Aside from the index's own internal consistency requirements, concurrent updates create issues about consistency between the parent table (the heap) and the index. Because PostgreSQL separates accesses and updates of the heap from those of the index, there are windows in which the index might be inconsistent with the heap. We handle this problem with the following rules:

- A new heap entry is made before making its index entries. (Therefore a concurrent index scan is likely to fail to see the heap entry. This is okay because the index reader would be uninterested in an uncommitted row anyway. But see Section 64.5.)
- When a heap entry is to be deleted (by VACUUM), all its index entries must be removed first.
- An index scan must maintain a pin on the index page holding the item last returned by `amgettuple`, and `ambulkdelete` cannot delete entries from pages that are pinned by other backends. The need for this rule is explained below.

Without the third rule, it is possible for an index reader to see an index entry just before it is removed by VACUUM, and then to arrive at the corresponding heap entry after that was removed by VACUUM.
This creates no serious problems if that item number is still unused when the reader reaches it, since an empty item slot will be ignored by `heap_fetch()`. But what if a third backend has already reused the item slot for something else? When using an MVCC-compliant snapshot, there is no problem because the new occupant of the slot is certain to be too new to pass the snapshot test. However, with a non-MVCC-compliant snapshot (such as `SnapshotAny`), it would be possible to accept and return a row that does not in fact match the scan keys. We could defend against this scenario by requiring the scan keys to be rechecked against the heap row in all cases, but that is too expensive. Instead, we use a pin on an index page as a proxy to indicate that the reader might still be “in flight” from the index entry to the matching heap entry. Making `ambulkdelete` block on such a pin ensures that `VACUUM` cannot delete the heap entry before the reader is done with it. This solution costs little in run time, and adds blocking overhead only in the rare cases where there actually is a conflict.

This solution requires that index scans be “synchronous”: we have to fetch each heap tuple immediately after scanning the corresponding index entry. This is expensive for a number of reasons. An “asynchronous” scan in which we collect many TIDs from the index, and only visit the heap tuples sometime later, requires much less index locking overhead and can allow a more efficient heap access pattern. Per the above analysis, we must use the synchronous approach for non-MVCC-compliant snapshots, but an asynchronous scan is workable for a query using an MVCC snapshot.

In an `amgetbitmap` index scan, the access method does not keep an index pin on any of the returned tuples. Therefore it is only safe to use such scans with MVCC-compliant snapshots.

When the `ampredlocks` flag is not set, any scan using that index access method within a serializable transaction will acquire a nonblocking predicate lock on the full index. This will generate a read-write conflict with the insert of any tuple into that index by a concurrent serializable transaction. If certain patterns of read-write conflicts are detected among a set of concurrent serializable transactions, one of those transactions may be canceled to protect data integrity. When the flag is set, it indicates that the index access method implements finer-grained predicate locking, which will tend to reduce the frequency of such transaction cancellations.

### 64.5. Index Uniqueness Checks

PostgreSQL enforces SQL uniqueness constraints using unique indexes, which are indexes that disallow multiple entries with identical keys. An access method that supports this feature sets `amcanunique` true. (At present, only b-tree supports it.) Columns listed in the `INCLUDE` clause are not considered when enforcing uniqueness.

Because of MVCC, it is always necessary to allow duplicate entries to exist physically in an index: the entries might refer to successive versions of a single logical row. The behavior we actually want to enforce is that no MVCC snapshot could include two rows with equal index keys. This breaks down into the following cases that must be checked when inserting a new row into a unique index:

- If a conflicting valid row has been deleted by the current transaction, it’s okay. (In particular, since an `UPDATE` always deletes the old row version before inserting the new version, this will allow an `UPDATE` on a row without changing the key.)

- If a conflicting row has been inserted by an as-yet-uncommitted transaction, the would-be inserter must wait to see if that transaction commits. If it rolls back then there is no conflict. If it commits without deleting the conflicting row again, there is a uniqueness violation. (In practice we just wait for the other transaction to end and then redo the visibility check in `toto`.)

- Similarly, if a conflicting valid row has been deleted by an as-yet-uncommitted transaction, the would-be inserter must wait for that transaction to commit or abort, and then repeat the test.

Furthermore, immediately before reporting a uniqueness violation according to the above rules, the access method must recheck the liveness of the row being inserted. If it is committed dead then no violation should be reported. (This case cannot occur during the ordinary scenario of inserting a row that’s just been created by the current transaction. It can happen during `CREATE UNIQUE INDEX CONCURRENTLY`, however.)
We require the index access method to apply these tests itself, which means that it must reach into the heap to check the commit status of any row that is shown to have a duplicate key according to the index contents. This is without a doubt ugly and non-modular, but it saves redundant work: if we did a separate probe then the index lookup for a conflicting row would be essentially repeated while finding the place to insert the new row’s index entry. What's more, there is no obvious way to avoid race conditions unless the conflict check is an integral part of insertion of the new index entry.

If the unique constraint is deferrable, there is additional complexity: we need to be able to insert an index entry for a new row, but defer any uniqueness-violation error until end of statement or even later. To avoid unnecessary repeat searches of the index, the index access method should do a preliminary uniqueness check during the initial insertion. If this shows that there is definitely no conflicting live tuple, we are done. Otherwise, we schedule a recheck to occur when it is time to enforce the constraint. If, at the time of the recheck, both the inserted tuple and some other tuple with the same key are live, then the error must be reported. (Note that for this purpose, “live” actually means “any tuple in the index entry's HOT chain is live”.) To implement this, the aminsert function is passed a checkUnique parameter having one of the following values:

- UNIQUE_CHECK_NO indicates that no uniqueness checking should be done (this is not a unique index).
- UNIQUE_CHECK_YES indicates that this is a non-deferrable unique index, and the uniqueness check must be done immediately, as described above.
- UNIQUE_CHECK_PARTIAL indicates that the unique constraint is deferrable. PostgreSQL will use this mode to insert each row’s index entry. The access method must allow duplicate entries into the index, and report any potential duplicates by returning false from aminsert. For each row for which false is returned, a deferred recheck will be scheduled.

The access method must identify any rows which might violate the unique constraint, but it is not an error for it to report false positives. This allows the check to be done without waiting for other transactions to finish; conflicts reported here are not treated as errors and will be rechecked later, by which time they may no longer be conflicts.

- UNIQUE_CHECK_EXISTING indicates that this is a deferred recheck of a row that was reported as a potential uniqueness violation. Although this is implemented by calling aminsert, the access method must not insert a new index entry in this case. The index entry is already present. Rather, the access method must check to see if there is another live index entry. If so, and if the target row is also still live, report error.

It is recommended that in a UNIQUE_CHECK_EXISTING call, the access method further verify that the target row actually does have an existing entry in the index, and report error if not. This is a good idea because the index tuple values passed to aminsert will have been recomputed. If the index definition involves functions that are not really immutable, we might be checking the wrong area of the index. Checking that the target row is found in the recheck verifies that we are scanning for the same tuple values as were used in the original insertion.

### 64.6. Index Cost Estimation Functions

The amcostestimate function is given information describing a possible index scan, including lists of WHERE and ORDER BY clauses that have been determined to be usable with the index. It must return estimates of the cost of accessing the index and the selectivity of the WHERE clauses (that is, the fraction of parent-table rows that will be retrieved during the index scan). For simple cases, nearly all the work of the cost estimator can be done by calling standard routines in the optimizer; the point of having an amcostestimate function is to allow index access methods to provide index-type-specific knowledge, in case it is possible to improve on the standard estimates.

Each amcostestimate function must have the signature:
Index Access Method
Interface Definition

```c
void
amcostestimate (PlannerInfo *root,
    IndexPath *path,
    double loop_count,
    Cost *indexStartupCost,
    Cost *indexTotalCost,
    Selectivity *indexSelectivity,
    double *indexCorrelation,
    double *indexPages);
```

The first three parameters are inputs:

`root`

The planner's information about the query being processed.

`path`

The index access path being considered. All fields except cost and selectivity values are valid.

`loop_count`

The number of repetitions of the index scan that should be factored into the cost estimates. This will typically be greater than one when considering a parameterized scan for use in the inside of a nestloop join. Note that the cost estimates should still be for just one scan; a larger `loop_count` means that it may be appropriate to allow for some caching effects across multiple scans.

The last five parameters are pass-by-reference outputs:

`*indexStartupCost`

Set to cost of index start-up processing

`*indexTotalCost`

Set to total cost of index processing

`*indexSelectivity`

Set to index selectivity

`*indexCorrelation`

Set to correlation coefficient between index scan order and underlying table's order

`*indexPages`

Set to number of index leaf pages

Note that cost estimate functions must be written in C, not in SQL or any available procedural language, because they must access internal data structures of the planner/optimizer.

The index access costs should be computed using the parameters used by `src/backend/optimizer/path/costsize.c`: a sequential disk block fetch has cost `seq_page_cost`, a nonsequential fetch has cost `random_page_cost`, and the cost of processing one index row should usually be taken as `cpu_index_tuple_cost`. In addition, an appropriate multiple of `cpu_operator_cost` should be charged for any comparison operators invoked during index processing (especially evaluation of the indexquals themselves).

The access costs should include all disk and CPU costs associated with scanning the index itself, but not the costs of retrieving or processing the parent-table rows that are identified by the index.
The “start-up cost” is the part of the total scan cost that must be expended before we can begin to fetch the first row. For most indexes this can be taken as zero, but an index type with a high start-up cost might want to set it nonzero.

The \textit{indexSelectivity} should be set to the estimated fraction of the parent table rows that will be retrieved during the index scan. In the case of a lossy query, this will typically be higher than the fraction of rows that actually pass the given qual conditions.

The \textit{indexCorrelation} should be set to the correlation (ranging between \(-1.0\) and \(1.0\)) between the index order and the table order. This is used to adjust the estimate for the cost of fetching rows from the parent table.

The \textit{indexPages} should be set to the number of leaf pages. This is used to estimate the number of workers for parallel index scan.

When \textit{loop\_count} is greater than one, the returned numbers should be averages expected for any one scan of the index.

\section*{Cost Estimation}

A typical cost estimator will proceed as follows:

1. Estimate and return the fraction of parent-table rows that will be visited based on the given qual conditions. In the absence of any index-type-specific knowledge, use the standard optimizer function \texttt{clauselist\_selectivity()}:

   \begin{verbatim}
   *indexSelectivity = clauselist_selectivity(root, path- >indexquals, path->indexinfo- >rel->relid, JOIN_INNER, NULL);
   \end{verbatim}

2. Estimate the number of index rows that will be visited during the scan. For many index types this is the same as \textit{indexSelectivity} times the number of rows in the index, but it might be more. (Note that the index's size in pages and rows is available from the \texttt{path->indexinfo} struct.)

3. Estimate the number of index pages that will be retrieved during the scan. This might be just \textit{indexSelectivity} times the index's size in pages.

4. Compute the index access cost. A generic estimator might do this:

   \begin{verbatim}
   /*
   * Our generic assumption is that the index pages will be read
   * sequentially, so they cost seq\_page\_cost each, not
   * random\_page\_cost.
   * Also, we charge for evaluation of the indexquals at each
   * index row.
   * All the costs are assumed to be paid incrementally during
   * the scan.
   */
   cost\_qual\_eval(&index\_qual\_cost, path->indexquals, root);
   *indexStartupCost = index\_qual\_cost.startup;
   *indexTotalCost = seq\_page\_cost * numIndexPages +
   (cpu\_index\_tuple\_cost + index\_qual\_cost.per\_tuple) *
   numIndexTuples;
   \end{verbatim}

However, the above does not account for amortization of index reads across repeated index scans.
5. Estimate the index correlation. For a simple ordered index on a single field, this can be retrieved from pg_statistic. If the correlation is not known, the conservative estimate is zero (no correlation).

Examples of cost estimator functions can be found in src/backend/utils/adt/selfuncs.c.
Chapter 65. Generic WAL Records

Although all built-in WAL-logged modules have their own types of WAL records, there is also a generic WAL record type, which describes changes to pages in a generic way. This is useful for extensions that provide custom access methods.

In comparison with Custom WAL Resource Managers, Generic WAL is simpler for an extension to implement and does not require the extension library to be loaded in order to apply the records.

**Note**

Generic WAL records are ignored during Logical Decoding. If logical decoding is required for your extension, consider a Custom WAL Resource Manager.

The API for constructing generic WAL records is defined in `access/generic_xlog.h` and implemented in `access/transam/generic_xlog.c`.

To perform a WAL-logged data update using the generic WAL record facility, follow these steps:

1. `state = GenericXLogStart(relation)` — start construction of a generic WAL record for the given relation.

2. `page = GenericXLogRegisterBuffer(state, buffer, flags)` — register a buffer to be modified within the current generic WAL record. This function returns a pointer to a temporary copy of the buffer's page, where modifications should be made. (Do not modify the buffer’s contents directly.) The third argument is a bit mask of flags applicable to the operation. Currently the only such flag is `GENERIC_XLOG_FULL_IMAGE`, which indicates that a full-page image rather than a delta update should be included in the WAL record. Typically this flag would be set if the page is new or has been rewritten completely. `GenericXLogRegisterBuffer` can be repeated if the WAL-logged action needs to modify multiple pages.

3. Apply modifications to the page images obtained in the previous step.

4. `GenericXLogFinish(state)` — apply the changes to the buffers and emit the generic WAL record.

WAL record construction can be canceled between any of the above steps by calling `GenericXLogAbort(state)`. This will discard all changes to the page image copies.

Please note the following points when using the generic WAL record facility:

- No direct modifications of buffers are allowed! All modifications must be done in copies acquired from `GenericXLogRegisterBuffer()`. In other words, code that makes generic WAL records should never call `BufferGetPage()` for itself. However, it remains the caller's responsibility to pin/unpin and lock/unlock the buffers at appropriate times. Exclusive lock must be held on each target buffer from before `GenericXLogRegisterBuffer()` until after `GenericXLogFinish()`.

- Registrations of buffers (step 2) and modifications of page images (step 3) can be mixed freely, i.e., both steps may be repeated in any sequence. Keep in mind that buffers should be registered in the same order in which locks are to be obtained on them during replay.

- The maximum number of buffers that can be registered for a generic WAL record is `MAX_GENERIC_XLOG_PAGES`. An error will be thrown if this limit is exceeded.

- Generic WAL assumes that the pages to be modified have standard layout, and in particular that there is no useful data between `pd_lower` and `pd_upper`. 
Generic WAL Records

- Since you are modifying copies of buffer pages, `GenericXLogStart()` does not start a critical section. Thus, you can safely do memory allocation, error throwing, etc. between `GenericXLogStart()` and `GenericXLogFinish()`. The only actual critical section is present inside `GenericXLogFinish()`. There is no need to worry about calling `GenericXLogAbort()` during an error exit, either.

- `GenericXLogFinish()` takes care of marking buffers dirty and setting their LSNs. You do not need to do this explicitly.

- For unlogged relations, everything works the same except that no actual WAL record is emitted. Thus, you typically do not need to do any explicit checks for unlogged relations.

- The generic WAL redo function will acquire exclusive locks to buffers in the same order as they were registered. After redoing all changes, the locks will be released in the same order.

- If `GENERIC_XLOG_FULL_IMAGE` is not specified for a registered buffer, the generic WAL record contains a delta between the old and the new page images. This delta is based on byte-by-byte comparison. This is not very compact for the case of moving data within a page, and might be improved in the future.
Chapter 66. Custom WAL Resource Managers

This chapter explains the interface between the core PostgreSQL system and custom WAL resource managers, which enable extensions to integrate directly with the WAL.

An extension, especially a Table Access Method or Index Access Method, may need to use WAL for recovery, replication, and/or Logical Decoding. Custom resource managers are a more flexible alternative to Generic WAL (which does not support logical decoding), but more complex for an extension to implement.

To create a new custom WAL resource manager, first define an RmgrData structure with implementations for the resource manager methods. Refer to src/backend/access/transam/README and src/include/access/xlog_internal.h in the PostgreSQL source.

```
/*
 * Method table for resource managers.
 * 
 * This struct must be kept in sync with the PG_RMGR definition in
 * rmgr.c.
 * 
 * rm_identify must return a name for the record based on xl_info
 * (without
 * reference to the rmid). For example, XLOG_BTREE_VACUUM would be
 * "VACUUM". rm_desc can then be called to obtain additional detail
 * for the
 * record, if available (e.g. the last block).
 *
 * rm_mask takes as input a page modified by the resource manager
 * and masks
 * out bits that shouldn't be flagged by wal_consistency_checking.
 * 
 * RmgrTable[] is indexed by RmgrId values (see rmgrlist.h). If
 * rm_name is
 * NULL, the corresponding RmgrTable entry is considered invalid.
 */
typedef struct RmgrData
{
    const char  *rm_name;
    void        (*rm_redo) (XLogReaderState *record);
    void        (*rm_desc) (StringInfo buf, XLogReaderState
*record);
    const char(*)*rm_identify) (uint8 info);
    void        (*rm_startup) (void);
    void        (*rm_cleanup) (void);
    void        (*rm_mask) (char *pagedata, BlockNumber blkno);
    void        (*rm_decode) (struct LogicalDecodingContext *ctx,
        struct XLogRecordBuffer *buf);
} RmgrData;
```

The src/test/modules/test_custom_rmgrs module contains a working example, which demonstrates usage of custom WAL resource managers.

Then, register your new resource manager.
/ * Register a new custom WAL resource manager. * * Resource manager IDs must be globally unique across all extensions. Refer * to https://wiki.postgresql.org/wiki/CustomWALResourceManagers to reserve a * unique RmgrId for your extension, to avoid conflicts with other extension * developers. During development, use RM_EXPERIMENTAL_ID to avoid needlessly * reserving a new ID. */ extern void RegisterCustomRmgr(RmgrId rmid, const RmgrData *rmgr); RegisterCustomRmgr must be called from the extension module's _PG_init function. While developing a new extension, use RM_EXPERIMENTAL_ID for rmid. When you are ready to release the extension to users, reserve a new resource manager ID at the Custom WAL Resource Manager\(^1\) page. Place the extension module implementing the custom resource manager in shared_preload_libraries so that it will be loaded early during PostgreSQL startup.\[\textbf{Note}\
The extension must remain in shared_preload_libraries as long as any custom WAL records may exist in the system. Otherwise PostgreSQL will not be able to apply or decode the custom WAL records, which may prevent the server from starting.\]\(^1\)https://wiki.postgresql.org/wiki/CustomWALResourceManagers
Chapter 67. B-Tree Indexes

67.1. Introduction

PostgreSQL includes an implementation of the standard btree (multi-way balanced tree) index data structure. Any data type that can be sorted into a well-defined linear order can be indexed by a btree index. The only limitation is that an index entry cannot exceed approximately one-third of a page (after TOAST compression, if applicable).

Because each btree operator class imposes a sort order on its data type, btree operator classes (or, really, operator families) have come to be used as PostgreSQL’s general representation and understanding of sorting semantics. Therefore, they’ve acquired some features that go beyond what would be needed just to support btree indexes, and parts of the system that are quite distant from the btree AM make use of them.

67.2. Behavior of B-Tree Operator Classes

As shown in Table 38.3, a btree operator class must provide five comparison operators, <, <=, =, >=, and >. One might expect that <> should also be part of the operator class, but it is not, because it would almost never be useful to use a <> WHERE clause in an index search. (For some purposes, the planner treats <> as associated with a btree operator class; but it finds that operator via the = operator’s negator link, rather than from pg_amop.)

When several data types share near-identical sorting semantics, their operator classes can be grouped into an operator family. Doing so is advantageous because it allows the planner to make deductions about cross-type comparisons. Each operator class within the family should contain the single-type operators (and associated support functions) for its input data type, while cross-type comparison operators and support functions are “loose” in the family. It is recommendable that a complete set of cross-type operators be included in the family, thus ensuring that the planner can represent any comparison conditions that it deduces from transitivity.

There are some basic assumptions that a btree operator family must satisfy:

- An = operator must be an equivalence relation; that is, for all non-null values A, B, C of the data type:
  - A = A is true (reflexive law)
  - if A = B, then B = A (symmetric law)
  - if A = B and B = C, then A = C (transitive law)
- A < operator must be a strong ordering relation; that is, for all non-null values A, B, C:
  - A < A is false (irreflexive law)
  - if A < B and B < C, then A < C (transitive law)
- Furthermore, the ordering is total; that is, for all non-null values A, B:
  - exactly one of A < B, A = B, and B < A is true (trichotomy law)
  (The trichotomy law justifies the definition of the comparison support function, of course.)

The other three operators are defined in terms of = and < in the obvious way, and must act consistently with them.

For an operator family supporting multiple data types, the above laws must hold when A, B, C are taken from any data types in the family. The transitive laws are the trickiest to ensure, as in cross-type situations they represent statements that the behaviors of two or three different operators are consistent.
As an example, it would not work to put `float8` and `numeric` into the same operator family, at least not with the current semantics that `numeric` values are converted to `float8` for comparison to a `float8`. Because of the limited accuracy of `float8`, this means there are distinct `numeric` values that will compare equal to the same `float8` value, and thus the transitive law would fail.

Another requirement for a multiple-data-type family is that any implicit or binary-coercion casts that are defined between data types included in the operator family must not change the associated sort ordering.

It should be fairly clear why a btree index requires these laws to hold within a single data type: without them there is no ordering to arrange the keys with. Also, index searches using a comparison key of a different data type require comparisons to behave sanely across two data types. The extensions to three or more data types within a family are not strictly required by the btree index mechanism itself, but the planner relies on them for optimization purposes.

### 67.3. B-Tree Support Functions

As shown in Table 38.9, btree defines one required and four optional support functions. The five user-defined methods are:

**order**

For each combination of data types that a btree operator family provides comparison operators for, it must provide a comparison support function, registered in `pg_amproc` with support function number 1 and `amproclefttype/amprocrighttype` equal to the left and right data types for the comparison (i.e., the same data types that the matching operators are registered with in `pg_amop`). The comparison function must take two non-null values `A` and `B` and return an `int32` value that is `< 0`, `0`, or `> 0` when `A < B`, `A = B`, or `A > B`, respectively. A null result is disallowed: all values of the data type must be comparable. See `src/backend/access/nbtree/nbt- compare.c` for examples.

If the compared values are of a collatable data type, the appropriate collation OID will be passed to the comparison support function, using the standard `PG_GET_COLLATION()` mechanism.

**sortsupport**

Optionally, a btree operator family may provide `sort support` function(s), registered under support function number 2. These functions allow implementing comparisons for sorting purposes in a more efficient way than naively calling the comparison support function. The APIs involved in this are defined in `src/include/utils/sortsupport.h`.

**in_range**

Optionally, a btree operator family may provide `in_range` support function(s), registered under support function number 3. These are not used during btree index operations; rather, they extend the semantics of the operator family so that it can support window clauses containing the `RANGE offset PRECEDING` and `RANGE offset FOLLOWING` frame bound types (see Section 4.2.8). Fundamentally, the extra information provided is how to add or subtract an `offset` value in a way that is compatible with the family's data ordering.

An `in_range` function must have the signature

```c
in_range(val typel, base typel, offset type2, sub bool, less bool)
returns bool
```

`val` and `base` must be of the same type, which is one of the types supported by the operator family (i.e., a type for which it provides an ordering). However, `offset` could be of a different
type, which might be one otherwise unsupported by the family. An example is that the built-in time_ops family provides an in_range function that has offset of type interval. A family can provide in_range functions for any of its supported types and one or more offset types. Each in_range function should be entered in pg_amproc with amproclefttype equal to type1 and amprocrighttype equal to type2.

The essential semantics of an in_range function depend on the two Boolean flag parameters. It should add or subtract base and offset, then compare val to the result, as follows:

- if !sub and !less, return val >= (base + offset)
- if !sub and less, return val <= (base + offset)
- if sub and !less, return val >= (base - offset)
- if sub and less, return val <= (base - offset)

Before doing so, the function should check the sign of offset: if it is less than zero, raise error ERRCODE_INVALID_PRECEDING_OR_FOLLOWING_SIZE (22013) with error text like “invalid preceding or following size in window function”. (This is required by the SQL standard, although nonstandard operator families might perhaps choose to ignore this restriction, since there seems to be little semantic necessity for it.) This requirement is delegated to the in_range function so that the core code needn't understand what “less than zero” means for a particular data type.

An additional expectation is that in_range functions should, if practical, avoid throwing an error if base + offset or base - offset would overflow. The correct comparison result can be determined even if that value would be out of the data type's range. Note that if the data type includes concepts such as “infinity” or “NaN”, extra care may be needed to ensure that in_range’s results agree with the normal sort order of the operator family.

The results of the in_range function must be consistent with the sort ordering imposed by the operator family. To be precise, given any fixed values of offset and sub, then:

- If in_range with less = true is true for some val1 and base, it must be true for every val2 <= val1 with the same base.
- If in_range with less = true is false for some val1 and base, it must be false for every val2 >= val1 with the same base.
- If in_range with less = true is true for some val1 and base1, it must be true for every base2 >= base1 with the same val.
- If in_range with less = true is false for some val1 and base1, it must be false for every base2 <= base1 with the same val.

Analogous statements with inverted conditions hold when less = false.

If the type being ordered (type1) is collatable, the appropriate collation OID will be passed to the in_range function, using the standard PG_GET_COLLATION() mechanism.

in_range functions need not handle NULL inputs, and typically will be marked strict.

equalimage

Optionally, a btree operator family may provide equalimage (“equality implies image equality”) support functions, registered under support function number 4. These functions allow the core code to determine when it is safe to apply the btree deduplication optimization. Currently, equalimage functions are only called when building or rebuilding an index.

An equalimage function must have the signature
equalimage(opcintype oid) returns bool

The return value is static information about an operator class and collation. Returning true indicates that the order function for the operator class is guaranteed to only return 0 ("arguments are equal") when its A and B arguments are also interchangeable without any loss of semantic information. Not registering an equalimage function or returning false indicates that this condition cannot be assumed to hold.

The opcintype argument is the pg_type.oid of the data type that the operator class indexes. This is a convenience that allows reuse of the same underlying equalimage function across operator classes. If opcintype is a collatable data type, the appropriate collation OID will be passed to the equalimage function, using the standard PG_GET_COLLATION() mechanism.

As far as the operator class is concerned, returning true indicates that deduplication is safe (or safe for the collation whose OID was passed to its equalimage function). However, the core code will only deem deduplication safe for an index when every indexed column uses an operator class that registers an equalimage function, and each function actually returns true when called.

Image equality is almost the same condition as simple bitwise equality. There is one subtle difference: When indexing a varlena data type, the on-disk representation of two image equal datums may not be bitwise equal due to inconsistent application of TOAST compression on input. Formally, when an operator class's equalimage function returns true, it is safe to assume that the datum_image_eq() C function will always agree with the operator class's order function (provided that the same collation OID is passed to both the equalimage and order functions).

Image equality is the same condition as simple bitwise equality. There is one subtle difference: When indexing a varlena data type, the on-disk representation of two image equal datums may not be bitwise equal due to inconsistent application of TOAST compression on input. Formally, when an operator class's equalimage function returns true, it is safe to assume that the datum_image_eq() C function will always agree with the operator class's order function (provided that the same collation OID is passed to both the equalimage and order functions).

The core code is fundamentally unable to deduce anything about the "equality implies image equality" status of an operator class within a multiple-data-type family based on details from other operator classes in the same family. Also, it is not sensible for an operator family to register a cross-type equalimage function, and attempting to do so will result in an error. This is because "equality implies image equality" status does not just depend on sorting/equality semantics, which are more or less defined at the operator family level. In general, the semantics that one particular data type implements must be considered separately.

The convention followed by the operator classes included with the core PostgreSQL distribution is to register a stock, generic equalimage function. Most operator classes register btequalimage(), which indicates that deduplication is safe unconditionally. Operator classes for collatable data types such as text register btvarstrequalimage(), which indicates that deduplication is safe with deterministic collations. Best practice for third-party extensions is to register their own custom function to retain control.

options

Optionally, a B-tree operator family may provide options ("operator class specific options") support functions, registered under support function number 5. These functions define a set of user-visible parameters that control operator class behavior.

An options support function must have the signature

options(relopts local_relopts *) returns void

The function is passed a pointer to a local_relopts struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the PG_HAS_OPCLASS_OPTIONS() and PG_GET_OPCLASS_OPTIONS() macros.

Currently, no B-Tree operator class has an options support function. B-tree doesn't allow flexible representation of keys like GiST, SP-GiST, GIN and BRIN do. So, options probably doesn't have much application in the current B-tree index access method. Nevertheless, this support function was added to B-tree for uniformity, and will probably find uses during further evolution of B-tree in PostgreSQL.
67.4. Implementation

This section covers B-Tree index implementation details that may be of use to advanced users. See src/backend/access/nbtree/README in the source distribution for a much more detailed, internals-focused description of the B-Tree implementation.

67.4.1. B-Tree Structure

PostgreSQL B-Tree indexes are multi-level tree structures, where each level of the tree can be used as a doubly-linked list of pages. A single metapage is stored in a fixed position at the start of the first segment file of the index. All other pages are either leaf pages or internal pages. Leaf pages are the pages on the lowest level of the tree. All other levels consist of internal pages. Each leaf page contains tuples that point to table rows. Each internal page contains tuples that point to the next level down in the tree. Typically, over 99% of all pages are leaf pages. Both internal pages and leaf pages use the standard page format described in Section 73.6.

New leaf pages are added to a B-Tree index when an existing leaf page cannot fit an incoming tuple. A page split operation makes room for items that originally belonged on the overflowing page by moving a portion of the items to a new page. Page splits must also insert a new downlink to the new page in the parent page, which may cause the parent to split in turn. Page splits “cascade upwards” in a recursive fashion. When the root page finally cannot fit a new downlink, a root page split operation takes place. This adds a new level to the tree structure by creating a new root page that is one level above the original root page.

67.4.2. Bottom-up Index Deletion

B-Tree indexes are not directly aware that under MVCC, there might be multiple extant versions of the same logical table row; to an index, each tuple is an independent object that needs its own index entry. “Version churn” tuples may sometimes accumulate and adversely affect query latency and throughput. This typically occurs with UPDATE-heavy workloads where most individual updates cannot apply the HOT optimization. Changing the value of only one column covered by one index during an UPDATE always necessitates a new set of index tuples — one for each and every index on the table. Note in particular that this includes indexes that were not “logically modified” by the UPDATE. All indexes will need a successor physical index tuple that points to the latest version in the table. Each new tuple within each index will generally need to coexist with the original “updated” tuple for a short period of time (typically until shortly after the UPDATE transaction commits).

B-Tree indexes incrementally delete version churn index tuples by performing bottom-up index deletion passes. Each deletion pass is triggered in reaction to an anticipated “version churn page split”. This only happens with indexes that are not logically modified by UPDATE statements, where concentrated build up of obsolete versions in particular pages would occur otherwise. A page split will usually be avoided, though it’s possible that certain implementation-level heuristics will fail to identify and delete even one garbage index tuple (in which case a page split or deduplication pass resolves the issue of an incoming new tuple not fitting on a leaf page). The worst-case number of versions that any index scan must traverse (for any single logical row) is an important contributor to overall system responsiveness and throughput. A bottom-up index deletion pass targets suspected garbage tuples in a single leaf page based on qualitative distinctions involving logical rows and versions. This contrasts with the “top-down” index cleanup performed by autovacuum workers, which is triggered when certain quantitative table-level thresholds are exceeded (see Section 25.1.6).

Note

Not all deletion operations that are performed within B-Tree indexes are bottom-up deletion operations. There is a distinct category of index tuple deletion: simple index tuple deletion. This is a deferred maintenance operation that deletes index tuples that are known to be safe to delete (those whose item identifier’s LP_DEAD bit is already set). Like bottom-up index...
deletion, simple index deletion takes place at the point that a page split is anticipated as a way of avoiding the split.

Simple deletion is opportunistic in the sense that it can only take place when recent index scans set the LP_DEAD bits of affected items in passing. Prior to PostgreSQL 14, the only category of B-Tree deletion was simple deletion. The main differences between it and bottom-up deletion are that only the former is opportunistically driven by the activity of passing index scans, while only the latter specifically targets version churn from UPDATEs that do not logically modify indexed columns.

Bottom-up index deletion performs the vast majority of all garbage index tuple cleanup for particular indexes with certain workloads. This is expected with any B-Tree index that is subject to significant version churn from UPDATEs that rarely or never logically modify the columns that the index covers. The average and worst-case number of versions per logical row can be kept low purely through targeted incremental deletion passes. It's quite possible that the on-disk size of certain indexes will never increase by even one single page/block despite constant version churn from UPDATEs. Even then, an exhaustive “clean sweep” by a VACUUM operation (typically run in an autovacuum worker process) will eventually be required as a part of collective cleanup of the table and each of its indexes.

Unlike VACUUM, bottom-up index deletion does not provide any strong guarantees about how old the oldest garbage index tuple may be. No index can be permitted to retain “floating garbage” index tuples that became dead prior to a conservative cutoff point shared by the table and all of its indexes collectively. This fundamental table-level invariant makes it safe to recycle table TIDs. This is how it is possible for distinct logical rows to reuse the same table TID over time (though this can never happen with two logical rows whose lifetimes span the same VACUUM cycle).

67.4.3. Deduplication

A duplicate is a leaf page tuple (a tuple that points to a table row) where all indexed key columns have values that match corresponding column values from at least one other leaf page tuple in the same index. Duplicate tuples are quite common in practice. B-Tree indexes can use a special, space-efficient representation for duplicates when an optional technique is enabled: deduplication.

Deduplication works by periodically merging groups of duplicate tuples together, forming a single posting list tuple for each group. The column key value(s) only appear once in this representation. This is followed by a sorted array of TIDs that point to rows in the table. This significantly reduces the storage size of indexes where each value (or each distinct combination of column values) appears several times on average. The latency of queries can be reduced significantly. Overall query throughput may increase significantly. The overhead of routine index vacuuming may also be reduced significantly.

**Note**

B-Tree deduplication is just as effective with “duplicates” that contain a NULL value, even though NULL values are never equal to each other according to the = member of any B-Tree operator class. As far as any part of the implementation that understands the on-disk B-Tree structure is concerned, NULL is just another value from the domain of indexed values.

The deduplication process occurs lazily, when a new item is inserted that cannot fit on an existing leaf page, though only when index tuple deletion could not free sufficient space for the new item (typically deletion is briefly considered and then skipped over). Unlike GIN posting list tuples, B-Tree posting list tuples do not need to expand every time a new duplicate is inserted; they are merely an alternative physical representation of the original logical contents of the leaf page. This design prioritizes consistent performance with mixed read-write workloads. Most client applications will at least see a moderate performance benefit from using deduplication. Deduplication is enabled by default.
CREATE INDEX and REINDEX apply deduplication to create posting list tuples, though the strategy they use is slightly different. Each group of duplicate ordinary tuples encountered in the sorted input taken from the table is merged into a posting list tuple before being added to the current pending leaf page. Individual posting list tuples are packed with as many TIDs as possible. Leaf pages are written out in the usual way, without any separate deduplication pass. This strategy is well-suited to CREATE INDEX and REINDEX because they are once-off batch operations.

Write-heavy workloads that don't benefit from deduplication due to having few or no duplicate values in indexes will incur a small, fixed performance penalty (unless deduplication is explicitly disabled). The deduplicate_items storage parameter can be used to disable deduplication within individual indexes. There is never any performance penalty with read-only workloads, since reading posting list tuples is at least as efficient as reading the standard tuple representation. Disabling deduplication isn't usually helpful.

It is sometimes possible for unique indexes (as well as unique constraints) to use deduplication. This allows leaf pages to temporarily "absorb" extra version churn duplicates. Deduplication in unique indexes augments bottom-up index deletion, especially in cases where a long-running transaction holds a snapshot that blocks garbage collection. The goal is to buy time for the bottom-up index deletion strategy to become effective again. Delaying page splits until a single long-running transaction naturally goes away can allow a bottom-up deletion pass to succeed where an earlier deletion pass failed.

<table>
<thead>
<tr>
<th>Tip</th>
</tr>
</thead>
<tbody>
<tr>
<td>A special heuristic is applied to determine whether a deduplication pass in a unique index should take place. It can often skip straight to splitting a leaf page, avoiding a performance penalty from wasting cycles on unhelpful deduplication passes. If you're concerned about the overhead of deduplication, consider setting deduplicate_items = off selectively. Leaving deduplication enabled in unique indexes has little downside.</td>
</tr>
</tbody>
</table>

Deduplication cannot be used in all cases due to implementation-level restrictions. Deduplication safety is determined when CREATE INDEX or REINDEX is run.

Note that deduplication is deemed unsafe and cannot be used in the following cases involving semantically significant differences among equal datums:

- text, varchar, and char cannot use deduplication when a nondeterministic collation is used. Case and accent differences must be preserved among equal datums.
- numeric cannot use deduplication. Numeric display scale must be preserved among equal datums.
- jsonb cannot use deduplication, since the jsonb B-Tree operator class uses numeric internally.
- float4 and float8 cannot use deduplication. These types have distinct representations for -0 and 0, which are nevertheless considered equal. This difference must be preserved.

There is one further implementation-level restriction that may be lifted in a future version of PostgreSQL:

- Container types (such as composite types, arrays, or range types) cannot use deduplication.

There is one further implementation-level restriction that applies regardless of the operator class or collation used:

- INCLUDE indexes can never use deduplication.
Chapter 68. GiST Indexes

68.1. Introduction

GiST stands for Generalized Search Tree. It is a balanced, tree-structured access method, that acts as a base template in which to implement arbitrary indexing schemes. B-trees, R-trees and many other indexing schemes can be implemented in GiST.

One advantage of GiST is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from the University of California at Berkeley's GiST Indexing Project web site\(^1\) and Marcel Kornacker's thesis, Access Methods for Next-Generation Database Systems\(^2\). The GiST implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their web site\(^3\).

68.2. Built-in Operator Classes

The core PostgreSQL distribution includes the GiST operator classes shown in Table 68.1. (Some of the optional modules described in Appendix F provide additional GiST operator classes.)

For historical reasons, the `inet_ops` operator class is not the default class for types `inet` and `cidr`. To use it, mention the class name in `CREATE INDEX`, for example:

```
CREATE INDEX ON my_table USING GIST (my_inet_column inet_ops);
```

### 68.3. Extensibility

Traditionally, implementing a new index access method meant a lot of difficult work. It was necessary to understand the inner workings of the database, such as the lock manager and Write-Ahead Log. The GiST interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GiST layer itself takes care of concurrency, logging and searching the tree structure.

This extensibility should not be confused with the extensibility of the other standard search trees in terms of the data they can handle. For example, PostgreSQL supports extensible B-trees and hash indexes. That means that you can use PostgreSQL to build a B-tree or hash over any data type you want. But B-trees only support range predicates (`<`, `=`, `>`), and hash indexes only support equality queries.

So if you index, say, an image collection with a PostgreSQL B-tree, you can only issue queries such as “is imagem equal to imagey”, “is imagem less than imagey” and “is imagem greater than imagey”. Depending on how you define “equals”, “less than” and “greater than” in this context, this could be useful. However, by using a GiST based index, you could create ways to ask domain-specific questions, perhaps “find all images of horses” or “find all over-exposed images”.

All it takes to get a GiST access method up and running is to implement several user-defined methods, which define the behavior of keys in the tree. Of course these methods have to be pretty fancy to support fancy queries, but for all the standard queries (B-trees, R-trees, etc.) they're relatively straightforward. In short, GiST combines extensibility along with generality, code reuse, and a clean interface.

There are five methods that an index operator class for GiST must provide, and six that are optional. Correctness of the index is ensured by proper implementation of the `same`, `consistent` and `union` methods, while efficiency (size and speed) of the index will depend on the `penalty` and `picksplit` methods. Two optional methods are `compress` and `decompress`, which allow an index to have internal tree data of a different type than the data it indexes. The leaves are to be of the indexed data type, while the other tree nodes can be of any C struct (but you still have to follow PostgreSQL data type rules here, see about `varlena` for variable sized data). If the tree's internal data type exists at the SQL level, the `STORAGE` option of the `CREATE OPERATOR CLASS` command can be used. The optional eighth method is `distance`, which is needed if the operator class wishes to support ordered scans (nearest-neighbor searches). The optional ninth method `fetch` is needed if the operator class wishes to support index-only scans, except when the `compress` method is omitted. The optional tenth method `options` is needed if the operator class has user-specified parameters. The optional eleventh method `sortsupport` is used to speed up building a GiST index.

Given an index entry `p` and a query value `q`, this function determines whether the index entry is “consistent” with the query; that is, could the predicate “`indexed_column indexable_operator q`” be true for any row represented by the index entry? For a leaf index entry this is equivalent to testing the indexable condition, while for an internal tree node this determines whether it is necessary to scan the subtree of the index represented by the tree node. When the result is true, a `recheck` flag must also be returned. This indicates whether the predicate is certainly true or only possibly true. If `recheck = false` then the index has tested the predicate condition exactly, whereas if `recheck = true` the row is only a candidate match. In that case the system will automatically evaluate the `indexable_operator` against the actual row value to see if it is really a match. This convention allows GiST to support both lossless and lossy index structures.

The SQL declaration of the function must look like this:
CREATE OR REPLACE FUNCTION my_consistent(internal, data_type, smallint, oid, internal) RETURNS bool AS 'MODULE_PATHNAME' LANGUAGE C STRICT;

And the matching code in the C module could then follow this skeleton:

```c
PG_FUNCTION_INFO_V1(my_consistent);

Datum my_consistent(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    data_type *query = PG_GETARG_DATA_TYPE_P(1);
    StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
    /* Oid subtype = PG_GETARG_OID(3); */
    bool *recheck = (bool *) PG_GETARG_POINTER(4);
    data_type *key = DatumGetDataType(entry->key);
    bool retval;

    /*
     * determine return value as a function of strategy, key and query.
     *
     * Use GIST_LEAF(entry) to know where you're called in the index tree,
     * which comes handy when supporting the = operator for example (you could
     * check for non empty union() in non-leaf nodes and equality in leaf
     * nodes).
     */
    *recheck = true;        /* or false if check is exact */

    PG_RETURN_BOOL(retval);
}
```

Here, `key` is an element in the index and `query` the value being looked up in the index. The `StrategyNumber` parameter indicates which operator of your operator class is being applied — it matches one of the operator numbers in the `CREATE OPERATOR CLASS` command.

Depending on which operators you have included in the class, the data type of `query` could vary with the operator, since it will be whatever type is on the right-hand side of the operator, which might be different from the indexed data type appearing on the left-hand side. (The above code skeleton assumes that only one type is possible; if not, fetching the `query` argument value would have to depend on the operator.) It is recommended that the SQL declaration of the consistent function use the opclass's indexed data type for the `query` argument, even though the actual type might be something else depending on the operator.

union

This method consolidates information in the tree. Given a set of entries, this function generates a new index entry that represents all the given entries.

The SQL declaration of the function must look like this:
CREATE OR REPLACE FUNCTION my_union(internal, internal)
RETURNS storage_type
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

And the matching code in the C module could then follow this skeleton:

PG_FUNCTION_INFO_V1(my_union);

Datum
my_union(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *)
    PG_GETARG_POINTER(0);
    GISTENTRY *ent = entryvec->vector;
    data_type *out, *
tmp, *
old;
    int numranges,
        i = 0;

    numranges = entryvec->n;
    tmp = DatumGetDataType(ent[0].key);
    out = tmp;

    if (numranges == 1)
    {
        out = data_type_deep_copy(tmp);
        PG_RETURN_DATA_TYPE_P(out);
    }
    for (i = 1; i < numranges; i++)
    {
        old = out;
        tmp = DatumGetDataType(ent[i].key);
        out = my_union_implementation(out, tmp);
    }
    PG_RETURN_DATA_TYPE_P(out);
}

As you can see, in this skeleton we're dealing with a data type where union(X, Y, Z) = union(union(X, Y), Z). It's easy enough to support data types where this is not the case, by implementing the proper union algorithm in this GiST support method.

The result of the union function must be a value of the index's storage type, whatever that is (it might or might not be different from the indexed column's type). The union function should return a pointer to newly palloc()ed memory. You can't just return the input value as-is, even if there is no type change.

As shown above, the union function's first internal argument is actually a GistEntryVector pointer. The second argument is a pointer to an integer variable, which can be ignored. (It used to be required that the union function store the size of its result value into that variable, but this is no longer necessary.)
**GiST Indexes**

**compress**

Converts a data item into a format suitable for physical storage in an index page. If the `compress` method is omitted, data items are stored in the index without modification.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_compress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```c
PG_FUNCTION_INFO_V1(my_compress);
Datum
my_compress(PG_FUNCTION_ARGS)
{
    GISTENTRY  *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY  *retval;

    if (entry->leafkey)
    {
        /* replace entry->key with a compressed version */
        compressed_data_type *compressed_data = palloc(sizeof(compressed_data_type));

        /* fill *compressed_data from entry->key ... */
        retval = palloc(sizeof(GISTENTRY));
        gistentryinit(*retval, PointerGetDatum(compressed_data),
                    entry->rel, entry->page, entry->offset,
                    FALSE);
    }
    else
    {
        /* typically we needn't do anything with non-leaf entries */
        retval = entry;
    }

    PG_RETURN_POINTER(retval);
}
```

You have to adapt `compressed_data_type` to the specific type you're converting to in order to compress your leaf nodes, of course.

**decompress**

Converts the stored representation of a data item into a format that can be manipulated by the other GiST methods in the operator class. If the `decompress` method is omitted, it is assumed that the other GiST methods can work directly on the stored data format. (decompress is not necessarily the reverse of the compress method; in particular, if compress is lossy then it's impossible for decompress to exactly reconstruct the original data. decompress is not necessarily equivalent to fetch, either, since the other GiST methods might not require full reconstruction of the data.)

The SQL declaration of the function must look like this:
CREATE OR REPLACE FUNCTION my_decompress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

And the matching code in the C module could then follow this skeleton:

PG_FUNCTION_INFO_V1(my_decompress);

Datum
my_decompress(PG_FUNCTION_ARGS)
{
  PG_RETURN_POINTER(PG_GETARG_POINTER(0));
}

The above skeleton is suitable for the case where no decompression is needed. (But, of course, omitting the method altogether is even easier, and is recommended in such cases.)

penalty

Returns a value indicating the “cost” of inserting the new entry into a particular branch of the tree. Items will be inserted down the path of least penalty in the tree. Values returned by penalty should be non-negative. If a negative value is returned, it will be treated as zero.

The SQL declaration of the function must look like this:

CREATE OR REPLACE FUNCTION my_penalty(internal, internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;  -- in some cases penalty functions need not be strict

And the matching code in the C module could then follow this skeleton:

PG_FUNCTION_INFO_V1(my_penalty);

Datum
my_penalty(PG_FUNCTION_ARGS)
{
  GISTENTRY  *origentry = (GISTENTRY *) PG_GETARG_POINTER(0);
  GISTENTRY  *newentry = (GISTENTRY *) PG_GETARG_POINTER(1);
  float      *penalty = (float *) PG_GETARG_POINTER(2);
  data_type  *orig = DatumGetDataType(origentry->key);
  data_type  *new = DatumGetDataType(newentry->key);

  *penalty = my_penalty_implementation(orig, new);
  PG_RETURN_POINTER(penalty);
}

For historical reasons, the penalty function doesn't just return a float result; instead it has to store the value at the location indicated by the third argument. The return value per se is ignored, though it's conventional to pass back the address of that argument.

The penalty function is crucial to good performance of the index. It'll get used at insertion time to determine which branch to follow when choosing where to add the new entry in the tree. At query time, the more balanced the index, the quicker the lookup.
When an index page split is necessary, this function decides which entries on the page are to stay on the old page, and which are to move to the new page.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_picksplit(internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
Datum
my_picksplit(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
    GIST_SPLITVEC *v = (GIST_SPLITVEC *) PG_GETARG_POINTER(1);
    OffsetNumber maxoff = entryvec->n - 1;
    GISTENTRY *ent = entryvec->vector;
    int i,
        nbytes;
    OffsetNumber *left,
        *right;
    data_type *tmp_union;
    data_type *unionL;
    data_type *unionR;
    GISTENTRY **raw_entryvec;

    maxoff = entryvec->n - 1;
    nbytes = (maxoff + 1) * sizeof(OffsetNumber);

    v->spl_left = (OffsetNumber *) palloc(nbytes);
    left = v->spl_left;
    v->spl_nleft = 0;

    v->spl_right = (OffsetNumber *) palloc(nbytes);
    right = v->spl_right;
    v->spl_nright = 0;

    unionL = NULL;
    unionR = NULL;

    /* Initialize the raw entry vector. */
    raw_entryvec = (GISTENTRY **) malloc(entryvec->n * sizeof(void *));
    for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
        raw_entryvec[i] = &(entryvec->vector[i]);

    for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
        {
```
int real_index = raw_entryvec[i] - entryvec->vector;

tmp_union = DatumGetDataType(entryvec->vector[real_index].key);
Assert(tmp_union != NULL);

/**
 * Choose where to put the index entries and update unionL and unionR
 * accordingly. Append the entries to either v->spl_left or v->spl_right, and care about the counters.
 */
if (my_choice_is_left(unionL, curl, unionR, curr))
{
    if (unionL == NULL)
        unionL = tmp_union;
    else
        unionL = my_union_implementation(unionL, tmp_union);

    *left = real_index;
    ++left;
    ++(v->spl_nleft);
}
else
{
    /*
     * Same on the right
     */
}

v->spl_ldatum = DataTypeGetDatum(unionL);
v->spl_rdatum = DataTypeGetDatum(unionR);
PG_RETURN_POINTER(v);
}

Notice that the picksplit function's result is delivered by modifying the passed-in v structure. The return value per se is ignored, though it's conventional to pass back the address of v.

Like penalty, the picksplit function is crucial to good performance of the index. Designing suitable penalty and picksplit implementations is where the challenge of implementing well-performing GiST indexes lies.

\texttt{same}

Returns true if two index entries are identical, false otherwise. (An “index entry” is a value of the index's storage type, not necessarily the original indexed column's type.)

The SQL declaration of the function must look like this:

\begin{verbatim}
CREATE OR REPLACE FUNCTION my_same(storage_type, storage_type, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
\end{verbatim}
GiST Indexes

And the matching code in the C module could then follow this skeleton:

```c
PG_FUNCTION_INFO_V1(my_same);

Datum
my_same(PG_FUNCTION_ARGS)
{
  prefix_range *v1 = PG_GETARG_PREFIX_RANGE_P(0);
  prefix_range *v2 = PG_GETARG_PREFIX_RANGE_P(1);
  bool       *result = (bool *) PG_GETARG_POINTER(2);

  *result = my_eq(v1, v2);
  PG_RETURN_POINTER(result);
}
```

For historical reasons, the `same` function doesn’t just return a Boolean result; instead it has to store the flag at the location indicated by the third argument. The return value per se is ignored, though it’s conventional to pass back the address of that argument.

**Distance**

Given an index entry \(p\) and a query value \(q\), this function determines the index entry’s “distance” from the query value. This function must be supplied if the operator class contains any ordering operators. A query using the ordering operator will be implemented by returning index entries with the smallest “distance” values first, so the results must be consistent with the operator’s semantics. For a leaf index entry the result just represents the distance to the index entry; for an internal tree node, the result must be the smallest distance that any child entry could have.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_distance(internal, data_type,
  smallint, oid, internal)
RETURNS float8
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```c
PG_FUNCTION_INFO_V1(my_distance);

Datum
my_distance(PG_FUNCTION_ARGS)
{
  GISTENTRY  *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
  data_type  *query = PG_GETARG_DATA_TYPE_P(1);
  StrategyNumber strategy = (StrategyNumber)
  PG_GETARG_UINT16(2);
  /* oid subtype = PG_GETARG_OID(3); */
  /* bool *recheck = (bool *) PG_GETARG_POINTER(4); */
  data_type  *key = DatumGetDataType(entry->key);
  double      retval;

  /*
  * determine return value as a function of strategy, key and query.
  */
```
The arguments to the distance function are identical to the arguments of the consistent function.

Some approximation is allowed when determining the distance, so long as the result is never greater than the entry's actual distance. Thus, for example, distance to a bounding box is usually sufficient in geometric applications. For an internal tree node, the distance returned must not be greater than the distance to any of the child nodes. If the returned distance is not exact, the function must set *recheck to true. (This is not necessary for internal tree nodes; for them, the calculation is always assumed to be inexact.) In this case the executor will calculate the accurate distance after fetching the tuple from the heap, and reorder the tuples if necessary.

If the distance function returns *recheck = true for any leaf node, the original ordering operator's return type must be float8 or float4, and the distance function's result values must be comparable to those of the original ordering operator, since the executor will sort using both distance function results and recalculated ordering-operator results. Otherwise, the distance function's result values can be any finite float8 values, so long as the relative order of the result values matches the order returned by the ordering operator. (Infinity and minus infinity are used internally to handle cases such as nulls, so it is not recommended that distance functions return these values.)

fetch

Converts the compressed index representation of a data item into the original data type, for index-only scans. The returned data must be an exact, non-lossy copy of the originally indexed value.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_fetch(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The argument is a pointer to a GISTENTRY struct. On entry, its key field contains a non-NULL leaf datum in compressed form. The return value is another GISTENTRY struct, whose key field contains the same datum in its original, uncompressed form. If the opclass's compress function does nothing for leaf entries, the fetch method can return the argument as-is. Or, if the opclass does not have a compress function, the fetch method can be omitted as well, since it would necessarily be a no-op.

The matching code in the C module could then follow this skeleton:

```c
PG_FUNCTION_INFO_V1(my_fetch);

Datum
my_fetch(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    input_data_type *in = DatumGetPointer(entry->key);
    fetched_data_type *fetched_data;
    GISTENTRY *retval;

    retval = palloc(sizeof(GISTENTRY));
    fetched_data = palloc(sizeof(fetched_data_type));

    /*
     * ...
GiST Indexes

* Convert 'fetched_data' into the a Datum of the original datatype.
*
/* fill *retval from fetched_data. */
gistentryinit(*retval, PointerGetDatum(converted_datum),
    entry->rel, entry->page, entry->offset,
    FALSE);

PG_RETURN_POINTER(retval);
}

If the compress method is lossy for leaf entries, the operator class cannot support index-only scans,
and must not define a fetch function.

options

Allows definition of user-visible parameters that control operator class behavior.

The SQL declaration of the function must look like this:

CREATE OR REPLACE FUNCTION my_options(internal)
RETURNS void
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

The function is passed a pointer to a local_relopts struct, which needs to be filled with a
set of operator class specific options. The options can be accessed from other support functions
using the PG_HAS_OPCLASS_OPTIONS() and PG_GET_OPCLASS_OPTIONS() macros.

An example implementation of my_options() and parameters use from other support functions
are given below:

typedef enum MyEnumType
{
    MY_ENUM_ON,
    MY_ENUM_OFF,
    MY_ENUM_AUTO
} MyEnumType;

typedef struct
{
    int32  vl_len_;    /* varlena header (do not touch
directly!) */
    int    int_param; /* integer parameter */
    double real_param; /* real parameter */
    MyEnumType enum_param; /* enum parameter */
    int    str_param;  /* string parameter */
} MyOptionsStruct;

/* String representation of enum values */
static relopt_enum_elt_def myEnumValues[] = {
    {"on", MY_ENUM_ON},
    {"off", MY_ENUM_OFF},
    {"auto", MY_ENUM_AUTO},
    {const char * NULL}   /* list terminator */
};
static char *str_param_default = "default";

/*
 * Sample validator: checks that string is not longer than 8 bytes.
 */
static void
validate_my_string_relopt(const char *value)
{
  if (strlen(value) > 8)
    ereport(ERROR,
            (errcode(ERRCODE_INVALID_PARAMETER_VALUE),
             errmsg("str_param must be at most 8 bytes")));
}

/*
 * Sample filler: switches characters to lower case.
 */
static Size
fill_my_string_relopt(const char *value, void *ptr)
{
  char   *tmp = str_tolower(value, strlen(value),
                            DEFAULT_COLLATION_OID);
  int     len = strlen(tmp);

  if (ptr)
    strcpy((char *) ptr, tmp);

  pfree(tmp);
  return len + 1;
}

PG_FUNCTION_INFO_V1(my_options);

Datum
my_options(PG_FUNCTION_ARGS)
{
  local_relopts *relopts = (local_relopts *)
    PG_GETARG_POINTER(0);

  init_local_reloptions(relopts, sizeof(MyOptionsStruct));
  add_local_int_reloption(relopts, "int_param", "integer parameter",
                          100, 0, 1000000,
                          offsetof(MyOptionsStruct, int_param));
  add_local_real_reloption(relopts, "real_param", "real parameter",
                           1.0, 0.0, 1000000.0,
                           offsetof(MyOptionsStruct, real_param));
  add_local_enum_reloption(relopts, "enum_param", "enum parameter",
                           myEnumValues, MY_ENUM_ON,
                           "Valid values are: "on", "off" and "auto".",
                           myEnumValues, MY_ENUM_ON,
                           "Valid values are: "on", "off" and "auto".",
                           myEnumValues, MY_ENUM_ON,
                           "Valid values are: "on", "off" and "auto".");

  return PG_GETARG_DATUM(1);
}
GiST Indexes

offsetof(MyOptionsStruct,
    enum_param));

add_local_string_reloption(relopts, "str_param", "string parameter",
    str_param_default, &validate_my_string_relopt, &fill_my_string_relopt,
    offsetof(MyOptionsStruct, str_param));

PG_RETURN_VOID();
}

PG_FUNCTION_INFO_V1(my_compress);

Datum

my_compress(PG_FUNCTION_ARGS)
{
    int     int_param = 100;
    double  real_param = 1.0;
    MyEnumType enum_param = MY_ENUM_ON;
    char    *str_param = str_param_default;

    /*
    * Normally, when opclass contains 'options' method, then
    * options are always
    * passed to support functions. However, if you add
    * 'options' method to
    * existing opclass, previously defined indexes have no
    * options, so the
    * check is required.
    */

    if (PG_HAS_OPCLASS_OPTIONS())
    {
        MyOptionsStruct *options = (MyOptionsStruct *)
            PG_GET_OPCLASS_OPTIONS();

        int_param = options->int_param;
        real_param = options->real_param;
        enum_param = options->enum_param;
        str_param = GET_STRING_RELOPTION(options, str_param);
    }

    /* the rest implementation of support function */
}

Since the representation of the key in GiST is flexible, it may depend on user-specified parameters. For instance, the length of key signature may be specified. See gtsvector_options() for example.

sortsupport

Returns a comparator function to sort data in a way that preserves locality. It is used by CREATE INDEX and REINDEX commands. The quality of the created index depends on how well the sort order determined by the comparator function preserves locality of the inputs.
The sortsupport method is optional. If it is not provided, CREATE INDEX builds the index by inserting each tuple to the tree using the penalty and picksplit functions, which is much slower.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_sortsupport(internal)
RETURNS void
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The argument is a pointer to a SortSupport struct. At a minimum, the function must fill in its comparator field. The comparator takes three arguments: two Datums to compare, and a pointer to the SortSupport struct. The Datums are the two indexed values in the format that they are stored in the index; that is, in the format returned by the compress method. The full API is defined in src/include/utils/sortsupport.h.

The matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_sortsupport);

static int
my_fastcmp(Datum x, Datum y, SortSupport ssup)
{
    /* establish order between x and y by computing some sorting
     * value z */

    int z1 = ComputeSpatialCode(x);
    int z2 = ComputeSpatialCode(y);

    return z1 == z2 ? 0 : z1 > z2 ? 1 : -1;
}

Datum
my_sortsupport(PG_FUNCTION_ARGS)
{
    SortSupport ssup = (SortSupport) PG_GETARG_POINTER(0);

    ssup->comparator = my_fastcmp;
    PG_RETURN_VOID();
}
```

All the GiST support methods are normally called in short-lived memory contexts; that is, CurrentMemoryContext will get reset after each tuple is processed. It is therefore not very important to worry about pfree'ing everything you palloc. However, in some cases it's useful for a support method to cache data across repeated calls. To do that, allocate the longer-lived data in fcinfo->flinfo->fn_mcxt, and keep a pointer to it in fcinfo->flinfo->fn_extra. Such data will survive for the life of the index operation (e.g., a single GiST index scan, index build, or index tuple insertion). Be careful to pfree the previous value when replacing a fn_extra value, or the leak will accumulate for the duration of the operation.

### 68.4. Implementation

#### 68.4.1. GiST Index Build Methods

The simplest way to build a GiST index is just to insert all the entries, one by one. This tends to be slow for large indexes, because if the index tuples are scattered across the index and the index is large
GiST Indexes

enough to not fit in cache, a lot of random I/O will be needed. PostgreSQL supports two alternative methods for initial build of a GiST index: sorted and buffered modes.

The sorted method is only available if each of the opclasses used by the index provides a sortsupport function, as described in Section 68.3. If they do, this method is usually the best, so it is used by default.

The buffered method works by not inserting tuples directly into the index right away. It can dramatically reduce the amount of random I/O needed for non-ordered data sets. For well-ordered data sets the benefit is smaller or non-existent, because only a small number of pages receive new tuples at a time, and those pages fit in cache even if the index as a whole does not.

The buffered method needs to call the penalty function more often than the simple method does, which consumes some extra CPU resources. Also, the buffers need temporary disk space, up to the size of the resulting index. Buffering can also influence the quality of the resulting index, in both positive and negative directions. That influence depends on various factors, like the distribution of the input data and the operator class implementation.

If sorting is not possible, then by default a GiST index build switches to the buffering method when the index size reaches effective_cache_size. Buffering can be manually forced or prevented by the buffering parameter to the CREATE INDEX command. The default behavior is good for most cases, but turning buffering off might speed up the build somewhat if the input data is ordered.

68.5. Examples

The PostgreSQL source distribution includes several examples of index methods implemented using GiST. The core system currently provides text search support (indexing for tsvector and ts-query) as well as R-Tree equivalent functionality for some of the built-in geometric data types (see src/backend/access/gist/gistproc.c). The following contrib modules also contain GiST operator classes:

btree_gist

B-tree equivalent functionality for several data types

cube

Indexing for multidimensional cubes

hstore

Module for storing (key, value) pairs

intarray

RD-Tree for one-dimensional array of int4 values

ltree

Indexing for tree-like structures

pg_trgm

Text similarity using trigram matching

seg

Indexing for “float ranges”
Chapter 69. SP-GiST Indexes

69.1. Introduction

SP-GiST is an abbreviation for space-partitioned GiST. SP-GiST supports partitioned search trees, which facilitate development of a wide range of different non-balanced data structures, such as quad-trees, k-d trees, and radix trees (tries). The common feature of these structures is that they repeatedly divide the search space into partitions that need not be of equal size. Searches that are well matched to the partitioning rule can be very fast.

These popular data structures were originally developed for in-memory usage. In main memory, they are usually designed as a set of dynamically allocated nodes linked by pointers. This is not suitable for direct storing on disk, since these chains of pointers can be rather long which would require too many disk accesses. In contrast, disk-based data structures should have a high fanout to minimize I/O. The challenge addressed by SP-GiST is to map search tree nodes to disk pages in such a way that a search need access only a few disk pages, even if it traverses many nodes.

Like GiST, SP-GiST is meant to allow the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from Purdue University’s SP-GiST Indexing Project web site. The SP-GiST implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their web site.

69.2. Built-in Operator Classes

The core PostgreSQL distribution includes the SP-GiST operator classes shown in Table 69.1.

Of the two operator classes for type `point`, `quad_point_ops` is the default. `kd_point_ops` supports the same operators but uses a different index data structure that may offer better performance in some applications.

The `quad_point_ops`, `kd_point_ops` and `poly_ops` operator classes support the `<->` ordering operator, which enables the k-nearest neighbor (k-NN) search over indexed point or polygon data sets.

### 69.3. Extensibility

SP-GiST offers an interface with a high level of abstraction, requiring the access method developer to implement only methods specific to a given data type. The SP-GiST core is responsible for efficient disk mapping and searching the tree structure. It also takes care of concurrency and logging considerations.

Leaf tuples of an SP-GiST tree usually contain values of the same data type as the indexed column, although it is also possible for them to contain lossy representations of the indexed column. Leaf tuples stored at the root level will directly represent the original indexed data value, but leaf tuples at lower levels might contain only a partial value, such as a suffix. In that case the operator class support functions must be able to reconstruct the original value using information accumulated from the inner tuples that are passed through to reach the leaf level.

When an SP-GiST index is created with `INCLUDE` columns, the values of those columns are also stored in leaf tuples. The `INCLUDE` columns are of no concern to the SP-GiST operator class, so they are not discussed further here.

Inner tuples are more complex, since they are branching points in the search tree. Each inner tuple contains a set of one or more `nodes`, which represent groups of similar leaf values. A node contains a downlink that leads either to another, lower-level inner tuple, or to a short list of leaf tuples that all lie on the same index page. Each node normally has a `label` that describes it; for example, in a radix tree the node label could be the next character of the string value. (Alternatively, an operator class can omit the node labels, if it works with a fixed set of nodes for all inner tuples; see Section 69.4.2.) Optionally, an inner tuple can have a `prefix` value that describes all its members. In a radix tree this
SP-GiST Indexes

could be the common prefix of the represented strings. The prefix value is not necessarily really a
prefix, but can be any data needed by the operator class; for example, in a quad-tree it can store the
central point that the four quadrants are measured with respect to. A quad-tree inner tuple would then
also contain four nodes corresponding to the quadrants around this central point.

Some tree algorithms require knowledge of level (or depth) of the current tuple, so the SP-GiST core
provides the possibility for operator classes to manage level counting while descending the tree. There
is also support for incrementally reconstructing the represented value when that is needed, and for
passing down additional data (called traverse values) during a tree descent.

Note

The SP-GiST core code takes care of null entries. Although SP-GiST indexes do store entries
for nulls in indexed columns, this is hidden from the index operator class code: no null index
entries or search conditions will ever be passed to the operator class methods. (It is assumed
that SP-GiST operators are strict and so cannot succeed for null values.) Null values are there-
fore not discussed further here.

There are five user-defined methods that an index operator class for SP-GiST must provide, and two are
optional. All five mandatory methods follow the convention of accepting two internal arguments,
the first of which is a pointer to a C struct containing input values for the support method, while the
second argument is a pointer to a C struct where output values must be placed. Four of the mandatory
methods just return void, since all their results appear in the output struct; but leaf_consistent
returns a boolean result. The methods must not modify any fields of their input structs. In all cases,
the output struct is initialized to zeroes before calling the user-defined method. The optional sixth
method compress accepts a datum to be indexed as the only argument and returns a value suitable
for physical storage in a leaf tuple. The optional seventh method options accepts an internal
pointer to a C struct, where opclass-specific parameters should be placed, and returns void.

The five mandatory user-defined methods are:

config

Returns static information about the index implementation, including the data type OIDs of the
prefix and node label data types.

The SQL declaration of the function must look like this:

CREATE FUNCTION my_config(internal, internal) RETURNS void ... 

The first argument is a pointer to a spgConfigIn C struct, containing input data for the function.
The second argument is a pointer to a spgConfigOut C struct, which the function must fill
with result data.

typedef struct spgConfigIn 
{
    Oid attType;        /* Data type to be indexed */
} spgConfigIn;

typedef struct spgConfigOut 
{
    Oid prefixes;     /* Data type of inner-tuple prefixes */
    Oid labelType;      /* Data type of inner-tuple node labels */
    Oid leafType;       /* Data type of leaf-tuple values */
} spgConfigOut;

2488
spgConfigOut;

attType is passed in order to support polymorphic index operator classes; for ordinary fixed-
data-type operator classes, it will always have the same value and so can be ignored.

For operator classes that do not use prefixes, prefixType can be set to VOIDOID. Likewise, for operator classes that do not use node labels, labelType can be set to VOIDOID. canRe-
turnData should be set true if the operator class is capable of reconstructing the originally-sup-
plied index value. longValuesOK should be set true only when the attType is of variable
length and the operator class is capable of segmenting long values by repeated suffixing (see
Section 69.4.1).

leafType should match the index storage type defined by the operator class's opckeytype
catalog entry. (Note that opckeytype can be zero, implying the storage type is the same as
the operator class's input type, which is the most common situation.) For reasons of backward
compatibility, the config method can set leafType to some other value, and that value will be
used; but this is deprecated since the index contents are then incorrectly identified in the catalogs. Also, it's permissible to leave leafType uninitialized (zero); that is interpreted as meaning the
index storage type derived from opckeytype.

When attType and leafType are different, the optional method compress must be provid-
ed. Method compress is responsible for transformation of datums to be indexed from attType
to leafType.

choose

Chooses a method for inserting a new value into an inner tuple.

The SQL declaration of the function must look like this:

CREATE FUNCTION my_choose(internal, internal) RETURNS void ...

The first argument is a pointer to a spgChooseIn C struct, containing input data for the function. The second argument is a pointer to a spgChooseOut C struct, which the function must fill
with result data.

typedef struct spgChooseIn
{
    Datum       datum;          /* original datum to be indexed */
    Datum       leafDatum;      /* current datum to be stored at leaf */
    int         level;          /* current level (counting from zero) */
    /* Data from current inner tuple */
    bool        allTheSame;     /* tuple is marked all-the-same? */
    bool        hasPrefix;      /* tuple has a prefix? */
    Datum       prefixDatum;    /* if so, the prefix value */
    int         nNodes;         /* number of nodes in the inner tuple */
    Datum      *nodeLabels;     /* node label values (NULL if none) */
} spgChooseIn;
typedef enum spgChooseResultType
{
    spgMatchNode = 1,    /* descend into existing node */
    spgAddNode,          /* add a node to the inner tuple */
    spgSplitTuple        /* split inner tuple (change its prefix) */
} spgChooseResultType;

typedef struct spgChooseOut
{
    spgChooseResultType resultType;  /* action code, see above */
    union
    {
        struct  /* results for spgMatchNode */
        {
            int     nodeN;    /* descend to this node */
            int     levelAdd; /* increment level by this much */
            Datum   restDatum; /* new leaf datum */
        }        matchNode;
        struct  /* results for spgAddNode */
        {
            Datum   nodeLabel; /* new node's label */
            int     nodeN;     /* where to insert it (index from 0) */
        }        addNode;
        struct  /* results for spgSplitTuple */
        {
            /* Info to form new upper-level inner tuple with one child tuple */
            bool    prefixHasPrefix; /* tuple should have a prefix? */
            Datum   prefixPrefixDatum; /* if so, its value */
            int     prefixNNodes;    /* number of nodes */
            Datum   *prefixNodeLabels; /* their labels (or NULL for NULL for */
            int     childNodeN;     /* no labels */
            /* which node gets child tuple */
            "Info to form new lower-level inner tuple with all old nodes */
            bool    postfixHasPrefix; /* tuple should have a prefix? */
            Datum   postfixPrefixDatum; /* if so, its value */
        }        splitTuple;
    }        result;
} spgChooseOut;

datum is the original datum of spgConfigIn.attType type that was to be inserted into the index. leafDatum is a value of spgConfigOut.leafType type, which is initially a result.
of method compress applied to datum when method compress is provided, or the same value as datum otherwise. leafDatum can change at lower levels of the tree if the choose or picksplit methods change it. When the insertion search reaches a leaf page, the current value of leafDatum is what will be stored in the newly created leaf tuple. level is the current inner tuple's level, starting at zero for the root level. allTheSame is true if the current inner tuple is marked as containing multiple equivalent nodes (see Section 69.4.3). hasPrefix is true if the current inner tuple contains a prefix; if so, prefixDatum is its value. nNodes is the number of child nodes contained in the inner tuple, and nodeLabels is an array of their label values, or NULL if there are no labels.

The choose function can determine either that the new value matches one of the existing child nodes, or that a new child node must be added, or that the new value is inconsistent with the tuple prefix and so the inner tuple must be split to create a less restrictive prefix.

If the new value matches one of the existing child nodes, set resultType to spgMatchNode. Set nodeN to the index (from zero) of that node in the node array. Set levelAdd to the increment in level caused by descending through that node, or leave it as zero if the operator class does not use levels. Set restDatum to equal leafDatum if the operator class does not modify datums from one level to the next, or otherwise set it to the modified value to be used as leafDatum at the next level.

If a new child node must be added, set resultType to spgAddNode. Set nodeLabel to the label to be used for the new node, and set nodeN to the index (from zero) at which to insert the node in the node array. After the node has been added, the choose function will be called again with the modified inner tuple; that call should result in an spgMatchNode result.

If the new value is inconsistent with the tuple prefix, set resultType to spgSplitTuple. This action moves all the existing nodes into a new lower-level inner tuple, and replaces the existing inner tuple with a tuple having a single downlink pointing to the new lower-level inner tuple. Set prefixHasPrefix to indicate whether the new upper tuple should have a prefix, and if so set prefixPrefixDatum to the prefix value. This new prefix value must be sufficiently less restrictive than the original to accept the new value to be indexed. Set prefixNNodes to the number of nodes needed in the new tuple, and set prefixNodeLabels to a palloc'd array holding their labels, or to NULL if node labels are not required. Note that the total size of the new upper tuple must be no more than the total size of the tuple it is replacing; this constrains the lengths of the new prefix and new labels. Set childNodeN to the index (from zero) of the node that will downlink to the new lower-level inner tuple. Set postfixHasPrefix to indicate whether the new lower-level inner tuple should have a prefix, and if so set postfixPrefixDatum to the prefix value. The combination of these two prefixes and the downlink node's label (if any) must have the same meaning as the original prefix, because there is no opportunity to alter the node labels that are moved to the new lower-level tuple, nor to change any child index entries. After the node has been split, the choose function will be called again with the replacement inner tuple. That call may return an spgAddNode result, if no suitable node was created by the spgSplitTuple action. Eventually choose must return spgMatchNode to allow the insertion to descend to the next level.

picksplit

Decides how to create a new inner tuple over a set of leaf tuples.

The SQL declaration of the function must look like this:

```sql
CREATE FUNCTION my_picksplit(internal, internal) RETURNS void ...
```

The first argument is a pointer to a spgPickSplitIn C struct, containing input data for the function. The second argument is a pointer to a spgPickSplitOut C struct, which the function must fill with result data.
typedef struct spgPickSplitIn
{
    int         nTuples;        /* number of leaf tuples */
    Datum      *datums;         /* their datums (array of length
nTuples) */
    int         level;          /* current level (counting from
zero) */
} spgPickSplitIn;

datatype struct spgPickSplitOut
{
    bool        hasPrefix;      /* new inner tuple should have a
prefix? */
    Datum       prefixDatum;    /* if so, its value */
    int         nNodes;         /* number of nodes for new inner
tuple */
    Datum      *nodeLabels;     /* their labels (or NULL for no
labels) */
    int        *mapTuplesToNodes;   /* node index for each leaf
tuple */
    Datum      *leafTupleDatums;    /* datum to store in each
new leaf tuple */
} spgPickSplitOut;

nTuples is the number of leaf tuples provided. datums is an array of their datum values of
spgConfigOut.leafType. type. level is the current level that all the leaf tuples share, which
will become the level of the new inner tuple.

Set hasPrefix to indicate whether the new inner tuple should have a prefix, and if so set pre-
fixDatum to the prefix value. Set nNodes to indicate the number of nodes that the new inner
tuple will contain, and set nodeLabels to an array of their label values, or to NULL if node
labels are not required. Set mapTuplesToNodes to an array that gives the index (from zero)
of the node that each leaf tuple should be assigned to. Set leafTupleDatums to an array of
the values to be stored in the new leaf tuples (these will be the same as the input datums if the
operator class does not modify datums from one level to the next). Note that the picksplit
function is responsible for palloc’ing the nodeLabels, mapTuplesToNodes and leafTu-
pleDatums arrays.

If more than one leaf tuple is supplied, it is expected that the picksplit function will classify
them into more than one node; otherwise it is not possible to split the leaf tuples across multiple
pages, which is the ultimate purpose of this operation. Therefore, if the picksplit function
ends up placing all the leaf tuples in the same node, the core SP-GiST code will override that
decision and generate an inner tuple in which the leaf tuples are assigned at random to several
identically-labeled nodes. Such a tuple is marked allTheSame to signify that this has happened.
The choose and inner_consistent functions must take suitable care with such inner tu-
iples. See Section 69.4.3 for more information.

picksplit can be applied to a single leaf tuple only in the case that the config function set
longValuesOK to true and a larger-than-a-page input value has been supplied. In this case the
point of the operation is to strip off a prefix and produce a new, shorter leaf datum value. The
call will be repeated until a leaf datum short enough to fit on a page has been produced. See
Section 69.4.1 for more information.

inner_consistent

Returns set of nodes (branches) to follow during tree search.

The SQL declaration of the function must look like this:
CREATE FUNCTION my_inner_consistent(internal, internal) RETURNS void ...

The first argument is a pointer to a spgInnerConsistentIn C struct, containing input data for the function. The second argument is a pointer to a spgInnerConsistentOut C struct, which the function must fill with result data.

typedef struct spgInnerConsistentIn
{
    ScanKey     scankeys;       /* array of operators and comparison values */
    ScanKey     orderbys;       /* array of ordering operators and comparison */
    int         nkeys;          /* length of scankeys array */
    int         norderbys;      /* length of orderbys array */
    Datum       reconstructedValue;     /* value reconstructed at parent */
    void       *traversalValue; /* opclass-specific traverse value */
    MemoryContext traversalMemoryContext; /* put new traverse values here */
    int         level;          /* current level (counting from zero) */
    bool        returnData;     /* original data must be returned? */
    /* Data from current inner tuple */
    bool        allTheSame;     /* tuple is marked all-the-same? */
    bool        hasPrefix;      /* tuple has a prefix? */
    Datum       prefixDatum;    /* if so, the prefix value */
    int         nNodes;         /* number of nodes in the inner tuple */
    Datum       *nodeLabels;    /* node label values (NULL if none) */
} spgInnerConsistentIn;

typedef struct spgInnerConsistentOut
{
    int         nNodes;         /* number of child nodes to be visited */
    int         *nodeNumbers;   /* their indexes in the node array */
    int         *levelAdds;     /* increment level by this much for each */
    Datum       *reconstructedValues; /* associated reconstructed values */
    void       **traversalValues; /* opclass-specific traverse values */
    double      **distances;    /* associated distances */
} spgInnerConsistentOut;

The array scankeys, of length nkeys, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them are interesting. (Note
that nkeys = 0 implies that all index entries satisfy the query.) Usually the consistent function only cares about the sk_strategy and sk_argument fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check sk_flags to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. The array orderby, of length norderby, describes ordering operators (if any) in the same manner. reconstructedValue is the value reconstructed for the parent tuple; it is (Datum) 0 at the root level or if the inner_consistent function did not provide a value at the parent level. traversalValue is a pointer to any traverse data passed down from the previous call of inner_consistent on the parent index tuple, or NULL at the root level. traversalMemoryContext is the memory context in which to store output traverse values (see below). level is the current inner tuple's level, starting at zero for the root level. returnData is true if reconstructed data is required for this query; this will only be so if the config function asserted canReturnData. allTheSame is true if the current inner tuple is marked “all-the-same”; in this case all the nodes have the same label (if any) and so either all or none of them match the query (see Section 69.4.3). hasPrefix is true if the current inner tuple contains a prefix; if so, prefixDatum is its value. nNodes is the number of child nodes contained in the inner tuple, and nodeLabels is an array of their label values, or NULL if the nodes do not have labels.

nNodes must be set to the number of child nodes that need to be visited by the search, and nodeNumbers must be set to an array of their indexes. If the operator class keeps track of levels, set levelAdds to an array of the level increments required when descending to each node to be visited. (Often these increments will be the same for all the nodes, but that's not necessarily so, so an array is used.) If value reconstruction is needed, set reconstructedValues to an array of the values reconstructed for each child node to be visited; otherwise, leave reconstructedValues as NULL. The reconstructed values are assumed to be of type spgConfigOut.leafType. (However, since the core system will do nothing with them except possibly copy them, it is sufficient for them to have the same typlen and typbyval properties as leafType.) If ordered search is performed, set distances to an array of distance values according to orderby array (nodes with lowest distances will be processed first). Leave it NULL otherwise. If it is desired to pass down additional out-of-band information (“traverse values”) to lower levels of the tree search, set traversalValues to an array of the appropriate traverse values, one for each child node to be visited; otherwise, leave traversalValues as NULL. Note that the inner_consistent function is responsible for palloc'ing the nodeNumbers, levelAdds, distances, reconstructedValues, and traversalValues arrays in the current memory context. However, any output traverse values pointed to by the traversalValues array should be allocated in traversalMemoryContext. Each traverse value must be a single palloc'd chunk.

leaf_consistent

Returns true if a leaf tuple satisfies a query.

The SQL declaration of the function must look like this:

```sql
CREATE FUNCTION my_leaf_consistent(internal, internal) RETURNS boolean ...  
```

The first argument is a pointer to a spgLeafConsistentIn C struct, containing input data for the function. The second argument is a pointer to a spgLeafConsistentOut C struct, which the function must fill with result data.

typedef struct spgLeafConsistentIn
{
    ScanKey     scankeys;       /* array of operators and
        comparison values */
    ScanKey     orderbys;       /* array of ordering operators
    and comparison...
int nkeys; /* length of scankeys array */
int norderbys; /* length of orderbys array */
Datum reconstructedValue; /* value reconstructed at parent */
void *traversalValue; /* opclass-specific traverse value */
int level; /* current level (counting from zero) */
bool returnData; /* original data must be returned? */
Datum leafDatum; /* datum in leaf tuple */

typedef struct spgLeafConsistentOut {
  Datum leafValue; /* reconstructed original data, if any */
  bool recheck; /* set true if operator must be rechecked */
  bool recheckDistances; /* set true if distances must be rechecked */
  double *distances; /* associated distances */
} spgLeafConsistentOut;

The array scankeys, of length nkeys, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them satisfy the query. (Note that nkeys = 0 implies that all index entries satisfy the query.) Usually the consistent function only cares about the sk_strategy and sk_argument fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check sk_flags to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. The array orderbys, of length norderbys, describes the ordering operators in the same manner. reconstructedValue is the value reconstructed for the parent tuple; it is (Datum) 0 at the root level or if the inner_consistent function did not provide a value at the parent level. traversalValue is a pointer to any traverse data passed down from the previous call of inner_consistent on the parent index tuple, or NULL at the root level. level is the current leaf tuple’s level, starting at zero for the root level. returnData is true if reconstructed data is required for this query; this will only be so if the config function asserted canReturnData. leafDatum is the key value of spgConfigOut.leafType stored in the current leaf tuple.

The function must return true if the leaf tuple matches the query, or false if not. In the true case, if returnData is true then leafValue must be set to the value (of type spgConfigIn.attType) originally supplied to be indexed for this leaf tuple. Also, recheck may be set to true if the match is uncertain and so the operator(s) must be re-applied to the actual heap tuple to verify the match. If ordered search is performed, set distances to an array of distance values according to orderbys array. Leave it NULL otherwise. If at least one of returned distances is not exact, set recheckDistances to true. In this case, the executor will calculate the exact distances after fetching the tuple from the heap, and will reorder the tuples if needed.

The optional user-defined methods are:

Datum compress(Datum in)

Converts a data item into a format suitable for physical storage in a leaf tuple of the index. It accepts a value of type spgConfigIn.attType and returns a value of type spgConfigOut.leafType. The output value must not contain an out-of-line TOAST pointer.
Note: the `compress` method is only applied to values to be stored. The consistent methods receive query `scankeys` unchanged, without transformation using `compress`.

**options**

Defines a set of user-visible parameters that control operator class behavior.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_options(internal)
RETURNS void
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Since the representation of the key in SP-GiST is flexible, it may depend on user-specified parameters.

All the SP-GiST support methods are normally called in a short-lived memory context; that is, `CurrentMemoryContext` will be reset after processing of each tuple. It is therefore not very important to worry about freeing everything you `palloc`. (The `config` method is an exception: it should try to avoid leaking memory. But usually the `config` method need do nothing but assign constants into the passed parameter struct.)

If the indexed column is of a collatable data type, the index collation will be passed to all the support methods, using the standard `PG_GET_COLLATION()` mechanism.

### 69.4. Implementation

This section covers implementation details and other tricks that are useful for implementers of SP-GiST operator classes to know.

#### 69.4.1. SP-GiST Limits

Individual leaf tuples and inner tuples must fit on a single index page (8kB by default). Therefore, when indexing values of variable-length data types, long values can only be supported by methods such as radix trees, in which each level of the tree includes a prefix that is short enough to fit on a page, and the final leaf level includes a suffix also short enough to fit on a page. The operator class should set `longValuesOK` to true only if it is prepared to arrange for this to happen. Otherwise, the SP-GiST core will reject any request to index a value that is too large to fit on an index page.

Likewise, it is the operator class’s responsibility that inner tuples do not grow too large to fit on an index page; this limits the number of child nodes that can be used in one inner tuple, as well as the maximum size of a prefix value.

Another limitation is that when an inner tuple’s node points to a set of leaf tuples, those tuples must all be in the same index page. (This is a design decision to reduce seeking and save space in the links that chain such tuples together.) If the set of leaf tuples grows too large for a page, a split is performed and an intermediate inner tuple is inserted. For this to fix the problem, the new inner tuple must divide the set of leaf values into more than one node group. If the operator class’s `picksplit` function fails to do that, the SP-GiST core resorts to extraordinary measures described in Section 69.4.3.

When `longValuesOK` is true, it is expected that successive levels of the SP-GiST tree will absorb more and more information into the prefixes and node labels of the inner tuples, making the required leaf datum smaller and smaller, so that eventually it will fit on a page. To prevent bugs in operator
classes from causing infinite insertion loops, the SP-GiST core will raise an error if the leaf datum does not become any smaller within ten cycles of choose method calls.

### 69.4.2. SP-GiST Without Node Labels

Some tree algorithms use a fixed set of nodes for each inner tuple; for example, in a quad-tree there are always exactly four nodes corresponding to the four quadrants around the inner tuple’s centroid point. In such a case the code typically works with the nodes by number, and there is no need for explicit node labels. To suppress node labels (and thereby save some space), the picksplit function can return NULL for the nodeLabels array, and likewise the choose function can return NULL for the prefixNodeLabels array during a spgSplitTuple action. This will in turn result in nodeLabels being NULL during subsequent calls to choose and inner_consistent. In principle, node labels could be used for some inner tuples and omitted for others in the same index.

When working with an inner tuple having unlabeled nodes, it is an error for choose to return spgAddNode, since the set of nodes is supposed to be fixed in such cases.

### 69.4.3. “All-the-Same” Inner Tuples

The SP-GiST core can override the results of the operator class’s picksplit function when picksplit fails to divide the supplied leaf values into at least two node categories. When this happens, the new inner tuple is created with multiple nodes that each have the same label (if any) that picksplit gave to the one node it did use, and the leaf values are divided at random among these equivalent nodes. The allTheSame flag is set on the inner tuple to warn the choose and inner_consistent functions that the tuple does not have the node set that they might otherwise expect.

When dealing with an allTheSame tuple, a choose result of spgMatchNode is interpreted to mean that the new value can be assigned to any of the equivalent nodes; the core code will ignore the supplied nodeN value and descend into one of the nodes at random (so as to keep the tree balanced). It is an error for choose to return spgAddNode, since that would make the nodes not all equivalent; the spgSplitTuple action must be used if the value to be inserted doesn’t match the existing nodes.

When dealing with an allTheSame tuple, the inner_consistent function should return either all or none of the nodes as targets for continuing the index search, since they are all equivalent. This may or may not require any special-case code, depending on how much the inner_consistent function normally assumes about the meaning of the nodes.

### 69.5. Examples

The PostgreSQL source distribution includes several examples of index operator classes for SP-GiST, as described in Table 69.1. Look into src/backend/access/spgist/ and src/backend/utils/adt/ to see the code.
Chapter 70. GIN Indexes

70.1. Introduction

GIN stands for Generalized Inverted Index. GIN is designed for handling cases where the items to be indexed are composite values, and the queries to be handled by the index need to search for element values that appear within the composite items. For example, the items could be documents, and the queries could be searches for documents containing specific words.

We use the word item to refer to a composite value that is to be indexed, and the word key to refer to an element value. GIN always stores and searches for keys, not item values per se.

A GIN index stores a set of (key, posting list) pairs, where a posting list is a set of row IDs in which the key occurs. The same row ID can appear in multiple posting lists, since an item can contain more than one key. Each key value is stored only once, so a GIN index is very compact for cases where the same key appears many times.

GIN is generalized in the sense that the GIN access method code does not need to know the specific operations that it accelerates. Instead, it uses custom strategies defined for particular data types. The strategy defines how keys are extracted from indexed items and query conditions, and how to determine whether a row that contains some of the key values in a query actually satisfies the query.

One advantage of GIN is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert. This is much the same advantage as using GiST.

The GIN implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov. There is more information about GIN on their website\(^1\).

70.2. Built-in Operator Classes

The core PostgreSQL distribution includes the GIN operator classes shown in Table 70.1. (Some of the optional modules described in Appendix F provide additional GIN operator classes.)

Table 70.1. Built-in GIN Operator Classes

Of the two operator classes for type `jsonb`, `jsonb_ops` is the default. `jsonb_path_ops` supports fewer operators but offers better performance for those operators. See Section 8.14.4 for details.

### 70.3. Extensibility

The GIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GIN layer itself takes care of concurrency, logging and searching the tree structure.

All it takes to get a GIN access method working is to implement a few user-defined methods, which define the behavior of keys in the tree and the relationships between keys, indexed items, and indexable queries. In short, GIN combines extensibility with generality, code reuse, and a clean interface.

There are two methods that an operator class for GIN must provide:

```c
Datum *extractValue(Datum itemValue, int32 *nkeys, bool **nullFlags)
```

Returns a palloc’d array of keys given an item to be indexed. The number of returned keys must be stored into *nkeys. If any of the keys can be null, also palloc an array of *nkeys bool fields, store its address at *nullFlags, and set these null flags as needed. *nullFlags can be left NULL (its initial value) if all keys are non-null. The return value can be NULL if the item contains no keys.

```c
Datum *extractQuery(Datum query, int32 *nkeys, StrategyNumber n, bool **pmatch, Pointer **extra_data, bool **nullFlags, int32 *searchMode)
```

Returns a palloc’d array of keys given a value to be queried; that is, `query` is the value on the right-hand side of an indexable operator whose left-hand side is the indexed column. `n` is the strategy number of the operator within the operator class (see Section 38.16.2). Often, `extractQuery` will need to consult `n` to determine the data type of `query` and the method it should use to extract key values. The number of returned keys must be stored into *nkeys. If any of the keys can be null, also palloc an array of *nkeys bool fields, store its address at *nullFlags, and set these null flags as needed. *nullFlags can be left NULL (its initial value) if all keys are non-null. The return value can be NULL if the query contains no keys.

*searchMode is an output argument that allows `extractQuery` to specify details about how the search will be done. If *searchMode is set to GIN_SEARCH_MODE_DEFAULT (which is the value it is initialized to before call), only items that match at least one of the returned keys are considered candidate matches. If *searchMode is set to GIN_SEARCH_MODE_INCLUDED_EMPTY, then in addition to items containing at least one matching key, items that contain no keys at all are considered candidate matches. (This mode is useful for implementing is-subset-of operators, for example.) If *searchMode is set to GIN_SEARCH_MODE_ALL, then all non-null items in the index are considered candidate matches, whether they match any of the returned keys or not. (This mode is much slower than the other two choices, since it requires scanning essentially the entire index, but it may be necessary to implement corner cases correctly. An operator that needs this mode in most cases is probably not a good candidate for a GIN operator class.) The symbols to use for setting this mode are defined in `access/gin.h`.

*pmatch is an output argument for use when partial match is supported. To use it, `extractQuery` must allocate an array of *nkeys bools and store its address at *pmatch. Each element of the array should be set to true if the corresponding key requires partial match, false if not. If *pmatch is set to NULL then GIN assumes partial match is not required. The variable is initialized to NULL before call, so this argument can simply be ignored by operator classes that do not support partial match.
extra_data is an output argument that allows extractQuery to pass additional data to the consistent and comparePartial methods. To use it, extractQuery must allocate an array of *nkeys pointers and store its address at *extra_data, then store whatever it wants to into the individual pointers. The variable is initialized to NULL before call, so this argument can simply be ignored by operator classes that do not require extra data. If *extra_data is set, the whole array is passed to the consistent method, and the appropriate element to the comparePartial method.

An operator class must also provide a function to check if an indexed item matches the query. It comes in two flavors, a Boolean consistent function, and a ternary triConsistent function. triConsistent covers the functionality of both, so providing triConsistent alone is sufficient. However, if the Boolean variant is significantly cheaper to calculate, it can be advantageous to provide both. If only the Boolean variant is provided, some optimizations that depend on refuting index items before fetching all the keys are disabled.

```c
bool consistent(bool check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], bool *recheck, Datum queryKeys[], bool nullFlags[])
```

Returns true if an indexed item satisfies the query operator with strategy number n (or might satisfy it, if the recheck indication is returned). This function does not have direct access to the indexed item's value, since GIN does not store items explicitly. Rather, what is available is knowledge about which key values extracted from the query appear in a given indexed item. The check array has length nkeys, which is the same as the number of keys previously returned by extractQuery for this query datum. Each element of the check array is true if the indexed item contains the corresponding query key, i.e., if (check[i] == true) the i-th key of the extractQuery result array is present in the indexed item. The original query datum is passed in case the consistent method needs to consult it, and so are the queryKeys[] and nullFlags[] arrays previously returned by extractQuery. extra_data is the extra-data array returned by extractQuery, or NULL if none.

When extractQuery returns a null key in queryKeys[], the corresponding check[] element is true if the indexed item contains a null key; that is, the semantics of check[] are like IS NOT DISTINCT FROM. The consistent function can examine the corresponding null-Flags[] element if it needs to tell the difference between a regular value match and a null match.

On success, *recheck should be set to true if the heap tuple needs to be rechecked against the query operator, or false if the index test is exact. That is, a false return value guarantees that the heap tuple does not match the query; a true return value with *recheck set to false guarantees that the heap tuple does match the query; and a true return value with *recheck set to true means that the heap tuple might match the query, so it needs to be fetched and rechecked by evaluating the query operator directly against the originally indexed item.

```c
GinTernaryValue triConsistent(GinTernaryValue check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], Datum queryKeys[], bool nullFlags[])
```

triConsistent is similar to consistent, but instead of Booleans in the check vector, there are three possible values for each key: GIN_TRUE, GIN_FALSE and GIN_MAYBE. GIN_FALSE and GIN_TRUE have the same meaning as regular Boolean values, while GIN_MAYBE means that the presence of that key is not known. When GIN_MAYBE values are present, the function should only return GIN_TRUE if the item certainly matches whether or not the index item contains the corresponding query keys. Likewise, the function must return GIN_FALSE only if the item certainly does not match, whether or not it contains the GIN_MAYBE keys. If the result depends on the GIN_MAYBE entries, i.e., the match cannot be confirmed or refuted based on the known query keys, the function must return GIN_MAYBE.

When there are no GIN_MAYBE values in the check vector, a GIN_MAYBE return value is the equivalent of setting the recheck flag in the Boolean consistent function.
In addition, GIN must have a way to sort the key values stored in the index. The operator class can define the sort ordering by specifying a comparison method:

```c
int compare(Datum a, Datum b)
```

Compares two keys (not indexed items!) and returns an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second. Null keys are never passed to this function.

Alternatively, if the operator class does not provide a `compare` method, GIN will look up the default `btree` operator class for the index key data type, and use its comparison function. It is recommended to specify the comparison function in a GIN operator class that is meant for just one data type, as looking up the `btree` operator class costs a few cycles. However, polymorphic GIN operator classes (such as `array_ops`) typically cannot specify a single comparison function.

An operator class for GIN can optionally supply the following methods:

```c
int comparePartial(Datum partial_key, Datum key, StrategyNumber n, Pointer extra_data)
```

Compare a partial-match query key to an index key. Returns an integer whose sign indicates the result: less than zero means the index key does not match the query, but the index scan should continue; zero means that the index key does match the query; greater than zero indicates that the index scan should stop because no more matches are possible. The strategy number `n` of the operator that generated the partial match query is provided, in case its semantics are needed to determine when to end the scan. Also, `extra_data` is the corresponding element of the extra-data array made by `extractQuery`, or `NULL` if none. Null keys are never passed to this function.

```c
void options(local_relopts *relopts)
```

Defines a set of user-visible parameters that control operator class behavior.

The `options` function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Since both key extraction of indexed values and representation of the key in GIN are flexible, they may depend on user-specified parameters.

To support “partial match” queries, an operator class must provide the `comparePartial` method, and its `extractQuery` method must set the `pmatch` parameter when a partial-match query is encountered. See Section 70.4.2 for details.

The actual data types of the various `Datum` values mentioned above vary depending on the operator class. The item values passed to `extractValue` are always of the operator class’s input type, and all key values must be of the class’s `STORAGE` type. The type of the `query` argument passed to `extractQuery`, `consistent` and `triConsistent` is whatever is the right-hand input type of the class member operator identified by the strategy number. This need not be the same as the indexed type, so long as key values of the correct type can be extracted from it. However, it is recommended that the SQL declarations of these three support functions use the opclass’s indexed data type for the `query` argument, even though the actual type might be something else depending on the operator.

### 70.4. Implementation

Internally, a GIN index contains a B-tree index constructed over keys, where each key is an element of one or more indexed items (a member of an array, for example) and where each tuple in a leaf page contains either a pointer to a B-tree of heap pointers (a “posting tree”), or a simple list of heap pointers
GIN Indexes

(a “posting list”) when the list is small enough to fit into a single index tuple along with the key value. Figure 70.1 illustrates these components of a GIN index.

As of PostgreSQL 9.1, null key values can be included in the index. Also, placeholder nulls are included in the index for indexed items that are null or contain no keys according to extractValue. This allows searches that should find empty items to do so.

Multicolumn GIN indexes are implemented by building a single B-tree over composite values (column number, key value). The key values for different columns can be of different types.

Figure 70.1. GIN Internals

70.4.1. GIN Fast Update Technique

Updating a GIN index tends to be slow because of the intrinsic nature of inverted indexes: inserting or updating one heap row can cause many inserts into the index (one for each key extracted from the indexed item). GIN is capable of postponing much of this work by inserting new tuples into a temporary, unsorted list of pending entries. When the table is vacuumed or autoanalyzed, or when gin_clean_pending_list function is called, or if the pending list becomes larger than gin_pending_list_limit, the entries are moved to the main GIN data structure using the same bulk insert techniques used during initial index creation. This greatly improves GIN index update speed, even counting the additional vacuum overhead. Moreover the overhead work can be done by a background process instead of in foreground query processing.

The main disadvantage of this approach is that searches must scan the list of pending entries in addition to searching the regular index, and so a large list of pending entries will slow searches significantly. Another disadvantage is that, while most updates are fast, an update that causes the pending list to become “too large” will incur an immediate cleanup cycle and thus be much slower than other updates. Proper use of autovacuum can minimize both of these problems.

If consistent response time is more important than update speed, use of pending entries can be disabled by turning off the fastupdate storage parameter for a GIN index. See CREATE INDEX for details.

70.4.2. Partial Match Algorithm

GIN can support “partial match” queries, in which the query does not determine an exact match for one or more keys, but the possible matches fall within a reasonably narrow range of key values (within the key sorting order determined by the compare support method). The extractQuery method, instead of returning a key value to be matched exactly, returns a key value that is the lower bound
of the range to be searched, and sets the pmatch flag true. The key range is then scanned using the comparePartial method. comparePartial must return zero for a matching index key, less than zero for a non-match that is still within the range to be searched, or greater than zero if the index key is past the range that could match.

## 70.5. GIN Tips and Tricks

**Create vs. insert**

Insertion into a GIN index can be slow due to the likelihood of many keys being inserted for each item. So, for bulk insertions into a table it is advisable to drop the GIN index and recreate it after finishing bulk insertion.

When fastupdate is enabled for GIN (see Section 70.4.1 for details), the penalty is less than when it is not. But for very large updates it may still be best to drop and recreate the index.

**maintenance_work_mem**

Build time for a GIN index is very sensitive to the maintenance_work_mem setting; it doesn’t pay to skimp on work memory during index creation.

**gin_pending_list_limit**

During a series of insertions into an existing GIN index that has fastupdate enabled, the system will clean up the pending-entry list whenever the list grows larger than gin_pending_list_limit. To avoid fluctuations in observed response time, it’s desirable to have pending-list cleanup occur in the background (i.e., via autovacuum). Foreground cleanup operations can be avoided by increasing gin_pending_list_limit or making autovacuum more aggressive. However, enlarging the threshold of the cleanup operation means that if a foreground cleanup does occur, it will take even longer.

gin_pending_list_limit can be overridden for individual GIN indexes by changing storage parameters, which allows each GIN index to have its own cleanup threshold. For example, it’s possible to increase the threshold only for the GIN index which can be updated heavily, and decrease it otherwise.

**gin_fuzzy_search_limit**

The primary goal of developing GIN indexes was to create support for highly scalable full-text search in PostgreSQL, and there are often situations when a full-text search returns a very large set of results. Moreover, this often happens when the query contains very frequent words, so that the large result set is not even useful. Since reading many tuples from the disk and sorting them could take a lot of time, this is unacceptable for production. (Note that the index search itself is very fast.)

To facilitate controlled execution of such queries, GIN has a configurable soft upper limit on the number of rows returned: the gin_fuzzy_search_limit configuration parameter. It is set to 0 (meaning no limit) by default. If a non-zero limit is set, then the returned set is a subset of the whole result set, chosen at random.

“Soft” means that the actual number of returned results could differ somewhat from the specified limit, depending on the query and the quality of the system’s random number generator.

From experience, values in the thousands (e.g., 5000 — 20000) work well.

## 70.6. Limitations

GIN assumes that indexable operators are strict. This means that extractValue will not be called at all on a null item value (instead, a placeholder index entry is created automatically), and extrac-
tQuery will not be called on a null query value either (instead, the query is presumed to be unsatisfiable). Note however that null key values contained within a non-null composite item or query value are supported.

70.7. Examples

The core PostgreSQL distribution includes the GIN operator classes previously shown in Table 70.1. The following contrib modules also contain GIN operator classes:

- **btree_gin**
  - B-tree equivalent functionality for several data types

- **hstore**
  - Module for storing (key, value) pairs

- **intarray**
  - Enhanced support for int[]

- **pg_trgm**
  - Text similarity using trigram matching
Chapter 71. BRIN Indexes

71.1. Introduction

BRIN stands for Block Range Index. BRIN is designed for handling very large tables in which certain columns have some natural correlation with their physical location within the table.

BRIN works in terms of block ranges (or “page ranges”). A block range is a group of pages that are physically adjacent in the table; for each block range, some summary info is stored by the index. For example, a table storing a store's sale orders might have a date column on which each order was placed, and most of the time the entries for earlier orders will appear earlier in the table as well; a table storing a ZIP code column might have all codes for a city grouped together naturally.

BRIN indexes can satisfy queries via regular bitmap index scans, and will return all tuples in all pages within each range if the summary info stored by the index is consistent with the query conditions. The query executor is in charge of rechecking these tuples and discarding those that do not match the query conditions — in other words, these indexes are lossy. Because a BRIN index is very small, scanning the index adds little overhead compared to a sequential scan, but may avoid scanning large parts of the table that are known not to contain matching tuples.

The specific data that a BRIN index will store, as well as the specific queries that the index will be able to satisfy, depend on the operator class selected for each column of the index. Data types having a linear sort order can have operator classes that store the minimum and maximum value within each block range, for instance; geometrical types might store the bounding box for all the objects in the block range.

The size of the block range is determined at index creation time by the pages_per_range storage parameter. The number of index entries will be equal to the size of the relation in pages divided by the selected value for pages_per_range. Therefore, the smaller the number, the larger the index becomes (because of the need to store more index entries), but at the same time the summary data stored can be more precise and more data blocks can be skipped during an index scan.

71.1.1. Index Maintenance

At the time of creation, all existing heap pages are scanned and a summary index tuple is created for each range, including the possibly-incomplete range at the end. As new pages are filled with data, page ranges that are already summarized will cause the summary information to be updated with data from the new tuples. When a new page is created that does not fall within the last summarized range, the range that the new page belongs to does not automatically acquire a summary tuple; those tuples remain unsummarized until a summarization run is invoked later, creating the initial summary for that range.

There are several ways to trigger the initial summarization of a page range. If the table is vacuumed, either manually or by autovacuum, all existing unsummarized page ranges are summarized. Also, if the index’s autosummarize parameter is enabled, which it isn't by default, whenever autovacuum runs in that database, summarization will occur for all unsummarized page ranges that have been filled, regardless of whether the table itself is processed by autovacuum; see below.

Lastly, the following functions can be used:

- `brin_summarize_new_values(regclass)` which summarizes all unsummarized ranges;
- `brin_summarize_range(regclass, bigint)` which summarizes only the range containing the given page, if it is unsummarized.

When autosummarization is enabled, a request is sent to autovacuum to execute a targeted summarization for a block range when an insertion is detected for the first item of the first page of the next block range, to be fulfilled the next time an autovacuum worker finishes running in the same database. If the request queue is full, the request is not recorded and a message is sent to the server log.
LOG: request for BRIN range summarization for index "brin_wi_idx"
page 128 was not recorded

When this happens, the range will remain unsummarized until the next regular vacuum run on the
table, or one of the functions mentioned above are invoked.

Conversely, a range can be de-summarized using the `brin_desummarize_range(regclass,
bigint)` function, which is useful when the index tuple is no longer a very good representation
because the existing values have changed. See Section 9.27.8 for details.

## 71.2. Built-in Operator Classes

The core PostgreSQL distribution includes the BRIN operator classes shown in Table 71.1.

The `minmax` operator classes store the minimum and the maximum values appearing in the indexed
column within the range. The `inclusion` operator classes store a value which includes the values in the
indexed column within the range. The `bloom` operator classes build a Bloom filter for all values in the
range. The `minmax-multi` operator classes store multiple minimum and maximum values, representing
values appearing in the indexed column within the range.

### Table 71.1. Built-in BRIN Operator Classes

### 71.2.1. Operator Class Parameters

Some of the built-in operator classes allow specifying parameters affecting behavior of the operator class. Each operator class has its own set of allowed parameters. Only the `bloom` and `minmax-multi` operator classes allow specifying parameters:

**bloom operator classes accept these parameters:**

- **n_distinct_per_range**
  
  Defines the estimated number of distinct non-null values in the block range, used by BRIN bloom indexes for sizing of the Bloom filter. It behaves similarly to `n_distinct` option for ALTER TABLE. When set to a positive value, each block range is assumed to contain this number of distinct non-null values. When set to a negative value, which must be greater than or equal to -1, the number of distinct non-null values is assumed to grow linearly with the maximum possible number of tuples in the block range (about 290 rows per block). The default value is \(-0.1\), and the minimum number of distinct non-null values is 16.

- **false_positive_rate**
  
  Defines the desired false positive rate used by BRIN bloom indexes for sizing of the Bloom filter. The values must be between 0.0001 and 0.25. The default value is 0.01, which is 1% false positive rate.

**minmax-multi operator classes accept these parameters:**

- **values_per_range**
  
  Defines the maximum number of values stored by BRIN minmax indexes to summarize a block range. Each value may represent either a point, or a boundary of an interval. Values must be between 8 and 256, and the default value is 32.

### 71.3. Extensibility

The BRIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The BRIN layer itself takes care of concurrency, logging and searching the index structure.

All it takes to get a BRIN access method working is to implement a few user-defined methods, which define the behavior of summary values stored in the index and the way they interact with scan keys. In short, BRIN combines extensibility with generality, code reuse, and a clean interface.
There are four methods that an operator class for BRIN must provide:

```c
BrinOpcInfo *opcInfo(Oid type_oid)
```

Returns internal information about the indexed columns' summary data. The return value must point to a palloc'd `BrinOpcInfo`, which has this definition:

```c
typedef struct BrinOpcInfo {
    uint16      oi_nstored;
    void       *oi_opaque;
    TypeCacheEntry *oi_typcache[FLEXIBLE_ARRAY_MEMBER];
} BrinOpcInfo;
```

`BrinOpcInfo.oi_opaque` can be used by the operator class routines to pass information between support functions during an index scan.

```c
bool consistent(BrinDesc *bdesc, BrinValues *column, ScanKey *keys, int nkeys)
```

Returns whether all the ScanKey entries are consistent with the given indexed values for a range. The attribute number to use is passed as part of the scan key. Multiple scan keys for the same attribute may be passed at once; the number of entries is determined by the `nkeys` parameter.

```c
bool consistent(BrinDesc *bdesc, BrinValues *column, ScanKey key)
```

Returns whether the ScanKey is consistent with the given indexed values for a range. The attribute number to use is passed as part of the scan key. This is an older backward-compatible variant of the consistent function.

```c
bool addValue(BrinDesc *bdesc, BrinValues *column, Datum newval, bool isnull)
```

Given an index tuple and an indexed value, modifies the indicated attribute of the tuple so that it additionally represents the new value. If any modification was done to the tuple, `true` is returned.

```c
bool unionTuples(BrinDesc *bdesc, BrinValues *a, BrinValues *b)
```

Consolidates two index tuples. Given two index tuples, modifies the indicated attribute of the first of them so that it represents both tuples. The second tuple is not modified.

An operator class for BRIN can optionally specify the following method:

```c
void options(local_relopts *relopts)
```

Defines a set of user-visible parameters that control operator class behavior.

The `options` function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Since both key extraction of indexed values and representation of the key in BRIN are flexible, they may depend on user-specified parameters.
The core distribution includes support for four types of operator classes: minmax, minmax-multi, inclusion and bloom. Operator class definitions using them are shipped for in-core data types as appropriate. Additional operator classes can be defined by the user for other data types using equivalent definitions, without having to write any source code; appropriate catalog entries being declared is enough. Note that assumptions about the semantics of operator strategies are embedded in the support functions' source code.

Operator classes that implement completely different semantics are also possible, provided implementations of the four main support functions described above are written. Note that backwards compatibility across major releases is not guaranteed: for example, additional support functions might be required in later releases.

To write an operator class for a data type that implements a totally ordered set, it is possible to use the minmax support functions alongside the corresponding operators, as shown in Table 71.2. All operator class members (functions and operators) are mandatory.

<table>

To write an operator class for a complex data type which has values included within another type, it's possible to use the inclusion support functions alongside the corresponding operators, as shown in Table 71.3. It requires only a single additional function, which can be written in any language. More functions can be defined for additional functionality. All operators are optional. Some operators require other operators, as shown as dependencies on the table.

</table>

Support function numbers 1 through 10 are reserved for the BRIN internal functions, so the SQL level functions start with number 11. Support function number 11 is the main function required to build the index. It should accept two arguments with the same data type as the operator class, and return the union of them. The inclusion operator class can store union values with different data types if it is defined with the STORAGE parameter. The return value of the union function should match the STORAGE data type.

Support function numbers 12 and 14 are provided to support irregularities of built-in data types. Function number 12 is used to support network addresses from different families which are not mergeable. Function number 14 is used to support empty ranges. Function number 13 is an optional but recommended one, which allows the new value to be checked before it is passed to the union function. As the BRIN framework can shortcut some operations when the union is not changed, using this function can improve index performance.

To write an operator class for a data type that implements only an equality operator and supports hashing, it is possible to use the bloom support procedures alongside the corresponding operators, as shown in Table 71.4. All operator class members (procedures and operators) are mandatory.

Support procedure numbers 1-10 are reserved for the BRIN internal functions, so the SQL level functions start with number 11. Support function number 11 is the main function required to build the index. It should accept one argument with the same data type as the operator class, and return a hash of the value.

The minmax-multi operator class is also intended for data types implementing a totally ordered set, and may be seen as a simple extension of the minmax operator class. While minmax operator class summarizes values from each block range into a single contiguous interval, minmax-multi allows summarization into multiple smaller intervals to improve handling of outlier values. It is possible to use the minmax-multi support procedures alongside the corresponding operators, as shown in Table 71.5.

All operator class members (procedures and operators) are mandatory.

</tr>
</tbody>
</table>

Both minmax and inclusion operator classes support cross-data-type operators, though with these the dependencies become more complicated. The minmax operator class requires a full set of operators to be defined with both arguments having the same data type. It allows additional data types to be supported by defining extra sets of operators. Inclusion operator class operator strategies are dependent on another operator strategy as shown in Table 71.3, or the same operator strategy as themselves. They require the dependency operator to be defined with the STORAGE data type as the left-hand-side argument and the other supported data type to be the right-hand-side argument of the supported operator. See float4_minmax_ops as an example of minmax, and box_inclusion_ops as an example of inclusion.
Chapter 72. Hash Indexes

72.1. Overview

PostgreSQL includes an implementation of persistent on-disk hash indexes, which are fully crash recoverable. Any data type can be indexed by a hash index, including data types that do not have a well-defined linear ordering. Hash indexes store only the hash value of the data being indexed, thus there are no restrictions on the size of the data column being indexed.

Hash indexes support only single-column indexes and do not allow uniqueness checking.

Hash indexes support only the = operator, so WHERE clauses that specify range operations will not be able to take advantage of hash indexes.

Each hash index tuple stores just the 4-byte hash value, not the actual column value. As a result, hash indexes may be much smaller than B-trees when indexing longer data items such as UUIDs, URLs, etc. The absence of the column value also makes all hash index scans lossy. Hash indexes may take part in bitmap index scans and backward scans.

Hash indexes are best optimized for SELECT and UPDATE-heavy workloads that use equality scans on larger tables. In a B-tree index, searches must descend through the tree until the leaf page is found. In tables with millions of rows, this descent can increase access time to data. The equivalent of a leaf page in a hash index is referred to as a bucket page. In contrast, a hash index allows accessing the bucket pages directly, thereby potentially reducing index access time in larger tables. This reduction in "logical I/O" becomes even more pronounced on indexes/data larger than shared_buffers/RAM.

Hash indexes have been designed to cope with uneven distributions of hash values. Direct access to the bucket pages works well if the hash values are evenly distributed. When inserts mean that the bucket page becomes full, additional overflow pages are chained to that specific bucket page, locally expanding the storage for index tuples that match that hash value. When scanning a hash bucket during queries, we need to scan through all of the overflow pages. Thus an unbalanced hash index might actually be worse than a B-tree in terms of number of block accesses required, for some data.

As a result of the overflow cases, we can say that hash indexes are most suitable for unique, nearly unique data or data with a low number of rows per hash bucket. One possible way to avoid problems is to exclude highly non-unique values from the index using a partial index condition, but this may not be suitable in many cases.

Like B-Trees, hash indexes perform simple index tuple deletion. This is a deferred maintenance operation that deletes index tuples that are known to be safe to delete (those whose item identifier's LP_DEAD bit is already set). If an insert finds no space is available on a page we try to avoid creating a new overflow page by attempting to remove dead index tuples. Removal cannot occur if the page is pinned at that time. Deletion of dead index pointers also occurs during VACUUM.

If it can, VACUUM will also try to squeeze the index tuples onto as few overflow pages as possible, minimizing the overflow chain. If an overflow page becomes empty, overflow pages can be recycled for reuse in other buckets, though we never return them to the operating system. There is currently no provision to shrink a hash index, other than by rebuilding it with REINDEX. There is no provision for reducing the number of buckets, either.

Hash indexes may expand the number of bucket pages as the number of rows indexed grows. The hash key-to-bucket-number mapping is chosen so that the index can be incrementally expanded. When a new bucket is to be added to the index, exactly one existing bucket will need to be "split", with some of its tuples being transferred to the new bucket according to the updated key-to-bucket-number mapping.

The expansion occurs in the foreground, which could increase execution time for user inserts. Thus, hash indexes may not be suitable for tables with rapidly increasing number of rows.
72.2. Implementation

There are four kinds of pages in a hash index: the meta page (page zero), which contains statically allocated control information; primary bucket pages; overflow pages; and bitmap pages, which keep track of overflow pages that have been freed and are available for re-use. For addressing purposes, bitmap pages are regarded as a subset of the overflow pages.

Both scanning the index and inserting tuples require locating the bucket where a given tuple ought to be located. To do this, we need the bucket count, highmask, and lowmask from the metapage; however, it's undesirable for performance reasons to have to lock and pin the metapage for every such operation. Instead, we retain a cached copy of the metapage in each backend's relcache entry. This will produce the correct bucket mapping as long as the target bucket hasn't been split since the last cache refresh.

Primary bucket pages and overflow pages are allocated independently since any given index might need more or fewer overflow pages relative to its number of buckets. The hash code uses an interesting set of addressing rules to support a variable number of overflow pages while not having to move primary bucket pages around after they are created.

Each row in the table indexed is represented by a single index tuple in the hash index. Hash index tuples are stored in bucket pages, and if they exist, overflow pages. We speed up searches by keeping the index entries in any one index page sorted by hash code, thus allowing binary search to be used within an index page. Note however that there is *no* assumption about the relative ordering of hash codes across different index pages of a bucket.

The bucket splitting algorithms to expand the hash index are too complex to be worthy of mention here, though are described in more detail in src/backend/access/hash/README. The split algorithm is crash safe and can be restarted if not completed successfully.
Chapter 73. Database Physical Storage

This chapter provides an overview of the physical storage format used by PostgreSQL databases.

73.1. Database File Layout

This section describes the storage format at the level of files and directories.

Traditionally, the configuration and data files used by a database cluster are stored together within the cluster’s data directory, commonly referred to as `PGDATA` (after the name of the environment variable that can be used to define it). A common location for `PGDATA` is `/var/lib/pgsql/data`. Multiple clusters, managed by different server instances, can exist on the same machine.

The `PGDATA` directory contains several subdirectories and control files, as shown in Table 73.1. In addition to these required items, the cluster configuration files `postgresql.conf`, `pg_hba.conf`, and `pg_ident.conf` are traditionally stored in `PGDATA`, although it is possible to place them elsewhere.

Table 73.1. Contents of `PGDATA`

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
For each database in the cluster there is a subdirectory within PGDATA/base, named after the database's OID in pg_database. This subdirectory is the default location for the database's files; in particular, its system catalogs are stored there.

Note that the following sections describe the behavior of the builtin heap table access method, and the builtin index access methods. Due to the extensible nature of PostgreSQL, other access methods might work differently.

Each table and index is stored in a separate file. For ordinary relations, these files are named after the table or index's filenode number, which can be found in pg_class.relfilenode. But for temporary relations, the file name is of the form tBBB_FFF, where BBB is the backend ID of the backend which created the file, and FFF is the filenode number. In either case, in addition to the main file (a/k/a main fork), each table and index has a free space map (see Section 73.3), which stores information about free space available in the relation. The free space map is stored in a file named with the filenode number plus the suffix _fsm. Tables also have a visibility map, stored in a fork with the suffix _vm, to track which pages are known to have no dead tuples. The visibility map is described further in Section 73.4. Unlogged tables and indexes have a third fork, known as the initialization fork, which is stored in a fork with the suffix _init (see Section 73.5).

Caution

Note that while a table's filenode often matches its OID, this is not necessarily the case; some operations, like TRUNCATE, REINDEX, CLUSTER and some forms of ALTER TABLE, can change the filenode while preserving the OID. Avoid assuming that filenode and table OID are the same. Also, for certain system catalogs including pg_class itself, pg_class.relfilenode contains zero. The actual filenode number of these catalogs is stored in a lower-level data structure, and can be obtained using the pg_relation_filenode() function.

When a table or index exceeds 1 GB, it is divided into gigabyte-sized segments. The first segment's file name is the same as the filenode; subsequent segments are named filenode.1, filenode.2, etc. This
arrangement avoids problems on platforms that have file size limitations. (Actually, 1 GB is just the default segment size. The segment size can be adjusted using the configuration option --with-segsize when building PostgreSQL.) In principle, free space map and visibility map forks could require multiple segments as well, though this is unlikely to happen in practice.

A table that has columns with potentially large entries will have an associated TOAST table, which is used for out-of-line storage of field values that are too large to keep in the table rows proper. pg_class.reltoastrelid links from a table to its TOAST table, if any. See Section 73.2 for more information.

The contents of tables and indexes are discussed further in Section 73.6.

Tablespaces make the scenario more complicated. Each user-defined tablespace has a symbolic link inside the PGDATA/pg_tblspc directory, which points to the physical tablespace directory (i.e., the location specified in the tablespace's CREATE TABLESPACE command). This symbolic link is named after the tablespace's OID. Inside the physical tablespace directory there is a subdirectory with a name that depends on the PostgreSQL server version, such as PG_9.0_201008051. (The reason for using this subdirectory is so that successive versions of the database can use the same CREATE TABLESPACE location value without conflicts.) Within the version-specific subdirectory, there is a subdirectory for each database that has elements in the tablespace, named after the database's OID. Tables and indexes are stored within that directory, using the filenode naming scheme. The pg_default tablespace is not accessed through pg_tblspc, but corresponds to PGDATA/base. Similarly, the pg_global tablespace is not accessed through pg_tblspc, but corresponds to PGDATA/global.

The pg_relation_filepath() function shows the entire path (relative to PGDATA) of any relation. It is often useful as a substitute for remembering many of the above rules. But keep in mind that this function just gives the name of the first segment of the main fork of the relation — you may need to append a segment number and/or _fsm, _vm, or _init to find all the files associated with the relation.

Temporary files (for operations such as sorting more data than can fit in memory) are created within PGDATA/base/pgsql_tmp, or within a pgsql_tmp subdirectory of a tablespace directory if a tablespace other than pg_default is specified for them. The name of a temporary file has the form pgsql_tmpPPP.NNN, where PPP is the PID of the owning backend and NNN distinguishes different temporary files of that backend.

73.2. TOAST

This section provides an overview of TOAST (The Oversized-Attribute Storage Technique).

PostgreSQL uses a fixed page size (commonly 8 kB), and does not allow tuples to span multiple pages. Therefore, it is not possible to store very large field values directly. To overcome this limitation, large field values are compressed and/or broken up into multiple physical rows. This happens transparently to the user, with only small impact on most of the backend code. The technique is affectionately known as TOAST (or "the best thing since sliced bread"). The TOAST infrastructure is also used to improve handling of large data values in-memory.

Only certain data types support TOAST — there is no need to impose the overhead on data types that cannot produce large field values. To support TOAST, a data type must have a variable-length (varlena) representation, in which, ordinarily, the first four-byte word of any stored value contains the total length of the value in bytes (including itself). TOAST does not constrain the rest of the data type's representation. The special representations collectively called TOASTed values work by modifying or reinterpreting this initial length word. Therefore, the C-level functions supporting a TOAST-able data type must be careful about how they handle potentially TOASTed input values: an input might not actually consist of a four-byte length word and contents until after it's been detoasted. (This is normally done by invoking PG_DETOAST_DATUM before doing anything with an input value, but in some cases more efficient approaches are possible. See Section 38.13.1 for more detail.)
TOAST usurps two bits of the varlena length word (the high-order bits on big-endian machines, the low-order bits on little-endian machines), thereby limiting the logical size of any value of a TOAST-able data type to 1 GB ($2^{30} - 1$ bytes). When both bits are zero, the value is an ordinary un-TOASTed value of the data type, and the remaining bits of the length word give the total datum size (including length word) in bytes. When the highest-order or lowest-order bit is set, the value has only a single-byte header instead of the normal four-byte header, and the remaining bits of that byte give the total datum size (including length byte) in bytes. This alternative supports space-efficient storage of values shorter than 127 bytes, while still allowing the data type to grow to 1 GB at need. Values with single-byte headers aren't aligned on any particular boundary, whereas values with four-byte headers are aligned on at least a four-byte boundary; this omission of alignment padding provides additional space savings that is significant compared to short values. As a special case, if the remaining bits of a single-byte header are all zero (which would be impossible for a self-inclusive length), the value is a pointer to out-of-line data, with several possible alternatives as described below. The type and size of such a TOAST pointer are determined by a code stored in the second byte of the datum. Lastly, when the highest-order or lowest-order bit is clear but the adjacent bit is set, the content of the datum has been compressed and must be decompressed before use. In this case the remaining bits of the four-byte length word give the total size of the compressed datum, not the original data. Note that compression is also possible for out-of-line data but the varlena header does not tell whether it has occurred — the content of the TOAST pointer tells that, instead.

The compression technique used for either in-line or out-of-line compressed data can be selected for each column by setting the COMPRESSION column option in CREATE TABLE or ALTER TABLE. The default for columns with no explicit setting is to consult the default_toast_compression parameter at the time data is inserted.

As mentioned, there are multiple types of TOAST pointer datums. The oldest and most common type is a pointer to out-of-line data stored in a TOAST table that is separate from, but associated with, the table containing the TOAST pointer datum itself. These on-disk pointer datums are created by the TOAST management code (in access/common/toast_internals.c) when a tuple to be stored on disk is too large to be stored as-is. Further details appear in Section 73.2.1. Alternatively, a TOAST pointer datum can contain a pointer to out-of-line data that appears elsewhere in memory. Such datums are necessarily short-lived, and will never appear on-disk, but they are very useful for avoiding copying and redundant processing of large data values. Further details appear in Section 73.2.2.

### 73.2.1. Out-of-Line, On-Disk TOAST Storage

If any of the columns of a table are TOAST-able, the table will have an associated TOAST table, whose OID is stored in the table's `pg_class.reltoastrelid` entry. On-disk TOASTed values are kept in the TOAST table, as described in more detail below.

Out-of-line values are divided (after compression if used) into chunks of at most `TOAST_MAX_CHUNK_SIZE` bytes (by default this value is chosen so that four chunk rows will fit on a page, making it about 2000 bytes). Each chunk is stored as a separate row in the TOAST table belonging to the owning table. Every TOAST table has the columns `chunk_id` (an OID identifying the particular TOASTed value), `chunk_seq` (a sequence number for the chunk within its value), and `chunk_data` (the actual data of the chunk). A unique index on `chunk_id` and `chunk_seq` provides fast retrieval of the values. A pointer datum representing an out-of-line on-disk TOASTed value therefore needs to store the OID of the TOAST table in which to look and the OID of the specific value (its `chunk_id`). For convenience, pointer datums also store the logical datum size (original uncompressed data length), physical stored size (different if compression was applied), and the compression method used, if any. Allowing for the varlena header bytes, the total size of an on-disk TOAST pointer datum is therefore 18 bytes regardless of the actual size of the represented value.

The TOAST management code is triggered only when a row value to be stored in a table is wider than `TOAST_TUPLE_THRESHOLD` bytes (normally 2 kB). The TOAST code will compress and/or move field values out-of-line until the row value is shorter than `TOAST_TUPLE_TARGET` bytes (also normally 2 kB, adjustable) or no more gains can be had. During an UPDATE operation, values of unchanged fields are normally preserved as-is; so an UPDATE of a row with out-of-line values incurs no TOAST costs if none of the out-of-line values change.
The TOAST management code recognizes four different strategies for storing TOAST-able columns on disk:

- **PLAIN** prevents either compression or out-of-line storage. This is the only possible strategy for columns of non-TOAST-able data types.

- **EXTENDED** allows both compression and out-of-line storage. This is the default for most TOAST-able data types. Compression will be attempted first, then out-of-line storage if the row is still too big.

- **EXTERNAL** allows out-of-line storage but not compression. Use of EXTERNAL will make substring operations on wide text and bytea columns faster (at the penalty of increased storage space) because these operations are optimized to fetch only the required parts of the out-of-line value when it is not compressed.

- **MAIN** allows compression but not out-of-line storage. (Actually, out-of-line storage will still be performed for such columns, but only as a last resort when there is no other way to make the row small enough to fit on a page.)

Each TOAST-able data type specifies a default strategy for columns of that data type, but the strategy for a given table column can be altered with `ALTER TABLE ... SET STORAGE`.

TOAST_TUPLE_TARGET can be adjusted for each table using `ALTER TABLE ... SET (toast_tuple_target = N)`

This scheme has a number of advantages compared to a more straightforward approach such as allowing row values to span pages. Assuming that queries are usually qualified by comparisons against relatively small key values, most of the work of the executor will be done using the main row entry. The big values of TOASTed attributes will only be pulled out (if selected at all) at the time the result set is sent to the client. Thus, the main table is much smaller and more of its rows fit in the shared buffer cache than would be the case without any out-of-line storage. Sort sets shrink also, and sorts will more often be done entirely in memory. A little test showed that a table containing typical HTML pages and their URLs was stored in about half of the raw data size including the TOAST table, and that the main table contained only about 10% of the entire data (the URLs and some small HTML pages). There was no run time difference compared to an un-TOASTed comparison table, in which all the HTML pages were cut down to 7 kB to fit.

### 73.2.2. Out-of-Line, In-Memory TOAST Storage

TOAST pointers can point to data that is not on disk, but is elsewhere in the memory of the current server process. Such pointers obviously cannot be long-lived, but they are nonetheless useful. There are currently two sub-cases: pointers to *indirect* data and pointers to *expanded* data.

Indirect TOAST pointers simply point at a non-indirect varlena value stored somewhere in memory. This case was originally created merely as a proof of concept, but it is currently used during logical decoding to avoid possibly having to create physical tuples exceeding 1 GB (as pulling all out-of-line field values into the tuple might do). The case is of limited use since the creator of the pointer datum is entirely responsible that the referenced data survives for as long as the pointer could exist, and there is no infrastructure to help with this.

Expanded TOAST pointers are useful for complex data types whose on-disk representation is not especially suited for computational purposes. As an example, the standard varlena representation of a PostgreSQL array includes dimensionality information, a nulls bitmap if there are any null elements, then the values of all the elements in order. When the element type itself is variable-length, the only way to find the \( N \)th element is to scan through all the preceding elements. This representation is appropriate for on-disk storage because of its compactness, but for computations with the array it's much nicer to have an "expanded" or "deconstructed" representation in which all the element starting locations have been identified. The TOAST pointer mechanism supports this need by allowing a pass-by-reference Datum to point to either a standard varlena value (the on-disk representation) or a
TOAST pointer that points to an expanded representation somewhere in memory. The details of this expanded representation are up to the data type, though it must have a standard header and meet the other API requirements given in src/include/utils/expandeddatum.h. C-level functions working with the data type can choose to handle either representation. Functions that do not know about the expanded representation, but simply apply PG_DETOAST_DATUM to their inputs, will automatically receive the traditional varlena representation; so support for an expanded representation can be introduced incrementally, one function at a time.

TOAST pointers to expanded values are further broken down into read-write and read-only pointers. The pointed-to representation is the same either way, but a function that receives a read-write pointer is allowed to modify the referenced value in-place, whereas one that receives a read-only pointer must not; it must first create a copy if it wants to make a modified version of the value. This distinction and some associated conventions make it possible to avoid unnecessary copying of expanded values during query execution.

For all types of in-memory TOAST pointer, the TOAST management code ensures that no such pointer datum can accidentally get stored on disk. In-memory TOAST pointers are automatically expanded to normal in-line varlena values before storage — and then possibly converted to on-disk TOAST pointers, if the containing tuple would otherwise be too big.

### 73.3. Free Space Map

Each heap and index relation, except for hash indexes, has a Free Space Map (FSM) to keep track of available space in the relation. It's stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a \_fsm suffix. For example, if the filenode of a relation is 12345, the FSM is stored in a file called 12345\_fsm, in the same directory as the main relation file.

The Free Space Map is organized as a tree of FSM pages. The bottom level FSM pages store the free space available on each heap (or index) page, using one byte to represent each such page. The upper levels aggregate information from the lower levels.

Within each FSM page is a binary tree, stored in an array with one byte per node. Each leaf node represents a heap page, or a lower level FSM page. In each non-leaf node, the higher of its children's values is stored. The maximum value in the leaf nodes is therefore stored at the root.

See src/backend/storage/freespace/README for more details on how the FSM is structured, and how it's updated and searched. The pg_freespacemap module can be used to examine the information stored in free space maps.

### 73.4. Visibility Map

Each heap relation has a Visibility Map (VM) to keep track of which pages contain only tuples that are known to be visible to all active transactions; it also keeps track of which pages contain only frozen tuples. It's stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a \_vm suffix. For example, if the filenode of a relation is 12345, the VM is stored in a file called 12345\_vm, in the same directory as the main relation file. Note that indexes do not have VMs.

The visibility map stores two bits per heap page. The first bit, if set, indicates that the page is all-visible, or in other words that the page does not contain any tuples that need to be vacuumed. This information can also be used by index-only scans to answer queries using only the index tuple. The second bit, if set, means that all tuples on the page have been frozen. That means that even an anti-wraparound vacuum need not revisit the page.

The map is conservative in the sense that we make sure that whenever a bit is set, we know the condition is true, but if a bit is not set, it might or might not be true. Visibility map bits are only set by vacuum, but are cleared by any data-modifying operations on a page.
The pg_visibility module can be used to examine the information stored in the visibility map.

73.5. The Initialization Fork

Each unlogged table, and each index on an unlogged table, has an initialization fork. The initialization fork is an empty table or index of the appropriate type. When an unlogged table must be reset to empty due to a crash, the initialization fork is copied over the main fork, and any other forks are erased (they will be recreated automatically as needed).

73.6. Database Page Layout

This section provides an overview of the page format used within PostgreSQL tables and indexes. Sequences and TOAST tables are formatted just like a regular table.

In the following explanation, a byte is assumed to contain 8 bits. In addition, the term item refers to an individual data value that is stored on a page. In a table, an item is a row; in an index, an item is an index entry.

Every table and index is stored as an array of pages of a fixed size (usually 8 kB, although a different page size can be selected when compiling the server). In a table, all the pages are logically equivalent, so a particular item (row) can be stored in any page. In indexes, the first page is generally reserved as a metapage holding control information, and there can be different types of pages within the index, depending on the index access method.

Table 73.2 shows the overall layout of a page. There are five parts to each page.

**Table 73.2. Overall Page Layout**

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PageHeaderData</td>
<td>24 bytes long. Contains general information about the page, including free space pointers.</td>
</tr>
<tr>
<td>ItemIdData</td>
<td>Array of item identifiers pointing to the actual items. Each entry is an (offset,length) pair. 4 bytes per item.</td>
</tr>
<tr>
<td>Free space</td>
<td>The unallocated space. New item identifiers are allocated from the start of this area, new items from the end.</td>
</tr>
<tr>
<td>Items</td>
<td>The actual items themselves.</td>
</tr>
<tr>
<td>Special space</td>
<td>Index access method specific data. Different methods store different data. Empty in ordinary tables.</td>
</tr>
</tbody>
</table>

The first 24 bytes of each page consists of a page header (PageHeaderData). Its format is detailed in Table 73.3. The first field tracks the most recent WAL entry related to this page. The second field contains the page checksum if data checksums are enabled. Next is a 2-byte field containing flag bits. This is followed by three 2-byte integer fields (pd_lower, pd_upper, and pd_special). These contain byte offsets from the page start to the start of unallocated space, to the end of unallocated space, and to the start of the special space. The next 2 bytes of the page header, pdpagesize_version, store both the page size and a version indicator. Beginning with PostgreSQL 8.3 the version number is 4; PostgreSQL 8.1 and 8.2 used version number 3; PostgreSQL 8.0 used version number 2; PostgreSQL 7.3 and 7.4 used version number 1; prior releases used version number 0. (The basic page

---

1 Actually, use of this page format is not required for either table or index access methods. The heap table access method always uses this format. All the existing index methods also use the basic format, but the data kept on index metapages usually doesn't follow the item layout rules.
layout and header format has not changed in most of these versions, but the layout of heap row headers has.) The page size is basically only present as a cross-check; there is no support for having more than one page size in an installation. The last field is a hint that shows whether pruning the page is likely to be profitable: it tracks the oldest un-pruned XMAX on the page.

### Table 73.3. PageHeaderData Layout

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Length</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pd_lsn</td>
<td>PageXLogRecPtr</td>
<td>8 bytes</td>
<td>LSN: next byte after last byte of WAL record for last change to this page</td>
</tr>
<tr>
<td>pd_checksum</td>
<td>uint16</td>
<td>2 bytes</td>
<td>Page checksum</td>
</tr>
<tr>
<td>pd_flags</td>
<td>uint16</td>
<td>2 bytes</td>
<td>Flag bits</td>
</tr>
<tr>
<td>pd_lower</td>
<td>LocationIndex</td>
<td>2 bytes</td>
<td>Offset to start of free space</td>
</tr>
<tr>
<td>pd_upper</td>
<td>LocationIndex</td>
<td>2 bytes</td>
<td>Offset to end of free space</td>
</tr>
<tr>
<td>pd_special</td>
<td>LocationIndex</td>
<td>2 bytes</td>
<td>Offset to start of special space</td>
</tr>
<tr>
<td>pd_pagesize_version</td>
<td>uint16</td>
<td>2 bytes</td>
<td>Page size and layout version number information</td>
</tr>
<tr>
<td>pd_prune_xid</td>
<td>TransactionId</td>
<td>4 bytes</td>
<td>Oldest unpruned XMAX on page, or zero if none</td>
</tr>
</tbody>
</table>

All the details can be found in `src/include/storage/bufpage.h`.

Following the page header are item identifiers (ItemIdData), each requiring four bytes. An item identifier contains a byte-offset to the start of an item, its length in bytes, and a few attribute bits which affect its interpretation. New item identifiers are allocated as needed from the beginning of the unallocated space. The number of item identifiers present can be determined by looking at `pd_lower`, which is increased to allocate a new identifier. Because an item identifier is never moved until it is freed, its index can be used on a long-term basis to reference an item, even when the item itself is moved around on the page to compact free space. In fact, every pointer to an item (ItemPointer, also known as CTID) created by PostgreSQL consists of a page number and the index of an item identifier.

The items themselves are stored in space allocated backwards from the end of unallocated space. The exact structure varies depending on what the table is to contain. Tables and sequences both use a structure named HeapTupleHeaderData, described below.

The final section is the “special section” which can contain anything the access method wishes to store. For example, b-tree indexes store links to the page’s left and right siblings, as well as some other data relevant to the index structure. Ordinary tables do not use a special section at all (indicated by setting `pd_special` to equal the page size).

Figure 73.1 illustrates how these parts are laid out in a page.
73.6.1. Table Row Layout

All table rows are structured in the same way. There is a fixed-size header (occupying 23 bytes on most machines), followed by an optional null bitmap, an optional object ID field, and the user data. The header is detailed in Table 73.4. The actual user data (columns of the row) begins at the offset indicated by t_hoff, which must always be a multiple of the MAXALIGN distance for the platform. The null bitmap is only present if the HEAP_HASNULL bit is set in t_infomask. If it is present it begins just after the fixed header and occupies enough bytes to have one bit per data column (that is, the number of bits that equals the attribute count in t_infomask2). In this list of bits, a 1 bit indicates not-null, a 0 bit is a null. When the bitmap is not present, all columns are assumed not-null. The object ID is only present if the HEAP_HASOID_OLD bit is set in t_infomask. If present, it appears just before the t_hoff boundary. Any padding needed to make t_hoff a MAXALIGN multiple will appear between the null bitmap and the object ID. (This in turn ensures that the object ID is suitably aligned.)

Table 73.4. HeapTupleHeaderData Layout

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Length</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>t_xmin</td>
<td>TransactionId</td>
<td>4 bytes</td>
<td>insert XID stamp</td>
</tr>
<tr>
<td>t_xmax</td>
<td>TransactionId</td>
<td>4 bytes</td>
<td>delete XID stamp</td>
</tr>
<tr>
<td>t_cid</td>
<td>CommandId</td>
<td>4 bytes</td>
<td>insert and/or delete CID stamp (overlays with t_xvac)</td>
</tr>
<tr>
<td>t_xvac</td>
<td>TransactionId</td>
<td>4 bytes</td>
<td>XID for VACUUM operation moving a row version</td>
</tr>
<tr>
<td>t_ctid</td>
<td>ItemPointerData</td>
<td>6 bytes</td>
<td>current TID of this or newer row version</td>
</tr>
<tr>
<td>t_infomask2</td>
<td>uint16</td>
<td>2 bytes</td>
<td>number of attributes, plus various flag bits</td>
</tr>
<tr>
<td>t_infomask</td>
<td>uint16</td>
<td>2 bytes</td>
<td>various flag bits</td>
</tr>
<tr>
<td>t_hoff</td>
<td>uint8</td>
<td>1 byte</td>
<td>offset to user data</td>
</tr>
</tbody>
</table>

All the details can be found in src/include/access/htup_details.h.

Interpreting the actual data can only be done with information obtained from other tables, mostly pg_attribute. The key values needed to identify field locations are attlen and attalign. There is no way to directly get a particular attribute, except when there are only fixed width fields and no null values. All this trickery is wrapped up in the functions heap_getattr, fastgetattr and heap_getsysattr.

2528
To read the data you need to examine each attribute in turn. First check whether the field is NULL according to the null bitmap. If it is, go to the next. Then make sure you have the right alignment. If the field is a fixed width field, then all the bytes are simply placed. If it's a variable length field (attlen = -1) then it's a bit more complicated. All variable-length data types share the common header structure `struct varlena`, which includes the total length of the stored value and some flag bits. Depending on the flags, the data can be either inline or in a TOAST table; it might be compressed, too (see Section 73.2).

### 73.7. Heap-Only Tuples (HOT)

To allow for high concurrency, PostgreSQL uses multiversion concurrency control (MVCC) to store rows. However, MVCC has some downsides for update queries. Specifically, updates require new versions of rows to be added to tables. This can also require new index entries for each updated row, and removal of old versions of rows and their index entries can be expensive.

To help reduce the overhead of updates, PostgreSQL has an optimization called heap-only tuples (HOT). This optimization is possible when:

- The update does not modify any columns referenced by the table's indexes, not including summarizing indexes. The only summarizing index method in the core PostgreSQL distribution is BRIN.
- There is sufficient free space on the page containing the old row for the updated row.

In such cases, heap-only tuples provide two optimizations:

- New index entries are not needed to represent updated rows, however, summary indexes may still need to be updated.
- Old versions of updated rows can be completely removed during normal operation, including `SELECTs`, instead of requiring periodic vacuum operations. (This is possible because indexes do not reference their page item identifiers.)

You can increase the likelihood of sufficient page space for HOT updates by decreasing a table's `fillfactor`. If you don't, HOT updates will still happen because new rows will naturally migrate to new pages and existing pages with sufficient free space for new row versions. The system view `pg_stat_all_tables` allows monitoring of the occurrence of HOT and non-HOT updates.
Chapter 74. Transaction Processing

This chapter provides an overview of the internals of PostgreSQL’s transaction management system. The word transaction is often abbreviated as \textit{xact}.

74.1. Transactions and Identifiers

Transactions can be created explicitly using \texttt{BEGIN} or \texttt{START TRANSACTION} and ended using \texttt{COMMIT} or \texttt{ROLLBACK}. SQL statements outside of explicit transactions automatically use single-statement transactions.

Every transaction is identified by a unique \texttt{VirtualTransactionId} (also called \texttt{virtualXID} or \texttt{vxid}), which is comprised of a backend ID (or \texttt{backendID}) and a sequentially-assigned number local to each backend, known as \texttt{localXID}. For example, the virtual transaction ID 4/12532 has a \texttt{backendID} of 4 and a \texttt{localXID} of 12532.

Non-virtual \texttt{TransactionId}s (or \texttt{xid}), e.g., 278394, are assigned sequentially to transactions from a global counter used by all databases within the PostgreSQL cluster. This assignment happens when a transaction first writes to the database. This means lower-numbered xids started writing before higher-numbered xids. Note that the order in which transactions perform their first database write might be different from the order in which the transactions started, particularly if the transaction started with statements that only performed database reads.

The internal transaction ID type \texttt{xid} is 32 bits wide and wraps around every 4 billion transactions. A 32-bit epoch is incremented during each wraparound. There is also a 64-bit type \texttt{xid8} which includes this epoch and therefore does not wrap around during the life of an installation; it can be converted to \texttt{xid} by casting. The functions in Table 9.80 return \texttt{xid8} values. Xids are used as the basis for PostgreSQL’s MVCC concurrency mechanism and streaming replication.

When a top-level transaction with a (non-virtual) \texttt{xid} commits, it is marked as committed in the \texttt{pg_xact} directory. Additional information is recorded in the \texttt{pg_commit_ts} directory if \texttt{track_commit_timestamp} is enabled.

In addition to \texttt{vxid} and \texttt{xid}, prepared transactions are also assigned Global Transaction Identifiers (GID). GIDs are string literals up to 200 bytes long, which must be unique amongst other currently prepared transactions. The mapping of GID to \texttt{xid} is shown in \texttt{pg_prepared_xacts}.

74.2. Transactions and Locking

The transaction IDs of currently executing transactions are shown in \texttt{pg_locks} in columns \texttt{virtualxid} and \texttt{transactionid}. Read-only transactions will have \texttt{virtualxids} but NULL \texttt{transactionids}, while both columns will be set in read-write transactions.

Some lock types wait on \texttt{virtualxid}, while other types wait on \texttt{transactionid}. Row-level read and write locks are recorded directly in the locked rows and can be inspected using the pgrowlocks extension. Row-level read locks might also require the assignment of multixact IDs (\texttt{mxid}; see Section 25.1.5.1).

74.3. Subtransactions

Subtransactions are started inside transactions, allowing large transactions to be broken into smaller units. Subtransactions can commit or abort without affecting their parent transactions, allowing parent transactions to continue. This allows errors to be handled more easily, which is a common application development pattern. The word subtransaction is often abbreviated as \textit{subxact}.

Subtransactions can be started explicitly using the \texttt{SAVEPOINT} command, but can also be started in other ways, such as PL/pg\texttt{SQL}'s \texttt{EXCEPTION} clause. PL/\texttt{Python} and PL/Tcl also support explicit
subtransactions. Subtransactions can also be started from other subtransactions. The top-level trans-
action and its child subtransactions form a hierarchy or tree, which is why we refer to the main trans-
action as the top-level transaction.

If a subtransaction is assigned a non-virtual transaction ID, its transaction ID is referred to as a “sub-
xisd”. Read-only subtransactions are not assigned subxids, but once they attempt to write, they will be
assigned one. This also causes all of a subxid's parents, up to and including the top-level transaction,
to be assigned non-virtual transaction ids. We ensure that a parent xid is always lower than any of
its child subxids.

The immediate parent xid of each subxid is recorded in the *pg_subtrans* directory. No entry is made
for top-level xids since they do not have a parent, nor is an entry made for read-only subtransactions.

When a subtransaction commits, all of its committed child subtransactions with subxids will also be
considered subcommitted in that transaction. When a subtransaction aborts, all of its child subtrans-
actions will also be considered aborted.

When a top-level transaction with an xid commits, all of its subcommitted child subtransactions are
also persistently recorded as committed in the *pg_xact* subdirectory. If the top-level transaction
aborts, all its subtransactions are also aborted, even if they were subcommitted.

The more subtransactions each transaction keeps open (not rolled back or released), the greater the
transaction management overhead. Up to 64 open subxids are cached in shared memory for each
backend; after that point, the storage I/O overhead increases significantly due to additional lookups
of subxid entries in *pg_subtrans*.

### 74.4. Two-Phase Transactions

PostgreSQL supports a two-phase commit (2PC) protocol that allows multiple distributed systems to
work together in a transactional manner. The commands are `PREPARE TRANSACTION`, `COMMIT
PREPARED` and `ROLLBACK PREPARED`. Two-phase transactions are intended for use by external
transaction management systems. PostgreSQL follows the features and model proposed by the X/Open
XA standard, but does not implement some less often used aspects.

When the user executes `PREPARE TRANSACTION`, the only possible next commands are `COMMIT
PREPARED` or `ROLLBACK PREPARED`. In general, this prepared state is intended to be of very short
duration, but external availability issues might mean transactions stay in this state for an extended
interval. Short-lived prepared transactions are stored only in shared memory and WAL. Transactions
that span checkpoints are recorded in the *pg_twophase* directory. Transactions that are currently
prepared can be inspected using `pg_prepared_xacts`.

---

2531
Chapter 75. System Catalog
Declarations and Initial Contents

PostgreSQL uses many different system catalogs to keep track of the existence and properties of database objects, such as tables and functions. Physically there is no difference between a system catalog and a plain user table, but the backend C code knows the structure and properties of each catalog, and can manipulate it directly at a low level. Thus, for example, it is inadvisable to attempt to alter the structure of a catalog on-the-fly; that would break assumptions built into the C code about how rows of the catalog are laid out. But the structure of the catalogs can change between major versions.

The structures of the catalogs are declared in specially formatted C header files in the src/include/catalog/ directory of the source tree. For each catalog there is a header file named after the catalog (e.g., pg_class.h for pg_class), which defines the set of columns the catalog has, as well as some other basic properties such as its OID.

Many of the catalogs have initial data that must be loaded into them during the “bootstrap” phase of initdb, to bring the system up to a point where it is capable of executing SQL commands. (For example, pg_class.h must contain an entry for itself, as well as one for each other system catalog and index.) This initial data is kept in editable form in data files that are also stored in the src/include/catalog/ directory. For example, pg_proc.dat describes all the initial rows that must be inserted into the pg_proc catalog.

To create the catalog files and load this initial data into them, a backend running in bootstrap mode reads a BKI (Backend Interface) file containing commands and initial data. The postgres.bki file used in this mode is prepared from the aforementioned header and data files, while building a PostgreSQL distribution, by a Perl script named genbki.pl. Although it's specific to a particular PostgreSQL release, postgres.bki is platform-independent and is installed in the share subdirectory of the installation tree.

genbki.pl also produces a derived header file for each catalog, for example pg_class_d.h for the pg_class catalog. This file contains automatically-generated macro definitions, and may contain other macros, enum declarations, and so on that can be useful for client C code that reads a particular catalog.

Most PostgreSQL developers don't need to be directly concerned with the BKI file, but almost any nontrivial feature addition in the backend will require modifying the catalog header files and/or initial data files. The rest of this chapter gives some information about that, and for completeness describes the BKI file format.

75.1. System Catalog Declaration Declaration Rules

The key part of a catalog header file is a C structure definition describing the layout of each row of the catalog. This begins with a CATALOG macro, which so far as the C compiler is concerned is just shorthand for typedef struct FormData_catalogname. Each field in the struct gives rise to a catalog column. Fields can be annotated using the BKI property macros described in genbki.h, for example to define a default value for a field or mark it as nullable or not nullable. The CATALOG line can also be annotated, with some other BKI property macros described in genbki.h, to define other properties of the catalog as a whole, such as whether it is a shared relation.

The system catalog cache code (and most catalog-munging code in general) assumes that the fixed-length portions of all system catalog tuples are in fact present, because it maps this C struct declaration onto them. Thus, all variable-length fields and nullable fields must be placed at the end, and they cannot be accessed as struct fields. For example, if you tried to set pg_type.typrelid to be NULL, it would fail when some piece of code tried to reference typetup->typrelid (or worse, typetup->typelem, because that follows typrelid). This would result in random errors or even segmentation violations.
As a partial guard against this type of error, variable-length or nullable fields should not be made directly visible to the C compiler. This is accomplished by wrapping them in 
#ifdef CATALOG_VARLEN
...
#endif
(where CATALOG_VARLEN is a symbol that is never defined). This prevents C code from carelessly trying to access fields that might not be there or might be at some other offset. As an independent guard against creating incorrect rows, we require all columns that should be non-nullable to be marked so in pg_attribute. The bootstrap code will automatically mark catalog columns as NOT NULL if they are fixed-width and are not preceded by any nullable or variable-width column. Where this rule is inadequate, you can force correct marking by using BKI_FORCE_NOT_NULL and BKI_FORCE_NULL annotations as needed.

Frontend code should not include any pg_xxx.h catalog header file, as these files may contain C code that won't compile outside the backend. (Typically, that happens because these files also contain declarations for functions in src/backend/catalog/files.) Instead, frontend code may include the corresponding generated pg_xxx_d.h header, which will contain OID defines and any other data that might be of use on the client side. If you want macros or other code in a catalog header to be visible to frontend code, write 
#ifdef EXPOSE_TO_CLIENT_CODE
...
#endif
around that section to instruct genbki.pl to copy that section to the pg_xxx_d.h header.

A few of the catalogs are so fundamental that they can't even be created by the BKI create command that's used for most catalogs, because that command needs to write information into these catalogs to describe the new catalog. These are called bootstrap catalogs, and defining one takes a lot of extra work: you have to manually prepare appropriate entries for them in the pre-loaded contents of pg_class and pg_type, and those entries will need to be updated for subsequent changes to the catalog's structure. (Bootstrap catalogs also need pre-loaded entries in pg_attribute, but fortunately genbki.pl handles that chore nowadays.) Avoid making new catalogs be bootstrap catalogs if at all possible.

75.2. System Catalog Initial Data

Each catalog that has any manually-created initial data (some do not) has a corresponding .dat file that contains its initial data in an editable format.

75.2.1. Data File Format

Each .dat file contains Perl data structure literals that are simply eval'd to produce an in-memory data structure consisting of an array of hash references, one per catalog row. A slightly modified excerpt from pg_database.dat will demonstrate the key features:

