planned but fails during the execution phase, only its planning statistics will be updated. If planning is skipped because a cached plan is used, only its execution statistics will be updated.

### F.32.2. The \texttt{pg_stat_statements_info} View

The statistics of the \texttt{pg_stat_statements} module itself are tracked and made available via a view named \texttt{pg_stat_statements_info}. This view contains only a single row. The columns of the view are shown in Table F.21.

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dealloc bigint</td>
<td>Total number of times \texttt{pg_stat_statements} entries about the least-executed statements were deallocated because more distinct statements than \texttt{pg_stat_statements.max} were observed</td>
</tr>
<tr>
<td>stats_reset</td>
<td>Time at which all statistics in the \texttt{pg_stat_statements} view were last reset.</td>
</tr>
</tbody>
</table>

### F.32.3. Functions

\texttt{pg_stat_statements_reset(userid Oid, dbid Oid, queryid bigint) returns void}

\texttt{pg_stat_statements_reset} discards statistics gathered so far by \texttt{pg_stat_statements} corresponding to the specified userid, dbid and queryid. If any of the parameters are not spec-
Additional Supplied Modules

ifed, the default value 0 (invalid) is used for each of them and the statistics that match with other parameters will be reset. If no parameter is specified or all the specified parameters are 0 (invalid), it will discard all statistics. If all statistics in the pg_stat_statements view are discarded, it will also reset the statistics in the pg_stat_statements_info view. By default, this function can only be executed by superusers. Access may be granted to others using GRANT.

pg_stat_statements(showtext boolean) returns setof record

The pg_stat_statements view is defined in terms of a function also named pg_stat_statements. It is possible for clients to call the pg_stat_statements function directly, and by specifying showtext := false have query text be omitted (that is, the OUT argument that corresponds to the view’s query column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all pg_stat_statements itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the pg_stat_statements data.

F.32.4. Configuration Parameters

pg_stat_statements.max (integer)

pg_stat_statements.max is the maximum number of statements tracked by the module (i.e., the maximum number of rows in the pg_stat_statements view). If more distinct statements than that are observed, information about the least-executed statements is discarded. The number of times such information was discarded can be seen in the pg_stat_statements_info view. The default value is 5000. This parameter can only be set at server start.

pg_stat_statements.track (enum)

pg_stat_statements.track controls which statements are counted by the module. Specify top to track top-level statements (those issued directly by clients), all to also track nested statements (such as statements invoked within functions), or none to disable statement statistics collection. The default value is top. Only superusers can change this setting.

pg_stat_statements.track_utility (boolean)

pg_stat_statements.track_utility controls whether utility commands are tracked by the module. Utility commands are all those other than SELECT, INSERT, UPDATE and DELETE. The default value is on. Only superusers can change this setting.

pg_stat_statements.track_planning (boolean)

pg_stat_statements.track_planning controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of pg_stat_statements entries. The default value is off. Only superusers can change this setting.

pg_stat_statements.save (boolean)

pg_stat_statements.save specifies whether to save statement statistics across server shutdowns. If it is off then statistics are not saved at shutdown nor reloaded at server start. The default value is on. This parameter can only be set in the postgresql.conf file or on the server command line.
The module requires additional shared memory proportional to `pg_stat_statements.max`. Note that this memory is consumed whenever the module is loaded, even if `pg_stat_statements.track` is set to `none`.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```plaintext
# postgresql.conf
shared_preload_libraries = 'pg_stat_statements'
compute_query_id = on
pg_stat_statements.max = 10000
pg_stat_statements.track = all
```

### F.32.6. Authors

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>. Query normalization added by Peter Geoghegan <peter@2ndquadrant.com>.

### F.33. pgstattuple

The pgstattuple module provides various functions to obtain tuple-level statistics.

Because these functions return detailed page-level information, access is restricted by default. By default, only the role pg_stat_scan_tables has EXECUTE privilege. Superusers of course bypass this restriction. After the extension has been installed, users may issue GRANT commands to change the privileges on the functions to allow others to execute them. However, it might be preferable to add those users to the pg_stat_scan_tables role instead.
F.33.1. Functions

pgstattuple(regclass) returns record

pgstattuple returns a relation's physical length, percentage of “dead” tuples, and other info. This may help users to determine whether vacuum is necessary or not. The argument is the target relation’s name (optionally schema-qualified) or OID. For example:

```
test=> SELECT * FROM pgstattuple('pg_catalog.pg_proc');
-=[ RECORD 1 ]---------
table_len | 458752
tuple_count | 1470
tuple_len | 438896
tuple_percent | 95.67
dead_tuple_count | 11
dead_tuple_len | 3157
dead_tuple_percent | 0.69
free_space | 8932
free_percent | 1.95
```

The output columns are described in Table F.22.

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_len</td>
<td>bigint</td>
<td>Physical relation length in bytes</td>
</tr>
<tr>
<td>tuple_count</td>
<td>bigint</td>
<td>Number of live tuples</td>
</tr>
<tr>
<td>tuple_len</td>
<td>bigint</td>
<td>Total length of live tuples in bytes</td>
</tr>
<tr>
<td>tuple_percent</td>
<td>float8</td>
<td>Percentage of live tuples</td>
</tr>
<tr>
<td>dead_tuple_count</td>
<td>bigint</td>
<td>Number of dead tuples</td>
</tr>
<tr>
<td>dead_tuple_len</td>
<td>bigint</td>
<td>Total length of dead tuples in bytes</td>
</tr>
<tr>
<td>dead_tuple_percent</td>
<td>float8</td>
<td>Percentage of dead tuples</td>
</tr>
<tr>
<td>free_space</td>
<td>bigint</td>
<td>Total free space in bytes</td>
</tr>
<tr>
<td>free_percent</td>
<td>float8</td>
<td>Percentage of free space</td>
</tr>
</tbody>
</table>

Note

The table_len will always be greater than the sum of the tuple_len, dead_tuple_len and free_space. The difference is accounted for by fixed page overhead, the per-page table of pointers to tuples, and padding to ensure that tuples are correctly aligned.

pgstattuple acquires only a read lock on the relation. So the results do not reflect an instantaneous snapshot; concurrent updates will affect them.

pgstattuple judges a tuple is “dead” if HeapTupleSatisfiesDirty returns false.
pgstattuple(text) returns record

This is the same as pgstattuple(regclass), except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

pgstatindex(regclass) returns record

pgstatindex returns a record showing information about a B-tree index. For example:

```
SELECT * FROM pgstatindex('pg_cast_oid_index');
```

```
- [ RECORD 1 ]---------------------
version     | 2
tree_level  | 0
index_size  | 16384
root_block_no | 1
internal_pages | 0
leaf_pages   | 1
empty_pages  | 0
deleted_pages | 0
avg_leaf_density | 54.27
leaf_fragmentation | 0
```

The output columns are:

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>integer</td>
<td>B-tree version number</td>
</tr>
<tr>
<td>tree_level</td>
<td>integer</td>
<td>Tree level of the root page</td>
</tr>
<tr>
<td>index_size</td>
<td>bigint</td>
<td>Total index size in bytes</td>
</tr>
<tr>
<td>root_block_no</td>
<td>bigint</td>
<td>Location of root page (zero if none)</td>
</tr>
<tr>
<td>internal_pages</td>
<td>bigint</td>
<td>Number of “internal” (upper-level) pages</td>
</tr>
<tr>
<td>leaf_pages</td>
<td>bigint</td>
<td>Number of leaf pages</td>
</tr>
<tr>
<td>empty_pages</td>
<td>bigint</td>
<td>Number of empty pages</td>
</tr>
<tr>
<td>deleted_pages</td>
<td>bigint</td>
<td>Number of deleted pages</td>
</tr>
<tr>
<td>avg_leaf_density</td>
<td>float8</td>
<td>Average density of leaf pages</td>
</tr>
<tr>
<td>leaf_fragmentation</td>
<td>float8</td>
<td>Leaf page fragmentation</td>
</tr>
</tbody>
</table>

The reported index_size will normally correspond to one more page than is accounted for by internal_pages + leaf_pages + empty_pages + deleted_pages, because it also includes the index's metapage.

As with pgstattuple, the results are accumulated page-by-page, and should not be expected to represent an instantaneous snapshot of the whole index.

pgstatindex(text) returns record

This is the same as pgstatindex(regclass), except that the target index is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.
pgstatginindex(regclass) returns record

pgstatginindex returns a record showing information about a GIN index. For example:

```sql
test=> SELECT * FROM pgstatginindex('test_gin_index');
-[ RECORD 1 ]---+
version | 1
pending_pages | 0
pending_tuples | 0
```

The output columns are:

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>integer</td>
<td>GIN version number</td>
</tr>
<tr>
<td>pending_pages</td>
<td>integer</td>
<td>Number of pages in the pending list</td>
</tr>
<tr>
<td>pending_tuples</td>
<td>bigint</td>
<td>Number of tuples in the pending list</td>
</tr>
</tbody>
</table>

pgstathashindex(regclass) returns record

pgstathashindex returns a record showing information about a HASH index. For example:

```sql
test=> select * from pgstathashindex('con_hash_index');
-[ RECORD 1 ]---------+
version | 4
bucket_pages | 33081
overflow_pages | 0
bitmap_pages | 1
unused_pages | 32455
live_items | 10204006
dead_items | 0
free_percent | 61.8005949100872
```

The output columns are:

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>integer</td>
<td>HASH version number</td>
</tr>
<tr>
<td>bucket_pages</td>
<td>bigint</td>
<td>Number of bucket pages</td>
</tr>
<tr>
<td>overflow_pages</td>
<td>bigint</td>
<td>Number of overflow pages</td>
</tr>
<tr>
<td>bitmap_pages</td>
<td>bigint</td>
<td>Number of bitmap pages</td>
</tr>
<tr>
<td>unused_pages</td>
<td>bigint</td>
<td>Number of unused pages</td>
</tr>
<tr>
<td>live_items</td>
<td>bigint</td>
<td>Number of live tuples</td>
</tr>
<tr>
<td>dead_items</td>
<td>bigint</td>
<td>Number of dead tuples</td>
</tr>
<tr>
<td>free_percent</td>
<td>float</td>
<td>Percentage of free space</td>
</tr>
</tbody>
</table>

pg_relpages(regclass) returns bigint

pg_relpages returns the number of pages in the relation.
pg_relpages(text) returns bigint

This is the same as pg_relpages(regclass), except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

pgstattuple_approx(regclass) returns record

pgstattuple_approx is a faster alternative to pgstattuple that returns approximate results. The argument is the target relation’s name or OID. For example:

test=> SELECT * FROM pgstattuple_approx('pg_catalog.pg_proc'::regclass);
-[ RECORD 1 ]-----------------------
table_len | 573440
scanned_percent | 2
approx_tuple_count | 2740
approx_tuple_len | 561210
approx_tuple_percent | 97.87
dead_tuple_count | 0
dead_tuple_len | 0
dead_tuple_percent | 0
approx_free_space | 11996
approx_free_percent | 2.09

The output columns are described in Table F.23.

Whereas pgstattuple always performs a full-table scan and returns an exact count of live and dead tuples (and their sizes) and free space, pgstattuple_approx tries to avoid the full-table scan and returns exact dead tuple statistics along with an approximation of the number and size of live tuples and free space.

It does this by skipping pages that have only visible tuples according to the visibility map (if a page has the corresponding VM bit set, then it is assumed to contain no dead tuples). For such pages, it derives the free space value from the free space map, and assumes that the rest of the space on the page is taken up by live tuples.

For pages that cannot be skipped, it scans each tuple, recording its presence and size in the appropriate counters, and adding up the free space on the page. At the end, it estimates the total number of live tuples based on the number of pages and tuples scanned (in the same way that VACUUM estimates pg_class.reltuples).

Table F.23. pgstattuple_approx Output Columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_len</td>
<td>bigint</td>
<td>Physical relation length in bytes (exact)</td>
</tr>
<tr>
<td>scanned_percent</td>
<td>float8</td>
<td>Percentage of table scanned</td>
</tr>
<tr>
<td>approx_tuple_count</td>
<td>bigint</td>
<td>Number of live tuples (estimated)</td>
</tr>
<tr>
<td>approx_tuple_len</td>
<td>bigint</td>
<td>Total length of live tuples in bytes (estimated)</td>
</tr>
<tr>
<td>approx_tuple_percent</td>
<td>float8</td>
<td>Percentage of live tuples</td>
</tr>
</tbody>
</table>
### Additional Supplied Modules

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dead_tuple_count</td>
<td>bigint</td>
<td>Number of dead tuples (exact)</td>
</tr>
<tr>
<td>dead_tuple_len</td>
<td>bigint</td>
<td>Total length of dead tuples in bytes (exact)</td>
</tr>
<tr>
<td>dead_tuple_percent</td>
<td>float8</td>
<td>Percentage of dead tuples</td>
</tr>
<tr>
<td>approx_free_space</td>
<td>bigint</td>
<td>Total free space in bytes (estimated)</td>
</tr>
<tr>
<td>approx_free_percent</td>
<td>float8</td>
<td>Percentage of free space</td>
</tr>
</tbody>
</table>

In the above output, the free space figures may not match the `pgstattuple` output exactly, because the free space map gives us an exact figure, but is not guaranteed to be accurate to the byte.

### F.34. pg_surgery

The `pg_surgery` module provides various functions to perform surgery on a damaged relation. These functions are unsafe by design and using them may corrupt (or further corrupt) your database. For example, these functions can easily be used to make a table inconsistent with its own indexes, to cause UNIQUE or FOREIGN KEY constraint violations, or even to make tuples visible which, when read, will cause a database server crash. They should be used with great caution and only as a last resort.

#### F.34.1. Functions

**heap_force_kill(regclass, tid[])** returns void

heap_force_kill marks “used” line pointers as “dead” without examining the tuples. The intended use of this function is to forcibly remove tuples that are not otherwise accessible. For example:

```
    test=> select * from t1 where ctid = '(0, 1)';
    ERROR: could not access status of transaction 4007513275
    DETAIL: Could not open file "pg_xact/0EED": No such file or directory.

    test=# select heap_force_kill('t1'::regclass, ARRAY['(0, 1)']::tid[]);
    heap_force_kill
    --------------------
    (1 row)

    test=# select * from t1 where ctid = '(0, 1)';
    (0 rows)
```

**heap_force_freeze(regclass, tid[])** returns void

heap_force_freeze marks tuples as frozen without examining the tuple data. The intended use of this function is to make accessible tuples which are inaccessible due to corrupted visibility infor-
Additional Supplied Modules

mation, or which prevent the table from being successfully vacuumed due to corrupted visibility information. For example:

test=> vacuum t1;
ERROR:  found xmin 507 from before relfrozenxid 515
CONTEXT:  while scanning block 0 of relation "public.t1"

test=# select ctid from t1 where xmin = 507;
      ctid
      ------
          (0,3)
(1 row)

test=# select heap_force_freeze('t1'::regclass, ARRAY['(0,3)']::tid[]);
heap_force_freeze

--------------
(1 row)

test=# select ctid from t1 where xmin = 2;
      ctid
      ------
          (0,3)
(1 row)

F.35. pg_trgm

The pg_trgm module provides functions and operators for determining the similarity of alphanumeric text based on trigram matching, as well as index operator classes that support fast searching for similar strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.35.1. Trigram (or Trigraph) Concepts

A trigram is a group of three consecutive characters taken from a string. We can measure the similarity of two strings by counting the number of trigrams they share. This simple idea turns out to be very effective for measuring the similarity of words in many natural languages.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
</table>

pg_trgm ignores non-word characters (non-alphanumeric) when extracting trigrams from a string. Each word is considered to have two spaces prefixed and one space suffixed when deter-
mining the set of trigrams contained in the string. For example, the set of trigrams in the string "cat" is "c", "ca", "cat", and "at ". The set of trigrams in the string "foo|bar" is " f", " fo", "foo", "oo ", " b", " ba", "bar", and "ar ".

### F.35.2. Functions and Operators

The functions provided by the pg_trgm module are shown in Table F.24, the operators in Table F.25.

**Table F.24. pg_trgm Functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>similarity(text, text) → real</td>
<td>Returns a number that indicates how similar the two arguments are. The range of the result is zero (indicating that the two strings are completely dissimilar) to one (indicating that the two strings are identical).</td>
</tr>
<tr>
<td>show_trgm(text) → text[]</td>
<td>Returns an array of all the trigrams in the given string. (In practice this is seldom useful except for debugging.)</td>
</tr>
<tr>
<td>word_similarity(text, text) → real</td>
<td>Returns a number that indicates the greatest similarity between the set of trigrams in the first string and any continuous extent of an ordered set of trigrams in the second string. For details, see the explanation below.</td>
</tr>
<tr>
<td>strict_word_similarity(text, text) → real</td>
<td>Same as word_similarity, but forces extent boundaries to match word boundaries. Since we don't have cross-word trigrams, this function actually returns greatest similarity between first string and any continuous extent of words of the second string.</td>
</tr>
<tr>
<td>show_limit() → real</td>
<td>Returns the current similarity threshold used by the % operator. This sets the minimum similarity between two words for them to be considered similar enough to be misspellings of each other, for example. <em>(Deprecated; instead use SHOW pg_trgm.similarity_threshold)</em></td>
</tr>
<tr>
<td>set_limit(real) → real</td>
<td>Sets the current similarity threshold that is used by the % operator. The threshold must be between 0 and 1 (default is 0.3). Returns the same value passed in. <em>(Deprecated; instead use SET pg_trgm.similarity_threshold)</em></td>
</tr>
</tbody>
</table>

Consider the following example:

```sql
# SELECT word_similarity('word', 'two words');
word_similarity
-----------
0.8
(1 row)
```

In the first string, the set of trigrams is {" w"," w"," wor"," ord"," rd "). In the second string, the ordered set of trigrams is {" t"," tw"," two"," wo "," w"," wo"," wor"," ord"," rd-
The most similar extent of an ordered set of trigrams in the second string is {" w", "wo", "wor", "ord"}, and the similarity is 0.8.

This function returns a value that can be approximately understood as the greatest similarity between the first string and any substring of the second string. However, this function does not add padding to the boundaries of the extent. Thus, the number of additional characters present in the second string is not considered, except for the mismatched word boundaries.

At the same time, `strict_word_similarity` selects an extent of words in the second string. In the example above, `strict_word_similarity` would select the extent of a single word 'words', whose set of trigrams is {" w", "wo", "wor", "ord", "rds", "ds "}.

```
# SELECT strict_word_similarity('word', 'two words'),
    similarity('word', 'words');
```

<table>
<thead>
<tr>
<th>strict_word_similarity</th>
<th>similarity</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.571429</td>
<td>0.571429</td>
</tr>
</tbody>
</table>

Thus, the `strict_word_similarity` function is useful for finding the similarity to whole words, while `word_similarity` is more suitable for finding the similarity for parts of words.

**Table F.25. pg_trgm Operators**

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>text % text</code> → boolean</td>
<td>Returns true if its arguments have a similarity that is greater than the current similarity threshold set by <code>pg_trgm.similarity_threshold</code>.</td>
</tr>
<tr>
<td><code>text &lt;% text</code> → boolean</td>
<td>Returns true if the similarity between the trigram set in the first argument and a continuous extent of an ordered trigram set in the second argument is greater than the current word similarity threshold set by <code>pg_trgm.word_similarity_threshold</code> parameter.</td>
</tr>
<tr>
<td><code>text %&gt; text</code> → boolean</td>
<td>Commutator of the <code>&lt;%</code> operator.</td>
</tr>
<tr>
<td><code>text &lt;&lt;% text</code> → boolean</td>
<td>Returns true if its second argument has a continuous extent of an ordered trigram set that matches word boundaries, and its similarity to the trigram set of the first argument is greater than the current strict word similarity threshold set by <code>pg_trgm.strict_word_similarity_threshold</code> parameter.</td>
</tr>
<tr>
<td><code>text %&gt;&gt; text</code> → boolean</td>
<td>Commutator of the <code>&lt;&lt;%</code> operator.</td>
</tr>
<tr>
<td><code>text &lt;-&gt; text</code> → real</td>
<td>Returns the “distance” between the arguments, that is one minus the <code>similarity()</code> value.</td>
</tr>
<tr>
<td><code>text &lt;-&gt; text</code> → real</td>
<td>Returns the “distance” between the arguments, that is one minus the <code>word_similarity()</code> value.</td>
</tr>
<tr>
<td><code>text &lt;-&gt; text</code> → real</td>
<td>Returns the “distance” between the arguments, that is one minus the <code>word_similarity()</code> value.</td>
</tr>
</tbody>
</table>
### Operator Description

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text &lt;&lt;-&gt; text → real</td>
<td>Commutator of the &lt;&lt;-&gt; operator. Returns the “distance” between the arguments, that is one minus the strict_word_similarity() value.</td>
</tr>
<tr>
<td>text &lt;-&gt;&gt;&gt; text → real</td>
<td>Commutator of the &lt;&lt;&lt;- operator.</td>
</tr>
</tbody>
</table>

#### F.35.3. GUC Parameters

- **pg_trgm.similarity_threshold(real)**
  - Sets the current similarity threshold that is used by the % operator. The threshold must be between 0 and 1 (default is 0.3).

- **pg_trgm.word_similarity_threshold(real)**
  - Sets the current word similarity threshold that is used by the <%% and %%% operators. The threshold must be between 0 and 1 (default is 0.6).

- **pg_trgm.strict_word_similarity_threshold(real)**
  - Sets the current strict word similarity threshold that is used by the <<%% and %<<<>> operators. The threshold must be between 0 and 1 (default is 0.5).

#### F.35.4. Index Support

The pg_trgm module provides GiST and GIN index operator classes that allow you to create an index over a text column for the purpose of very fast similarity searches. These index types support the above-described similarity operators, and additionally support trigram-based index searches for LIKE, ILIKE, ~, ~* and = queries. Inequality operators are not supported. Note that those indexes may not be as efficient as regular B-tree indexes for equality operator.

**Example:**

```sql
CREATE TABLE test_trgm (t text);
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops);
```

or

```sql
CREATE INDEX trgm_idx ON test_trgm USING GIN (t gin_trgm_ops);
```

**gist_trgm_ops** GiST opclass approximates a set of trigrams as a bitmap signature. Its optional integer parameter siglen determines the signature length in bytes. The default length is 12 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

**Example of creating such an index with a signature length of 32 bytes:**

```sql
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops siglen = 32);
```
CREATE INDEX trgm_idx ON test_trgm USING GIST (t
gist_trgm_ops(siglen=32));

At this point, you will have an index on the t column that you can use for similarity searching. A typical query is

```
SELECT t, similarity(t, 'word') AS sml
FROM test_trgm
WHERE t % 'word'
ORDER BY sml DESC, t;
```

This will return all values in the text column that are sufficiently similar to word, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

A variant of the above query is

```
SELECT t, t <-> 'word' AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes. It will usually beat the first formulation when only a small number of the closest matches is wanted.