```
[
  # A comment could appear here.
  { oid => '1', oid_symbol => 'Template1DbOid',
    descr => 'database\'s default template',
    dataloc => 'default1', encoding => 'ENCODING',
    datatemplate => 't', datallowconn => 't', datconnlimit => '-1',
    datfrozenxid => '0', datminmmid => '1',
    datatablespace => 'pg_default',
    datcollate => 'LC_COLLATE',
    datctype => 'LC_CTYPE',
    daticulocale => 'ICU_LOCALE', datacl => '_null_' },
]
```

Points to note:

- The overall file layout is: open square bracket, one or more sets of curly braces each of which represents a catalog row, close square bracket. Write a comma after each closing curly brace.
Within each catalog row, write comma-separated key => value pairs. The allowed keys are the names of the catalog's columns, plus the metadata keys oid, oid_symbol, array_type_oid, and descr. (The use of oid and oid_symbol is described in Section 75.2.2 below, while array_type_oid is described in Section 75.2.4. descr supplies a description string for the object, which will be inserted into pg_description or pg_shdescription as appropriate.) While the metadata keys are optional, the catalog's defined columns must all be provided, except when the catalog's .h file specifies a default value for the column. (In the example above, the datdba field has been omitted because pg_database.h supplies a suitable default value for it.)

All values must be single-quoted. Escape single quotes used within a value with a backslash. Backslashes meant as data can, but need not, be doubled; this follows Perl's rules for simple quoted literals. Note that backslashes appearing as data will be treated as escapes by the bootstrap scanner, according to the same rules as for escape string constants (see Section 4.1.2.2); for example \t converts to a tab character. If you actually want a backslash in the final value, you will need to write four of them: Perl strips two, leaving " for the bootstrap scanner to see.

Null values are represented by _null_. (Note that there is no way to create a value that is just that string.)

Comments are preceded by #, and must be on their own lines.

Field values that are OIDs of other catalog entries should be represented by symbolic names rather than actual numeric OIDs. (In the example above, datatablespace contains such a reference.) This is described in Section 75.2.3 below.

Since hashes are unordered data structures, field order and line layout aren't semantically significant. However, to maintain a consistent appearance, we set a few rules that are applied by the formatting script reformat_dat_file.pl:

Within each pair of curly braces, the metadata fields oid, oid_symbol, array_type_oid, and descr (if present) come first, in that order, then the catalog's own fields appear in their defined order.

Newlines are inserted between fields as needed to limit line length to 80 characters, if possible. A newline is also inserted between the metadata fields and the regular fields.

If the catalog's .h file specifies a default value for a column, and a data entry has that same value, reformat_dat_file.pl will omit it from the data file. This keeps the data representation compact.

reformat_dat_file.pl preserves blank lines and comment lines as-is. It's recommended to run reformat_dat_file.pl before submitting catalog data patches. For convenience, you can simply change to src/include/catalog/ and run make reformat-dat-files.

If you want to add a new method of making the data representation smaller, you must implement it in reformat_dat_file.pl and also teach Catalog::ParseData() how to expand the data back into the full representation.

### 75.2.2. OID Assignment

A catalog row appearing in the initial data can be given a manually-assigned OID by writing an oid => nnnn metadata field. Furthermore, if an OID is assigned, a C macro for that OID can be created by writing an oid_symbol => name metadata field.

Pre-loaded catalog rows must have preassigned OIDs if there are OID references to them in other pre-loaded rows. A preassigned OID is also needed if the row's OID must be referenced from C code. If neither case applies, the oid metadata field can be omitted, in which case the bootstrap code assigns an OID automatically. In practice we usually preassign OIDs for all or none of the pre-loaded rows in a given catalog, even if only some of them are actually cross-referenced.
Writing the actual numeric value of any OID in C code is considered very bad form; always use a macro instead. Direct references to `pg_proc` OIDs are common enough that there's a special mechanism to create the necessary macros automatically; see `src/backend/utils/Gen_grtabl.pl`. Similarly — but, for historical reasons, not done the same way — there's an automatic method for creating macros for `pg_type` OIDs. `oid_symbol` entries are therefore not necessary in those two catalogs. Likewise, macros for the `pg_class` OIDs of system catalogs and indexes are set up automatically. For all other system catalogs, you have to manually specify any macros you need via `oid_symbol` entries.

To find an available OID for a new pre-loaded row, run the script `src/include/catalog/unused_oids`. It prints inclusive ranges of unused OIDs (e.g., the output line `45-900` means OIDs 45 through 900 have not been allocated yet). Currently, OIDs 1–9999 are reserved for manual assignment; the `unused_oids` script simply looks through the catalog headers and `.dat` files to see which ones do not appear. You can also use the `duplicate_oids` script to check for mistakes. (`genbki.pl` will assign OIDs for any rows that didn't get one hand-assigned to them, and it will also detect duplicate OIDs at compile time.)

When choosing OIDs for a patch that is not expected to be committed immediately, best practice is to use a group of more-or-less consecutive OIDs starting with some random choice in the range 8000—9999. This minimizes the risk of OID collisions with other patches being developed concurrently. To keep the 8000—9999 range free for development purposes, after a patch has been committed to the master git repository its OIDs should be renumbered into available space below that range. Typically, this will be done near the end of each development cycle, moving all OIDs consumed by patches committed in that cycle at the same time. The script `renumber_oids.pl` can be used for this purpose. If an uncommitted patch is found to have OID conflicts with some recently-committed patch, `renumber_oids.pl` may also be useful for recovering from that situation.

Because of this convention of possibly renumbering OIDs assigned by patches, the OIDs assigned by a patch should not be considered stable until the patch has been included in an official release. We do not change manually-assigned object OIDs once released, however, as that would create assorted compatibility problems.

If `genbki.pl` needs to assign an OID to a catalog entry that does not have a manually-assigned OID, it will use a value in the range 10000—11999. The server's OID counter is set to 10000 at the start of a bootstrap run, so that any objects created on-the-fly during bootstrap processing also receive OIDs in this range. (The usual OID assignment mechanism takes care of preventing any conflicts.)

Objects with OIDs below `FirstUnpinnedObjectId` (12000) are considered “pinned”, preventing them from being deleted. (There are a small number of exceptions, which are hard-wired into `IsPinnedObject()`. `initdb` forces the OID counter up to `FirstUnpinnedObjectId` as soon as it's ready to create unpinned objects. Thus objects created during the later phases of `initdb`, such as objects created while running the `information_schema.sql` script, will not be pinned, while all objects known to `genbki.pl` will be.

OIDs assigned during normal database operation are constrained to be 16384 or higher. This ensures that the range 10000—16383 is free for OIDs assigned automatically by `genbki.pl` or during `initdb`. These automatically-assigned OIDs are not considered stable, and may change from one installation to another.

### 75.2.3. OID Reference Lookup

In principle, cross-references from one initial catalog row to another could be written just by writing the preassigned OID of the referenced row in the referencing field. However, that is against project policy, because it is error-prone, hard to read, and subject to breakage if a newly-assigned OID is renumbered. Therefore `genbki.pl` provides mechanisms to write symbolic references instead. The rules are as follows:

- Use of symbolic references is enabled in a particular catalog column by attaching `BKI_LOOKUP(lookuprule)` to the column's definition, where `lookuprule` is the name of
the referenced catalog, e.g., `pg_proc`. `BKI_LOOKUP` can be attached to columns of type `Oid`, `regproc`, `oidvector`, or `Oid[]`; in the latter two cases it implies performing a lookup on each element of the array.

- It's also permissible to attach `BKI_LOOKUP` to integer columns to reference character set encodings, which are not currently represented as catalog OIDs, but have a set of values known to `genbki.pl`.

- In some catalog columns, it's allowed for entries to be zero instead of a valid reference. If this is allowed, write `BKI_LOOKUP_OPT` instead of `BKI_LOOKUP`. Then you can write 0 for an entry. (If the column is declared `regproc`, you can optionally write - instead of 0.) Except for this special case, all entries in a `BKI_LOOKUP` column must be symbolic references. `genbki.pl` will warn about unrecognized names.

- Most kinds of catalog objects are simply referenced by their names. Note that type names must exactly match the referenced `pg_type` entry's `typname`; you do not get to use any aliases such as `integer` for `int4`.

- A function can be represented by its `proname`, if that is unique among the `pg_proc.dat` entries (this works like `regproc` input). Otherwise, write it as `proname(argtypename,argtypename,...)`, like `regprocedure`. The argument type names must be spelled exactly as they are in the `pg_proc.dat` entry's `proargtypes` field. Do not insert any spaces.

- Operators are represented by `opname(lefttype,righttype)`, writing the type names exactly as they appear in the `pg_operator.dat` entry's `oprleft` and `oprright` fields. (Write 0 for the omitted operand of a unary operator.)

- The names of opclasses and opfamilies are only unique within an access method, so they are represented by `access_method_name/object_name`.

- In none of these cases is there any provision for schema-qualification; all objects created during bootstrap are expected to be in the `pg_catalog` schema.

`genbki.pl` resolves all symbolic references while it runs, and puts simple numeric OIDs into the emitted BKI file. There is therefore no need for the bootstrap backend to deal with symbolic references.

It's desirable to mark OID reference columns with `BKI_LOOKUP` or `BKI_LOOKUP_OPT` even if the catalog has no initial data that requires lookup. This allows `genbki.pl` to record the foreign key relationships that exist in the system catalogs. That information is used in the regression tests to check for incorrect entries. See also the macros `DECLARE_FOREIGN_KEY, DECLARE_FOREIGN_KEY_OPT, DECLARE_ARRAY_FOREIGN_KEY, and DECLARE_ARRAY_FOREIGN_KEY_OPT`, which are used to declare foreign key relationships that are too complex for `BKI_LOOKUP` (typically, multi-column foreign keys).

### 75.2.4. Automatic Creation of Array Types

Most scalar data types should have a corresponding array type (that is, a standard varlena array type whose element type is the scalar type, and which is referenced by the `typarray` field of the scalar type's `pg_type` entry). `genbki.pl` is able to generate the `pg_type` entry for the array type automatically in most cases.

To use this facility, just write an `array_type_oid => nnnn` metadata field in the scalar type's `pg_type` entry, specifying the OID to use for the array type. You may then omit the `typarray` field, since it will be filled automatically with that OID.

The generated array type's name is the scalar type's name with an underscore prepended. The array entry's other fields are filled from `BKI_ARRAY_DEFAULT(value)` annotations in `pg_type.h`, or if there isn't one, copied from the scalar type. (There's also a special case for `typalign`.) Then the `typelem` and `typarray` fields of the two entries are set to cross-reference each other.
75.2.5. Recipes for Editing Data Files

Here are some suggestions about the easiest ways to perform common tasks when updating catalog data files.

Add a new column with a default to a catalog: Add the column to the header file with a `BKI_DEFAULT(value)` annotation. The data file need only be adjusted by adding the field in existing rows where a non-default value is needed.

Add a default value to an existing column that doesn’t have one: Add a `BKI_DEFAULT` annotation to the header file, then run `make reformat-dat-files` to remove now-redundant field entries.

Remove a column, whether it has a default or not: Remove the column from the header, then run `make reformat-dat-files` to remove now-useless field entries.

Change or remove an existing default value: You cannot simply change the header file, since that will cause the current data to be interpreted incorrectly. First run `make expand-dat-files` to rewrite the data files with all default values inserted explicitly, then change or remove the `BKI_DEFAULT` annotation, then run `make reformat-dat-files` to remove superfluous fields again.

Ad-hoc bulk editing: `reformat_dat_file.pl` can be adapted to perform many kinds of bulk changes. Look for its block comments showing where one-off code can be inserted. In the following example, we are going to consolidate two Boolean fields in `pg_proc` into a char field:

1. Add the new column, with a default, to `pg_proc.h`:

   ```
   +    /* see PROKIND_ categories below */
   +    char        prokind BKI_DEFAULT(f);
   ```

2. Create a new script based on `reformat_dat_file.pl` to insert appropriate values on-the-fly:

   ```
   # At this point we have the full row in memory as a hash
   # and can do any operations we want. As written, it
   # removes default values, but this script can be
   # adapted to
   # do one-off bulk-editing.
   # One-off change to migrate to prokind
   # Default has already been filled in by now, so
   # change to other
   # values as appropriate
   +    if ($values{proisagg} eq 't')
   +       $values{prokind} = 'a';
   +    }
   +    elsif ($values{proiswindow} eq 't')
   +       $values{prokind} = 'w';
   +    }
   ```

3. Run the new script:

   ```
   $ cd src/include/catalog
   $ perl rewrite_dat_with_prokind.pl pg_proc.dat
   ```
At this point `pg_proc.dat` has all three columns, `prokind`, `proisagg`, and `proiswindow`, though they will appear only in rows where they have non-default values.

4. Remove the old columns from `pg_proc.h`:

```c
-    /* is it an aggregate? */
-    bool    proisagg BKI_DEFAULT(f);
-    /* is it a window function? */
-    bool    proiswindow BKI_DEFAULT(f);
```

5. Finally, run `make reformat-dat-files` to remove the useless old entries from `pg_proc.dat`.

For further examples of scripts used for bulk editing, see `convert_oid2name.pl` and `remove_pg_type_oid_symbols.pl` attached to this message: https://www.postgresql.org/message-id/CAJVSVGVX8gXnPm+Xa=DxR7kFyprcQ1tNcCT5D03ShfnM6jehA@mail.gmail.com

### 75.3. BKI File Format

This section describes how the PostgreSQL backend interprets BKI files. This description will be easier to understand if the `postgres.bki` file is at hand as an example.

BKI input consists of a sequence of commands. Commands are made up of a number of tokens, depending on the syntax of the command. Tokens are usually separated by whitespace, but need not be if there is no ambiguity. There is no special command separator; the next token that syntactically cannot belong to the preceding command starts a new one. (Usually you would put a new command on a new line, for clarity.) Tokens can be certain key words, special characters (parentheses, commas, etc.), identifiers, numbers, or single-quoted strings. Everything is case sensitive.

Lines starting with `#` are ignored.

### 75.4. BKI Commands

```c
create tablename tableoid [bootstrap] [shared_relation] [rowtype_oid oid]
(name1 = type1 [FORCE NOT NULL | FORCE NULL] [, name2 = type2 [FORCE NOT NULL | FORCE NULL] [, ...]])
```

Create a table named `tablename`, and having the OID `tableoid`, with the columns given in parentheses.

The following column types are supported directly by `bootstrap.c`: `bool`, `bytea`, `char` (1 byte), `name`, `int2`, `int4`, `regproc`, `regclass`, `regtype`, `text`, `oid`, `tid`, `xid`, `cid`, `_int4` (array), `_text` (array), `_oid` (array), `_char` (array), `_aclitem` (array). Although it is possible to create tables containing columns of other types, this cannot be done until after `pg_type` has been created and filled with appropriate entries. (That effectively means that only these column types can be used in bootstrap catalogs, but non-bootstrap catalogs can contain any built-in type.)

When `bootstrap` is specified, the table will only be created on disk; nothing is entered into `pg_class`, `pg_attribute`, etc., for it. Thus the table will not be accessible by ordinary SQL operations until such entries are made the hard way (with `insert` commands). This option is used for creating `pg_class` etc. themselves.

The table is created as shared if `shared_relation` is specified. The table's row type OID (`pg_type OID`) can optionally be specified via the `rowtype_oid` clause; if not specified, an
OID is automatically generated for it. (The rowtype_oid clause is useless if bootstrap is specified, but it can be provided anyway for documentation.)

open tablename

Open the table named tablename for insertion of data. Any currently open table is closed.

close tablename

Close the open table. The name of the table must be given as a cross-check.

insert ([oid_value] value1 value2 ...)

Insert a new row into the open table using value1, value2, etc., for its column values.

NULL values can be specified using the special key word _null_. Values that do not look like identifiers or digit strings must be single-quoted. (To include a single quote in a value, write it twice. Escape-string-style backslash escapes are allowed in the string, too.)

declare [unique] index indexname indexoid on tablename using amname (opclass1 name1 [, ...])

Create an index named indexname, having OID indexoid, on the table named tablename, using the amname access method. The fields to index are called name1, name2 etc., and the operator classes to use are opclass1, opclass2 etc., respectively. The index file is created and appropriate catalog entries are made for it, but the index contents are not initialized by this command.

declare toast toasttableoid toastindexoid on tablename

Create a TOAST table for the table named tablename. The TOAST table is assigned OID toasttableoid and its index is assigned OID toastindexoid. As with declare index, filling of the index is postponed.

build indices

Fill in the indices that have previously been declared.

75.5. Structure of the Bootstrap BKI File

The open command cannot be used until the tables it uses exist and have entries for the table that is to be opened. (These minimum tables are pg_class, pg_attribute, pg_proc, and pg_type.) To allow those tables themselves to be filled, create with the bootstrap option implicitly opens the created table for data insertion.

Also, the declare index and declare toast commands cannot be used until the system catalogs they need have been created and filled in.

Thus, the structure of the postgres.bki file has to be:

1. create bootstrap one of the critical tables
2. insert data describing at least the critical tables
3. close
4. Repeat for the other critical tables.
5. create (without bootstrap) a noncritical table
6. open
7. insert desired data
8. close
9. Repeat for the other noncritical tables.
10. Define indexes and toast tables.
11. build indices

There are doubtless other, undocumented ordering dependencies.

### 75.6. BKI Example

The following sequence of commands will create the table `test_table` with OID 420, having three columns `oid`, `cola` and `colb` of type `oid`, `int4` and `text`, respectively, and insert two rows into the table:

```sql
create test_table 420 (oid = oid, cola = int4, colb = text)
open test_table
insert ( 421 1 'value 1' )
insert ( 422 2 _null_ )
close test_table
```
Chapter 76. How the Planner Uses Statistics

This chapter builds on the material covered in Section 14.1 and Section 14.2 to show some additional details about how the planner uses the system statistics to estimate the number of rows each part of a query might return. This is a significant part of the planning process, providing much of the raw material for cost calculation.

The intent of this chapter is not to document the code in detail, but to present an overview of how it works. This will perhaps ease the learning curve for someone who subsequently wishes to read the code.

76.1. Row Estimation Examples

The examples shown below use tables in the PostgreSQL regression test database. The outputs shown are taken from version 8.3. The behavior of earlier (or later) versions might vary. Note also that since ANALYZE uses random sampling while producing statistics, the results will change slightly after any new ANALYZE.

Let's start with a very simple query:

```
EXPLAIN SELECT * FROM tenk1;
```

```
QUERY PLAN
-------------------------------------------------------------
Seq Scan on tenk1  (cost=0.00..458.00 rows=10000 width=244)
```

How the planner determines the cardinality of `tenk1` is covered in Section 14.2, but is repeated here for completeness. The number of pages and rows is looked up in `pg_class`:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 'tenk1';
```

```
relpages | reltuples
----------+-----------
358 | 10000
```

These numbers are current as of the last VACUUM or ANALYZE on the table. The planner then fetches the actual current number of pages in the table (this is a cheap operation, not requiring a table scan). If that is different from `retpages` then `reltuples` is scaled accordingly to arrive at a current number-of-rows estimate. In the example above, the value of `retpages` is up-to-date so the rows estimate is the same as `reltuples`.

Let's move on to an example with a range condition in its WHERE clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000;
```

```
QUERY PLAN
-------------------------------------------------------------------
-------------
Bitmap Heap Scan on tenk1  (cost=24.06..394.64 rows=1007 width=244)
  Recheck Cond: (unique1 < 1000)
  ->  Bitmap Index Scan on tenk1_unique1  (cost=0.00..23.80 rows=1007 width=0)
```

2541
How the Planner Uses Statistics

Index Cond: (unique1 < 1000)

The planner examines the WHERE clause condition and looks up the selectivity function for the operator < in pg_operator. This is held in the column oprrest, and the entry in this case is scalarltsel. The scalarltsel function retrieves the histogram for unique1 from pg_statistic. For manual queries it is more convenient to look in the simpler pg_stats view:

```
SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='unique1';
```

```
histogram_bounds
------------------------------------------------------
{0,993,1997,3050,4040,5036,5957,7057,8029,9016,9995}
```

Next the fraction of the histogram occupied by "< 1000" is worked out. This is the selectivity. The histogram divides the range into equal frequency buckets, so all we have to do is locate the bucket that our value is in and count part of it and all of the ones before. The value 1000 is clearly in the second bucket (993–1997). Assuming a linear distribution of values inside each bucket, we can calculate the selectivity as:

\[
\text{selectivity} = \frac{1 + (1000 - \text{bucket}[2].\text{min})/(\text{bucket}[2].\text{max} - \text{bucket}[2].\text{min})}{\text{num_buckets}}
\]

\[
= \frac{1 + (1000 - 993)/(1997 - 993)}{10}
\]

\[
= 0.100697
\]

that is, one whole bucket plus a linear fraction of the second, divided by the number of buckets. The estimated number of rows can now be calculated as the product of the selectivity and the cardinality of tenk1:

\[
\text{rows} = \text{rel_cardinality} \times \text{selectivity}
\]

\[
= 10000 \times 0.100697
\]

\[
= 1007 \text{ (rounding off)}
\]

Next let's consider an example with an equality condition in its WHERE clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'CRAAAA';
```

```
QUERY PLAN
----------------------------------------------------------
Seq Scan on tenk1  (cost=0.00..483.00 rows=30 width=244)
  Filter: (stringu1 = 'CRAAAA'::name)
```

Again the planner examines the WHERE clause condition and looks up the selectivity function for =, which is eqsel. For equality estimation the histogram is not useful; instead the list of most common values (MCVs) is used to determine the selectivity. Let's have a look at the MCVs, with some additional columns that will be useful later:

```
SELECT null_frac, n_distinct, most_common_vals, most_common_freqs
FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';
```

```
null_frac     | 0
n_distinct    | 676
most_common_vals | {EJAAAA, BBAAAA, CRAAAA, FAAAAA, FEAAAA, GAAAAA, JOAAAA, MCAAAA, NAAAAA, WAAAAA}
```
How the Planner Uses Statistics

most_common_freqs | {0.00333333, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003}

Since CRAAAA appears in the list of MCVs, the selectivity is merely the corresponding entry in the list of most common frequencies (MCFs):

selectivity = mcf[3]  
            = 0.003

As before, the estimated number of rows is just the product of this with the cardinality of tenk1:

rows = 10000 * 0.003  
      = 30

Now consider the same query, but with a constant that is not in the MCV list:

EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'xxx';

QUERY PLAN
-------------------------------------------
Seq Scan on tenk1  (cost=0.00..483.00 rows=15 width=244)  
Filter: (stringu1 = 'xxx'::name)

This is quite a different problem: how to estimate the selectivity when the value is not in the MCV list. The approach is to use the fact that the value is not in the list, combined with the knowledge of the frequencies for all of the MCVs:

selectivity = (1 - sum(mcv_freqs))/(num_distinct - num_mcv)  
            = (1 - (0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003))/(676 - 10)  
            = 0.0014559

That is, add up all the frequencies for the MCVs and subtract them from one, then divide by the number of other distinct values. This amounts to assuming that the fraction of the column that is not any of the MCVs is evenly distributed among all the other distinct values. Notice that there are no null values so we don’t have to worry about those (otherwise we’d subtract the null fraction from the numerator as well). The estimated number of rows is then calculated as usual:

rows = 10000 * 0.0014559  
      = 15  (rounding off)

The previous example with unique1 < 1000 was an oversimplification of what scalarltsel really does; now that we have seen an example of the use of MCVs, we can fill in some more detail. The example was correct as far as it went, because since unique1 is a unique column it has no MCVs (obviously, no value is any more common than any other value). For a non-unique column, there will normally be both a histogram and an MCV list, and the histogram does not include the portion of the column population represented by the MCVs. We do things this way because it allows more precise estimation. In this situation scalarltsel directly applies the condition (e.g., “< 1000”) to each value of the MCV list, and adds up the frequencies of the MCVs for which the condition is true. This gives an exact estimate of the selectivity within the portion of the table that is MCVs. The histogram is then used in the same way as above to estimate the selectivity in the portion of the table that is not MCVs, and then the two numbers are combined to estimate the overall selectivity. For example, consider
How the Planner Uses Statistics

EXPLAIN SELECT * FROM tenk1 WHERE stringu1 < 'IAAAAA';

QUERY PLAN
------------------------------------------------------------
Seq Scan on tenk1  (cost=0.00..483.00 rows=3077 width=244)
  Filter: (stringu1 < 'IAAAAA':::name)
We already saw the MCV information for stringu1, and here is its histogram:

SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';

histogram_bounds
-------------------------------------------------------------------
-------------
(AAAAAA, CQAAAA, FRAAAA, IBAAAA, KRAAAA, NFAAAA, PSAAAA, SGAAAA, VAAAAA, XLAAAA, ZZAAAA)

Checking the MCV list, we find that the condition stringu1 < 'IAAAAA' is satisfied by the first six entries and not the last four, so the selectivity within the MCV part of the population is

selectivity = sum(relevant mvfs)
= 0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003
= 0.01833333

Summing all the MCFs also tells us that the total fraction of the population represented by MCVs is 0.03033333, and therefore the fraction represented by the histogram is 0.96966667 (again, there are no nulls, else we’d have to exclude them here). We can see that the value IAAAAA falls nearly at the end of the third histogram bucket. Using some rather cheesy assumptions about the frequency of different characters, the planner arrives at the estimate 0.298387 for the portion of the histogram population that is less than IAAAAA. We then combine the estimates for the MCV and non-MCV populations:

selectivity = mcv_selectivity + histogram_selectivity * histogram_fraction
= 0.01833333 + 0.298387 * 0.96966667
= 0.307669

rows = 10000 * 0.307669
= 3077  (rounding off)

In this particular example, the correction from the MCV list is fairly small, because the column distribution is actually quite flat (the statistics showing these particular values as being more common than others are mostly due to sampling error). In a more typical case where some values are significantly more common than others, this complicated process gives a useful improvement in accuracy because the selectivity for the most common values is found exactly.

Now let’s consider a case with more than one condition in the WHERE clause:

EXPLAIN SELECT * FROM tenk1 WHERE uniquel < 1000 AND stringu1 = 'xxx';

QUERY PLAN
---------------------------
---------------------------
Bitmap Heap Scan on tenk1  (cost=23.80..396.91 rows=1 width=244)
How the Planner Uses Statistics

Recheck Cond: (unique1 < 1000)
Filter: (stringu1 = 'xxx'::name)
-> Bitmap Index Scan on tenk1_unique1 (cost=0.00..23.80 rows=1007 width=0)
    Index Cond: (unique1 < 1000)

The planner assumes that the two conditions are independent, so that the individual selectivities of the clauses can be multiplied together:

\[
selectivity = selectivity(unique1 < 1000) \times selectivity(stringu1 = 'xxx')
= 0.100697 \times 0.0014559
= 0.0001466
\]

rows = 10000 \times 0.0001466 = 1 \text{ (rounding off)}

Notice that the number of rows estimated to be returned from the bitmap index scan reflects only the condition used with the index; this is important since it affects the cost estimate for the subsequent heap fetches.

Finally we will examine a query that involves a join:

EXPLAIN SELECT * FROM tenk1 t1, tenk2 t2
WHERE t1.unique1 < 50 AND t1.unique2 = t2.unique2;

QUERY PLAN

-------------------------------------------------------------------
-------------------
Nested Loop  (cost=4.64..456.23 rows=50 width=488)
  -> Bitmap Heap Scan on tenk1 t1  (cost=4.64..142.17 rows=50 width=244)
    Recheck Cond: (unique1 < 50)
    -> Bitmap Index Scan on tenk1_unique1  (cost=0.00..4.63 rows=50 width=0)
      Index Cond: (unique1 < 50)
  -> Index Scan using tenk2_unique2 on tenk2 t2  (cost=0.00..6.27 rows=1 width=244)
    Index Cond: (unique2 = t1.unique2)

The restriction on tenk1.unique1 < 50, is evaluated before the nested-loop join. This is handled analogously to the previous range example. This time the value 50 falls into the first bucket of the unique1 histogram:

\[
selectivity = (0 + (50 - \text{bucket[1].min})/(\text{bucket[1].max} - \text{bucket[1].min}))/\text{num_buckets}
= (0 + (50 - 0)/(993 - 0))/10
= 0.005035
\]

rows = 10000 \times 0.005035 = 50 \text{ (rounding off)}

The restriction for the join is t2.unique2 = t1.unique2. The operator is just our familiar =, however the selectivity function is obtained from the oprjoin column of pg_operator, and is eqjoinsel. eqjoinsel looks up the statistical information for both tenk2 and tenk1:
SELECT tablename, null_frac, n_distinct, most_common_vals FROM pg_stats
WHERE tablename IN ('tenk1', 'tenk2') AND attname='unique2';

<table>
<thead>
<tr>
<th>tablename</th>
<th>null_frac</th>
<th>n_distinct</th>
<th>most_common_vals</th>
</tr>
</thead>
<tbody>
<tr>
<td>tenk1</td>
<td>0</td>
<td>-1</td>
<td></td>
</tr>
<tr>
<td>tenk2</td>
<td>0</td>
<td>-1</td>
<td></td>
</tr>
</tbody>
</table>

In this case there is no MCV information for unique2 because all the values appear to be unique, so we use an algorithm that relies only on the number of distinct values for both relations together with their null fractions:

\[
\text{selectivity} = (1 - \text{null_frac}_1) \times (1 - \text{null_frac}_2) \times \min(1/\text{num_distinct}_1, 1/\text{num_distinct}_2)
\]
\[
\text{selectivity} = (1 - 0) \times (1 - 0) / \max(10000, 10000)
\]
\[
\text{selectivity} = 0.0001
\]

This is, subtract the null fraction from one for each of the relations, and divide by the maximum of the numbers of distinct values. The number of rows that the join is likely to emit is calculated as the cardinality of the Cartesian product of the two inputs, multiplied by the selectivity:

\[
\text{rows} = (\text{outer_cardinality} \times \text{inner_cardinality}) \times \text{selectivity}
\]
\[
\text{rows} = (50 \times 10000) \times 0.0001
\]
\[
\text{rows} = 50
\]

Had there been MCV lists for the two columns, eqjoinsel would have used direct comparison of the MCV lists to determine the join selectivity within the part of the column populations represented by the MCVs. The estimate for the remainder of the populations follows the same approach shown here.

Notice that we showed inner_cardinality as 10000, that is, the unmodified size of tenk2. It might appear from inspection of the EXPLAIN output that the estimate of join rows comes from 50 * 1, that is, the number of outer rows times the estimated number of rows obtained by each inner index scan on tenk2. But this is not the case: the join relation size is estimated before any particular join plan has been considered. If everything is working well then the two ways of estimating the join size will produce about the same answer, but due to round-off error and other factors they sometimes diverge significantly.

For those interested in further details, estimation of the size of a table (before any WHERE clauses) is done in src/backend/optimizer/util/plancat.c. The generic logic for clause selectivities is in src/backend/optimizer/path/clausesel.c. The operator-specific selectivity functions are mostly found in src/backend/utils/adt/selfuncs.c.

### 76.2. Multivariate Statistics Examples

#### 76.2.1. Functional Dependencies

Multivariate correlation can be demonstrated with a very simple data set — a table with two columns, both containing the same values:

```
CREATE TABLE t (a INT, b INT);
INSERT INTO t SELECT i % 100, i % 100 FROM generate_series(1, 10000) s(i);
ANALYZE t;
```

As explained in Section 14.2, the planner can determine cardinality of t using the number of pages and rows obtained from pg_class:
SELECT relpages, reltuples FROM pg_class WHERE relname = 't';

<table>
<thead>
<tr>
<th>relpages</th>
<th>reltuples</th>
</tr>
</thead>
<tbody>
<tr>
<td>45</td>
<td>10000</td>
</tr>
</tbody>
</table>

The data distribution is very simple; there are only 100 distinct values in each column, uniformly distributed.

The following example shows the result of estimating a WHERE condition on the a column:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1;
```

```
QUERY PLAN
---
Seq Scan on t  (cost=0.00..170.00 rows=100 width=8) (actual rows=100 loops=1)
  Filter: (a = 1)
  Rows Removed by Filter: 9900
```

The planner examines the condition and determines the selectivity of this clause to be 1%. By comparing this estimate and the actual number of rows, we see that the estimate is very accurate (in fact exact, as the table is very small). Changing the WHERE condition to use the b column, an identical plan is generated. But observe what happens if we apply the same condition on both columns, combining them with AND:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 1;
```

```
QUERY PLAN
---
Seq Scan on t  (cost=0.00..195.00 rows=1 width=8) (actual rows=100 loops=1)
  Filter: ((a = 1) AND (b = 1))
  Rows Removed by Filter: 9900
```

The planner estimates the selectivity for each condition individually, arriving at the same 1% estimates as above. Then it assumes that the conditions are independent, and so it multiplies their selectivities, producing a final selectivity estimate of just 0.01%. This is a significant underestimate, as the actual number of rows matching the conditions (100) is two orders of magnitude higher.

This problem can be fixed by creating a statistics object that directs ANALYZE to calculate function-al-dependency multivariate statistics on the two columns:

```
CREATE STATISTICS stts (dependencies) ON a, b FROM t;
ANALYZE t;
```

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 1;
```

```
QUERY PLAN
---
Seq Scan on t  (cost=0.00..195.00 rows=100 width=8) (actual rows=100 loops=1)
  Filter: ((a = 1) AND (b = 1))
  Rows Removed by Filter: 9900
```
76.2.2. Multivariate N-Distinct Counts

A similar problem occurs with estimation of the cardinality of sets of multiple columns, such as the number of groups that would be generated by a `GROUP BY` clause. When `GROUP BY` lists a single column, the n-distinct estimate (which is visible as the estimated number of rows returned by the HashAggregate node) is very accurate:

```sql
EXPLAIN (ANALYZE, TIMING OFF) SELECT COUNT(*) FROM t GROUP BY a;
```

```
QUERY PLAN

HashAggregate  (cost=195.00..196.00 rows=100 width=12) (actual rows=100 loops=1)
  Group Key: a
  ->  Seq Scan on t  (cost=0.00..145.00 rows=10000 width=4) (actual rows=10000 loops=1)

But without multivariate statistics, the estimate for the number of groups in a query with two columns in `GROUP BY`, as in the following example, is off by an order of magnitude:

```sql
EXPLAIN (ANALYZE, TIMING OFF) SELECT COUNT(*) FROM t GROUP BY a, b;
```

```
QUERY PLAN

HashAggregate  (cost=220.00..230.00 rows=1000 width=16) (actual rows=100 loops=1)
  Group Key: a, b
  ->  Seq Scan on t  (cost=0.00..145.00 rows=10000 width=8) (actual rows=10000 loops=1)
```

By redefining the statistics object to include n-distinct counts for the two columns, the estimate is much improved:

```sql
DROP STATISTICS stts;
CREATE STATISTICS stts (dependencies, ndistinct) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF) SELECT COUNT(*) FROM t GROUP BY a, b;
```

```
QUERY PLAN

HashAggregate  (cost=220.00..221.00 rows=100 width=16) (actual rows=100 loops=1)
  Group Key: a, b
  ->  Seq Scan on t  (cost=0.00..145.00 rows=10000 width=8) (actual rows=10000 loops=1)
```

76.2.3. MCV Lists

As explained in Section 76.2.1, functional dependencies are very cheap and efficient type of statistics, but their main limitation is their global nature (only tracking dependencies at the column level, not between individual column values).

This section introduces multivariate variant of MCV (most-common values) lists, a straightforward extension of the per-column statistics described in Section 76.1. These statistics address the limitation by storing individual values, but it is naturally more expensive, both in terms of building the statistics in `ANALYZE`, storage and planning time.
Let's look at the query from Section 76.2.1 again, but this time with a MCV list created on the same set of columns (be sure to drop the functional dependencies, to make sure the planner uses the newly created statistics).

DROP STATISTICS stts;
CREATE STATISTICS stts2 (mcv) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 1;

QUERY PLAN

Seq Scan on t  (cost=0.00..195.00 rows=100 width=8) (actual rows=100 loops=1)
  Filter: ((a = 1) AND (b = 1))
  Rows Removed by Filter: 9900

The estimate is as accurate as with the functional dependencies, mostly thanks to the table being fairly small and having a simple distribution with a low number of distinct values. Before looking at the second query, which was not handled by functional dependencies particularly well, let's inspect the MCV list a bit.

Inspecting the MCV list is possible using pg_mcv_list_items set-returning function.

SELECT m.* FROM pg_statistic_ext join pg_statistic_ext_data on (oid = stxoid), pg_mcv_list_items(stxdmcv) m WHERE stxname = 'stts2';

<table>
<thead>
<tr>
<th>index</th>
<th>values</th>
<th>nulls</th>
<th>frequency</th>
<th>base_frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>{0, 0}</td>
<td>{f,f}</td>
<td>0.01</td>
<td>0.0001</td>
</tr>
<tr>
<td>1</td>
<td>{1, 1}</td>
<td>{f,f}</td>
<td>0.01</td>
<td>0.0001</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>49</td>
<td>{49, 49}</td>
<td>{f,f}</td>
<td>0.01</td>
<td>0.0001</td>
</tr>
<tr>
<td>50</td>
<td>{50, 50}</td>
<td>{f,f}</td>
<td>0.01</td>
<td>0.0001</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>97</td>
<td>{97, 97}</td>
<td>{f,f}</td>
<td>0.01</td>
<td>0.0001</td>
</tr>
<tr>
<td>98</td>
<td>{98, 98}</td>
<td>{f,f}</td>
<td>0.01</td>
<td>0.0001</td>
</tr>
<tr>
<td>99</td>
<td>{99, 99}</td>
<td>{f,f}</td>
<td>0.01</td>
<td>0.0001</td>
</tr>
</tbody>
</table>

(100 rows)

This confirms there are 100 distinct combinations in the two columns, and all of them are about equally likely (1% frequency for each one). The base frequency is the frequency computed from per-column statistics, as if there were no multi-column statistics. Had there been any null values in either of the columns, this would be identified in the nulls column.

When estimating the selectivity, the planner applies all the conditions on items in the MCV list, and then sums the frequencies of the matching ones. See mcv_clauselist_selectivity in src/backend/statistics/mcv.c for details.

Compared to functional dependencies, MCV lists have two major advantages. Firstly, the list stores actual values, making it possible to decide which combinations are compatible.

EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 10;

QUERY PLAN
Secondly, MCV lists handle a wider range of clause types, not just equality clauses like functional dependencies. For example, consider the following range query for the same table:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a <= 49 AND b > 49;
```

**QUERY PLAN**

```
Seq Scan on t  (cost=0.00..195.00 rows=1 width=8) (actual rows=0 loops=1)
  Filter: ((a <= 49) AND (b > 49))
  Rows Removed by Filter: 10000
```

### 76.3. Planner Statistics and Security

Access to the table `pg_statistic` is restricted to superusers, so that ordinary users cannot learn about the contents of the tables of other users from it. Some selectivity estimation functions will use a user-provided operator (either the operator appearing in the query or a related operator) to analyze the stored statistics. For example, in order to determine whether a stored most common value is applicable, the selectivity estimator will have to run the appropriate `=` operator to compare the constant in the query to the stored value. Thus the data in `pg_statistic` is potentially passed to user-defined operators. An appropriately crafted operator can intentionally leak the passed operands (for example, by logging them or writing them to a different table), or accidentally leak them by showing their values in error messages, in either case possibly exposing data from `pg_statistic` to a user who should not be able to see it.

In order to prevent this, the following applies to all built-in selectivity estimation functions. When planning a query, in order to be able to use stored statistics, the current user must either have `SELECT` privilege on the table or the involved columns, or the operator used must be `LEAKPROOF` (more accurately, the function that the operator is based on). If not, then the selectivity estimator will behave as if no statistics are available, and the planner will proceed with default or fall-back assumptions.

If a user does not have the required privilege on the table or columns, then in many cases the query will ultimately receive a permission-denied error, in which case this mechanism is invisible in practice. But if the user is reading from a security-barrier view, then the planner might wish to check the statistics of an underlying table that is otherwise inaccessible to the user. In that case, the operator should be leak-proof or the statistics will not be used. There is no direct feedback about that, except that the plan might be suboptimal. If one suspects that this is the case, one could try running the query as a more privileged user, to see if a different plan results.

This restriction applies only to cases where the planner would need to execute a user-defined operator on one or more values from `pg_statistic`. Thus the planner is permitted to use generic statistical information, such as the fraction of null values or the number of distinct values in a column, regardless of access privileges.

Selectivity estimation functions contained in third-party extensions that potentially operate on statistics with user-defined operators should follow the same security rules. Consult the PostgreSQL source code for guidance.
Chapter 77. Backup Manifest Format

The backup manifest generated by pg_basebackup is primarily intended to permit the backup to be verified using pg_verifybackup. However, it is also possible for other tools to read the backup manifest file and use the information contained therein for their own purposes. To that end, this chapter describes the format of the backup manifest file.

A backup manifest is a JSON document encoded as UTF-8. (Although in general JSON documents are required to be Unicode, PostgreSQL permits the json and jsonb data types to be used with any supported server encoding. There is no similar exception for backup manifests.) The JSON document is always an object; the keys that are present in this object are described in the next section.

77.1. Backup Manifest Top-level Object

The backup manifest JSON document contains the following keys.

PostgreSQL-Backup-Manifest-Version

The associated value is always the integer 1.

Files

The associated value is always a list of objects, each describing one file that is present in the backup. No entries are present in this list for the WAL files that are needed in order to use the backup, or for the backup manifest itself. The structure of each object in the list is described in Section 77.2.

WAL-Ranges

The associated value is always a list of objects, each describing a range of WAL records that must be readable from a particular timeline in order to make use of the backup. The structure of these objects is further described in Section 77.3.

Manifest-Checksum

This key is always present on the last line of the backup manifest file. The associated value is a SHA256 checksum of all the preceding lines. We use a fixed checksum method here to make it possible for clients to do incremental parsing of the manifest. While a SHA256 checksum is significantly more expensive than a CRC32C checksum, the manifest should normally be small enough that the extra computation won’t matter very much.

77.2. Backup Manifest File Object

The object which describes a single file contains either a Path key or an Encoded-Path key. Normally, the Path key will be present. The associated string value is the path of the file relative to the root of the backup directory. Files located in a user-defined tablespace will have paths whose first two components are pg_tblspc and the OID of the tablespace. If the path is not a string that is legal in UTF-8, or if the user requests that encoded paths be used for all files, then the Encoded-Path key will be present instead. This stores the same data, but it is encoded as a string of hexadecimal digits. Each pair of hexadecimal digits in the string represents a single octet.

The following two keys are always present:

Size

The expected size of this file, as an integer.
Last-Modified

The last modification time of the file as reported by the server at the time of the backup. Unlike the other fields stored in the backup, this field is not used by pg_verifybackup. It is included only for informational purposes.

If the backup was taken with file checksums enabled, the following keys will be present:

Checksum-Algorithm

The checksum algorithm used to compute a checksum for this file. Currently, this will be the same for every file in the backup manifest, but this may change in future releases. At present, the supported checksum algorithms are CRC32C, SHA224, SHA256, SHA384, and SHA512.

Checksum

The checksum computed for this file, stored as a series of hexadecimal characters, two for each byte of the checksum.

77.3. Backup Manifest WAL Range Object

The object which describes a WAL range always has three keys:

Timeline

The timeline for this range of WAL records, as an integer.

Start-LSN

The LSN at which replay must begin on the indicated timeline in order to make use of this backup. The LSN is stored in the format normally used by PostgreSQL; that is, it is a string consisting of two strings of hexadecimal characters, each with a length of between 1 and 8, separated by a slash.

End-LSN

The earliest LSN at which replay on the indicated timeline may end when making use of this backup. This is stored in the same format as Start-LSN.

Ordinarily, there will be only a single WAL range. However, if a backup is taken from a standby which switches timelines during the backup due to an upstream promotion, it is possible for multiple ranges to be present, each with a different timeline. There will never be multiple WAL ranges present for the same timeline.

Appendix A. PostgreSQL Error Codes

All messages emitted by the PostgreSQL server are assigned five-character error codes that follow the SQL standard’s conventions for “SQLSTATE” codes. Applications that need to know which error condition has occurred should usually test the error code, rather than looking at the textual error message. The error codes are less likely to change across PostgreSQL releases, and also are not subject to change due to localization of error messages. Note that some, but not all, of the error codes produced by PostgreSQL are defined by the SQL standard; some additional error codes for conditions not defined by the standard have been invented or borrowed from other databases.

According to the standard, the first two characters of an error code denote a class of errors, while the last three characters indicate a specific condition within that class. Thus, an application that does not recognize the specific error code might still be able to infer what to do from the error class.

Table A.1 lists all the error codes defined in PostgreSQL 16.3. (Some are not actually used at present, but are defined by the SQL standard.) The error classes are also shown. For each error class there is a “standard” error code having the last three characters 000. This code is used only for error conditions that fall within the class but do not have any more-specific code assigned.

The symbol shown in the column “Condition Name” is the condition name to use in PL/pgSQL. Condition names can be written in either upper or lower case. (Note that PL/pgSQL does not recognize warning, as opposed to error, condition names; those are classes 00, 01, and 02.)

For some types of errors, the server reports the name of a database object (a table, table column, data type, or constraint) associated with the error; for example, the name of the unique constraint that caused a unique_violation error. Such names are supplied in separate fields of the error report message so that applications need not try to extract them from the possibly-localized human-readable text of the message. As of PostgreSQL 9.3, complete coverage for this feature exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

Appendix B. Date/Time Support

PostgreSQL uses an internal heuristic parser for all date/time input support. Dates and times are input as strings, and are broken up into distinct fields with a preliminary determination of what kind of information can be in the field. Each field is interpreted and either assigned a numeric value, ignored, or rejected. The parser contains internal lookup tables for all textual fields, including months, days of the week, and time zones.

This appendix includes information on the content of these lookup tables and describes the steps used by the parser to decode dates and times.

B.1. Date/Time Input Interpretation

Date/time input strings are decoded using the following procedure.

1. Break the input string into tokens and categorize each token as a string, time, time zone, or number.
   a. If the numeric token contains a colon (:], this is a time string. Include all subsequent digits and colons.
   b. If the numeric token contains a dash (-), slash (/), or two or more dots (.), this is a date string which might have a text month. If a date token has already been seen, it is instead interpreted as a time zone name (e.g., America/New_York).
   c. If the token is numeric only, then it is either a single field or an ISO 8601 concatenated date (e.g., 19990113 for January 13, 1999) or time (e.g., 141516 for 14:15:16).
   d. If the token starts with a plus (+) or minus (-), then it is either a numeric time zone or a special field.
2. If the token is an alphabetic string, match up with possible strings:
   a. See if the token matches any known time zone abbreviation. These abbreviations are supplied by the configuration file described in Section B.4.
   b. If not found, search an internal table to match the token as either a special string (e.g., today), day (e.g., Thursday), month (e.g., January), or noise word (e.g., at, on).
   c. If still not found, throw an error.
3. When the token is a number or number field:
   a. If there are eight or six digits, and if no other date fields have been previously read, then interpret as a “concatenated date” (e.g., 19990118 or 990118). The interpretation is YYYY-MM-DD or YYMMDD.
   b. If the token is three digits and a year has already been read, then interpret as day of year.
   c. If four or six digits and a year has already been read, then interpret as a time (HHMM or HHMMSS).
   d. If three or more digits and no date fields have yet been found, interpret as a year (this forces yy-mm-dd ordering of the remaining date fields).
   e. Otherwise the date field ordering is assumed to follow the DateStyle setting: mm-dd-yy, dd-mm-yy, or yy-mm-dd. Throw an error if a month or day field is found to be out of range.
4. If BC has been specified, negate the year and add one for internal storage. (There is no year zero in the Gregorian calendar, so numerically 1 BC becomes year zero.)
5. If BC was not specified, and if the year field was two digits in length, then adjust the year to four digits. If the field is less than 70, then add 2000, otherwise add 1900.

**Tip**

Gregorian years AD 1–99 can be entered by using 4 digits with leading zeros (e.g., 0099 is AD 99).

## B.2. Handling of Invalid or Ambiguous Timestamps

Ordinarily, if a date/time string is syntactically valid but contains out-of-range field values, an error will be thrown. For example, input specifying the 31st of February will be rejected.

During a daylight-savings-time transition, it is possible for a seemingly valid timestamp string to represent a nonexistent or ambiguous timestamp. Such cases are not rejected; the ambiguity is resolved by determining which UTC offset to apply. For example, supposing that the TimeZone parameter is set to America/New_York, consider

```sql
=> SELECT '2018-03-11 02:30'::timestamptz;
  timestamptz
------------------------
  2018-03-11 03:30:00-04
(1 row)
```

Because that day was a spring-forward transition date in that time zone, there was no civil time instant 2:30AM; clocks jumped forward from 2AM EST to 3AM EDT. PostgreSQL interprets the given time as if it were standard time (UTC-5), which then renders as 3:30AM EDT (UTC-4).

Conversely, consider the behavior during a fall-back transition:

```sql
=> SELECT '2018-11-04 01:30'::timestamptz;
  timestamptz
------------------------
  2018-11-04 01:30:00-05
(1 row)
```

On that date, there were two possible interpretations of 1:30AM; there was 1:30AM EDT, and then an hour later after clocks jumped back from 2AM EDT to 1AM EST, there was 1:30AM EST. Again, PostgreSQL interprets the given time as if it were standard time (UTC-5). We can force the other interpretation by specifying daylight-savings time:

```sql
=> SELECT '2018-11-04 01:30 EDT'::timestamptz;
  timestamptz
------------------------
  2018-11-04 01:30:00-04
(1 row)
```

The precise rule that is applied in such cases is that an invalid timestamp that appears to fall within a jump-forward daylight savings transition is assigned the UTC offset that prevailed in the time zone just before the transition, while an ambiguous timestamp that could fall on either side of a jump-back transition is assigned the UTC offset that prevailed just after the transition. In most time zones this is equivalent to saying that “the standard-time interpretation is preferred when in doubt”.  

2570
Date/Time Support

In all cases, the UTC offset associated with a timestamp can be specified explicitly, using either a numeric UTC offset or a time zone abbreviation that corresponds to a fixed UTC offset. The rule just given applies only when it is necessary to infer a UTC offset for a time zone in which the offset varies.

B.3. Date/Time Key Words

Table B.1 shows the tokens that are recognized as names of months.

</table>
B.4. Date/Time Configuration Files

Since timezone abbreviations are not well standardized, PostgreSQL provides a means to customize the set of abbreviations accepted by the server. The timezone_abbreviations run-time parameter determines the active set of abbreviations. While this parameter can be altered by any database user, the possible values for it are under the control of the database administrator — they are in fact names of configuration files stored in .../share/timezonesets/ of the installation directory. By adding or altering files in that directory, the administrator can set local policy for timezone abbreviations.

timezone_abbreviations can be set to any file name found in .../share/timezonesets/, if the file's name is entirely alphabetic. (The prohibition against non-alphabetic characters in timezone_abbreviations prevents reading files outside the intended directory, as well as reading editor backup files and other extraneous files.)

A timezone abbreviation file can contain blank lines and comments beginning with #. Non-comment lines must have one of these formats:

```
zone_abbreviation offset
zone_abbreviation offset D
zone_abbreviation time_zone_name
@INCLUDE file_name
@OVERRIDE
```

A zone_abbreviation is just the abbreviation being defined. An offset is an integer giving the equivalent offset in seconds from UTC, positive being east from Greenwich and negative being west. For example, -18000 would be five hours west of Greenwich, or North American east coast standard time. D indicates that the zone name represents local daylight-savings time rather than standard time.

Alternatively, a time_zone_name can be given, referencing a zone name defined in the IANA timezone database. The zone's definition is consulted to see whether the abbreviation is or has been in use in that zone, and if so, the appropriate meaning is used — that is, the meaning that was currently in use at the timestamp whose value is being determined, or the meaning in use immediately before that if it wasn't current at that time, or the oldest meaning if it was used only after that time. This behavior is essential for dealing with abbreviations whose meaning has historically varied. It is also allowed to define an abbreviation in terms of a zone name in which that abbreviation does not appear; then using the abbreviation is just equivalent to writing out the zone name.

Tip

Using a simple integer offset is preferred when defining an abbreviation whose offset from UTC has never changed, as such abbreviations are much cheaper to process than those that require consulting a time zone definition.

The @INCLUDE syntax allows inclusion of another file in the .../share/timezonesets/ directory. Inclusion can be nested, to a limited depth.

The @OVERRIDE syntax indicates that subsequent entries in the file can override previous entries (typically, entries obtained from included files). Without this, conflicting definitions of the same timezone abbreviation are considered an error.

In an unmodified installation, the file Default contains all the non-conflicting time zone abbreviations for most of the world. Additional files Australia and India are provided for those regions: these files first include the Default file and then add or modify abbreviations as needed.

For reference purposes, a standard installation also contains files Africa.txt, America.txt, etc., containing information about every time zone abbreviation known to be in use according to the
IANA timezone database. The zone name definitions found in these files can be copied and pasted into a custom configuration file as needed. Note that these files cannot be directly referenced as timezone_abbreviations settings, because of the dot embedded in their names.

---

**Note**

If an error occurs while reading the time zone abbreviation set, no new value is applied and the old set is kept. If the error occurs while starting the database, startup fails.

---

**Caution**

Time zone abbreviations defined in the configuration file override non-timezone meanings built into PostgreSQL. For example, the Australia configuration file defines SAT (for South Australian Standard Time). When this file is active, SAT will not be recognized as an abbreviation for Saturday.

---

**Caution**

If you modify files in .../share/timezonesets/, it is up to you to make backups — a normal database dump will not include this directory.

---

### B.5. POSIX Time Zone Specifications

PostgreSQL can accept time zone specifications that are written according to the POSIX standard’s rules for the TZ environment variable. POSIX time zone specifications are inadequate to deal with the complexity of real-world time zone history, but there are sometimes reasons to use them.

A POSIX time zone specification has the form

```
STD offset [ DST [ dstoffset ] [ , rule ] ]
```

(For readability, we show spaces between the fields, but spaces should not be used in practice.) The fields are:

- **STD** is the zone abbreviation to be used for standard time.

- **offset** is the zone's standard-time offset from UTC.

- **DST** is the zone abbreviation to be used for daylight-savings time. If this field and the following ones are omitted, the zone uses a fixed UTC offset with no daylight-savings rule.

- **dstoffset** is the daylight-savings offset from UTC. This field is typically omitted, since it defaults to one hour less than the standard-time offset, which is usually the right thing.

- **rule** defines the rule for when daylight savings is in effect, as described below.

In this syntax, a zone abbreviation can be a string of letters, such as EST, or an arbitrary string surrounded by angle brackets, such as <UTC-05>. Note that the zone abbreviations given here are only used for output, and even then only in some timestamp output formats. The zone abbreviations recognized in timestamp input are determined as explained in Section B.4.

The offset fields specify the hours, and optionally minutes and seconds, difference from UTC. They have the format `hh[:mm[:ss]]` optionally with a leading sign (+ or −). The positive sign is used
for zones west of Greenwich. (Note that this is the opposite of the ISO-8601 sign convention used elsewhere in PostgreSQL.) \( hh \) can have one or two digits; \( mm \) and \( ss \) (if used) must have two.

The daylight-savings transition rule has the format

\[
dstdate [ / dsttime ] , stddate [ / stdtime ]
\]

(As before, spaces should not be included in practice.) The \( dstdate \) and \( dsttime \) fields define when daylight-savings time starts, while \( stddate \) and \( stdtime \) define when standard time starts. (In some cases, notably in zones south of the equator, the former might be later in the year than the latter.) The date fields have one of these formats:

\( n \)

A plain integer denotes a day of the year, counting from zero to 364, or to 365 in leap years.

\( Jn \)

In this form, \( n \) counts from 1 to 365, and February 29 is not counted even if it is present. (Thus, a transition occurring on February 29 could not be specified this way. However, days after February have the same numbers whether it's a leap year or not, so that this form is usually more useful than the plain-integer form for transitions on fixed dates.)

\( Mm.n.d \)

This form specifies a transition that always happens during the same month and on the same day of the week. \( m \) identifies the month, from 1 to 12. \( n \) specifies the \( n \)'th occurrence of the weekday identified by \( d \). \( n \) is a number between 1 and 4, or 5 meaning the last occurrence of that weekday in the month (which could be the fourth or the fifth). \( d \) is a number between 0 and 6, with 0 indicating Sunday. For example, \( M3.2.0 \) means "the second Sunday in March".

The time fields in a transition rule have the same format as the offset fields described previously, except that they cannot contain signs. They define the current local time at which the change to the other time occurs. If omitted, they default to 02:00:00.

If a daylight-savings abbreviation is given but the transition rule field is omitted, the fallback behavior is to use the rule \( M3.2.0,M11.1.0 \), which corresponds to USA practice as of 2020 (that is, spring forward on the second Sunday of March, fall back on the first Sunday of November, both transitions occurring at 2AM prevailing time). Note that this rule does not give correct USA transition dates for years before 2007.

As an example, \( CET-1CEST,M3.5.0,M10.5.0/3 \) describes current (as of 2020) timekeeping practice in Paris. This specification says that standard time has the abbreviation CET and is one hour ahead (east) of UTC; daylight savings time has the abbreviation CEST and is implicitly two hours ahead of UTC; daylight savings time begins on the last Sunday in March at 2AM CET and ends on the last Sunday in October at 3AM CEST.

The four timezone names \( EST5EDT, CST6CDT, MST7MDT, \) and \( PST8PDT \) look like they are POSIX zone specifications. However, they actually are treated as named time zones because (for historical reasons) there are files by those names in the IANA time zone database. The practical implication

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>The ( M ) format is sufficient to describe many common daylight-savings transition laws. But note that none of these variants can deal with daylight-savings law changes, so in practice the historical data stored for named time zones (in the IANA time zone database) is necessary to interpret past time stamps correctly.</td>
</tr>
</tbody>
</table>
of this is that these zone names will produce valid historical USA daylight-savings transitions, even when a plain POSIX specification would not.

One should be wary that it is easy to misspell a POSIX-style time zone specification, since there is no check on the reasonableness of the zone abbreviation(s). For example, \texttt{SET TIMEZONE TO FOOBAR0} will work, leaving the system effectively using a rather peculiar abbreviation for UTC.

### B.6. History of Units

The SQL standard states that “Within the definition of a ‘datetime literal’, the ‘datetime values’ are constrained by the natural rules for dates and times according to the Gregorian calendar”. PostgreSQL follows the SQL standard’s lead by counting dates exclusively in the Gregorian calendar, even for years before that calendar was in use. This rule is known as the \textit{proleptic Gregorian calendar}.

The Julian calendar was introduced by Julius Caesar in 45 BC. It was in common use in the Western world until the year 1582, when countries started changing to the Gregorian calendar. In the Julian calendar, the tropical year is approximated as $365 \frac{1}{4} \text{ days} = 365.25 \text{ days}$. This gives an error of about 1 day in 128 years.

The accumulating calendar error prompted Pope Gregory XIII to reform the calendar in accordance with instructions from the Council of Trent. In the Gregorian calendar, the tropical year is approximated as $365 + \frac{97}{400} \text{ days} = 365.2425 \text{ days}$. Thus it takes approximately 3300 years for the tropical year to shift one day with respect to the Gregorian calendar.

The approximation $365+97/400$ is achieved by having 97 leap years every 400 years, using the following rules:

- Every year divisible by 4 is a leap year.
- However, every year divisible by 100 is not a leap year.
- However, every year divisible by 400 is a leap year after all.

So, 1700, 1800, 1900, 2100, and 2200 are not leap years. But 1600, 2000, and 2400 are leap years. By contrast, in the older Julian calendar all years divisible by 4 are leap years.

The papal bull of February 1582 decreed that 10 days should be dropped from October 1582 so that 15 October should follow immediately after 4 October. This was observed in Italy, Poland, Portugal, and Spain. Other Catholic countries followed shortly after, but Protestant countries were reluctant to change, and the Greek Orthodox countries didn’t change until the start of the 20th century. The reform was observed by Great Britain and its dominions (including what is now the USA) in 1752. Thus 2 September 1752 was followed by 14 September 1752. This is why Unix systems that have the \texttt{cal} program produce the following:

```sh
$ cal 9 1752
  September 1752
 M T W T F S
1 2 14 15 16
17 18 19 20 21 22 23
24 25 26 27 28 29 30
```

But, of course, this calendar is only valid for Great Britain and dominions, not other places. Since it would be difficult and confusing to try to track the actual calendars that were in use in various places at various times, PostgreSQL does not try, but rather follows the Gregorian calendar rules for all dates, even though this method is not historically accurate.

Different calendars have been developed in various parts of the world, many predating the Gregorian system. For example, the beginnings of the Chinese calendar can be traced back to the 14th century BC. Legend has it that the Emperor Huangdi invented that calendar in 2637 BC. The People’s Republic of China uses the Gregorian calendar for civil purposes. The Chinese calendar is used for determining festivals.

2575
B.7. Julian Dates

The Julian Date system is a method for numbering days. It is unrelated to the Julian calendar, though it is confusingly named similarly to that calendar. The Julian Date system was invented by the French scholar Joseph Justus Scaliger (1540–1609) and probably takes its name from Scaliger's father, the Italian scholar Julius Caesar Scaliger (1484–1558).

In the Julian Date system, each day has a sequential number, starting from JD 0 (which is sometimes called the Julian Date). JD 0 corresponds to 1 January 4713 BC in the Julian calendar, or 24 November 4714 BC in the Gregorian calendar. Julian Date counting is most often used by astronomers for labeling their nightly observations, and therefore a date runs from noon UTC to the next noon UTC, rather than from midnight to midnight: JD 0 designates the 24 hours from noon UTC on 24 November 4714 BC to noon UTC on 25 November 4714 BC.

Although PostgreSQL supports Julian Date notation for input and output of dates (and also uses Julian dates for some internal datetime calculations), it does not observe the nicety of having dates run from noon to noon. PostgreSQL treats a Julian Date as running from local midnight to local midnight, the same as a normal date.

This definition does, however, provide a way to obtain the astronomical definition when you need it: do the arithmetic in time zone UTC+12. For example,

```sql
=> SELECT extract(julian from '2021-06-23 7:00:00-04'::timestamptz at time zone 'UTC+12');
   extract
-----------------------------
 2459388.95833333333333333333
(1 row)
=> SELECT extract(julian from '2021-06-23 8:00:00-04'::timestamptz at time zone 'UTC+12');
   extract
--------------------------------------
 2459389.0000000000000000000000000000
(1 row)
=> SELECT extract(julian from date '2021-06-23');
   extract
---------
 2459389
(1 row)
```
Appendix C. SQL Key Words

Table C.1 lists all tokens that are key words in the SQL standard and in PostgreSQL 16.3. Background information can be found in Section 4.1.1. (For space reasons, only the latest two versions of the SQL standard, and SQL-92 for historical comparison, are included. The differences between those and the other intermediate standard versions are small.)

SQL distinguishes between reserved and non-reserved key words. According to the standard, reserved key words are the only real key words; they are never allowed as identifiers. Non-reserved key words only have a special meaning in particular contexts and can be used as identifiers in other contexts. Most non-reserved key words are actually the names of built-in tables and functions specified by SQL. The concept of non-reserved key words essentially only exists to declare that some predefined meaning is attached to a word in some contexts.

In the PostgreSQL parser, life is a bit more complicated. There are several different classes of tokens ranging from those that can never be used as an identifier to those that have absolutely no special status in the parser, but are considered ordinary identifiers. (The latter is usually the case for functions specified by SQL.) Even reserved key words are not completely reserved in PostgreSQL, but can be used as column labels (for example, SELECT 55 AS CHECK, even though CHECK is a reserved key word).

In Table C.1 in the column for PostgreSQL we classify as “non-reserved” those key words that are explicitly known to the parser but are allowed as column or table names. Some key words that are otherwise non-reserved cannot be used as function or data type names and are marked accordingly. (Most of these words represent built-in functions or data types with special syntax. The function or type is still available but it cannot be redefined by the user.) Labeled “reserved” are those tokens that are not allowed as column or table names. Some reserved key words are allowable as names for functions or data types; this is also shown in the table. If not so marked, a reserved key word is only allowed as a column label. A blank entry in this column means that the word is treated as an ordinary identifier by PostgreSQL.

Furthermore, while most key words can be used as “bare” column labels without writing AS before them (as described in Section 7.3.2), there are a few that require a leading AS to avoid ambiguity. These are marked in the table as “requires AS”.

As a general rule, if you get spurious parser errors for commands that use any of the listed key words as an identifier, you should try quoting the identifier to see if the problem goes away.

It is important to understand before studying Table C.1 that the fact that a key word is not reserved in PostgreSQL does not mean that the feature related to the word is not implemented. Conversely, the presence of a key word does not indicate the existence of a feature.

Appendix D. SQL Conformance

This section attempts to outline to what extent PostgreSQL conforms to the current SQL standard. The following information is not a full statement of conformance, but it presents the main topics in as much detail as is both reasonable and useful for users.

The formal name of the SQL standard is ISO/IEC 9075 “Database Language SQL”. A revised version of the standard is released from time to time; the most recent update appearing in 2023. The 2023 version is referred to as ISO/IEC 9075:2023, or simply as SQL:2023. The versions prior to that were SQL:2016, SQL:2011, SQL:2008, SQL:2006, SQL:2003, SQL:1999, and SQL-92. Each version replaces the previous one, so claims of conformance to earlier versions have no official merit. PostgreSQL development aims for conformance with the latest official version of the standard where such conformance does not contradict traditional features or common sense. Many of the features required by the SQL standard are supported, though sometimes with slightly differing syntax or function. Further moves towards conformance can be expected over time.

SQL-92 defined three feature sets for conformance: Entry, Intermediate, and Full. Most database management systems claiming SQL standard conformance were conforming at only the Entry level, since the entire set of features in the Intermediate and Full levels was either too voluminous or in conflict with legacy behaviors.

Starting with SQL:1999, the SQL standard defines a large set of individual features rather than the ineffectively broad three levels found in SQL-92. A large subset of these features represents the “Core” features, which every conforming SQL implementation must supply. The rest of the features are purely optional.

The standard is split into a number of parts, each also known by a shorthand name:

- ISO/IEC 9075-1 Framework (SQL/Framework)
- ISO/IEC 9075-2 Foundation (SQL/Foundation)
- ISO/IEC 9075-3 Call Level Interface (SQL/CLI)
- ISO/IEC 9075-4 Persistent Stored Modules (SQL/PSM)
- ISO/IEC 9075-9 Management of External Data (SQL/MED)
- ISO/IEC 9075-10 Object Language Bindings (SQL/OLB)
- ISO/IEC 9075-11 Information and Definition Schemas (SQL/Schemata)
- ISO/IEC 9075-13 Routines and Types using the Java Language (SQL/JRT)
- ISO/IEC 9075-14 XML-related specifications (SQL/XML)
- ISO/IEC 9075-15 Multi-dimensional arrays (SQL/MDA)
- ISO/IEC 9075-16 Property Graph Queries (SQL/PGQ)

Note that some part numbers are not (or no longer) used.
PostgreSQL supports most of the major features of SQL:2023. Out of 177 mandatory features required for full Core conformance, PostgreSQL conforms to at least 170. In addition, there is a long list of supported optional features. It might be worth noting that at the time of writing, no current version of any database management system claims full conformance to Core SQL:2023.

In the following two sections, we provide a list of those features that PostgreSQL supports, followed by a list of the features defined in SQL:2023 which are not yet supported in PostgreSQL. Both of these lists are approximate: There might be minor details that are nonconforming for a feature that is listed as supported, and large parts of an unsupported feature might in fact be implemented. The main body of the documentation always contains the most accurate information about what does and does not work.

---

### Note

Feature codes containing a hyphen are subfeatures. Therefore, if a particular subfeature is not supported, the main feature is listed as unsupported even if some other subfeatures are supported.

---

### D.1. Supported Features

## D.2. Unsupported Features

The following features defined in SQL:2023 are not implemented in this release of PostgreSQL. In a few cases, equivalent functionality is available.

**D.3. XML Limits and Conformance to SQL/XML**

Significant revisions to the XML-related specifications in ISO/IEC 9075-14 (SQL/XML) were introduced with SQL:2006. PostgreSQL's implementation of the XML data type and related functions largely follows the earlier 2003 edition, with some borrowing from later editions. In particular:

- Where the current standard provides a family of XML data types to hold "document" or "content" in untyped or XML Schema-typed variants, and a type `XML(SEQUENCE)` to hold arbitrary pieces of XML content, PostgreSQL provides the single `xml` type, which can hold "document" or "content". There is no equivalent of the standard's "sequence" type.

- PostgreSQL provides two functions introduced in SQL:2006, but in variants that use the XPath 1.0 language, rather than XML Query as specified for them in the standard.

This section presents some of the resulting differences you may encounter.
D.3.1. Queries Are Restricted to XPath 1.0

The PostgreSQL-specific functions `xpath()` and `xpath_exists()` query XML documents using the XPath language. PostgreSQL also provides XPath-only variants of the standard functions `XML EXISTS` and `XMLTABLE`, which officially use the XQuery language. For all of these functions, PostgreSQL relies on the libxml2 library, which provides only XPath 1.0.

There is a strong connection between the XQuery language and XPath versions 2.0 and later: any expression that is syntactically valid and executes successfully in both produces the same result (with a minor exception for expressions containing numeric character references or predefined entity references, which XQuery replaces with the corresponding character while XPath leaves them alone). But there is no such connection between these languages and XPath 1.0; it was an earlier language and differs in many respects.

There are two categories of limitation to keep in mind: the restriction from XQuery to XPath for the functions specified in the SQL standard, and the restriction of XPath to version 1.0 for both the standard and the PostgreSQL-specific functions.

D.3.1.1. Restriction of XQuery to XPath

Features of XQuery beyond those of XPath include:

- XQuery expressions can construct and return new XML nodes, in addition to all possible XPath values. XPath can create and return values of the atomic types (numbers, strings, and so on) but can only return XML nodes that were already present in documents supplied as input to the expression.
- XQuery has control constructs for iteration, sorting, and grouping.
- XQuery allows declaration and use of local functions.

Recent XPath versions begin to offer capabilities overlapping with these (such as functional-style `for-each` and `sort`, anonymous functions, and `parse-xml` to create a node from a string), but such features were not available before XPath 3.0.

D.3.1.2. Restriction of XPath to 1.0

For developers familiar with XQuery and XPath 2.0 or later, XPath 1.0 presents a number of differences to contend with:

- The fundamental type of an XQuery/XPath expression, the `sequence`, which can contain XML nodes, atomic values, or both, does not exist in XPath 1.0. A 1.0 expression can only produce a node-set (containing zero or more XML nodes), or a single atomic value.
- Unlike an XQuery/XPath sequence, which can contain any desired items in any desired order, an XPath 1.0 node-set has no guaranteed order and, like any set, does not allow multiple appearances of the same item.

Note

The libxml2 library does seem to always return node-sets to PostgreSQL with their members in the same relative order they had in the input document. Its documentation does not commit to this behavior, and an XPath 1.0 expression cannot control it.

- While XQuery/XPath provides all of the types defined in XML Schema and many operators and functions over those types, XPath 1.0 has only node-sets and the three atomic types `boolean`, `double`, and `string`.
• XPath 1.0 has no conditional operator. An XQuery/XPath expression such as if ( hat ) then hat/@size else "no hat" has no XPath 1.0 equivalent.

• XPath 1.0 has no ordering comparison operator for strings. Both "cat" < "dog" and "cat" > "dog" are false, because each is a numeric comparison of two NaNs. In contrast, = and != do compare the strings as strings.

• XPath 1.0 blurs the distinction between value comparisons and general comparisons as XQuery/XPath define them. Both sale/@hatsize = 7 and sale/@customer = "alice" are existentially quantified comparisons, true if there is any sale with the given value for the attribute, but sale/@taxable = false() is a value comparison to the effective boolean value of a whole node-set. It is true only if no sale has a taxable attribute at all.

• In the XQuery/XPath data model, a document node can have either document form (i.e., exactly one top-level element, with only comments and processing instructions outside of it) or content form (with those constraints relaxed). Its equivalent in XPath 1.0, the root node, can only be in document form. This is part of the reason an xml value passed as the context item to any PostgreSQL XPath-based function must be in document form.

The differences highlighted here are not all of them. In XQuery and the 2.0 and later versions of XPath, there is an XPath 1.0 compatibility mode, and the W3C lists of function library changes and language changes applied in that mode offer a more complete (but still not exhaustive) account of the differences. The compatibility mode cannot make the later languages exactly equivalent to XPath 1.0.

**D.3.1.3. Mappings between SQL and XML Data Types and Values**

In SQL:2006 and later, both directions of conversion between standard SQL data types and the XML Schema types are specified precisely. However, the rules are expressed using the types and semantics of XQuery/XPath, and have no direct application to the different data model of XPath 1.0.

When PostgreSQL maps SQL data values to XML (as in xml:element), or XML to SQL (as in the output columns of xmltable), except for a few cases treated specially, PostgreSQL simply assumes that the XML data type’s XPath 1.0 string form will be valid as the text-input form of the SQL datatype, and conversely. This rule has the virtue of simplicity while producing, for many data types, results similar to the mappings specified in the standard.

Where interoperability with other systems is a concern, for some data types, it may be necessary to use data type formatting functions (such as those in Section 9.8) explicitly to produce the standard mappings.

**D.3.2. Incidental Limits of the Implementation**

This section concerns limits that are not inherent in the libxml2 library, but apply to the current implementation in PostgreSQL.

**D.3.2.1. Only BY VALUE Passing Mechanism Is Supported**

The SQL standard defines two passing mechanisms that apply when passing an XML argument from SQL to an XML function or receiving a result: BY REF, in which a particular XML value retains its node identity, and BY VALUE, in which the content of the XML is passed but node identity is not preserved. A mechanism can be specified before a list of parameters, as the default mechanism for all of them, or after any parameter, to override the default.

To illustrate the difference, if x is an XML value, these two queries in an SQL:2006 environment would produce true and false, respectively:

---

1 https://www.w3.org/TR/2010/REC-xpath-functions-20101214/#xpath1-compatibility
2 https://www.w3.org/TR/xpath20/#id-backwards-compatibility
SQL Conformance

```sql
SELECT XMLQUERY('$a is $b' PASSING BY REF x AS a, x AS b NULL ON EMPTY);
SELECT XMLQUERY('$a is $b' PASSING BY VALUE x AS a, x AS b NULL ON EMPTY);
```

PostgreSQL will accept `BY VALUE` or `BY REF` in an `XMLEXISTS` or `XMLTABLE` construct, but it ignores them. The `xml` data type holds a character-string serialized representation, so there is no node identity to preserve, and passing is always effectively `BY VALUE`.

**D.3.2.2. Cannot Pass Named Parameters to Queries**

The XPath-based functions support passing one parameter to serve as the XPath expression's context item, but do not support passing additional values to be available to the expression as named parameters.

**D.3.2.3. No XML (SEQUENCE) Type**

The PostgreSQL `xml` data type can only hold a value in `DOCUMENT` or `CONTENT` form. An XQuery/XPath expression context item must be a single XML node or atomic value, but XPath 1.0 further restricts it to be only an XML node, and has no node type allowing `CONTENT`. The upshot is that a well-formed `DOCUMENT` is the only form of XML value that PostgreSQL can supply as an XPath context item.
Appendix E. Release Notes

The release notes contain the significant changes in each PostgreSQL release, with major features and migration issues listed at the top. The release notes do not contain changes that affect only a few users or changes that are internal and therefore not user-visible. For example, the optimizer is improved in almost every release, but the improvements are usually observed by users as simply faster queries.

A complete list of changes for each release can be obtained by viewing the Git logs for each release. The `pgsql-committers` email list\(^1\) records all source code changes as well. There is also a web interface\(^2\) that shows changes to specific files.

The name appearing next to each item represents the major developer for that item. Of course all changes involve community discussion and patch review, so each item is truly a community effort.

### E.1. Release 16.3

**Release date:** 2024-05-09

This release contains a variety of fixes from 16.2. For information about new features in major release 16, see Section E.4.

#### E.1.1. Migration to Version 16.3

A dump/restore is not required for those running 16.X.

However, a security vulnerability was found in the system views `pg_stats_ext` and `pg_stats_ext_exprs`, potentially allowing authenticated database users to see data they shouldn't. If this is of concern in your installation, follow the steps in the first changelog entry below to rectify it.

Also, if you are upgrading from a version earlier than 16.2, see Section E.2.

#### E.1.2. Changes

- Restrict visibility of `pg_stats_ext` and `pg_stats_ext_exprs` entries to the table owner (Nathan Bossart)

  These views failed to hide statistics for expressions that involve columns the accessing user does not have permission to read. View columns such as `most_common_vals` might expose security-relevant data. The potential interactions here are not fully clear, so in the interest of erring on the side of safety, make rows in these views visible only to the owner of the associated table.

  The PostgreSQL Project thanks Lukas Fittl for reporting this problem. (CVE-2024-4317)

  By itself, this fix will only fix the behavior in newly initdb'd database clusters. If you wish to apply this change in an existing cluster, you will need to do the following:

  1. Find the SQL script `fix-CVE-2024-4317.sql` in the `share` directory of the PostgreSQL installation (typically located somewhere like `/usr/share/postgresql/`). Be sure to use the script appropriate to your PostgreSQL major version. If you do not see this file, either your version is not vulnerable (only v14–v16 are affected) or your minor version is too old to have the fix.

  2. In *each* database of the cluster, run the `fix-CVE-2024-4317.sql` script as superuser. In `psql` this would look like

\(^1\) [https://www.postgresql.org/list/pgsql-committers/](https://www.postgresql.org/list/pgsql-committers/)

\(^2\) [https://git.postgresql.org/gitweb/?p=postgresql.git;a=summary]
Release Notes

\i /usr/share/postgresql/fix-CVE-2024-4317.sql

(adjust the file path as appropriate). Any error probably indicates that you've used the wrong script version. It will not hurt to run the script more than once.

3. Do not forget to include the template0 and template1 databases, or the vulnerability will still exist in databases you create later. To fix template0, you'll need to temporarily make it accept connections. Do that with

ALTER DATABASE template0 WITH ALLOW_CONNECTIONS true;

and then after fixing template0, undo it with

ALTER DATABASE template0 WITH ALLOW_CONNECTIONS false;

- Fix INSERT from multiple VALUES rows into a target column that is a domain over an array or composite type (Tom Lane)

Such cases would either fail with surprising complaints about mismatched datatypes, or insert unexpected coercions that could lead to odd results.

- Require SELECT privilege on the target table for MERGE with a DO NOTHING clause (Álvaro Herrera)

SELECT privilege would be required in all practical cases anyway, but require it even if the query reads no columns of the target table. This avoids an edge case in which MERGE would require no privileges whatever, which seems undesirable even when it's a do-nothing command.

- Fix handling of self-modified tuples in MERGE (Dean Rasheed)

Throw an error if a target row joins to more than one source row, as required by the SQL standard. (The previous coding could silently ignore this condition if a concurrent update was involved.) Also, throw a non-misleading error if a target row is already updated by a later command in the current transaction, thanks to a BEFORE trigger or a volatile function used in the query.

- Fix incorrect pruning of NULL partition when a table is partitioned on a boolean column and the query has a boolean IS NOT clause (David Rowley)

A NULL value satisfies a clause such as boolcol IS NOT FALSE, so pruning away a partition containing NULLs yielded incorrect answers.

- Make ALTER FOREIGN TABLE SET SCHEMA move any owned sequences into the new schema (Tom Lane)

Moving a regular table to a new schema causes any sequences owned by the table to be moved to that schema too (along with indexes and constraints). This was overlooked for foreign tables, however.

- Make ALTER TABLE ... ADD COLUMN create identity/serial sequences with the same persistence as their owning tables (Peter Eisentraut)

CREATE UNLOGGED TABLE will make any owned sequences be unlogged too. ALTER TABLE missed that consideration, so that an added identity column would have a logged sequence, which seems pointless.

- Improve ALTER TABLE ... ALTER COLUMN TYPE's error message when there is a dependent function or publication (Tom Lane)

- In CREATE DATABASE, recognize strategy keywords case-insensitively for consistency with other options (Tomas Vondra)
• Fix EXPLAIN’s counting of heap pages accessed by a bitmap heap scan (Melanie Plageman)

Previously, heap pages that contain no visible tuples were not counted; but it seems more consistent to count all pages returned by the bitmap index scan.

• Fix EXPLAIN’s output for subplans in MERGE (Dean Rasheed)

EXPLAIN would sometimes fail to properly display subplan Params referencing variables in other parts of the plan tree.

• Avoid deadlock during removal of orphaned temporary tables (Mikhail Zhilin)

If the session that creates a temporary table crashes without removing the table, autovacuum will eventually try to remove the orphaned table. However, an incoming session that’s been assigned the same temporary namespace will do that too. If a temporary table has a dependency (such as an owned sequence) then a deadlock could result between these two cleanup attempts.

• Fix updating of visibility map state in VACUUM with the DISABLE_PAGE_SKIPPING option (Heikki Linnakangas)

Due to an oversight, this mode caused all heap pages to be dirtied, resulting in excess I/O. Also, visibility map bits that were incorrectly set would not get cleared.

• Avoid race condition while examining per-relation frozen-XID values (Noah Misch)

VACUUM’s computation of per-database frozen-XID values from per-relation values could get confused by a concurrent update of those values by another VACUUM.

• Fix buffer usage reporting for parallel vacuuming (Anthonin Bonnefoy)

Buffer accesses performed by parallel workers were not getting counted in the statistics reported in VERBOSE mode.

• Ensure that join conditions generated from equivalence classes are applied at the correct plan level (Tom Lane)

In versions before PostgreSQL 16, it was possible for generated conditions to be evaluated below outer joins when they should be evaluated above (after) the outer join, leading to incorrect query results. All versions have a similar hazard when considering joins to UNION ALL trees that have constant outputs for the join column in some SELECT arms.

• Fix “could not find pathkey item to sort” errors occurring while planning aggregate functions with ORDER BY or DISTINCT options (David Rowley)

This is similar to a fix applied in 16.1, but it solves the problem for parallel plans.

• Prevent potentially-incorrect optimization of some window functions (David Rowley)

Disable “run condition” optimization of ntile() and count() with non-constant arguments. This avoids possible misbehavior with sub-selects, typically leading to errors like “WindowFunc not found in subplan target lists”.

• Avoid unnecessary use of moving-aggregate mode with a non-moving window frame (Vallimaharajan G)

When a plain aggregate is used as a window function, and the window frame start is specified as UNBOUNDED PRECEDING, the frame’s head cannot move so we do not need to use the special (and more expensive) moving-aggregate mode. This optimization was intended all along, but due to a coding error it never triggered.

• Avoid use of already-freed data while planning partition-wise joins under GEQO (Tom Lane)
This would typically end in a crash or unexpected error message.

- Avoid freeing still-in-use data in Memoize (Tender Wang, Andrei Lepikhov)

  In production builds this error frequently didn't cause any problems, as the freed data would most likely not get overwritten before it was used.

- Fix incorrectly-reported statistics kind codes in “requested statistics kind \(X\) is not yet built” error messages (David Rowley)

- Use a hash table instead of linear search for “catcache list” objects (Tom Lane)

  This change solves performance problems that were reported for certain operations in installations with many thousands of roles.

- Be more careful with \texttt{RECORD}-returning functions in \texttt{FROM} (Tom Lane)

  The output columns of such a function call must be defined by an \texttt{AS} clause that specifies the column names and data types. If the actual function output value doesn't match that, an error is supposed to be thrown at runtime. However, some code paths would examine the actual value prematurely, and potentially issue strange errors or suffer assertion failures if it doesn't match expectations.

- Fix confusion about the return rowtype of SQL-language procedures (Tom Lane)

  A procedure implemented in SQL language that returns a single composite-type column would cause an assertion failure or core dump.

- Add protective stack depth checks to some recursive functions (Egor Chindyaskin)

- Fix mis-rounding and overflow hazards in \texttt{date\_bin()} (Moaaz Assali)

  In the case where the source timestamp is before the origin timestamp and their difference is already an exact multiple of the stride, the code incorrectly subtracted the stride anyway. Also, detect some integer-overflow cases that would have produced incorrect results.

- Detect integer overflow when adding or subtracting an \texttt{interval} to/from a \texttt{timestamp} (Joseph Koshakow)

  Some cases that should cause an out-of-range error produced an incorrect result instead.

- Avoid race condition in \texttt{pg\_get\_expr()} (Tom Lane)

  If the relation referenced by the argument is dropped concurrently, the function's intention is to return \texttt{NULL}, but sometimes it failed instead.

- Fix detection of old transaction IDs in XID status functions (Karina Litskevich)

  Transaction IDs more than \(2^{31}\) transactions in the past could be misidentified as recent, leading to misbehavior of \texttt{pg\_xact\_status()} or \texttt{txid\_status()}.

- Ensure that a table's freespace map won't return a page that's past the end of the table (Ronan Dunklau)

  Because the freespace map isn't WAL-logged, this was possible in edge cases involving an OS crash, a replica promote, or a PITR restore. The result would be a “could not read block” error.

- Fix file descriptor leakage when an error is thrown while waiting in \texttt{WaitEventSetWait} (Etsuro Fujita)

- Avoid corrupting exception stack if an FDW implements async append but doesn't configure any wait conditions for the Append plan node to wait for (Alexander Pyhalov)
• Throw an error if an index is accessed while it is being reindexed (Tom Lane)

Previously this was just an assertion check, but promote it into a regular runtime error. This will provide a more on-point error message when reindexing a user-defined index expression that attempts to access its own table.

• Ensure that index-only scans on name columns return a fully-padded value (David Rowley)

The value physically stored in the index is truncated, and previously a pointer to that value was returned to callers. This provoked complaints when testing under valgrind. In theory it could result in crashes, though none have been reported.

• Fix race condition that could lead to reporting an incorrect conflict cause when invalidating a replication slot (Bertrand Drouvot)

• Fix race condition in deciding whether a table sync operation is needed in logical replication (Vignesh C)

An invalidation event arriving while a subscriber identifies which tables need to be synced would be forgotten about, so that any tables newly in need of syncing might not get processed in a timely fashion.

• Fix crash with DSM allocations larger than 4GB (Heikki Linnakangas)

• Disconnect if a new server session’s client socket cannot be put into non-blocking mode (Heikki Linnakangas)

It was once theoretically possible for us to operate with a socket that’s in blocking mode; but that hasn’t worked fully in a long time, so fail at connection start rather than misbehave later.

• Fix inadequate error reporting with OpenSSL 3.0.0 and later (Heikki Linnakangas, Tom Lane)

System-reported errors passed through by OpenSSL were reported with a numeric error code rather than anything readable.

• Fix thread-safety of error reporting for getaddrinfo() on Windows (Thomas Munro)

A multi-threaded libpq client program could get an incorrect or corrupted error message after a network lookup failure.

• Avoid concurrent calls to bindtextdomain() in libpq and ecpglib (Tom Lane)

Although GNU gettext’s implementation seems to be fine with concurrent calls, the version available on Windows is not.

• Fix crash in ecpg’s preprocessor if the program tries to redefine a macro that was defined on the preprocessor command line (Tom Lane)

• In ecpg, avoid issuing false “unsupported feature will be passed to server” warnings (Tom Lane)

• Ensure that the string result of ecpg’s intoasc() function is correctly zero-terminated (Oleg Tselebrovskiy)

• In initdb’s -c option, match parameter names case-insensitively (Tom Lane)

The server treats parameter names case-insensitively, so this code should too. This avoids putting redundant entries into the generated postgresql.conf file.

• In psql, avoid leaking a query result after the query is cancelled (Tom Lane)

This happened only when cancelling a non-last query in a query string made with \; separators.
• Fix `pg_dumpall` so that role comments, if present, will be dumped regardless of the setting of `--no-role-passwords` (Daniel Gustafsson, Álvaro Herrera)

• Skip files named `.DS_Store` in `pg_basebackup`, `pg_checksums`, and `pg_rewind` (Daniel Gustafsson)

  This avoids problems on macOS, where the Finder may create such files.

• Fix PL/pgSQL’s parsing of single-line comments (```--```-style comments) following expressions (Erik Wienhold, Tom Lane)

  This mistake caused parse errors if such a comment followed a `WHEN` expression in a PL/pgSQL `CASE` statement.

• In `contrib/amcheck`, don’t report false match failures due to short- versus long-header values (Andrey Borodin, Michael Zhilin)

  A variable-length datum in a heap tuple or index tuple could have either a short or a long header, depending on compression parameters that applied when it was made. Treat these cases as equivalent rather than complaining if there’s a difference.

• Fix bugs in BRIN output functions (Tomas Vondra)

  These output functions are only used for displaying index entries in `contrib/pageinspect`, so the errors are of limited practical concern.

• In `contrib/postgres_fdw`, avoid emitting requests to sort by a constant (David Rowley)

  This could occur in cases involving `UNION ALL` with constant-emitting subqueries. Sorting by a constant is useless of course, but it also risks being misinterpreted by the remote server, leading to “ORDER BY position \(N\) is not in select list” errors.

• Make `contrib/postgres_fdw` set the remote session’s time zone to `GMT` not `UTC` (Tom Lane)

  This should have the same results for practical purposes. However, `GMT` is recognized by hardwired code in the server, while `UTC` is looked up in the timezone database. So the old code could fail in the unlikely event that the remote server’s timezone database is missing entries.

• In `contrib/xml2`, avoid use of library functions that have been deprecated in recent versions of `libxml2` (Dmitry Koval)

• Fix incompatibility with LLVM 18 (Thomas Munro, Dmitry Dolgov)

• Allow `make check` to work with the musl C library (Thomas Munro, Bruce Momjian, Tom Lane)

---

**E.2. Release 16.2**

**Release date:** 2024-02-08

This release contains a variety of fixes from 16.1. For information about new features in major release 16, see Section E.4.

**E.2.1. Migration to Version 16.2**

A dump/restore is not required for those running 16.X.

However, one bug was fixed that could have resulted in corruption of GIN indexes during concurrent updates. If you suspect such corruption, reindex affected indexes after installing this update.

Also, if you are upgrading from a version earlier than 16.1, see Section E.3.
E.2.2. Changes

- Tighten security restrictions within `REFRESH MATERIALIZED VIEW CONCURRENTLY` (Heikki Linnakangas)

  One step of a concurrent refresh command was run under weak security restrictions. If a materialized view's owner could persuade a superuser or other high-privileged user to perform a concurrent refresh on that view, the view's owner could control code executed with the privileges of the user running `REFRESH`. Fix things so that all user-determined code is run as the view's owner, as expected.

  The only known exploit for this error does not work in PostgreSQL 16.0 and later, so it may be that v16 is not vulnerable in practice.

  The PostgreSQL Project thanks Pedro Gallegos for reporting this problem. (CVE-2024-0985)

- Fix memory leak when performing JIT inlining (Andres Freund, Daniel Gustafsson)

  There have been multiple reports of backend processes suffering out-of-memory conditions after sufficiently many JIT compilations. This fix should resolve that.

- Avoid generating incorrect partitioned-join plans (Richard Guo)

  Some uncommon situations involving lateral references could create incorrect plans. Affected queries could produce wrong answers, or odd failures such as “variable not found in subplan target list”, or executor crashes.

- Fix incorrect wrapping of subquery output expressions in `PlaceHolderVars` (Tom Lane)

  This fixes incorrect results when a subquery is underneath an outer join and has an output column that laterally references something outside the outer join’s scope. The output column might not appear as NULL when it should do so due to the action of the outer join.

- Fix misprocessing of window function run conditions (Richard Guo)

  This oversight could lead to “WindowFunc not found in subplan target lists” errors.

- Fix detection of inner-side uniqueness for Memoize plans (Richard Guo)

  This mistake could lead to “cache entry already complete” errors.

- Fix computation of nullingrels when constant-folding field selection (Richard Guo)

  Failure to do this led to errors like “wrong varnullingrels (b) (expected (b 3)) for Var 2/2”.

- Skip inappropriate actions when `MERGE` causes a cross-partition update (Dean Rasheed)

  When executing a `MERGE UPDATE` action on a partitioned table, if the `UPDATE` is turned into a `DELETE` and `INSERT` due to changing a partition key column, skip firing `AFTER UPDATE ROW` triggers, as well as other post-update actions such as RLS checks. These actions would typically fail, which is why a regular `UPDATE` doesn’t do them in such cases; `MERGE` shouldn’t either.

- Cope with `BEFORE ROW DELETE` triggers in cross-partition `MERGE` updates (Dean Rasheed)

  If such a trigger attempted to prevent the update by returning NULL, `MERGE` would suffer an error or assertion failure.

- Prevent access to a no-longer-pinned buffer in `BEFORE ROW UPDATE` triggers (Alexander Lakhin, Tom Lane)

  If the tuple being updated had just been updated and moved to another page by another session, there was a narrow window where we would attempt to fetch data from the new tuple version without any
pin on its buffer. In principle this could result in garbage data appearing in non-updated columns of the proposed new tuple. The odds of problems in practice seem rather low, however.

• Avoid requesting an oversize shared-memory area in parallel hash join (Thomas Munro, Andrei Lepikhov, Alexander Korotkov)

The limiting value was too large, allowing “invalid DSA memory alloc request size” errors to occur with sufficiently large expected hash table sizes.

• Fix corruption of local buffer state when an error occurs while trying to extend a temporary table (Tender Wang)

• Fix use of wrong tuple slot while evaluating DISTINCT aggregates that have multiple arguments (David Rowley)

This mistake could lead to errors such as “attribute 1 of type record has wrong type”.

• Avoid assertion failures in heap_update() and heap_delete() when a tuple to be updated by a foreign-key enforcement trigger fails the extra visibility crosscheck (Alexander Lakhin)

This error had no impact in non-assert builds.

• Fix overly tight assertion about false_positive_rate parameter of BRIN bloom operator classes (Alexander Lakhin)

This error had no impact in non-assert builds, either.

• Fix possible failure during ALTER TABLE ADD COLUMN on a complex inheritance tree (Tender Wang)

If a grandchild table would inherit the new column via multiple intermediate parents, the command failed with “tuple already updated by self”.

• Fix problems with duplicate token names in ALTER TEXT SEARCH CONFIGURATION ... MAPPING commands (Tender Wang, Michael Paquier)

• Fix DROP ROLE with duplicate role names (Michael Paquier)

Previously this led to a “tuple already updated by self” failure. Instead, ignore the duplicate.

• Properly lock the associated table during DROP STATISTICS (Tomas Vondra)

Failure to acquire the lock could result in “tuple concurrently deleted” errors if the DROP executes concurrently with ANALYZE.

• Fix function volatility checking for GENERATED and DEFAULT expressions (Tom Lane)

These places could fail to detect insertion of a volatile function default-argument expression, or decide that a polymorphic function is volatile although it is actually immutable on the datatype of interest. This could lead to improperly rejecting or accepting a GENERATED clause, or to mistakenly applying the constant-default-value optimization in ALTER TABLE ADD COLUMN.

• Detect that a new catalog cache entry became stale while detoasting its fields (Tom Lane)

We expand any out-of-line fields in a catalog tuple before inserting it into the catalog caches. That involves database access which might cause invalidation of catalog cache entries — but the new entry isn’t in the cache yet, so we would miss noticing that it should get invalidated. The result is a race condition in which an already-stale cache entry could get made, and then persist indefinitely. This would lead to hard-to-predict misbehavior. Fix by rechecking the tuple’s visibility after detoasting.

• Fix edge-case integer overflow detection bug on some platforms (Dean Rasheed)
Computing 0 – INT64_MIN should result in an overflow error, and did on most platforms. However, platforms with neither integer overflow builtins nor 128-bit integers would fail to spot the overflow, instead returning INT64_MIN.

- Detect Julian-date overflow when adding or subtracting an interval to/from a timestamp (Tom Lane)

Some cases that should cause an out-of-range error produced an incorrect result instead.

- Add more checks for overflow in interval_mul() and interval_div() (Dean Rasheed)

Some cases that should cause an out-of-range error produced an incorrect result instead.

- Allow scram_SaltedPassword() to be interrupted (Bowen Shi)

With large scram_iterations values, this function could take a long time to run. Allow it to be interrupted by query cancel requests.

- Ensure cached statistics are discarded after a change to stats_fetch_consistency (Shinya Kato)

In some code paths, it was possible for stale statistics to be returned.

- Make the pg_file_settings view check validity of unapplied values for settings with backend or superuser-backend context (Tom Lane)

Invalid values were not noted in the view as intended. This escaped detection because there are very few settings in these groups.

- Match collation too when matching an existing index to a new partitioned index (Peter Eisentraut)

Previously we could accept an index that has a different collation from the corresponding element of the partition key, possibly leading to misbehavior.

- Avoid failure if a child index is dropped concurrently with REINDEX INDEX on a partitioned index (Fei Changhong)

- Fix insufficient locking when cleaning up an incomplete split of a GIN index's internal page (Fei Changhong, Heikki Linnakangas)

The code tried to do this with shared rather than exclusive lock on the buffer. This could lead to index corruption if two processes attempted the cleanup concurrently.

- Avoid premature release of buffer pin in GIN index insertion (Tom Lane)

If an index root page split occurs concurrently with our own insertion, the code could fail with “buffer NNNN is not owned by resource owner”.

- Avoid failure with partitioned SP-GiST indexes (Tom Lane)

Trying to use an index of this kind could lead to “No such file or directory” errors.

- Fix ownership tests for large objects (Tom Lane)

Operations on large objects that require ownership privilege failed with “unrecognized class ID: 2613”, unless run by a superuser.

- Fix ownership change reporting for large objects (Tom Lane)

A no-op ALTER LARGE OBJECT OWNER command (that is, one selecting the existing owner) passed the wrong class ID to the PostAlterHook, probably confusing any extension using that hook.
• Fix reporting of I/O timing data in EXPLAIN (BUFFERS) (Michael Paquier)

The numbers labeled as “shared/local” actually refer only to shared buffers, so change that label to “shared”.

• Ensure durability of CREATE DATABASE (Noah Misch)

If an operating system crash occurred during or shortly after CREATE DATABASE, recovery could fail, or subsequent connections to the new database could fail. If a base backup was taken in that window, similar problems could be observed when trying to use the backup. The symptom would be that the database directory, PG_VERSION file, or pg_filenode.map file was missing or empty.

• Add more LOG messages when starting and ending recovery from a backup (Andres Freund)

This change provides additional information in the postmaster log that may be useful for diagnosing recovery problems.

• Prevent standby servers from incorrectly processing dead index tuples during subtransactions (Fei Changhong)

The startedInRecovery flag was not correctly set for a subtransaction. This affects only processing of dead index tuples. It could allow a query in a subtransaction to ignore index entries that it should return (if they are already dead on the primary server, but not dead to the standby transaction), or to prematurely mark index entries as dead that are not yet dead on the primary. It is not clear that the latter case has any serious consequences, but it's not the intended behavior.

• Fix signal handling in walreceiver processes (Heikki Linnakangas)

Revert a change that made walreceivers non-responsive to SIGTERM while waiting for the replication connection to be established.

• Fix integer overflow hazard in checking whether a record will fit into the WAL decoding buffer (Thomas Munro)

This bug appears to be only latent except when running a 32-bit PostgreSQL build on a 64-bit platform.

• Fix deadlock between a logical replication apply worker, its tablesync worker, and a session process trying to alter the subscription (Shlok Kyal)

One edge of the deadlock loop did not involve a lock wait, so the deadlock went undetected and would persist until manual intervention.

• Ensure that column default values are correctly transmitted by the pgoutput logical replication plugin (Nikhil Benesch)

ALTER TABLE ADD COLUMN with a constant default value for the new column avoids rewriting existing tuples, instead expecting that reading code will insert the correct default into a tuple that lacks that column. If replication was subsequently initiated on the table, pgoutput would transmit NULL instead of the correct default for such a column, causing incorrect replication on the subscriber.

• Fix failure of logical replication’s initial sync for a table with no columns (Vignesh C)

This case generated an improperly-formatted COPY command.

• Re-validate a subscription's connection string before use (Vignesh C)

This is meant to detect cases where a subscription was created without a password (which is allowed to superusers) but then the subscription owner is changed to a non-superuser.

• Return the correct status code when a new client disconnects without responding to the server's password challenge (Liu Lang, Tom Lane)
In some cases we'd treat this as a loggable error, which was not the intention and tends to create log spam, since common clients like psql frequently do this. It may also confuse extensions that use ClientAuthentication_hook.

- **Fix incompatibility with OpenSSL 3.2** (Tristan Partin, Bo Andreson)
  Use the BIO "app_data" field for our private storage, instead of assuming it's okay to use the "data" field. This mistake didn't cause problems before, but with 3.2 it leads to crashes and complaints about double frees.

- **Be more wary about OpenSSL not setting errno on error** (Tom Lane)
  If errno isn't set, assume the cause of the reported failure is read EOF. This fixes rare cases of strange error reports like "could not accept SSL connection: Success".

- **Fix file descriptor leakage when a foreign data wrapper's ForeignAsyncRequest function fails** (Heikki Linnakangas)

- **Fix minor memory leak in connection string validation for CREATE SUBSCRIPTION** (Jeff Davis)

- **Report ENOMEM errors from file-related system calls as ERRNAME_OUT_OF_MEMORY, not ERLCODE_INTERNAL_ERROR** (Alexander Kuzmenkov)

- **In PL/pgSQL, support SQL commands that are CREATE FUNCTION/CREATE PROCEDURE with SQL-standard bodies** (Tom Lane)
  Previously, such cases failed with parsing errors due to the semicolon(s) appearing in the function body.

- **Fix libpq's handling of errors in pipelines** (Álvaro Herrera)
  The pipeline state could get out of sync if an error is returned for reasons other than a query problem (for example, if the connection is lost). Potentially this would lead to a busy-loop in the calling application.

- **Make libpq's PQsendFlushRequest() function flush the client output buffer under the same rules as other PQsend functions** (Jelte Fennema-Nio)
  In pipeline mode, it may still be necessary to call PQflush() as well; but this change removes some inconsistency.

- **Avoid race condition when libpq initializes OpenSSL support concurrently in two different threads** (Willi Mann, Michael Paquier)

- **Fix timing-dependent failure in GSSAPI data transmission** (Tom Lane)
  When using GSSAPI encryption in non-blocking mode, libpq sometimes failed with “GSSAPI caller failed to retransmit all data needing to be retried”.

- **Change initdb to always un-comment the postgresql.conf entries for the lc_XXX parameters** (Kyotaro Horiguchi)
  initdb used to work this way before v16, and now it does again. The change caused initdb's --no-locale option to not have the intended effect on lc_messages.

- **In pg_dump, don't dump RLS policies or security labels for extension member objects** (Tom Lane, Jacob Champion)
  Previously, commands would be included in the dump to set these properties, which is really incorrect since they should be considered as internal affairs of the extension. Moreover, the restoring
user might not have adequate privilege to set them, and indeed the dumping user might not have enough privilege to dump them (since dumping RLS policies requires acquiring lock on their table).

- In pg_dump, don't dump an extended statistics object if its underlying table isn't being dumped (Rian McGuire, Tom Lane)

  This conforms to the behavior for other dependent objects such as indexes.

- Properly detect out-of-memory in one code path in pg_dump (Daniel Gustafsson)

- Make it an error for a pgbench script to end with an open pipeline (Anthonin Bonnefoy)

  Previously, pgbench would behave oddly if a `\startpipeline` command lacked a matching `\endpipeline`. This seems like a scripting mistake rather than a case that pgbench needs to handle nicely, so throw an error.

- Fix crash in contrib/intarray if an array with an element equal to INT_MAX is inserted into a gist__int_ops index (Alexander Lakhin, Tom Lane)

- Report a better error when contrib/pageinspect's `hash_bitmap_info()` function is applied to a partitioned hash index (Alexander Lakhin, Michael Paquier)

- Report a better error when contrib/pgstattuple's `pgstathashindex()` function is applied to a partitioned hash index (Alexander Lakhin)

- On Windows, suppress autorun options when launching subprocesses in pg_ctl and pg_regress (Kyotaro Horiguchi)

  When launching a child process via `cmd.exe`, pass the `/D` flag to prevent executing any autorun commands specified in the registry. This avoids possibly-surprising side effects.

- Move `is_valid_ascii()` from `mb/pg_wchar.h` to `utils/ascii.h` (Jubilee Young)

  This change avoids the need to include `<simd.h>` in `pg_wchar.h`, which was causing problems for some third-party code.

- Fix compilation failures with libxml2 version 2.12.0 and later (Tom Lane)

- Fix compilation failure of `WAL_DEBUG` code on Windows (Bharath Rupireddy)

- Suppress compiler warnings from Python's header files (Peter Eisentraut, Tom Lane)

  Our preferred compiler options provoke warnings about constructs appearing in recent versions of Python's header files. When using gcc, we can suppress these warnings with a pragma.

- Avoid deprecation warning when compiling with LLVM 18 (Thomas Munro)

- Update time zone data files to `tzdata` release 2024a for DST law changes in Greenland, Kazakhstan, and Palestine, plus corrections for the Antarctic stations Casey and Vostok. Also historical corrections for Vietnam, Toronto, and Miquelon.

### E.3. Release 16.1

**Release date:** 2023-11-09

This release contains a variety of fixes from 16.0. For information about new features in major release 16, see Section E.4.

### E.3.1. Migration to Version 16.1

A dump/restore is not required for those running 16.X.
However, several mistakes have been discovered that could lead to certain types of indexes yielding wrong search results or being unnecessarily inefficient. It is advisable to REINDEX potentially-affected indexes after installing this update. See the fourth through seventh changelog entries below.

## E.3.2. Changes

- **Fix handling of unknown-type arguments in `DISTINCT "any"` aggregate functions (Tom Lane)**
  
  This error led to a `text`-type value being interpreted as an `unknown`-type value (that is, a zero-terminated string) at runtime. This could result in disclosure of server memory following the `text` value.

  The PostgreSQL Project thanks Jingzhou Fu for reporting this problem. (CVE-2023-5868)

- **Detect integer overflow while computing new array dimensions (Tom Lane)**

  When assigning new elements to array subscripts that are outside the current array bounds, an undetected integer overflow could occur in edge cases. Memory stomps that are potentially exploitable for arbitrary code execution are possible, and so is disclosure of server memory.

  The PostgreSQL Project thanks Pedro Gallegos for reporting this problem. (CVE-2023-5869)

- **Prevent the `pg_signal_backend` role from signalling background workers and autovacuum processes (Noah Misch, Jelte Fennema-Nio)**

  The documentation says that `pg_signal_backend` cannot issue signals to superuser-owned processes. It was able to signal these background processes, though, because they advertise a role OID of zero. Treat that as indicating superuser ownership. The security implications of cancelling one of these process types are fairly small so far as the core code goes (we’ll just start another one), but extensions might add background workers that are more vulnerable.

  Also ensure that the `is_superuser` parameter is set correctly in such processes. No specific security consequences are known for that oversight, but it might be significant for some extensions.

  The PostgreSQL Project thanks Hemanth Sandrana and Mahendrakar Srinivasarao for reporting this problem. (CVE-2023-5870)

- **Fix misbehavior during recursive page split in GiST index build (Heikki Linnakangas)**

  Fix a case where the location of a page downlink was incorrectly tracked, and introduce some logic to allow recovering from such situations rather than silently doing the wrong thing. This error could result in incorrect answers from subsequent index searches. It may be advisable to reindex all GiST indexes after installing this update.

- **Prevent de-duplication of btree index entries for interval columns (Noah Misch)**

  There are `interval` values that are distinguishable but compare equal, for example `24:00:00` and `1 day`. This breaks assumptions made by btree de-duplication, so `interval` columns need to be excluded from de-duplication. This oversight can cause incorrect results from index-only scans. Moreover, after updating `amcheck` will report an error for almost all such indexes. Users should reindex any btree indexes on `interval` columns.

- **Process date values more sanely in BRIN `datetime_minmax_multi_ops` indexes (Tomas Vondra)**

  The distance calculation for dates was backward, causing poor decisions about which entries to merge. The index still produces correct results, but is much less efficient than it should be. Reindexing BRIN `minmax_multi` indexes on `date` columns is advisable.

- **Process large `timestamp` and `timestamptz` values more sanely in BRIN `datetime_minmax_multi_ops` indexes (Tomas Vondra)**
Infinities were mistakenly treated as having distance zero rather than a large distance from other values, causing poor decisions about which entries to merge. Also, finite-but-very-large values (near the endpoints of the representable timestamp range) could result in internal overflows, again causing poor decisions. The index still produces correct results, but is much less efficient than it should be. Reindexing BRIN minmax_multi indexes on timestamp and timestamptz columns is advisable if the column contains, or has contained, infinities or large finite values.

- Avoid calculation overflows in BRIN interval_minmax_multi_ops indexes with extreme interval values (Tomas Vondra)

  This bug might have caused unexpected failures while trying to insert large interval values into such an index.

- Fix partition step generation and runtime partition pruning for hash-partitioned tables with multiple partition keys (David Rowley)

  Some cases involving an IS NULL condition on one of the partition keys could result in a crash.

- Fix inconsistent rechecking of concurrently-updated rows during MERGE (Dean Rasheed)

  In READ COMMITTED mode, an update that finds that its target row was just updated by a concurrent transaction will recheck the query’s WHERE conditions on the updated row. MERGE failed to ensure that the proper rows of other joined tables were used during this recheck, possibly resulting in incorrect decisions about whether the newly-updated row should be updated again by MERGE.

- Correctly identify the target table in an inherited UPDATE/DELETE/MERGE even when the parent table is excluded by constraints (Amit Langote, Tom Lane)

  If the initially-named table is excluded by constraints, but not all its inheritance descendants are, the first non-excluded descendant was identified as the primary target table. This would lead to firing statement-level triggers associated with that table, rather than the initially-named table as should happen. In v16, the same oversight could also lead to “invalid perminfoindex 0 in RTE with relid NNNN” errors.

- Fix edge case in btree mark/restore processing of ScalarArrayOpExpr clauses (Peter Geoghegan)

  When restoring an indexscan to a previously marked position, the code could miss required setup steps if the scan had advanced exactly to the end of the matches for a ScalarArrayOpExpr (that is, an indexcol = ANY (ARRAY[])) clause. This could result in missing some rows that should have been fetched.

- Fix intra-query memory leak in Memoize execution (Orlov Aleksej, David Rowley)

- Fix intra-query memory leak when a set-returning function repeatedly returns zero rows (Tom Lane)

- Don’t crash if cursor_to_xmlschema() is applied to a non-data-returning Portal (Boyu Yang)

- Fix improper sharing of origin filter condition across successive pg_logical_slot_get_changes() calls (Hou Zhijie)

  The origin condition set by one call of this function would be re-used by later calls that did not specify the origin argument. This was not intended.

- Throw the intended error if pgrowlocks() is applied to a partitioned table (David Rowley)

  Previously, a not-on-point complaint “only heap AM is supported” would be raised.

- Handle invalid indexes more cleanly in assorted SQL functions (Noah Misch)

  Report an error if pgstatindex(), pgstatgindex(), pgstattashindex(), or pgstattuple() is applied to an invalid index. If brin_desumma-
rize_range(), brin_summarize_new_values(), brin_summarize_range(), or gin_clean_pending_list() is applied to an invalid index, do nothing except to report a debug-level message. Formerly these functions attempted to process the index, and might fail in strange ways depending on what the failed CREATE_INDEX had left behind.

- Avoid premature memory allocation failure with long inputs to to_tsvector() (Tom Lane)
- Fix over-allocation of the constructed tsvector in tsvectorrecv() (Denis Erokhin)

If the incoming vector includes position data, the binary receive function left wasted space (roughly equal to the size of the position data) in the finished tsvector. In extreme cases this could lead to “maximum total lexeme length exceeded” failures for vectors that were under the length limit when emitted. In any case it could lead to wasted space on-disk.

- Improve checks for corrupt PGLZ compressed data (Flavien Guedez)
- Fix ALTER_SUBSCRIPTION so that a commanded change in the run_as_owner option is actually applied (Hou Zhijie)
- Fix bulk table insertion into partitioned tables (Andres Freund)

Improper sharing of insertion state across partitions could result in failures during COPY FROM, typically manifesting as “could not read block NNNN in file XXXX: read only 0 of 8192 bytes” errors.

- In COPY FROM, avoid evaluating column default values that will not be needed by the command (Laurenz Albe)

This avoids a possible error if the default value isn't actually valid for the column, or if the default's expression would fail in the current execution context. Such edge cases sometimes arise while restoring dumps, for example. Previous releases did not fail in this situation, so prevent v16 from doing so.

- In COPY FROM, fail cleanly when an unsupported encoding conversion is needed (Tom Lane)

Recent refactoring accidentally removed the intended error check for this, such that it ended in “cache lookup failed for function 0” instead of a useful error message.

- Avoid crash in EXPLAIN if a parameter marked to be displayed by EXPLAIN has a NULL boot-time value (Xing Guo, Aleksander Alekseev, Tom Lane)

No built-in parameter fits this description, but an extension could define such a parameter.

- Ensure we have a snapshot while dropping ON COMMIT DROP temp tables (Tom Lane)

This prevents possible misbehavior if any catalog entries for the temp tables have fields wide enough to require toasting (such as a very complex CHECK condition).

- Avoid improper response to shutdown signals in child processes just forked by system() (Nathan Bossart)

This fix avoids a race condition in which a child process that has been forked off by system(), but hasn't yet exec'd the intended child program, might receive and act on a signal intended for the parent server process. That would lead to duplicate cleanup actions being performed, which will not end well.

- Cope with torn reads of pg_control in frontend programs (Thomas Munro)

On some file systems, reading pg_control may not be an atomic action when the server concurrently writes that file. This is detectable via a bad CRC. Retry a few times to see if the file becomes valid before we report error.
• Avoid torn reads of \texttt{pg\_control} in relevant SQL functions (Thomas Munro)

Acquire the appropriate lock before reading \texttt{pg\_control}, to ensure we get a consistent view of that file.

• Fix “could not find pathkey item to sort” errors occurring while planning aggregate functions with \texttt{ORDER BY} or \texttt{DISTINCT} options (David Rowley)

• Avoid integer overflow when computing size of backend activity string array (Jakub Wartak)

On 64-bit machines we will allow values of \texttt{track\_activity\_query\_size} large enough to cause 32-bit overflow when multiplied by the allowed number of connections. The code actually allocating the per-backend local array was careless about this though, and allocated the array incorrectly.

• Fix briefly showing inconsistent progress statistics for \texttt{ANALYZE} on inherited tables (Heikki Linnakangas)

The block-level counters should be reset to zero at the same time we update the current-relation field.

• Fix the background writer to report any WAL writes it makes to the statistics counters (Nazir Bilal Yavuz)

• Fix confusion about forced-flush behavior in \texttt{pgstat\_report\_wal()} (Ryoga Yoshida, Michael Paquier)

This could result in some statistics about WAL I/O being forgotten in a shutdown.

• Fix statistics tracking of temporary-table extensions (Karina Litskevich, Andres Freund)

These were counted as normal-table writes when they should be counted as temp-table writes.

• When \texttt{track\_io\_timing} is enabled, include the time taken by relation extension operations as write time (Nazir Bilal Yavuz)

• Track the dependencies of cached \texttt{CALL} statements, and re-plan them when needed (Tom Lane)

DDL commands, such as replacement of a function that has been inlined into a \texttt{CALL} argument, can create the need to re-plan a \texttt{CALL} that has been cached by PL/pgSQL. That was not happening, leading to misbehavior or strange errors such as “cache lookup failed”.

• Avoid a possible pfree-a-NULL-pointer crash after an error in OpenSSL connection setup (Sergey Shinderuk)

• Track nesting depth correctly when inspecting \texttt{RECORD}-type Vars from outer query levels (Richard Guo)

This oversight could lead to assertion failures, core dumps, or “bogus varno” errors.

• Track hash function and negator function dependencies of ScalarArrayOpExpr plan nodes (David Rowley)

In most cases this oversight was harmless, since these functions would be unlikely to disappear while the node’s original operator remains present.

• Fix error-handling bug in \texttt{RECORD} type cache management (Thomas Munro)

An out-of-memory error occurring at just the wrong point could leave behind inconsistent state that would lead to an infinite loop.

• Treat out-of-memory failures as fatal while reading WAL (Michael Paquier)
Previously this would be treated as a bogus-data condition, leading to the conclusion that we’d reached the end of WAL, which is incorrect and could lead to inconsistent WAL replay.

- Fix possible recovery failure due to trying to allocate memory based on a bogus WAL record length field (Thomas Munro, Michael Paquier)

- Fix “could not duplicate handle” error occurring on Windows when min_dynamic_shared_memory is set above zero (Thomas Munro)

- Fix order of operations in GenericXLogFinish (Jeff Davis)
  
  This code violated the conditions required for crash safety by writing WAL before marking changed buffers dirty. No core code uses this function, but extensions do (contrib/bloom does, for example).

- Remove incorrect assertion in PL/Python exception handling (Alexander Lakhin)

- Fix pg_dump to dump the new run_as_owner option of subscriptions (Philip Warner)
  
  Due to this oversight, subscriptions would always be restored with run_as_owner set to false, which is not equivalent to their behavior in pre-v16 releases.

- Fix pg_restore so that selective restores will include both table-level and column-level ACLs for selected tables (Euler Taveira, Tom Lane)
  
  Formerly, only the table-level ACL would get restored if both types were present.

- Add logic to pg_upgrade to check for use of abstime, reltime, and tinterval data types (Álvaro Herrera)
  
  These obsolete data types were removed in PostgreSQL version 12, so check to make sure they aren’t present in an older database before claiming it can be upgraded.

- Avoid false “too many client connections” errors in pgbench on Windows (Noah Misch)

- Fix vacuumdb’s handling of multiple -N switches (Nathan Bossart, Kuwamura Masaki)
  
  Multiple -N switches should exclude tables in multiple schemas, but in fact excluded nothing due to faulty construction of a generated query.

- Fix vacuumdb to honor its --buffer-usage-limit option in analyze-only mode (Ryoga Yoshida, David Rowley)

- In contrib/amcheck, do not report interrupted page deletion as corruption (Noah Misch)
  
  This fix prevents false-positive reports of “the first child of leftmost target page is not leftmost of its level”, “block NNNN is not leftmost” or “left link/right link pair in index XXXX not in agreement”. They appeared if amcheck ran after an unfinished btree index page deletion and before VACUUM had cleaned things up.

- Fix failure of contrib/btree_gin indexes on interval columns, when an indexscan using the < or <= operator is performed (Dean Rasheed)
  
  Such an indexscan failed to return all the entries it should.

- Add support for LLVM 16 and 17 (Thomas Munro, Dmitry Dolgov)

- Suppress assorted build-time warnings on recent macOS (Tom Lane)
  
  Xcode 15 (released with macOS Sonoma) changed the linker’s behavior in a way that causes many duplicate-library warnings while building PostgreSQL. These were harmless, but they’re annoying so avoid citing the same libraries twice. Also remove use of the -multiply_defined sup-
press linker switch, which apparently has been a no-op for a long time, and is now actively complained of.

- When building contrib/unaccent’s rules file, fall back to using python if --with-python was not given and make variable PYTHON was not set (Japin Li)
- Remove PHOT (Phoenix Islands Time) from the default timezone abbreviations list (Tom Lane)

Presence of this abbreviation in the default list can cause failures on recent Debian and Ubuntu releases, as they no longer install the underlying tzdb entry by default. Since this is a made-up abbreviation for a zone with a total human population of about two dozen, it seems unlikely that anyone will miss it. If someone does, they can put it back via a custom abbreviations file.

E.4. Release 16

Release date: 2023-09-14

E.4.1. Overview

PostgreSQL 16 contains many new features and enhancements, including:

- Allow parallelization of FULL and internal right OUTER hash joins
- Allow logical replication from standby servers
- Allow logical replication subscribers to apply large transactions in parallel
- Allow monitoring of I/O statistics using the new pg_stat_io view
- Add SQL/JSON constructors and identity functions
- Improve performance of vacuum freezing
- Add support for regular expression matching of user and database names in pg_hba.conf, and user names in pg_ident.conf

The above items and other new features of PostgreSQL 16 are explained in more detail in the sections below.

E.4.2. Migration to Version 16

A dump/restore using pg_dumpall or use of pg_upgrade or logical replication is required for those wishing to migrate data from any previous release. See Section 19.6 for general information on migrating to new major releases.

Version 16 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- Change assignment rules for PL/pgSQL bound cursor variables (Tom Lane)
  Previously, the string value of such variables was set to match the variable name during cursor assignment; now it will be assigned during OPEN, and will not match the variable name. To restore the previous behavior, assign the desired portal name to the cursor variable before OPEN.
- Disallow NULLS NOT DISTINCT indexes for primary keys (Daniel Gustafsson)
- Change REINDEX DATABASE and reindexdb to not process indexes on system catalogs (Simon Riggs)
  Processing such indexes is still possible using REINDEX SYSTEM and reindexdb --system.
• Tighten GENERATED expression restrictions on inherited and partitioned tables (Amit Langote, Tom Lane)

Columns of parent/partitioned and child/partition tables must all have the same generation status, though now the actual generation expressions can be different.

• Remove pg_walinspect functions pg_get_wal_records_info_till_end_of_wal() and pg_get_wal_stats_till_end_of_wal() (Bharath Rupireddy)

• Rename server variable force_parallel_mode to debug_parallel_query (David Rowley)

• Remove the ability to create views manually with ON SELECT rules (Tom Lane)

• Remove the server variable vacuum_defer_cleanup_age (Andres Freund)

This has been unnecessary since hot_standby_feedback and replication slots were added.

• Remove server variable promote_trigger_file (Simon Riggs)

This was used to promote a standby to primary, but is now more easily accomplished with pg_ctl promote or pg_promote().

• Remove read-only server variables lc_collate and lc_ctype (Peter Eisentraut)

Collations and locales can vary between databases so having them as read-only server variables was unhelpful.

• Role inheritance now controls the default inheritance status of member roles added during GRANT (Robert Haas)

The role's default inheritance behavior can be overridden with the new GRANT ... WITH INHERIT clause. This allows inheritance of some roles and not others because the members' inheritance status is set at GRANT time. Previously the inheritance status of member roles was controlled only by the role's inheritance status, and changes to a role's inheritance status affected all previous and future member roles.

• Restrict the privileges of CREATEROLE and its ability to modify other roles (Robert Haas)

Previously roles with CREATEROLE privileges could change many aspects of any non-superuser role. Such changes, including adding members, now require the role requesting the change to have ADMIN OPTION permission. For example, they can now change the CREATEDB, REPLICATION, and BYPASSRLS properties only if they also have those permissions.

• Remove symbolic links for the postmaster binary (Peter Eisentraut)

## E.4.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 16 and the previous major release.

### E.4.3.1. Server

#### E.4.3.1.1. Optimizer

• Allow incremental sorts in more cases, including DISTINCT (David Rowley)

• Add the ability for aggregates having ORDER BY or DISTINCT to use pre-sorted data (David Rowley)

The new server variable enable_presorted_aggregate can be used to disable this.
• Allow memoize atop a UNION ALL (Richard Guo)

• Allow anti-joins to be performed with the non-nullable input as the inner relation (Richard Guo)

• Allow parallelization of FULL and internal right OUTER hash joins (Melanie Plageman, Thomas Munro)

• Improve the accuracy of GIN index access optimizer costs (Ronan Dunklau)

**E.4.3.1.2. General Performance**

• Allow more efficient addition of heap and index pages (Andres Freund)

• During non-freeze operations, perform page freezing where appropriate (Peter Geoghegan)

  This makes full-table freeze vacuums less necessary.

• Allow window functions to use the faster ROWS mode internally when RANGE mode is active but unnecessary (David Rowley)

• Allow optimization of always-increasing window functions ntile(), cume_dist() and percent_rank() (David Rowley)

• Allow aggregate functions string_agg() and array_agg() to be parallelized (David Rowley)

• Improve performance by caching RANGE and LIST partition lookups (Amit Langote, Hou Zhijie, David Rowley)

• Allow control of the shared buffer usage by vacuum and analyze (Melanie Plageman)

  The VACUUM/ANALYZE option is BUFFER_USAGE_LIMIT, and the vacuumdb option is --buffer-usage-limit. The default value is set by server variable vacuum_buffer_usage_limit, which also controls autovacuum.

• Support wal_sync_method=fdatasync on Windows (Thomas Munro)

• Allow HOT updates if only BRIN-indexed columns are updated (Matthias van de Meent, Josef Simanek, Tomas Vondra)

• Improve the speed of updating the process title (David Rowley)

• Allow xid/subxid searches and ASCII string detection to use vector operations (Nathan Bossart, John Naylor)

  ASCII detection is particularly useful for COPY FROM. Vector operations are also used for some C array searches.

• Reduce overhead of memory allocations (Andres Freund, David Rowley)

**E.4.3.1.3. Monitoring**

• Add system view pg_stat_io view to track I/O statistics (Melanie Plageman)

• Record statistics on the last sequential and index scans on tables (Dave Page)

  This information appears in pg_stat_*_tables and pg_stat_*_indexes.

• Record statistics on the occurrence of updated rows moving to new pages (Corey Huinker)

  The pg_stat_*_tables column is n_tup_newpage_upd.
• Add speculative lock information to the pg_locks system view (Masahiko Sawada, Noriyoshi Shinoda)

  The transaction id is displayed in the transactionid column and the speculative insertion token is displayed in the objid column.

• Add the display of prepared statement result types to the pg_prepared_statements view (Dagfinn Ilmari Mannsäker)

• Create subscription statistics entries at subscription creation time so stats_reset is accurate (Andres Freund)

  Previously entries were created only when the first statistics were reported.

• Correct the I/O accounting for temp relation writes shown in pg_stat_database (Melanie Plageman)

• Add function pg_stat_get_backend_subxact() to report on a session’s subtransaction cache (Dilip Kumar)

• Have pg_stat_get_backend_idset(), pg_stat_get_backend_activity(), and related functions use the unchanging backend id (Nathan Bossart)

  Previously the index values might change during the lifetime of the session.

• Report stand-alone backends with a special backend type (Melanie Plageman)

• Add wait event SpinDelay to report spinlock sleep delays (Andres Freund)

• Create new wait event DSMAllocate to indicate waiting for dynamic shared memory allocation (Thomas Munro)

  Previously this type of wait was reported as DSMFillZeroWrite, which was also used by mmap() allocations.

• Add the database name to the process title of logical WAL senders (Tatsuhiro Nakamori)

  Physical WAL senders do not display a database name.

• Add checkpoint and REDO LSN information to log_checkpoints messages (Bharath Rupireddy, Kyotaro Horiguchi)

• Provide additional details during client certificate failures (Jacob Champion)

### E.4.3.1.4. Privileges

• Add predefined role pg_create_subscription with permission to create subscriptions (Robert Haas)

• Allow subscriptions to not require passwords (Robert Haas)

  This is accomplished with the option password_required=false.

• Simplify permissions for LOCK TABLE (Jeff Davis)

  Previously a user’s ability to perform LOCK TABLE at various lock levels was limited to the lock levels required by the commands they had permission to execute on the table. For example, someone with UPDATE permission could perform all lock levels except ACCESS SHARE, even though it was a lesser lock level. Now users can issue lesser lock levels if they already have permission for greater lock levels.

• Allow ALTER GROUP group_name ADD USER user_name to be performed with ADMIN OPTION (Robert Haas)
Previously `CREATEROLE` permission was required.

- Allow `GRANT` to use `WITH ADMIN TRUE/FALSE` syntax (Robert Haas)
  
  Previously only the `WITH ADMIN OPTION` syntax was supported.

- Allow roles that create other roles to automatically inherit the new role’s rights or the ability to `SET ROLE` to the new role (Robert Haas, Shī Yu)

  This is controlled by server variable `createrole_self_grant`.

- Prevent users from changing the default privileges of non-inherited roles (Robert Haas)

  This is now only allowed for inherited roles.

- When granting role membership, require the granted-by role to be a role that has appropriate permissions (Robert Haas)

  This is a requirement even when a non-bootstrap superuser is granting role membership.

- Allow non-superusers to grant permissions using a granted-by user that is not the current user (Robert Haas)

  The current user still must have sufficient permissions given by the specified granted-by user.

- Add `GRANT` to control permission to use `SET ROLE` (Robert Haas)

  This is controlled by a new `GRANT ... SET` option.

- Add dependency tracking to roles which have granted privileges (Robert Haas)

  For example, removing `ADMIN OPTION` will fail if there are privileges using that option; `CASCADE` must be used to revoke dependent permissions.

- Add dependency tracking of grantors for `GRANT` records (Robert Haas)

  This guarantees that `pg_auth_members.grantor` values are always valid.

- Allow multiple role membership records (Robert Haas)

  Previously a new membership grant would remove a previous matching membership grant, even if other aspects of the grant did not match.

- Prevent removal of superuser privileges for the bootstrap user (Robert Haas)

  Restoring such users could lead to errors.

- Allow `makeaclitem()` to accept multiple privilege names (Robins Tharakan)

  Previously only a single privilege name, like `SELECT`, was accepted.

### E.4.3.1.5. Server Configuration

- Add support for Kerberos credential delegation (Stephen Frost)

  This is enabled with server variable `gss_accept_delegation` and `libpq` connection parameter `gssdelegation`.

- Allow the SCRAM iteration count to be set with server variable `scram_iterations` (Daniel Gustafsson)

- Improve performance of server variable management (Tom Lane)
• Tighten restrictions on which server variables can be reset (Masahiko Sawada)

Previously, while certain variables, like transaction_isolation, were not affected by
RESET ALL, they could be individually reset in inappropriate situations.

• Move various postgresql.conf items into new categories (Shinya Kato)

This also affects the categories displayed in the pg_settings view.

• Prevent configuration file recursion beyond 10 levels (Julien Rouhaud)

• Allow autovacuum to more frequently honor changes to delay settings (Melanie Plageman)

Rather than honor changes only at the start of each relation, honor them at the start of each block.

• Remove restrictions that archive files be durably renamed (Nathan Bossart)

The archive_command command is now more likely to be called with already-archived files
after a crash.

• Prevent archive_library and archive_command from being set at the same time (Nathan Bossart)

Previously archive_library would override archive_command.

• Allow the postmaster to terminate children with an abort signal (Tom Lane)

This allows collection of a core dump for a stuck child process. This is controlled by
send_abort_for_crash and send_abort_for_kill. The postmaster's -T switch is now
the same as setting send_abort_for_crash.

• Remove the non-functional postmaster -n option (Tom Lane)

• Allow the server to reserve backend slots for roles with pg_use_reserved_connections
membership (Nathan Bossart)

The number of reserved slots is set by server variable reserved_connections.

• Allow huge pages to work on newer versions of Windows 10 (Thomas Munro)

This adds the special handling required to enable huge pages on newer versions of Windows 10.

• Add debug_io_direct setting for developer usage (Thomas Munro, Andres Freund, Bharath
Rupireddy)

While primarily for developers, wal_sync_method=open_sync/open_datasync has been
modified to not use direct I/O with wal_level=minimal; this is now enabled with de-
bug_io_direct=wal.

• Add function pg_split_walfile_name() to report the segment and timeline values of WAL
file names (Bharath Rupireddy)

**E.4.3.1.6. pg_hba.conf**

• Add support for regular expression matching on database and role entries in pg_hba.conf
(Bertrand Drouvot)

Regular expression patterns are prefixed with a slash. Database and role names that begin with
slashes need to be double-quoted if referenced in pg_hba.conf.

• Improve user-column handling of pg_ident.conf to match pg_hba.conf (Jelte Fennema)
Specifically, add support for all role membership with +, and regular expressions with a leading slash. Any user name that matches these patterns must be double-quoted.

- Allow include files in `pg_hba.conf` and `pg_ident.conf` (Julien Rouhaud)
  These are controlled by `include`, `include_if_exists`, and `include_dir`. System views `pg_hba_file_rules` and `pg_ident_file_mappings` now display the file name.

- Allow `pg_hba.conf` tokens to be of unlimited length (Tom Lane)

- Add rule and map numbers to the system view `pg_hba_file_rules` (Julien Rouhaud)

**E.4.3.1.7. Localization**

- Determine the default encoding from the locale when using ICU (Jeff Davis)
  Previously the default was always `UTF-8`.

- Have `CREATE DATABASE` and `CREATE COLLATION`'s `LOCALE` options, and `initdb` and `createdb --locale` options, control non-libc collation providers (Jeff Davis)
  Previously they only controlled libc providers.

- Add predefined collations `unicode` and `ucs_basic` (Peter Eisentraut)
  This only works if ICU support is enabled.

- Allow custom ICU collation rules to be created (Peter Eisentraut)
  This is done using `CREATE COLLATION`'s new `RULES` clause, as well as new options for `CREATE DATABASE`, `createdb`, and `initdb`.

- Allow Windows to import system locales automatically (Juan José Santamaría Flecha)

**E.4.3.2. Logical Replication**

- Allow logical decoding on standbys (Bertrand Drouvot, Andres Freund, Amit Khandekar)
  Snapshot WAL records are required for logical slot creation but cannot be created on standbys. To avoid delays, the new function `pg_log_standby_snapshot()` allows creation of such records.

- Add server variable to control how logical decoding publishers transfer changes and how subscribers apply them (Shi Yu)
  The variable is `debug_logical_replication_streaming`.

- Allow logical replication initial table synchronization to copy rows in binary format (Melih Mutlu)
  This is only possible for subscriptions marked as binary.

- Allow parallel application of logical replication (Hou Zhijie, Wang Wei, Amit Kapila)
  The `CREATE SUBSCRIPTION STREAMING` option now supports parallel to enable application of large transactions by parallel workers. The number of parallel workers is controlled by the new server variable `max_parallel_apply_workers_per_subscription`. Wait events `LogicalParallelApplyMain`, `LogicalParallelApplyStateChange`, and `LogicalApplySendData` were also added. Column `leader_pid` was added to system view `pg_stat_subscription` to track parallel activity.
• Improve performance for logical replication apply without a primary key (Onder Kalaci, Amit Kapila)

Specifically, REPLICA IDENTITY FULL can now use btree indexes rather than sequentially scanning the table to find matches.

• Allow logical replication subscribers to process only changes that have no origin (Vignesh C, Amit Kapila)

This can be used to avoid replication loops. This is controlled by the new CREATE SUBSCRIPTION ... ORIGIN option.

• Perform logical replication SELECT and DML actions as the table owner (Robert Haas)

This improves security and now requires subscription owners to be either superusers or to have SET ROLE permission on all roles owning tables in the replication set. The previous behavior of performing all operations as the subscription owner can be enabled with the subscription run_as_owner option.

• Have wal_retrieve_retry_interval operate on a per-subscription basis (Nathan Bossart)

Previously the retry time was applied globally. This also adds wait events >LogicalRepLauncherDSA and LogicalRepLauncherHash.

E.4.3.3. Utility Commands

• Add EXPLAIN option GENERIC_PLAN to display the generic plan for a parameterized query (Laurenz Albe)

• Allow a COPY FROM value to map to a column’s DEFAULT (Israel Barth Rubio)

• Allow COPY into foreign tables to add rows in batches (Andrey Lepikhov, Etsuro Fujita)

This is controlled by the postgres_fdw option batch_size.

• Allow the STORAGE type to be specified by CREATE TABLE (Teodor Sigaev, Aleksander Alekseev)

Previously only ALTER TABLE could control this.

• Allow truncate triggers on foreign tables (Yugo Nagata)

• Allow VACUUM and vacuumdb to only process TOAST tables (Nathan Bossart)

This is accomplished by having VACUUM turn off PROCESS_MAIN or by vacuumdb using the --no-process-main option.

• Add VACUUM options to skip or update all frozen statistics (Tom Lane, Nathan Bossart)

The options are SKIP_DATABASE_STATS and ONLY_DATABASE_STATS.

• Change REINDEX DATABASE and REINDEX SYSTEM to no longer require an argument (Simon Riggs)

Previously the database name had to be specified.

• Allow CREATE STATISTICS to generate a statistics name if none is specified (Simon Riggs)

E.4.3.4. Data Types

• Allow non-decimal integer literals (Peter Eisentraut)
For example, 0x42F, 0o273, and 0b100101.

- Allow NUMERIC to process hexadecimal, octal, and binary integers of any size (Dean Rasheed)
  Previously only unquoted eight-byte integers were supported with these non-decimal bases.
- Allow underscores in integer and numeric constants (Peter Eisentraut, Dean Rasheed)
  This can improve readability for long strings of digits.
- Accept the spelling +infinity in datetime input (Vik Fearing)
- Prevent the specification of epoch and infinity together with other fields in datetime strings (Joseph Koshakow)
- Remove undocumented support for date input in the form YyearMmonthDday (Joseph Koshakow)
- Add functions pg_input_is_valid() and pg_input_error_info() to check for type conversion errors (Tom Lane)

**E.4.3.5. General Queries**

- Allow subqueries in the FROM clause to omit aliases (Dean Rasheed)
- Add support for enhanced numeric literals in SQL/JSON paths (Peter Eisentraut)
  For example, allow hexadecimal, octal, and binary integers and underscores between digits.

**E.4.3.6. Functions**

- Add SQL/JSON constructors (Nikita Glukhov, Teodor Sigaev, Oleg Bartunov, Alexander Ko-rotkov, Amit Langote)
  The new functions JSON_ARRAY(), JSON_ARRAYAGG(), JSON_OBJECT(), and JSON_OB-JECTAGG() are part of the SQL standard.
- Add SQL/JSON object checks (Nikita Glukhov, Teodor Sigaev, Oleg Bartunov, Alexander Ko-rotkov, Amit Langote, Andrew Dunstan)
  The IS JSON checks include checks for values, arrays, objects, scalars, and unique keys.
- Allow JSON string parsing to use vector operations (John Naylor)
- Improve the handling of full text highlighting function ts_headline() for OR and NOT expres-
sions (Tom Lane)
- Add functions to add, subtract, and generate timestamptz values in a specified time zone (Przemsław Sztoch, Gurjeet Singh)
  The functions are date_add(), date_subtract(), and generate_series().
- Change date_trunc(unit, timestamptz, time_zone) to be an immutable function (Przemysław Sztoch)
  This allows the creation of expression indexes using this function.
- Add server variable SYSTEM_USER (Bertrand Drouvot)
  This reports the authentication method and its authenticated user.
• Add functions array_sample() and array_shuffle() (Martin Kalcher)

• Add aggregate function ANY_VALUE() which returns any value from a set (Vik Fearing)

• Add function random_normal() to supply normally-distributed random numbers (Paul Ramsey)

• Add error function erf() and its complement erfc() (Dean Rasheed)

• Improve the accuracy of numeric power() for integer exponents (Dean Rasheed)

• Add XMLSERIALIZE() option INDENT to pretty-print its output (Jim Jones)

• Change pg_collation_actual_version() to return a reasonable value for the default collation (Jeff Davis)

  Previously it returned NULL.

• Allow pg_read_file() and pg_read_binary_file() to ignore missing files (Kyotaro Horiguchi)

• Add byte specification (B) to pg_size_bytes() (Peter Eisentraut)

• Allow to_reg* functions to accept numeric OIDs as input (Tom Lane)

**E.4.3.7. PL/pgSQL**

• Add the ability to get the current function's OID in PL/pgSQL (Pavel Stehule)

  This is accomplished with GET DIAGNOSTICS variable = PG_ROUTINE_OID.

**E.4.3.8. libpq**

• Add libpq connection option require_auth to specify a list of acceptable authentication methods (Jacob Champion)

  This can also be used to disallow certain authentication methods.

• Allow multiple libpq-specified hosts to be randomly selected (Jelte Fennema)

  This is enabled with load_balance_hosts=random and can be used for load balancing.

• Add libpq option sslcertmode to control transmission of the client certificate (Jacob Champion)

  The option values are disable, allow, and require.

• Allow libpq to use the system certificate pool for certificate verification (Jacob Champion, Thomas Habets)

  This is enabled with sslrootcert=system, which also enables sslmode=verify-full.

**E.4.3.9. Client Applications**

• Allow ECPG variable declarations to use typedef names that match unreserved SQL keywords (Tom Lane)

  This change does prevent keywords which match C typedef names from being processed as keywords in later EXEC SQL blocks.

**E.4.3.9.1. psql**

• Allow psql to control the maximum width of header lines in expanded format (Platon Pronko)
This is controlled by `xheader_width`.

- Add `psql` command `\drg` to show role membership details (Pavel Luzanov)
  
The `Member of` output column has been removed from `\du` and `\dg` because this new command displays this information in more detail.

- Allow `psql`'s access privilege commands to show system objects (Nathan Bossart)
  
The options are `\dpS` and `\zS`.

- Add `FOREIGN` designation to `psql \d+` for foreign table children and partitions (Ian Lawrence Barwick)

- Prevent `\df+` from showing function source code (Isaac Morland)
  
Function bodies are more easily viewed with `\sf`.

- Allow `psql` to submit queries using the extended query protocol (Peter Eisentraut)
  
Passing arguments to such queries is done using the new `psql \bind` command.

- Allow `psql \watch` to limit the number of executions (Andrey Borodin)
  
The `\watch` options can now be named when specified.

- Detect invalid values for `psql \watch`, and allow zero to specify no delay (Andrey Borodin)

- Allow `psql` scripts to obtain the exit status of shell commands and queries (Corey Huinker, Tom Lane)
  
The new `psql` control variables are `SHELL_ERROR` and `SHELL.EXIT_CODE`.

- Various `psql` tab completion improvements (Vignesh C, Aleksander Alekseev, Dagfinn Ilmari Mannsäker, Shi Yu, Michael Paquier, Ken Kato, Peter Smith)

  **E.4.3.9.2. pg_dump**

  - Add `pg_dump` control of dumping child tables and partitions (Gilles Darold)
    

  - Add LZ4 and Zstandard compression to `pg_dump` (Georgios Kokolatos, Justin Pryzby)

  - Allow `pg_dump` and `pg_basebackup` to use `long` mode for compression (Justin Pryzby)

  - Improve `pg_dump` to accept a more consistent compression syntax (Georgios Kokolatos)
    
    Options like `--compress=gzip:5`.

  **E.4.3.10. Server Applications**

  - Add `initdb` option to set server variables for the duration of `initdb` and all future server starts (Tom Lane)
    
    The option is `-c name=value`.

  - Add options to `createuser` to control more user options (Shinya Kato)
    
    Specifically, the new options control the valid-until date, bypassing of row-level security, and role membership.
• Deprecate createuser --role (Nathan Bossart)

This option could be easily confused with new createuser role membership options, so option --member-of has been added with the same functionality. The --role option can still be used.

• Allow control of vacuumdb schema processing (Gilles Darold)

These are controlled by options --schema and --exclude-schema.

• Use new VACUUM options to improve the performance of vacuumdb (Tom Lane, Nathan Bossart)

• Have pg_upgrade set the new cluster's locale and encoding (Jeff Davis)

This removes the requirement that the new cluster be created with the same locale and encoding settings.

• Add pg_upgrade option to specify the default transfer mode (Peter Eisentraut)

The option is --copy.

• Improve pg_basebackup to accept numeric compression options (Georgios Kokolatos, Michael Paquier)

Options like --compress=server-5 are now supported.

• Fix pg_basebackup to handle tablespaces stored in the PGDATA directory (Robert Haas)

• Add pg_waldump option --save-fullpage to dump full page images (David Christensen)

• Allow pg_waldump options -t/--timeline to accept hexadecimal values (Peter Eisentraut)

• Add support for progress reporting to pg_verifybackup (Masahiko Sawada)

• Allow pg_rewind to properly track timeline changes (Heikki Linnakangas)

Previously if pg_rewind was run after a timeline switch but before a checkpoint was issued, it might incorrectly determine that a rewind was unnecessary.

• Have pg_receivewal and pg_recvlogical cleanly exit on SIGTERM (Christoph Berg)

This signal is often used by systemd.

E.4.3.11. Source Code

• Build ICU support by default (Jeff Davis)

This removes build flag --with-icu and adds flag --without-icu.

• Add support for SSE2 (Streaming SIMD Extensions 2) vector operations on x86-64 architectures (John Naylor)

• Add support for Advanced SIMD (Single Instruction Multiple Data) (NEON) instructions on ARM architectures (Nathan Bossart)

• Have Windows binaries built with MSVC use RandomizedBaseAddress (ASLR) (Michael Paquier)

This was already enabled on MinGW builds.

• Prevent extension libraries from exporting their symbols by default (Andres Freund, Tom Lane)

Functions that need to be called from the core backend or other extensions must now be explicitly marked PGDLEXPORT.
• Require Windows 10 or newer versions (Michael Paquier, Juan José Santamaría Flecha)
  Previously Windows Vista and Windows XP were supported.
• Require Perl version 5.14 or later (John Naylor)
• Require Bison version 2.3 or later (John Naylor)
• Require Flex version 2.5.35 or later (John Naylor)
• Require MIT Kerberos for GSSAPI support (Stephen Frost)
• Remove support for Visual Studio 2013 (Michael Paquier)
• Remove support for HP-UX (Thomas Munro)
• Remove support for HP/Intel Itanium (Thomas Munro)
• Remove support for M68K, M88K, M32R, and SuperH CPU architectures (Thomas Munro)
• Remove libpq support for SCM credential authentication (Michael Paquier)
  Backend support for this authentication method was removed in PostgresSQL 9.1.
• Add meson build system (Andres Freund, Nazir Bilal Yavuz, Peter Eisentraut)
  This eventually will replace the Autoconf and Windows-based MSVC build systems.
• Add pgindent options (Andrew Dunstan)
  The new options are --show-diff, --silent-diff, --commit, and --help, and allow multiple --exclude options. Also require the typedef file to be explicitly specified. Options --code-base and --build were also removed.
• Add pg_bsd_indent source code to the main tree (Tom Lane)
• Improve make_ctags and make_etags (Yugo Nagata)
  Adjust pg_attribute columns for efficiency (Peter Eisentraut)

E4.3.12. Additional Modules

• Improve use of extension-based indexes on boolean columns (Zongliang Quan, Tom Lane)
• Add support for Daitch-Mokotoff Soundex to fuzzystrmatch (Dag Lem)
• Allow auto_explain to log values passed to parameterized statements (Dagfinn Ilmari Mannsäker)
  This affects queries using server-side PREPARE/EXECUTE and client-side parse/bind. Logging is controlled by auto_explain.log_parameter_max_length; by default query parameters will be logged with no length restriction.
• Have auto_explain’s log_verbose mode honor the value of compute_query_id (Atsushi Torikoshi)
Previously even if `compute_query_id` was enabled, `log_verbose` was not showing the query identifier.

- Change the maximum length of ltree labels from 256 to 1000 and allow hyphens (Garen Torikian)
- Have `pg_stat_statements` normalize constants used in utility commands (Michael Paquier)

Previously constants appeared instead of placeholders, e.g., $1$.

- Add `pg_walinspect` function `pg_get_wal_block_info()` to report WAL block information (Michael Paquier, Melanie Plageman, Bharath Rupireddy)
- Change how `pg_walinspect` functions `pg_get_wal_records_info()` and `pg_get_wal_stats()` interpret ending LSNs (Bharath Rupireddy)

Previously ending LSNs which represent nonexistent WAL locations would generate an error, while they will now be interpreted as the end of the WAL.

- Add detailed descriptions of WAL records in `pg_walinspect` and `pg_waldump` (Melanie Plageman, Peter Geoghegan)
- Add `pageinspect` function `bt_multi_page_stats()` to report statistics on multiple pages (Hamid Akhtar)

This is similar to `bt_page_stats()` except it can report on a range of pages.

- Add empty range output column to `pageinspect` function `brin_page_items()` (Tomas Vondra)
- Redesign archive modules to be more flexible (Nathan Bossart)

Initialization changes will require modules written for older versions of Postgres to be updated.

- Correct inaccurate `pg_stat_statements` row tracking extended query protocol statements (Sami Imseih)
- Add `pg_buffercache` function `pg_buffercache_usage_counts()` to report usage totals (Nathan Bossart)
- Add `pg_buffercache` function `pg_buffercache_summary()` to report summarized buffer statistics (Melih Mutlu)
- Allow the schemas of required extensions to be referenced in extension scripts using the new syntax `@extschema:referenced_extension_name@` (Regina Obe)
- Allow required extensions to be marked as non-relocatable using `no_relocate` (Regina Obe)

This allows `@extschema:referenced_extension_name@` to be treated as a constant for the lifetime of the extension.

### E.4.3.12.1. `postgres_fdw`

- Allow `postgres_fdw` to do aborts in parallel (Etsuro Fujita)

  This is enabled with `postgres_fdw` option `parallel_abort`.

- Make `ANALYZE` on foreign `postgres_fdw` tables more efficient (Tomas Vondra)

  The `postgres_fdw` option `analyze_sampling` controls the sampling method.

- Restrict shipment of `reg*` type constants in `postgres_fdw` to those referencing built-in objects or extensions marked as shippable (Tom Lane)

- Have `postgres_fdw` and `dblink` handle interrupts during connection establishment (Andres Freund)
E.4.4. Acknowledgments

E.5. Prior Releases

Release notes for prior release branches can be found at https://www.postgresql.org/docs/release/
Appendix F. Additional Supplied Modules and Extensions

This appendix and the next one contain information on the optional components found in the contrib directory of the PostgreSQL distribution. These include porting tools, analysis utilities, and plug-in features that are not part of the core PostgreSQL system. They are separate mainly because they address a limited audience or are too experimental to be part of the main source tree. This does not preclude their usefulness.

This appendix covers extensions and other server plug-in module libraries found in contrib. Appendix G covers utility programs.

When building from the source distribution, these optional components are not built automatically, unless you build the "world" target (see Step 2). You can build and install all of them by running:

```
make
make install
```

in the contrib directory of a configured source tree; or to build and install just one selected module, do the same in that module's subdirectory. Many of the modules have regression tests, which can be executed by running:

```
make check
```

before installation or

```
make installcheck
```

once you have a PostgreSQL server running.

If you are using a pre-packaged version of PostgreSQL, these components are typically made available as a separate subpackage, such as postgresql-contrib.

Many components supply new user-defined functions, operators, or types, packaged as extensions. To make use of one of these extensions, after you have installed the code you need to register the new SQL objects in the database system. This is done by executing a CREATE EXTENSION command.

In a fresh database, you can simply do

```
CREATE EXTENSION extension_name;
```

This command registers the new SQL objects in the current database only, so you need to run it in every database in which you want the extension's facilities to be available. Alternatively, run it in database template1 so that the extension will be copied into subsequently-created databases by default.

For all extensions, the CREATE EXTENSION command must be run by a database superuser, unless the extension is considered "trusted". Trusted extensions can be run by any user who has CREATE privilege on the current database. Extensions that are trusted are identified as such in the sections that follow. Generally, trusted extensions are ones that cannot provide access to outside-the-database functionality.

The following extensions are trusted in a default installation:

- btree_gin
- btree_gist
- fuzzystrmatch
- hstore
- ltrees
- pgcrypto
- tcn
- tsm_system_rows

2665
### Additional Supplied Modules and Extensions

<table>
<thead>
<tr>
<th>Module</th>
<th>Module</th>
<th>Module</th>
<th>Module</th>
</tr>
</thead>
<tbody>
<tr>
<td>citext</td>
<td>intarray</td>
<td>pg_trgm</td>
<td>tsm_system_time</td>
</tr>
<tr>
<td>cube</td>
<td>isn</td>
<td>seg</td>
<td>unaccent</td>
</tr>
<tr>
<td>dict_int</td>
<td>lo</td>
<td>tablefunc</td>
<td>uuid-ossp</td>
</tr>
</tbody>
</table>

Many extensions allow you to install their objects in a schema of your choice. To do that, add `SCHEMA schema_name` to the `CREATE EXTENSION` command. By default, the objects will be placed in your current creation target schema, which in turn defaults to `public`.

Note, however, that some of these components are not "extensions" in this sense, but are loaded into the server in some other way, for instance by way of `shared_preload_libraries`. See the documentation of each component for details.
F.1. adminpack — pgAdmin support toolpack

adminpack provides a number of support functions which pgAdmin and other administration and management tools can use to provide additional functionality, such as remote management of server log files. Use of all these functions is only allowed to database superusers by default, but may be allowed to other users by using the `GRANT` command.

The functions shown in Table F.1 provide write access to files on the machine hosting the server. (See also the functions in Table 9.101, which provide read-only access.) Only files within the database cluster directory can be accessed, unless the user is a superuser or given privileges of one of the `pg_read_server_files` or `pg_write_server_files` roles, as appropriate for the function, but either a relative or absolute path is allowable.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pg_catalog.pg_file_write(filename text, data text, append boolean) → bigint</code></td>
<td>Writes, or appends to, a text file.</td>
</tr>
<tr>
<td><code>pg_catalog.pg_file_sync(filename text) → void</code></td>
<td>Flushes a file or directory to disk.</td>
</tr>
<tr>
<td><code>pg_catalog.pg_file_rename(oldname text, newname text [, archivename text ]) → boolean</code></td>
<td>Renames a file.</td>
</tr>
<tr>
<td><code>pg_catalog.pg_file_unlink(filename text) → boolean</code></td>
<td>Removes a file.</td>
</tr>
<tr>
<td><code>pg_catalog.pg_logdir_ls() → setof record</code></td>
<td>Lists the log files in the log_directory directory.</td>
</tr>
</tbody>
</table>

`pg_file_write` writes the specified `data` into the file named by `filename`. If `append` is false, the file must not already exist. If `append` is true, the file can already exist, and will be appended to if so. Returns the number of bytes written.

`pg_file_sync` fsyncs the specified file or directory named by `filename`. An error is thrown on failure (e.g., the specified file is not present). Note that data sync retry has no effect on this function, and therefore a PANIC-level error will not be raised even on failure to flush database files.

`pg_file_rename` renames a file. If `archivename` is omitted or NULL, it simply renames `oldname` to `newname` (which must not already exist). If `archivename` is provided, it first renames `newname` to `archivename` (which must not already exist), and then renames `oldname` to `newname`. In event of failure of the second rename step, it will try to rename `archivename` back to `newname` before reporting the error. Returns true on success, false if the source file(s) are not present or not writable; other cases throw errors.

`pg_file_unlink` removes the specified file. Returns true on success, false if the specified file is not present or the `unlink()` call fails; other cases throw errors.

`pg_logdir_ls` returns the start timestamps and path names of all the log files in the log_directory directory. The `log_filename` parameter must have its default setting (`postgresql-%Y-%m-%d_%H%M%S.log`) to use this function.
### F.2. amcheck — tools to verify table and index consistency

The `amcheck` module provides functions that allow you to verify the logical consistency of the structure of relations.

The B-Tree checking functions verify various *invariants* in the structure of the representation of particular relations. The correctness of the access method functions behind index scans and other important operations relies on these invariants always holding. For example, certain functions verify, among other things, that all B-Tree pages have items in “logical” order (e.g., for B-Tree indexes on `text`, index tuples should be in collated lexical order). If that particular invariant somehow fails to hold, we can expect binary searches on the affected page to incorrectly guide index scans, resulting in wrong answers to SQL queries. If the structure appears to be valid, no error is raised.

Verification is performed using the same procedures as those used by index scans themselves, which may be user-defined operator class code. For example, B-Tree index verification relies on comparisons made with one or more B-Tree support function 1 routines. See Section 38.16.3 for details of operator class support functions.

Unlike the B-Tree checking functions which report corruption by raising errors, the heap checking function `verify_heapam` checks a table and attempts to return a set of rows, one row per corruption detected. Despite this, if facilities that `verify_heapam` relies upon are themselves corrupted, the function may be unable to continue and may instead raise an error.

Permission to execute `amcheck` functions may be granted to non-superusers, but before granting such permissions careful consideration should be given to data security and privacy concerns. Although the corruption reports generated by these functions do not focus on the contents of the corrupted data so much as on the structure of that data and the nature of the corruptions found, an attacker who gains permission to execute these functions, particularly if the attacker can also induce corruption, might be able to infer something of the data itself from such messages.

#### F.2.1. Functions

The `bt_index_check` function tests that its target, a B-Tree index, respects a variety of invariants. Example usage:

```sql

test=# SELECT bt_index_check(index => c.oid, heapallindexed =>
                   i.indisunique),
                   c.relname,
                   c.relpages
               FROM pg_index i
             JOIN pg_opclass op ON i.indclass[0] = op.oid
             JOIN pg_am am ON op.opcmethod = am.oid
             JOIN pg_class c ON i.indexrelid = c.oid
             JOIN pg_namespace n ON c.relnamespace = n.oid
             WHERE am.amname = 'btree' AND n.nspname = 'pg_catalog'
             -- Don't check temp tables, which may be from another session:
             AND c.relpersistence != 't'
             -- Function may throw an error when this is omitted:
             AND c.relkind = 'i' AND i.indisready AND i.indisvalid
             ORDER BY c.relpages DESC LIMIT 10;
```

<table>

<td>43</td>
</tr>
</tbody>
</table>
This example shows a session that performs verification of the 10 largest catalog indexes in the database “test”. Verification of the presence of heap tuples as index tuples is requested for the subset that are unique indexes. Since no error is raised, all indexes tested appear to be logically consistent. Naturally, this query could easily be changed to call `bt_index_check` for every index in the database where verification is supported.

`bt_index_check` acquires an `AccessShareLock` on the target index and the heap relation it belongs to. This lock mode is the same lock mode acquired on relations by simple `SELECT` statements. `bt_index_check` does not verify invariants that span child/parent relationships, but will verify the presence of all heap tuples as index tuples within the index when `heapallindexed` is true. When a routine, lightweight test for corruption is required in a live production environment, using `bt_index_check` often provides the best trade-off between thoroughness of verification and limiting the impact on application performance and availability.

`bt_index_parent_check(index regclass, heapallindexed boolean, root-descend boolean) returns void`

`bt_index_parent_check` tests that its target, a B-Tree index, respects a variety of invariants. Optionally, when the `heapallindexed` argument is true, the function verifies the presence of all heap tuples that should be found within the index. When the optional `rootdescend` argument is true, verification re-finds tuples on the leaf level by performing a new search from the root page for each tuple. The checks that can be performed by `bt_index_parent_check` are a superset of the checks that can be performed by `bt_index_check`. `bt_index_parent_check` can be thought of as a more thorough variant of `bt_index_check`: unlike `bt_index_check`, `bt_index_parent_check` also checks invariants that span parent/child relationships, including checking that there are no missing downlinks in the index structure. `bt_index_parent_check` follows the general convention of raising an error if it finds a logical inconsistency or other problem.

A `ShareLock` is required on the target index by `bt_index_parent_check` (a `ShareLock` is also acquired on the heap relation). These locks prevent concurrent data modification from `INSERT`, `UPDATE`, and `DELETE` commands. The locks also prevent the underlying relation from being concurrently processed by `VACUUM`, as well as all other utility commands. Note that the function holds locks only while running, not for the entire transaction.

`bt_index_parent_check`'s additional verification is more likely to detect various pathological cases. These cases may involve an incorrectly implemented B-Tree operator class used by the index that is checked, or, hypothetically, undiscovered bugs in the underlying B-Tree index access method code. Note that `bt_index_parent_check` cannot be used when hot standby mode is enabled (i.e., on read-only physical replicas), unlike `bt_index_check`.

**Tip**

`bt_index_check` and `bt_index_parent_check` both output log messages about the verification process at `DEBUG1` and `DEBUG2` severity levels. These messages provide detailed information about the verification process that may be of interest to PostgreSQL developers. Advanced users may also find this information helpful, since it provides additional context should verification actually detect an inconsistency. Running:
SET client_min_messages = DEBUG1;

in an interactive psql session before running a verification query will display messages about
the progress of verification with a manageable level of detail.

verify_heapam(relation regclass, on_error_stop boolean, check_toast
boolean, skip text, startblock bigint, endblock bigint, blkno OUT
bigint, offnum OUT integer, attnum OUT integer, msg OUT text) returns
setof record

Checks a table, sequence, or materialized view for structural corruption, where pages in the re-
lation contain data that is invalidly formatted, and for logical corruption, where pages are struc-
turally valid but inconsistent with the rest of the database cluster.

The following optional arguments are recognized:

on_error_stop

If true, corruption checking stops at the end of the first block in which any corruptions are
found.

Defaults to false.

check_toast

If true, toasted values are checked against the target relation's TOAST table.

This option is known to be slow. Also, if the toast table or its index is corrupt, checking it
against toast values could conceivably crash the server, although in many cases this would
just produce an error.

Defaults to false.

skip

If not none, corruption checking skips blocks that are marked as all-visible or all-frozen, as
specified. Valid options are all-visible, all-frozen and none.

Defaults to none.

startblock

If specified, corruption checking begins at the specified block, skipping all previous blocks.
It is an error to specify a startblock outside the range of blocks in the target table.

By default, checking begins at the first block.

endblock

If specified, corruption checking ends at the specified block, skipping all remaining blocks.
It is an error to specify an endblock outside the range of blocks in the target table.

By default, all blocks are checked.

For each corruption detected, verify_heapam returns a row with the following columns:

blkno

The number of the block containing the corrupt page.
offnum
The OffsetNumber of the corrupt tuple.

attnum
The attribute number of the corrupt column in the tuple, if the corruption is specific to a column and not the tuple as a whole.

msg
A message describing the problem detected.

F.2.2. Optional heapallindexed Verification

When the heapallindexed argument to B-Tree verification functions is true, an additional phase of verification is performed against the table associated with the target index relation. This consists of a “dummy” CREATE INDEX operation, which checks for the presence of all hypothetical new index tuples against a temporary, in-memory summarizing structure (this is built when needed during the basic first phase of verification). The summarizing structure “fingerprint” every tuple found within the target index. The high level principle behind heapallindexed verification is that a new index that is equivalent to the existing, target index must only have entries that can be found in the existing structure.

The additional heapallindexed phase adds significant overhead: verification will typically take several times longer. However, there is no change to the relation-level locks acquired when heapallindexed verification is performed.

The summarizing structure is bound in size by maintenance_work_mem. In order to ensure that there is no more than a 2% probability of failure to detect an inconsistency for each heap tuple that should be represented in the index, approximately 2 bytes of memory are needed per tuple. As less memory is made available per tuple, the probability of missing an inconsistency slowly increases. This approach limits the overhead of verification significantly, while only slightly reducing the probability of detecting a problem, especially for installations where verification is treated as a routine maintenance task. Any single absent or malformed tuple has a new opportunity to be detected with each new verification attempt.

F.2.3. Using amcheck Effectively

amcheck can be effective at detecting various types of failure modes that data checksums will fail to catch. These include:

- Structural inconsistencies caused by incorrect operator class implementations.

  This includes issues caused by the comparison rules of operating system collations changing. Comparisons of datums of a collatable type like text must be immutable (just as all comparisons used for B-Tree index scans must be immutable), which implies that operating system collation rules must never change. Though rare, updates to operating system collation rules can cause these issues. More commonly, an inconsistency in the collation order between a primary server and a standby server is implicated, possibly because the major operating system version in use is inconsistent. Such inconsistencies will generally only arise on standby servers, and so can generally only be detected on standby servers.

  If a problem like this arises, it may not affect each individual index that is ordered using an affected collation, simply because indexed values might happen to have the same absolute ordering regardless of the behavioral inconsistency. See Section 24.1 and Section 24.2 for further details about how PostgreSQL uses operating system locales and collations.

- Structural inconsistencies between indexes and the heap relations that are indexed (when heapallindexed verification is performed).
There is no cross-checking of indexes against their heap relation during normal operation. Symptoms of heap corruption can be subtle.

- Corruption caused by hypothetical undiscovered bugs in the underlying PostgreSQL access method code, sort code, or transaction management code.

Automatic verification of the structural integrity of indexes plays a role in the general testing of new or proposed PostgreSQL features that could plausibly allow a logical inconsistency to be introduced. Verification of table structure and associated visibility and transaction status information plays a similar role. One obvious testing strategy is to call `amcheck` functions continuously when running the standard regression tests. See Section 33.1 for details on running the tests.

- File system or storage subsystem faults where checksums happen to simply not be enabled.

Note that `amcheck` examines a page as represented in some shared memory buffer at the time of verification if there is only a shared buffer hit when accessing the block. Consequently, `amcheck` does not necessarily examine data read from the file system at the time of verification. Note that when checksums are enabled, `amcheck` may raise an error due to a checksum failure when a corrupt block is read into a buffer.

- Corruption caused by faulty RAM, or the broader memory subsystem.

PostgreSQL does not protect against correctable memory errors and it is assumed you will operate using RAM that uses industry standard Error Correcting Codes (ECC) or better protection. However, ECC memory is typically only immune to single-bit errors, and should not be assumed to provide absolute protection against failures that result in memory corruption.

When `heapallindexed` verification is performed, there is generally a greatly increased chance of detecting single-bit errors, since strict binary equality is tested, and the indexed attributes within the heap are tested.

Structural corruption can happen due to faulty storage hardware, or relation files being overwritten or modified by unrelated software. This kind of corruption can also be detected with data page checksums.

Relation pages which are correctly formatted, internally consistent, and correct relative to their own internal checksums may still contain logical corruption. As such, this kind of corruption cannot be detected with checksums. Examples include toasted values in the main table which lack a corresponding entry in the toast table, and tuples in the main table with a Transaction ID that is older than the oldest valid Transaction ID in the database or cluster.

Multiple causes of logical corruption have been observed in production systems, including bugs in the PostgreSQL server software, faulty and ill-conceived backup and restore tools, and user error.

Corrupt relations are most concerning in live production environments, precisely the same environments where high risk activities are least welcome. For this reason, `verify_heapam` has been designed to diagnose corruption without undue risk. It cannot guard against all causes of backend crashes, as even executing the calling query could be unsafe on a badly corrupted system. Access to catalog tables is performed and could be problematic if the catalogs themselves are corrupted.

In general, `amcheck` can only prove the presence of corruption; it cannot prove its absence.

### F.2.4. Repairing Corruption

No error concerning corruption raised by `amcheck` should ever be a false positive. `amcheck` raises errors in the event of conditions that, by definition, should never happen, and so careful analysis of `amcheck` errors is often required.

There is no general method of repairing problems that `amcheck` detects. An explanation for the root cause of an invariant violation should be sought. `pageinspect` may play a useful role in diagnosing corruption that `amcheck` detects. A `REINDEX` may not be effective in repairing corruption.
F.3. auth_delay — pause on authentication failure

auth_delay causes the server to pause briefly before reporting authentication failure, to make brute-force attacks on database passwords more difficult. Note that it does nothing to prevent denial-of-service attacks, and may even exacerbate them, since processes that are waiting before reporting authentication failure will still consume connection slots.

In order to function, this module must be loaded via shared_preload_libraries in postgresql.conf.

F.3.1. Configuration Parameters

auth_delay.milliseconds (integer)

The number of milliseconds to wait before reporting an authentication failure. The default is 0.

These parameters must be set in postgresql.conf. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'auth_delay'
auth_delay.milliseconds = '500'
```

F.3.2. Author

KaiGai Kohei <kaigai@ak.jp.nec.com>
F.4. auto_explain — log execution plans of slow queries

The auto_explain module provides a means for logging execution plans of slow statements automatically, without having to run EXPLAIN by hand. This is especially helpful for tracking down un-optimized queries in large applications.

The module provides no SQL-accessible functions. To use it, simply load it into the server. You can load it into an individual session:

```
LOAD 'auto_explain';
```

(You must be superuser to do that.) More typical usage is to preload it into some or all sessions by including `auto_explain` in `session_preload_libraries` or `shared_preload_libraries` in `postgresql.conf`. Then you can track unexpectedly slow queries no matter when they happen. Of course there is a price in overhead for that.

F.4.1. Configuration Parameters

There are several configuration parameters that control the behavior of auto_explain. Note that the default behavior is to do nothing, so you must set at least `auto_explain.log_min_duration` if you want any results.

`auto_explain.log_min_duration(integer)`

`auto_explain.log_min_duration` is the minimum statement execution time, in milliseconds, that will cause the statement's plan to be logged. Setting this to 0 logs all plans. -1 (the default) disables logging of plans. For example, if you set it to 250ms then all statements that run 250ms or longer will be logged. Only superusers can change this setting.

`auto_explain.log_parameter_max_length(integer)`

`auto_explain.log_parameter_max_length` controls the logging of query parameter values. A value of -1 (the default) logs the parameter values in full. 0 disables logging of parameter values. A value greater than zero truncates each parameter value to that many bytes. Only superusers can change this setting.

`auto_explain.log_analyze(boolean)`

`auto_explain.log_analyze` causes EXPLAIN ANALYZE output, rather than just EXPLAIN output, to be printed when an execution plan is logged. This parameter is off by default. Only superusers can change this setting.

```
Note

When this parameter is on, per-plan-node timing occurs for all statements executed, whether or not they run long enough to actually get logged. This can have an extremely negative impact on performance. Turning off auto_explain.log_timing ameliorates the performance cost, at the price of obtaining less information.
```

`auto_explain.log_buffers(boolean)`

`auto_explain.log_buffers` controls whether buffer usage statistics are printed when an execution plan is logged; it's equivalent to the `BUFFERS` option of EXPLAIN. This parameter has
no effect unless auto_explain.log_analyze is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_wal(boolean)`

`auto_explain.log_wal` controls whether WAL usage statistics are printed when an execution plan is logged; it's equivalent to the WAL option of EXPLAIN. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_timing(boolean)`

`auto_explain.log_timing` controls whether per-node timing information is printed when an execution plan is logged; it's equivalent to the TIMING option of EXPLAIN. The overhead of repeatedly reading the system clock can slow down queries significantly on some systems, so it may be useful to set this parameter to off when only actual row counts, and not exact times, are needed. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is on by default. Only superusers can change this setting.

`auto_explain.log_triggers(boolean)`

`auto_explain.log_triggers` causes trigger execution statistics to be included when an execution plan is logged. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.logVerbose(boolean)`

`auto_explain.logVerbose` controls whether verbose details are printed when an execution plan is logged; it's equivalent to the VERBOSE option of EXPLAIN. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_settings(boolean)`

`auto_explain.log_settings` controls whether information about modified configuration options is printed when an execution plan is logged. Only options affecting query planning with value different from the built-in default value are included in the output. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_format(enum)`

`auto_explain.log_format` selects the EXPLAIN output format to be used. The allowed values are `text`, `xml`, `json`, and `yaml`. The default is `text`. Only superusers can change this setting.

`auto_explain.log_level(enum)`

`auto_explain.log_level` selects the log level at which auto_explain will log the query plan. Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `INFO`, `NOTICE`, `WARNING`, and `LOG`. The default is `LOG`. Only superusers can change this setting.

`auto_explain.log_nested_statements(boolean)`

`auto_explain.log_nested_statements` causes nested statements (statements executed inside a function) to be considered for logging. When it is off, only top-level query plans are logged. This parameter is off by default. Only superusers can change this setting.

`auto_explain.sample_rate(real)`

`auto_explain.sample_rate` causes auto_explain to only explain a fraction of the statements in each session. The default is 1, meaning explain all the queries. In case of nested statements, either all will be explained or none. Only superusers can change this setting.
In ordinary usage, these parameters are set in `postgresql.conf`, although superusers can alter them on-the-fly within their own sessions. Typical usage might be:

```sql
# postgresql.conf
session_preload_libraries = 'auto_explain'

auto_explain.log_min_duration = '3s'
```

**F.4.2. Example**

```
postgres=# LOAD 'auto_explain';
postgres=# SET auto_explain.log_min_duration = 0;
postgres=# SET auto_explain.log_analyze = true;
postgres=# SELECT count(*)
    FROM pg_class, pg_index
    WHERE oid = indrelid AND indisunique;
```

This might produce log output such as:

```
LOG: duration: 3.651 ms plan:
    Query Text: SELECT count(*)
        FROM pg_class, pg_index
        WHERE oid = indrelid AND indisunique;
    Aggregate (cost=16.79..16.80 rows=1 width=0) (actual time=3.626..3.627 rows=1 loops=1)
        -> Hash Join (cost=4.17..16.55 rows=92 width=0) (actual time=3.349..3.594 rows=92 loops=1)
            Hash Cond: (pg_class.oid = pg_index.indrelid)
            -> Seq Scan on pg_class (cost=0.00..9.55 rows=255 width=4) (actual time=0.016..0.140 rows=255 loops=1)
            -> Hash (cost=3.02..3.02 rows=92 width=4) (actual time=3.238..3.238 rows=92 loops=1)
                Buckets: 1024  Batches: 1  Memory Usage: 4kB
                Filter: indisunique
```

**F.4.3. Author**

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>
F.5. basebackup_to_shell — example "shell"
pg_basebackup module

basebackup_to_shell adds a custom basebackup target called shell. This makes it possible
to run pg_basebackup --target=shell or, depending on how this module is configured,
pg_basebackup --target=shell:DETAIL_STRING, and cause a server command chosen
by the server administrator to be executed for each tar archive generated by the backup process. The
command will receive the contents of the archive via standard input.

This module is primarily intended as an example of how to create a new backup targets via an extension
module, but in some scenarios it may be useful for its own sake. In order to function, this module must
be loaded via shared_preload_libraries or local_preload_libraries.

F.5.1. Configuration Parameters

basebackup_to_shell.command (string)

The command which the server should execute for each archive generated by the backup process.
If %f occurs in the command string, it will be replaced by the name of the archive (e.g.
base.tar). If %d occurs in the command string, it will be replaced by the target detail provid-
ed by the user. A target detail is required if %d is used in the command string, and prohibited
otherwise. For security reasons, it may contain only alphanumeric characters. If %% occurs in the
command string, it will be replaced by a single %. If % occurs in the command string followed by
any other character or at the end of the string, an error occurs.

basebackup_to_shell.required_role (string)

The role required in order to make use of the shell backup target. If this is not set, any replication
user may make use of the shell backup target.

F.5.2. Author

Robert Haas <rhaas@postgresql.org>
F.6. basic_archive — an example WAL archive module

basic_archive is an example of an archive module. This module copies completed WAL segment files to the specified directory. This may not be especially useful, but it can serve as a starting point for developing your own archive module. For more information about archive modules, see Chapter 51.

In order to function, this module must be loaded via archive_library, and archive_mode must be enabled.

F.6.1. Configuration Parameters

basic_archive.archive_directory (string)

The directory where the server should copy WAL segment files. This directory must already exist. The default is an empty string, which effectively halts WAL archiving, but if archive_mode is enabled, the server will accumulate WAL segment files in the expectation that a value will soon be provided.

These parameters must be set in postgresql.conf. Typical usage might be:

```
# postgresql.conf
archive_mode = 'on'
archive_library = 'basic_archive'
basic_archive.archive_directory = '/path/to/archive/directory'
```

F.6.2. Notes

Server crashes may leave temporary files with the prefix archtemp in the archive directory. It is recommended to delete such files before restarting the server after a crash. It is safe to remove such files while the server is running as long as they are unrelated to any archiving still in progress, but users should use extra caution when doing so.

F.6.3. Author

Nathan Bossart
F.7. bloom — bloom filter index access method

bloom provides an index access method based on Bloom filters¹.

A Bloom filter is a space-efficient data structure that is used to test whether an element is a member of a set. In the case of an index access method, it allows fast exclusion of non-matching tuples via signatures whose size is determined at index creation.

A signature is a lossy representation of the indexed attribute(s), and as such is prone to reporting false positives; that is, it may be reported that an element is in the set, when it is not. So index search results must always be rechecked using the actual attribute values from the heap entry. Larger signatures reduce the odds of a false positive and thus reduce the number of useless heap visits, but of course also make the index larger and hence slower to scan.

This type of index is most useful when a table has many attributes and queries test arbitrary combinations of them. A traditional btree index is faster than a bloom index, but it can require many btree indexes to support all possible queries where one needs only a single bloom index. Note however that bloom indexes only support equality queries, whereas btree indexes can also perform inequality and range searches.

F.7.1. Parameters

A bloom index accepts the following parameters in its WITH clause:

length

Length of each signature (index entry) in bits. It is rounded up to the nearest multiple of 16. The default is 80 bits and the maximum is 4096.

col1 — col32

Number of bits generated for each index column. Each parameter's name refers to the number of the index column that it controls. The default is 2 bits and the maximum is 4095. Parameters for index columns not actually used are ignored.

F.7.2. Examples

This is an example of creating a bloom index:

```
CREATE INDEX bloomidx ON tbloom USING bloom (i1,i2,i3)
WITH (length=80, col1=2, col2=2, col3=4);
```

The index is created with a signature length of 80 bits, with attributes i1 and i2 mapped to 2 bits, and attribute i3 mapped to 4 bits. We could have omitted the length, col1, and col2 specifications since those have the default values.

Here is a more complete example of bloom index definition and usage, as well as a comparison with equivalent btree indexes. The bloom index is considerably smaller than the btree index, and can perform better.

```
=\# CREATE TABLE tbloom AS
```
Additional Supplied Modules and Extensions

SELECT
  (random() * 1000000)::int as i1,
  (random() * 1000000)::int as i2,
  (random() * 1000000)::int as i3,
  (random() * 1000000)::int as i4,
  (random() * 1000000)::int as i5,
  (random() * 1000000)::int as i6
FROM
  generate_series(1,10000000);
SELECT 10000000

A sequential scan over this large table takes a long time:

=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
QUERY PLAN

-------------------------------------------------------------------
| Seq Scan on tbloom  (cost=0.00..2137.14 rows=3 width=24) (actual time=16.971..16.971 rows=0 loops=1) |
| Filter: ((i2 = 898732) AND (i5 = 123451)) |
ROWS Removed by Filter: 100000
Planning Time: 0.346 ms
Execution Time: 16.988 ms
(5 rows)

Even with the btree index defined the result will still be a sequential scan:

=# CREATE INDEX btreeidx ON tbloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('btreeidx'));
pg_size_pretty
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>3976 kB</td>
</tr>
</tbody>
</table>
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
QUERY PLAN

-------------------------------------------------------------------
| Seq Scan on tbloom  (cost=0.00..2137.00 rows=2 width=24) (actual time=12.805..12.805 rows=0 loops=1) |
| Filter: ((i2 = 898732) AND (i5 = 123451)) |
ROWS Removed by Filter: 100000
Planning Time: 0.138 ms
Execution Time: 12.817 ms
(5 rows)

Having the bloom index defined on the table is better than btree in handling this type of search:

=# CREATE INDEX bloomidx ON tbloom USING bloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('bloomidx'));
pg_size_pretty
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>2682</td>
</tr>
</tbody>
</table>
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
QUERY PLAN

-------------------------------------------------------------------
| Seq Scan on tbloom  (cost=0.00..2137.00 rows=2 width=24) (actual time=12.805..12.805 rows=0 loops=1) |
| Filter: ((i2 = 898732) AND (i5 = 123451)) |
ROWS Removed by Filter: 100000
Planning Time: 0.138 ms
Execution Time: 12.817 ms
(5 rows)
1584 kB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;

--------------------------------------------------------------------------------------
Bitmap Heap Scan on tbloom (cost=1792.00..1799.69 rows=2 width=24) (actual time=0.388..0.388 rows=0 loops=1)
  Recheck Cond: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Index Recheck: 29
  Heap Blocks: exact=28
  -> Bitmap Index Scan on bloomidx (cost=0.00..1792.00 rows=2 width=0) (actual time=0.356..0.356 rows=29 loops=1)
    Index Cond: ((i2 = 898732) AND (i5 = 123451))
Planning Time: 0.099 ms
Execution Time: 0.408 ms
(9 rows)

Now, the main problem with the btree search is that btree is inefficient when the search conditions do not constrain the leading index column(s). A better strategy for btree is to create a separate index on each column. Then the planner will choose something like this:

=# CREATE INDEX btreeidx1 ON tbloom (i1);
CREATE INDEX
=# CREATE INDEX btreeidx2 ON tbloom (i2);
CREATE INDEX
=# CREATE INDEX btreeidx3 ON tbloom (i3);
CREATE INDEX
=# CREATE INDEX btreeidx4 ON tbloom (i4);
CREATE INDEX
=# CREATE INDEX btreeidx5 ON tbloom (i5);
CREATE INDEX
=# CREATE INDEX btreeidx6 ON tbloom (i6);
CREATE INDEX
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;

--------------------------------------------------------------------------------------
Bitmap Heap Scan on tbloom (cost=24.34..32.03 rows=2 width=24) (actual time=0.028..0.029 rows=0 loops=1)
  Recheck Cond: ((i5 = 123451) AND (i2 = 898732))
  -> BitmapAnd (cost=24.34..24.34 rows=2 width=0) (actual time=0.027..0.027 rows=0 loops=1)
    -> Bitmap Index Scan on btreeidx5 (cost=0.00..12.04 rows=500 width=0) (actual time=0.026..0.026 rows=29 loops=1)
      Index Cond: (i5 = 123451)
    -> Bitmap Index Scan on btreeidx2 (cost=0.00..12.04 rows=500 width=0) (never executed)
      Index Cond: (i2 = 898732)
Planning Time: 0.491 ms
Execution Time: 0.055 ms
(9 rows)

Although this query runs much faster than with either of the single indexes, we pay a penalty in index size. Each of the single-column btree indexes occupies 2 MB, so the total space needed is 12 MB, eight times the space used by the bloom index.
F.7.3. Operator Class Interface

An operator class for bloom indexes requires only a hash function for the indexed data type and an equality operator for searching. This example shows the operator class definition for the text data type:

```
CREATE OPERATOR CLASS text_ops
DEFAULT FOR TYPE text USING bloom AS
  OPERATOR 1 =(text, text),
  FUNCTION 1 hashtext(text);
```

F.7.4. Limitations

- Only operator classes for int4 and text are included with the module.
- Only the = operator is supported for search. But it is possible to add support for arrays with union and intersection operations in the future.
- bloom access method doesn't support UNIQUE indexes.
- bloom access method doesn't support searching for NULL values.

F.7.5. Authors

Teodor Sigaev <teodor@postgrespro.ru>, Postgres Professional, Moscow, Russia

Alexander Korotkov <a.korotkov@postgrespro.ru>, Postgres Professional, Moscow, Russia

Oleg Bartunov <obartunov@postgrespro.ru>, Postgres Professional, Moscow, Russia
F.8. btrees_gin — GIN operator classes with B-tree behavior

btrees_gin provides GIN operator classes that implement B-tree equivalent behavior for the data types int2, int4, int8, float4, float8, timestamp with time zone, timestamp without time zone, time with time zone, time without time zone, date, interval, oid, money, "char", varchar, text, bytea, bit, varbit, macaddr, macaddr8, inet, cidr, uuid, name, bool, bpchar, and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they are useful for GIN testing and as a base for developing other GIN operator classes. Also, for queries that test both a GIN-indexable column and a B-tree-indexable column, it might be more efficient to create a multicolumn GIN index that uses one of these operator classes than to create two separate indexes that would have to be combined via bitmap ANDing.