Also you can use an index on the t column for word similarity or strict word similarity. Typical queries are:

```
SELECT t, word_similarity('word', t) AS sml
FROM test_trgm
WHERE 'word' <<% t
ORDER BY sml DESC, t;
```

and

```
SELECT t, strict_word_similarity('word', t) AS sml
FROM test_trgm
WHERE 'word' <<<% t
ORDER BY sml DESC, t;
```

This will return all values in the text column for which there is a continuous extent in the corresponding ordered trigram set that is sufficiently similar to the trigram set of word, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

Possible variants of the above queries are:

```
SELECT t, 'word' <<<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

and

```
SELECT t, 'word' <<<->> t AS dist
```

2874
FROM test_trgm
ORDER BY dist LIMIT 10;

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes.

Beginning in PostgreSQL 9.1, these index types also support index searches for LIKE and ILIKE, for example

SELECT * FROM test_trgm WHERE t LIKE '%foo%bar';

The index search works by extracting trigrams from the search string and then looking these up in the index. The more trigrams in the search string, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

Beginning in PostgreSQL 9.3, these index types also support index searches for regular-expression matches (~ and ~* operators), for example

SELECT * FROM test_trgm WHERE t ~ '(foo|bar)';

The index search works by extracting trigrams from the regular expression and then looking these up in the index. The more trigrams that can be extracted from the regular expression, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

For both LIKE and regular-expression searches, keep in mind that a pattern with no extractable trigrams will degenerate to a full-index scan.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

F.35.5. Text Search Integration

Trigram matching is a very useful tool when used in conjunction with a full text index. In particular it can help to recognize misspelled input words that will not be matched directly by the full text search mechanism.

The first step is to generate an auxiliary table containing all the unique words in the documents:

CREATE TABLE words AS SELECT word FROM
ts_stat('SELECT to_tsvector(''simple'', bodytext) FROM
documents');

where documents is a table that has a text field bodytext that we wish to search. The reason for using the simple configuration with the to_tsvector function, instead of using a language-specific configuration, is that we want a list of the original (unstemmed) words.

Next, create a trigram index on the word column:

CREATE INDEX words_idx ON words USING GIN (word gin_trgm_ops);

Now, a SELECT query similar to the previous example can be used to suggest spellings for misspelled words in user search terms. A useful extra test is to require that the selected words are also of similar length to the misspelled word.
Additional Supplied Modules

Note

Since the `words` table has been generated as a separate, static table, it will need to be periodical-
ly regenerated so that it remains reasonably up-to-date with the document collection. Keeping it
exactly current is usually unnecessary.

F.36. pg_visibility

The `pg_visibility` module provides a means for examining the visibility map (VM) and page-level
visibility information of a table. It also provides functions to check the integrity of a visibility map and
force it to be rebuilt.

Three different bits are used to store information about page-level visibility. The all-visible bit in the
visibility map indicates that every tuple in the corresponding page of the relation is visible to every current
and future transaction. The all-frozen bit in the visibility map indicates that every tuple in the page is
frozen; that is, no future vacuum will need to modify the page until such time as a tuple is inserted, updated,
deleted, or locked on that page. The page header's `PD_ALL_VISIBLE` bit has the same meaning as the
all-visible bit in the visibility map, but is stored within the data page itself rather than in a separate data
structure. These two bits will normally agree, but the page's all-visible bit can sometimes be set while the
visibility map bit is clear after a crash recovery. The reported values can also disagree because of a change
that occurs after `pg_visibility` examines the visibility map and before it examines the data page. Any
event that causes data corruption can also cause these bits to disagree.

Functions that display information about `PD_ALL_VISIBLE` bits are much more costly than those that
only consult the visibility map, because they must read the relation's data blocks rather than only the (much
smaller) visibility map. Functions that check the relation's data blocks are similarly expensive.

F.36.1. Functions

`pg_visibility_map(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean) returns record`

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation.
pg_visibility(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean) returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation, plus the PD_ALL_VISIBLE bit of that block.

pg_visibility_map(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean) returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation.

pg_visibility(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean) returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation, plus the PD_ALL_VISIBLE bit of each block.

pg_visibility_map_summary(relation regclass, all_visible OUT bigint, all_frozen OUT bigint) returns record

Returns the number of all-visible pages and the number of all-frozen pages in the relation according to the visibility map.

pg_check_frozen(relation regclass, t_ctid OUT tid) returns setof tid

Returns the TIDs of non-frozen tuples stored in pages marked all-frozen in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

pg_check_visible(relation regclass, t_ctid OUT tid) returns setof tid

Returns the TIDs of non-all-visible tuples stored in pages marked all-visible in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

pg_truncate_visibility_map(relation regclass) returns void

Truncates the visibility map for the given relation. This function is useful if you believe that the visibility map for the relation is corrupt and wish to force rebuilding it. The first VACUUM executed on the given relation after this function is executed will scan every page in the relation and rebuild the visibility map. (Until that is done, queries will treat the visibility map as containing all zeroes.)

By default, these functions are executable only by superusers and roles with privileges of the pg_stat_scan_tables role, with the exception of pg_truncate_visibility_map(relation regclass) which can only be executed by superusers.

F.36.2. Author

Robert Haas <rhaas@postgresql.org>

F.37. pg_walinspect

The pg_walinspect module provides SQL functions that allow you to inspect the contents of write-ahead log of a running PostgreSQL database cluster at a low level, which is useful for debugging or analytical or reporting or educational purposes. It is similar to pg_waldump, but accessible through SQL rather than a separate utility.
All the functions of this module will provide the WAL information using the current server's timeline ID.

All the functions of this module will try to find the first valid WAL record that is at or after the given \texttt{in\_lsn} or \texttt{start\_lsn} and will emit error if no such record is available. Similarly, the \texttt{end\_lsn} must be available, and if it falls in the middle of a record, the entire record must be available.

\begin{table}
\centering
\begin{tabular}{llllllllll}
\text{start\_lsn} & \text{end\_lsn} & \text{prev\_lsn} & \text{xid} & \text{resource\_manager} & \text{record\_type} & \text{record\_length} & \text{main\_data\_length} & \text{fpi\_length} & \text{description} \\
\hline
0/14FA118 & 0/14FB4B0 & 0/14F9958 & 725 & Btree & INSERT\_LEAF & 5013 & 2 & 4960 & off 246 \\
0/14FB4B0 & 0/14FD050 & 0/14FA118 & 725 & Btree & INSERT\_LEAF & 7045 & 2 & 6992 & off 130 \\
\end{tabular}
\end{table}

\textbf{Note}

Some functions, such as \texttt{pg\_logical\_emit\_message}, return the LSN \textit{after} the record just inserted. Therefore, if you pass that LSN as \texttt{in\_lsn} or \texttt{start\_lsn} to one of these functions, it will return the \textit{next} record.

By default, use of these functions is restricted to superusers and members of the \texttt{pg\_read\_server\_files} role. Access may be granted by superusers to others using \texttt{GRANT}.

\section{F.37.1. General Functions}

\texttt{pg\_get\_wal\_record\_info}(\texttt{in\_lsn pg\_lsn}, \texttt{start\_lsn OUT pg\_lsn}, \texttt{end\_lsn OUT pg\_lsn}, \texttt{prev\_lsn OUT pg\_lsn}, \texttt{xid OUT xid}, \texttt{resource\_manager OUT text}, \texttt{record\_type OUT text}, \texttt{record\_length OUT int4}, \texttt{main\_data\_length OUT int4}, \texttt{fpi\_length OUT int4}, \texttt{description OUT text}, \texttt{block\_ref OUT text})

Gets WAL record information of a given LSN. If the given LSN isn't at the start of a WAL record, it gives the information of the next available valid WAL record; or an error if no such record is found.

\texttt{pg\_get\_wal\_records\_info}(\texttt{start\_lsn pg\_lsn}, \texttt{end\_lsn pg\_lsn}, \texttt{start\_lsn OUT pg\_lsn}, \texttt{end\_lsn OUT pg\_lsn}, \texttt{prev\_lsn OUT pg\_lsn}, \texttt{xid OUT xid}, \texttt{resource\_manager OUT text}, \texttt{record\_type OUT text}, \texttt{record\_length OUT int4}, \texttt{main\_data\_length OUT int4}, \texttt{fpi\_length OUT int4}, \texttt{description OUT text}, \texttt{block\_ref OUT text}) \texttt{returns setof record}

Gets information of all the valid WAL records between \texttt{start\_lsn} and \texttt{end\_lsn}. Returns one row per WAL record. If \texttt{start\_lsn} or \texttt{end\_lsn} are not yet available, the function will raise an error. For example, usage of the function is as follows:

\begin{verbatim}
postgres=# select start\_lsn, end\_lsn, prev\_lsn, xid, resource\_manager, record\_type, record\_length, main\_data\_length, fpi\_length, description from pg\_get\_wal\_records\_info('0/14F9A30', '0/15011D7');
\end{verbatim}

\begin{verbatim}
start\_lsn | end\_lsn | prev\_lsn | xid | resource\_manager | record\_type | record\_length | main\_data\_length | fpi\_length | description
---+-----------+-----------+-----+------------------|-------------+---------------+------------------+------------+-------------------+
0/14FA118 | 0/14FB4B0 | 0/14F9958 | 725 | Btree            | INSERT\_LEAF | 5013 | 2 | 4960 | off 246
0/14FB4B0 | 0/14FD050 | 0/14FA118 | 725 | Btree            | INSERT\_LEAF | 7045 | 2 | 6992 | off 130
\end{verbatim}

2878
pg_get_wal_records_info_till_end_of_wal(start_lsn pg_lsn, start_lsn OUT pg_lsn, end_lsn OUT pg_lsn, prev_lsn OUT pg_lsn, xid OUT xid, resource_manager OUT text, record_type OUT text, record_length OUT int4, main_data_length OUT int4, fpi_length OUT int4, description OUT text, block_ref OUT text) returns setof record

This function is same as pg_get_wal_records_info() except that it gets information of all the valid WAL records from start_lsn till the end of WAL.

pg_get_wal_stats(start_lsn pg_lsn, end_lsn pg_lsn, per_record boolean DEFAULT false, "resource_manager/record_type" OUT text, count OUT int8, count_percentage OUT float4, record_length OUT int8, record_length_percentage OUT float4, fpi_length OUT int8, fpi_length_percentage OUT float4, combined_size OUT int8, combined_size_percentage OUT float4) returns setof record

Gets statistics of all the valid WAL records between start_lsn and end_lsn. By default, it returns one row per resource_manager type. When per_record is set to true, it returns one row per record_type. If start_lsn or end_lsn are not yet available, the function will raise an error. For example, usage of the function is as follows:
### Additional Supplied Modules

```sql

returns setof record

This function is same as pg_get_wal_stats() except that it gets statistics of all the valid WAL 
records from start_lsn till end of WAL.

F.37.2. Author

Bharath Rupireddy <bharath.rupireddyforpostgres@gmail.com>

F.38. postgres_fdw

The postgres_fdw module provides the foreign-data wrapper postgres_fdw, which can be used 
to access data stored in external PostgreSQL servers.

The functionality provided by this module overlaps substantially with the functionality of the older dblink 
module. But postgres_fdw provides more transparent and standards-compliant syntax for accessing 
remote tables, and can give better performance in many cases.

To prepare for remote access using postgres_fdw:

1. Install the postgres_fdw extension using CREATE EXTENSION.
2. Create a foreign server object, using CREATE SERVER, to represent each remote database you want 
to connect to. Specify connection information, except user and password, as options of the server 
object.
3. Create a user mapping, using CREATE USER MAPPING, for each database user you want to allow to 
access each foreign server. Specify the remote user name and password to use as user and password 
options of the user mapping.
4. Create a foreign table, using CREATE FOREIGN TABLE or IMPORT FOREIGN SCHEMA, for 
each remote table you want to access. The columns of the foreign table must match the referenced 
remote table. You can, however, use table and/or column names different from the remote table’s, if 
you specify the correct remote names as options of the foreign table object.

Now you need only SELECT from a foreign table to access the data stored in its underlying remote table. 
You can also modify the remote table using INSERT, UPDATE, DELETE, COPY, or TRUNCATE. (Of 
course, the remote user you have specified in your user mapping must have privileges to do these things.)

Note that the ONLY option specified in SELECT, UPDATE, DELETE or TRUNCATE has no effect when 
accessing or modifying the remote table.

Note that postgres_fdw currently lacks support for INSERT statements with an ON CONFLICT DO 
UPDATE clause. However, the ON CONFLICT DO NOTHING clause is supported, provided a unique 
index inference specification is omitted. Note also that postgres_fdw supports row movement invoked 
by UPDATE statements executed on partitioned tables, but it currently does not handle the case where a 
remote partition chosen to insert a moved row into is also an UPDATE target partition that will be updated 
elsewhere in the same command.

It is generally recommended that the columns of a foreign table be declared with exactly the same da-
ta types, and collations if applicable, as the referenced columns of the remote table. Although post-
gres_fdw is currently rather forgiving about performing data type conversions at need, surprising se-
mantic anomalies may arise when types or collations do not match, due to the remote server interpreting query conditions differently from the local server.

Note that a foreign table can be declared with fewer columns, or with a different column order, than its underlying remote table has. Matching of columns to the remote table is by name, not position.

F.38.1. FDW Options of postgres_fdw

F.38.1.1. Connection Options

A foreign server using the postgres_fdw foreign data wrapper can have the same options that libpq accepts in connection strings, as described in Section 34.1.2, except that these options are not allowed or have special handling:

- **user**, **password** and **sslpassword** (specify these in a user mapping, instead, or use a service file)
- **client_encoding** (this is automatically set from the local server encoding)
- **application_name** - this may appear in *either or both* a connection and postgres_fdw.application_name. If both are present, postgres_fdw.application_name overrides the connection setting. Unlike libpq, postgres_fdw allows application_name to include “escape sequences”. See postgres_fdw.application_name for details.
- **fallback_application_name** (always set to postgres_fdw)
- **sslkey** and **sslcert** - these may appear in *either or both* a connection and a user mapping. If both are present, the user mapping setting overrides the connection setting.

Only superusers may create or modify user mappings with the sslcert or sslkey settings.

Only superusers may connect to foreign servers without password authentication, so always specify the password option for user mappings belonging to non-superusers.

A superuser may override this check on a per-user-mapping basis by setting the user mapping option password_required 'false', e.g.,

```
ALTER USER MAPPING FOR some_non_superuser SERVER loopback_nopw OPTIONS (ADD password_required 'false');
```

To prevent unprivileged users from exploiting the authentication rights of the unix user the postgres server is running as to escalate to superuser rights, only the superuser may set this option on a user mapping.

Care is required to ensure that this does not allow the mapped user the ability to connect as superuser to the mapped database per CVE-2007-3278 and CVE-2007-6601. Don’t set password_required=false on the public role. Keep in mind that the mapped user can potentially use any client certificates, .pg-pass, .pg_service.conf etc. in the unix home directory of the system user the postgres server runs as. They can also use any trust relationship granted by authentication modes like peer or ident authentication.

F.38.1.2. Object Name Options

These options can be used to control the names used in SQL statements sent to the remote PostgreSQL server. These options are needed when a foreign table is created with names different from the underlying remote table's names.

```
schema_name (string)
```

This option, which can be specified for a foreign table, gives the schema name to use for the foreign table on the remote server. If this option is omitted, the name of the foreign table's schema is used.
Additional Supplied Modules

table_name(string)

This option, which can be specified for a foreign table, gives the table name to use for the foreign table on the remote server. If this option is omitted, the foreign table's name is used.

column_name(string)

This option, which can be specified for a column of a foreign table, gives the column name to use for the column on the remote server. If this option is omitted, the column's name is used.

F.38.1.3. Cost Estimation Options

postgres_fdw retrieves remote data by executing queries against remote servers, so ideally the estimated cost of scanning a foreign table should be whatever it costs to be done on the remote server, plus some overhead for communication. The most reliable way to get such an estimate is to ask the remote server and then add something for overhead — but for simple queries, it may not be worth the cost of an additional remote query to get a cost estimate. So postgres_fdw provides the following options to control how cost estimation is done:

use_remote_estimate(boolean)

This option, which can be specified for a foreign table or a foreign server, controls whether postgres_fdw issues remote EXPLAIN commands to obtain cost estimates. A setting for a foreign table overrides any setting for its server, but only for that table. The default is false.

fdw_startup_cost(floating point)

This option, which can be specified for a foreign server, is a floating point value that is added to the estimated startup cost of any foreign-table scan on that server. This represents the additional overhead of establishing a connection, parsing and planning the query on the remote side, etc. The default value is 100.

fdw_tuple_cost(floating point)

This option, which can be specified for a foreign server, is a floating point value that is used as extra cost per-tuple for foreign-table scans on that server. This represents the additional overhead of data transfer between servers. You might increase or decrease this number to reflect higher or lower network delay to the remote server. The default value is 0.01.

When use_remote_estimate is true, postgres_fdw obtains row count and cost estimates from the remote server and then adds fdw_startup_cost and fdw_tuple_cost to the cost estimates. When use_remote_estimate is false, postgres_fdw performs local row count and cost estimation and then adds fdw_startup_cost and fdw_tuple_cost to the cost estimates. This local estimation is unlikely to be very accurate unless local copies of the remote table's statistics are available. Running ANALYZE on the foreign table is the way to update the local statistics; this will perform a scan of the remote table and then calculate and store statistics just as though the table were local. Keeping local statistics can be a useful way to reduce per-query planning overhead for a remote table — but if the remote table is frequently updated, the local statistics will soon be obsolete.

F.38.1.4. Remote Execution Options

By default, only WHERE clauses using built-in operators and functions will be considered for execution on the remote server. Clauses involving non-built-in functions are checked locally after rows are fetched. If such functions are available on the remote server and can be relied on to produce the same results as
they do locally, performance can be improved by sending such WHERE clauses for remote execution. This behavior can be controlled using the following option:

extensions (string)

This option is a comma-separated list of names of PostgreSQL extensions that are installed, in compatible versions, on both the local and remote servers. Functions and operators that are immutable and belong to a listed extension will be considered shippable to the remote server. This option can only be specified for foreign servers, not per-table.

When using the extensions option, it is the user's responsibility that the listed extensions exist and behave identically on both the local and remote servers. Otherwise, remote queries may fail or behave unexpectedly.

fetch_size (integer)

This option specifies the number of rows postgres_fdw should get in each fetch operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 100.

batch_size (integer)

This option specifies the number of rows postgres_fdw should insert in each insert operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 1.

Note the actual number of rows postgres_fdw inserts at once depends on the number of columns and the provided batch_size value. The batch is executed as a single query, and the libpq protocol (which postgres_fdw uses to connect to a remote server) limits the number of parameters in a single query to 65535. When the number of columns * batch_size exceeds the limit, the batch_size will be adjusted to avoid an error.

F.38.1.5. Asynchronous Execution Options

postgres_fdw supports asynchronous execution, which runs multiple parts of an Append node concurrently rather than serially to improve performance. This execution can be controlled using the following option:

async_capable (boolean)

This option controls whether postgres_fdw allows foreign tables to be scanned concurrently for asynchronous execution. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is false.

In order to ensure that the data being returned from a foreign server is consistent, postgres_fdw will only open one connection for a given foreign server and will run all queries against that server sequentially even if there are multiple foreign tables involved, unless those tables are subject to different user mappings. In such a case, it may be more performant to disable this option to eliminate the overhead associated with running queries asynchronously.

Asynchronous execution is applied even when an Append node contains subplan(s) executed synchronously as well as subplan(s) executed asynchronously. In such a case, if the asynchronous subplans are ones processed using postgres_fdw, tuples from the asynchronous subplans are not returned until after at least one synchronous subplan returns all tuples, as that subplan is executed while
the asynchronous subplans are waiting for the results of asynchronous queries sent to foreign servers. This behavior might change in a future release.

F.38.1.6. Transaction Management Options

As described in the Transaction Management section, in `postgres_fdw` transactions are managed by creating corresponding remote transactions, and subtransactions are managed by creating corresponding remote subtransactions. When multiple remote transactions are involved in the current local transaction, by default `postgres_fdw` commits those remote transactions serially when the local transaction is committed. When multiple remote subtransactions are involved in the current local subtransaction, by default `postgres_fdw` commits those remote subtransactions serially when the local subtransaction is committed. Performance can be improved with the following option:

```
parallel_commit(boolean)
```

This option controls whether `postgres_fdw` commits in parallel remote transactions opened on a foreign server in a local transaction when the local transaction is committed. This setting also applies to remote and local subtransactions. This option can only be specified for foreign servers, not portable. The default is `false`.

If multiple foreign servers with this option enabled are involved in a local transaction, multiple remote transactions on those foreign servers are committed in parallel across those foreign servers when the local transaction is committed.

When this option is enabled, a foreign server with many remote transactions may see a negative performance impact when the local transaction is committed.

F.38.1.7. Updatability Options

By default all foreign tables using `postgres_fdw` are assumed to be updatable. This may be overridden using the following option:

```
updatable(boolean)
```

This option controls whether `postgres_fdw` allows foreign tables to be modified using `INSERT`, `UPDATE` and `DELETE` commands. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact updatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server. Note however that the `information_schema` views will report a `postgres_fdw` foreign table to be updatable (or not) according to the setting of this option, without any check of the remote server.

F.38.1.8. Truncatability Options

By default all foreign tables using `postgres_fdw` are assumed to be truncatable. This may be overridden using the following option:

```
truncatable(boolean)
```

This option controls whether `postgres_fdw` allows foreign tables to be truncated using the `TRUNCATE` command. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact truncatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server.
F.38.1.9. Importing Options

`postgres_fdw` is able to import foreign table definitions using `IMPORT FOREIGN SCHEMA`. This command creates foreign table definitions on the local server that match tables or views present on the remote server. If the remote tables to be imported have columns of user-defined data types, the local server must have compatible types of the same names.

Importing behavior can be customized with the following options (given in the `IMPORT FOREIGN SCHEMA` command):

`import_collate(boolean)`

This option controls whether column `COLLATE` options are included in the definitions of foreign tables imported from a foreign server. The default is `true`. You might need to turn this off if the remote server has a different set of collation names than the local server does, which is likely to be the case if it's running on a different operating system. If you do so, however, there is a very severe risk that the imported table columns' collations will not match the underlying data, resulting in anomalous query behavior.

Even when this parameter is set to `true`, importing columns whose collation is the remote server's default can be risky. They will be imported with `COLLATE "default"`, which will select the local server's default collation, which could be different.

`import_default(boolean)`

This option controls whether column `DEFAULT` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `false`. If you enable this option, be wary of defaults that might get computed differently on the local server than they would be on the remote server; `nextval()` is a common source of problems. The `IMPORT` will fail altogether if an imported default expression uses a function or operator that does not exist locally.

`import_generated(boolean)`

This option controls whether column `GENERATED` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `true`. The `IMPORT` will fail altogether if an imported generated expression uses a function or operator that does not exist locally.