This module is considered "trusted", that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.8.1. Example Usage

CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIN (a);
-- query
SELECT * FROM test WHERE a < 10;

F.8.2. Authors

Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See http://www.sai.msu.su/~megera/oddmuse/index.cgi/Gin for additional information.
btree_gist provides GiST index operator classes that implement B-tree equivalent behavior for the data types int2, int4, int8, float4, float8, numeric, timestamp with time zone, time with time zone, time without time zone, date, interval, oid, money, char, varchar, text, bytea, bit, varbit, macaddr, macaddr8, inet, cidr, uuid, bool and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they provide some other features that are not available with a B-tree index, as described below. Also, these operator classes are useful when a multicolumn GiST index is needed, wherein some of the columns are of data types that are only indexable with GiST but other columns are just simple data types. Lastly, these operator classes are useful for GiST testing and as a base for developing other GiST operator classes.

In addition to the typical B-tree search operators, btree_gist also provides index support for <> ("not equals"). This may be useful in combination with an exclusion constraint, as described below.

Also, for data types for which there is a natural distance metric, btree_gist defines a distance operator <->, and provides GiST index support for nearest-neighbor searches using this operator. Distance operators are provided for int2, int4, int8, float4, float8, timestamp with time zone, time without time zone, date, interval, oid, and money.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.9.1. Example Usage

Simple example using btree_gist instead of btree:

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIST (a);
-- query
SELECT * FROM test WHERE a < 10;
-- nearest-neighbor search: find the ten entries closest to "42"
SELECT *, a <-> 42 AS dist FROM test ORDER BY a <-> 42 LIMIT 10;
```

Use an exclusion constraint to enforce the rule that a cage at a zoo can contain only one kind of animal:

```
=> CREATE TABLE zoo (  
cage INTEGER,  
animal TEXT,  
EXCLUDE USING GIST (cage WITH =, animal WITH <>)
);

=> INSERT INTO zoo VALUES(123, 'zebra');  
INSERT 0 1  
=> INSERT INTO zoo VALUES(123, 'zebra');  
INSERT 0 1  
=> INSERT INTO zoo VALUES(123, 'lion');
```
Additional Supplied Modules and Extensions

ERROR: conflicting key value violates exclusion constraint "zoo_cage_animal_excl"
DETAIL: Key (cage, animal)=(123, lion) conflicts with existing key (cage, animal)=(123, zebra).
=> INSERT INTO zoo VALUES(124, 'lion');
INSERT 0 1

F.9.2. Authors

Teodor Sigaev (<teodor@stack.net>), Oleg Bartunov (<oleg@sai.msu.su>), Janko Richter (<jankorichter@yahoo.de>), and Paul Jungwirth (<pj@illuminatedcomputing.com>). See http://www.sai.msu.su/~megera/postgres/gist/ for additional information.
F.10. citext — a case-insensitive character string type

The citext module provides a case-insensitive character string type, citext. Essentially, it internally calls lower when comparing values. Otherwise, it behaves almost exactly like text.

Tip
Consider using nondeterministic collations (see Section 24.2.2.4) instead of this module. They can be used for case-insensitive comparisons, accent-insensitive comparisons, and other combinations, and they handle more Unicode special cases correctly.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.10.1. Rationale

The standard approach to doing case-insensitive matches in PostgreSQL has been to use the lower function when comparing values, for example

```
SELECT * FROM tab WHERE lower(col) = LOWER(?);
```

This works reasonably well, but has a number of drawbacks:

• It makes your SQL statements verbose, and you always have to remember to use lower on both the column and the query value.

• It won't use an index, unless you create a functional index using lower.

• If you declare a column as UNIQUE or PRIMARY KEY, the implicitly generated index is case-sensitive. So it's useless for case-insensitive searches, and it won't enforce uniqueness case-insensitively.

The citext data type allows you to eliminate calls to lower in SQL queries, and allows a primary key to be case-insensitive. citext is locale-aware, just like text, which means that the matching of upper case and lower case characters is dependent on the rules of the database's LC_CTYPE setting. Again, this behavior is identical to the use of lower in queries. But because it's done transparently by the data type, you don't have to remember to do anything special in your queries.

F.10.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE users (  
    nick CITEXT PRIMARY KEY,  
    pass TEXT NOT NULL  
);  

INSERT INTO users VALUES ( 'larry',  
    sha256(random()::text::bytea) );  
INSERT INTO users VALUES ( 'Tom',  
    sha256(random()::text::bytea) );
```
INSERT INTO users VALUES ( 'Damian', sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'NEAL', sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'Bjørn', sha256(random()::text::bytea) );

SELECT * FROM users WHERE nick = 'Larry';

The SELECT statement will return one tuple, even though the nick column was set to larry and the query was for Larry.

F.10.3. String Comparison Behavior

citext performs comparisons by converting each string to lower case (as though lower were called) and then comparing the results normally. Thus, for example, two strings are considered equal if lower would produce identical results for them.

In order to emulate a case-insensitive collation as closely as possible, there are citext-specific versions of a number of string-processing operators and functions. So, for example, the regular expression operators ~ and ~* exhibit the same behavior when applied to citext: they both match case-insensitively. The same is true for !~ and !~*, as well as for the LIKE operators ~~ and ~*, and !~~ and !~*. If you'd like to match case-sensitively, you can cast the operator's arguments to text.

Similarly, all of the following functions perform matching case-insensitively if their arguments are citext:

• regexp_match()
• regexp_matches()
• regexp_replace()
• regexp_split_to_array()
• regexp_split_to_table()
• replace()
• split_part()
• strpos()
• translate()

For the regexp functions, if you want to match case-sensitively, you can specify the "c" flag to force a case-sensitive match. Otherwise, you must cast to text before using one of these functions if you want case-sensitive behavior.

F.10.4. Limitations

• citext's case-folding behavior depends on the LC_CTYPE setting of your database. How it compares values is therefore determined when the database is created. It is not truly case-insensitive in the terms defined by the Unicode standard. Effectively, what this means is that, as long as you're happy with your collation, you should be happy with citext's comparisons. But if you have data in different languages stored in your database, users of one language may find their query results are not as expected if the collation is for another language.

• As of PostgreSQL 9.1, you can attach a COLLATE specification to citext columns or data values. Currently, citext operators will honor a non-default COLLATE specification while comparing
case-folded strings, but the initial folding to lower case is always done according to the database’s LC_CTYPE setting (that is, as though COLLATE "default" were given). This may be changed in a future release so that both steps follow the input COLLATE specification.

• `citext` is not as efficient as `text` because the operator functions and the B-tree comparison functions must make copies of the data and convert it to lower case for comparisons. Also, only `text` can support B-Tree deduplication. However, `citext` is slightly more efficient than using `lower` to get case-insensitive matching.

• `citext` doesn’t help much if you need data to compare case-sensitively in some contexts and case-insensitively in other contexts. The standard answer is to use the `text` type and manually use the `lower` function when you need to compare case-insensitively; this works all right if case-insensitive comparison is needed only infrequently. If you need case-insensitive behavior most of the time and case-sensitive infrequently, consider storing the data as `citext` and explicitly casting the column to `text` when you want case-sensitive comparison. In either situation, you will need two indexes if you want both types of searches to be fast.

• The schema containing the `citext` operators must be in the current `search_path` (typically `public`); if it is not, the normal case-sensitive `text` operators will be invoked instead.

• The approach of lower-casing strings for comparison does not handle some Unicode special cases correctly, for example when one upper-case letter has two lower-case letter equivalents. Unicode distinguishes between case mapping and case folding for this reason. Use nondeterministic collations instead of `citext` to handle that correctly.

F.10.5. Author

David E. Wheeler <david@kineticode.com>

Inspired by the original `citext` module by Donald Fraser.
F.11. cube — a multi-dimensional cube data type

This module implements a data type `cube` for representing multidimensional cubes.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.11.1. Syntax

Table F.2 shows the valid external representations for the `cube` type. `x`, `y`, etc. denote floating-point numbers.

Table F.2. Cube External Representations

<table>
<thead>
<tr>
<th>External Syntax</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x</code></td>
<td>A one-dimensional point (or, zero-length one-dimensional interval)</td>
</tr>
<tr>
<td><code>x</code>, <code>y</code>, etc.</td>
<td>Same as above</td>
</tr>
<tr>
<td><code>(x)</code></td>
<td>Same as above</td>
</tr>
<tr>
<td><code>x1, x2, ..., xn</code></td>
<td>A point in n-dimensional space, represented internally as a zero-volume cube</td>
</tr>
<tr>
<td><code>(x1, x2, ..., xn)</code></td>
<td>Same as above</td>
</tr>
<tr>
<td><code>(x), (y)</code></td>
<td>A one-dimensional interval starting at <code>x</code> and ending at <code>y</code> or vice versa; the order does not matter</td>
</tr>
<tr>
<td><code>[(x), (y)]</code></td>
<td>Same as above</td>
</tr>
<tr>
<td><code>(x1, ..., xn), (y1, ..., yn)</code></td>
<td>An n-dimensional cube represented by a pair of its diagonally opposite corners</td>
</tr>
<tr>
<td><code>[(x1, ..., xn), (y1, ..., yn)]</code></td>
<td>Same as above</td>
</tr>
</tbody>
</table>

It does not matter which order the opposite corners of a cube are entered in. The `cube` functions automatically swap values if needed to create a uniform “lower left — upper right” internal representation. When the corners coincide, `cube` stores only one corner along with an “is point” flag to avoid wasting space.

White space is ignored on input, so `[(x), (y)]` is the same as `[ (x), (y) ]`.

F.11.2. Precision

Values are stored internally as 64-bit floating point numbers. This means that numbers with more than about 16 significant digits will be truncated.

F.11.3. Usage

Table F.3 shows the specialized operators provided for type `cube`.

Table F.3. Cube Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cube &amp; cube</code></td>
<td>→ boolean</td>
</tr>
<tr>
<td></td>
<td>Do the cubes overlap?</td>
</tr>
<tr>
<td><code>cube @&gt; cube</code></td>
<td>→ boolean</td>
</tr>
</tbody>
</table>
### Additional Supplied Modules and Extensions

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cube &lt;@ cube</code></td>
<td><code>boolean</code> Does the first cube contain the second?</td>
</tr>
<tr>
<td><code>cube -&gt; integer</code></td>
<td><code>float8</code> Extracts the <code>n</code>-th coordinate of the cube (counting from 1).</td>
</tr>
<tr>
<td><code>cube ~&gt; integer</code></td>
<td><code>float8</code> Extracts the <code>n</code>-th coordinate of the cube, counting in the following way: <code>n = 2 * k - 1</code> means lower bound of <code>k</code>-th dimension, <code>n = 2 * k</code> means upper bound of <code>k</code>-th dimension. Negative <code>n</code> denotes the inverse value of the corresponding positive coordinate. This operator is designed for KNN-GiST support.</td>
</tr>
<tr>
<td><code>cube &lt;-&gt; cube</code></td>
<td><code>float8</code> Computes the Euclidean distance between the two cubes.</td>
</tr>
<tr>
<td><code>cube &lt;#&gt; cube</code></td>
<td><code>float8</code> Computes the taxicab (L-1 metric) distance between the two cubes.</td>
</tr>
<tr>
<td><code>cube &lt;=&gt; cube</code></td>
<td><code>float8</code> Computes the Chebyshev (L-inf metric) distance between the two cubes.</td>
</tr>
</tbody>
</table>

In addition to the above operators, the usual comparison operators shown in Table 9.1 are available for type `cube`. These operators first compare the first coordinates, and if those are equal, compare the second coordinates, etc. They exist mainly to support the b-tree index operator class for `cube`, which can be useful for example if you would like a UNIQUE constraint on a `cube` column. Otherwise, this ordering is not of much practical use.

The `cube` module also provides a GiST index operator class for `cube` values. A `cube` GiST index can be used to search for values using the `=`, `&&`, `@>`, and `<@` operators in `WHERE` clauses.

In addition, a `cube` GiST index can be used to find nearest neighbors using the metric operators `<->`, `<#>`, and `<=>` in `ORDER BY` clauses. For example, the nearest neighbor of the 3-D point (0.5, 0.5, 0.5) could be found efficiently with:

```sql
SELECT c FROM test ORDER BY c <-> cube(array[0.5,0.5,0.5]) LIMIT 1;
```

The `<->` operator can also be used in this way to efficiently retrieve the first few values sorted by a selected coordinate. For example, to get the first few cubes ordered by the first coordinate (lower left corner) ascending one could use the following query:

```sql
SELECT c FROM test ORDER BY c ~> 1 LIMIT 5;
```

And to get 2-D cubes ordered by the first coordinate of the upper right corner descending:

```sql
SELECT c FROM test ORDER BY c ~> 3 DESC LIMIT 5;
```

Table F.4 shows the available functions.

### Table F.4. Cube Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cube(float8) -&gt; cube</code></td>
<td>Makes a one dimensional cube with both coordinates the same.</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>cube(1) → (1)</td>
<td>Makes a one dimensional cube.</td>
</tr>
<tr>
<td>cube(float8, float8) → cube</td>
<td>Makes a zero-volume cube using the coordinates defined by the array.</td>
</tr>
<tr>
<td>cube(float8[],) → cube</td>
<td>Makes a cube with upper right and lower left coordinates as defined by the two arrays, which must be of the same length.</td>
</tr>
<tr>
<td>cube(cube, float8) → cube</td>
<td>Makes a new cube by adding a dimension on to an existing cube, with the same values for both endpoints of the new coordinate. This is useful for building cubes piece by piece from calculated values.</td>
</tr>
<tr>
<td>cube(cube, float8, float8) → cube</td>
<td>Makes a new cube by adding a dimension on to an existing cube. This is useful for building cubes piece by piece from calculated values.</td>
</tr>
<tr>
<td>cube_dim(cube) → integer</td>
<td>Returns the number of dimensions of the cube.</td>
</tr>
<tr>
<td>cube_ll_coord(cube, integer) → float8</td>
<td>Returns the n-th coordinate value for the lower left corner of the cube.</td>
</tr>
<tr>
<td>cube_ur_coord(cube, integer) → float8</td>
<td>Returns the n-th coordinate value for the upper right corner of the cube.</td>
</tr>
<tr>
<td>cube_is_point(cube) → boolean</td>
<td>Returns true if the cube is a point, that is, the two defining corners are the same.</td>
</tr>
<tr>
<td>cube_distance(cube, cube) → float8</td>
<td>Returns the distance between two cubes. If both cubes are points, this is the normal distance function.</td>
</tr>
<tr>
<td>cube_subset(cube, integer[]) → cube</td>
<td>Makes a new cube from an existing cube, using a list of dimension indexes from an array. Can be used to extract the endpoints of a single dimension, or to drop dimensions, or to reorder them as desired.</td>
</tr>
</tbody>
</table>
### Additional Supplied Modules and Extensions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Example(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cube_subset(cube('1,3,5),(6,7,8'), ARRAY[3,2,1,1])</code></td>
<td>Produces a subset of a cube using a multi-dimensional range.</td>
<td><code>(5, 3, 1, 1), (8, 7, 6, 6)</code></td>
</tr>
<tr>
<td><code>cube_union(cube, cube)</code></td>
<td>Produces the union of two cubes.</td>
<td><code>cube_union('1,2', '(3,4)') → (1, 2), (3, 4)</code></td>
</tr>
<tr>
<td><code>cube_inter(cube, cube)</code></td>
<td>Produces the intersection of two cubes.</td>
<td><code>cube_inter('1,2', '(3,4)') → (3, 4), (1, 2)</code></td>
</tr>
<tr>
<td><code>cube_enlarge(cube, r double, n integer)</code></td>
<td>Increases the size of the cube by the specified radius in at least n dimensions.</td>
<td><code>cube_enlarge('(1,2), (3,4)', 0.5, 3) → (0.5, 1.5, -0.5), (3.5, 4.5, 0.5)</code></td>
</tr>
</tbody>
</table>

#### F.11.4. Defaults

This union:

```
select cube_union('(0,5,2),(2,3,1)', '0');
cube_union
---------------
(0, 0, 0), (2, 5, 2)
(1 row)
```

does not contradict common sense, neither does the intersection:

```
select cube_inter('(0,-1),(1,1)', '(-2),(2)');
cube_inter
------------
(0, 0), (1, 0)
(1 row)
```

In all binary operations on differently-dimensioned cubes, the lower-dimensional one is assumed to be a Cartesian projection, i.e., having zeroes in place of coordinates omitted in the string representation. The above examples are equivalent to:

```
cube_union('(0,5,2),(2,3,1)', '(0,0,0),(0,0,0)');
cube_inter('(0,-1),(1,1)', '(-2,0),(2,0)');
```

The following containment predicate uses the point syntax, while in fact the second argument is internally represented by a box. This syntax makes it unnecessary to define a separate point type and functions for (box, point) predicates.
Additional Supplied
Modules and Extensions

```sql
select cube_contains('(0,0),(1,1)', '0.5,0.5');
cube_contains
-------------
t
(1 row)
```

F.11.5. Notes

For examples of usage, see the regression test sql/cube.sql.

To make it harder for people to break things, there is a limit of 100 on the number of dimensions of cubes. This is set in cubedata.h if you need something bigger.

F.11.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (https://dsf.berkeley.edu/jmh/) for elucidating the gist of the GiST (http://gist.cs.berkeley.edu/), and to his former student Andy Dong for his example written for Illustra. I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

Minor updates to this package were made by Bruno Wolff III <bruno@wolff.to> in August/September of 2002. These include changing the precision from single precision to double precision and adding some new functions.

Additional updates were made by Joshua Reich <josh@root.net> in July 2006. These include `cube(float8[], float8[])` and cleaning up the code to use the V1 call protocol instead of the deprecated V0 protocol.
Additional Supplied
Modules and Extensions

F.12. dblink — connect to other PostgreSQL databases

dblink is a module that supports connections to other PostgreSQL databases from within a database session.

See also postgres_fdw, which provides roughly the same functionality using a more modern and standards-compliant infrastructure.
**dblink_connect**

*dblink_connect* — opens a persistent connection to a remote database

**Synopsis**

```plaintext
dblink_connect(text connstr) returns text
dblink_connect(text connname, text connstr) returns text
```

**Description**

*dblink_connect()* establishes a connection to a remote PostgreSQL database. The server and database to be contacted are identified through a standard libpq connection string. Optionally, a name can be assigned to the connection. Multiple named connections can be open at once, but only one unnamed connection is permitted at a time. The connection will persist until closed or until the database session is ended.

The connection string may also be the name of an existing foreign server. It is recommended to use the foreign-data wrapper *dblink_fdw* when defining the foreign server. See the example below, as well as CREATE SERVER and CREATE USER MAPPING.

**Arguments**

- **connname**

  The name to use for this connection; if omitted, an unnamed connection is opened, replacing any existing unnamed connection.

- **connstr**

  Libpq-style connection info string, for example `hostaddr=127.0.0.1 port=5432 dbname=mydb user=postgres password=mypasswd options=-csearch_path=`. For details see Section 34.1.1. Alternatively, the name of a foreign server.

**Return Value**

Returns status, which is always *OK* (since any error causes the function to throw an error instead of returning).

**Notes**

If untrusted users have access to a database that has not adopted a secure schema usage pattern, begin each session by removing publicly-writable schemas from *search_path*. One could, for example, add `options=-csearch_path=` to *connstr*. This consideration is not specific to *dblink*; it applies to every interface for executing arbitrary SQL commands.

Only superusers may use *dblink_connect* to create non-password-authenticated and non-GSSAPI-authenticated connections. If non-superusers need this capability, use *dblink_connect_u* instead.

It is unwise to choose connection names that contain equal signs, as this opens a risk of confusion with connection info strings in other *dblink* functions.

**Examples**

```sql
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
```
CREATE SERVER fdtest FOREIGN DATA WRAPPER dblink_fdw OPTIONS (hostaddr '127.0.0.1', dbname 'contrib_regression');

CREATE USER regress_dblink_user WITH PASSWORD 'secret';
CREATE USER MAPPING FOR regress_dblink_user SERVER fdtest OPTIONS (user 'regress_dblink_user', password 'secret');
GRANT USAGE ON FOREIGN SERVER fdtest TO regress_dblink_user;
GRANT SELECT ON TABLE foo TO regress_dblink_user;

\set ORIGINAL_USER :USER
\c - regress_dblink_user
SELECT dblink_connect('myconn', 'fdtest');
dblink_connect
OK
(1 row)

SELECT * FROM dblink('myconn', 'SELECT * FROM foo') AS t(a int, b text, c text[]);
a | b | c
----+---+---------------
0 | a | {a0,b0,c0}
1 | b | {a1,b1,c1}
2 | c | {a2,b2,c2}
3 | d | {a3,b3,c3}
4 | e | {a4,b4,c4}
5 | f | {a5,b5,c5}
6 | g | {a6,b6,c6}
7 | h | {a7,b7,c7}
8 | i | {a8,b8,c8}
9 | j | {a9,b9,c9}
10 | k | {a10,b10,c10}
(11 rows)

\c - :ORIGINAL_USER
REVOKE USAGE ON FOREIGN SERVER fdtest FROM regress_dblink_user;
REVOKE SELECT ON TABLE foo FROM regress_dblink_user;
DROP USER MAPPING FOR regress_dblink_user SERVER fdtest;
DROP USER regress_dblink_user;
DROP SERVER fdtest;
**dblink_connect_u**

`dblink_connect_u` — opens a persistent connection to a remote database, insecurely

### Synopsis

`dblink_connect_u(text connstr) returns text`

`dblink_connect_u(text connname, text connstr) returns text`

### Description

`dblink_connect_u()` is identical to `dblink_connect()`, except that it will allow non-superusers to connect using any authentication method.

If the remote server selects an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur, because the session will appear to have originated from the user as which the local PostgreSQL server runs. Also, even if the remote server does demand a password, it is possible for the password to be supplied from the server environment, such as a `~/.pgpass` file belonging to the server's user. This opens not only a risk of impersonation, but the possibility of exposing a password to an untrustworthy remote server. Therefore, `dblink_connect_u()` is initially installed with all privileges revoked from `PUBLIC`, making it un-callable except by superusers. In some situations it may be appropriate to grant `EXECUTE` permission for `dblink_connect_u()` to specific users who are considered trustworthy, but this should be done with care. It is also recommended that any `~/.pgpass` file belonging to the server's user not contain any records specifying a wildcard host name.

For further details see `dblink_connect()`.
**dblink_disconnect**

dblink_disconnect — closes a persistent connection to a remote database

**Synopsis**

dblink_disconnect() returns text
dblink_disconnect(text conname) returns text

**Description**

dblink_disconnect() closes a connection previously opened by dblink_connect(). The form with no arguments closes an unnamed connection.

**Arguments**

*conname*

The name of a named connection to be closed.

**Return Value**

Returns status, which is always OK (since any error causes the function to throw an error instead of returning).

**Examples**

```
SELECT dblink_disconnect();
  dblink_disconnect
                 -----------
          OK
(1 row)

SELECT dblink_disconnect('myconn');
  dblink_disconnect
                 -----------
          OK
(1 row)
```
dblink

- dblink — executes a query in a remote database

**Synopsis**

```sql
dblink(text connname, text sql [, bool fail_on_error]) returns setof record
dblink(text connstr, text sql [, bool fail_on_error]) returns setof record
dblink(text sql [, bool fail_on_error]) returns setof record
```

**Description**

`dblink` executes a query (usually a `SELECT`, but it can be any SQL statement that returns rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

**Arguments**

- **connname**
  
  Name of the connection to use; omit this parameter to use the unnamed connection.

- **connstr**
  
  A connection info string, as previously described for `dblink_connect`.

- **sql**
  
  The SQL query that you wish to execute in the remote database, for example `select * from foo`.

- **fail_on_error**
  
  If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

**Return Value**

The function returns the row(s) produced by the query. Since `dblink` can be used with any query, it is declared to return `record`, rather than specifying any particular set of columns. This means that you must specify the expected set of columns in the calling query — otherwise PostgreSQL would not know what to expect. Here is an example:

```sql
SELECT *
FROM dblink('dbname=mydb options=-csearch_path=',
  'select proname, prosrc from pg_proc')
  AS t1(proname name, prosrc text)
WHERE proname LIKE 'bytea%';
```
The “alias” part of the FROM clause must specify the column names and types that the function will return. (Specifying column names in an alias is actually standard SQL syntax, but specifying column types is a PostgreSQL extension.) This allows the system to understand what * should expand to, and what proname in the WHERE clause refers to, in advance of trying to execute the function. At runtime, an error will be thrown if the actual query result from the remote database does not have the same number of columns shown in the FROM clause. The column names need not match, however, and dblink does not insist on exact type matches either. It will succeed so long as the returned data strings are valid input for the column type declared in the FROM clause.

**Notes**

A convenient way to use dblink with predetermined queries is to create a view. This allows the column type information to be buried in the view, instead of having to spell it out in every query. For example,

```sql
CREATE VIEW myremote_pg_proc AS
  SELECT *
    FROM dblink('dbname=postgres options=-csearch_path=',
                  'select proname, prosrc from pg_proc')
    AS t1(proname name, prosrc text);

SELECT * FROM myremote_pg_proc WHERE proname LIKE 'bytea%';
```

**Examples**

```sql
SELECT * FROM dblink('dbname=postgres options=-csearch_path=',
                       'select proname, prosrc from pg_proc')
    AS t1(proname name, prosrc text) WHERE proname LIKE 'bytea%';

**dblink_exec**

*dblink_exec* — executes a command in a remote database

**Synopsis**

```sql
dblink_exec(text connname, text sql [, bool fail_on_error]) returns text
dblink_exec(text connstr, text sql [, bool fail_on_error]) returns text
dblink_exec(text sql [, bool fail_on_error]) returns text
```

**Description**

*dblink_exec* executes a command (that is, any SQL statement that doesn't return rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for *dblink_connect*, and the indicated connection is made just for the duration of this command.

**Arguments**

- **connname**
  - Name of the connection to use; omit this parameter to use the unnamed connection.

- **connstr**
  - A connection info string, as previously described for *dblink_connect*.

- **sql**
  - The SQL command that you wish to execute in the remote database, for example `insert into foo values(0, 'a', '{"a0","b0","c0"}')`.

- **fail_on_error**
  - If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

**Return Value**

Returns status, either the command's status string or `ERROR`.

**Examples**

```sql
SELECT dblink_connect('dbname=dblink_test_standby');
dblink_connect
----------------
OK
(1 row)
```
SELECT dblink_exec('insert into foo values(21, ''z'', ''{{"a0","b0","c0"}}''');
    dblink_exec
-------------------
    INSERT 943366 1
    (1 row)

SELECT dblink_connect('myconn', 'dbname=regression');
    dblink_connect
------------
    OK
    (1 row)

SELECT dblink_exec('myconn', 'insert into foo values(21, ''z'', ''{{"a0","b0","c0"}}''');
    dblink_exec
---------------------
    INSERT 6432584 1
    (1 row)

SELECT dblink_exec('myconn', 'insert into pg_class values (''foo''),false);
NOTICE:  sql error
DETAIL:  ERROR:  null value in column "relnamespace" violates not-null constraint
    dblink_exec
------------
    ERROR
    (1 row)
**dblink_open**

`dblink_open` — opens a cursor in a remote database

**Synopsis**

```c
dblink_open(text cursorname, text sql [, bool fail_on_error]) returns text
```

```c
dblink_open(text connname, text cursorname, text sql [, bool fail_on_error]) returns text
```

**Description**

`dblink_open()` opens a cursor in a remote database. The cursor can subsequently be manipulated with `dblink_fetch()` and `dblink_close()`.

**Arguments**

- `connname`
  
  Name of the connection to use; omit this parameter to use the unnamed connection.

- `cursorname`
  
  The name to assign to this cursor.

- `sql`
  
  The SELECT statement that you wish to execute in the remote database, for example `select * from pg_class`.

- `fail_on_error`
  
  If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

**Return Value**

Returns status, either `OK` or `ERROR`.

**Notes**

Since a cursor can only persist within a transaction, `dblink_open` starts an explicit transaction block (BEGIN) on the remote side, if the remote side was not already within a transaction. This transaction will be closed again when the matching `dblink_close` is executed. Note that if you use `dblink_exec` to change data between `dblink_open` and `dblink_close`, and then an error occurs or you use `dblink_disconnect` before `dblink_close`, your change will be lost because the transaction will be aborted.

**Examples**

```sql
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
```
SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');

----------------
OK
(1 row)
**dblink_fetch**

`dblink_fetch` — returns rows from an open cursor in a remote database

**Synopsis**

```sql
dblink_fetch(text cursorname, int howmany [, bool fail_on_error])
returns setof record
```

```sql
dblink_fetch(text connname, text cursorname, int howmany [, bool fail_on_error]) returns setof record
```

**Description**

`dblink_fetch` fetches rows from a cursor previously established by `dblink_open`.

**Arguments**

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*cursorname*

The name of the cursor to fetch from.

*howmany*

The maximum number of rows to retrieve. The next `howmany` rows are fetched, starting at the current cursor position, moving forward. Once the cursor has reached its end, no more rows are produced.

*fail_on_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

**Return Value**

The function returns the row(s) fetched from the cursor. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

**Notes**

On a mismatch between the number of return columns specified in the `FROM` clause, and the actual number of columns returned by the remote cursor, an error will be thrown. In this event, the remote cursor is still advanced by as many rows as it would have been if the error had not occurred. The same is true for any other error occurring in the local query after the remote `FETCH` has been done.

**Examples**

```sql
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
```

```sql
dblink_connect
-------------
```
SELECT dblink_open('foo', 'select proname, prosrc from pg_proc
where proname like ''bytea%''');
dblink_open
-------------
OK
(1 row)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source
text);
  funcname | source
----------+----------
  byteacat | byteacat
  byteacmp | byteacmp
  byteaeq  | byteaeq
  byteage  | byteage
  byteagt  | byteagt
(5 rows)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source
text);
  funcname  |  source
-----------+-----------
  byteain   | byteain
  byteale   | byteale
  bytealike | bytealike
  bytealt   | bytealt
  byteane   | byteane
(5 rows)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source
text);
  funcname  |   source
------------+------------
  byteanlike | byteanlike
  byteaout   | byteaout
(2 rows)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source
text);
  funcname | source
----------+--------
(0 rows)
**dblink_close**

dblink_close — closes a cursor in a remote database

**Synopsis**

dblink_close(text cursorname [, bool fail_on_error]) returns text
dblink_close(text connname, text cursorname [, bool fail_on_error])
returns text

**Description**

dblink_close closes a cursor previously opened with dblink_open.

**Arguments**

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*cursorname*

The name of the cursor to close.

*fail_on_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to ERROR.

**Return Value**

Returns status, either OK or ERROR.

**Notes**

If dblink_open started an explicit transaction block, and this is the last remaining open cursor in this connection, dblink_close will issue the matching COMMIT.

**Examples**

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
  dblink_connect
--------------
 OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
  dblink_open
------------
 OK
(1 row)

SELECT dblink_close('foo');
```
Additional Supplied
Modules and Extensions

dblink_close
----------
OK
(1 row)
**dblink_get_connections**

*dblink_get_connections* — returns the names of all open named dblink connections

**Synopsis**

```text
dblink_get_connections() returns text[]
```

**Description**

*dblink_get_connections* returns an array of the names of all open named dblink connections.

**Return Value**

Returns a text array of connection names, or NULL if none.

**Examples**

```sql
SELECT dblink_get_connections();
```
**dblink_error_message**

*dblink_error_message* — gets last error message on the named connection

**Synopsis**

`dblink_error_message(text connname) returns text`

**Description**

`dblink_error_message` fetches the most recent remote error message for a given connection.

**Arguments**

*connname*

Name of the connection to use.

**Return Value**

Returns last error message, or *OK* if there has been no error in this connection.

**Notes**

When asynchronous queries are initiated by `dblink_send_query`, the error message associated with the connection might not get updated until the server's response message is consumed. This typically means that `dblink_is_busy` or `dblink_get_result` should be called prior to `dblink_error_message`, so that any error generated by the asynchronous query will be visible.

**Examples**

```sql
SELECT dblink_error_message('dtest1');
```
**dblink_send_query**

`dblink_send_query` — sends an async query to a remote database

### Synopsis

```
dblink_send_query(text connname, text sql) returns int
```

### Description

`dblink_send_query` sends a query to be executed asynchronously, that is, without immediately waiting for the result. There must not be an async query already in progress on the connection.

After successfully dispatching an async query, completion status can be checked with `dblink_is_busy`, and the results are ultimately collected with `dblink_get_result`. It is also possible to attempt to cancel an active async query using `dblink_cancel_query`.

### Arguments

- **connname**
  
  Name of the connection to use.

- **sql**
  
  The SQL statement that you wish to execute in the remote database, for example `select * from pg_class`.

### Return Value

Returns 1 if the query was successfully dispatched, 0 otherwise.

### Examples

```sql
SELECT dblink_send_query('dtest1', 'SELECT * FROM foo WHERE f1 < 3');
```
**dblink_is_busy**

dblink_is_busy — checks if connection is busy with an async query

**Synopsis**

dblink_is_busy(text connname) returns int

**Description**

dblink_is_busy tests whether an async query is in progress.

**Arguments**

connname

Name of the connection to check.

**Return Value**

Returns 1 if connection is busy, 0 if it is not busy. If this function returns 0, it is guaranteed that dblink_get_result will not block.

**Examples**

SELECT dblink_is_busy('dtest1');

**dblink_get_notify**

dblink_get_notify — retrieve async notifications on a connection

**Synopsis**

```
dblink_get_notify() returns setof (notify_name text, be_pid int, extra text)
dblink_get_notify(text connname) returns setof (notify_name text, be_pid int, extra text)
```

**Description**

`dblink_get_notify` retrieves notifications on either the unnamed connection, or on a named connection if specified. To receive notifications via dblink, `LISTEN` must first be issued, using `dblink_exec`. For details see `LISTEN` and `NOTIFY`.

**Arguments**

`connname`

The name of a named connection to get notifications on.

**Return Value**

Returns `setof (notify_name text, be_pid int, extra text)`, or an empty set if none.

**Examples**

```sql
SELECT dblink_exec('LISTEN virtual');
```

```
dblink_exec
-------------
LISTEN
(1 row)
```

```sql
SELECT * FROM dblink_get_notify();
```

```
notify_name | be_pid | extra
-------------+--------+-------
(0 rows)
```

```sql
NOTIFY virtual;
```

```sql
NOTIFY
```

```sql
SELECT * FROM dblink_get_notify();
```

```
notify_name | be_pid | extra
-------------+--------+-------
  virtual    |  1229  |
(1 row)
```
**dblink_get_result**

dblink_get_result — gets an async query result

**Synopsis**

dblink_get_result(text connname [, bool fail_on_error]) returns setof record

**Description**

dblink_get_result collects the results of an asynchronous query previously sent with dblink_send_query. If the query is not already completed, dblink_get_result will wait until it is.

**Arguments**

*connname*

Name of the connection to use.

*fail_on_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

**Return Value**

For an async query (that is, an SQL statement returning rows), the function returns the row(s) produced by the query. To use this function, you will need to specify the expected set of columns, as previously discussed for dblink.

For an async command (that is, an SQL statement not returning rows), the function returns a single row with a single text column containing the command’s status string. It is still necessary to specify that the result will have a single text column in the calling FROM clause.

**Notes**

This function *must* be called if dblink_send_query returned 1. It must be called once for each query sent, and one additional time to obtain an empty set result, before the connection can be used again.

When using dblink_send_query and dblink_get_result, dblink fetches the entire remote query result before returning any of it to the local query processor. If the query returns a large number of rows, this can result in transient memory bloat in the local session. It may be better to open such a query as a cursor with dblink_open and then fetch a manageable number of rows at a time. Alternatively, use plain dblink(), which avoids memory bloat by spooling large result sets to disk.

**Examples**

contrib_regression=# SELECT dblink_connect('dtest1', 'dbname=contrib_regression');
dblink_connect
----------------
OK (1 row)

contrib_regression=# SELECT * FROM
dblink_send_query('dtest1', 'select * from foo where f1 < 3') AS t1;
t1
----
1
(1 row)

contrib_regression=# SELECT * FROM dblink_send_query('dtest1', 'select * from foo where f1 < 3; select * from foo where f1 > 6') AS t1;
t1
----
1
(1 row)

(4 rows)

contrib_regression=# SELECT * FROM dblink_send_query('dtest1', 'select * from foo where f1 < 3; select * from foo where f1 > 6') AS t1;
t1
----
1
(1 row)
**dblink_cancel_query**

dblink_cancel_query — cancels any active query on the named connection

**Synopsis**

dblink_cancel_query(text connname) returns text

**Description**

dblink_cancel_query attempts to cancel any query that is in progress on the named connection. Note that this is not certain to succeed (since, for example, the remote query might already have finished). A cancel request simply improves the odds that the query will fail soon. You must still complete the normal query protocol, for example by calling dblink_get_result.

**Arguments**

connname

Name of the connection to use.

**Return Value**

Returns OK if the cancel request has been sent, or the text of an error message on failure.

**Examples**

```
SELECT dblink_cancel_query('dtest1');
```
**dblink_get_pkey**

*dblink_get_pkey* — returns the positions and field names of a relation's primary key fields

**Synopsis**

```
dblink_get_pkey(text relname) returns setof dblink_pkey_results
```

**Description**

*dblink_get_pkey* provides information about the primary key of a relation in the local database. This is sometimes useful in generating queries to be sent to remote databases.

**Arguments**

relname

Name of a local relation, for example *foo* or *myschema.mytab*. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

**Return Value**

Returns one row for each primary key field, or no rows if the relation has no primary key. The result row type is defined as

```
CREATE TYPE dblink_pkey_results AS (position int, colname text);
```

The position column simply runs from 1 to \( N \); it is the number of the field within the primary key, not the number within the table's columns.

**Examples**

```
CREATE TABLE foobar (
    f1 int,
    f2 int,
    f3 int,
    PRIMARY KEY (f1, f2, f3)
);
CREATE TABLE

SELECT * FROM dblink_get_pkey('foobar');

<table>
<thead>
<tr>
<th>position</th>
<th>colname</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>f1</td>
</tr>
<tr>
<td>2</td>
<td>f2</td>
</tr>
<tr>
<td>3</td>
<td>f3</td>
</tr>
</tbody>
</table>

(3 rows)
```
**dblink_build_sql_insert**

*dblink_build_sql_insert* — builds an INSERT statement using a local tuple, replacing the primary key field values with alternative supplied values

**Synopsis**

```sql
dblink_build_sql_insert(text relname,
                        int2vector primary_key_attnums,
                        integer num_primary_key_atts,
                        text[] src_pk_att_vals_array,
                        text[] tgt_pk_att_vals_array) returns text
```

**Description**

`dblink_build_sql_insert` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds an SQL INSERT command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.)

**Arguments**

- **relname**
  
  Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

- **primary_key_attnums**
  
  Attribute numbers (1-based) of the primary key fields, for example `1 2`.

- **num_primary_key_atts**
  
  The number of primary key fields.

- **src_pk_att_vals_array**
  
  Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

- **tgt_pk_att_vals_array**
  
  Values of the primary key fields to be placed in the resulting INSERT command. Each field is represented in text form.

**Return Value**

Returns the requested SQL statement as text.

**Notes**

As of PostgreSQL 9.0, the attribute numbers in `primary_key_attnums` are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous
versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```sql
SELECT dblink_build_sql_insert('foo', '1 2', 2, '{"1", "a"}', '{"1", "b"a"}');
```

```sql
<table>
<thead>
<tr>
<th>dblink_build_sql_insert</th>
</tr>
</thead>
<tbody>
<tr>
<td>INSERT INTO foo(f1,f2,f3) VALUES('1','b''a','1')</td>
</tr>
<tr>
<td>(1 row)</td>
</tr>
</tbody>
</table>
```

**dblink_build_sql_delete**

dblink_build_sql_delete — builds a DELETE statement using supplied values for primary key field values

**Synopsis**

dblink_build_sql_delete(text relname, int2vector primary_key_attnums, integer num_primary_key_atts, text[] tgt_pk_att_vals_array) returns text

**Description**

dblink_build_sql_delete can be useful in doing selective replication of a local table to a remote database. It builds an SQL DELETE command that will delete the row with the given primary key values.

**Arguments**

*relname*

Name of a local relation, for example foo or myschema.mytab. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

*primary_key_attnums*

Attribute numbers (1-based) of the primary key fields, for example 1 2.

*num_primary_key_atts*

The number of primary key fields.

*tgt_pk_att_vals_array*

Values of the primary key fields to be used in the resulting DELETE command. Each field is represented in text form.

**Return Value**

Returns the requested SQL statement as text.

**Notes**

As of PostgreSQL 9.0, the attribute numbers in primary_key_attnums are interpreted as logical column numbers, corresponding to the column's position in SELECT * FROM relname. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

**Examples**

```
SELECT dblink_build_sql_delete('"MyFoo"', '1 2', 2, '{"1", "b"'});
```

2724
DELETE FROM "MyFoo" WHERE f1='1' AND f2='b'
(1 row)
**dblink_build_sql_update**

`dblink_build_sql_update` — builds an UPDATE statement using a local tuple, replacing the primary key field values with alternative supplied values

**Synopsis**

```
dblink_build_sql_update(text relname,  
        int2vector primary_key_attnums,  
        integer num_primary_key_atts,  
        text[] src_pk_att_vals_array,  
        text[] tgt_pk_att_vals_array) returns text
```

**Description**

`dblink_build_sql_update` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds an SQL UPDATE command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.) The UPDATE command always assigns all fields of the row — the main difference between this and `dblink_build_sql_insert` is that it's assumed that the target row already exists in the remote table.

**Arguments**

- **relname**
  Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

- **primary_key_attnums**
  Attribute numbers (1-based) of the primary key fields, for example `1 2`.

- **num_primary_key_atts**
  The number of primary key fields.

- **src_pk_att_vals_array**
  Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

- **tgt_pk_att_vals_array**
  Values of the primary key fields to be placed in the resulting UPDATE command. Each field is represented in text form.

**Return Value**

Returns the requested SQL statement as text.

**Notes**

As of PostgreSQL 9.0, the attribute numbers in `primary_key_attnums` are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous
Additional Supplied
Modules and Extensions

versions interpreted the numbers as physical column positions. There is a difference if any column(s)
to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_update('foo', '1 2', 2, '{"1", "a"}',
    '{"1", "b"}');

              dblink_build_sql_update
--------------------------------------------
UPDATE foo SET f1='1', f2='b', f3='1' WHERE f1='1' AND f2='b'
(1 row)
```
F.13. dict_int — example full-text search dictionary for integers

dict_int is an example of an add-on dictionary template for full-text search. The motivation for this example dictionary is to control the indexing of integers (signed and unsigned), allowing such numbers to be indexed while preventing excessive growth in the number of unique words, which greatly affects the performance of searching.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.13.1. Configuration

The dictionary accepts three options:

• The `maxlen` parameter specifies the maximum number of digits allowed in an integer word. The default value is 6.

• The `rejectlong` parameter specifies whether an overlength integer should be truncated or ignored. If `rejectlong` is `false` (the default), the dictionary returns the first `maxlen` digits of the integer. If `rejectlong` is `true`, the dictionary treats an overlength integer as a stop word, so that it will not be indexed. Note that this also means that such an integer cannot be searched for.

• The `absval` parameter specifies whether leading “+” or “−” signs should be removed from integer words. The default is `false`. When `true`, the sign is removed before `maxlen` is applied.

F.13.2. Usage

Installing the `dict_int` extension creates a text search template `intdict_template` and a dictionary `intdict` based on it, with the default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY intdict (MAXLEN = 4, REJECTLONG = true);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb# select ts_lexize('intdict', '12345678');
ts_lexize
--------
{123456}
```

but real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
  ALTER MAPPING FOR int, uint WITH intdict;
```
F.14. dict_xsyn — example synonym full-text search dictionary

dict_xsyn (Extended Synonym Dictionary) is an example of an add-on dictionary template for full-text search. This dictionary type replaces words with groups of their synonyms, and so makes it possible to search for a word using any of its synonyms.

F.14.1. Configuration

A dict_xsyn dictionary accepts the following options:

• matchorig controls whether the original word is accepted by the dictionary. Default is true.

• matchsynonyms controls whether the synonyms are accepted by the dictionary. Default is false.

• keeporig controls whether the original word is included in the dictionary's output. Default is true.

• keepsynonyms controls whether the synonyms are included in the dictionary's output. Default is true.

• rules is the base name of the file containing the list of synonyms. This file must be stored in $SHAREDIR/tsearch_data/ (where $SHAREDIR means the PostgreSQL installation's shared-data directory). Its name must end in .rules (which is not to be included in the rules parameter).

The rules file has the following format:

• Each line represents a group of synonyms for a single word, which is given first on the line. Synonyms are separated by whitespace, thus:

    word syn1 syn2 syn3

• The sharp (#) sign is a comment delimiter. It may appear at any position in a line. The rest of the line will be skipped.

Look at xsyn_sample.rules, which is installed in $SHAREDIR/tsearch_data/, for an example.

F.14.2. Usage

Installing the dict_xsyn extension creates a text search template xsyn_template and a dictionary xsyn based on it, with default parameters. You can alter the parameters, for example

    mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules',
    KEEPORIG=false);
    ALTER TEXT SEARCH DICTIONARY

or create new dictionaries based on the template.

To test the dictionary, you can try

    mydb=# SELECT ts_lexize('xsyn', 'word');
    ts_lexize
Additional Supplied
Modules and Extensions

{syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules',
KEEPORIG=true);
ALTER TEXT SEARCH DICTIONARY

mydb=# SELECT ts_lexize('xsyn', 'word');
  ts_lexize
-----------------------
  {word,syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules',
KEEPORIG=false, MATCHSYNONYMS=true);
ALTER TEXT SEARCH DICTIONARY

mydb=# SELECT ts_lexize('xsyn', 'syn1');
  ts_lexize
-----------------------
  {syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules',
KEEPORIG=true, MATCHORIG=false, KEEPSYNONYMS=false);
ALTER TEXT SEARCH DICTIONARY

mydb=# SELECT ts_lexize('xsyn', 'syn1');
  ts_lexize
-----------------------
  {word}

Real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:

ALTER TEXT SEARCH CONFIGURATION english
  ALTER MAPPING FOR word, asciiword WITH xsyn, english_stem;
F.15. earthdistance — calculate great-circle distances

The earthdistance module provides two different approaches to calculating great circle distances on the surface of the Earth. The one described first depends on the cube module. The second one is based on the built-in point data type, using longitude and latitude for the coordinates.

In this module, the Earth is assumed to be perfectly spherical. (If that's too inaccurate for you, you might want to look at the PostGIS project.)

The cube module must be installed before earthdistance can be installed (although you can use the CASCADE option of CREATE EXTENSION to install both in one command).

Caution

It is strongly recommended that earthdistance and cube be installed in the same schema, and that that schema be one for which CREATE privilege has not been and will not be granted to any untrusted users. Otherwise there are installation-time security hazards if earthdistance's schema contains objects defined by a hostile user. Furthermore, when using earthdistance's functions after installation, the entire search path should contain only trusted schemas.

F.15.1. Cube-Based Earth Distances

Data is stored in cubes that are points (both corners are the same) using 3 coordinates representing the x, y, and z distance from the center of the Earth. A domain earth over type cube is provided, which includes constraint checks that the value meets these restrictions and is reasonably close to the actual surface of the Earth.

The radius of the Earth is obtained from the earth() function. It is given in meters. But by changing this one function you can change the module to use some other units, or to use a different value of the radius that you feel is more appropriate.

This package has applications to astronomical databases as well. Astronomers will probably want to change earth() to return a radius of 180/pi() so that distances are in degrees.

Functions are provided to support input in latitude and longitude (in degrees), to support output of latitude and longitude, to calculate the great circle distance between two points and to easily specify a bounding box usable for index searches.

The provided functions are shown in Table F.5.

Table F.5. Cube-Based Earthdistance Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>earth() → float8</td>
<td>Returns the assumed radius of the Earth.</td>
</tr>
<tr>
<td>sec_to_gc(float8) → float8</td>
<td>Converts the normal straight line (secant) distance between two points on the surface of the Earth to the great circle distance between them.</td>
</tr>
</tbody>
</table>

1: https://postgis.net/
### Additional Supplied Modules and Extensions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gc_to_sec(\text{float8}) → float8</td>
<td>Converts the great circle distance between two points on the surface of the Earth to the normal straight line (secant) distance between them.</td>
</tr>
<tr>
<td>ll_to_earth(float8, float8) → earth</td>
<td>Returns the location of a point on the surface of the Earth given its latitude (argument 1) and longitude (argument 2) in degrees.</td>
</tr>
<tr>
<td>latitude(earth) → float8</td>
<td>Returns the latitude in degrees of a point on the surface of the Earth.</td>
</tr>
<tr>
<td>longitude(earth) → float8</td>
<td>Returns the longitude in degrees of a point on the surface of the Earth.</td>
</tr>
<tr>
<td>earth_distance(earth, earth) → float8</td>
<td>Returns the great circle distance between two points on the surface of the Earth.</td>
</tr>
<tr>
<td>earth_box(earth, float8) → cube</td>
<td>Returns a box suitable for an indexed search using the <code>cube @&gt;</code> operator for points within a given great circle distance of a location. Some points in this box are further than the specified great circle distance from the location, so a second check using <code>earth_distance</code> should be included in the query.</td>
</tr>
</tbody>
</table>

#### F.15.2. Point-Based Earth Distances

The second part of the module relies on representing Earth locations as values of type `point`, in which the first component is taken to represent longitude in degrees, and the second component is taken to represent latitude in degrees. Points are taken as (longitude, latitude) and not vice versa because longitude is closer to the intuitive idea of x-axis and latitude to y-axis.

A single operator is provided, shown in Table F.6.

### Table F.6. Point-Based Earthdistance Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>point &lt;@&gt; point → float8</td>
<td>Computes the distance in statute miles between two points on the Earth's surface.</td>
</tr>
</tbody>
</table>

Note that unlike the `cube`-based part of the module, units are hardwired here: changing the `earth()` function will not affect the results of this operator.

One disadvantage of the longitude/latitude representation is that you need to be careful about the edge conditions near the poles and near +/- 180 degrees of longitude. The `cube`-based representation avoids these discontinuities.
F.16. file_fdw — access data files in the server's file system

The `file_fdw` module provides the foreign-data wrapper `file_fdw`, which can be used to access data files in the server's file system, or to execute programs on the server and read their output. The data file or program output must be in a format that can be read by `COPY FROM`; see `COPY` for details. Access to data files is currently read-only.

A foreign table created using this wrapper can have the following options:

- **filename**
  Specifies the file to be read. Relative paths are relative to the data directory. Either `filename` or `program` must be specified, but not both.

- **program**
  Specifies the command to be executed. The standard output of this command will be read as though `COPY FROM PROGRAM` were used. Either `program` or `filename` must be specified, but not both.

- **format**
  Specifies the data format, the same as `COPY`'s `FORMAT` option.

- **header**
  Specifies whether the data has a header line, the same as `COPY`'s `HEADER` option.

- **delimiter**
  Specifies the data delimiter character, the same as `COPY`'s `DELIMITER` option.

- **quote**
  Specifies the data quote character, the same as `COPY`'s `QUOTE` option.

- **escape**
  Specifies the data escape character, the same as `COPY`'s `ESCAPE` option.

- **null**
  Specifies the data null string, the same as `COPY`'s `NULL` option.

- **encoding**
  Specifies the data encoding, the same as `COPY`'s `ENCODING` option.

Note that while `COPY` allows options such as `HEADER` to be specified without a corresponding value, the foreign table option syntax requires a value to be present in all cases. To activate `COPY` options typically written without a value, you can pass the value `TRUE`, since all such options are Booleans.

A column of a foreign table created using this wrapper can have the following options:

- **force_not_null**
  This is a Boolean option. If true, it specifies that values of the column should not be matched against the null string (that is, the table-level `null` option). This has the same effect as listing the column in `COPY`'s `FORCE_NOT_NULL` option.
force_null

This is a Boolean option. If true, it specifies that values of the column which match the null string are returned as NULL even if the value is quoted. Without this option, only unquoted values matching the null string are returned as NULL. This has the same effect as listing the column in COPY's FORCE_NULL option.

COPY's FORCE_QUOTE option is currently not supported by file_fdw.

These options can only be specified for a foreign table or its columns, not in the options of the file_fdw foreign-data wrapper, nor in the options of a server or user mapping using the wrapper.

Changing table-level options requires being a superuser or having the privileges of the role pg_read_server_files (to use a filename) or the role pg_execute_server_program (to use a program), for security reasons: only certain users should be able to control which file is read or which program is run. In principle regular users could be allowed to change the other options, but that's not supported at present.

When specifying the program option, keep in mind that the option string is executed by the shell. If you need to pass any arguments to the command that come from an untrusted source, you must be careful to strip or escape any characters that might have special meaning to the shell. For security reasons, it is best to use a fixed command string, or at least avoid passing any user input in it.

For a foreign table using file_fdw, EXPLAIN shows the name of the file to be read or program to be run. For a file, unless COSTS OFF is specified, the file size (in bytes) is shown as well.

Example F.1. Create a Foreign Table for PostgreSQL CSV Logs

One of the obvious uses for file_fdw is to make the PostgreSQL activity log available as a table for querying. To do this, first you must be logging to a CSV file, which here we will call pglog.csv.

First, install file_fdw as an extension:

```
CREATE EXTENSION file_fdw;
```

Then create a foreign server:

```
CREATE SERVER pglog FOREIGN DATA WRAPPER file_fdw;
```

Now you are ready to create the foreign data table. Using the CREATE FOREIGN TABLE command, you will need to define the columns for the table, the CSV file name, and its format:

```
CREATE FOREIGN TABLE pglog (  
  log_time timestamp(3) with time zone,  
  user_name text,  
  database_name text,  
  process_id integer,  
  connection_from text,  
  session_id text,  
  session_line_num bigint,  
  command_tag text,  
  session_start_time timestamp with time zone,  
  virtual_transaction_id text,  
  transaction_id bigint,  
  error_severity text,  
  sql_state_code text,  
  message text,  
  detail text,
```
That's it — now you can query your log directly. In production, of course, you would need to define some way to deal with log rotation.
F.17. fuzzystrmatch — determine string similarities and distance

The fuzzystrmatch module provides several functions to determine similarities and distance between strings.

Caution

At present, the soundex, metaphone, dmetaphone, and dmetaphone_alt functions do not work well with multibyte encodings (such as UTF-8). Use daitch_mokotoff or levenshtein with such data.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.17.1. Soundex

The Soundex system is a method of matching similar-sounding names by converting them to the same code. It was initially used by the United States Census in 1880, 1900, and 1910. Note that Soundex is not very useful for non-English names.

The fuzzystrmatch module provides two functions for working with Soundex codes:

```
soundex(text) returns text
difference(text, text) returns int
```

The soundex function converts a string to its Soundex code. The difference function converts two strings to their Soundex codes and then reports the number of matching code positions. Since Soundex codes have four characters, the result ranges from zero to four, with zero being no match and four being an exact match. (Thus, the function is misnamed — similarity would have been a better name.)

Here are some usage examples:

```
SELECT soundex('hello world!');

SELECT soundex('Anne'), soundex('Ann'), difference('Anne', 'Ann');
SELECT soundex('Anne'), soundex('Andrew'), difference('Anne', 'Andrew');
SELECT soundex('Anne'), soundex('Margaret'), difference('Anne', 'Margaret');

CREATE TABLE s (nm text);
INSERT INTO s VALUES ('john');
INSERT INTO s VALUES ('joan');
INSERT INTO s VALUES ('wobbly');
INSERT INTO s VALUES ('jack');

SELECT * FROM s WHERE soundex(nm) = soundex('john');
SELECT * FROM s WHERE difference(s.nm, 'john') > 2;
```
F.17.2. Daitch-Mokotoff Soundex

Like the original Soundex system, Daitch-Mokotoff Soundex matches similar-sounding names by converting them to the same code. However, Daitch-Mokotoff Soundex is significantly more useful for non-English names than the original system. Major improvements over the original system include:

- The code is based on the first six meaningful letters rather than four.
- A letter or combination of letters maps into ten possible codes rather than seven.
- Where two consecutive letters have a single sound, they are coded as a single number.
- When a letter or combination of letters may have different sounds, multiple codes are emitted to cover all possibilities.

This function generates the Daitch-Mokotoff soundex codes for its input:

\[
daitch_mokotoff(source\ text)\ \text{returns}\ text[\]
\]

The result may contain one or more codes depending on how many plausible pronunciations there are, so it is represented as an array.

Since a Daitch-Mokotoff soundex code consists of only 6 digits, `source` should be preferably a single word or name.

Here are some examples:

```
SELECT daitch_mokotoff('George');
daitch_mokotoff
-----------------
{595000}

SELECT daitch_mokotoff('John');
daitch_mokotoff
-----------------
{160000,460000}

SELECT daitch_mokotoff('Bierschbach');
daitch_mokotoff
-----------------------------------------------------------
{794575,794574,794750,794740,745750,745740,747500,747400}

SELECT daitch_mokotoff('Schwartzenegger');
daitch_mokotoff
-----------------
{479465}
```

For matching of single names, returned text arrays can be matched directly using the `&&` operator: any overlap can be considered a match. A GIN index may be used for efficiency, see Chapter 70 and this example:

```
CREATE TABLE s (nm text);
CREATE INDEX ix_s_dm ON s USING gin (daitch_mokotoff(nm)) WITH (fastupdate = off);

INSERT INTO s (nm) VALUES
    ('Schwartzenegger'),
    ('John'),
    ('James'),
```
('Steinman'),
('Steinmetz');

SELECT * FROM s WHERE daitch_mokotoff(nm) &&
  daitch_mokotoff('Swartzenegger');
SELECT * FROM s WHERE daitch_mokotoff(nm) &&
  daitch_mokotoff('Jane');
SELECT * FROM s WHERE daitch_mokotoff(nm) &&
  daitch_mokotoff('Jens');

For indexing and matching of any number of names in any order, Full Text Search features can be
used. See Chapter 12 and this example:

CREATE FUNCTION soundex_tsvector(v_name text) RETURNS tsvector
BEGIN ATOMIC
  SELECT to_tsvector('simple',
    string_agg(array_to_string(daitch_mokotoff(n),
      ' '), ' ')
  FROM regexp_split_to_table(v_name, '\s+') AS n;
END;

CREATE FUNCTION soundex_tsquery(v_name text) RETURNS tsquery
BEGIN ATOMIC
  SELECT string_agg('(' || array_to_string(daitch_mokotoff(n), '|')
    || ' ', '&')::tsquery
  FROM regexp_split_to_table(v_name, '\s+') AS n;
END;

CREATE TABLE s (nm text);
CREATE INDEX ix_s_txt ON s USING gin (soundex_tsvector(nm)) WITH
  (fastupdate = off);

INSERT INTO s (nm) VALUES
  ('John Doe'),
  ('Jane Roe'),
  ('Public John Q.'),
  ('George Best'),
  ('John Yamson');

SELECT * FROM s WHERE soundex_tsvector(nm) @@
  soundex_tsquery('john');
SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('jane
doe');
SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('john
public');
SELECT * FROM s WHERE soundex_tsvector(nm) @@
  soundex_tsquery('besst, giorgio');
SELECT * FROM s WHERE soundex_tsvector(nm) @@
  soundex_tsquery('Jameson John');

If it is desired to avoid recalculation of soundex codes during index rechecks, an index on a separate
column can be used instead of an index on an expression. A stored generated column can be used for
this; see Section 5.3.

F.17.3. Levenshtein

This function calculates the Levenshtein distance between two strings:
levenshtein(source text, target text, ins_cost int, del_cost int, sub_cost int) returns int
levenshtein(source text, target text) returns int
levenshtein_less_equal(source text, target text, ins_cost int, del_cost int, sub_cost int, max_d int) returns int
levenshtein_less_equal(source text, target text, max_d int) returns int

Both source and target can be any non-null string, with a maximum of 255 characters. The cost parameters specify how much to charge for a character insertion, deletion, or substitution, respectively. You can omit the cost parameters, as in the second version of the function; in that case they all default to 1.

levenshtein_less_equal is an accelerated version of the Levenshtein function for use when only small distances are of interest. If the actual distance is less than or equal to max_d, then levenshtein_less_equal returns the correct distance; otherwise it returns some value greater than max_d. If max_d is negative then the behavior is the same as levenshtein.

Examples:

test=# SELECT levenshtein('GUMBO', 'GAMBOL');
        levenshtein
    ---------
        2
(1 row)
test=# SELECT levenshtein('GUMBO', 'GAMBOL', 2, 1, 1);
        levenshtein
    ---------
        3
(1 row)
test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 2);
  levenshtein_less_equal
------------------------
        3
(1 row)
test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 4);
  levenshtein_less_equal
------------------------
        4
(1 row)

F.17.4. Metaphone

Metaphone, like Soundex, is based on the idea of constructing a representative code for an input string. Two strings are then deemed similar if they have the same codes.

This function calculates the metaphone code of an input string:

metaphone(source text, max_output_length int) returns text

source has to be a non-null string with a maximum of 255 characters. max_output_length sets the maximum length of the output metaphone code; if longer, the output is truncated to this length.
Example:

test=# SELECT metaphone('GUMBO', 4);
metaphone
-------
KM
(1 row)

F.17.5. Double Metaphone

The Double Metaphone system computes two “sounds like” strings for a given input string — a “primary” and an “alternate”. In most cases they are the same, but for non-English names especially they can be a bit different, depending on pronunciation. These functions compute the primary and alternate codes:

dmetaphone(source text) returns text
dmetaphone_alt(source text) returns text

There is no length limit on the input strings.

Example:

test=# SELECT dmetaphone('gumbo');
dmetaphone
-------
KMP
(1 row)
F.18. hstore — hstore key/value datatype

This module implements the hstore data type for storing sets of key/value pairs within a single PostgreSQL value. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data. Keys and values are simply text strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.18.1. hstore External Representation

The text representation of an hstore, used for input and output, includes zero or more key => value pairs separated by commas. Some examples:

k => v
foo => bar, baz => whatever
"1-a" => "anything at all"

The order of the pairs is not significant (and may not be reproduced on output). Whitespace between pairs or around the => sign is ignored. Double-quote keys and values that include whitespace, commas, =s or >s. To include a double quote or a backslash in a key or value, escape it with a backslash.

Each key in an hstore is unique. If you declare an hstore with duplicate keys, only one will be stored in the hstore and there is no guarantee as to which will be kept:

```
SELECT 'a=>1,a=>2'::hstore;
   hstore
-------------
   "a"=>"1"
```

A value (but not a key) can be an SQL NULL. For example:

```
key => NULL
```

The NULL keyword is case-insensitive. Double-quote the NULL to treat it as the ordinary string “NULL”.

Note

Keep in mind that the hstore text format, when used for input, applies before any required quoting or escaping. If you are passing an hstore literal via a parameter, then no additional processing is needed. But if you’re passing it as a quoted literal constant, then any single-quote characters and (depending on the setting of the standard_conforming_strings configuration parameter) backslash characters need to be escaped correctly. See Section 4.1.2.1 for more on the handling of string constants.

On output, double quotes always surround keys and values, even when it’s not strictly necessary.

F.18.2. hstore Operators and Functions

The operators provided by the hstore module are shown in Table F.7, the functions in Table F.8.
### Table F.7. hstore Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>hstore -&gt; text -&gt; text</code></td>
<td>Returns value associated with given key, or NULL if not present.</td>
<td><code>'a=&gt;x, b=&gt;y': hstore -&gt; 'a' -&gt; x</code></td>
</tr>
<tr>
<td><code>hstore -&gt; text[] -&gt; text[]</code></td>
<td>Returns values associated with given keys, or NULL if not present.</td>
<td><code>'a=x, b=y, c=z': hstore -&gt; ARRAY['c', 'a'] -&gt; {&quot;z&quot;, &quot;x&quot;}</code></td>
</tr>
<tr>
<td>`hstore</td>
<td></td>
<td>hstore`</td>
</tr>
<tr>
<td><code>hstore ? text -&gt; boolean</code></td>
<td>Does hstore contain key?</td>
<td><code>'a=1': hstore ? 'a' -&gt; t</code></td>
</tr>
<tr>
<td><code>hstore ?&amp; text[] -&gt; boolean</code></td>
<td>Does hstore contain all the specified keys?</td>
<td><code>'a=1, b=2': hstore ?&amp; ARRAY['a', 'b'] -&gt; t</code></td>
</tr>
<tr>
<td>`hstore ?</td>
<td>text[] -&gt; boolean`</td>
<td>Does hstore contain any of the specified keys?</td>
</tr>
<tr>
<td><code>hstore @&gt; hstore</code></td>
<td>Does left operand contain right?</td>
<td><code>'a=b, b=1, c=NULL': hstore @&gt; 'b=1' -&gt; t</code></td>
</tr>
<tr>
<td><code>hstore &lt;@ hstore</code></td>
<td>Is left operand contained in right?</td>
<td><code>'a=c': hstore &lt;@ 'a=&gt;b, b=1, c=NULL' -&gt; f</code></td>
</tr>
<tr>
<td><code>hstore - text -&gt; hstore</code></td>
<td>Deletes key from left operand.</td>
<td><code>'a=1, b=2, c=3': hstore - 'b': text -&gt; &quot;a&quot;=&quot;1&quot;, &quot;c&quot;=&quot;3&quot;</code></td>
</tr>
<tr>
<td><code>hstore - text[] -&gt; hstore</code></td>
<td>Deletes keys from left operand.</td>
<td><code>'a=1, b=2, c=3': hstore - ARRAY['a', 'b'] -&gt; &quot;c&quot;=&quot;3&quot;</code></td>
</tr>
<tr>
<td><code>hstore - hstore</code></td>
<td>Deletes pairs from left operand that match pairs in the right operand.</td>
<td><code>'a=1, b=2, c=3': hstore - 'a=4, b=2': hstore -&gt; &quot;a&quot;=&quot;1&quot;, &quot;c&quot;=&quot;3&quot;</code></td>
</tr>
<tr>
<td><code>anyelement #= hstore</code></td>
<td>Replaces fields in the left operand (which must be a composite type) with matching values from hstore.</td>
<td><code>ROW(1,3) #= 'f1=&gt;11': hstore -&gt; (11, 3)</code></td>
</tr>
<tr>
<td><code>%% hstore -&gt; text[]</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

</tr>
<tr>
<td>skeys(hstore) setof text</td>
<td>Extracts an hstore's keys as a set.</td>
<td>skeys('a=&gt;1,b=&gt;2') → a, b</td>
</tr>
<tr>
<td>svals(hstore) setof text</td>
<td>Extracts an hstore's values as a set.</td>
<td>svals('a=&gt;1,b=&gt;2') → {1, 2}</td>
</tr>
<tr>
<td>avals(hstore) text[]</td>
<td>Extracts an hstore's values as an array.</td>
<td>avals('a=&gt;1,b=&gt;2') → {1, 2}</td>
</tr>
<tr>
<td>svals(hstore) setof text</td>
<td>Extracts an hstore's values as a set.</td>
<td>svals('a=&gt;1,b=&gt;2') → 1, 2</td>
</tr>
</tbody>
</table>
## Additional Supplied Modules and Extensions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Example(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>hstore_to_array(hstore) → text[]</code></td>
<td>Extracts an <code>hstore</code>'s keys and values as an array of alternating keys and values.</td>
<td><code>hstore_to_array('a=&gt;1,b=&gt;2') → {a,1,b,2}</code></td>
</tr>
<tr>
<td><code>hstore_to_matrix(hstore) → text[]</code></td>
<td>Extracts an <code>hstore</code>'s keys and values as a two-dimensional array.</td>
<td><code>hstore_to_matrix('a=&gt;1,b=&gt;2') → {{a,1},{b,2}}</code></td>
</tr>
<tr>
<td><code>hstore_to_json(hstore) → json</code></td>
<td>Converts an <code>hstore</code> to a JSON value, converting all non-null values to JSON strings. This function is used implicitly when an <code>hstore</code> value is cast to <code>json</code>.</td>
<td><code>hstore_to_json(&quot;a key&quot;:1, b=&gt;t, c=&gt;null, d=&gt;12345, e=&gt;012345, f=&gt;1.234, g=&gt;2.345e+4&quot;) → {&quot;a key&quot;: 1, &quot;b&quot;: true, &quot;c&quot;: null, &quot;d&quot;: 12345, &quot;e&quot;: &quot;012345&quot;, &quot;f&quot;: 1.234, &quot;g&quot;: 2.345e+4}</code></td>
</tr>
<tr>
<td><code>hstore_to_jsonb(hstore) → jsonb</code></td>
<td>Converts an <code>hstore</code> to a <code>jsonb</code> value, converting all non-null values to JSON strings. This function is used implicitly when an <code>hstore</code> value is cast to <code>jsonb</code>.</td>
<td><code>hstore_to_jsonb(&quot;a key&quot;:1, b=&gt;t, c=&gt;null, d=&gt;12345, e=&gt;012345, f=&gt;1.234, g=&gt;2.345e+4&quot;) → {&quot;a key&quot;: 1, &quot;b&quot;: true, &quot;c&quot;: null, &quot;d&quot;: 12345, &quot;e&quot;: &quot;012345&quot;, &quot;f&quot;: 1.234, &quot;g&quot;: 2.345e+4}</code></td>
</tr>
<tr>
<td><code>hstore_to_json_loose(hstore) → json</code></td>
<td>Converts an <code>hstore</code> to a JSON value, but attempts to distinguish numerical and Boolean values so they are unquoted in the JSON.</td>
<td><code>hstore_to_json_loose(&quot;a key&quot;:1, b=&gt;t, c=&gt;null, d=&gt;12345, e=&gt;012345, f=&gt;1.234, g=&gt;2.345e+4&quot;) → {&quot;a key&quot;: 1, &quot;b&quot;: true, &quot;c&quot;: null, &quot;d&quot;: 12345, &quot;e&quot;: &quot;012345&quot;, &quot;f&quot;: 1.234, &quot;g&quot;: 2.345e+4}</code></td>
</tr>
<tr>
<td><code>hstore_to_jsonb_loose(hstore) → jsonb</code></td>
<td>Converts an <code>hstore</code> to a <code>jsonb</code> value, but attempts to distinguish numerical and Boolean values so they are unquoted in the JSON.</td>
<td><code>hstore_to_jsonb_loose(&quot;a key&quot;:1, b=&gt;t, c=&gt;null, d=&gt;12345, e=&gt;012345, f=&gt;1.234, g=&gt;2.345e+4&quot;) → {&quot;a key&quot;: 1, &quot;b&quot;: true, &quot;c&quot;: null, &quot;d&quot;: 12345, &quot;e&quot;: &quot;012345&quot;, &quot;f&quot;: 1.234, &quot;g&quot;: 2.345e+4}</code></td>
</tr>
<tr>
<td><code>slice(hstore,text[]) → hstore</code></td>
<td>Extracts a subset of an <code>hstore</code> containing only the specified keys.</td>
<td><code>slice('a=&gt;1,b=&gt;2,c=&gt;3':hstore, ARRAY['b','c','x']) → {&quot;b&quot;:&quot;2&quot;, &quot;c&quot;:&quot;3&quot;}</code></td>
</tr>
</tbody>
</table>
| `each(hstore) → setof record(key text,value text)` | Extracts an `hstore`'s keys and values as a set of records. | `select * from each('a=>1,b=>2') →

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>1</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------------------------</td>
</tr>
<tr>
<td>exist(hstore, text) → boolean</td>
<td>Does hstore contain key?</td>
</tr>
<tr>
<td>defined(hstore, text) → boolean</td>
<td>Does hstore contain a non-NULL value for key?</td>
</tr>
<tr>
<td>delete(hstore, text) → hstore</td>
<td>Deletes pair with matching key.</td>
</tr>
<tr>
<td>delete(hstore, text[]) → hstore</td>
<td>Deletes pairs with matching keys.</td>
</tr>
<tr>
<td>delete(hstore, hstore) → hstore</td>
<td>Deletes pairs matching those in the second argument.</td>
</tr>
<tr>
<td>populate_record(anyelement, hstore) → anyelement</td>
<td>Replaces fields in the left operand (which must be a composite type) with matching values from hstore.</td>
</tr>
</tbody>
</table>

In addition to these operators and functions, values of the hstore type can be subscripted, allowing them to act like associative arrays. Only a single subscript of type text can be specified; it is interpreted as a key and the corresponding value is fetched or stored. For example,

```sql
CREATE TABLE mytable (h hstore);
INSERT INTO mytable VALUES ('a'=>b, c=>d);
SELECT h['a'] FROM mytable;
  h
  b
(1 row)

UPDATE mytable SET h['c'] = 'new';
SELECT h FROM mytable;
  h
----------------------
"a"=>"b", "c"=>"new"
(1 row)
```

A subscripted fetch returns NULL if the subscript is NULL or that key does not exist in the hstore. (Thus, a subscripted fetch is not greatly different from the -> operator.) A subscripted update fails if the subscript is NULL; otherwise, it replaces the value for that key, adding an entry to the hstore if the key does not already exist.

### F.18.3. Indexes

hstore has GiST and GIN index support for the @>, ?, ?& and ? | operators. For example:
CREATE INDEX hidx ON testhstore USING GIST (h);
CREATE INDEX hidx ON testhstore USING GIN (h);

gist_hstore_ops GiST opclass approximates a set of key/value pairs as a bitmap signature. Its optional integer parameter siglen determines the signature length in bytes. The default length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

CREATE INDEX hidx ON testhstore USING GIST (h gist_hstore_ops(siglen=32));

hstore also supports btree or hash indexes for the = operator. This allows hstore columns to be declared UNIQUE, or to be used in GROUP BY, ORDER BY or DISTINCT expressions. The sort ordering for hstore values is not particularly useful, but these indexes may be useful for equivalence lookups. Create indexes for = comparisons as follows:

CREATE INDEX hidx ON testhstore USING BTREE (h);
CREATE INDEX hidx ON testhstore USING HASH (h);

F.18.4. Examples

Add a key, or update an existing key with a new value:

UPDATE tab SET h['c'] = '3';

Another way to do the same thing is:

UPDATE tab SET h = h || hstore('c', '3');

If multiple keys are to be added or changed in one operation, the concatenation approach is more efficient than scripting:

UPDATE tab SET h = h || hstore(array['q', 'w'], array['11', '12']);

Delete a key:

UPDATE tab SET h = delete(h, 'k1');

Convert a record to an hstore:

CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');

SELECT hstore(t) FROM test AS t;

-----------------------------
"col1"=>"123", "col2"=>"foo", "col3"=>"bar"
Convert an \texttt{hstore} to a predefined record type:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
SELECT * FROM populate_record(null::test,
    "col1"=>"456", "col2"=>"zzz");
```

```
col1 | col2 | col3
------|------|------
456   | zzz  |      
(1 row)
```

Modify an existing record using the values from an \texttt{hstore}:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');
SELECT (r).* FROM (SELECT t #= "col3"=>'baz' AS r FROM test t) s;
```

```
col1 | col2 | col3
------|------|------
123   | foo  | baz  
(1 row)
```

\section*{F.18.5. Statistics}

The \texttt{hstore} type, because of its intrinsic liberality, could contain a lot of different keys. Checking for valid keys is the task of the application. The following examples demonstrate several techniques for checking keys and obtaining statistics.

Simple example:

```
SELECT * FROM each('aaa=>bq, b=>NULL, ""=>1');
```

```
Using a table:

CREATE TABLE stat AS SELECT (each(h)).key, (each(h)).value FROM testhstore;

Online statistics:

```
SELECT key, count(*) FROM
    (SELECT (each(h)).key FROM testhstore) AS stat
GROUP BY key
ORDER BY count DESC, key;
```

```
key    | count
-------+-------
line   |  883  
query  |  207  
pos    |  203  
node   |  202  
space  |  197  
status |  195  
public |  194  
```

2747
F.18.6. Compatibility

As of PostgreSQL 9.0, hstore uses a different internal representation than previous versions. This presents no obstacle for dump/restore upgrades since the text representation (used in the dump) is unchanged.

In the event of a binary upgrade, upward compatibility is maintained by having the new code recognize old-format data. This will entail a slight performance penalty when processing data that has not yet been modified by the new code. It is possible to force an upgrade of all values in a table column by doing an UPDATE statement as follows:

UPDATE tablename SET hstorecol = hstorecol || '';

Another way to do it is:

ALTER TABLE tablename ALTER hstorecol TYPE hstore USING hstorecol || '';

The ALTER TABLE method requires an ACCESS EXCLUSIVE lock on the table, but does not result in bloating the table with old row versions.

F.18.7. Transforms

Additional extensions are available that implement transforms for the hstore type for the languages PL/Perl and PL/Python. The extensions for PL/Perl are called hstore_plperl and hstore_plperlu, for trusted and untrusted PL/Perl. If you install these transforms and specify them when creating a function, hstore values are mapped to Perl hashes. The extension for PL/Python is called hstore_plpython3u. If you use it, hstore values are mapped to Python dictionaries.

Caution

It is strongly recommended that the transform extensions be installed in the same schema as hstore. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

F.19. intagg — integer aggregator and enumerator

The intagg module provides an integer aggregator and an enumerator. intagg is now obsolete, because there are built-in functions that provide a superset of its capabilities. However, the module is still provided as a compatibility wrapper around the built-in functions.

F.19.1. Functions

The aggregator is an aggregate function \texttt{int_array_aggregate(integer)} that produces an integer array containing exactly the integers it is fed. This is a wrapper around \texttt{array_agg}, which does the same thing for any array type.

The enumerator is a function \texttt{int_array_enum(integer[])} that returns \texttt{setof integer}. It is essentially the reverse operation of the aggregator: given an array of integers, expand it into a set of rows. This is a wrapper around \texttt{unnest}, which does the same thing for any array type.

F.19.2. Sample Uses

Many database systems have the notion of a one to many table. Such a table usually sits between two indexed tables, for example:

\begin{verbatim}
CREATE TABLE left (id INT PRIMARY KEY, ...);
CREATE TABLE right (id INT PRIMARY KEY, ...);
CREATE TABLE one_to_many(left INT REFERENCES left, right INT REFERENCES right);
\end{verbatim}

It is typically used like this:

\begin{verbatim}
SELECT right.* from right JOIN one_to_many ON (right.id =
  one_to_many.right)
  WHERE one_to_many.left = item;
\end{verbatim}

This will return all the items in the right hand table for an entry in the left hand table. This is a very common construct in SQL.

Now, this methodology can be cumbersome with a very large number of entries in the \texttt{one_to_many} table. Often, a join like this would result in an index scan and a fetch for each right hand entry in the table for a particular left hand entry. If you have a very dynamic system, there is not much you can do. However, if you have some data which is fairly static, you can create a summary table with the aggregator.

\begin{verbatim}
CREATE TABLE summary AS
  SELECT left, int_array_aggregate(right) AS right
  FROM one_to_many
  GROUP BY left;
\end{verbatim}

This will create a table with one row per left item, and an array of right items. Now this is pretty useless without some way of using the array; that’s why there is an array enumerator. You can do

\begin{verbatim}
SELECT left, int_array_enum(right) FROM summary WHERE left = item;
\end{verbatim}

The above query using \texttt{int_array_enum} produces the same results as
SELECT left, right FROM one_to_many WHERE left = item;

The difference is that the query against the summary table has to get only one row from the table, whereas the direct query against one_to_many must index scan and fetch a row for each entry.

On one system, an EXPLAIN showed a query with a cost of 8488 was reduced to a cost of 329. The original query was a join involving the one_to_many table, which was replaced by:

SELECT right, count(right) FROM 
    ( SELECT left, int_array_enum(right) AS right 
        FROM summary JOIN (SELECT left FROM left_table WHERE left = item) AS lefts 
        ON (summary.left = lefts.left) 
    ) AS list 
GROUP BY right 
ORDER BY count DESC;
The `intarray` module provides a number of useful functions and operators for manipulating null-free arrays of integers. There is also support for indexed searches using some of the operators.

All of these operations will throw an error if a supplied array contains any NULL elements.

Many of these operations are only sensible for one-dimensional arrays. Although they will accept input arrays of more dimensions, the data is treated as though it were a linear array in storage order.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.20.1. `intarray` Functions and Operators

The functions provided by the `intarray` module are shown in Table F.9, the operators in Table F.10.

#### Table F.9. `intarray` Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Example(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>icount</td>
<td>Returns the number of elements in the array.</td>
<td>icount('1,2,3'::integer[]) → 3</td>
</tr>
<tr>
<td>sort</td>
<td>Sorts the array in either ascending or descending order. <code>dir</code> must be <code>asc</code> or <code>desc</code>.</td>
<td>sort('(1,3,2)'::integer[], 'desc') → {3,2,1}</td>
</tr>
<tr>
<td>sort_asc</td>
<td>Sorts in ascending order.</td>
<td>sort(array[11,77,44]) → {11,44,77}</td>
</tr>
<tr>
<td>sort_desc</td>
<td>Sorts in descending order.</td>
<td>sort_desc(array[11,77,44]) → {77,44,11}</td>
</tr>
<tr>
<td>uniq</td>
<td>Removes adjacent duplicates. Often used with <code>sort</code> to remove all duplicates.</td>
<td>uniq('1,2,2,3,1,1'::integer[]) → {1,2,3,1}</td>
</tr>
<tr>
<td>idx</td>
<td>Returns index of the first array element matching <code>item</code>, or 0 if no match.</td>
<td>idx(array[11,22,33,22,11], 22) → 2</td>
</tr>
<tr>
<td>subarray</td>
<td>Extracts the portion of the array starting at position <code>start</code> with <code>len</code> elements.</td>
<td>subarray('(1,2,3,2,1)'::integer[], 2, 3) → {2,3,2}</td>
</tr>
</tbody>
</table>

#### Table F.10. `intarray` Operators

The operators provided by the `intarray` module are shown in Table F.10.
### Additional Supplied Modules and Extensions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Example(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>intset(integer) → integer[]</td>
<td>Makes a single-element array.</td>
<td>intset(42) → {42}</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Table F.10. intarray Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operator</td>
</tr>
<tr>
<td>---------</td>
</tr>
<tr>
<td>integer[] &amp;&amp; integer[] → boolean</td>
</tr>
<tr>
<td>integer[] @&gt; integer[] → boolean</td>
</tr>
<tr>
<td>integer[] &lt;@ integer[] → boolean</td>
</tr>
<tr>
<td># integer[] → integer</td>
</tr>
<tr>
<td>integer[] # integer → integer</td>
</tr>
<tr>
<td>integer[] + integer → integer[]</td>
</tr>
<tr>
<td>integer[] + integer[] → integer[]</td>
</tr>
<tr>
<td>integer[] - integer → integer[]</td>
</tr>
<tr>
<td>integer[] - integer[] → integer[]</td>
</tr>
<tr>
<td>integer[]</td>
</tr>
<tr>
<td>integer[]</td>
</tr>
<tr>
<td>integer[] &amp; integer[] → integer[]</td>
</tr>
<tr>
<td>integer[] @@ query_int → boolean</td>
</tr>
<tr>
<td>query_int ~~ integer[] → boolean</td>
</tr>
</tbody>
</table>

The operators &&, @> and <@ are equivalent to PostgreSQL’s built-in operators of the same names, except that they work only on integer arrays that do not contain nulls, while the built-in operators work for any array type. This restriction makes them faster than the built-in operators in many cases.

The @@ and ~~ operators test whether an array satisfies a *query*, which is expressed as a value of a specialized data type `query_int`. A *query* consists of integer values that are checked against...
the elements of the array, possibly combined using the operators & (AND), | (OR), and ! (NOT). Parentheses can be used as needed. For example, the query $1 \& (2 | 3)$ matches arrays that contain 1 and also contain either 2 or 3.

**F.20.2. Index Support**

`intarray` provides index support for the & & , @> , and @@ operators, as well as regular array equality.

Two parameterized GiST index operator classes are provided: `gist__int_ops` (used by default) is suitable for small- to medium-size data sets, while `gist__intbig_ops` uses a larger signature and is more suitable for indexing large data sets (i.e., columns containing a large number of distinct array values). The implementation uses an RD-tree data structure with built-in lossy compression.

`gist__int_ops` approximates an integer set as an array of integer ranges. Its optional integer parameter `numranges` determines the maximum number of ranges in one index key. The default value of `numranges` is 100. Valid values are between 1 and 253. Using larger arrays as GiST index keys leads to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

`gist__intbig_ops` approximates an integer set as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

There is also a non-default GIN operator class `gin__int_ops`, which supports these operators as well as @{`.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

**F.20.3. Example**

```sql
-- a message can be in one or more "sections"
CREATE TABLE message (mid INT PRIMARY KEY, sections INT[], ...);

-- create specialized index with signature length of 32 bytes
CREATE INDEX message_rdtree_idx ON message USING GIST (sections gist__intbig_ops (siglen = 32));

-- select messages in section 1 OR 2 - OVERLAP operator
SELECT message.mid FROM message WHERE message.sections &\& '{1,2}';

-- select messages in sections 1 AND 2 - CONTAINS operator
SELECT message.mid FROM message WHERE message.sections @> '{1,2}';

-- the same, using QUERY operator
SELECT message.mid FROM message WHERE message.sections @@ '1&2':/:query_int;
```

**F.20.4. Benchmark**

The source directory `contrib/intarray/bench` contains a benchmark test suite, which can be run against an installed PostgreSQL server. (It also requires `DBD::Pg` to be installed.) To run:

```bash
cd ../contrib/intarray/bench
createdb TEST
```
psql -c "CREATE EXTENSION intarray" TEST
./create_test.pl | psql TEST
./bench.pl

The `bench.pl` script has numerous options, which are displayed when it is run without any arguments.

**F.20.5. Authors**

All work was done by Teodor Sigaev (<teodor@sigaev.ru>) and Oleg Bartunov (<oleg@sai.msu.su>). See http://www.sai.msu.su/~megera/postgres/gist/ for additional information. Andrey Oktyabrski did a great work on adding new functions and operations.
The isn module provides data types for the following international product numbering standards: EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials). Numbers are validated on input according to a hard-coded list of prefixes; this list of prefixes is also used to hyphenate numbers on output. Since new prefixes are assigned from time to time, the list of prefixes may be out of date. It is hoped that a future version of this module will obtain the prefix list from one or more tables that can be easily updated by users as needed; however, at present, the list can only be updated by modifying the source code and recompiling. Alternatively, prefix validation and hyphenation support may be dropped from a future version of this module.

This module is considered "trusted", that is, it can be installed by non-superusers who have CREATE privilege on the current database.

### F.21.1. Data Types

Table F.11 shows the data types provided by the isn module.

**Table F.11. isn Data Types**

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAN13</td>
<td>European Article Numbers, always displayed in the EAN13 display format</td>
</tr>
<tr>
<td>ISBN13</td>
<td>International Standard Book Numbers to be displayed in the new EAN13 display format</td>
</tr>
<tr>
<td>ISMN13</td>
<td>International Standard Music Numbers to be displayed in the new EAN13 display format</td>
</tr>
<tr>
<td>ISSN13</td>
<td>International Standard Serial Numbers to be displayed in the new EAN13 display format</td>
</tr>
<tr>
<td>ISBN</td>
<td>International Standard Book Numbers to be displayed in the old short display format</td>
</tr>
<tr>
<td>ISMN</td>
<td>International Standard Music Numbers to be displayed in the old short display format</td>
</tr>
<tr>
<td>ISSN</td>
<td>International Standard Serial Numbers to be displayed in the old short display format</td>
</tr>
<tr>
<td>UPC</td>
<td>Universal Product Codes</td>
</tr>
</tbody>
</table>

Some notes:
1. ISBN13, ISMN13, ISSN13 numbers are all EAN13 numbers.
2. EAN13 numbers aren't always ISBN13, ISMN13 or ISSN13 (some are).
3. Some ISBN13 numbers can be displayed as ISBN.
4. Some ISMN13 numbers can be displayed as ISMN.
5. Some ISSN13 numbers can be displayed as ISSN.
6. UPC numbers are a subset of the EAN13 numbers (they are basically EAN13 without the first 0 digit).
7. All UPC, ISBN, ISMN and ISSN numbers can be represented as EAN13 numbers.
Internally, all these types use the same representation (a 64-bit integer), and all are interchangeable. Multiple types are provided to control display formatting and to permit tighter validity checking of input that is supposed to denote one particular type of number.

The ISBN, ISMN, and ISSN types will display the short version of the number (ISxN 10) whenever it's possible, and will show ISxN 13 format for numbers that do not fit in the short version. The EAN13, ISBN13, ISMN13 and ISSN13 types will always display the long version of the ISxN (EAN13).

### F.21.2. Casts

The isn module provides the following pairs of type casts:

- ISBN13 <-> EAN13
- ISMN13 <-> EAN13
- ISSN13 <-> EAN13
- ISBN <-> EAN13
- ISMN <-> EAN13
- ISSN <-> EAN13
- UPC <-> EAN13
- ISMN <-> ISMN13
- ISSN <-> ISSN13

When casting from EAN13 to another type, there is a run-time check that the value is within the domain of the other type, and an error is thrown if not. The other casts are simply relabelings that will always succeed.

### F.21.3. Functions and Operators

The isn module provides the standard comparison operators, plus B-tree and hash indexing support for all these data types. In addition there are several specialized functions; shown in Table F.12. In this table, isn means any one of the module's data types.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>isn_weak(boolean) → boolean</td>
<td>Sets the weak input mode, and returns new setting.</td>
</tr>
<tr>
<td>isn_weak() → boolean</td>
<td>Returns the current status of the weak mode.</td>
</tr>
<tr>
<td>make_valid(isn) → isn</td>
<td>Validates an invalid number (clears the invalid flag).</td>
</tr>
<tr>
<td>is_valid(isn) → boolean</td>
<td>Checks for the presence of the invalid flag.</td>
</tr>
</tbody>
</table>

*Weak* mode is used to be able to insert invalid data into a table. Invalid means the check digit is wrong, not that there are missing numbers.
Why would you want to use the weak mode? Well, it could be that you have a huge collection of ISBN numbers, and that there are so many of them that for weird reasons some have the wrong check digit (perhaps the numbers were scanned from a printed list and the OCR got the numbers wrong, perhaps the numbers were manually captured... who knows). Anyway, the point is you might want to clean the mess up, but you still want to be able to have all the numbers in your database and maybe use an external tool to locate the invalid numbers in the database so you can verify the information and validate it more easily; so for example you’d want to select all the invalid numbers in the table.

When you insert invalid numbers in a table using the weak mode, the number will be inserted with the corrected check digit, but it will be displayed with an exclamation mark (!) at the end, for example 0-11-000322-5!. This invalid marker can be checked with the is_valid function and cleared with the make_valid function.

You can also force the insertion of invalid numbers even when not in the weak mode, by appending the ! character at the end of the number.

Another special feature is that during input, you can write ? in place of the check digit, and the correct check digit will be inserted automatically.

F.21.4. Examples

--Using the types directly:
SELECT isbn('978-0-393-04002-9');
SELECT isbn13('0901690546');
SELECT issn('1436-4522');

--Casting types:
-- note that you can only cast from ean13 to another type when the
-- number would be valid in the realm of the target type;
-- thus, the following will NOT work: select
isbn(ean13('0220356483481'));
-- but these will:
SELECT upc(ean13('0220356483481'));
SELECT ean13(upc('220356483481'));

--Create a table with a single column to hold ISBN numbers:
CREATE TABLE test (id isbn);
INSERT INTO test VALUES('9780393040029');

--Automatically calculate check digits (observe the '?'):
INSERT INTO test VALUES('220500896?');
INSERT INTO test VALUES('978055215372?');
SELECT issn('3251231?');
SELECT ismn('979047213542?');

--Using the weak mode:
SELECT isn_weak(true);
INSERT INTO test VALUES('978-0-11-000533-4');
INSERT INTO test VALUES('9780141219307');
INSERT INTO test VALUES('2-205-00876-X');
SELECT isn_weak(false);

SELECT id FROM test WHERE NOT is_valid(id);
UPDATE test SET id = make_valid(id) WHERE id = '2-205-00876-X!';

SELECT * FROM test;
SELECT isbn13(id) FROM test;

F.21.5. Bibliography

The information to implement this module was collected from several sites, including:

- https://www.isbn-international.org/
- https://www.issn.org/
- https://www.ismn-international.org/
- https://www.wikipedia.org/

The prefixes used for hyphenation were also compiled from:

- https://www.gs1.org/standards/id-keys
- https://www.isbn-international.org/content/isbn-users-manual
- https://www.ismn-international.org/ranges.html

Care was taken during the creation of the algorithms and they were meticulously verified against the suggested algorithms in the official ISBN, ISMN, ISSN User Manuals.

F.21.6. Author

Germán Méndez Bravo (Kronuz), 2004–2006

This module was inspired by Garrett A. Wollman's isbn_issn code.
F.22. lo — manage large objects

The lo module provides support for managing Large Objects (also called LOs or BLOBs). This includes a data type lo and a trigger lo_manage.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.22.1. Rationale

One of the problems with the JDBC driver (and this affects the ODBC driver also), is that the specification assumes that references to BLOBs (Binary Large OBjects) are stored within a table, and if that entry is changed, the associated BLOB is deleted from the database.

As PostgreSQL stands, this doesn't occur. Large objects are treated as objects in their own right; a table entry can reference a large object by OID, but there can be multiple table entries referencing the same large object OID, so the system doesn't delete the large object just because you change or remove one such entry.

Now this is fine for PostgreSQL-specific applications, but standard code using JDBC or ODBC won't delete the objects, resulting in orphan objects — objects that are not referenced by anything, and simply occupy disk space.

The lo module allows fixing this by attaching a trigger to tables that contain LO reference columns. The trigger essentially just does a lo_unlink whenever you delete or modify a value referencing a large object. When you use this trigger, you are assuming that there is only one database reference to any large object that is referenced in a trigger-controlled column!

The module also provides a data type lo, which is really just a domain over the oid type. This is useful for differentiating database columns that hold large object references from those that are OIDs of other things. You don't have to use the lo type to use the trigger, but it may be convenient to use it to keep track of which columns in your database represent large objects that you are managing with the trigger. It is also rumored that the ODBC driver gets confused if you don't use lo for BLOB columns.

F.22.2. How to Use It

Here's a simple example of usage:

```sql
CREATE TABLE image (title text, raster lo);
CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON image
    FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
```

For each column that will contain unique references to large objects, create a BEFORE UPDATE OR DELETE trigger, and give the column name as the sole trigger argument. You can also restrict the trigger to only execute on updates to the column by using BEFORE UPDATE OF column_name. If you need multiple lo columns in the same table, create a separate trigger for each one, remembering to give a different name to each trigger on the same table.

F.22.3. Limitations

- Dropping a table will still orphan any objects it contains, as the trigger is not executed. You can avoid this by preceding the DROP TABLE with DELETE FROM table.

TRUNCATE has the same hazard.
If you already have, or suspect you have, orphaned large objects, see the vacuumlo module to help you clean them up. It's a good idea to run vacuumlo occasionally as a back-stop to the lo_manage trigger.

- Some frontends may create their own tables, and will not create the associated trigger(s). Also, users may not remember (or know) to create the triggers.

**F.22.4. Author**

Peter Mount <peter@retep.org.uk>
Additional Supplied Modules and Extensions

F.23. ltree — hierarchical tree-like data type

This module implements a data type `ltree` for representing labels of data stored in a hierarchical tree-like structure. Extensive facilities for searching through label trees are provided.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.23.1. Definitions

A *label* is a sequence of alphanumeric characters, underscores, and hyphens. Valid alphanumeric character ranges are dependent on the database locale. For example, in C locale, the characters `A-Za-z0-9_-` are allowed. Labels must be no more than 1000 characters long.

Examples: 42, Personal_Services

A *label path* is a sequence of zero or more labels separated by dots, for example `L1.L2.L3`, representing a path from the root of a hierarchical tree to a particular node. The length of a label path cannot exceed 65535 labels.

Example: Top.Countries.Europe.Russia

The `ltree` module provides several data types:

- `ltree` stores a label path.
- `lquery` represents a regular-expression-like pattern for matching `ltree` values. A simple word matches that label within a path. A star symbol (`*`) matches zero or more labels. These can be joined with dots to form a pattern that must match the whole label path. For example:

```
foo           Match the exact label path foo
*.foo.*       Match any label path containing the label foo
*.foo         Match any label path whose last label is foo
```

Both star symbols and simple words can be quantified to restrict how many labels they can match:

```
*{n}          Match exactly n labels
*{n,m}        Match at least n but not more than m labels
*{,m}         Match at most m labels — same as *{0,m}
foo{,m}       Match at least n but not more than m occurrences of foo
foo{,}        Match any number of occurrences of foo, including zero
```

In the absence of any explicit quantifier, the default for a star symbol is to match any number of labels (that is, `{,}`) while the default for a non-star item is to match exactly once (that is, `{1}`).

There are several modifiers that can be put at the end of a non-star `lquery` item to make it match more than just the exact match:

```
@            Match case-insensitively, for example a@ matches A
*            Match any label with this prefix, for example foo*
%            Match initial underscore-separated words
```

2761
The behavior of `%` is a bit complicated. It tries to match words rather than the entire label. For example `foo_bar%` matches `foo_bar_baz` but not `foo_barbaz`. If combined with `*`, prefix matching applies to each word separately, for example `foo_bar%*` matches `foo1_bar2_baz` but not `foo1_br2_baz`.

Also, you can write several possibly-modified non-star items separated with `|` (OR) to match any of those items, and you can put `!` (NOT) at the start of a non-star group to match any label that doesn't match any of the alternatives. A quantifier, if any, goes at the end of the group; it means some number of matches for the group as a whole (that is, some number of labels matching or not matching any of the alternatives).

Here's an annotated example of `lquery`:

```
Top.*{0,2}.sport*@.!football|tennis{1,}.Russ*|Spain
```

This query will match any label path that:

a. begins with the label `Top`
b. and next has zero to two labels before
c. a label beginning with the case-insensitive prefix `sport`
d. then has one or more labels, none of which match `football` nor `tennis`
e. and then ends with a label beginning with `Russ` or exactly matching `Spain`.

- `ltxtquery` represents a full-text-search-like pattern for matching `ltree` values. An `ltxtquery` value contains words, possibly with the modifiers `@`, `*`, `%` at the end; the modifiers have the same meanings as in `lquery`. Words can be combined with `&` (AND), `|` (OR), `!` (NOT), and parentheses. The key difference from `lquery` is that `ltxtquery` matches words without regard to their position in the label path.

Here's an example `ltxtquery`:

```
Europe & Russia@ & !Transportation
```

This will match paths that contain the label `Europe` and any label beginning with `Russia` (case-insensitive), but not paths containing the label `Transportation`. The location of these words within the path is not important. Also, when `%` is used, the word can be matched to any underscore-separated word within a label, regardless of position.

Note: `ltxtquery` allows whitespace between symbols, but `ltree` and `lquery` do not.

### F.23.2. Operators and Functions

Type `ltree` has the usual comparison operators `=, <>, <, >, <, =, >=`. Comparison sorts in the order of a tree traversal, with the children of a node sorted by label text. In addition, the specialized operators shown in Table F.13 are available.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ltree @&gt; ltree</code></td>
<td>boolean</td>
</tr>
<tr>
<td></td>
<td>Is left argument an ancestor of right (or equal)?</td>
</tr>
<tr>
<td>Operator</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>ltree &lt;@ ltree</code> → boolean</td>
<td>Is left argument a descendant of right (or equal)?</td>
</tr>
<tr>
<td><code>ltree ~ lquery</code> → boolean</td>
<td>Does <code>ltree</code> match <code>lquery</code>?</td>
</tr>
<tr>
<td><code>lquery ~ ltree</code> → boolean</td>
<td>Does <code>lquery</code> match any <code>ltree</code> in array?</td>
</tr>
<tr>
<td><code>ltree @ lquery[]</code> → boolean</td>
<td>Does <code>lquery</code> array contain any path matching <code>ltree</code>?</td>
</tr>
<tr>
<td><code>lquery[] @ ltree</code> → boolean</td>
<td>Does <code>ltree</code> array contain any path matching any <code>lquery</code>?</td>
</tr>
<tr>
<td>`ltree</td>
<td></td>
</tr>
<tr>
<td>`ltree</td>
<td></td>
</tr>
<tr>
<td><code>ltree[] @&gt; ltree</code> → boolean</td>
<td>Returns first array entry that is an ancestor of <code>ltree</code>, or NULL if none.</td>
</tr>
<tr>
<td><code>lquery ~ ltree[]</code> → boolean</td>
<td>Does array contain any path matching <code>lquery</code>?</td>
</tr>
<tr>
<td><code>lquery[] ~ ltree[]</code> → boolean</td>
<td>Does <code>lquery</code> array contain any path matching any <code>ltree</code>?</td>
</tr>
<tr>
<td><code>ltree[] @ ltxtquery</code> → boolean</td>
<td>Does <code>ltree</code> match <code>ltxtquery</code>?</td>
</tr>
<tr>
<td><code>ltxtquery @ ltree</code> → boolean</td>
<td>Does <code>ltree</code> match <code>ltxtquery</code>?</td>
</tr>
<tr>
<td><code>ltree[] &lt;@ ltree[]</code> → boolean</td>
<td>Returns first array entry that is a descendant of <code>ltree</code>, or NULL if none.</td>
</tr>
<tr>
<td><code>ltree[] @&gt; ltree</code> → ltree</td>
<td>Returns first array entry that matches <code>lquery</code>, or NULL if none.</td>
</tr>
<tr>
<td><code>lquery[] ?@ ltxtquery</code> → ltree</td>
<td>Returns first array entry that matches <code>ltxtquery</code>, or NULL if none.</td>
</tr>
</tbody>
</table>

The operators `<@, @>, @` and `~` have analogues `^<@, ^@, ^@, ^~`, which are the same except they do not use indexes. These are useful only for testing purposes.
The available functions are shown in Table F.14.

Table F.14. ltree Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Example(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>subltree(ltree, start integer, end integer) → ltree</code></td>
<td>Returns subpath of <code>ltree</code> from position <code>start</code> to position <code>end</code>-1 (counting from 0).</td>
<td><code>subltree('Top.Child1.Child2', 1, 2) → Child1</code></td>
</tr>
<tr>
<td><code>subpath(ltree, offset integer, len integer) → ltree</code></td>
<td>Returns subpath of <code>ltree</code> starting at position <code>offset</code>, with length <code>len</code>. If <code>offset</code> is negative, subpath starts that far from the end of the path. If <code>len</code> is negative, leaves that many labels off the end of the path.</td>
<td><code>subpath('Top.Child1.Child2', 0, 2) → Top.Child1</code></td>
</tr>
<tr>
<td><code>nlevel(ltree) → integer</code></td>
<td>Returns number of labels in path.</td>
<td><code>nlevel('Top.Child1.Child2') → 3</code></td>
</tr>
<tr>
<td><code>index(a ltree, b ltree) → integer</code></td>
<td>Returns position of first occurrence of <code>b</code> in <code>a</code>, or -1 if not found.</td>
<td><code>index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6') → 6</code></td>
</tr>
<tr>
<td><code>index(a ltree, b ltree, offset integer) → integer</code></td>
<td>Returns position of first occurrence of <code>b</code> in <code>a</code>, or -1 if not found. The search starts at position <code>offset</code>; negative <code>offset</code> means start <code>-offset</code> labels from the end of the path.</td>
<td><code>index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6', -4) → 9</code></td>
</tr>
<tr>
<td><code>text2ltree(text) → ltree</code></td>
<td>Casts <code>text</code> to <code>ltree</code>.</td>
<td></td>
</tr>
<tr>
<td><code>ltree2text(ltree) → text</code></td>
<td>Casts <code>ltree</code> to <code>text</code>.</td>
<td></td>
</tr>
<tr>
<td><code>lca(ltree[], ltree[...]) → ltree</code></td>
<td>Computes longest common ancestor of paths (up to 8 arguments are supported).</td>
<td><code>lca('1.2.3', '1.2.3.4.5.6.8') → 1.2</code></td>
</tr>
<tr>
<td><code>lca(ltree[]) → ltree</code></td>
<td>Computes longest common ancestor of paths in array.</td>
<td><code>lca(array['1.2.3':ltree,'1.2.3.4']) → 1.2</code></td>
</tr>
</tbody>
</table>

F.23.3. Indexes

`ltree` supports several types of indexes that can speed up the indicated operators:

- B-tree index over `ltree`: `<, <=, =, >=, >`
- GiST index over `ltree (gist_ltree_ops opclass)`: `<, <=, =, >=, @, @>`, `@?`
gist_ltree_ops GiST opclass approximates a set of path labels as a bitmap signature. Its optional integer parameter siglen determines the signature length in bytes. The default signature length is 8 bytes. The length must be a positive multiple of int alignment (4 bytes on most machines) up to 2024. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with the default signature length of 8 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path gist_ltree_ops(siglen=100));
```

- GiST index over ltree[] (gist__ltree_ops opclass): ltree[] <@ ltree, ltree @> ltree[], @, ~, ?

gist__ltree_ops GiST opclass works similarly to gist_ltree_ops and also takes signature length as a parameter. The default value of siglen in gist__ltree_ops is 28 bytes.

Example of creating such an index with the default signature length of 28 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path gist__ltree_ops(siglen=100));
```

Note: This index type is lossy.

**F.23.4. Example**

This example uses the following data (also available in file contrib/ltree/ltreetest.sql in the source distribution):

```
CREATE TABLE test (path ltree);
INSERT INTO test VALUES ('Top');
INSERT INTO test VALUES ('Top.Science');
INSERT INTO test VALUES ('Top.Science.Astronomy');
INSERT INTO test VALUES ('Top.Science.Astronomy.Astrophysics');
INSERT INTO test VALUES ('Top.Science.Astronomy.Cosmology');
INSERT INTO test VALUES ('Top.Hobbies');
INSERT INTO test VALUES ('Top.Hobbies.Amateurs_Astronomy');
INSERT INTO test VALUES ('Top.Collections');
INSERT INTO test VALUES ('Top.Collections.Pictures');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Astronauts');
```

2765
CREATE INDEX path_gist_idx ON test USING GIST (path);
CREATE INDEX path_idx ON test USING BTREE (path);

Now, we have a table `test` populated with data describing the hierarchy shown below:

```
Top                                    
    /   |   \                                 
  Science Hobbies Collections           
    /   |   \                                 
  Astronomy Amateurs_Astronomy Pictures 
    /   |                                 
  Astrophysics Cosmology                
    /   \                             
  Galaxies Stars Astronauts
```

We can do inheritance:

```
ltreeest=> SELECT path FROM test WHERE path <@ 'Top.Science';
 path
--------------------------
 Top.Science
 Top.Science.Astronomy
 Top.Science.Astronomy.Astrophysics
(4 rows)
```

Here are some examples of path matching:

```
ltreeest=> SELECT path FROM test WHERE path ~ '*.Astronomy.*';
 path
--------------------------
 Top.Science.Astronomy
 Top.Science.Astronomy.Astrophysics
 Top.Collections.Pictures.Astronomy
(7 rows)
```

```
ltreeest=> SELECT path FROM test WHERE path ~ '*.!pictures@.Astronomy.*';
 path
--------------------------
 Top.Science.Astronomy
 Top.Science.Astronomy.Astrophysics
(3 rows)
```

Here are some examples of full text search:

```
ltreeest=> SELECT path FROM test WHERE path @ 'Astro*% & !pictures@';
 path
--------------------------
 2766
```
Additional Supplied Modules and Extensions

Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Hobbies.Amateurs_Astronomy
(4 rows)

ltreetest=> SELECT path FROM test WHERE path @ 'Astro* & ! pictures@';
    path
-------------------------
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
(3 rows)

Path construction using functions:

ltreetest=> SELECT subpath(path,0,2)||'Space'||subpath(path,2) FROM test WHERE path <@ 'Top.Science.Astronomy';
  ?column?
--------------------------
Top.Science.Space.Astronomy
(3 rows)

We could simplify this by creating an SQL function that inserts a label at a specified position in a path:

CREATE FUNCTION ins_label(ltree, int, text) RETURNS ltree
AS 'select subpath($1,0,$2) || $3 || subpath($1,$2);'
LANGUAGE SQL IMMUTABLE;

ltreetest=> SELECT ins_label(path,2,'Space') FROM test WHERE path <@ 'Top.Science.Astronomy';
  ins_label
--------------------------
Top.Science.Space.Astronomy
(3 rows)

F.23.5. Transforms

The `ltree_plpython3u` extension implements transforms for the `ltree` type for PL/Python. If installed and specified when creating a function, `ltree` values are mapped to Python lists. (The reverse is currently not supported, however.)

Caution

It is strongly recommended that the transform extension be installed in the same schema as `ltree`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.
F.23.6. Authors

All work was done by Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See http://www.sai.msu.su/~megera/postgres/gist/ for additional information. Authors would like to thank Eugeny Rodichev for helpful discussions. Comments and bug reports are welcome.
F.24. old_snapshot — inspect old_snapshot_threshold state

The old_snapshot module allows inspection of the server state that is used to implement old_snapshot_threshold.

F.24.1. Functions

pg_old_snapshot_time_mapping(array_offset OUT int4, end_timestamp OUT timestamptz, newest_xmin OUT xid) returns setof record

Returns all of the entries in the server’s timestamp to XID mapping. Each entry represents the newest xmin of any snapshot taken in the corresponding minute.
Additional Supplied  
Modules and Extensions

F.25. pageinspect — low-level inspection of database pages

The pageinspect module provides functions that allow you to inspect the contents of database pages at a low level, which is useful for debugging purposes. All of these functions may be used only by superusers.

F.25.1. General Functions

get_raw_page(relname text, fork text, blkno bigint) returns bytea

get_raw_page reads the specified block of the named relation and returns a copy as a bytea value. This allows a single time-consistent copy of the block to be obtained. fork should be 'main' for the main data fork, 'fsm' for the free space map, 'vm' for the visibility map, or 'init' for the initialization fork.

get_raw_page(relname text, blkno bigint) returns bytea

A shorthand version of get_raw_page, for reading from the main fork. Equivalent to get_raw_page(relname, 'main', blkno)

page_header(page bytea) returns record

page_header shows fields that are common to all PostgreSQL heap and index pages. A page image obtained with get_raw_page should be passed as argument. For example:

    test=# SELECT * FROM page_header(get_raw_page('pg_class', 0));
    lsn    | checksum | flags | lower | upper | special |
    -----------+----------+--------+-------+-------+---------|
    pagesize | version | prune_xid
    +------------+----------+--------------------+
    0/24A1B50 | 0        | 1      | 232   | 368   | 8192    |
    8192      | 4        | 0

    The returned columns correspond to the fields in the PageHeaderData struct. See src/include/storage/bufpage.h for details.

    The checksum field is the checksum stored in the page, which might be incorrect if the page is somehow corrupted. If data checksums are not enabled for this instance, then the value stored is meaningless.

page_checksum(page bytea, blkno bigint) returns smallint

page_checksum computes the checksum for the page, as if it was located at the given block.

A page image obtained with get_raw_page should be passed as argument. For example:

    test=# SELECT page_checksum(get_raw_page('pg_class', 0), 0);
    page_checksum
    ---------------
    13443

    Note that the checksum depends on the block number, so matching block numbers should be passed (except when doing esoteric debugging).
The checksum computed with this function can be compared with the checksum result field of the function page_header. If data checksums are enabled for this instance, then the two values should be equal.

\[ \text{fsm\_page\_contents(page bytea) returns text} \]

\[ \text{fsm\_page\_contents shows the internal node structure of an FSM page. For example:} \]

\[ \text{test=} \# \text{ SELECT fsm\_page\_contents(get\_raw\_page('pg\_class', 'fsm', 0));} \]

The output is a multiline string, with one line per node in the binary tree within the page. Only those nodes that are not zero are printed. The so-called "next" pointer, which points to the next slot to be returned from the page, is also printed.

See src/backend/storage/freespace/README for more information on the structure of an FSM page.

**F.25.2. Heap Functions**

\[ \text{heap\_page\_items(page bytea) returns setof record} \]

\[ \text{heap\_page\_items shows all line pointers on a heap page. For those line pointers that are in use, tuple headers as well as tuple raw data are also shown. All tuples are shown, whether or not the tuples were visible to an MVCC snapshot at the time the raw page was copied.} \]

A heap page image obtained with get_raw_page should be passed as argument. For example:

\[ \text{test=} \# \text{ SELECT * FROM heap\_page\_items(get\_raw\_page('pg\_class', 0));} \]

See src/include/storage/itemid.h and src/include/access/htup_details.h for explanations of the fields returned.

The heap_tuple_infomask_flags function can be used to unpack the flag bits of t_infolong and t_infomask2 for heap tuples.

\[ \text{tuple\_data\_split(rel\_oid oid, t\_data bytea, t\_infomask integer, t\_infomask2 integer, t\_bits text [, do\_detoast bool]) returns bytea[]} \]

\[ \text{tuple\_data\_split splits tuple data into attributes in the same way as backend internals.} \]

\[ \text{test=} \# \text{ SELECT tuple\_data\_split('pg\_class':::regclass, t\_data, t\_infomask, t\_infomask2, t\_bits) FROM heap\_page\_items(get\_raw\_page('pg\_class', 0));} \]

This function should be called with the same arguments as the return attributes of heap_page_items.

If do_detoast is true, attributes will be detoasted as needed. Default value is false.

\[ \text{heap\_page\_item\_attrs(page bytea, rel\_oid regclass [, do\_detoast bool]) returns setof record} \]

\[ \text{heap\_page\_item\_attrs is equivalent to heap\_page\_items except that it returns tuple raw data as an array of attributes that can optionally be detoasted by do\_detoast which is false by default.} \]

A heap page image obtained with get_raw_page should be passed as argument. For example:
test=# SELECT * FROM 
    heap_page_item_attrs(get_raw_page('pg_class', 0), 
    'pg_class'::regclass);
heap_tuple_infomask_flags(t_infomask integer, t_infomask2 integer)
returns record
heap_tuple_infomask_flags decodes the t_infomask and t_infomask2 returned 
by heap_page_items into a human-readable set of arrays made of flag names, with one col-
umn for all the flags and one column for combined flags. For example:

```
test=# SELECT t_ctid, raw_flags, combined_flags 
    FROM heap_page_items(get_raw_page('pg_class', 0)), 
    LATERAL heap_tuple_infomask_flags(t_infomask, 
    t_infomask2) 
    WHERE t_infomask IS NOT NULL OR t_infomask2 IS NOT 
    NULL;
```

This function should be called with the same arguments as the return attributes of 
heap_page_items.

Combined flags are displayed for source-level macros that take into account the value of more 
than one raw bit, such as HEAP_XMIN_FROZEN.

See src/include/access/htup_details.h for explanations of the flag names re-
turned.

### F.25.3. B-Tree Functions

**bt_metap**<br>

bt_metap (relname text) returns record

bt_metap returns information about a B-tree index's metapage. For example:

```
test=# SELECT * FROM bt_metap('pg_cast_oid_index');
-[
[ RECORD 1 ]-----------------------
magic | 340322
version | 4
root | 1
level | 0
fastroot | 1
fastlevel | 0
last_cleanup_num_delpages | 0
last_cleanup_num_tuples | 230
allequalimage | f
```

**bt_page_stats**<br>

bt_page_stats (relname text, blkno bigint) returns record

bt_page_stats returns summary information about a data page of a B-tree index. For exam-
ple:

```
test=# SELECT * FROM bt_page_stats('pg_cast_oid_index', 1); 
-[
[ RECORD 1 ]-+-----
blkno | 1
type | 1
live_items | 224
dead_items | 0
```

2772
Additional Supplied
Modules and Extensions

avg_item_size | 16
page_size     | 8192
free_size     | 3668
btpo_prev     | 0
btpo_next     | 0
btpo_level    | 0
btpo_flags    | 3

\[
\text{bt\_multi\_page\_stats}(\text{relname text, blkno bigint, blk\_count bigint})
\]
\[
\text{returns setof record}
\]

bt\_multi\_page\_stats returns the same information as bt\_page\_stats, but does so for each page of the range of pages beginning at blkno and extending for blk\_count pages. If blk\_count is negative, all pages from blkno to the end of the index are reported on. For example:

test=# SELECT * FROM bt\_multi\_page\_stats('pg\_proc\_oid\_index', 5, 2);

<table>
<thead>
<tr>
<th>blkno</th>
<th>type</th>
<th>live_items</th>
<th>dead_items</th>
<th>avg_item_size</th>
<th>page_size</th>
<th>free_size</th>
<th>btpo_prev</th>
<th>btpo_next</th>
<th>btpo_level</th>
<th>btpo_flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>1</td>
<td>367</td>
<td>0</td>
<td>16</td>
<td>8192</td>
<td>808</td>
<td>4</td>
<td>6</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>6</td>
<td>1</td>
<td>367</td>
<td>0</td>
<td>16</td>
<td>8192</td>
<td>808</td>
<td>5</td>
<td>7</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

bt\_page\_items(relname text, blkno bigint) returns setof record

bt\_page\_items returns detailed information about all of the items on a B-tree index page. For example:

test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, \text{tids}[0:2] AS some\_tids
    FROM bt\_page\_items('tenk2\_hundred', 5);

<table>
<thead>
<tr>
<th>itemoffset</th>
<th>ctid</th>
<th>itemlen</th>
<th>nulls</th>
<th>vars</th>
<th>data</th>
<th>dead</th>
<th>htid</th>
<th>some_tids</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>(16,1)</td>
<td>16</td>
<td>f</td>
<td>f</td>
<td>30 \text{00 00 00}</td>
<td>0</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

2773
This is a B-tree leaf page. All tuples that point to the table happen to be posting list tuples (all of which store a total of 100 6 byte TIDs). There is also a "high key" tuple at itemoffset number 1. \( \text{ctid} \) is used to store encoded information about each tuple in this example, though leaf page tuples often store a heap TID directly in the \( \text{ctid} \) field instead. \( \text{tids} \) is the list of TIDs stored as a posting list.

In an internal page (not shown), the block number part of \( \text{ctid} \) is a “downlink”, which is a block number of another page in the index itself. The offset part (the second number) of \( \text{ctid} \) stores encoded information about the tuple, such as the number of columns present (suffix truncation may have removed unneeded suffix columns). Truncated columns are treated as having the value “minus infinity”.

\( \text{htid} \) shows a heap TID for the tuple, regardless of the underlying tuple representation. This value may match \( \text{ctid} \), or may be decoded from the alternative representations used by posting list tuples and tuples from internal pages. Tuples in internal pages usually have the implementation level heap TID column truncated away, which is represented as a NULL \( \text{htid} \) value.

Note that the first item on any non-rightmost page (any page with a non-zero value in the \( \text{bt-po_next} \) field) is the page’s “high key”, meaning its \( \text{data} \) serves as an upper bound on all items appearing on the page, while its \( \text{ctid} \) field does not point to another block. Also, on internal pages, the first real data item (the first item that is not a high key) reliably has every column truncated away, leaving no actual value in its \( \text{data} \) field. Such an item does have a valid downlink in its \( \text{ctid} \) field, however.

For more details about the structure of B-tree indexes, see Section 67.4.1. For more details about deduplication and posting lists, see Section 67.4.3.

\[ \text{bt_page_items}(\text{page bytea}) \text{ returns setof record} \]

It is also possible to pass a page to \text{bt_page_items} as a bytea value. A page image obtained with \text{get_raw_page} should be passed as argument. So the last example could also be rewritten like this:
Additional Supplied Modules and Extensions

F.25.4. BRIN Functions

`brin_page_type(page bytea) returns text`

`brin_page_type` returns the page type of the given BRIN index page, or throws an error if the page is not a valid BRIN page. For example:

```
test=# SELECT brin_page_type(get_raw_page('brinidx', 0));
```

<table>
<thead>
<tr>
<th>brin_page_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>meta</td>
</tr>
</tbody>
</table>

`brin_metapage_info(page bytea) returns record`

`brin_metapage_info` returns assorted information about a BRIN index metapage. For example:

```
test=# SELECT * FROM brin_metapage_info(get_raw_page('brinidx', 0));
```

<table>
<thead>
<tr>
<th>magic</th>
<th>version</th>

<td></td>
</tr>
</tbody>
</table>

(13 rows)
Additional Supplied Modules and Extensions

| 0xA8109CFA | 1 | 4 | 2 |

brin_revmap_data(page bytea) returns setof tid

brin_revmap_data returns the list of tuple identifiers in a BRIN index range map page. For example:

```
test=# SELECT * FROM brin_revmap_data(get_raw_page('brinidx', 2)) LIMIT 5;
```

```
<table>
<thead>
<tr>
<th>pages</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>(6,140)</td>
</tr>
<tr>
<td>(6,141)</td>
</tr>
</tbody>
</table>
```

brin_page_items(page bytea, index oid) returns setof record

brin_page_items returns the data stored in the BRIN data page. For example:

```
test=# SELECT * FROM brin_page_items(get_raw_page('brinidx', 5), 'brinidx') ORDER BY blknum, attnum LIMIT 6;
```

```
<table>
<thead>
<tr>
<th>itemoffset</th>

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

The returned columns correspond to the fields in the BrinMemTuple and BrinValues structs. See src/include/access/brin_tuple.h for details.

F.25.5. GIN Functions

gin_metapage_info(page bytea) returns record

gin_metapage_info returns information about a GIN index metapage. For example:

```
test=# SELECT * FROM gin_metapage_info(get_raw_page('gin_index', 0));
```

```
- [ RECORD 1 ]-----+--------
pending_head | 4294967295
pending_tail  | 4294967295
tail_free_size | 0
```

### F.25.6. GiST Functions

**gist_page_opaque_info(page bytea) returns record**

`gist_page_opaque_info` returns information from a GiST index page's opaque area, such as the NSN, rightlink and page type. For example:

```sql
test=# SELECT * FROM
gist_page_opaque_info(get_raw_page('test_gist_idx', 2));
```

<table>
<thead>
<tr>
<th>first_tid</th>
<th>nbytes</th>
<th>some_tids</th>

</table>
F.25.7. Hash Functions

hash_page_type(page bytea) returns text

hash_page_type returns page type of the given HASH index page. For example:

```
test=# SELECT hash_page_type(get_raw_page('con_hash_index', 0));
hash_page_type
--------------------
metapage
```

hash_page_stats(page bytea) returns setof record

hash_page_stats returns information about a bucket or overflow page of a HASH index. For example:

```
test=# SELECT * FROM hash_page_stats(get_raw_page('con_hash_index', 1));
- [ RECORD 1 ]---+-----------
live_items | 407
dead_items | 0
page_size | 8192
free_size | 8
hasho_prevblkno | 4096
hasho_nextblkno | 8474
hasho_bucket | 0
hasho_flag | 66
hasho_page_id | 65408
```

hash_page_items(page bytea) returns setof record

hash_page_items returns information about the data stored in a bucket or overflow page of a HASH index page. For example:

```
test=# SELECT * FROM hash_page_items(get_raw_page('con_hash_index', 1)) LIMIT 5;
itemoffset |   ctid    |    data
------------+-----------+------------
1 | (899,77)  | 1053474816
2 | (897,29)  | 1053474816
3 | (894,207) | 1053474816
4 | (892,159) | 1053474816
5 | (890,111) | 1053474816
```

hash_bitmap_info(index oid, blkno bigint) returns record

hash_bitmap_info shows the status of a bit in the bitmap page for a particular overflow page of HASH index. For example:
Additional Supplied
Modules and Extensions

test=# SELECT * FROM hash_bitmap_info('con_hash_index', 2052);
bitmapblkno | bitmapbit | bitstatus
-------------+-----------+-----------
       65 |         3 | t

hash_metapage_info(page bytea) returns record

hash_metapage_info returns information stored in the meta page of a HASH index. For example:

test=# SELECT magic, version, ntuples, ffactor, bsize, bmsize, bmshift,
        maxbucket, highmask, lowmask, ovflpoint, firstfree,
        nmaps, procid,
        regexp_replace(spares::text, '(,0)*', '}') as spares,
        regexp_replace(mapp::text, '(,0)*', '}') as mapp
FROM hash_metapage_info(get_raw_page('con_hash_index', 0));

[ RECORD 1 ]-------------------------------------------------

------------------------------------------------------------------------------------------------------------------
| magic     | version | ntuples | ffactor | bsize | bmsize | bmshift | maxbucket | highmask | lowmask | ovflpoint | firstfree | nmaps | procid | spares         | mapp        |
------------------------------------------------------------------------------------------------------------------
| 105121344 | 4       | 500500  | 40      | 8152  | 4096   | 15      | 12512     | 16383    | 8191    | 28       | 1204      | 1     | 450    | {0,0,0,0,0,0,1,1,1,1,1,1,1,1,3,4,4,4,45,55,58,59,508,567,628,704,1193,1202,1204} | {65} |
F.26. passwordcheck — verify password strength

The passwordcheck module checks users’ passwords whenever they are set with CREATE ROLE or ALTER ROLE. If a password is considered too weak, it will be rejected and the command will terminate with an error.

To enable this module, add '$libdir/passwordcheck' to shared_preload_libraries in postgresql.conf, then restart the server.

You can adapt this module to your needs by changing the source code. For example, you can use CrackLib\(^2\) to check passwords — this only requires uncommenting two lines in the Makefile and rebuilding the module. (We cannot include CrackLib by default for license reasons.) Without CrackLib, the module enforces a few simple rules for password strength, which you can modify or extend as you see fit.

Caution

To prevent unencrypted passwords from being sent across the network, written to the server log or otherwise stolen by a database administrator, PostgreSQL allows the user to supply pre-encrypted passwords. Many client programs make use of this functionality and encrypt the password before sending it to the server.

This limits the usefulness of the passwordcheck module, because in that case it can only try to guess the password. For this reason, passwordcheck is not recommended if your security requirements are high. It is more secure to use an external authentication method such as GSSAPI (see Chapter 21) than to rely on passwords within the database.

Alternatively, you could modify passwordcheck to reject pre-encrypted passwords, but forcing users to set their passwords in clear text carries its own security risks.

\(^2\) [https://github.com/cracklib/cracklib]
F.27. pg_buffercache — inspect PostgreSQL buffer cache state

The `pg_buffercache` module provides a means for examining what's happening in the shared buffer cache in real time.

This module provides the `pg_buffercache_pages()` function (wrapped in the `pg_buffercache` view), the `pg_buffercache_summary()` function, and the `pg_buffercache_usage_counts()` function.

The `pg_buffercache_pages()` function returns a set of records, each row describing the state of one shared buffer entry. The `pg_buffercache` view wraps the function for convenient use.

The `pg_buffercache_summary()` function returns a single row summarizing the state of the shared buffer cache.

The `pg_buffercache_usage_counts()` function returns a set of records, each row describing the number of buffers with a given usage count.

By default, use is restricted to superusers and roles with privileges of the `pg_monitor` role. Access may be granted to others using `GRANT`.

F.27.1. The `pg_buffercache` View

The definitions of the columns exposed by the view are shown in Table F.15.

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bufferid</code></td>
<td>ID, in the range 1..shared_buffers</td>
</tr>
<tr>
<td><code>relfilenode</code></td>
<td>Filenode number of the relation</td>
</tr>
<tr>
<td><code>reltablespace</code></td>
<td>Tablespace OID of the relation</td>
</tr>
<tr>
<td><code>reldatabase</code></td>
<td>Database OID of the relation</td>
</tr>
<tr>
<td><code>relforknumber</code></td>
<td>Fork number within the relation; see <code>common/relnpath.h</code></td>
</tr>
<tr>
<td><code>relblocknumber</code></td>
<td>Page number within the relation</td>
</tr>
<tr>
<td><code>isdirty</code></td>
<td>Is the page dirty?</td>
</tr>
<tr>
<td><code>usagecount</code></td>
<td>Clock-sweep access count</td>
</tr>
<tr>
<td><code>pinning_backends</code></td>
<td>Number of backends pinning this buffer</td>
</tr>
</tbody>
</table>

There is one row for each buffer in the shared cache. Unused buffers are shown with all fields null except `bufferid`. Shared system catalogs are shown as belonging to database zero.
Because the cache is shared by all the databases, there will normally be pages from relations not belonging to the current database. This means that there may not be matching join rows in `pg_class` for some rows, or that there could even be incorrect joins. If you are trying to join against `pg_class`, it's a good idea to restrict the join to rows having `reldatabase` equal to the current database's OID or zero.

Since buffer manager locks are not taken to copy the buffer state data that the view will display, accessing `pg_buffercache` view has less impact on normal buffer activity but it doesn't provide a consistent set of results across all buffers. However, we ensure that the information of each buffer is self-consistent.

### F.27.2. The `pg_buffercache_summary()` Function

The definitions of the columns exposed by the function are shown in Table F.16.

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>buffers_used</code> int4</td>
<td>Number of used shared buffers</td>
</tr>
<tr>
<td><code>buffers_unused</code> int4</td>
<td>Number of unused shared buffers</td>
</tr>
<tr>
<td><code>buffers_dirty</code> int4</td>
<td>Number of dirty shared buffers</td>
</tr>
<tr>
<td><code>buffers_pinned</code> int4</td>
<td>Number of pinned shared buffers</td>
</tr>
<tr>
<td><code>usagecount_avg</code> float8</td>
<td>Average usage count of used shared buffers</td>
</tr>
</tbody>
</table>

The `pg_buffercache_summary()` function returns a single row summarizing the state of all shared buffers. Similar and more detailed information is provided by the `pg_buffercache` view, but `pg_buffercache_summary()` is significantly cheaper.

Like the `pg_buffercache` view, `pg_buffercache_summary()` does not acquire buffer manager locks. Therefore concurrent activity can lead to minor inaccuracies in the result.

### F.27.3. The `pg_buffercache_usage_counts()` Function

The definitions of the columns exposed by the function are shown in Table F.17.

<table>
<thead>
<tr>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>usage_count</code> int4</td>
<td>A possible buffer usage count</td>
</tr>
<tr>
<td><code>buffers</code> int4</td>
<td>Number of buffers with the usage count</td>
</tr>
<tr>
<td><code>dirty</code> int4</td>
<td>Number of dirty buffers with the usage count</td>
</tr>
<tr>
<td><code>pinned</code> int4</td>
<td></td>
</tr>
</tbody>
</table>
The `pg_buffercache_usage_counts()` function returns a set of rows summarizing the states of all shared buffers, aggregated over the possible usage count values. Similar and more detailed information is provided by the `pg_buffercache` view, but `pg_buffercache_usage_counts()` is significantly cheaper.

Like the `pg_buffercache` view, `pg_buffercache_usage_counts()` does not acquire buffer manager locks. Therefore concurrent activity can lead to minor inaccuracies in the result.