`import_not_null(boolean)`

This option controls whether column `NOT NULL` constraints are included in the definitions of foreign tables imported from a foreign server. The default is `true`.

Note that constraints other than `NOT NULL` will never be imported from the remote tables. Although PostgreSQL does support check constraints on foreign tables, there is no provision for importing them automatically, because of the risk that a constraint expression could evaluate differently on the local and remote servers. Any such inconsistency in the behavior of a check constraint could lead to hard-to-detect errors in query optimization. So if you wish to import check constraints, you must do so manually, and you should verify the semantics of each one carefully. For more detail about the treatment of check constraints on foreign tables, see `CREATE FOREIGN TABLE`.

Tables or foreign tables which are partitions of some other table are imported only when they are explicitly specified in `LIMIT TO` clause. Otherwise they are automatically excluded from `IMPORT FOREIGN SCHEMA`. Since all data can be accessed through the partitioned table which is the root of the partitioning hierarchy, importing only partitioned tables should allow access to all the data without creating extra objects.
F.38.1.10. Connection Management Options

By default, all connections that postgres_fdw establishes to foreign servers are kept open in the local session for re-use.

`keep_connections (boolean)`

This option controls whether postgres_fdw keeps the connections to the foreign server open so that subsequent queries can re-use them. It can only be specified for a foreign server. The default is on. If set to off, all connections to this foreign server will be discarded at the end of each transaction.

F.38.2. Functions

`postgres_fdw_get_connections(OUT server_name text, OUT valid boolean)` returns setof record

This function returns the foreign server names of all the open connections that postgres_fdw established from the local session to the foreign servers. It also returns whether each connection is valid or not. false is returned if the foreign server connection is used in the current local transaction but its foreign server or user mapping is changed or dropped (Note that server name of an invalid connection will be NULL if the server is dropped), and then such invalid connection will be closed at the end of that transaction. true is returned otherwise. If there are no open connections, no record is returned. Example usage of the function:

```sql
postgres=# SELECT * FROM postgres_fdw_get_connections() ORDER BY 1;
server_name | valid
-------------+-------
loopback1    | t
loopback2    | f
```

`postgres_fdw_disconnect(server_name text) returns boolean`

This function discards the open connections that are established by postgres_fdw from the local session to the foreign server with the given name. Note that there can be multiple connections to the given server using different user mappings. If the connections are used in the current local transaction, they are not disconnected and warning messages are reported. This function returns true if it disconnects at least one connection, otherwise false. If no foreign server with the given name is found, an error is reported. Example usage of the function:

```sql
postgres=# SELECT postgres_fdw_disconnect('loopback1');
postgres_fdw_disconnect
-------------------------
t
```

`postgres_fdw_disconnect_all() returns boolean`

This function discards all the open connections that are established by postgres_fdw from the local session to foreign servers. If the connections are used in the current local transaction, they are not disconnected and warning messages are reported. This function returns true if it disconnects at least one connection, otherwise false. Example usage of the function:

```sql
postgres=# SELECT postgres_fdw_disconnect_all();
```
**F.38.3. Connection Management**

`postgres_fdw` establishes a connection to a foreign server during the first query that uses a foreign table associated with the foreign server. By default this connection is kept and re-used for subsequent queries in the same session. This behavior can be controlled using `keep_connections` option for a foreign server. If multiple user identities (user mappings) are used to access the foreign server, a connection is established for each user mapping.

When changing the definition of or removing a foreign server or a user mapping, the associated connections are closed. But note that if any connections are in use in the current local transaction, they are kept until the end of the transaction. Closed connections will be re-established when they are necessary by future queries using a foreign table.

Once a connection to a foreign server has been established, it's by default kept until the local or corresponding remote session exits. To disconnect a connection explicitly, `keep_connections` option for a foreign server may be disabled, or `postgres_fdw_disconnect` and `postgres_fdw_disconnect_all` functions may be used. For example, these are useful to close connections that are no longer necessary, thereby releasing connections on the foreign server.

**F.38.4. Transaction Management**

During a query that references any remote tables on a foreign server, `postgres_fdw` opens a transaction on the remote server if one is not already open corresponding to the current local transaction. The remote transaction is committed or aborted when the local transaction commits or aborts. Savepoints are similarly managed by creating corresponding remote savepoints.

The remote transaction uses `SERIALIZABLE` isolation level when the local transaction has `SERIALIZABLE` isolation level; otherwise it uses `REPEATABLE READ` isolation level. This choice ensures that if a query performs multiple table scans on the remote server, it will get snapshot-consistent results for all the scans. A consequence is that successive queries within a single transaction will see the same data from the remote server, even if concurrent updates are occurring on the remote server due to other activities. That behavior would be expected anyway if the local transaction uses `SERIALIZABLE` or `REPEATABLE READ` isolation level, but it might be surprising for a `READ COMMITTED` local transaction. A future PostgreSQL release might modify these rules.

Note that it is currently not supported by `postgres_fdw` to prepare the remote transaction for two-phase commit.

**F.38.5. Remote Query Optimization**

`postgres_fdw` attempts to optimize remote queries to reduce the amount of data transferred from foreign servers. This is done by sending query `WHERE` clauses to the remote server for execution, and by not retrieving table columns that are not needed for the current query. To reduce the risk of misexecution of queries, `WHERE` clauses are not sent to the remote server unless they use only data types, operators, and functions that are built-in or belong to an extension that's listed in the foreign server's `extensions` option. Operators and functions in such clauses must be `IMMUTABLE` as well. For an `UPDATE` or `DELETE` query, `postgres_fdw` attempts to optimize the query execution by sending the whole query to the remote server if there are no query `WHERE` clauses that cannot be sent to the remote server, no local joins for the query, no row-level local `BEFORE` or `AFTER` triggers or stored generated columns on the target
table, and no \texttt{CHECK} \texttt{OPTION} constraints from parent views. In \texttt{UPDATE}, expressions to assign to target columns must use only built-in data types, \texttt{IMMUTABLE} operators, or \texttt{IMMUTABLE} functions, to reduce the risk of misexecution of the query.

When \texttt{postgres_fdw} encounters a join between foreign tables on the same foreign server, it sends the entire join to the foreign server, unless for some reason it believes that it will be more efficient to fetch rows from each table individually, or unless the table references involved are subject to different user mappings. While sending the \texttt{JOIN} clauses, it takes the same precautions as mentioned above for the \texttt{WHERE} clauses.

The query that is actually sent to the remote server for execution can be examined using \texttt{EXPLAIN \textit{VERBOSE}}.

\textbf{F.38.6. Remote Query Execution Environment}

In the remote sessions opened by \texttt{postgres_fdw}, the \texttt{search_path} parameter is set to just \texttt{pg_catalog}, so that only built-in objects are visible without schema qualification. This is not an issue for queries generated by \texttt{postgres_fdw} itself, because it always supplies such qualification. However, this can pose a hazard for functions that are executed on the remote server via triggers or rules on remote tables. For example, if a remote table is actually a view, any functions used in that view will be executed with the restricted search path. It is recommended to schema-qualify all names in such functions, or else attach \texttt{SET search_path} options (see \texttt{CREATE FUNCTION}) to such functions to establish their expected search path environment.

\texttt{postgres_fdw} likewise establishes remote session settings for various parameters:

\begin{itemize}
  \item \texttt{TimeZone} is set to \texttt{UTC}
  \item \texttt{DateStyle} is set to \texttt{ISO}
  \item \texttt{IntervalStyle} is set to \texttt{postgres}
  \item extra\texttt{float_digits} is set to 3 for remote servers 9.0 and newer and is set to 2 for older versions
\end{itemize}

These are less likely to be problematic than \texttt{search_path}, but can be handled with function \texttt{SET} options if the need arises.

It is \textit{not} recommended that you override this behavior by changing the session-level settings of these parameters; that is likely to cause \texttt{postgres_fdw} to malfunction.

\textbf{F.38.7. Cross-Version Compatibility}

\texttt{postgres_fdw} can be used with remote servers dating back to PostgreSQL 8.3. Read-only capability is available back to 8.1. A limitation however is that \texttt{postgres_fdw} generally assumes that immutable built-in functions and operators are safe to send to the remote server for execution, if they appear in a \texttt{WHERE} clause for a foreign table. Thus, a built-in function that was added since the remote server's release might be sent to it for execution, resulting in “function does not exist” or a similar error. This type of failure can be worked around by rewriting the query, for example by embedding the foreign table reference in a \texttt{sub-SELECT} with \texttt{OFFSET 0} as an optimization fence, and placing the problematic function or operator outside the \texttt{sub-SELECT}.

\textbf{F.38.8. Configuration Parameters}

\begin{verbatim}
postgres_fdw.application_name(string)
\end{verbatim}

Specifies a value for application\_name configuration parameter used when \texttt{postgres_fdw} establishes a connection to a foreign server. This overrides application\_name option of the server
Additional Supplied Modules

object. Note that change of this parameter doesn’t affect any existing connections until they are re-established.

`postgres_fdw.application_name` can be any string of any length and contain even non-ASCII characters. However when it’s passed to and used as `application_name` in a foreign server, note that it will be truncated to less than `NAMEDATALEN` characters and anything other than printable ASCII characters will be replaced with question marks (?). See `application_name` for details.

% characters begin “escape sequences” that are replaced with status information as outlined below. Unrecognized escapes are ignored. Other characters are copied straight to the application name. Note that it’s not allowed to specify a plus/minus sign or a numeric literal after the % and before the option, for alignment and padding.

<table>
<thead>
<tr>
<th>Escape</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>%a</td>
<td>Application name on local server</td>
</tr>
<tr>
<td>%c</td>
<td>Session ID on local server (see <code>log_line_prefix</code> for details)</td>
</tr>
<tr>
<td>%C</td>
<td>Cluster name on local server (see <code>cluster_name</code> for details)</td>
</tr>
<tr>
<td>%u</td>
<td>User name on local server</td>
</tr>
<tr>
<td>%d</td>
<td>Database name on local server</td>
</tr>
<tr>
<td>%p</td>
<td>Process ID of backend on local server</td>
</tr>
<tr>
<td>%%</td>
<td>Literal %</td>
</tr>
</tbody>
</table>

For example, suppose user `local_user` establishes a connection from database `local_db` to `foreign_db` as user `foreign_user`, the setting `'db=%d, user=%u'` is replaced with `'db=local_db, user=local_user'`.

**F.38.9. Examples**

Here is an example of creating a foreign table with `postgres_fdw`. First install the extension:

```sql
CREATE EXTENSION postgres_fdw;
```

Then create a foreign server using `CREATE SERVER`. In this example we wish to connect to a PostgreSQL server on host `192.83.123.89` listening on port `5432`. The database to which the connection is made is named `foreign_db` on the remote server:

```sql
CREATE SERVER foreign_server
    FOREIGN DATA WRAPPER postgres_fdw
    OPTIONS (host '192.83.123.89', port '5432', dbname 'foreign_db');
```

A user mapping, defined with `CREATE USER MAPPING`, is needed as well to identify the role that will be used on the remote server:

```sql
CREATE USER MAPPING FOR local_user
    SERVER foreign_server
    OPTIONS (user 'foreign_user', password 'password');
```
Now it is possible to create a foreign table with `CREATE FOREIGN TABLE`. In this example we wish to access the table named `some_schema.some_table` on the remote server. The local name for it will be `foreign_table`:

```sql
CREATE FOREIGN TABLE foreign_table (  
id integer NOT NULL,  
data text
)
  SERVER foreign_server
  OPTIONS (schema_name 'some_schema', table_name 'some_table');
```

It's essential that the data types and other properties of the columns declared in `CREATE FOREIGN TABLE` match the actual remote table. Column names must match as well, unless you attach `column_name` options to the individual columns to show how they are named in the remote table. In many cases, use of `IMPORT FOREIGN SCHEMA` is preferable to constructing foreign table definitions manually.

### F.38.10. Author

Shigeru Hanada <shigeru.hanada@gmail.com>

### F.39. seg

This module implements a data type `seg` for representing line segments, or floating point intervals. `seg` can represent uncertainty in the interval endpoints, making it especially useful for representing laboratory measurements.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.39.1. Rationale

The geometry of measurements is usually more complex than that of a point in a numeric continuum. A measurement is usually a segment of that continuum with somewhat fuzzy limits. The measurements come out as intervals because of uncertainty and randomness, as well as because the value being measured may naturally be an interval indicating some condition, such as the temperature range of stability of a protein.

Using just common sense, it appears more convenient to store such data as intervals, rather than pairs of numbers. In practice, it even turns out more efficient in most applications.

Further along the line of common sense, the fuzziness of the limits suggests that the use of traditional numeric data types leads to a certain loss of information. Consider this: your instrument reads 6.50, and you input this reading into the database. What do you get when you fetch it? Watch:

```sql
test=> select 6.50 :: float8 as "pH";
   pH
---
   6.5
(1 row)
```

In the world of measurements, 6.50 is not the same as 6.5. It may sometimes be critically different. The experimenters usually write down (and publish) the digits they trust. 6.50 is actually a fuzzy interval
contained within a bigger and even fuzzier interval, 6.5, with their center points being (probably) the only common feature they share. We definitely do not want such different data items to appear the same.

Conclusion? It is nice to have a special data type that can record the limits of an interval with arbitrarily variable precision. Variable in the sense that each data element records its own precision.

Check this out:

```
test=> select '6.25 .. 6.50'::seg as "pH";

       pH
  ------------
    6.25 .. 6.50

(1 row)
```

### F.39.2. Syntax

The external representation of an interval is formed using one or two floating-point numbers joined by the range operator (.. or ...). Alternatively, it can be specified as a center point plus or minus a deviation. Optional certainty indicators (<, > or ~) can be stored as well. (Certainty indicators are ignored by all the built-in operators, however.) Table F.26 gives an overview of allowed representations; Table F.27 shows some examples.

In Table F.26, \( x \), \( y \), and \( \delta \) denote floating-point numbers. \( x \) and \( y \), but not \( \delta \), can be preceded by a certainty indicator.

**Table F.26. seg External Representations**

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( x )</td>
<td>Single value (zero-length interval)</td>
</tr>
<tr>
<td>( x .. y )</td>
<td>Interval from ( x ) to ( y )</td>
</tr>
<tr>
<td>( x \ (\pm) \delta )</td>
<td>Interval from ( x - \delta ) to ( x + \delta )</td>
</tr>
<tr>
<td>( x .. )</td>
<td>Open interval with lower bound ( x )</td>
</tr>
<tr>
<td>( .. x )</td>
<td>Open interval with upper bound ( x )</td>
</tr>
</tbody>
</table>

**Table F.27. Examples of Valid seg Input**

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.0</td>
<td>Creates a zero-length segment (a point, if you will)</td>
</tr>
<tr>
<td>~5.0</td>
<td>Creates a zero-length segment and records ~ in the data. ~ is ignored by seg operations, but is preserved as a comment.</td>
</tr>
<tr>
<td>&lt;5.0</td>
<td>Creates a point at 5.0. &lt; is ignored but is preserved as a comment.</td>
</tr>
<tr>
<td>&gt;5.0</td>
<td>Creates a point at 5.0. &gt; is ignored but is preserved as a comment.</td>
</tr>
<tr>
<td>5(\pm)0.3</td>
<td>Creates an interval 4.7 .. 5.3. Note that the (\pm) notation isn't preserved.</td>
</tr>
<tr>
<td>50 ..</td>
<td>Everything that is greater than or equal to 50</td>
</tr>
<tr>
<td>.. 0</td>
<td>Everything that is less than or equal to 0</td>
</tr>
<tr>
<td>1.5e-2 .. 2E-2</td>
<td>Creates an interval 0.015 .. 0.02</td>
</tr>
<tr>
<td>1 ... 2</td>
<td>The same as 1..2, or 1 .. 2, or 1..2 (spaces around the range operator are ignored)</td>
</tr>
</tbody>
</table>

Because the ... operator is widely used in data sources, it is allowed as an alternative spelling of the .. operator. Unfortunately, this creates a parsing ambiguity: it is not clear whether the upper bound in
0...23 is meant to be 23 or 0.23. This is resolved by requiring at least one digit before the decimal point in all numbers in seg input.

As a sanity check, seg rejects intervals with the lower bound greater than the upper, for example 5 .. 2.

**F.39.3. Precision**

seg values are stored internally as pairs of 32-bit floating point numbers. This means that numbers with more than 7 significant digits will be truncated.

Numbers with 7 or fewer significant digits retain their original precision. That is, if your query returns 0.00, you will be sure that the trailing zeroes are not the artifacts of formatting: they reflect the precision of the original data. The number of leading zeroes does not affect precision: the value 0.0067 is considered to have just 2 significant digits.

**F.39.4. Usage**

The seg module includes a GiST index operator class for seg values. The operators supported by the GiST operator class are shown in Table F.28.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>seg &lt;&lt; seg</code> → boolean</td>
<td>Is the first seg entirely to the left of the second? <code>[a, b] &lt;&lt; [c, d]</code> is true if <code>b &lt; c</code>.</td>
</tr>
<tr>
<td><code>seg &gt;&gt; seg</code> → boolean</td>
<td>Is the first seg entirely to the right of the second? <code>[a, b] &gt;&gt; [c, d]</code> is true if <code>a &gt; d</code>.</td>
</tr>
<tr>
<td><code>seg &amp;&lt; seg</code> → boolean</td>
<td>Does the first seg not extend to the right of the second? <code>[a, b] &amp;&lt; [c, d]</code> is true if <code>b &lt;= d</code>.</td>
</tr>
<tr>
<td><code>seg &amp;&gt; seg</code> → boolean</td>
<td>Does the first seg not extend to the left of the second? <code>[a, b] &amp;&gt; [c, d]</code> is true if <code>a &gt;= c</code>.</td>
</tr>
<tr>
<td><code>seg = seg</code> → boolean</td>
<td>Are the two segs equal?</td>
</tr>
<tr>
<td><code>seg &amp;&amp; seg</code> → boolean</td>
<td>Do the two segs overlap?</td>
</tr>
<tr>
<td><code>seg @&gt; seg</code> → boolean</td>
<td>Does the first seg contain the second?</td>
</tr>
<tr>
<td><code>seg &lt;@ seg</code> → boolean</td>
<td>Is the first seg contained in the second?</td>
</tr>
</tbody>
</table>

In addition to the above operators, the usual comparison operators shown in Table 9.1 are available for type seg. These operators first compare `(a)` to `(c)`, and if these are equal, compare `(b)` to `(d)`. That results in reasonably good sorting in most cases, which is useful if you want to use ORDER BY with this type.

**F.39.5. Notes**

For examples of usage, see the regression test `sql/seg.sql`.  

---

2894
The mechanism that converts \((+-)\) to regular ranges isn't completely accurate in determining the number of significant digits for the boundaries. For example, it adds an extra digit to the lower boundary if the resulting interval includes a power of ten:

```
postgres=> select '10(+-)1'::seg as seg;
  seg
--------
  9.0 .. 11    -- should be: 9 .. 11
```

The performance of an R-tree index can largely depend on the initial order of input values. It may be very helpful to sort the input table on the `seg` column; see the script `sort-segments.pl` for an example.

### F.39.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (https://dsf.berkeley.edu/jmh/) for elucidating the gist of the GiST (http://gist.cs.berkeley.edu/). I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

### F.40. sepgsql

`sepgsql` is a loadable module that supports label-based mandatory access control (MAC) based on SELinux security policy.

**Warning**

The current implementation has significant limitations, and does not enforce mandatory access control for all actions. See Section F.40.7.

### F.40.1. Overview

This module integrates with SELinux to provide an additional layer of security checking above and beyond what is normally provided by PostgreSQL. From the perspective of SELinux, this module allows PostgreSQL to function as a user-space object manager. Each table or function access initiated by a DML query will be checked against the system security policy. This check is in addition to the usual SQL permissions checking performed by PostgreSQL.

SELinux access control decisions are made using security labels, which are represented by strings such as `system_u:object_r:sepgsql_table_t:s0`. Each access control decision involves two labels: the label of the subject attempting to perform the action, and the label of the object on which the operation is to be performed. Since these labels can be applied to any sort of object, access control decisions for objects stored within the database can be (and, with this module, are) subjected to the same general criteria used for objects of any other type, such as files. This design is intended to allow a centralized security policy to protect information assets independent of the particulars of how those assets are stored.

The `SECURITY LABEL` statement allows assignment of a security label to a database object.
F.40.2. Installation

sepgsql can only be used on Linux 2.6.28 or higher with SELinux enabled. It is not available on any other platform. You will also need libselinux 2.1.10 or higher and selinux-policy 3.9.13 or higher (although some distributions may backport the necessary rules into older policy versions).

The sestatus command allows you to check the status of SELinux. A typical display is:

$ sestatus
SELinux status: enabled
SELinuxfs mount: /selinux
Current mode: enforcing
Mode from config file: enforcing
Policy version: 24
Policy from config file: targeted

If SELinux is disabled or not installed, you must set that product up first before installing this module.

To build this module, include the option --with-selinux in your PostgreSQL configure command. Be sure that the libselinux-devel RPM is installed at build time.

To use this module, you must include sepgsql in the shared_preload_libraries parameter in postgresql.conf. The module will not function correctly if loaded in any other manner. Once the module is loaded, you should execute sepgsql.sql in each database. This will install functions needed for security label management, and assign initial security labels.

Here is an example showing how to initialize a fresh database cluster with sepgsql functions and security labels installed. Adjust the paths shown as appropriate for your installation:

$ export PGDATA=/path/to/data/directory
$ initdb
$ vi $PGDATA/postgresql.conf
    change
    #shared_preload_libraries = '' # (change requires restart)
    to
    shared_preload_libraries = 'sepgsql' # (change requires restart)
$ for DBNAME in template0 template1 postgres; do
    postgres --single -F -c exit_on_error=true $DBNAME \
        </usr/local/pgsql/share/contrib/sepgsql.sql >/dev/null
    done

Please note that you may see some or all of the following notifications depending on the particular versions you have of libselinux and selinux-policy:

/etc/selinux/targeted CONTEXTS/sepgsql_contexts: line 33 has invalid object type db_blobs
/etc/selinux/targeted CONTEXTS/sepgsql_contexts: line 36 has invalid object type db_language
/etc/selinux/targeted CONTEXTS/sepgsql_contexts: line 37 has invalid object type db_language
Additional Supplied Modules

/etc/selinux/targeted/contexts/sepgsql_contexts: line 38 has invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 39 has invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 40 has invalid object type db_language

These messages are harmless and should be ignored.

If the installation process completes without error, you can now start the server normally.

F.40.3. Regression Tests

Due to the nature of SELinux, running the regression tests for sepgsql requires several extra configuration steps, some of which must be done as root. The regression tests will not be run by an ordinary make check or make installcheck command; you must set up the configuration and then invoke the test script manually. The tests must be run in the contrib/sepgsql directory of a configured PostgreSQL build tree. Although they require a build tree, the tests are designed to be executed against an installed server, that is they are comparable to make installcheck not make check.

First, set up sepgsql in a working database according to the instructions in Section F.40.2. Note that the current operating system user must be able to connect to the database as superuser without password authentication.

Second, build and install the policy package for the regression test. The sepgsql-regtest policy is a special purpose policy package which provides a set of rules to be allowed during the regression tests. It should be built from the policy source file sepgsql-regtest.te, which is done using make with a Makefile supplied by SELinux. You will need to locate the appropriate Makefile on your system; the path shown below is only an example. (This Makefile is usually supplied by the selinux-policy-devel or selinux-policy RPM.) Once built, install this policy package using the semodule command, which loads supplied policy packages into the kernel. If the package is correctly installed, semodule -l should list sepgsql-regtest as an available policy package:

$ cd .../contrib/sepgsql
$ make -f /usr/share/selinux/devel/Makefile
$ sudo semodule -u sepgsql-regtest.pp
$ sudo semodule -l | grep sepgsql
sepgsql-regtest 1.07

Third, turn on sepgsql_regression_test_mode. For security reasons, the rules in sepgsql-regtest are not enabled by default; the sepgsql_regression_test_mode parameter enables the rules needed to launch the regression tests. It can be turned on using the setsebool command:

$ sudo setsebool sepgsql_regression_test_mode on
$ getsebool sepgsql_regression_test_mode
sepgsql_regression_test_mode --> on

Fourth, verify your shell is operating in the unconfined_t domain:

$ id -Z
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
See Section F.40.8 for details on adjusting your working domain, if necessary.

Finally, run the regression test script:

```bash
$ ./test_sepgsql
```

This script will attempt to verify that you have done all the configuration steps correctly, and then it will run the regression tests for the `sepgsql` module.

After completing the tests, it's recommended you disable the `sepgsql_regression_test_mode` parameter:

```bash
$ sudo setsebool sepgsql_regression_test_mode off
```

You might prefer to remove the `sepgsql-regtest` policy entirely:

```bash
$ sudo semodule -r sepgsql-regtest
```

### F.40.4. GUC Parameters

**sepgsql.permissive (boolean)**

This parameter enables `sepgsql` to function in permissive mode, regardless of the system setting. The default is off. This parameter can only be set in the `postgresql.conf` file or on the server command line.

When this parameter is on, `sepgsql` functions in permissive mode, even if SELinux in general is working in enforcing mode. This parameter is primarily useful for testing purposes.

**sepgsql.debug_audit (boolean)**

This parameter enables the printing of audit messages regardless of the system policy settings. The default is off, which means that messages will be printed according to the system settings.

The security policy of SELinux also has rules to control whether or not particular accesses are logged. By default, access violations are logged, but allowed accesses are not.

This parameter forces all possible logging to be turned on, regardless of the system policy.

### F.40.5. Features

#### F.40.5.1. Controlled Object Classes

The security model of SELinux describes all the access control rules as relationships between a subject entity (typically, a client of the database) and an object entity (such as a database object), each of which is identified by a security label. If access to an unlabeled object is attempted, the object is treated as if it were assigned the label `unlabeled_t`.

Currently, `sepgsql` allows security labels to be assigned to schemas, tables, columns, sequences, views, and functions. When `sepgsql` is in use, security labels are automatically assigned to supported database objects at creation time. This label is called a default security label, and is decided according to the system...
security policy, which takes as input the creator's label, the label assigned to the new object's parent object and optionally name of the constructed object.

A new database object basically inherits the security label of the parent object, except when the security policy has special rules known as type-transition rules, in which case a different label may be applied. For schemas, the parent object is the current database; for tables, sequences, views, and functions, it is the containing schema; for columns, it is the containing table.

**F.40.5.2. DML Permissions**

For tables, `db_table:select`, `db_table:insert`, `db_table:update` or `db_table:delete` are checked for all the referenced target tables depending on the kind of statement; in addition, `db_table:select` is also checked for all the tables that contain columns referenced in the `WHERE` or `RETURNING` clause, as a data source for `UPDATE`, and so on.

Column-level permissions will also be checked for each referenced column. `db_column:select` is checked on not only the columns being read using `SELECT`, but those being referenced in other DML statements; `db_column:update` or `db_column:insert` will also be checked for columns being modified by `UPDATE` or `INSERT`.

For example, consider:

```
UPDATE t1 SET x = 2, y = func1(y) WHERE z = 100;
```

Here, `db_column:update` will be checked for `t1.x`, since it is being updated, `db_column:{select update}` will be checked for `t1.y`, since it is both updated and referenced, and `db_column:select` will be checked for `t1.z`, since it is only referenced. `db_table:{select update}` will also be checked at the table level.

For sequences, `db_sequence:get_value` is checked when we reference a sequence object using `SELECT`; however, note that we do not currently check permissions on execution of corresponding functions such as `lastval()`.

For views, `db_view:expand` will be checked, then any other required permissions will be checked on the objects being expanded from the view, individually.

For functions, `db_procedure:{execute}` will be checked when user tries to execute a function as a part of query, or using fast-path invocation. If this function is a trusted procedure, it also checks `db_procedure:{entrypoint}` permission to check whether it can perform as entry point of trusted procedure.

In order to access any schema object, `db_schema:search` permission is required on the containing schema. When an object is referenced without schema qualification, schemas on which this permission is not present will not be searched (just as if the user did not have `USAGE` privilege on the schema). If an explicit schema qualification is present, an error will occur if the user does not have the requisite permission on the named schema.

The client must be allowed to access all referenced tables and columns, even if they originated from views which were then expanded, so that we apply consistent access control rules independent of the manner in which the table contents are referenced.

The default database privilege system allows database superusers to modify system catalogs using DML commands, and reference or modify toast tables. These operations are prohibited when `sepgsql` is enabled.
F.40.5.3. DDL Permissions

SELinux defines several permissions to control common operations for each object type; such as creation, alter, drop and relabel of security label. In addition, several object types have special permissions to control their characteristic operations; such as addition or deletion of name entries within a particular schema.

Creating a new database object requires create permission. SELinux will grant or deny this permission based on the client's security label and the proposed security label for the new object. In some cases, additional privileges are required:

- CREATE DATABASE additionally requires getattr permission for the source or template database.

- Creating a schema object additionally requires add_name permission on the parent schema.

- Creating a table additionally requires permission to create each individual table column, just as if each table column were a separate top-level object.

- Creating a function marked as LEAKPROOF additionally requires install permission. (This permission is also checked when LEAKPROOF is set for an existing function.)

When DROP command is executed, drop will be checked on the object being removed. Permissions will be also checked for objects dropped indirectly via CASCADE. Deletion of objects contained within a particular schema (tables, views, sequences and procedures) additionally requires remove_name on the schema.

When ALTER command is executed, setattr will be checked on the object being modified for each object types, except for subsidiary objects such as the indexes or triggers of a table, where permissions are instead checked on the parent object. In some cases, additional permissions are required:

- Moving an object to a new schema additionally requires remove_name permission on the old schema and add_name permission on the new one.

- Setting the LEAKPROOF attribute on a function requires install permission.

- Using SECURITY LABEL on an object additionally requires relabelfrom permission for the object in conjunction with its old security label and relabelto permission for the object in conjunction with its new security label. (In cases where multiple label providers are installed and the user tries to set a security label, but it is not managed by SELinux, only setattr should be checked here. This is currently not done due to implementation restrictions.)

F.40.5.4. Trusted Procedures

Trusted procedures are similar to security definer functions or setuid commands. SELinux provides a feature to allow trusted code to run using a security label different from that of the client, generally for the purpose of providing highly controlled access to sensitive data (e.g., rows might be omitted, or the precision of stored values might be reduced). Whether or not a function acts as a trusted procedure is controlled by its security label and the operating system security policy. For example:

```
postgres=# CREATE TABLE customer (  
    cid     int primary key,  
    cname   text,  
    credit  text  
);  
CREATE TABLE  
postgres=# SECURITY LABEL ON COLUMN customer.credit  
IS 'system_u:object_r:sepgsql_secret_table_t:s0';
```
SECURITY LABEL
postgres=# CREATE FUNCTION show_credit(int) RETURNS text
AS 'SELECT regexp_replace(credit, '^[0-9]+', 'xxxx')
FROM customer WHERE cid = $1'
LANGUAGE sql;
CREATE FUNCTION
postgres=# SECURITY LABEL ON FUNCTION show_credit(int)
IS 'system_u:object_r:sepgsql_trusted_proc_exec_t:s0';
SECURITY LABEL

The above operations should be performed by an administrative user.

postgres=# SELECT * FROM customer;
ERROR:  SELinux: security policy violation
postgres=# SELECT cid, cname, show_credit(cid) FROM customer;
cid | cname   | show_credit
-----+---------+---------------------
1   | taro    | 1111-2222-3333-xxxx
2   | hanako  | 5555-6666-7777-xxxx
(2 rows)

In this case, a regular user cannot reference customer.credit directly, but a trusted procedure show_credit allows the user to print the credit card numbers of customers with some of the digits masked out.

F.40.5.5. Dynamic Domain Transitions

It is possible to use SELinux's dynamic domain transition feature to switch the security label of the client process, the client domain, to a new context, if that is allowed by the security policy. The client domain needs the setcurrent permission and also dyntransition from the old to the new domain.

Dynamic domain transitions should be considered carefully, because they allow users to switch their label, and therefore their privileges, at their option, rather than (as in the case of a trusted procedure) as mandated by the system. Thus, the dyntransition permission is only considered safe when used to switch to a domain with a smaller set of privileges than the original one. For example:

regression=# select sepgsql_getcon();
sepgsql_getcon
------------------------------------------
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
(1 row)
regression=# SELECT
  sepgsql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-s0:c1.c4');
sepgsql_setcon
-------------
t
(1 row)
regression=# SELECT
  sepgsql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-s0:c1.c1023');

2901
Additional Supplied Modules

ERROR: SELinux: security policy violation

In this example above we were allowed to switch from the larger MCS range c1.c1023 to the smaller range c1.c4, but switching back was denied.

A combination of dynamic domain transition and trusted procedure enables an interesting use case that fits the typical process life-cycle of connection pooling software. Even if your connection pooling software is not allowed to run most of SQL commands, you can allow it to switch the security label of the client using the sepgsql_setcon() function from within a trusted procedure; that should take some credential to authorize the request to switch the client label. After that, this session will have the privileges of the target user, rather than the connection pooler. The connection pooler can later revert the security label change by again using sepgsql_setcon() with NULL argument, again invoked from within a trusted procedure with appropriate permissions checks. The point here is that only the trusted procedure actually has permission to change the effective security label, and only does so when given proper credentials. Of course, for secure operation, the credential store (table, procedure definition, or whatever) must be protected from unauthorized access.

F.40.5.6. Miscellaneous

We reject the LOAD command across the board, because any module loaded could easily circumvent security policy enforcement.

F.40.6. Sepgsql Functions

Table F.29 shows the available functions.

Table F.29. Sepgsql Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sepgsql_getcon() → text</td>
<td>Returns the client domain, the current security label of the client.</td>
</tr>
<tr>
<td>sepgsql_setcon(text) → boolean</td>
<td>Switches the client domain of the current session to the new domain, if allowed by the security policy. It also accepts NULL input as a request to transition to the client's original domain.</td>
</tr>
<tr>
<td>sepgsql_mcstrans_in(text) → text</td>
<td>Translates the given qualified MLS/MCS range into raw format if the mcstrans daemon is running.</td>
</tr>
<tr>
<td>sepgsql_mcstrans_out(text) → text</td>
<td>Translates the given raw MLS/MCS range into qualified format if the mcstrans daemon is running.</td>
</tr>
<tr>
<td>sepgsql_restorecon(text) → boolean</td>
<td>Sets up initial security labels for all objects within the current database. The argument may be NULL, or the name of a specfile to be used as alternative of the system default.</td>
</tr>
</tbody>
</table>

F.40.7. Limitations

Data Definition Language (DDL) Permissions

Due to implementation restrictions, some DDL operations do not check permissions.
Data Control Language (DCL) Permissions

Due to implementation restrictions, DCL operations do not check permissions.

Row-level access control

PostgreSQL supports row-level access, but sepgsql does not.

Covert channels

sepgsql does not try to hide the existence of a certain object, even if the user is not allowed to reference it. For example, we can infer the existence of an invisible object as a result of primary key conflicts, foreign key violations, and so on, even if we cannot obtain the contents of the object. The existence of a top secret table cannot be hidden; we only hope to conceal its contents.

This document provides a wide spectrum of knowledge to administer SELinux on your systems. It focuses primarily on Red Hat operating systems, but is not limited to them.

Fedora SELinux FAQ

This document answers frequently asked questions about SELinux. It focuses primarily on Fedora, but is not limited to Fedora.

F.40.9. Author

KaiGai Kohei <kaigai@ak.jp.nec.com>

F.41. spi

The spi module provides several workable examples of using the Server Programming Interface (SPI) and triggers. While these functions are of some value in their own right, they are even more useful as examples to modify for your own purposes. The functions are general enough to be used with any table, but you have to specify table and field names (as described below) while creating a trigger.

Each of the groups of functions described below is provided as a separately-installable extension.

F.41.1. refint — Functions for Implementing Referential Integrity

check_primary_key() and check_foreign_key() are used to check foreign key constraints. (This functionality is long since superseded by the built-in foreign key mechanism, of course, but the module is still useful as an example.)

6 https://wiki.postgresql.org/wiki/SEPostgreSQL
7 https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/7/html/selinux_users_and_administrators_guide/index
8 https://fedoraproject.org/wiki/SELinux_FAQ
check_primary_key() checks the referencing table. To use, create a BEFORE INSERT OR UPDATE trigger using this function on a table referencing another table. Specify as the trigger arguments: the referencing table's column name(s) which form the foreign key, the referenced table name, and the column names in the referenced table which form the primary/unique key. To handle multiple foreign keys, create a trigger for each reference.

check_foreign_key() checks the referenced table. To use, create a BEFORE DELETE OR UPDATE trigger using this function on a table referenced by other table(s). Specify as the trigger arguments: the number of referencing tables for which the function has to perform checking, the action if a referencing key is found (cascade — to delete the referencing row, restrict — to abort transaction if referencing keys exist, setnull — to set referencing key fields to null), the triggered table's column names which form the primary/unique key, then the referencing table name and column names (repeated for as many referencing tables as were specified by first argument). Note that the primary/unique key columns should be marked NOT NULL and should have a unique index.

There are examples in refint.example.

F.41.2. autoinc — Functions for Autoincrementing Fields

autoinc() is a trigger that stores the next value of a sequence into an integer field. This has some overlap with the built-in “serial column” feature, but it is not the same: autoinc() will override attempts to substitute a different field value during inserts, and optionally it can be used to increment the field during updates, too.

To use, create a BEFORE INSERT (or optionally BEFORE INSERT OR UPDATE) trigger using this function. Specify two trigger arguments: the name of the integer column to be modified, and the name of the sequence object that will supply values. (Actually, you can specify any number of pairs of such names, if you’d like to update more than one autoincrementing column.)

There is an example in autoinc.example.

F.41.3. insert_username — Functions for Tracking Who Changed a Table

insert_username() is a trigger that stores the current user's name into a text field. This can be useful for tracking who last modified a particular row within a table.

To use, create a BEFORE INSERT and/or UPDATE trigger using this function. Specify a single trigger argument: the name of the text column to be modified.

There is an example in insert_username.example.

F.41.4. moddatetime — Functions for Tracking Last Modification Time

moddatetime() is a trigger that stores the current time into a timestamp field. This can be useful for tracking the last modification time of a particular row within a table.

To use, create a BEFORE UPDATE trigger using this function. Specify a single trigger argument: the name of the column to be modified. The column must be of type timestamp or timestamp with time zone.

There is an example in moddatetime.example.
Additional Supplied Modules

F.42. sslinfo

The sslinfo module provides information about the SSL certificate that the current client provided when connecting to PostgreSQL. The module is useless (most functions will return NULL) if the current connection does not use SSL.

Some of the information available through this module can also be obtained using the built-in system view `pg_stat_ssl`.

This extension won't build at all unless the installation was configured with `--with-ssl=openssl`.

F.42.1. Functions Provided

- `ssl_is_used()` returns boolean
  
  Returns true if current connection to server uses SSL, and false otherwise.

- `ssl_version()` returns text
  
  Returns the name of the protocol used for the SSL connection (e.g., TLSv1.0, TLSv1.1, TLSv1.2 or TLSv1.3).

- `ssl_cipher()` returns text
  
  Returns the name of the cipher used for the SSL connection (e.g., DHE-RSA-AES256-SHA).

- `ssl_client_cert_present()` returns boolean
  
  Returns true if current client has presented a valid SSL client certificate to the server, and false otherwise. (The server might or might not be configured to require a client certificate.)

- `ssl_client_serial()` returns numeric
  
  Returns serial number of current client certificate. The combination of certificate serial number and certificate issuer is guaranteed to uniquely identify a certificate (but not its owner — the owner ought to regularly change their keys, and get new certificates from the issuer).

  So, if you run your own CA and allow only certificates from this CA to be accepted by the server, the serial number is the most reliable (albeit not very mnemonic) means to identify a user.

- `ssl_client_dn()` returns text
  
  Returns the full subject of the current client certificate, converting character data into the current database encoding. It is assumed that if you use non-ASCII characters in the certificate names, your database is able to represent these characters, too. If your database uses the SQL_ASCII encoding, non-ASCII characters in the name will be represented as UTF-8 sequences.

  The result looks like `/CN=Somebody /C=Some country/O=Some organization`.

- `ssl_issuer_dn()` returns text
  
  Returns the full issuer name of the current client certificate, converting character data into the current database encoding. Encoding conversions are handled the same as for `ssl_client_dn`.

  The combination of the return value of this function with the certificate serial number uniquely identifies the certificate.
This function is really useful only if you have more than one trusted CA certificate in your server's certificate authority file, or if this CA has issued some intermediate certificate authority certificates.

```plaintext
ssl_client_dn_field(fieldname text) returns text
```

This function returns the value of the specified field in the certificate subject, or NULL if the field is not present. Field names are string constants that are converted into ASN1 object identifiers using the OpenSSL object database. The following values are acceptable:

- commonName (alias CN)
- surname (alias SN)
- name
- givenName (alias GN)
- countryName (alias C)
- localityName (alias L)
- stateOrProvinceName (alias ST)
- organizationName (alias O)
- organizationalUnitName (alias OU)
- title
- description
- initials
- postalCode
- streetAddress
- generationQualifier
- description
- dnQualifier
- x500UniqueIdentifier
- pseudonym
- role
- emailAddress

All of these fields are optional, except `commonName`. It depends entirely on your CA's policy which of them would be included and which wouldn't. The meaning of these fields, however, is strictly defined by the X.500 and X.509 standards, so you cannot just assign arbitrary meaning to them.

```plaintext
ssl_issuer_field(fieldname text) returns text
```

Same as `ssl_client_dn_field`, but for the certificate issuer rather than the certificate subject.

```plaintext
ssl_extension_info() returns setof record
```

Provide information about extensions of client certificate: extension name, extension value, and if it is a critical extension.

Dmitry Voronin <carriingfate92@yandex.ru>

E-Mail of Cryptocom OpenSSL development group: <openssl@cryptocom.ru>

**F.43. tablefunc**
The `tablefunc` module includes various functions that return tables (that is, multiple rows). These functions are useful both in their own right and as examples of how to write C functions that return multiple rows.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

**F.43.1. Functions Provided**

Table F.30 summarizes the functions provided by the `tablefunc` module.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>normal_rand</code></td>
<td>Produces a set of normally distributed random values.</td>
</tr>
<tr>
<td><code>crosstab</code></td>
<td>Produces a “pivot table” containing row names plus $N$ value columns, where $N$ is determined by the row type specified in the calling query.</td>
</tr>
<tr>
<td><code>crosstabN</code></td>
<td>Produces a “pivot table” containing row names plus $N$ value columns. <code>crosstab2</code>, <code>crosstab3</code>, and <code>crosstab4</code> are predefined, but you can create additional <code>crosstabN</code> functions as described below.</td>
</tr>
<tr>
<td><code>crosstab</code></td>
<td>Produces a “pivot table” with the value columns specified by a second query.</td>
</tr>
<tr>
<td><code>crosstab</code></td>
<td>Obsolete version of <code>crosstab(text)</code>. The parameter $N$ is now ignored, since the number of value columns is always determined by the calling query.</td>
</tr>
<tr>
<td><code>connectby</code></td>
<td>Produces a representation of a hierarchical tree structure.</td>
</tr>
</tbody>
</table>

**F.43.1.1. normal_rand**

`normal_rand(int numvals, float8 mean, float8 stddev) returns setof float8`

`normal_rand` produces a set of normally distributed random values (Gaussian distribution).

`numvals` is the number of values to be returned from the function. `mean` is the mean of the normal distribution of values and `stddev` is the standard deviation of the normal distribution of values.

For example, this call requests 1000 values with a mean of 5 and a standard deviation of 3:

```sql
test=# SELECT * FROM normal_rand(1000, 5, 3);
```
The `crosstab` function is used to produce “pivot” displays, wherein data is listed across the page rather than down. For example, we might have data like

```
row1    val11
row1    val12
row1    val13
...
row2    val21
row2    val22
row2    val23
...
```

which we wish to display like

```
row1    val11   val12   val13   ...
row2    val21   val22   val23   ...
...
```

The `crosstab` function takes a text parameter that is an SQL query producing raw data formatted in the first way, and produces a table formatted in the second way.

The `sql` parameter is an SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. `N` is an obsolete parameter, ignored if supplied (formerly this had to match the number of output value columns, but now that is determined by the calling query).

For example, the provided query might produce a set something like:

```
row_name    cat    value
----------+-------+-------
row1        cat1    val1
```
The crosstab function is declared to return setof record, so the actual names and types of the output columns must be defined in the FROM clause of the calling SELECT statement, for example:

```
SELECT * FROM crosstab('...' AS ct(row_name text, category_1 text, category_2 text);
```

This example produces a set something like:

```
<== value  columns  ==> 
row_name category_1 category_2
----------+------------+------------
row1    val1    val2
row2    val5    val6
```

The FROM clause must define the output as one row_name column (of the same data type as the first result column of the SQL query) followed by N value columns (all of the same data type as the third result column of the SQL query). You can set up as many output value columns as you wish. The names of the output columns are up to you.

The crosstab function produces one output row for each consecutive group of input rows with the same row_name value. It fills the output value columns, left to right, with the value fields from these rows. If there are fewer rows in a group than there are output value columns, the extra output columns are filled with nulls; if there are more rows, the extra input rows are skipped.

In practice the SQL query should always specify ORDER BY 1,2 to ensure that the input rows are properly ordered, that is, values with the same row_name are brought together and correctly ordered within the row. Notice that crosstab itself does not pay any attention to the second column of the query result; it's just there to be ordered by, to control the order in which the third-column values appear across the page.

Here is a complete example:

```
CREATE TABLE ct(id SERIAL, rowid TEXT, attribute TEXT, value TEXT);
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att1','val1');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att2','val2');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att3','val3');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att4','val4');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att1','val5');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att2','val6');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att3','val7');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att4','val8');
SELECT *
FROM crosstab(
    'select rowid, attribute, value
```
from ct
    where attribute = ''att2'' or attribute = ''att3''
    order by 1,2')
AS ct(row_name text, category_1 text, category_2 text, category_3
text);

row_name | category_1 | category_2 | category_3
----------+------------+------------+------------
test1    | val2       | val3       | |
test2    | val6       | val7       | |
(2 rows)

You can avoid always having to write out a FROM clause to define the output columns, by setting up a
custom crosstab function that has the desired output row type wired into its definition. This is described
in the next section. Another possibility is to embed the required FROM clause in a view definition.

Note

See also the \crosstabview command in psql, which provides functionality similar to
crosstab().

F.43.1.3. crosstabN(text)

crosstabN(text sql)

The crosstabN functions are examples of how to set up custom wrappers for the general crosstab
function, so that you need not write out column names and types in the calling SELECT query. The
tablefunc module includes crosstab2, crosstab3, and crosstab4, whose output row types
are defined as

CREATE TYPE tablefunc_crosstab_N AS {
    row_name TEXT,
    category_1 TEXT,
    category_2 TEXT,
    ...,
    category_N TEXT
};

Thus, these functions can be used directly when the input query produces row_name and value columns
of type text, and you want 2, 3, or 4 output values columns. In all other ways they behave exactly as
described above for the general crosstab function.

For instance, the example given in the previous section would also work as

SELECT *
FROM crosstab3(
    'select rowid, attribute, value
from ct
where attribute = 'att2' or attribute = 'att3'
order by 1,2);

These functions are provided mostly for illustration purposes. You can create your own return types and functions based on the underlying crosstab() function. There are two ways to do it:

• Create a composite type describing the desired output columns, similar to the examples in contrib/tablefunc/tablefunc--1.0.sql. Then define a unique function name accepting one text parameter and returning setof your_type_name, but linking to the same underlying crosstab C function. For example, if your source data produces row names that are text, and values that are float8, and you want 5 value columns:

CREATE TYPE my_crosstab_float8_5_cols AS (
    my_row_name text,
    my_category_1 float8,
    my_category_2 float8,
    my_category_3 float8,
    my_category_4 float8,
    my_category_5 float8
);

CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(text)
    RETURNS setof my_crosstab_float8_5_cols
    AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;

• Use OUT parameters to define the return type implicitly. The same example could also be done this way:

CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(
    IN text,
    OUT my_row_name text,
    OUT my_category_1 float8,
    OUT my_category_2 float8,
    OUT my_category_3 float8,
    OUT my_category_4 float8,
    OUT my_category_5 float8)
    RETURNS setof record
    AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;

F.43.1.4. crosstab(text, text)

crosstab(text source_sql, text category_sql)

The main limitation of the single-parameter form of crosstab is that it treats all values in a group alike, inserting each value into the first available column. If you want the value columns to correspond to specific categories of data, and some groups might not have data for some of the categories, that doesn't work well. The two-parameter form of crosstab handles this case by providing an explicit list of the categories corresponding to the output columns.

source_sql is an SQL statement that produces the source set of data. This statement must return one row_name column, one category column, and one value column. It may also have one or more “extra” columns. The row_name column must be first. The category and value columns must be the
last two columns, in that order. Any columns between row_name and category are treated as “extra”. The “extra” columns are expected to be the same for all rows with the same row_name value.

For example, source_sql might produce a set something like:

```
SELECT row_name, extra_col, cat, value FROM foo ORDER BY 1;
```

```
<table>
<thead>
<tr>
<th>row_name</th>
<th>extra_col</th>
<th>cat</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>row1</td>
<td>extra1</td>
<td>cat1</td>
<td>val1</td>
</tr>
<tr>
<td>row1</td>
<td>extra1</td>
<td>cat2</td>
<td>val2</td>
</tr>
<tr>
<td>row1</td>
<td>extra1</td>
<td>cat4</td>
<td>val4</td>
</tr>
<tr>
<td>row2</td>
<td>extra2</td>
<td>cat1</td>
<td>val5</td>
</tr>
<tr>
<td>row2</td>
<td>extra2</td>
<td>cat2</td>
<td>val6</td>
</tr>
<tr>
<td>row2</td>
<td>extra2</td>
<td>cat3</td>
<td>val7</td>
</tr>
<tr>
<td>row2</td>
<td>extra2</td>
<td>cat4</td>
<td>val8</td>
</tr>
</tbody>
</table>
```

category_sql is an SQL statement that produces the set of categories. This statement must return only one column. It must produce at least one row, or an error will be generated. Also, it must not produce duplicate values, or an error will be generated. category_sql might be something like:

```
SELECT DISTINCT cat FROM foo ORDER BY 1;
```

```
cat
---
cat1
cat2
cat3
cat4
```

The crosstab function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the FROM clause of the calling SELECT statement, for example:

```
SELECT * FROM crosstab('...', '...')
  AS ct(row_name text, extra text, cat1 text, cat2 text, cat3 text, cat4 text);
```

This will produce a result something like:

```
<== value columns ==>  
<table>
<thead>
<tr>
<th>row_name</th>
<th>extra</th>
<th>cat1</th>
<th>cat2</th>
<th>cat3</th>
<th>cat4</th>
</tr>
</thead>
<tbody>
<tr>
<td>row1</td>
<td>extra1</td>
<td>val1</td>
<td>val2</td>
<td></td>
<td>val4</td>
</tr>
<tr>
<td>row2</td>
<td>extra2</td>
<td>val5</td>
<td>val6</td>
<td>val7</td>
<td>val8</td>
</tr>
</tbody>
</table>
```

The FROM clause must define the proper number of output columns of the proper data types. If there are \( N \) columns in the source_sql query’s result, the first \( N-2 \) of them must match up with the first \( N-2 \) output columns. The remaining output columns must have the type of the last column of the source_sql query’s result, and there must be exactly as many of them as there are rows in the category_sql query’s result.

The crosstab function produces one output row for each consecutive group of input rows with the same row_name value. The output row_name column, plus any “extra” columns, are copied from the first row of the group. The output value columns are filled with the value fields from rows having matching
category values. If a row's category does not match any output of the category_sql query, its value is ignored. Output columns whose matching category is not present in any input row of the group are filled with nulls.

In practice the source_sql query should always specify ORDER BY 1 to ensure that values with the same row_name are brought together. However, ordering of the categories within a group is not important. Also, it is essential to be sure that the order of the category_sql query's output matches the specified output column order.

Here are two complete examples:

create table sales(year int, month int, qty int);
insert into sales values(2007, 1, 1000);
insert into sales values(2007, 2, 1500);
insert into sales values(2007, 7, 500);
insert into sales values(2007, 11, 1500);
insert into sales values(2007, 12, 2000);
insert into sales values(2008, 1, 1000);

select * from crosstab(
   'select year, month, qty from sales order by 1',
   'select m from generate_series(1,12) m'
) as (year int, "Jan" int, "Feb" int, "Mar" int, "Apr" int, "May" int, "Jun" int, "Jul" int, "Aug" int, "Sep" int, "Oct" int, "Nov" int, "Dec" int)
);

year | Jan | Feb | Mar | Apr | May | Jun | Jul | Aug | Sep | Oct |
Nov | Dec
-------------------------------
2007 | 1000 | 1500 |     |     |     | 500 |     |     |     |     |
1500 | 2000 |
2008 | 1000 |     |     |     |     |     |     |     |     |     |
(2 rows)

CREATE TABLE cth(rowid text, rowdt timestamp, attribute text, val text);
INSERT INTO cth VALUES('test1','01 March 2003','temperature','42');
INSERT INTO cth VALUES('test1','01 March 2003','test_result','PASS');
INSERT INTO cth VALUES('test1','01 March 2003','volts','2.6987');
INSERT INTO cth VALUES('test2','02 March 2003','temperature','53');
INSERT INTO cth VALUES('test2','02 March 2003','test_result','FAIL');
INSERT INTO cth VALUES('test2','02 March 2003','test_startdate','01 March 2003');
INSERT INTO cth VALUES('test2','02 March 2003','volts','3.1234');

SELECT * FROM crosstab
(
    'SELECT rowid, rowdt, attribute, val FROM cth ORDER BY 1',
    'SELECT DISTINCT attribute FROM cth ORDER BY 1'
)
AS
(
    rowid text,
    rowdt timestamp,
    temperature int4,
    test_result text,
    test_startdate timestamp,
    volts float8
);

rowid |          rowdt           | temperature | test_result |
      |                       |            |             |
--------------------------+--------+--------------------------+--------
test1 | Sat Mar 01 00:00:00 2003 |          42 | PASS        |
      | 2.6987
      | test2 | Sun Mar 02 00:00:00 2003 |          53 | FAIL        |
      | Sat Mar 01 00:00:00 2003 | 3.1234
(2 rows)

You can create predefined functions to avoid having to write out the result column names and types in each query. See the examples in the previous section. The underlying C function for this form of *crosstab* is named *crosstab_hash*.

**F.43.1.5. connectby**

`connectby(text relname, text keyid_fld, text parent_keyid_fld [, text orderby_fld ], text start_with, int max_depth [, text branch_delim ])`

The `connectby` function produces a display of hierarchical data that is stored in a table. The table must have a key field that uniquely identifies rows, and a parent-key field that references the parent (if any) of each row. `connectby` can display the sub-tree descending from any row.

Table F.31 explains the parameters.

**Table F.31. connectby Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>relname</td>
<td>Name of the source relation</td>
</tr>
<tr>
<td>keyid_fld</td>
<td>Name of the key field</td>
</tr>
<tr>
<td>parent_keyid_fld</td>
<td>Name of the parent-key field</td>
</tr>
<tr>
<td>orderby_fld</td>
<td>Name of the field to order siblings by (optional)</td>
</tr>
</tbody>
</table>
### Additional Supplied Modules

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>start_with</td>
<td>Key value of the row to start at</td>
</tr>
<tr>
<td>max_depth</td>
<td>Maximum depth to descend to, or zero for unlimited depth</td>
</tr>
<tr>
<td>branch_delim</td>
<td>String to separate keys with in branch output (optional)</td>
</tr>
</tbody>
</table>

The key and parent-key fields can be any data type, but they must be the same type. Note that the `start_with` value must be entered as a text string, regardless of the type of the key field.

The `connectby` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```sql
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0, '~')
AS t(keyid text, parent_keyid text, level int, branch text, pos int);
```

The first two output columns are used for the current row's key and its parent row's key; they must match the type of the table's key field. The third output column is the depth in the tree and must be of type `integer`. If a `branch_delim` parameter was given, the next output column is the branch display and must be of type `text`. Finally, if an `orderby_fld` parameter was given, the last output column is a serial number, and must be of type `integer`.

The “branch” output column shows the path of keys taken to reach the current row. The keys are separated by the specified `branch_delim` string. If no branch display is wanted, omit both the `branch_delim` parameter and the branch column in the output column list.

If the ordering of siblings of the same parent is important, include the `orderby_fld` parameter to specify which field to order siblings by. This field can be of any sortable data type. The output column list must include a final integer serial-number column, if and only if `orderby_fld` is specified.

The parameters representing table and field names are copied as-is into the SQL queries that `connectby` generates internally. Therefore, include double quotes if the names are mixed-case or contain special characters. You may also need to schema-qualify the table name.

In large tables, performance will be poor unless there is an index on the parent-key field.

It is important that the `branch_delim` string not appear in any key values, else `connectby` may incorrectly report an infinite-recursion error. Note that if `branch_delim` is not provided, a default value of `~` is used for recursion detection purposes.

Here is an example:

```sql
CREATE TABLE connectby_tree(keyid text, parent_keyid text, pos int);

INSERT INTO connectby_tree VALUES('row1',NULL, 0);
INSERT INTO connectby_tree VALUES('row2','row1', 0);
INSERT INTO connectby_tree VALUES('row3','row1', 0);
INSERT INTO connectby_tree VALUES('row4','row2', 1);
INSERT INTO connectby_tree VALUES('row5','row2', 0);
INSERT INTO connectby_tree VALUES('row6','row4', 0);
INSERT INTO connectby_tree VALUES('row7','row3', 0);
```

2915
Additional Supplied Modules

```sql
INSERT INTO connectby_tree VALUES('row8','row6', 0);
INSERT INTO connectby_tree VALUES('row9','row5', 0);

-- with branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0, '~')
AS t(keyid text, parent_keyid text, level int, branch text);
keyid | parent_keyid | level | branch
-------+--------------+-------+---------------------
row2  |              |     0 | row2
row4  | row2         |     1 | row2~row4
row6  | row4         |     2 | row2~row4~row6
row8  | row6         |     3 | row2~row4~row6~row8
row5  | row2         |     1 | row2~row5
row9  | row5         |     2 | row2~row5~row9
(6 rows)

-- without branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0)
AS t(keyid text, parent_keyid text, level int);
keyid | parent_keyid | level
-------+--------------+-------
row2  |              |     0
row4  | row2         |     1
row6  | row4         |     2
row8  | row6         |     3
row5  | row2         |     1
row9  | row5         |     2
(6 rows)

-- with branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0, '~')
AS t(keyid text, parent_keyid text, level int, branch text, pos int);
keyid | parent_keyid | level | branch        | pos
-------+--------------+-------+---------------------+-----
row2  |              |     0 | row2                |   1
row5  | row2         |     1 | row2~row5           |   2
row9  | row5         |     2 | row2~row5~row9      |   3
row4  | row2         |     1 | row2~row4           |   4
row6  | row4         |     2 | row2~row4~row6      |   5
row8  | row6         |     3 | row2~row4~row6~row8 |   6
(6 rows)

-- without branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0)
AS t(keyid text, parent_keyid text, level int, pos int);
keyid | parent_keyid | level | pos
-------+--------------+-------+-----
row2  |              |     0 | 2916
row5  | row2         |     1 | row2-row5
row9  | row5         |     2 | row2-row5-row9
row4  | row2         |     1 | row2-row4
row6  | row4         |     2 | row2-row4-row6
row8  | row6         |     3 | row2-row4-row6-row8
(6 rows)
```

F.43.2. Author
Joe Conway

F.44. tcn

The tcn module provides a trigger function that notifies listeners of changes to any table on which it is attached. It must be used as an AFTER trigger FOR EACH ROW.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

Only one parameter may be supplied to the function in a CREATE TRIGGER statement, and that is optional. If supplied it will be used for the channel name for the notifications. If omitted tcn will be used for the channel name.

The payload of the notifications consists of the table name, a letter to indicate which type of operation was performed, and column name/value pairs for primary key columns. Each part is separated from the next by a comma. For ease of parsing using regular expressions, table and column names are always wrapped in double quotes, and data values are always wrapped in single quotes. Embedded quotes are doubled.

A brief example of using the extension follows.

test=# create table tcndata
  test-#   (a int not null,
  test-#     b date not null,
  test-#     c text,
  test-#     primary key (a, b)
  test-#   );
CREATE TABLE
test=# create trigger tcndata_tcn_trigger
  test-#   after insert or update or delete on tcndata
  test-#     for each row execute function
  test-#       triggered_change_notification();
CREATE TRIGGER
test=# listen tcn;
LISTEN
test=# insert into tcndata values (1, date '2012-12-22', 'one'),
  test-#   (1, date '2012-12-23', 'another'),
  test-#   (2, date '2012-12-23', 'two');
INSERT 0 3
Asynchronous notification "tcn" with payload
  ""tcndata",I,"a"='1',"b"='2012-12-22'" received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1',"b"='2012-12-23'" received from server process with PID 22770.

Asynchronous notification "tcn" with payload ""tcndata",I,"a"='2',"b"='2012-12-23'" received from server process with PID 22770.

test=# update tcndata set c = 'uno' where a = 1;
UPDATE 2

Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1',"b"='2012-12-22'" received from server process with PID 22770.

Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1',"b"='2012-12-23'" received from server process with PID 22770.

test=# delete from tcndata where a = 1 and b = date '2012-12-22';
DELETE 1

Asynchronous notification "tcn" with payload ""tcndata",D,"a"='1',"b"='2012-12-22'" received from server process with PID 22770.

F.45. test_decoding

test_decoding is an example of a logical decoding output plugin. It doesn't do anything especially useful, but can serve as a starting point for developing your own output plugin.

test_decoding receives WAL through the logical decoding mechanism and decodes it into text representations of the operations performed.

Typical output from this plugin, used over the SQL logical decoding interface, might be:

```sql
postgres=# SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'include-xids', '0');
```

<table>
<thead>
<tr>
<th>lsn</th>
<th>xid</th>
<th>data</th>
</tr>
</thead>
<tbody>
<tr>
<td>0/16D30F8</td>
<td>691</td>
<td>BEGIN</td>
</tr>
<tr>
<td>0/16D32A0</td>
<td>691</td>
<td>table public.data: INSERT: id[int4]:2 data[text]: 'arg'</td>
</tr>
<tr>
<td>0/16D32A0</td>
<td>691</td>
<td>table public.data: INSERT: id[int4]:3 data[text]: 'demo'</td>
</tr>
<tr>
<td>0/16D32D8</td>
<td>692</td>
<td>BEGIN</td>
</tr>
<tr>
<td>0/16D3398</td>
<td>692</td>
<td>table public.data: DELETE: id[int4]:2</td>
</tr>
<tr>
<td>0/16D3398</td>
<td>692</td>
<td>table public.data: DELETE: id[int4]:3</td>
</tr>
<tr>
<td>0/16D3398</td>
<td>692</td>
<td>COMMIT</td>
</tr>
</tbody>
</table>

(8 rows)

We can also get the changes of the in-progress transaction, and the typical output might be:

```sql
postgres[33712]=#* SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'stream-changes', '1');
```

<table>
<thead>
<tr>
<th>lsn</th>
<th>xid</th>
<th>data</th>
</tr>
</thead>
</table>

2918
F.46. tsm_system_rows

The tsm_system_rows module provides the table sampling method SYSTEM_ROWS, which can be used in the TABLESAMPLE clause of a SELECT command.

This table sampling method accepts a single integer argument that is the maximum number of rows to read. The resulting sample will always contain exactly that many rows, unless the table does not contain enough rows, in which case the whole table is selected.

Like the built-in SYSTEM sampling method, SYSTEM_ROWS performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are requested.

SYSTEM_ROWS does not support the REPEATABLE clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.46.1. Examples

Here is an example of selecting a sample of a table with SYSTEM_ROWS. First install the extension:

```sql
CREATE EXTENSION tsm_system_rows;
```

Then you can use it in a SELECT command, for instance:

```sql
SELECT * FROM my_table TABLESAMPLE SYSTEM_ROWS(100);
```

This command will return a sample of 100 rows from the table my_table (unless the table does not have 100 visible rows, in which case all its rows are returned).

F.47. tsm_system_time

The tsm_system_time module provides the table sampling method SYSTEM_TIME, which can be used in the TABLESAMPLE clause of a SELECT command.

This table sampling method accepts a single floating-point argument that is the maximum number of milliseconds to spend reading the table. This gives you direct control over how long the query takes, at the
price that the size of the sample becomes hard to predict. The resulting sample will contain as many rows
as could be read in the specified time, unless the whole table has been read first.

Like the built-in `SYSTEM` sampling method, `SYSTEM_TIME` performs block-level sampling, so that the
sample is not completely random but may be subject to clustering effects, especially if only a small number
of rows are selected.

`SYSTEM_TIME` does not support the `REPEATABLE` clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

**F.47.1. Examples**

Here is an example of selecting a sample of a table with `SYSTEM_TIME`. First install the extension:

```
CREATE EXTENSION tsm_system_time;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_TIME(1000);
```

This command will return as large a sample of `my_table` as it can read in 1 second (1000 milliseconds).
Of course, if the whole table can be read in under 1 second, all its rows will be returned.

**F.48. `unaccent`**

`unaccent` is a text search dictionary that removes accents (diacritic signs) from lexemes. It’s a filtering
dictionary, which means its output is always passed to the next dictionary (if any), unlike the normal
behavior of dictionaries. This allows accent-insensitive processing for full text search.

The current implementation of `unaccent` cannot be used as a normalizing dictionary for the the-
saurus dictionary.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

**F.48.1. Configuration**

An `unaccent` dictionary accepts the following options:

- **RULES** is the base name of the file containing the list of translation rules. This file must be stored in
  `$SHAREDIR/tsearch_data/` (where `$SHAREDIR` means the PostgreSQL installation’s shared-data directory). Its name must end in `.rules` (which is not to be included in the `RULES` parameter).

The rules file has the following format:

- Each line represents one translation rule, consisting of a character with accent followed by a character
  without accent. The first is translated into the second. For example,

```
À   A
Â   A
```
Additional Supplied Modules

The two characters must be separated by whitespace, and any leading or trailing whitespace on a line is ignored.

- Alternatively, if only one character is given on a line, instances of that character are deleted; this is useful in languages where accents are represented by separate characters.

- Actually, each “character” can be any string not containing whitespace, so unaccent dictionaries could be used for other sorts of substring substitutions besides diacritic removal.

- As with other PostgreSQL text search configuration files, the rules file must be stored in UTF-8 encoding. The data is automatically translated into the current database's encoding when loaded. Any lines containing untranslatable characters are silently ignored, so that rules files can contain rules that are not applicable in the current encoding.

A more complete example, which is directly useful for most European languages, can be found in unaccent.rules, which is installed in $SHAREDIR/tsearch_data/ when the unaccent module is installed. This rules file translates characters with accents to the same characters without accents, and it also expands ligatures into the equivalent series of simple characters (for example, ÅE to AE).

F.48.2. Usage

Installing the unaccent extension creates a text search template unaccent and a dictionary unaccent based on it. The unaccent dictionary has the default parameter setting RULES='unaccent', which makes it immediately usable with the standard unaccent.rules file. If you wish, you can alter the parameter, for example

```
mydb=# ALTER TEXT SEARCH DICTIONARY unaccent (RULES='my_rules');
```

or create new dictionaries based on the template.

To test the dictionary, you can try:

```
mydb=# select ts_lexize('unaccent','Hôtel');
ts_lexize
------------
{Hotel}
(1 row)
```

Here is an example showing how to insert the unaccent dictionary into a text search configuration:

```
mydb=# CREATE TEXT SEARCH CONFIGURATION fr ( COPY = french );
mydb=# ALTER TEXT SEARCH CONFIGURATION fr
    ALTER MAPPING FOR hword, hword_part, word
    WITH unaccent, french_stem;
mydb=# select to_tsvector('fr','Hôtels de la Mer');
to_tsvector
```
Additional Supplied Modules

-------------
'hotel':1 'mer':4
(1 row)

mydb=# select to_tsvector('fr','Hôtel de la Mer') @@
to_tsquery('fr','Hotels');
?column?
----------
t
(1 row)

mydb=# select ts_headline('fr','Hôtel de la Mer',to_tsquery('fr','Hotels'));
  ts_headline
------------------------
  <b>Hôtel</b> de la Mer
(1 row)

F.48.3. Functions

The unaccent() function removes accents (diacritic signs) from a given string. Basically, it's a wrapper around unaccent-type dictionaries, but it can be used outside normal text search contexts.

unaccent([dictionary regdictionary, ] string text) returns text

If the dictionary argument is omitted, the text search dictionary named unaccent and appearing in the same schema as the unaccent() function itself is used.

For example:

SELECT unaccent('unaccent', 'Hôtel');
SELECT unaccent('Hôtel');

F.49. uuid-ossp

The uuid-ossp module provides functions to generate universally unique identifiers (UUIDs) using one of several standard algorithms. There are also functions to produce certain special UUID constants. This module is only necessary for special requirements beyond what is available in core PostgreSQL. See Section 9.14 for built-in ways to generate UUIDs.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.49.1. uuid-ossp Functions

Table F.32 shows the functions available to generate UUIDs. The relevant standards ITU-T Rec. X.667, ISO/IEC 9834-8:2005, and RFC 4122\(^9\) specify four algorithms for generating UUIDs, identified by the version numbers 1, 3, 4, and 5. (There is no version 2 algorithm.) Each of these algorithms could be suitable for a different set of applications.

\(^9\) https://tools.ietf.org/html/rfc4122
Table F.32. Functions for UUID Generation

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>uuid_generate_v1()</code> → <code>uuid</code></td>
<td>Generates a version 1 UUID. This involves the MAC address of the computer and a time stamp. Note that UUIDs of this kind reveal the identity of the computer that created the identifier and the time at which it did so, which might make it unsuitable for certain security-sensitive applications.</td>
</tr>
<tr>
<td><code>uuid_generate_v1mc()</code> → <code>uuid</code></td>
<td>Generates a version 1 UUID, but uses a random multicast MAC address instead of the real MAC address of the computer.</td>
</tr>
<tr>
<td><code>uuid_generate_v3(namespace uuid, name text) → uuid</code></td>
<td>Generates a version 3 UUID in the given namespace using the specified input name. The namespace should be one of the special constants produced by the <code>uuid_ns_*()</code> functions shown in Table F.33. (It could be any UUID in theory.) The name is an identifier in the selected namespace. For example:</td>
</tr>
<tr>
<td><code>SELECT uuid_generate_v3(uuid_ns_url(), 'http://www.postgresql.org');</code></td>
<td></td>
</tr>
<tr>
<td>The name parameter will be MD5-hashed, so the cleartext cannot be derived from the generated UUID. The generation of UUIDs by this method has no random or environment-dependent element and is therefore reproducible.</td>
<td></td>
</tr>
<tr>
<td><code>uuid_generate_v4()</code> → <code>uuid</code></td>
<td>Generates a version 4 UUID, which is derived entirely from random numbers.</td>
</tr>
<tr>
<td><code>uuid_generate_v5(namespace uuid, name text) → uuid</code></td>
<td>Generates a version 5 UUID, which works like a version 3 UUID except that SHA-1 is used as a hashing method. Version 5 should be preferred over version 3 because SHA-1 is thought to be more secure than MD5.</td>
</tr>
</tbody>
</table>

Table F.33. Functions Returning UUID Constants

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>uuid_nil()</code> → <code>uuid</code></td>
<td>Returns a “nil” UUID constant, which does not occur as a real UUID.</td>
</tr>
<tr>
<td><code>uuid_ns_dns()</code> → <code>uuid</code></td>
<td>Returns a constant designating the DNS namespace for UUIDs.</td>
</tr>
<tr>
<td><code>uuid_ns_url()</code> → <code>uuid</code></td>
<td>Returns a constant designating the URL namespace for UUIDs.</td>
</tr>
<tr>
<td><code>uuid_ns_oid()</code> → <code>uuid</code></td>
<td>Returns a constant designating the ISO object identifier (OID) namespace for UUIDs. (This pertains to ASN.1 OIDs, which are unrelated to the OIDs used in PostgreSQL.)</td>
</tr>
<tr>
<td><code>uuid_ns_x500()</code> → <code>uuid</code></td>
<td></td>
</tr>
</tbody>
</table>
F.49.2. Building **uuid-oss**

Historically this module depended on the OSSP UUID library, which accounts for the module's name. While the OSSP UUID library can still be found at http://www.ossp.org/pkg/lib/uuid/, it is not well maintained, and is becoming increasingly difficult to port to newer platforms. **uuid-oss** can now be built without the OSSP library on some platforms. On FreeBSD, NetBSD, and some other BSD-derived platforms, suitable UUID creation functions are included in the core libc library. On Linux, macOS, and some other platforms, suitable functions are provided in the libuuid library, which originally came from the e2fsprogs project (though on modern Linux it is considered part of util-linux-ng). When invoking configure, specify --with-uuid=bsd to use the BSD functions, or --with-uuid=e2fs to use e2fsprogs' libuuid, or --with-uuid=ossp to use the OSSP UUID library. More than one of these libraries might be available on a particular machine, so configure does not automatically choose one.

F.49.3. Author

**Peter Eisentraut**<peter_e@gmx.net>

F.50. **xml2**

The xml2 module provides XPath querying and XSLT functionality.

F.50.1. Deprecation Notice

From PostgreSQL 8.3 on, there is XML-related functionality based on the SQL/XML standard in the core server. That functionality covers XML syntax checking and XPath queries, which is what this module does, and more, but the API is not at all compatible. It is planned that this module will be removed in a future version of PostgreSQL in favor of the newer standard API, so you are encouraged to try converting your applications. If you find that some of the functionality of this module is not available in an adequate form with the newer API, please explain your issue to <pgsql-hackers@lists.postgresql.org> so that the deficiency can be addressed.

F.50.2. Description of Functions

Table F.34 shows the functions provided by this module. These functions provide straightforward XML parsing and XPath queries.

**Table F.34. xml2 Functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml_valid(document text) \rightarrow boolean</td>
<td>Parses the given document and returns true if the document is well-formed XML. (Note: this is an alias for the standard PostgreSQL function xml_is_well_formed(). The name xml_valid() is technically incorrect since validity and well-formedness have different meanings in XML.)</td>
</tr>
</tbody>
</table>
### Function

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xpath_string( <code>document text, query text</code>) → text</td>
</tr>
<tr>
<td>Evaluates the XPath query on the supplied document, and casts the result to <code>text</code>.</td>
</tr>
</tbody>
</table>

| xpath_number( `document text, query text`) → real |
| Evaluates the XPath query on the supplied document, and casts the result to `real`. |

| xpath_bool( `document text, query text`) → boolean |
| Evaluates the XPath query on the supplied document, and casts the result to `boolean`. |

| xpath_nodeset( `document text, query text, toptag text, itemtag text`) → text |
| Evaluates the query on the document and wraps the result in XML tags. If the result is multivalued, the output will look like: |

```xml
<toptag>
  <itemtag>Value 1 which could be an XML fragment</itemtag>
  <itemtag>Value 2....</itemtag>
</toptag>
```

If either `toptag` or `itemtag` is an empty string, the relevant tag is omitted.

| xpath_nodeset( `document text, query text, itemtag text`) → text |
| Like xpath_nodeset( `document, query, toptag, itemtag`) but result omits `toptag`. |

| xpath_nodeset( `document text, query text`) → text |
| Like xpath_nodeset( `document, query, toptag, itemtag`) but result omits both tags. |

| xpath_list( `document text, query text, separator text`) → text |
| Evaluates the query on the document and returns multiple values separated by the specified separator, for example `Value 1,Value 2,Value 3` if `separator` is `,`. |

| xpath_list( `document text, query text`) → text |
| This is a wrapper for the above function that uses `,` as the separator. |

### F.50.3. xpath_table

`xpath_table(text key, text document, text relation, text xpaths, text criteria) returns setof record`

`xpath_table` is a table function that evaluates a set of XPath queries on each of a set of documents and returns the results as a table. The primary key field from the original document table is returned as the first column of the result so that the result set can readily be used in joins. The parameters are described in Table F.35.

#### Table F.35. xpath_table Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>key</code></td>
<td>the name of the “key” field — this is just a field to be used as the first column of the output table, i.e., it identifies the record from which each output row came (see note below about multiple values)</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>document</td>
<td>the name of the field containing the XML document</td>
</tr>
<tr>
<td>relation</td>
<td>the name of the table or view containing the documents</td>
</tr>
<tr>
<td>xpaths</td>
<td>one or more XPath expressions, separated by</td>
</tr>
<tr>
<td>criteria</td>
<td>the contents of the WHERE clause. This cannot be omitted, so use true or 1=1 if you want to process all the rows in the relation</td>
</tr>
</tbody>
</table>

These parameters (except the XPath strings) are just substituted into a plain SQL SELECT statement, so you have some flexibility — the statement is

```
SELECT <key>, <document> FROM <relation> WHERE <criteria>
```

so those parameters can be *anything* valid in those particular locations. The result from this SELECT needs to return exactly two columns (which it will unless you try to list multiple fields for key or document). Beware that this simplistic approach requires that you validate any user-supplied values to avoid SQL injection attacks.

The function has to be used in a FROM expression, with an AS clause to specify the output columns; for example

```
SELECT * FROM xpath_table('article_id', 'article_xml', 'articles', '/article/author|/article/pages|/article/title', 'date_entered > '2003-01-01' ') AS t(article_id integer, author text, page_count integer, title text);
```

The AS clause defines the names and types of the columns in the output table. The first is the “key” field and the rest correspond to the XPath queries. If there are more XPath queries than result columns, the extra queries will be ignored. If there are more result columns than XPath queries, the extra columns will be NULL.

Notice that this example defines the page_count result column as an integer. The function deals internally with string representations, so when you say you want an integer in the output, it will take the string representation of the XPath result and use PostgreSQL input functions to transform it into an integer (or whatever type the AS clause requests). An error will result if it can’t do this — for example if the result is empty — so you may wish to just stick to text as the column type if you think your data has any problems.

The calling SELECT statement doesn’t necessarily have to be just SELECT * — it can reference the output columns by name or join them to other tables. The function produces a virtual table with which you can perform any operation you wish (e.g., aggregation, joining, sorting etc.). So we could also have:

```
SELECT t.title, p.fullname, p.email
FROM xpath_table('article_id', 'article_xml', 'articles', '/article/title|/article/author/@id', 'xpath_string(article_xml,''/article/@date'') > ''2003-03-20'' ') AS t(article_id integer, title text, author_id integer),
    tblPeopleInfo AS p
WHERE t.author_id = p.person_id;
```
as a more complicated example. Of course, you could wrap all of this in a view for convenience.

### F.50.3.1. Multivalued Results

The `xpath_table` function assumes that the results of each XPath query might be multivalued, so the number of rows returned by the function may not be the same as the number of input documents. The first row returned contains the first result from each query, the second row the second result from each query. If one of the queries has fewer values than the others, null values will be returned instead.

In some cases, a user will know that a given XPath query will return only a single result (perhaps a unique document identifier) — if used alongside an XPath query returning multiple results, the single-valued result will appear only on the first row of the result. The solution to this is to use the key field as part of a join against a simpler XPath query. As an example:

```sql
CREATE TABLE test (
    id int PRIMARY KEY,
    xml text
);

INSERT INTO test VALUES (1, '<doc num="C1">
    <line num="L1"><a>1</a><b>2</b><c>3</c></line>
    <line num="L2"><a>11</a><b>22</b><c>33</c></line>
</doc>');

INSERT INTO test VALUES (2, '<doc num="C2">
    <line num="L1"><a>111</a><b>222</b><c>333</c></line>
    <line num="L2"><a>111</a><b>222</b><c>333</c></line>
</doc>');

SELECT * FROM
    xpath_table('id','xml','test',
        '/doc/@num|/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
        'true')
    AS t(id int, doc_num varchar(10), line_num varchar(10), val1 int, val2 int, val3 int)
WHERE id = 1 ORDER BY doc_num, line_num

<table>
<thead>
<tr>
<th>id</th>
<th>doc_num</th>
<th>line_num</th>
<th>val1</th>
<th>val2</th>
<th>val3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>C1</td>
<td>L1</td>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>1</td>
<td></td>
<td>L2</td>
<td>11</td>
<td>22</td>
<td>33</td>
</tr>
</tbody>
</table>
```

To get `doc_num` on every line, the solution is to use two invocations of `xpath_table` and join the results:

```sql
SELECT t.*,i.doc_num FROM
    xpath_table('id', 'xml', 'test',
        '/doc/@num|/doc/line/a|/doc/line/b|/doc/line/c',
        'true')
    AS t(id int, line_num varchar(10), val1 int, val2 int, val3 int),
    xpath_table('id', 'xml', 'test', '/doc/@num', 'true')
    AS i(id int, doc_num varchar(10))
```
WHERE i.id=t.id AND i.id=1
ORDER BY doc_num, line_num;

<table>
<thead>
<tr>
<th>id</th>
<th>line_num</th>
<th>val1</th>
<th>val2</th>
<th>val3</th>
<th>doc_num</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>L1</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>C1</td>
</tr>
<tr>
<td>1</td>
<td>L2</td>
<td>11</td>
<td>22</td>
<td>33</td>
<td>C1</td>
</tr>
</tbody>
</table>

(2 rows)

F.50.4. XSLT Functions

The following functions are available if libxslt is installed:

F.50.4.1. xslt_process

xslt_process(text document, text stylesheet, text paramlist) returns text

This function applies the XSL stylesheet to the document and returns the transformed result. The paramlist is a list of parameter assignments to be used in the transformation, specified in the form a=1,b=2. Note that the parameter parsing is very simple-minded: parameter values cannot contain commas!

There is also a two-parameter version of xslt_process which does not pass any parameters to the transformation.

F.50.5. Author

John Gray <jgray@azuli.co.uk>

Development of this module was sponsored by Torchbox Ltd. (www.torchbox.com). It has the same BSD license as PostgreSQL.
Appendix G. Additional Supplied Programs

This appendix and the previous one contain information regarding the modules that can be found in the contrib directory of the PostgreSQL distribution. See Appendix F for more information about the contrib section in general and server extensions and plug-ins found in contrib specifically.

This appendix covers utility programs found in contrib. Once installed, either from source or a packaging system, they are found in the bin directory of the PostgreSQL installation and can be used like any other program.

G.1. Client Applications

This section covers PostgreSQL client applications in contrib. They can be run from anywhere, independent of where the database server resides. See also PostgreSQL Client Applications for information about client applications that are part of the core PostgreSQL distribution.
oid2name

oid2name — resolve OIDs and file nodes in a PostgreSQL data directory

Synopsis

oid2name [option...]

Description

oid2name is a utility program that helps administrators to examine the file structure used by PostgreSQL. To make use of it, you need to be familiar with the database file structure, which is described in Chapter 72.

Note

The name “oid2name” is historical, and is actually rather misleading, since most of the time when you use it, you will really be concerned with tables' filenode numbers (which are the file names visible in the database directories). Be sure you understand the difference between table OIDs and table filenodes!

oid2name connects to a target database and extracts OID, filenode, and/or table name information. You can also have it show database OIDs or tablespace OIDs.

Options

oid2name accepts the following command-line arguments:

- f filenode
  --filenode=filenode
  show info for table with filenode filenode.

- i
  --indexes
  include indexes and sequences in the listing.

- o oid
  --oid=oid
  show info for table with OID oid.

- q
  --quiet
  omit headers (useful for scripting).

- s
  --tablespaces
  show tablespace OIDs.
Additional Supplied Programs

-S
--system-objects

include system objects (those in information_schema, pg_toast and pg_catalog schemas).

-t tablename_pattern
--table=tablename_pattern

show info for table(s) matching tablename_pattern.

-V
--version

Print the oid2name version and exit.

-x
--extended

display more information about each object shown: tablespace name, schema name, and OID.

-?
--help

Show help about oid2name command line arguments, and exit.

oid2name also accepts the following command-line arguments for connection parameters:

-d database
--dbname=database

database to connect to.

-h host
--host=host

database server's host.

-H host

database server's host. Use of this parameter is deprecated as of PostgreSQL 12.

-p port
--port=port

database server's port.

-U username
--username=username

user name to connect as.

To display specific tables, select which tables to show by using -o, -f and/or -t. -o takes an OID, -f takes a filenode, and -t takes a table name (actually, it's a LIKE pattern, so you can use things like foo %). You can use as many of these options as you like, and the listing will include all objects matched by any of the options. But note that these options can only show objects in the database given by -d.

If you don't give any of -o, -f or -t, but do give -d, it will list all tables in the database named by -d. In this mode, the -S and -i options control what gets listed.
Additional Supplied Programs

If you don't give \( -d \) either, it will show a listing of database OIDs. Alternatively you can give \( -s \) to get a tablespace listing.

**Environment**

PGHOST
PGPORT
PGUSER

Default connection parameters.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 34.15).

The environment variable \texttt{PG\_COLOR} specifies whether to use color in diagnostic messages. Possible values are \texttt{always}, \texttt{auto} and \texttt{never}.

**Notes**

\texttt{oid2name} requires a running database server with non-corrupt system catalogs. It is therefore of only limited use for recovering from catastrophic database corruption situations.

**Examples**

```bash
$ # what's in this database server, anyway?
$ oid2name
All databases:
   Oid  Database Name  Tablespace
-----------------------------
17228       alvherre  pg_default
17255     regression  pg_default
17227      template0  pg_default
  1      template1  pg_default

$ oid2name -s
All tablespaces:
   Oid  Tablespace Name
-------------------------
 1663       pg_default
 1664        pg_global
155151         fastdisk
155152          bigdisk

$ # OK, let's look into database alvherre
$ cd $PGDATA/base/17228

$ # get top 10 db objects in the default tablespace, ordered by size
$ ls -lS * | head -10
-rw-------  1 alvherre alvherre  136536064 sep 14 09:51 155173
-rw-------  1 alvherre alvherre  17965056 sep 14 09:51 1155291
-rw-------  1 alvherre alvherre  2104224 sep 14 09:51 16717
-rw-------  1 alvherre alvherre  5181632 sep 14 17:51 1255
-rw-------  1 alvherre alvherre  237568 sep 14 09:50 16674
```
Additional Supplied Programs

$ # I wonder what file 155173 is ...
$ oid2name -d alvherre -f 155173
From database "alvherre":
    Filenode    Table Name
    ----------------------
    155173    accounts

<thead>
<tr>
<th>Filenode</th>
<th>Table Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>155156</td>
<td>foo</td>
</tr>
</tbody>
</table>

Author

B. Palmer <bpalmer@crimelabs.net>
vacuumlo

vacuumlo — remove orphaned large objects from a PostgreSQL database

Synopsis

vacuumlo [option...] dbname...

Description

vacuumlo is a simple utility program that will remove any “orphaned” large objects from a PostgreSQL database. An orphaned large object (LO) is considered to be any LO whose OID does not appear in any oid or lo data column of the database.

If you use this, you may also be interested in the lo_manage trigger in the lo module. lo_manage is useful to try to avoid creating orphaned LOs in the first place.

All databases named on the command line are processed.

Options

vacuumlo accepts the following command-line arguments:

- limit
  --limit=limit

  Remove no more than limit large objects per transaction (default 1000). Since the server acquires a lock per LO removed, removing too many LOs in one transaction risks exceeding max_locks_per_transaction. Set the limit to zero if you want all removals done in a single transaction.

- dry-run
  --dry-run

  Don't remove anything, just show what would be done.

- verbose
  --verbose

  Write a lot of progress messages.

- version
  --version

  Print the vacuumlo version and exit.

- help
  --help

  Show help about vacuumlo command line arguments, and exit.

vacuumlo also accepts the following command-line arguments for connection parameters:
Additional Supplied Programs

-h host
--host=host

Database server's host.

-p port
--port=port

Database server's port.

-U username
--username=username

User name to connect as.

-w
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W
--password

Force vacuumlo to prompt for a password before connecting to a database.

This option is never essential, since vacuumlo will automatically prompt for a password if the server demands password authentication. However, vacuumlo will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

Environment

PGHOST
PGPORT
PGUSER

Default connection parameters.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 34.15).

The environment variable PG_COLOR specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

Notes

vacuumlo works by the following method: First, vacuumlo builds a temporary table which contains all of the OIDs of the large objects in the selected database. It then scans through all columns in the database that are of type oid or lo, and removes matching entries from the temporary table. (Note: Only types with these names are considered; in particular, domains over them are not considered.) The remaining entries in the temporary table identify orphaned LOs. These are removed.

Peter Mount <peter@retep.org.uk>
G.2. Server Applications

Some applications run on the PostgreSQL server itself. Currently, no such applications are included in the contrib directory. See also PostgreSQL Server Applications for information about server applications that are part of the core PostgreSQL distribution.
Appendix H. External Projects

PostgreSQL is a complex software project, and managing the project is difficult. We have found that many enhancements to PostgreSQL can be more efficiently developed separately from the core project.

H.1. Client Interfaces

There are only two client interfaces included in the base PostgreSQL distribution:

- libpq is included because it is the primary C language interface, and because many other client interfaces are built on top of it.
- ECPG is included because it depends on the server-side SQL grammar, and is therefore sensitive to changes in PostgreSQL itself.

All other language interfaces are external projects and are distributed separately. Table H.1 includes a list of some of these projects. Note that some of these packages might not be released under the same license as PostgreSQL. For more information on each language interface, including licensing terms, refer to its website and documentation.

H.2. Administration Tools

There are several administration tools available for PostgreSQL. The most popular is pgAdmin\(^1\), and there are several commercially available ones as well.

\(^1\)https://www.pgadmin.org/
H.3. Procedural Languages

PostgreSQL includes several procedural languages with the base distribution: PL/pgSQL, PL/Tcl, PL/Perl, and PL/Python.

In addition, there are a number of procedural languages that are developed and maintained outside the core PostgreSQL distribution. Table H.2 lists some of these packages. Note that some of these projects might not be released under the same license as PostgreSQL. For more information on each procedural language, including licensing information, refer to its website and documentation.

</tbody>
</table>

H.4. Extensions

PostgreSQL is designed to be easily extensible. For this reason, extensions loaded into the database can function just like features that are built in. The contrib/ directory shipped with the source code contains several extensions, which are described in Appendix F. Other extensions are developed independently, like PostGIS². Even PostgreSQL replication solutions can be developed externally. For example, Slony-I³ is a popular primary/standby replication solution that is developed independently from the core project.

² https://postgis.net/
³ https://www.slony.info
Appendix I. The Source Code Repository

The PostgreSQL source code is stored and managed using the Git version control system. A public mirror of the master repository is available; it is updated within a minute of any change to the master repository.

Our wiki, https://wiki.postgresql.org/wiki/Working_with_Git, has some discussion on working with Git.

Note that building PostgreSQL from the source repository requires reasonably up-to-date versions of bison, flex, and Perl. These tools are not needed to build from a distribution tarball, because the files that these tools are used to build are included in the tarball. Other tool requirements are the same as shown in Section 17.2.

I.1. Getting the Source via Git

With Git you will make a copy of the entire code repository on your local machine, so you will have access to all history and branches offline. This is the fastest and most flexible way to develop or test patches.

**Git**

1. You will need an installed version of Git, which you can get from https://git-scm.com. Many systems already have a recent version of Git installed by default, or available in their package distribution system.

2. To begin using the Git repository, make a clone of the official mirror:

   ```
git clone https://git.postgresql.org/git/postgresql.git
   ```

   This will copy the full repository to your local machine, so it may take a while to complete, especially if you have a slow Internet connection. The files will be placed in a new subdirectory `postgresql` of your current directory.

   The Git mirror can also be reached via the Git protocol. Just change the URL prefix to `git`, as in:

   ```
git clone git://git.postgresql.org/git/postgresql.git
   ```

3. Whenever you want to get the latest updates in the system, `cd` into the repository, and run:

   ```
git fetch
   ```

   Git can do a lot more things than just fetch the source. For more information, consult the Git man pages, or see the website at https://git-scm.com.
Appendix J. Documentation

PostgreSQL has four primary documentation formats:

- Plain text, for pre-installation information
- HTML, for on-line browsing and reference
- PDF, for printing
- man pages, for quick reference.

Additionally, a number of plain-text README files can be found throughout the PostgreSQL source tree, documenting various implementation issues.

HTML documentation and man pages are part of a standard distribution and are installed by default. PDF format documentation is available separately for download.

J.1. DocBook

The documentation sources are written in DocBook, which is a markup language defined in XML. In what follows, the terms DocBook and XML are both used, but technically they are not interchangeable.

DocBook allows an author to specify the structure and content of a technical document without worrying about presentation details. A document style defines how that content is rendered into one of several final forms. DocBook is maintained by the OASIS group\(^1\). The official DocBook site\(^2\) has good introductory and reference documentation and a complete O'Reilly book for your online reading pleasure. The NewbieDoc Docbook Guide\(^3\) is very helpful for beginners. The FreeBSD Documentation Project\(^4\) also uses DocBook and has some good information, including a number of style guidelines that might be worth considering.

J.2. Tool Sets

The following tools are used to process the documentation. Some might be optional, as noted.

DocBook DTD\(^5\)

This is the definition of DocBook itself. We currently use version 4.5; you cannot use later or earlier versions. You need the XML variant of the DocBook DTD, not the SGML variant.

DocBook XSL Stylesheets\(^6\)

These contain the processing instructions for converting the DocBook sources to other formats, such as HTML.

The minimum required version is currently 1.77.0, but it is recommended to use the latest available version for best results.

---

1 https://www.oasis-open.org
2 https://www.oasis-open.org/docbook/
4 https://www.freebsd.org/docproj/docproj.html
5 https://www.oasis-open.org/docbook/
Libxml2\(^7\) for \texttt{xml2lint}

This library and the \texttt{xml2lint} tool it contains are used for processing XML. Many developers will already have Libxml2 installed, because it is also used when building the PostgreSQL code. Note, however, that \texttt{xml2lint} might need to be installed from a separate subpackage.

Libxslt\(^8\) for \texttt{xsltproc}

\texttt{xsltproc} is an XSLT processor, that is, a program to convert XML to other formats using XSLT stylesheets.

FOP\(^9\)

This is a program for converting, among other things, XML to PDF.

We have documented experience with several installation methods for the various tools that are needed to process the documentation. These will be described below. There might be some other packaged distributions for these tools. Please report package status to the documentation mailing list, and we will include that information here.

You can get away with not installing DocBook XML and the DocBook XSLT stylesheets locally, because the required files will be downloaded from the Internet and cached locally. This may in fact be the preferred solution if your operating system packages provide only an old version of these files, or if no packages are available at all. If you want to prevent any attempt to access the Internet while building the documentation, you need to pass the \texttt{--nonet} option to \texttt{xml2lint} and \texttt{xsltproc}; see below for an example.

**J.2.1. Installation on Fedora, RHEL, and Derivatives**

To install the required packages, use:

```
yum install docbook-dtds docbook-style-xsl fop libxml2
```

**J.2.2. Installation on FreeBSD**

To install the required packages with \texttt{pkg}, use:

```
 pkg install docbook-xml docbook-xsl fop libxslt
```

When building the documentation from the \texttt{doc} directory you'll need to use \texttt{gmake}, because the makefile provided is not suitable for FreeBSD's \texttt{make}.

**J.2.3. Debian Packages**

There is a full set of packages of the documentation tools available for Debian GNU/Linux. To install, simply use:

```
apt-get install docbook-xml docbook-xsl fop libxml2-utils xsltproc
```

\(^7\) http://xmlsoft.org/
\(^8\) http://xmlsoft.org/XSLT/
\(^9\) https://xmlgraphics.apache.org/fop/
J.2.4. macOS

On macOS, you can build the HTML and man documentation without installing anything extra. If you want to build PDFs or want to install a local copy of DocBook, you can get those from your preferred package manager.

If you use MacPorts, the following will get you set up:

```
sudo port install docbook-xml-4.5 docbook-xsl fop
```

If you use Homebrew, use this:

```
brew install docbook docbook-xsl fop
```

J.2.5. Detection by configure

Before you can build the documentation you need to run the configure script, as you would when building the PostgreSQL programs themselves. Check the output near the end of the run; it should look something like this:

```
checking for xmllint... xmllint
checking for xsltproc... xsltproc
checking for fop... fop
checking for dbtoepub... dbtoepub
```

If xmllint or xsltproc is not found, you will not be able to build any of the documentation. fop is only needed to build the documentation in PDF format. dbtoepub is only needed to build the documentation in EPUB format.

If necessary, you can tell configure where to find these programs, for example

```
./configure ... XMLLINT=/opt/local/bin/xmllint ...
```

Also, if you want to ensure that xmllint and xsltproc will not perform any network access, you can do something like

```
./configure ... XMLLINT="xmllint --nonet" XSLTPROC="xsltproc --nonet" ...
```

J.3. Building the Documentation

Once you have everything set up, change to the directory doc/src/sgml and run one of the commands described in the following subsections to build the documentation. (Remember to use GNU make.)

J.3.1. HTML

To build the HTML version of the documentation:
This is also the default target. The output appears in the subdirectory `html`.

To produce HTML documentation with the stylesheet used on postgresql.org\(^\text{10}\) instead of the default simple style use:

\[ \text{doc/src/sgml}\]$  \text{make STYLE=website html}  

If the `STYLE=website` option is used, the generated HTML files include references to stylesheets hosted on postgresql.org\(^\text{11}\) and require network access to view.

### J.3.2. Manpages

We use the DocBook XSL stylesheets to convert DocBook `refentry` pages to *roff output suitable for man pages. To create the man pages, use the command:

\[ \text{doc/src/sgml}\]$  \text{make man}  

### J.3.3. PDF

To produce a PDF rendition of the documentation using FOP, you can use one of the following commands, depending on the preferred paper format:

- For A4 format:

\[ \text{doc/src/sgml}\]$  \text{make postgres-A4.pdf}  

- For U.S. letter format:

\[ \text{doc/src/sgml}\]$  \text{make postgres-US.pdf}  

Because the PostgreSQL documentation is fairly big, FOP will require a significant amount of memory. Because of that, on some systems, the build will fail with a memory-related error message. This can usually be fixed by configuring Java heap settings in the configuration file `~/.foprc`, for example:

```bash
# FOP binary distribution
FOP_OPTS='\-Xmx1500m'
# Debian
JAVA_ARGS='\-Xmx1500m'
# Red Hat
ADDITIONAL_FLAGS='\-Xmx1500m'
```

There is a minimum amount of memory that is required, and to some extent more memory appears to make things a bit faster. On systems with very little memory (less than 1 GB), the build will either be very slow due to swapping or will not work at all.

Other XSL-FO processors can also be used manually, but the automated build process only supports FOP.

\(^\text{10}\) [https://www.postgresql.org/docs/current/](https://www.postgresql.org/docs/current/)
\(^\text{11}\) [https://www.postgresql.org/docs/current/](https://www.postgresql.org/docs/current/)
J.3.4. Plain Text Files

The installation instructions are also distributed as plain text, in case they are needed in a situation where better reading tools are not available. The INSTALL file corresponds to Chapter 17, with some minor changes to account for the different context. To recreate the file, change to the directory doc/src/sgml and enter make INSTALL. Building text output requires Pandoc version 1.13 or newer as an additional build tool.

In the past, the release notes and regression testing instructions were also distributed as plain text, but this practice has been discontinued.

J.3.5. Syntax Check

Building the documentation can take very long. But there is a method to just check the correct syntax of the documentation files, which only takes a few seconds:

doc/src/sgml$ make check

J.4. Documentation Authoring

The documentation sources are most conveniently modified with an editor that has a mode for editing XML, and even more so if it has some awareness of XML schema languages so that it can know about DocBook syntax specifically.

Note that for historical reasons the documentation source files are named with an extension .sgml even though they are now XML files. So you might need to adjust your editor configuration to set the correct mode.

J.4.1. Emacs

nXML Mode, which ships with Emacs, is the most common mode for editing XML documents with Emacs. It will allow you to use Emacs to insert tags and check markup consistency, and it supports DocBook out of the box. Check the nXML manual\textsuperscript{12} for detailed documentation.

src/tools/editors/emacs.samples contains recommended settings for this mode.

J.5. Style Guide

J.5.1. Reference Pages

Reference pages should follow a standard layout. This allows users to find the desired information more quickly, and it also encourages writers to document all relevant aspects of a command. Consistency is not only desired among PostgreSQL reference pages, but also with reference pages provided by the operating system and other packages. Hence the following guidelines have been developed. They are for the most part consistent with similar guidelines established by various operating systems.

Reference pages that describe executable commands should contain the following sections, in this order. Sections that do not apply can be omitted. Additional top-level sections should only be used in special circumstances; often that information belongs in the “Usage” section.

\textsuperscript{12}https://www.gnu.org/software/emacs/manual/html_mono/nxml-mode.html
Documentation

Name
This section is generated automatically. It contains the command name and a half-sentence summary of its functionality.

Synopsis
This section contains the syntax diagram of the command. The synopsis should normally not list each command-line option; that is done below. Instead, list the major components of the command line, such as where input and output files go.

Description
Several paragraphs explaining what the command does.

Options
A list describing each command-line option. If there are a lot of options, subsections can be used.

Exit Status
If the program uses 0 for success and non-zero for failure, then you do not need to document it. If there is a meaning behind the different non-zero exit codes, list them here.

Usage
Describe any sublanguage or run-time interface of the program. If the program is not interactive, this section can usually be omitted. Otherwise, this section is a catch-all for describing run-time features. Use subsections if appropriate.

Environment
List all environment variables that the program might use. Try to be complete; even seemingly trivial variables like SHELL might be of interest to the user.

Files
List any files that the program might access implicitly. That is, do not list input and output files that were specified on the command line, but list configuration files, etc.

Diagnostics
Explain any unusual output that the program might create. Refrain from listing every possible error message. This is a lot of work and has little use in practice. But if, say, the error messages have a standard format that the user can parse, this would be the place to explain it.

Notes
Anything that doesn’t fit elsewhere, but in particular bugs, implementation flaws, security considerations, compatibility issues.

Examples
Examples

History
If there were some major milestones in the history of the program, they might be listed here. Usually, this section can be omitted.
Author

Author (only used in the contrib section)

See Also

Cross-references, listed in the following order: other PostgreSQL command reference pages, PostgreSQL SQL command reference pages, citation of PostgreSQL manuals, other reference pages (e.g., operating system, other packages), other documentation. Items in the same group are listed alphabetically.

Reference pages describing SQL commands should contain the following sections: Name, Synopsis, Description, Parameters, Outputs, Notes, Examples, Compatibility, History, See Also. The Parameters section is like the Options section, but there is more freedom about which clauses of the command can be listed. The Outputs section is only needed if the command returns something other than a default command-completion tag. The Compatibility section should explain to what extent this command conforms to the SQL standard(s), or to which other database system it is compatible. The See Also section of SQL commands should list SQL commands before cross-references to programs.
Appendix K. PostgreSQL Limits

Table K.1 describes various hard limits of PostgreSQL. However, practical limits, such as performance limitations or available disk space may apply before absolute hard limits are reached.

Table K.1. PostgreSQL Limitations

<table>
<thead>
<tr>
<th>Item</th>
<th>Upper Limit</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>database size</td>
<td>unlimited</td>
<td></td>
</tr>
<tr>
<td>number of databases</td>
<td>4,294,950,911</td>
<td></td>
</tr>
<tr>
<td>relations per database</td>
<td>1,431,650,303</td>
<td></td>
</tr>
<tr>
<td>relation size</td>
<td>32 TB</td>
<td>with the default BLCKSZ of 8192 bytes</td>
</tr>
<tr>
<td>rows per table</td>
<td>limited by the number of tuples that can fit onto 4,294,967,295 pages</td>
<td></td>
</tr>
<tr>
<td>columns per table</td>
<td>1600</td>
<td>further limited by tuple size fitting on a single page; see note below</td>
</tr>
<tr>
<td>columns in a result set</td>
<td>1664</td>
<td></td>
</tr>
<tr>
<td>field size</td>
<td>1 GB</td>
<td></td>
</tr>
<tr>
<td>identifier length</td>
<td>63 bytes</td>
<td>can be increased by recompiling PostgreSQL</td>
</tr>
<tr>
<td>indexes per table</td>
<td>unlimited</td>
<td>constrained by maximum relations per database</td>
</tr>
<tr>
<td>columns per index</td>
<td>32</td>
<td>can be increased by recompiling PostgreSQL</td>
</tr>
<tr>
<td>partition keys</td>
<td>32</td>
<td>can be increased by recompiling PostgreSQL</td>
</tr>
</tbody>
</table>

The maximum number of columns for a table is further reduced as the tuple being stored must fit in a single 8192-byte heap page. For example, excluding the tuple header, a tuple made up of 1600 int columns would consume 6400 bytes and could be stored in a heap page, but a tuple of 1600 bigint columns would consume 12800 bytes and would therefore not fit inside a heap page. Variable-length fields of types such as text, varchar, and char can have their values stored out of line in the table’s TOAST table when the values are large enough to require it. Only an 18-byte pointer must remain inside the tuple in the table’s heap. For shorter length variable-length fields, either a 4-byte or 1-byte field header is used and the value is stored inside the heap tuple.

Columns that have been dropped from the table also contribute to the maximum column limit. Moreover, although the dropped column values for newly created tuples are internally marked as null in the tuple’s null bitmap, the null bitmap also occupies space.
Appendix L. Acronyms

Appendix M. Glossary

This is a list of terms and their meaning in the context of PostgreSQL and relational database systems in general.

**ACID**

*Atomicity, Consistency, Isolation, and Durability.* This set of properties of database transactions is intended to guarantee validity in concurrent operation and even in event of errors, power failures, etc.

**Aggregate function (routine)**

A function that combines (aggregates) multiple input values, for example by counting, averaging or adding, yielding a single output value.

For more information, see Section 9.21.

See Also Window function (routine).

**Analytic function**

See Window function (routine).

**Analyze (operation)**

The act of collecting statistics from data in tables and other relations to help the query planner to make decisions about how to execute queries.

(Don't confuse this term with the ANALYZE option to the EXPLAIN command.)

For more information, see ANALYZE.

**Atomic**

In reference to a *datum*: the fact that its value cannot be broken down into smaller components.

In reference to a *database transaction*: see atomicity.

**Atomicity**

The property of a transaction that either all its operations complete as a single unit or none do. In addition, if a system failure occurs during the execution of a transaction, no partial results are visible after recovery. This is one of the ACID properties.

**Attribute**

An element with a certain name and data type found within a tuple.

**Autovacuum (process)**

A set of background processes that routinely perform vacuum and analyze operations. The auxiliary process that coordinates the work and is always present (unless autovacuum is disabled) is known as the autovacuum launcher, and the processes that carry out the tasks are known as the autovacuum workers.

For more information, see Section 25.1.6.

**Auxiliary process**

A process within an instance that is in charge of some specific background task for the instance. The auxiliary processes consist of the autovacuum launcher (but not the autovacuum workers), the background writer, the checkpoint writer, the logger, the startup process, the WAL archiver, the WAL receiver (but not the WAL senders), and the WAL writer.
Glossary

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Backend (process)</td>
<td>Process of an instance which acts on behalf of a client session and handles its requests. (Don't confuse this term with the similar terms Background Worker or Background Writer).</td>
</tr>
<tr>
<td>Background worker (process)</td>
<td>Process within an instance, which runs system- or user-supplied code. Serves as infrastructure for several features in PostgreSQL, such as logical replication and parallel queries. In addition, Extensions can add custom background worker processes. For more information, see Chapter 48.</td>
</tr>
<tr>
<td>Background writer (process)</td>
<td>An auxiliary process that writes dirty data pages from shared memory to the file system. It wakes up periodically, but works only for a short period in order to distribute its expensive I/O activity over time to avoid generating larger I/O peaks which could block other processes. For more information, see Section 20.4.5.</td>
</tr>
<tr>
<td>Base Backup</td>
<td>A binary copy of all database cluster files. It is generated by the tool pg_basebackup. In combination with WAL files it can be used as the starting point for recovery, log shipping, or streaming replication.</td>
</tr>
<tr>
<td>Bloat</td>
<td>Space in data pages which does not contain current row versions, such as unused (free) space or outdated row versions.</td>
</tr>
<tr>
<td>Cast</td>
<td>A conversion of a datum from its current data type to another data type. For more information, see CREATE CAST.</td>
</tr>
<tr>
<td>Catalog</td>
<td>The SQL standard uses this term to indicate what is called a database in PostgreSQL's terminology. (Don't confuse this term with system catalog).</td>
</tr>
<tr>
<td>Check constraint</td>
<td>A type of constraint defined on a relation which restricts the values allowed in one or more attributes. The check constraint can make reference to any attribute of the same row in the relation, but cannot reference other rows of the same relation or other relations. For more information, see Section 5.4.</td>
</tr>
<tr>
<td>Checkpoint</td>
<td>A point in the WAL sequence at which it is guaranteed that the heap and index data files have been updated with all information from shared memory modified before that checkpoint; a checkpoint record is written and flushed to WAL to mark that point. A checkpoint is also the act of carrying out all the actions that are necessary to reach a checkpoint as defined above. This process is initiated when predefined conditions are met, such as a specified amount of time has passed, or a certain volume of records has been written; or it can be invoked by the user with the command CHECKPOINT.</td>
</tr>
<tr>
<td>2957</td>
<td></td>
</tr>
<tr>
<td><strong>Glossary</strong></td>
<td></td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>Checkpointer (process)</td>
<td>An <em>auxiliary process</em> that is responsible for executing <em>checkpoints</em>.</td>
</tr>
<tr>
<td>Class (archaic)</td>
<td>See Relation.</td>
</tr>
<tr>
<td>Client (process)</td>
<td>Any process, possibly remote, that establishes a <em>session</em> by connecting to an <em>instance</em> to interact with a <em>database</em>.</td>
</tr>
<tr>
<td>Column</td>
<td>An <em>attribute</em> found in a <em>table</em> or <em>view</em>.</td>
</tr>
<tr>
<td>Commit</td>
<td>The act of finalizing a <em>transaction</em> within the <em>database</em>, which makes it visible to other transactions and assures its <em>durability</em>. For more information, see COMMIT.</td>
</tr>
<tr>
<td>Concurrency</td>
<td>The concept that multiple independent operations happen within the <em>database</em> at the same time. In PostgreSQL, concurrency is controlled by the <em>multiversion concurrency control</em> mechanism.</td>
</tr>
<tr>
<td>Connection</td>
<td>An established line of communication between a client process and a <em>backend</em> process, usually over a network, supporting a <em>session</em>. This term is sometimes used as a synonym for session. For more information, see Section 20.3.</td>
</tr>
<tr>
<td>Consistency</td>
<td>The property that the data in the <em>database</em> is always in compliance with <em>integrity constraints</em>. Transactions may be allowed to violate some of the constraints transiently before it commits, but if such violations are not resolved by the time it commits, such a transaction is automatically <em>rolled back</em>. This is one of the ACID properties.</td>
</tr>
<tr>
<td>Constraint</td>
<td>A restriction on the values of data allowed within a <em>table</em>, or in attributes of a <em>domain</em>. For more information, see Section 5.4.</td>
</tr>
<tr>
<td>Cumulative Statistics System</td>
<td>A system which, if enabled, accumulates statistical information about the <em>instance's</em> activities. For more information, see Section 28.2.</td>
</tr>
<tr>
<td>Data area</td>
<td>See Data directory.</td>
</tr>
<tr>
<td>Database</td>
<td>A named collection of <em>local SQL objects</em>. For more information, see Section 23.1.</td>
</tr>
<tr>
<td>Database cluster</td>
<td>A collection of databases and global SQL objects, and their common static and dynamic metadata. Sometimes referred to as a <em>cluster</em>. In PostgreSQL, the term <em>cluster</em> is also sometimes used to refer to an instance. (Don't confuse this term with the SQL command <code>CLUSTER</code>.)</td>
</tr>
<tr>
<td>Database server</td>
<td>See Instance.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>----------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Data directory</td>
<td>The base directory on the file system of a server that contains all data files and subdirectories associated with a database cluster (with the exception of tablespaces, and optionally WAL). The environment variable PGDATA is commonly used to refer to the data directory.</td>
</tr>
<tr>
<td></td>
<td>A cluster's storage space comprises the data directory plus any additional tablespaces. For more information, see Section 72.1.</td>
</tr>
<tr>
<td>Data page</td>
<td>The basic structure used to store relation data. All pages are of the same size. Data pages are typically stored on disk, each in a specific file, and can be read to shared buffers where they can be modified, becoming dirty. They become clean when written to disk. New pages, which initially exist in memory only, are also dirty until written.</td>
</tr>
<tr>
<td></td>
<td>For more information, see DELETE.</td>
</tr>
<tr>
<td>Datum</td>
<td>The internal representation of one value of an SQL data type.</td>
</tr>
<tr>
<td>Delete</td>
<td>An SQL command which removes rows from a given table or relation. For more information, see DELETE.</td>
</tr>
<tr>
<td>Domain</td>
<td>A user-defined data type that is based on another underlying data type. It acts the same as the underlying type except for possibly restricting the set of allowed values.</td>
</tr>
<tr>
<td></td>
<td>For more information, see Section 8.18.</td>
</tr>
<tr>
<td>Durability</td>
<td>The assurance that once a transaction has been committed, the changes remain even after a system failure or crash. This is one of the ACID properties.</td>
</tr>
<tr>
<td>Epoch</td>
<td>See Transaction ID.</td>
</tr>
<tr>
<td>Extension</td>
<td>A software add-on package that can be installed on an instance to get extra features. For more information, see Section 38.17.</td>
</tr>
<tr>
<td>File segment</td>
<td>A physical file which stores data for a given relation. File segments are limited in size by a configuration value (typically 1 gigabyte), so if a relation exceeds that size, it is split into multiple segments.</td>
</tr>
<tr>
<td></td>
<td>For more information, see Section 72.1. (Don't confuse this term with the similar term WAL segment).</td>
</tr>
<tr>
<td>Foreign data wrapper</td>
<td>A means of representing data that is not contained in the local database so that it appears as if were in local table(s). With a foreign data wrapper it is possible to define a foreign server and foreign tables.</td>
</tr>
<tr>
<td></td>
<td>For more information, see CREATE FOREIGN DATA WRAPPER.</td>
</tr>
<tr>
<td>Foreign key</td>
<td>A type of constraint defined on one or more columns in a table which requires the value(s) in those columns to identify zero or one row in another (or, infrequently, the same) table.</td>
</tr>
</tbody>
</table>
Foreign server

A named collection of foreign tables which all use the same foreign data wrapper and have other configuration values in common.

For more information, see CREATE SERVER.

Foreign table (relation)

A relation which appears to have rows and columns similar to a regular table, but will forward requests for data through its foreign data wrapper, which will return result sets structured according to the definition of the foreign table.

For more information, see CREATE FOREIGN TABLE.

Fork

Each of the separate segmented file sets in which a relation is stored. The main fork is where the actual data resides. There also exist two secondary forks for metadata: the free space map and the visibility map. Unlogged relations also have an init fork.

Free space map (fork)

A storage structure that keeps metadata about each data page of a table's main fork. The free space map entry for each page stores the amount of free space that's available for future tuples, and is structured to be efficiently searched for available space for a new tuple of a given size.

For more information, see Section 72.3.

Function (routine)

A type of routine that receives zero or more arguments, returns zero or more output values, and is constrained to run within one transaction. Functions are invoked as part of a query, for example via SELECT. Certain functions can return sets; those are called set-returning functions.

Functions can also be used for triggers to invoke.

For more information, see CREATE FUNCTION.

Grant

An SQL command that is used to allow a user or role to access specific objects within the database.

For more information, see GRANT.

Heap

Contains the values of row attributes (i.e., the data) for a relation. The heap is realized within one or more file segments in the relation's main fork.

Host

A computer that communicates with other computers over a network. This is sometimes used as a synonym for server. It is also used to refer to a computer where client processes run.

Index (relation)

A relation that contains data derived from a table or materialized view. Its internal structure supports fast retrieval of and access to the original data.

For more information, see CREATE INDEX.

Insert

An SQL command used to add new data into a table.

For more information, see INSERT.
### Instance
A group of *backend* and *auxiliary processes* that communicate using a common shared memory area. One *postmaster process* manages the instance; one instance manages exactly one *database cluster* with all its databases. Many instances can run on the same *server* as long as their TCP ports do not conflict.

The instance handles all key features of a DBMS: read and write access to files and shared memory, assurance of the ACID properties, *connections to client processes*, privilege verification, crash recovery, replication, etc.

### Isolation
The property that the effects of a transaction are not visible to *concurrent transactions* before it commits. This is one of the ACID properties.

For more information, see Section 13.2.

### Join
An operation and SQL keyword used in *queries* for combining data from multiple *relations*.

### Key
A means of identifying a *row* within a *table* or other *relation* by values contained within one or more *attributes* in that relation.

### Lock
A mechanism that allows a process to limit or prevent simultaneous access to a resource.

### Log file
Log files contain human-readable text lines about events. Examples include login failures, long-running queries, etc.

For more information, see Section 25.3.

### Logged
A *table* is considered *logged* if changes to it are sent to the WAL. By default, all regular tables are logged. A table can be specified as *unlogged* either at creation time or via the `ALTER TABLE` command.

### Logger (process)
An *auxiliary process* which, if enabled, writes information about database events into the current *log file*. When reaching certain time- or volume-dependent criteria, a new log file is created. Also called *syslogger*.

For more information, see Section 20.8.

### Log record
Archaic term for a *WAL record*.

### Master (server)
See Primary (server).

### Materialized
The property that some information has been pre-computed and stored for later use, rather than computing it on-the-fly.

This term is used in *materialized view*, to mean that the data derived from the view's query is stored on disk separately from the sources of that data.

This term is also used to refer to some multi-step queries to mean that the data resulting from executing a given step is stored in memory (with the possibility of spilling to disk), so that it can be read multiple times by another step.
<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Materialized view (relation)</td>
<td>A relation that is defined by a <code>SELECT</code> statement (just like a view), but stores data in the same way that a table does. It cannot be modified via <code>INSERT</code>, <code>UPDATE</code>, or <code>DELETE</code> operations. For more information, see CREATE MATERIALIZED VIEW.</td>
</tr>
<tr>
<td>Multi-version concurrency control (MVCC)</td>
<td>A mechanism designed to allow several transactions to be reading and writing the same rows without one process causing other processes to stall. In PostgreSQL, MVCC is implemented by creating copies (versions) of tuples as they are modified; after transactions that can see the old versions terminate, those old versions need to be removed.</td>
</tr>
<tr>
<td>Null</td>
<td>A concept of non-existence that is a central tenet of relational database theory. It represents the absence of a definite value.</td>
</tr>
<tr>
<td>Optimizer</td>
<td>See Query planner.</td>
</tr>
<tr>
<td>Parallel query</td>
<td>The ability to handle parts of executing a query to take advantage of parallel processes on servers with multiple CPUs.</td>
</tr>
<tr>
<td>Partition</td>
<td>One of several disjoint (not overlapping) subsets of a larger set. In reference to a partitioned table: One of the tables that each contain part of the data of the partitioned table, which is said to be the parent. The partition is itself a table, so it can also be queried directly; at the same time, a partition can sometimes be a partitioned table, allowing hierarchies to be created. In reference to a window function in a query, a partition is a user-defined criterion that identifies which neighboring rows of the query's result set can be considered by the function.</td>
</tr>
<tr>
<td>Partitioned table (relation)</td>
<td>A relation that is in semantic terms the same as a table, but whose storage is distributed across several partitions.</td>
</tr>
<tr>
<td>Postmaster (process)</td>
<td>The very first process of an instance. It starts and manages the auxiliary processes and creates backend processes on demand. For more information, see Section 19.3.</td>
</tr>
<tr>
<td>Primary key</td>
<td>A special case of a unique constraint defined on a table or other relation that also guarantees that all of the attributes within the primary key do not have null values. As the name implies, there can be only one primary key per table, though it is possible to have multiple unique constraints that also have no null-capable attributes.</td>
</tr>
<tr>
<td>Primary (server)</td>
<td>When two or more databases are linked via replication, the server that is considered the authoritative source of information is called the primary, also known as a master.</td>
</tr>
<tr>
<td>Procedure (routine)</td>
<td>A type of routine. Their distinctive qualities are that they do not return values, and that they are allowed to make transactional statements such as COMMIT and ROLLBACK. They are invoked via the CALL command. For more information, see CREATE PROCEDURE.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Query</td>
<td>A request sent by a client to a backend, usually to return results or to modify data on the database.</td>
</tr>
<tr>
<td>Query planner</td>
<td>The part of PostgreSQL that is devoted to determining (planning) the most efficient way to execute queries. Also known as query optimizer, optimizer, or simply planner.</td>
</tr>
<tr>
<td>Record</td>
<td>See Tuple.</td>
</tr>
<tr>
<td>Recycling</td>
<td>See WAL file.</td>
</tr>
<tr>
<td>Referential integrity</td>
<td>A means of restricting data in one relation by a foreign key so that it must have matching data in another relation.</td>
</tr>
<tr>
<td>Relation</td>
<td>The generic term for all objects in a database that have a name and a list of attributes defined in a specific order. Tables, sequences, views, foreign tables, materialized views, composite types, and indexes are all relations. More generically, a relation is a set of tuples; for example, the result of a query is also a relation.</td>
</tr>
<tr>
<td>Replica (server)</td>
<td>A database that is paired with a primary database and is maintaining a copy of some or all of the primary database's data. The foremost reasons for doing this are to allow for greater access to that data, and to maintain availability of the data in the event that the primary becomes unavailable.</td>
</tr>
<tr>
<td>Replication</td>
<td>The act of reproducing data on one server onto another server called a replica. This can take the form of physical replication, where all file changes from one server are copied verbatim, or logical replication where a defined subset of data changes are conveyed using a higher-level representation.</td>
</tr>
<tr>
<td>Result set</td>
<td>A relation transmitted from a backend process to a client upon the completion of an SQL command, usually a SELECT but it can be an INSERT, UPDATE, or DELETE command if the RETURNING clause is specified. The fact that a result set is a relation means that a query can be used in the definition of another query, becoming a subquery.</td>
</tr>
<tr>
<td>Revoke</td>
<td>A command to prevent access to a named set of database objects for a named list of roles. For more information, see REVOKE.</td>
</tr>
<tr>
<td>Role</td>
<td>A collection of access privileges to the instance. Roles are themselves a privilege that can be granted to other roles. This is often done for convenience or to ensure completeness when multiple users need the same privileges. For more information, see CREATE ROLE.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Rollback</td>
<td>A command to undo all of the operations performed since the beginning of a transaction. For more information, see ROLLBACK.</td>
</tr>
<tr>
<td>Routine</td>
<td>A defined set of instructions stored in the database system that can be invoked for execution. A routine can be written in a variety of programming languages. Routines can be functions (including set-returning functions and trigger functions), aggregate functions, and procedures. Many routines are already defined within PostgreSQL itself, but user-defined ones can also be added.</td>
</tr>
<tr>
<td>Row</td>
<td>See Tuple.</td>
</tr>
<tr>
<td>Savepoint</td>
<td>A special mark in the sequence of steps in a transaction. Data modifications after this point in time may be reverted to the time of the savepoint. For more information, see SAVEPOINT.</td>
</tr>
<tr>
<td>Schema</td>
<td>A schema is a namespace for SQL objects, which all reside in the same database. Each SQL object must reside in exactly one schema. All system-defined SQL objects reside in schema pg_catalog. More generically, the term schema is used to mean all data descriptions (table definitions, constraints, comments, etc.) for a given database or subset thereof. For more information, see Section 5.9.</td>
</tr>
<tr>
<td>Segment</td>
<td>See File segment.</td>
</tr>
<tr>
<td>Select</td>
<td>The SQL command used to request data from a database. Normally, SELECT commands are not expected to modify the database in any way, but it is possible that functions invoked within the query could have side effects that do modify data. For more information, see SELECT.</td>
</tr>
<tr>
<td>Sequence (relation)</td>
<td>A type of relation that is used to generate values. Typically the generated values are sequential non-repeating numbers. They are commonly used to generate surrogate primary key values.</td>
</tr>
<tr>
<td>Server</td>
<td>A computer on which PostgreSQL instances run. The term server denotes real hardware, a container, or a virtual machine. This term is sometimes used to refer to an instance or to a host.</td>
</tr>
<tr>
<td>Session</td>
<td>A state that allows a client and a backend to interact, communicating over a connection.</td>
</tr>
<tr>
<td>Shared memory</td>
<td>RAM which is used by the processes common to an instance. It mirrors parts of database files, provides a transient area for WAL records, and stores additional common information. Note that shared memory belongs to the complete instance, not to a single database.</td>
</tr>
</tbody>
</table>
### Glossary

**The largest part of shared memory is known as shared buffers** and is used to mirror part of data files, organized into pages. When a page is modified, it is called a dirty page until it is written back to the file system.

For more information, see Section 20.4.1.

<table>
<thead>
<tr>
<th>SQL object</th>
<th>Any object that can be created with a <code>CREATE</code> command. Most objects are specific to one database, and are commonly known as local objects.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Most local objects reside in a specific schema in their containing database, such as relations (all types), routines (all types), data types, etc. The names of such objects of the same type in the same schema are enforced to be unique.</td>
</tr>
<tr>
<td></td>
<td>There also exist local objects that do not reside in schemas; some examples are extensions, data type casts, and foreign data wrappers. The names of such objects of the same type are enforced to be unique within the database.</td>
</tr>
<tr>
<td></td>
<td>Other object types, such as roles, tablespaces, replication origins, subscriptions for logical replication, and databases themselves are not local SQL objects since they exist entirely outside of any specific database; they are called global objects. The names of such objects are enforced to be unique within the whole database cluster.</td>
</tr>
<tr>
<td>SQL standard</td>
<td>A series of documents that define the SQL language.</td>
</tr>
<tr>
<td>Standby (server)</td>
<td>See Replica (server).</td>
</tr>
<tr>
<td>Startup process</td>
<td>An auxiliary process that replays WAL during crash recovery and in a physical replica.</td>
</tr>
<tr>
<td>(The name is historical: the startup process was named before replication was implemented; the name refers to its task as it relates to the server startup following a crash.)</td>
<td></td>
</tr>
<tr>
<td>System catalog</td>
<td>A collection of tables which describe the structure of all SQL objects of the instance. The system catalog resides in the schema <code>pg_catalog</code>. These tables contain data in internal representation and are not typically considered useful for user examination; a number of user-friendly views, also in schema <code>pg_catalog</code>, offer more convenient access to some of that information, while additional tables and views exist in schema <code>information_schema</code> (see Chapter 37) that expose some of the same and additional information as mandated by the SQL standard.</td>
</tr>
<tr>
<td></td>
<td>For more information, see Section 5.9.</td>
</tr>
<tr>
<td>Table</td>
<td>A collection of tuples having a common data structure (the same number of attributes, in the same order, having the same name and type per position). A table is the most common form of relation in PostgreSQL.</td>
</tr>
</tbody>
</table>
Glossary

For more information, see CREATE TABLE.

Tablespace
A named location on the server file system. All SQL objects which require storage beyond their definition in the system catalog must belong to a single tablespace. Initially, a database cluster contains a single usable tablespace which is used as the default for all SQL objects, called pg_default.

For more information, see Section 23.6.

Temporary table
Tables that exist either for the lifetime of a session or a transaction, as specified at the time of creation. The data in them is not visible to other sessions, and is not logged. Temporary tables are often used to store intermediate data for a multi-step operation.

For more information, see CREATE TABLE.

TOAST
A mechanism by which large attributes of table rows are split and stored in a secondary table, called the TOAST table. Each relation with large attributes has its own TOAST table.

For more information, see Section 72.2.

Transaction
A combination of commands that must act as a single atomic command: they all succeed or all fail as a single unit, and their effects are not visible to other sessions until the transaction is complete, and possibly even later, depending on the isolation level.

For more information, see Section 13.2.

Transaction ID
The numerical, unique, sequentially-assigned identifier that each transaction receives when it first causes a database modification. Frequently abbreviated as xid. When stored on disk, xids are only 32-bits wide, so only approximately four billion write transaction IDs can be generated; to permit the system to run for longer than that, epochs are used, also 32 bits wide. When the counter reaches the maximum xid value, it starts over at 3 (values under that are reserved) and the epoch value is incremented by one. In some contexts, the epoch and xid values are considered together as a single 64-bit value.

For more information, see Section 8.19.

Transactions per second (TPS)
Average number of transactions that are executed per second, totaled across all sessions active for a measured run. This is used as a measure of the performance characteristics of an instance.

Trigger
A function which can be defined to execute whenever a certain operation (INSERT, UPDATE, DELETE, TRUNCATE) is applied to a relation. A trigger executes within the same transaction as the statement which invoked it, and if the function fails, then the invoking statement also fails.

For more information, see CREATE TRIGGER.

Tuple
A collection of attributes in a fixed order. That order may be defined by the table (or other relation) where the tuple is contained, in which
Glossary

case the tuple is often called a *row*. It may also be defined by the
structure of a result set, in which case it is sometimes called a *record*.

**Unique constraint**
A type of *constraint* defined on a *relation* which restricts the values
allowed in one or a combination of columns so that each value or
combination of values can only appear once in the relation — that is,
no other row in the relation contains values that are equal to those.

Because *null values* are not considered equal to each other, multiple
rows with null values are allowed to exist without violating the unique
constraint.

**Unlogged**
The property of certain *relations* that the changes to them are not re-
fracted in the *WAL*. This disables replication and crash recovery for
these relations.

The primary use of unlogged tables is for storing transient work data
that must be shared across processes.

*Temporary tables* are always unlogged.

**Update**
An SQL command used to modify *rows* that may already exist in a
specified *table*. It cannot create or remove rows.

For more information, see UPDATE.

**User**
A *role* that has the LOGIN privilege.

**User mapping**
The translation of login credentials in the local database to credentials
in a remote data system defined by a *foreign data wrapper*.

For more information, see CREATE USER MAPPING.

**Vacuum**
The process of removing outdated *tuple versions* from tables or mate-
rialized views, and other closely related processing required by Post-
greSQL's implementation of *MVCC*. This can be initiated through the
use of the VACUUM command, but can also be handled automatically
via autovacuum processes.

For more information, see Section 25.1 .

**View**
A *relation* that is defined by a SELECT statement, but has no storage
of its own. Any time a query references a view, the definition of the
view is substituted into the query as if the user had typed it as a sub-
query instead of the name of the view.

For more information, see CREATE VIEW.

**Visibility map (fork)**
A storage structure that keeps metadata about each data page of a ta-
ble's main fork. The visibility map entry for each page stores two bits:
the first one (*all-visible*) indicates that all tuples in the page are
visible to all transactions. The second one (*all-frozen*) indicates
that all tuples in the page are marked frozen.

**WAL**
See Write-ahead log.

**WAL archiver (process)**
An *auxiliary process* which, if enabled, saves copies of *WAL files* for
the purpose of creating backups or keeping replicas current.
## Glossary

For more information, see Section 26.3.

<table>
<thead>
<tr>
<th>Glossary Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WAL file</td>
<td>Also known as WAL segment or WAL segment file. Each of the sequentially-numbered files that provide storage space for WAL. The files are all of the same predefined size and are written in sequential order, interspersing changes as they occur in multiple simultaneous sessions. If the system crashes, the files are read in order, and each of the changes is replayed to restore the system to the state it was in before the crash. Each WAL file can be released after a checkpoint writes all the changes in it to the corresponding data files. Releasing the file can be done either by deleting it, or by changing its name so that it will be used in the future, which is called recycling. For more information, see Section 30.6.</td>
</tr>
<tr>
<td>WAL record</td>
<td>A low-level description of an individual data change. It contains sufficient information for the data change to be re-executed (replayed) in case a system failure causes the change to be lost. WAL records use a non-printable binary format. For more information, see Section 30.6.</td>
</tr>
<tr>
<td>WAL receiver (process)</td>
<td>An auxiliary process that runs on a replica to receive WAL from the primary server for replay by the startup process. For more information, see Section 27.2.</td>
</tr>
<tr>
<td>WAL segment</td>
<td>See WAL file.</td>
</tr>
<tr>
<td>WAL sender (process)</td>
<td>A special backend process that streams WAL over a network. The receiving end can be a WAL receiver in a replica, pg_receivewal, or any other client program that speaks the replication protocol.</td>
</tr>
<tr>
<td>WAL writer (process)</td>
<td>A process that writes WAL records from shared memory to WAL files. For more information, see Section 20.5.</td>
</tr>
<tr>
<td>Window function (routine)</td>
<td>A type of function used in a query that applies to a partition of the query’s result set; the function's result is based on values found in rows of the same partition or frame. All aggregate functions can be used as window functions, but window functions can also be used to, for example, give ranks to each of the rows in the partition. Also known as analytic functions. For more information, see Section 3.5.</td>
</tr>
<tr>
<td>Write-ahead log</td>
<td>The journal that keeps track of the changes in the database cluster as user- and system-invoked operations take place. It comprises many individual WAL records written sequentially to WAL files.</td>
</tr>
</tbody>
</table>
Appendix N. Color Support

Most programs in the PostgreSQL package can produce colorized console output. This appendix describes how that is configured.

N.1. When Color is Used

To use colorized output, set the environment variable PG_COLOR as follows:

1. If the value is always, then color is used.
2. If the value is auto and the standard error stream is associated with a terminal device, then color is used.
3. Otherwise, color is not used.

N.2. Configuring the Colors

The actual colors to be used are configured using the environment variable PG_COLORS (note plural). The value is a colon-separated list of key=value pairs. The keys specify what the color is to be used for. The values are SGR (Select Graphic Rendition) specifications, which are interpreted by the terminal.

The following keys are currently in use:

- **error**
  - used to highlight the text “error” in error messages
- **warning**
  - used to highlight the text “warning” in warning messages
- **note**
  - used to highlight the text “detail” and “hint” in such messages
- **locus**
  - used to highlight location information (e.g., program name and file name) in messages

The default value is error=01;31:warning=01;35:note=01;36:locus=01 (01;31 = bold red, 01;35 = bold magenta, 01;36 = bold cyan, 01 = bold default color).

**Tip**

This color specification format is also used by other software packages such as GCC, GNU core-utils, and GNU grep.
Appendix O. Obsolete or Renamed Features

Functionality is sometimes removed from PostgreSQL, feature, setting and file names sometimes change, or documentation moves to different places. This section directs users coming from old versions of the documentation or from external links to the appropriate new location for the information they need.

O.1. recovery.conf file merged into postgresql.conf

PostgreSQL 11 and below used a configuration file named recovery.conf to manage replicas and standbys. Support for this file was removed in PostgreSQL 12. See the release notes for PostgreSQL 12 for details on this change.

On PostgreSQL 12 and above, archive recovery, streaming replication, and PITR are configured using normal server configuration parameters. These are set in postgresql.conf or via ALTER SYSTEM like any other parameter.

The server will not start if a recovery.conf exists.

The trigger_file setting has been renamed to promote_trigger_file.

The standby_mode setting has been removed. A standby.signal file in the data directory is used instead. See Standby Server Operation for details.

O.2. Default Roles Renamed to Predefined Roles

PostgreSQL 13 and below used the term “Default Roles”. However, as these roles are not able to actually be changed and are installed as part of the system at initialization time, the more appropriate term to use is “Predefined Roles”. See Section 22.5 for current documentation regarding Predefined Roles, and the release notes for PostgreSQL 14 for details on this change.

O.3. pg_xlogdump renamed to pg_waldump

PostgreSQL 9.6 and below provided a command named pg_xlogdump to read write-ahead-log (WAL) files. This command was renamed to pg_waldump. See pg_waldump for documentation of pg_waldump and see the release notes for PostgreSQL 10 for details on this change.

O.4. pg_resetxlog renamed to pg_resetwal

PostgreSQL 9.6 and below provided a command named pg_resetxlog to reset the write-ahead-log (WAL) files. This command was renamed to pg_resetwal. See pg_resetwal for documentation of pg_resetwal and see the release notes for PostgreSQL 10 for details on this change.

O.5. pg_receivexlog renamed to pg_receivewal
PostgreSQL 9.6 and below provided a command named `pg_receivexlog` to fetch write-ahead-log (WAL) files. This command was renamed to `pg_receivewal`, see `pg_receivewal` for documentation of `pg_receivewal` and see the release notes for PostgreSQL 10 for details on this change.
Bibliography

Selected references and readings for SQL and PostgreSQL.

Some white papers and technical reports from the original POSTGRES development team are available at the University of California, Berkeley, Computer Science Department web site.