### F.27.4. Sample Output

```sql
regression=# SELECT n.nspname, c.relname, count(*) AS buffers FROM pg_buffercache b JOIN pg_class c ON b.relfilenode = pg_relation_filenode(c.oid) AND b.reldatabase IN (0, (SELECT oid FROM pg_database WHERE datname = current_database())) JOIN pg_namespace n ON n.oid = c.relnamespace GROUP BY n.nspname, c.relname ORDER BY 3 DESC LIMIT 10;

<table>
<thead>
<tr>
<th>nspname</th>
<th>relname</th>
<th>buffers</th>
</tr>
</thead>
<tbody>
<tr>

Debugging advice: Tom Lane <tgl@sss.pgh.pa.us>
F.28. pgcrypto — cryptographic functions

The pgcrypto module provides cryptographic functions for PostgreSQL.

This module is considered "trusted", that is, it can be installed by non-superusers who have CREATE privilege on the current database.

pgcrypto requires OpenSSL and won't be installed if OpenSSL support was not selected when PostgreSQL was built.

F.28.1. General Hashing Functions

F.28.1.1. digest()

digest(data text, type text) returns bytea
digest(data bytea, type text) returns bytea

Computes a binary hash of the given data. type is the algorithm to use. Standard algorithms are md5, sha1, sha224, sha256, sha384 and sha512. Moreover, any digest algorithm OpenSSL supports is automatically picked up.

If you want the digest as a hexadecimal string, use encode() on the result. For example:

```
CREATE OR REPLACE FUNCTION sha1(bytea) returns text AS $$
SELECT encode(digest($1, 'sha1'), 'hex')
$$ LANGUAGE SQL STRICT IMMUTABLE;
```

F.28.1.2. hmac()

hmac(data text, key text, type text) returns bytea
hmac(data bytea, key bytea, type text) returns bytea

Calculates hashed MAC for data with key. type is the same as in digest().

This is similar to digest() but the hash can only be recalculated knowing the key. This prevents the scenario of someone altering data and also changing the hash to match.

If the key is larger than the hash block size it will first be hashed and the result will be used as key.

F.28.2. Password Hashing Functions

The functions crypt() and gen_salt() are specifically designed for hashing passwords. crypt() does the hashing and gen_salt() prepares algorithm parameters for it.

The algorithms in crypt() differ from the usual MD5 or SHA1 hashing algorithms in the following respects:

1. They are slow. As the amount of data is so small, this is the only way to make brute-forcing passwords hard.
2. They use a random value, called the salt, so that users having the same password will have different encrypted passwords. This is also an additional defense against reversing the algorithm.
3. They include the algorithm type in the result, so passwords hashed with different algorithms can co-exist.
4. Some of them are adaptive — that means when computers get faster, you can tune the algorithm to be slower, without introducing incompatibility with existing passwords.
Table F.18 lists the algorithms supported by the `crypt()` function.

### Table F.18. Supported Algorithms for `crypt()`

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Max Password Length</th>
<th>Adaptive?</th>
<th>Salt Bits</th>
<th>Output Length</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bf</td>
<td>72</td>
<td>yes</td>
<td>128</td>
<td>60</td>
<td>Blowfish-based, variant 2a</td>
</tr>
<tr>
<td>md5</td>
<td>unlimited</td>
<td>no</td>
<td>48</td>
<td>34</td>
<td>MD5-based crypt</td>
</tr>
<tr>
<td>xdes</td>
<td>8</td>
<td>yes</td>
<td>24</td>
<td>20</td>
<td>Extended DES</td>
</tr>
<tr>
<td>des</td>
<td>8</td>
<td>no</td>
<td>12</td>
<td>13</td>
<td>Original UNIX crypt</td>
</tr>
</tbody>
</table>

#### F.28.2.1. `crypt()`

`crypt(password text, salt text) returns text`

Calculates a crypt(3)-style hash of `password`. When storing a new password, you need to use `gen_salt()` to generate a new `salt` value. To check a password, pass the stored hash value as `salt`, and test whether the result matches the stored value.

Example of setting a new password:

```sql
UPDATE ... SET pswhash = crypt('new password', gen_salt('md5'));
```

Example of authentication:

```sql
SELECT (pswhash = crypt('entered password', pswhash)) AS pswmatch
FROM ... ;
```

This returns `true` if the entered password is correct.

#### F.28.2.2. `gen_salt()`

`gen_salt(type text [, iter_count integer ]) returns text`

Generates a new random salt string for use in `crypt()`. The salt string also tells `crypt()` which algorithm to use.

The `type` parameter specifies the hashing algorithm. The accepted types are: des, xdes, md5 and bf.

The `iter_count` parameter lets the user specify the iteration count, for algorithms that have one. The higher the count, the more time it takes to hash the password and therefore the more time to break it. Although with too high a count the time to calculate a hash may be several years — which is somewhat impractical. If the `iter_count` parameter is omitted, the default iteration count is used. Allowed values for `iter_count` depend on the algorithm and are shown in Table F.19.

### Table F.19. Iteration Counts for `crypt()`

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Default</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>xdes</td>
<td>725</td>
<td>1</td>
<td>16777215</td>
</tr>
</tbody>
</table>
For \( x_{des} \) there is an additional limitation that the iteration count must be an odd number.

To pick an appropriate iteration count, consider that the original DES crypt was designed to have the speed of 4 hashes per second on the hardware of that time. Slower than 4 hashes per second would probably dampen usability. Faster than 100 hashes per second is probably too fast.

Table F.20 gives an overview of the relative slowness of different hashing algorithms. The table shows how much time it would take to try all combinations of characters in an 8-character password, assuming that the password contains either only lower case letters, or upper- and lower-case letters and numbers. In the `crypt-bf` entries, the number after a slash is the `iter_count` parameter of `gen_salt`.

### Table F.20. Hash Algorithm Speeds

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Hashes/sec</th>
<th>For [a-z]</th>
<th>For [A-Za-z0-9]</th>
<th>Duration relative to md5 hash</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>crypt-bf/8</code></td>
<td>1792</td>
<td>4 years</td>
<td>3927 years</td>
<td>100k</td>
</tr>
<tr>
<td><code>crypt-bf/7</code></td>
<td>3648</td>
<td>2 years</td>
<td>1929 years</td>
<td>50k</td>
</tr>
<tr>
<td><code>crypt-bf/6</code></td>
<td>7168</td>
<td>1 year</td>
<td>982 years</td>
<td>25k</td>
</tr>
<tr>
<td><code>crypt-bf/5</code></td>
<td>13504</td>
<td>188 days</td>
<td>521 years</td>
<td>12.5k</td>
</tr>
<tr>
<td><code>crypt-md5</code></td>
<td>171584</td>
<td>15 days</td>
<td>41 years</td>

<td>157.5 minutes</td>
<td>108 days</td>
<td>7</td>
</tr>
<tr>
<td><code>sha1</code></td>
<td>37774272</td>
<td>90 minutes</td>
<td>68 days</td>
<td>4</td>
</tr>
<tr>
<td><code>md5 (hash)</code></td>
<td>150085504</td>
<td>22.5 minutes</td>
<td>17 days</td>
<td>1</td>
</tr>
</tbody>
</table>

Notes:

- The machine used is an Intel Mobile Core i3.
- `crypt-des` and `crypt-md5` algorithm numbers are taken from John the Ripper v1.6.38 `-test` output.
- `md5` hash numbers are from mdcrack 1.2.
- `sha1` numbers are from lcrack-20031130-beta.
- `crypt-bf` numbers are taken using a simple program that loops over 1000 8-character passwords. That way the speed with different numbers of iterations can be shown. For reference: john `-test` shows 13506 loops/sec for `crypt-bf/5`. (The very small difference in results is in accordance with the fact that the `crypt-bf` implementation in `pgcrypto` is the same one used in John the Ripper.)

Note that “try all combinations” is not a realistic exercise. Usually password cracking is done with the help of dictionaries, which contain both regular words and various mutations of them. So, even somewhat word-like passwords could be cracked much faster than the above numbers suggest, while a 6-character non-word-like password may escape cracking. Or not.

### F.28.3. PGP Encryption Functions

The functions here implement the encryption part of the OpenPGP (RFC 4880\(^3\)) standard. Supported are both symmetric-key and public-key encryption.

An encrypted PGP message consists of 2 parts, or packets:

\(^3\)https://datatracker.ietf.org/doc/html/rfc4880
• Packet containing a session key — either symmetric-key or public-key encrypted.

• Packet containing data encrypted with the session key.

When encrypting with a symmetric key (i.e., a password):

1. The given password is hashed using a String2Key (S2K) algorithm. This is rather similar to crypt() algorithms — purposefully slow and with random salt — but it produces a full-length binary key.

2. If a separate session key is requested, a new random key will be generated. Otherwise the S2K key will be used directly as the session key.

3. If the S2K key is to be used directly, then only S2K settings will be put into the session key packet. Otherwise the session key will be encrypted with the S2K key and put into the session key packet.

When encrypting with a public key:

1. A new random session key is generated.

2. It is encrypted using the public key and put into the session key packet.

In either case the data to be encrypted is processed as follows:

1. Optional data-manipulation: compression, conversion to UTF-8, and/or conversion of line-endings.

2. The data is prefixed with a block of random bytes. This is equivalent to using a random IV.

3. A SHA1 hash of the random prefix and data is appended.

4. All this is encrypted with the session key and placed in the data packet.

F.28.3.1. pgp_sym_encrypt ()

pgp_sym_encrypt(data text, psw text [, options text ]) returns bytea

pgp_sym_encrypt_bytea(data bytea, psw text [, options text ]) returns bytea

Encrypt data with a symmetric PGP key psw. The options parameter can contain option settings, as described below.

F.28.3.2. pgp_sym_decrypt ()

pgp_sym_decrypt(msg bytea, psw text [, options text ]) returns text

pgp_sym_decrypt_bytea(msg bytea, psw text [, options text ]) returns bytea

Decrypt a symmetric-key-encrypted PGP message.

Decrypting bytea data with pgp_sym_decrypt is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with pgp_sym_decrypt_bytea is fine.

The options parameter can contain option settings, as described below.

F.28.3.3. pgp_pub_encrypt ()
pgp_pub_encrypt(data text, key bytea [, options text ]) returns bytea
pgp_pub_encrypt_bytea(data bytea, key bytea [, options text ]) returns bytea

Encrypt data with a public PGP key key. Giving this function a secret key will produce an error.

The options parameter can contain option settings, as described below.

F.28.3.4. pgp_pub_decrypt()

pgp_pub_decrypt(msg bytea, key bytea [, psw text [, options text ]]) returns text
pgp_pub_decrypt_bytea(msg bytea, key bytea [, psw text [, options text ]]) returns bytea

Decrypt a public-key-encrypted message. key must be the secret key corresponding to the public key that was used to encrypt. If the secret key is password-protected, you must give the password in psw. If there is no password, but you want to specify options, you need to give an empty password.

Decrypting bytea data with pgp_pub_decrypt is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with pgp_pub_decrypt_bytea is fine.

The options parameter can contain option settings, as described below.

F.28.3.5. pgp_key_id()

pgp_key_id(bytea) returns text
pgp_key_id extracts the key ID of a PGP public or secret key. Or it gives the key ID that was used for encrypting the data, if given an encrypted message.

It can return 2 special key IDs:

• SYMKEY
  The message is encrypted with a symmetric key.

• ANYKEY
  The message is public-key encrypted, but the key ID has been removed. That means you will need to try all your secret keys on it to see which one decrypts it. pgcrypto itself does not produce such messages.

Note that different keys may have the same ID. This is rare but a normal event. The client application should then try to decrypt with each one, to see which fits — like handling ANYKEY.

F.28.3.6. armor(), dearmor()

armor(data bytea [, , keys text[], values text[] ] ) returns text
dearmor(data text) returns bytea

These functions wrap/unwrap binary data into PGP ASCII-armor format, which is basically Base64 with CRC and additional formatting.

If the keys and values arrays are specified, an armor header is added to the armored format for each key/value pair. Both arrays must be single-dimensional, and they must be of the same length. The keys and values cannot contain any non-ASCII characters.
F.28.3.7. pgp_armor_headers

pgp_armor_headers(data text, key out text, value out text) returns setof record

pgp_armor_headers() extracts the armor headers from data. The return value is a set of rows with two columns, key and value. If the keys or values contain any non-ASCII characters, they are treated as UTF-8.

F.28.3.8. Options for PGP Functions

Options are named to be similar to GnuPG. An option's value should be given after an equal sign; separate options from each other with commas. For example:

pgp_sym_encrypt(data, psw, 'compress-algo=1, cipher-algo=aes256')

All of the options except convert-crlf apply only to encrypt functions. Decrypt functions get the parameters from the PGP data.

The most interesting options are probably compress-algo and unicode-mode. The rest should have reasonable defaults.

F.28.3.8.1. cipher-algo

Which cipher algorithm to use.

Values: bf, aes128, aes192, aes256, 3des, cast5
Default: aes128
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.28.3.8.2. compress-algo

Which compression algorithm to use. Only available if PostgreSQL was built with zlib.

Values:
  0 - no compression
  1 - ZIP compression
  2 - ZLIB compression (= ZIP plus meta-data and block CRCs)
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.28.3.8.3. compress-level

How much to compress. Higher levels compress smaller but are slower. 0 disables compression.

Values: 0, 1-9
Default: 6
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.28.3.8.4. convert-crlf

Whether to convert \n into \r\n when encrypting and \r\n to \n when decrypting. RFC 4880 specifies that text data should be stored using \r\n line-feeds. Use this to get fully RFC-compliant behavior.
Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt, pgp_sym_decrypt, pgp_pub_decrypt

**F.28.3.8.5. disable-mdc**

Do not protect data with SHA-1. The only good reason to use this option is to achieve compatibility with ancient PGP products, predating the addition of SHA-1 protected packets to RFC 4880. Recent gnupg.org and pgp.com software supports it fine.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

**F.28.3.8.6. sess-key**

Use separate session key. Public-key encryption always uses a separate session key; this option is for symmetric-key encryption, which by default uses the S2K key directly.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt

**F.28.3.8.7. s2k-mode**

Which S2K algorithm to use.

Values:
- 0 - Without salt. Dangerous!
- 1 - With salt but with fixed iteration count.
- 3 - Variable iteration count.
Default: 3
Applies to: pgp_sym_encrypt

**F.28.3.8.8. s2k-count**

The number of iterations of the S2K algorithm to use. It must be a value between 1024 and 65011712, inclusive.

Default: A random value between 65536 and 253952
Applies to: pgp_sym_encrypt, only with s2k-mode=3

**F.28.3.8.9. s2k-digest-algo**

Which digest algorithm to use in S2K calculation.

Values: md5, sha1
Default: sha1
Applies to: pgp_sym_encrypt

**F.28.3.8.10. s2k-cipher-algo**

Which cipher to use for encrypting separate session key.
Values: bf, aes, aes128, aes192, aes256
Default: use cipher-algo
Applies to: pgp_sym_encrypt

**F.28.3.8.11. unicode-mode**

Whether to convert textual data from database internal encoding to UTF-8 and back. If your database already is UTF-8, no conversion will be done, but the message will be tagged as UTF-8. Without this option it will not be.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

**F.28.3.9. Generating PGP Keys with GnuPG**

To generate a new key:

```
gpg --gen-key
```

The preferred key type is “DSA and Elgamal”.

For RSA encryption you must create either DSA or RSA sign-only key as master and then add an RSA encryption subkey with `gpg --edit-key`.

To list keys:

```
gpg --list-secret-keys
```

To export a public key in ASCII-armor format:

```
gpg -a --export KEYID > public.key
```

To export a secret key in ASCII-armor format:

```
gpg -a --export-secret-keys KEYID > secret.key
```

You need to use `dearmor()` on these keys before giving them to the PGP functions. Or if you can handle binary data, you can drop `-a` from the command.

For more details see `man gpg`, The GNU Privacy Handbook\(^4\) and other documentation on https://www.gnupg.org/.

**F.28.3.10. Limitations of PGP Code**

- No support for signing. That also means that it is not checked whether the encryption subkey belongs to the master key.
- No support for encryption key as master key. As such practice is generally discouraged, this should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with `pgcrypto`, but create new ones, as the usage scenario is rather different.

F.28.4. Raw Encryption Functions

These functions only run a cipher over data; they don’t have any advanced features of PGP encryption. Therefore they have some major problems:

1. They use user key directly as cipher key.
2. They don’t provide any integrity checking, to see if the encrypted data was modified.
3. They expect that users manage all encryption parameters themselves, even IV.
4. They don’t handle text.

So, with the introduction of PGP encryption, usage of raw encryption functions is discouraged.

```sql
encrypt(data bytea, key bytea, type text) returns bytea
decrypt(data bytea, key bytea, type text) returns bytea
```

```sql
encrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
decrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
```

Encrypt/decrypt data using the cipher method specified by `type`. The syntax of the `type` string is:

```
algorithm [ - mode ] [ /pad: padding ]
```

where `algorithm` is one of:

- `bf` — Blowfish
- `aes` — AES (Rijndael-128, -192 or -256)

and `mode` is one of:

- `cbc` — next block depends on previous (default)
- `ecb` — each block is encrypted separately (for testing only)

and `padding` is one of:

- `pkcs` — data may be any length (default)
- `none` — data must be multiple of cipher block size

So, for example, these are equivalent:

```sql
encrypt(data, 'fooz', 'bf')
encrypt(data, 'fooz', 'bf-cbc/pad:pkcs')
```

In `encrypt_iv` and `decrypt_iv`, the `iv` parameter is the initial value for the CBC mode; it is ignored for ECB. It is clipped or padded with zeroes if not exactly block size. It defaults to all zeroes in the functions without this parameter.

F.28.5. Random-Data Functions
gen_random_bytes(count integer) returns bytea

Returns `count` cryptographically strong random bytes. At most 1024 bytes can be extracted at a time. This is to avoid draining the randomness generator pool.

gen_random_uuid() returns uuid

Returns a version 4 (random) UUID. (Obsolete, this function internally calls the core function of the same name.)

**F.28.6. Notes**

**F.28.6.1. Configuration**

`pgcrypto` configures itself according to the findings of the main PostgreSQL configure script. The options that affect it are `--with-zlib` and `--with-ssl=openssl`.

When compiled with zlib, PGP encryption functions are able to compress data before encrypting.

`pgcrypto` requires OpenSSL. Otherwise, it will not be built or installed.

When compiled against OpenSSL 3.0.0 and later versions, the legacy provider must be activated in the `openssl.cnf` configuration file in order to use older ciphers like DES or Blowfish.

**F.28.6.2. NULL Handling**

As is standard in SQL, all functions return NULL, if any of the arguments are NULL. This may create security risks on careless usage.

**F.28.6.3. Security Limitations**

All `pgcrypto` functions run inside the database server. That means that all the data and passwords move between `pgcrypto` and client applications in clear text. Thus you must:

1. Connect locally or use SSL connections.
2. Trust both system and database administrator.

If you cannot, then better do crypto inside client application.

The implementation does not resist side-channel attacks. For example, the time required for a `pgcrypto` decryption function to complete varies among ciphertexts of a given size.

**F.28.7. Author**

Marko Kreen <markokr@gmail.com>

`pgcrypto` uses code from the following sources:

</tr>
</tbody>
</table>

F.29. pg_freespacemap — examine the free space map

The pg_freespacemap module provides a means for examining the free space map (FSM). It provides a function called `pg_freespace`, or two overloaded functions, to be precise. The functions show the value recorded in the free space map for a given page, or for all pages in the relation.

By default use is restricted to superusers and roles with privileges of the `pg_stat_scan_tables` role. Access may be granted to others using `GRANT`.

F.29.1. Functions

`pg_freespace(rel regclass IN, blkno bigint IN) returns int2`

Returns the amount of free space on the page of the relation, specified by `blkno`, according to the FSM.

`pg_freespace(rel regclass IN, blkno OUT bigint, avail OUT int2)`

Displays the amount of free space on each page of the relation, according to the FSM. A set of `(blkno bigint, avail int2)` tuples is returned, one tuple for each page in the relation.

The values stored in the free space map are not exact. They're rounded to precision of 1/256th of `BLCKSZ` (32 bytes with default `BLCKSZ`), and they're not kept fully up-to-date as tuples are inserted and updated.

For indexes, what is tracked is entirely-unused pages, rather than free space within pages. Therefore, the values are not meaningful, just whether a page is full or empty.

F.29.2. Sample Output

```
postgres=# SELECT * FROM pg_freespace('foo');
blkno | avail
-------+-------
     0 |     0
     1 |     0
     2 |     0
     3 |    32
     4 |   704
     5 |   704
     6 |   704
     7 |  1216
     8 |   704
     9 |   704
    10 |   704
    11 |   704
    12 |   704
    13 |   704
    14 |   704
    15 |   704
    16 |   704
    17 |   704
    18 |   704
    19 |  3648
(20 rows)
```
postgres=# SELECT * FROM pg_freespace('foo', 7);
pg_freespace
----------
  1216
(1 row)

F.30. pg_prewarm — preload relation data into buffer caches

The pg_prewarm module provides a convenient way to load relation data into either the operating system buffer cache or the PostgreSQL buffer cache. Prewarming can be performed manually using the pg_prewarm function, or can be performed automatically by including pg_prewarm in shared_preload_libraries. In the latter case, the system will run a background worker which periodically records the contents of shared buffers in a file called autoprewarm.blocks and will, using 2 background workers, reload those same blocks after a restart.

F.30.1. Functions

```sql
pg_prewarm(regclass, mode text default 'buffer', fork text default 'main',
           first_block int8 default null,
           last_block int8 default null) RETURNS int8
```

The first argument is the relation to be prewarmed. The second argument is the prewarming method to be used, as further discussed below; the third is the relation fork to be prewarmed, usually main. The fourth argument is the first block number to prewarm (NULL is accepted as a synonym for zero). The fifth argument is the last block number to prewarm (NULL means prewarm through the last block in the relation). The return value is the number of blocks prewarmed.

There are three available prewarming methods. prefetch issues asynchronous prefetch requests to the operating system, if this is supported, or throws an error otherwise. read reads the requested range of blocks; unlike prefetch, this is synchronous and supported on all platforms and builds, but may be slower. buffer reads the requested range of blocks into the database buffer cache.

Note that with any of these methods, attempting to prewarm more blocks than can be cached — by the OS when using prefetch or read, or by PostgreSQL when using buffer — will likely result in lower-numbered blocks being evicted as higher numbered blocks are read in. Prewarmed data also enjoys no special protection from cache evictions, so it is possible that other system activity may evict the newly prewarmed blocks shortly after they are read; conversely, prewarming may also evict other data from cache. For these reasons, prewarming is typically most useful at startup, when caches are largely empty.

```sql
autoprewarm_start_worker() RETURNS void
```

Launch the main autoprewarm worker. This will normally happen automatically, but is useful if automatic prewarm was not configured at server startup time and you wish to start up the worker at a later time.

```sql
autoprewarm_dump_now() RETURNS int8
```

Update autoprewarm.blocks immediately. This may be useful if the autoprewarm worker is not running but you anticipate running it after the next restart. The return value is the number of records written to autoprewarm.blocks.

F.30.2. Configuration Parameters

```sql
pg_prewarm.autoprewarm(boolean)
```

Controls whether the server should run the autoprewarm worker. This is on by default. This parameter can only be set at server start.
pg_prewarm.autoprewarm_interval (integer)

This is the interval between updates to autoprewarm.blocks. The default is 300 seconds. If set to 0, the file will not be dumped at regular intervals, but only when the server is shut down.

These parameters must be set in postgresql.conf. Typical usage might be:

```bash
# postgresql.conf
shared_preload_libraries = 'pg_prewarm'

pg_prewarm.autoprewarm = true
pg_prewarm.autoprewarm_interval = 300s
```

F.30.3. Author

Robert Haas <rhaas@postgresql.org>
F.31. pgrowlocks — show a table's row locking information

The pgrowlocks module provides a function to show row locking information for a specified table. By default use is restricted to superusers, roles with privileges of the pg_stat_scan_tables role, and users with SELECT permissions on the table.

F.31.1. Overview

\[ \text{pgrowlocks}(\text{text}) \text{ returns setof record} \]

The parameter is the name of a table. The result is a set of records, with one row for each locked row within the table. The output columns are shown in Table F.21.

Table F.21. pgrowlocks Output Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>locked_row</td>
<td>tid</td>
<td>Tuple ID (TID) of locked row</td>
</tr>
<tr>
<td>locker</td>
<td>xid</td>
<td>Transaction ID of locker, or multixact ID if multitransaction; see Section 74.1</td>
</tr>
<tr>
<td>multi</td>
<td>boolean</td>
<td>True if locker is a multitransaction</td>
</tr>
<tr>
<td>xids</td>
<td>xid[]</td>
<td>Transaction IDs of lockers (more than one if multitransaction)</td>
</tr>
<tr>
<td>modes</td>
<td>text[]</td>
<td>Lock mode of lockers (more than one if multitransaction), an array of Key Share, Share, For No Key Update, No Key Update, For Update, Update.</td>
</tr>
<tr>
<td>pids</td>
<td>integer[]</td>
<td>Process IDs of locking backends (more than one if multitransaction)</td>
</tr>
</tbody>
</table>

pgrowlocks takes AccessShareLock for the target table and reads each row one by one to collect the row locking information. This is not very speedy for a large table. Note that:

1. If an ACCESS EXCLUSIVE lock is taken on the table, pgrowlocks will be blocked.

2. pgrowlocks is not guaranteed to produce a self-consistent snapshot. It is possible that a new row lock is taken, or an old lock is freed, during its execution.

pgrowlocks does not show the contents of locked rows. If you want to take a look at the row contents at the same time, you could do something like this:

```
SELECT * FROM accounts AS a, pgrowlocks('accounts') AS p
WHERE p.locked_row = a.ctid;
```

Be aware however that such a query will be very inefficient.
F.31.2. Sample Output

```
=# SELECT * FROM pgrowlocks('t1');
locked_row | locker | multi | xids   | modes            | pids
------------+--------+-------+--------+------------------+--------
(0,1)       | 609    | f     | {609}  | "For Share"      | {3161} 
(0,2)       | 609    | f     | {609}  | "For Share"      | {3161} 
(0,3)       | 607    | f     | {607}  | "For Update"     | {3107} 
(0,4)       | 607    | f     | {607}  | "For Update"     | {3107} 
(4 rows)
```

Tatsuo Ishii
F.32. pg_stat_statements — track statistics of SQL planning and execution

The pg_stat_statements module provides a means for tracking planning and execution statistics of all SQL statements executed by a server.

The module must be loaded by adding pg_stat_statements to shared_preload_libraries in postgresql.conf, because it requires additional shared memory. This means that a server restart is needed to add or remove the module. In addition, query identifier calculation must be enabled in order for the module to be active, which is done automatically if compute_query_id is set to auto or on, or any third-party module that calculates query identifiers is loaded.

When pg_stat_statements is active, it tracks statistics across all databases of the server. To access and manipulate these statistics, the module provides views pg_stat_statements and pg_stat_statements_info, and the utility functions pg_stat_statements_reset and pg_stat_statements. These are not available globally but can be enabled for a specific database with CREATE EXTENSION pg_stat_statements.

F.32.1. The pg_stat_statements View

The statistics gathered by the module are made available via a view named pg_stat_statements. This view contains one row for each distinct combination of database ID, user ID, query ID and whether it’s a top-level statement or not (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in Table F.22.

Table F.22. pg_stat_statements Columns

</table>

For security reasons, only superusers and roles with privileges of the pg_read_all_stats role are allowed to see the SQL text and queryid of queries executed by other users. Other users can see the statistics, however, if the view has been installed in their database.

Plannable queries (that is, SELECT, INSERT, UPDATE, DELETE, and MERGE) and utility commands are combined into a single pg_stat_statements entry whenever they have identical query structures according to an internal hash calculation. Typically, two queries will be considered the same for this purpose if they are semantically equivalent except for the values of literal constants appearing in the query.

**Note**

The following details about constant replacement and queryid only apply when compute_query_id is enabled. If you use an external module instead to compute queryid, you should refer to its documentation for details.

When a constant’s value has been ignored for purposes of matching the query to other queries, the constant is replaced by a parameter symbol, such as $1, in the pg_stat_statements display. The rest of the query text is that of the first query that had the particular queryid hash value associated with the pg_stat_statements entry.
Queries on which normalization can be applied may be observed with constant values in \texttt{pg_stat_statements}, especially when there is a high rate of entry deallocations. To reduce the likelihood of this happening, consider increasing \texttt{pg_stat_statements.max}. The \texttt{pg_stat_statements_info} view, discussed below in Section F.32.2, provides statistics about entry deallocations.

In some cases, queries with visibly different texts might get merged into a single \texttt{pg_stat_statements} entry. Normally this will happen only for semantically equivalent queries, but there is a small chance of hash collisions causing unrelated queries to be merged into one entry. (This cannot happen for queries belonging to different users or databases, however.)

Since the \texttt{queryid} hash value is computed on the post-parse-analysis representation of the queries, the opposite is also possible: queries with identical texts might appear as separate entries, if they have different meanings as a result of factors such as different \texttt{search_path} settings.

Consumers of \texttt{pg_stat_statements} may wish to use \texttt{queryid} (perhaps in combination with \texttt{dbid} and \texttt{userid}) as a more stable and reliable identifier for each entry than its query text. However, it is important to understand that there are only limited guarantees around the stability of the \texttt{queryid} hash value. Since the identifier is derived from the post-parse-analysis tree, its value is a function of, among other things, the internal object identifiers appearing in this representation. This has some counterintuitive implications. For example, \texttt{pg_stat_statements} will consider two apparently-identical queries to be distinct, if they reference a table that was dropped and recreated between the executions of the two queries. The hashing process is also sensitive to differences in machine architecture and other facets of the platform. Furthermore, it is not safe to assume that \texttt{queryid} will be stable across major versions of PostgreSQL.

Two servers participating in replication based on physical WAL replay can be expected to have identical \texttt{queryid} values for the same query. However, logical replication schemes do not promise to keep replicas identical in all relevant details, so \texttt{queryid} will not be a useful identifier for accumulating costs across a set of logical replicas. If in doubt, direct testing is recommended.

Generally, it can be assumed that \texttt{queryid} values are stable between minor version releases of PostgreSQL, providing that instances are running on the same machine architecture and the catalog metadata details match. Compatibility will only be broken between minor versions as a last resort.

The parameter symbols used to replace constants in representative query texts start from the next number after the highest $n$ parameter in the original query text, or $1$ if there was none. It's worth noting that in some cases there may be hidden parameter symbols that affect this numbering. For example, PL/pgSQL uses hidden parameter symbols to insert values of function local variables into queries, so that a PL/pgSQL statement like \texttt{SELECT i + 1 INTO j} would have representative text like \texttt{SELECT i + $2}.

The representative query texts are kept in an external disk file, and do not consume shared memory. Therefore, even very lengthy query texts can be stored successfully. However, if many long query texts are accumulated, the external file might grow unmanageably large. As a recovery method if that happens, \texttt{pg_stat_statements} may choose to discard the query texts, whereupon all existing entries in the \texttt{pg_stat_statements} view will show null query fields, though the statistics associated with each \texttt{queryid} are preserved. If this happens, consider reducing \texttt{pg_stat_statements.max} to prevent recurrences.

\texttt{plans} and \texttt{calls} aren't always expected to match because planning and execution statistics are updated at their respective end phase, and only for successful operations. For example, if a statement is successfully planned but fails during the execution phase, only its planning statistics will be updated. If planning is skipped because a cached plan is used, only its execution statistics will be updated.

### F.32.2. The \texttt{pg_stat_statements_info} View

The statistics of the \texttt{pg_stat_statements} module itself are tracked and made available via a view named \texttt{pg_stat_statements_info}. This view contains only a single row. The columns of the view are shown in Table F.23.
Additional Supplied
Modules and Extensions

Table F.23. pg_stat_statements_info Columns

</tr>
</tbody>
</table>

F.32.3. Functions

pg_stat_statements_reset(userid Oid, dbid Oid, queryid bigint) returns void

pg_stat_statements_reset discards statistics gathered so far by pg_stat_statements corresponding to the specified userid, dbid and queryid. If any of the parameters are not specified, the default value 0 (invalid) is used for each of them and the statistics that match with other parameters will be reset. If no parameter is specified or all the specified parameters are 0 (invalid), it will discard all statistics. If all statistics in the pg_stat_statements view are discarded, it will also reset the statistics in the pg_stat_statements_info view. By default, this function can only be executed by superusers. Access may be granted to others using GRANT.

pg_stat_statements(showtext boolean) returns setof record

The pg_stat_statements view is defined in terms of a function also named pg_stat_statements. It is possible for clients to call the pg_stat_statements function directly, and by specifying showtext := false have query text be omitted (that is, the OUT argument that corresponds to the view's query column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all pg_stat_statements itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the pg_stat_statements data.

F.32.4. Configuration Parameters

pg_stat_statements.max(integer)

pg_stat_statements.max is the maximum number of statements tracked by the module (i.e., the maximum number of rows in the pg_stat_statements view). If more distinct statements than that are observed, information about the least-executed statements is discarded. The number of times such information was discarded can be seen in the pg_stat_statements_info view. The default value is 5000. This parameter can only be set at server start.

pg_stat_statements.track(enum)

pg_stat_statements.track controls which statements are counted by the module. Specify top to track top-level statements (those issued directly by clients), all to also track nested statements (such as statements invoked within functions), or none to disable statement statistics collection. The default value is top. Only superusers can change this setting.

pg_stat_statements.track_utility(boolean)

pg_stat_statements.track_utility controls whether utility commands are tracked by the module. Utility commands are all those other than SELECT, INSERT, UPDATE, DELETE, and MERGE. The default value is on. Only superusers can change this setting.
pg_stat_statements.track_planning (boolean)

pg_stat_statements.track_planning controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of pg_stat_statements entries. The default value is \textit{off}. Only superusers can change this setting.

pg_stat_statements.save (boolean)

pg_stat_statements.save specifies whether to save statement statistics across server shutdowns. If it is \textit{off} then statistics are not saved at shutdown nor reloaded at server start. The default value is \textit{on}. This parameter can only be set in the \texttt{postgresql.conf} file or on the server command line.

The module requires additional shared memory proportional to pg_stat_statements.max. Note that this memory is consumed whenever the module is loaded, even if pg_stat_statements.track is set to none.

These parameters must be set in \texttt{postgresql.conf}. Typical usage might be:

\begin{verbatim}
# postgresql.conf
shared_preload_libraries = 'pg_stat_statements'
compute_query_id = on
pg_stat_statements.max = 10000
pg_stat_statements.track = all
\end{verbatim}

F.32.6. Authors

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>. Query normalization added by Peter Geoghegan <peter@2ndquadrant.com>.
F.33. pgstattuple — obtain tuple-level statistics

The pgstattuple module provides various functions to obtain tuple-level statistics.

Because these functions return detailed page-level information, access is restricted by default. By default, only the role pg_stat_scan_tables has EXECUTE privilege. Superusers of course bypass this restriction. After the extension has been installed, users may issue GRANT commands to change the privileges on the functions to allow others to execute them. However, it might be preferable to add those users to the pg_stat_scan_tables role instead.

F.33.1. Functions

pgstattuple(regclass) returns record

pgstattuple returns a relation's physical length, percentage of "dead" tuples, and other info. This may help users to determine whether vacuum is necessary or not. The argument is the target relation's name (optionally schema-qualified) or OID. For example:

test=> SELECT * FROM pgstattuple('pg_catalog.pg_proc');
-[ RECORD 1 ]------------------------
  table_len | 458752
  tuple_count | 1470
  tuple_len | 438896
  tuple_percent | 95.67
  dead_tuple_count | 11
  dead_tuple_len | 3157
  dead_tuple_percent | 0.69
  free_space | 8932
  free_percent | 1.95

The output columns are described in Table F.24.

Table F.24. pgstattuple Output Columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_len</td>
<td>bigint</td>
<td>Physical relation length in bytes</td>
</tr>
<tr>
<td>tuple_count</td>
<td>bigint</td>
<td>Number of live tuples</td>
</tr>
<tr>
<td>tuple_len</td>
<td>bigint</td>
<td>Total length of live tuples in bytes</td>
</tr>
<tr>
<td>tuple_percent</td>
<td>float8</td>
<td>Percentage of live tuples</td>
</tr>
<tr>
<td>dead_tuple_count</td>
<td>bigint</td>
<td>Number of dead tuples</td>
</tr>
<tr>
<td>dead_tuple_len</td>
<td>bigint</td>
<td>Total length of dead tuples in bytes</td>
</tr>
<tr>
<td>dead_tuple_percent</td>
<td>float8</td>
<td>Percentage of dead tuples</td>
</tr>
<tr>
<td>free_space</td>
<td>bigint</td>
<td>Total free space in bytes</td>
</tr>
<tr>
<td>free_percent</td>
<td>float8</td>
<td>Percentage of free space</td>
</tr>
</tbody>
</table>

Note

The table_len will always be greater than the sum of the tuple_len, dead_tuple_len and free_space. The difference is accounted for by fixed page overhead.
the per-page table of pointers to tuples, and padding to ensure that tuples are correctly aligned.

\texttt{pgstattuple} acquires only a read lock on the relation. So the results do not reflect an instantaneous snapshot; concurrent updates will affect them.

\texttt{pgstattuple} judges a tuple is “dead” if \texttt{HeapTupleSatisfiesDirty} returns false.

\texttt{pgstattuple}\,(\texttt{text}) \ returns \ \texttt{record}

This is the same as \texttt{pgstattuple}\,(\texttt{regclass}), except that the target relation is specified as \texttt{TEXT}. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

\texttt{pgstatindex}\,(\texttt{regclass}) \ returns \ \texttt{record}

\texttt{pgstatindex} returns a record showing information about a B-tree index. For example:

\begin{verbatim}
 test=> SELECT * FROM pgstatindex('pg_cast_oid_index');
-\[ RECORD 1 \]--------
 version | 2
 tree_level | 0
 index_size | 16384
 root_block_no | 1
 internal_pages | 0
 leaf_pages | 1
 empty_pages | 0
 deleted_pages | 0
 avg_leaf_density | 54.27
 leaf_fragmentation | 0
\end{verbatim}

The output columns are:

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>integer</td>
<td>B-tree version number</td>
</tr>
<tr>
<td>tree_level</td>
<td>integer</td>
<td>Tree level of the root page</td>
</tr>
<tr>
<td>index_size</td>
<td>bigint</td>
<td>Total index size in bytes</td>
</tr>
<tr>
<td>root_block_no</td>
<td>bigint</td>
<td>Location of root page (zero if none)</td>
</tr>
<tr>
<td>internal_pages</td>
<td>bigint</td>
<td>Number of “internal” (upper-level) pages</td>
</tr>
<tr>
<td>leaf_pages</td>
<td>bigint</td>
<td>Number of leaf pages</td>
</tr>
<tr>
<td>empty_pages</td>
<td>bigint</td>
<td>Number of empty pages</td>
</tr>
<tr>
<td>deleted_pages</td>
<td>bigint</td>
<td>Number of deleted pages</td>
</tr>
<tr>
<td>avg_leaf_density</td>
<td>float8</td>
<td>Average density of leaf pages</td>
</tr>
<tr>
<td>leaf_fragmentation</td>
<td>float8</td>
<td>Leaf page fragmentation</td>
</tr>
</tbody>
</table>

The reported \texttt{index_size} will normally correspond to one more page than is accounted for by \texttt{internal_pages} + \texttt{leaf_pages} + \texttt{empty_pages} + \texttt{deleted_pages}, because it also includes the index’s metapage.

As with \texttt{pgstattuple}, the results are accumulated page-by-page, and should not be expected to represent an instantaneous snapshot of the whole index.
pgstatindex(text) returns record

This is the same as pgstatindex(regclass), except that the target index is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

pgstatginindex(regclass) returns record

pgstatginindex returns a record showing information about a GIN index. For example:

```
test=> SELECT * FROM pgstatginindex('test_gin_index');
-=[ RECORD 1 ]------
  version        | 1
  pending_pages  | 0
  pending_tuples | 0
```

The output columns are:

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>integer</td>
<td>GIN version number</td>
</tr>
<tr>
<td>pending_pages</td>
<td>integer</td>
<td>Number of pages in the pending list</td>
</tr>
<tr>
<td>pending_tuples</td>
<td>bigint</td>
<td>Number of tuples in the pending list</td>
</tr>
</tbody>
</table>

pgstathashindex(regclass) returns record

pgstathashindex returns a record showing information about a HASH index. For example:

```
test=> select * from pgstathashindex('con_hash_index');
-=[ RECORD 1 ]------------------
  version        | 4
  bucket_pages   | 33081
  overflow_pages | 0
  bitmap_pages   | 1
  unused_pages   | 32455
  live_items     | 10204006
  dead_items     | 0
  free_percent   | 61.8005949100872
```

The output columns are:

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>integer</td>
<td>HASH version number</td>
</tr>
<tr>
<td>bucket_pages</td>
<td>bigint</td>
<td>Number of bucket pages</td>
</tr>
<tr>
<td>overflow_pages</td>
<td>bigint</td>
<td>Number of overflow pages</td>
</tr>
<tr>
<td>bitmap_pages</td>
<td>bigint</td>
<td>Number of bitmap pages</td>
</tr>
<tr>
<td>unused_pages</td>
<td>bigint</td>
<td>Number of unused pages</td>
</tr>
<tr>
<td>live_items</td>
<td>bigint</td>
<td>Number of live tuples</td>
</tr>
<tr>
<td>dead_tuples</td>
<td>bigint</td>
<td>Number of dead tuples</td>
</tr>
<tr>
<td>free_percent</td>
<td>float</td>
<td>Percentage of free space</td>
</tr>
</tbody>
</table>

pg_relpages(regclass) returns bigint

pg_relpages returns the number of pages in the relation.
pg_relpages(text) returns bigint

This is the same as pg_relpages(regclass), except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

pgstattuple_approx(regclass) returns record

pgstattuple_approx is a faster alternative to pgstattuple that returns approximate results. The argument is the target relation’s name or OID. For example:

test=> SELECT * FROM pgstattuple_approx('pg_catalog.pg_proc '::regclass);
- [ RECORD 1 ]-------------------
  table_len          | 573440
  scanned_percent    | 2
  approx_tuple_count | 2740
  approx_tuple_len   | 561210
  approx_tuple_percent | 97.87
  dead_tuple_count   | 0
  dead_tuple_len     | 0
  dead_tuple_percent | 0
  approx_free_space  | 11996
  approx_free_percent | 2.09

The output columns are described in Table F.25.

Whereas pgstattuple always performs a full-table scan and returns an exact count of live and dead tuples (and their sizes) and free space, pgstattuple_approx tries to avoid the full-table scan and returns exact dead tuple statistics along with an approximation of the number and size of live tuples and free space.

It does this by skipping pages that have only visible tuples according to the visibility map (if a page has the corresponding VM bit set, then it is assumed to contain no dead tuples). For such pages, it derives the free space value from the free space map, and assumes that the rest of the space on the page is taken up by live tuples.

For pages that cannot be skipped, it scans each tuple, recording its presence and size in the appropriate counters, and adding up the free space on the page. At the end, it estimates the total number of live tuples based on the number of pages and tuples scanned (in the same way that VACUUM estimates pg_class.reltuples).

**Table F.25. pgstattuple_approx Output Columns**

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_len</td>
<td>bigint</td>
<td>Physical relation length in bytes (exact)</td>
</tr>
<tr>
<td>scanned_percent</td>
<td>float8</td>
<td>Percentage of table scanned</td>
</tr>
<tr>
<td>approx_tuple_count</td>
<td>bigint</td>
<td>Number of live tuples (estimated)</td>
</tr>
<tr>
<td>approx_tuple_len</td>
<td>bigint</td>
<td>Total length of live tuples in bytes (estimated)</td>
</tr>
<tr>
<td>approx_tuple_percent</td>
<td>float8</td>
<td>Percentage of live tuples</td>
</tr>
<tr>
<td>dead_tuple_count</td>
<td>bigint</td>
<td>Number of dead tuples (exact)</td>
</tr>
<tr>
<td>dead_tuple_len</td>
<td>bigint</td>
<td>Total length of dead tuples in bytes (exact)</td>
</tr>
</tbody>
</table>
### Additional Supplied Modules and Extensions

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dead_tuple_percent</td>
<td>float8</td>
<td>Percentage of dead tuples</td>
</tr>
<tr>
<td>approx_free_space</td>
<td>bigint</td>
<td>Total free space in bytes (estimated)</td>
</tr>
<tr>
<td>approx_free_percent</td>
<td>float8</td>
<td>Percentage of free space</td>
</tr>
</tbody>
</table>

In the above output, the free space figures may not match the `pgstattuple` output exactly, because the free space map gives us an exact figure, but is not guaranteed to be accurate to the byte.

### F.33.2. Authors

Tatsuo Ishii, Satoshi Nagayasu and Abhijit Menon-Sen
F.34. pg_surgery — perform low-level surgery on relation data

The pg_surgery module provides various functions to perform surgery on a damaged relation. These functions are unsafe by design and using them may corrupt (or further corrupt) your database. For example, these functions can easily be used to make a table inconsistent with its own indexes, to cause UNIQUE or FOREIGN KEY constraint violations, or even to make tuples visible which, when read, will cause a database server crash. They should be used with great caution and only as a last resort.

F.34.1. Functions

heap_force_kill(regclass, tid[]) returns void

heap_force_kill marks “used” line pointers as “dead” without examining the tuples. The intended use of this function is to forcibly remove tuples that are not otherwise accessible. For example:

```sql
test=> select * from t1 where ctid = '(0, 1)';
ERROR:  could not access status of transaction 4007513275
DETAIL:  Could not open file "pg_xact/0EED": No such file or directory.

test=# select heap_force_kill('t1'::regclass, ARRAY['(0, 1)']::tid[]);
heap_force_kill
-------------
(1 row)

test=# select * from t1 where ctid = '(0, 1)';
(0 rows)
```

heap_force_freeze(regclass, tid[]) returns void

heap_force_freeze marks tuples as frozen without examining the tuple data. The intended use of this function is to make accessible tuples which are inaccessible due to corrupted visibility information, or which prevent the table from being successfully vacuumed due to corrupted visibility information. For example:

```sql
test=> vacuum t1;
ERROR:  found xmin 507 from before relfrozenxid 515
CONTEXT:  while scanning block 0 of relation "public.t1"

test=# select ctid from t1 where xmin = 507;
ctid
-----
(0,3)
(1 row)

test=# select heap_force_freeze('t1'::regclass, ARRAY['(0, 3)']::tid[]);
heap_force_freeze
-------------------
2815
```
Additional Supplied Modules and Extensions

(1 row)

```
test=# select ctid from t1 where xmin = 2;
  ctid
-------
   (0,3)
(1 row)
```

Ashutosh Sharma <ashu.coek88@gmail.com>
Additional Supplied
Modules and Extensions

F.35. pg_trgm — support for similarity of text using trigram matching

The pg_trgm module provides functions and operators for determining the similarity of alphanumeric text based on trigram matching, as well as index operator classes that support fast searching for similar strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.35.1. Trigram (or Trigraph) Concepts

A trigram is a group of three consecutive characters taken from a string. We can measure the similarity of two strings by counting the number of trigrams they share. This simple idea turns out to be very effective for measuring the similarity of words in many natural languages.

Note

pg_trgm ignores non-word characters (non-alphanumerics) when extracting trigrams from a string. Each word is considered to have two spaces prefixed and one space suffixed when determining the set of trigrams contained in the string. For example, the set of trigrams in the string “cat” is “ c”, “ ca”, “cat”, and “at”. The set of trigrams in the string “foo|bar” is “ f”, “ fo”, “foo”, “oo “, “ b”, “ ba”, “bar”, and “ar “.

F.35.2. Functions and Operators

The functions provided by the pg_trgm module are shown in Table F.26, the operators in Table F.27.

Table F.26. pg_trgm Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>similarity(text, text) → real</td>
<td>Returns a number that indicates how similar the two arguments are. The range of the result is zero (indicating that the two strings are completely dissimilar) to one (indicating that the two strings are identical).</td>
</tr>
<tr>
<td>show_trgm(text) → text[]</td>
<td>Returns an array of all the trigrams in the given string. (In practice this is seldom useful except for debugging.)</td>
</tr>
<tr>
<td>word_similarity(text, text) → real</td>
<td>Returns a number that indicates the greatest similarity between the set of trigrams in the first string and any continuous extent of an ordered set of trigrams in the second string. For details, see the explanation below.</td>
</tr>
<tr>
<td>strict_word_similarity(text, text) → real</td>
<td>Same as word_similarity, but forces extent boundaries to match word boundaries. Since we don't have cross-word trigrams, this function actually returns greatest similarity between first string and any continuous extent of words of the second string.</td>
</tr>
<tr>
<td>show_limit() → real</td>
<td>Returns the current similarity threshold used by the % operator. This sets the minimum similarity between two words for them to be considered similar enough to be mis-</td>
</tr>
</tbody>
</table>
Additional Supplied
Modules and Extensions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>spellings of each other, for example. (Deprecated; instead use SHOW pg_trgm.similarity_threshold.)</td>
<td></td>
</tr>
<tr>
<td>set_limit (real) → real</td>
<td>Sets the current similarity threshold that is used by the % operator. The threshold must be between 0 and 1 (default is 0.3). Returns the same value passed in. (Deprecated; instead use SET pg_trgm.similarity_threshold.)</td>
</tr>
</tbody>
</table>

Consider the following example:

```sql
# SELECT word_similarity('word', 'two words');
word_similarity
-----------------
0.8
(1 row)
```

In the first string, the set of trigrams is {" w"," wo"," wor"," ord"," rd "). In the second string, the ordered set of trigrams is {" t"," tw"," two"," wo"," w"," wo"," wor"," or-d"," rds"," ds "). The most similar extent of an ordered set of trigrams in the second string is {" w"," wo"," wor"," ord"}, and the similarity is 0.8.

This function returns a value that can be approximately understood as the greatest similarity between the first string and any substring of the second string. However, this function does not add padding to the boundaries of the extent. Thus, the number of additional characters present in the second string is not considered, except for the mismatched word boundaries.

At the same time, strict_word_similarity selects an extent of words in the second string. In the example above, strict_word_similarity would select the extent of a single word 'words', whose set of trigrams is {" w"," wo"," wor"," ord"," rds"," ds ").

```sql
# SELECT strict_word_similarity('word', 'two words'),
similarity('word', 'words');
strict_word_similarity | similarity
------------------------+------------
0.571429 |   0.571429
(1 row)
```

Thus, the strict_word_similarity function is useful for finding the similarity to whole words, while word_similarity is more suitable for finding the similarity for parts of words.

### Table F.27. pg_trgm Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text % text → boolean</td>
<td>Returns true if its arguments have a similarity that is greater than the current similarity threshold set by pg_trgm.similarity_threshold.</td>
</tr>
<tr>
<td>text &lt;% text → boolean</td>
<td>Returns true if the similarity between the trigram set in the first argument and a continuous extent of an ordered trigram set in the second argument is greater than the current word similarity threshold set by pg_trgm.word_similarity_threshold parameter.</td>
</tr>
<tr>
<td>text %&gt; text → boolean</td>
<td></td>
</tr>
<tr>
<td>Operator</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>text &lt;&lt;% text → boolean</td>
<td>Returns true if its second argument has a continuous extent of an ordered trigram set that matches word boundaries, and its similarity to the trigram set of the first argument is greater than the current strict word similarity threshold set by the pg_trgm.strict_word_similarity_threshold parameter.</td>
</tr>
<tr>
<td>text %&gt;&gt; text → boolean</td>
<td>Commutator of the &lt;&lt;% operator.</td>
</tr>
<tr>
<td>text &lt;-&gt; text → real</td>
<td>Returns the “distance” between the arguments, that is one minus the similarity() value.</td>
</tr>
<tr>
<td>text &lt;-&gt; text → real</td>
<td>Returns the “distance” between the arguments, that is one minus the word_similarity() value.</td>
</tr>
<tr>
<td>text &lt;-&gt;&gt; text → real</td>
<td>Commutator of the &lt;-&gt; operator.</td>
</tr>
<tr>
<td>text &lt;&lt;-&gt; text → real</td>
<td>Returns the “distance” between the arguments, that is one minus the strict_word_similarity() value.</td>
</tr>
<tr>
<td>text &lt;&lt;-&gt;&gt; text → real</td>
<td>Commutator of the &lt;&lt;-&gt;&gt; operator.</td>
</tr>
</tbody>
</table>

**F.35.3. GUC Parameters**

- **pg_trgm.similarity_threshold(real)**
  
  Sets the current similarity threshold that is used by the % operator. The threshold must be between 0 and 1 (default is 0.3).

- **pg_trgm.word_similarity_threshold(real)**
  
  Sets the current word similarity threshold that is used by the < and %> operators. The threshold must be between 0 and 1 (default is 0.6).

- **pg_trgm.strict_word_similarity_threshold(real)**
  
  Sets the current strict word similarity threshold that is used by the <<% and %>> operators. The threshold must be between 0 and 1 (default is 0.5).

**F.35.4. Index Support**

The pg_trgm module provides GiST and GIN index operator classes that allow you to create an index over a text column for the purpose of very fast similarity searches. These index types support the above-described similarity operators, and additionally support trigram-based index searches for LIKE, ILIKE, ~, * and = queries. The similarity comparisons are case-insensitive in a default build of pg_trgm. Inequality operators are not supported. Note that those indexes may not be as efficient as regular B-tree indexes for equality operator.

Example:
CREATE TABLE test_trgm (t text);
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops);

or

CREATE INDEX trgm_idx ON test_trgm USING GIN (t gin_trgm_ops);

\texttt{gist\_trgm\_ops} GiST opclass approximates a set of trigrams as a bitmap signature. Its optional integer parameter \texttt{siglen} determines the signature length in bytes. The default length is 12 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops(siglen=32));

At this point, you will have an index on the \texttt{t} column that you can use for similarity searching. A typical query is

\begin{verbatim}
SELECT t, similarity(t, 'word') AS sml
   FROM test_trgm
   WHERE t % 'word'
   ORDER BY sml DESC, t;
\end{verbatim}

This will return all values in the text column that are sufficiently similar to \textit{word}, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

A variant of the above query is

\begin{verbatim}
SELECT t, t <-> 'word' AS dist
   FROM test_trgm
   ORDER BY dist LIMIT 10;
\end{verbatim}

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes. It will usually beat the first formulation when only a small number of the closest matches is wanted.

Also you can use an index on the \texttt{t} column for word similarity or strict word similarity. Typical queries are:

\begin{verbatim}
SELECT t, word_similarity('word', t) AS sml
   FROM test_trgm
   WHERE 'word' <% t
   ORDER BY sml DESC, t;
\end{verbatim}

and

\begin{verbatim}
SELECT t, strict_word_similarity('word', t) AS sml
   FROM test_trgm
   WHERE 'word' <<% t
   ORDER BY sml DESC, t;
\end{verbatim}

This will return all values in the text column for which there is a continuous extent in the corresponding ordered trigram set that is sufficiently similar to the trigram set of \textit{word}, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.
Possible variants of the above queries are:

```sql
SELECT t, 'word' <<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

and

```sql
SELECT t, 'word' <<<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes.

Beginning in PostgreSQL 9.1, these index types also support index searches for LIKE and ILIKE, for example

```sql
SELECT * FROM test_trgm WHERE t LIKE '%foo%bar';
```

The index search works by extracting trigrams from the search string and then looking these up in the index. The more trigrams in the search string, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

Beginning in PostgreSQL 9.3, these index types also support index searches for regular-expression matches (~ and ~* operators), for example

```sql
SELECT * FROM test_trgm WHERE t ~ '(foo|bar)';
```

The index search works by extracting trigrams from the regular expression and then looking these up in the index. The more trigrams that can be extracted from the regular expression, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

For both LIKE and regular-expression searches, keep in mind that a pattern with no extractable trigrams will degenerate to a full-index scan.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

### F.35.5. Text Search Integration

Trigram matching is a very useful tool when used in conjunction with a full text index. In particular it can help to recognize misspelled input words that will not be matched directly by the full text search mechanism.

The first step is to generate an auxiliary table containing all the unique words in the documents:

```sql
CREATE TABLE words AS SELECT word FROM
ts_stat('SELECT to_tsvector(''simple'', bodytext) FROM documents');
```

where documents is a table that has a text field bodytext that we wish to search. The reason for using the simple configuration with the to_tsvector function, instead of using a language-specific configuration, is that we want a list of the original (unstemmed) words.

Next, create a trigram index on the word column:
CREATE INDEX words_idx ON words USING GIN (word gin_trgm_ops);

Now, a SELECT query similar to the previous example can be used to suggest spellings for misspelled words in user search terms. A useful extra test is to require that the selected words are also of similar length to the misspelled word.

**Note**

Since the words table has been generated as a separate, static table, it will need to be periodically regenerated so that it remains reasonably up-to-date with the document collection. Keeping it exactly current is usually unnecessary.

F.36. pg_visibility — visibility map information and utilities

The pg_visibility module provides a means for examining the visibility map (VM) and page-level visibility information of a table. It also provides functions to check the integrity of a visibility map and to force it to be rebuilt.

Three different bits are used to store information about page-level visibility. The all-visible bit in the visibility map indicates that every tuple in the corresponding page of the relation is visible to every current and future transaction. The all-frozen bit in the visibility map indicates that every tuple in the page is frozen; that is, no future vacuum will need to modify the page until such time as a tuple is inserted, updated, deleted, or locked on that page. The page header's PD_ALL_VISIBLE bit has the same meaning as the all-visible bit in the visibility map, but is stored within the data page itself rather than in a separate data structure. These two bits will normally agree, but the page's all-visible bit can sometimes be set while the visibility map bit is clear after a crash recovery. The reported values can also disagree because of a change that occurs after pg_visibility examines the visibility map and before it examines the data page. Any event that causes data corruption can also cause these bits to disagree.

Functions that display information about PD_ALL_VISIBLE bits are much more costly than those that only consult the visibility map, because they must read the relation's data blocks rather than only the (much smaller) visibility map. Functions that check the relation's data blocks are similarly expensive.

F.36.1. Functions

pg_visibility_map(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean) returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation.

pg_visibility(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean) returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation, plus the PD_ALL_VISIBLE bit of that block.

pg_visibility_map(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean) returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation.

pg_visibility(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean) returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation, plus the PD_ALL_VISIBLE bit of each block.

pg_visibility_map_summary(relation regclass, all_visible OUT bigint, all_frozen OUT bigint) returns record

Returns the number of all-visible pages and the number of all-frozen pages in the relation according to the visibility map.
pg_check_frozen(relation regclass, t_ctid OUT tid) returns setof tid

Returns the TIDs of non-frozen tuples stored in pages marked all-frozen in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

pg_check_visible(relation regclass, t_ctid OUT tid) returns setof tid

Returns the TIDs of non-all-visible tuples stored in pages marked all-visible in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

pg_truncate_visibility_map(relation regclass) returns void

Truncates the visibility map for the given relation. This function is useful if you believe that the visibility map for the relation is corrupt and wish to force rebuilding it. The first VACUUM executed on the given relation after this function is executed will scan every page in the relation and rebuild the visibility map. (Until that is done, queries will treat the visibility map as containing all zeroes.)

By default, these functions are executable only by superusers and roles with privileges of the pg_stat_scan_tables role, with the exception of pg_truncate_visibility_map(relation regclass) which can only be executed by superusers.

F.36.2. Author

Robert Haas <rhaas@postgresql.org>
F.37. pg_walinspect — low-level WAL inspection

The pg_walinspect module provides SQL functions that allow you to inspect the contents of write-ahead log of a running PostgreSQL database cluster at a low level, which is useful for debugging, analytical, reporting or educational purposes. It is similar to pg_waldump, but accessible through SQL rather than a separate utility.

All the functions of this module will provide the WAL information using the server's current timeline ID.

### Note

The pg_walinspect functions are often called using an LSN argument that specifies the location at which a known WAL record of interest begins. However, some functions, such as pg_logical_emit_message, return the LSN after the record that was just inserted.

### Tip

All of the pg_walinspect functions that show information about records that fall within a certain LSN range are permissive about accepting end_lsn arguments that are after the server's current LSN. Using an end_lsn “from the future” will not raise an error.

It may be convenient to provide the value FFFFFFFF/FFFFFFFF (the maximum valid pg_lsn value) as an end_lsn argument. This is equivalent to providing an end_lsn argument matching the server's current LSN.

By default, use of these functions is restricted to superusers and members of the pg_read_server_files role. Access may be granted by superusers to others using GRANT.

F.37.1. General Functions

pg_get_wal_record_info(in_lsn pg_lsn) returns record

Gets WAL record information about a record that is located at or after the in_lsn argument. For example:

```
pagres=# SELECT * FROM pg_get_wal_record_info('0/E419E28');
-[
 start_lsn | 0/E419E28
 end_lsn | 0/E419E68
 prev_lsn | 0/E419D78
 xid | 0
 resource_manager | Heap2
 record_type | VACUUM
 record_length | 58
 main_data_length | 2
 fpi_length | 0
 description | unused: 5, unused: [1, 2, 3, 4, 5]
 block_ref | blkref #0: rel 1663/16385/1249 fork main blk 364
```
Additional Supplied
Modules and Extensions

If $in_{\text{lsn}}$ isn’t at the start of a WAL record, information about the next valid WAL record is shown instead. If there is no next valid WAL record, the function raises an error.

\[
\text{pg\_get\_wal\_records\_info}(start\_lsn \text{ pg\_lsn}, \text{ end\_lsn pg\_lsn}) \text{ returns setof record}
\]

Gets information of all the valid WAL records between $start\_lsn$ and $end\_lsn$. Returns one row per WAL record. For example:

```
postgres=# SELECT * FROM pg_get_wal_records_info('0/1E913618', '0/1E913740') LIMIT 1;
```

```
+--------------------------------------------------------------
| start_lsn        | 0/1E913618     |
| end_lsn          | 0/1E913650     |
| prev_lsn         | 0/1E9135A0     |
| xid              | 0              |
| resource_manager | Standby        |
| record_type      | RUNNING_XACTS  |
| record_length    | 50             |
| main_data_length | 24             |
| fpi_length       | 0              |
| description      | nextXid 33775  |
|                  | latestCompletedXid 33774 |
|                  | oldestRunningXid 33775 |
| block_ref        |                |
```

The function raises an error if $start\_lsn$ is not available.

\[
\text{pg\_get\_wal\_block\_info}(start\_lsn \text{ pg\_lsn}, \text{ end\_lsn pg\_lsn, show\_data boolean DEFAULT true}) \text{ returns setof record}
\]

Gets information about each block reference from all the valid WAL records between $start\_lsn$ and $end\_lsn$ with one or more block references. Returns one row per block reference per WAL record. For example:

```
postgres=# SELECT * FROM pg_get_wal_block_info('0/1230278', '0/12302B8');
```

```
+--------------------------------------------------------------+-[ RECORD 1 ]-----+--------------------------------------------------------------
| start_lsn         | 0/1230278     |
| end_lsn           | 0/12302B8     |
| prev_lsn          | 0/122FD40     |
| block_id          | 0             |
| reltablespace     | 1663          |
| reldatabase       | 1             |
| relfilenode       | 2658          |
| relforknumber     | 0             |
| relblocknumber    | 11            |
| xid               | 341           |
| resource_manager  | Btree         |
| record_type       | INSERT_LEAF   |
| record_length     | 64            |
| main_data_length  | 2             |
| block_data_length | 16            |
| block_fpi_length  | 0             |
| block_fpi_info    |               |
| description       | off: 46       |
| block_data        | \x00002a0007001040263000070696400 |
```

block_fpi_data

This example involves a WAL record that only contains one block reference, but many WAL records contain several block references. Rows output by `pg_get_wal_block_info` are guaranteed to have a unique combination of `start_lsn` and `block_id` values.

Much of the information shown here matches the output that `pg_get_wal_records_info` would show, given the same arguments. However, `pg_get_wal_block_info` unnests the information from each WAL record into an expanded form by outputting one row per block reference, so certain details are tracked at the block reference level rather than at the whole-record level. This structure is useful with queries that track how individual blocks changed over time. Note that records with no block references (e.g., COMMIT WAL records) will have no rows returned, so `pg_get_wal_block_info` may actually return fewer rows than `pg_get_wal_records_info`.

The `reltablespace`, `reldatabase`, and `relfilenode` parameters reference `pg_tablespace.oid`, `pg_database.oid`, and `pg_class.relfilenode` respectively. The `relforknumber` field is the fork number within the relation for the block reference; see `common/relpath.h` for details.

**Tip**

The `pg_filenode_relation` function (see Table 9.97) can help you to determine which relation was modified during original execution.

It is possible for clients to avoid the overhead of materializing block data. This may make function execution significantly faster. When `show_data` is set to false, `block_data` and `block_fpi_data` values are omitted (that is, the `block_data` and `block_fpi_data` OUT arguments are NULL for all rows returned). Obviously, this optimization is only feasible with queries where block data isn’t truly required.

The function raises an error if `start_lsn` is not available.

```sql
pg_get_wal_stats(start_lsn pg_lsn, end_lsn pg_lsn, per_record boolean DEFAULT false) returns setof record
```

Gets statistics of all the valid WAL records between `start_lsn` and `end_lsn`. By default, it returns one row per `resource_manager` type. When `per_record` is set to true, it returns one row per `record_type`. For example:

```sql
postgres=# SELECT * FROM pg_get_wal_stats('0/1E847D00', '0/1E84F500')
WHERE count > 0 AND
    "resource_manager/record_type" = 'Transaction'
LIMIT 1;
```

```
- [ RECORD 1 ]-----------------------------------------------
resource_manager/record_type | Transaction
count                         | 2
count_percentage              | 8
record_size                   | 875
record_size_percentage        | 41.23468426013195
fpi_size                      | 0
fpi_size_percentage           | 0
combined_size                 | 875
combined_size_percentage      | 2.8634072910530795
```

The function raises an error if `start_lsn` is not available.

Bharath Rupireddy <bharath.rupireddyforpostgres@gmail.com>
F.38. postgres_fdw — access data stored in external PostgreSQL servers

The postgres_fdw module provides the foreign-data wrapper postgres_fdw, which can be used to access data stored in external PostgreSQL servers.

The functionality provided by this module overlaps substantially with the functionality of the older dblink module. But postgres_fdw provides more transparent and standards-compliant syntax for accessing remote tables, and can give better performance in many cases.

To prepare for remote access using postgres_fdw:

1. Install the postgres_fdw extension using CREATE EXTENSION.
2. Create a foreign server object, using CREATE SERVER, to represent each remote database you want to connect to. Specify connection information, except user and password, as options of the server object.
3. Create a user mapping, using CREATE USER MAPPING, for each database user you want to allow to access each foreign server. Specify the remote user name and password to use as user and password options of the user mapping.
4. Create a foreign table, using CREATE FOREIGN TABLE or IMPORT FOREIGN SCHEMA, for each remote table you want to access. The columns of the foreign table must match the referenced remote table. You can, however, use table and/or column names different from the remote table's, if you specify the correct remote names as options of the foreign table object.

Now you need only SELECT from a foreign table to access the data stored in its underlying remote table. You can also modify the remote table using INSERT, UPDATE, DELETE, COPY, or TRUNCATE. (Of course, the remote user you have specified in your user mapping must have privileges to do these things.)

Note that the ONLY option specified in SELECT, UPDATE, DELETE or TRUNCATE has no effect when accessing or modifying the remote table.

Note that postgres_fdw currently lacks support for INSERT statements with an ON CONFLICT DO UPDATE clause. However, the ON CONFLICT DO NOTHING clause is supported, provided a unique index inference specification is omitted. Note also that postgres_fdw supports row movement invoked by UPDATE statements executed on partitioned tables, but it currently does not handle the case where a remote partition chosen to insert a moved row into is also an UPDATE target partition that will be updated elsewhere in the same command.

It is generally recommended that the columns of a foreign table be declared with exactly the same data types, and collations if applicable, as the referenced columns of the remote table. Although postgres_fdw is currently rather forgiving about performing data type conversions at need, surprising semantic anomalies may arise when types or collations do not match, due to the remote server interpreting query conditions differently from the local server.

Note that a foreign table can be declared with fewer columns, or with a different column order, than its underlying remote table has. Matching of columns to the remote table is by name, not position.

F.38.1. FDW Options of postgres_fdw

F.38.1.1. Connection Options

A foreign server using the postgres_fdw foreign data wrapper can have the same options that libpq accepts in connection strings, as described in Section 34.1.2, except that these options are not allowed or have special handling:

- user, password and sslpassword (specify these in a user mapping, instead, or use a service file)
• client_encoding (this is automatically set from the local server encoding)
• application_name - this may appear in either or both a connection and postgres_fdw.application_name. If both are present, postgres_fdw.application_name overrides the connection setting. Unlike libpq, postgres_fdw allows application_name to include “escape sequences”. See postgres_fdw.application_name for details.
• fallback_application_name (always set to postgres_fdw)
• sslcert and sslkey - these may appear in either or both a connection and a user mapping. If both are present, the user mapping setting overrides the connection setting.

Only superusers may create or modify user mappings with the sslcert or sslkey settings.

Non-superusers may connect to foreign servers using password authentication or with GSSAPI delegated credentials, so specify the password option for user mappings belonging to non-superusers where password authentication is required.

A superuser may override this check on a per-user-mapping basis by setting the user mapping option password_required 'false', e.g.,

ALTER USER MAPPING FOR some_non_superuser SERVER loopback_nopw OPTIONS (ADD password_required 'false');

To prevent unprivileged users from exploiting the authentication rights of the unix user the postgres server is running as to escalate to superuser rights, only the superuser may set this option on a user mapping.

Care is required to ensure that this does not allow the mapped user the ability to connect as superuser to the mapped database per CVE-2007-3278 and CVE-2007-6601. Don't set password_required=false on the public role. Keep in mind that the mapped user can potentially use any client certificates, .pgpass, .pg_service.conf etc. in the unix home directory of the system user the postgres server runs as. They can also use any trust relationship granted by authentication modes like peer or ident authentication.

F.38.1.2. Object Name Options

These options can be used to control the names used in SQL statements sent to the remote PostgreSQL server. These options are needed when a foreign table is created with names different from the underlying remote table's names.

 schema_name (string)

This option, which can be specified for a foreign table, gives the schema name to use for the foreign table on the remote server. If this option is omitted, the name of the foreign table's schema is used.

table_name (string)

This option, which can be specified for a foreign table, gives the table name to use for the foreign table on the remote server. If this option is omitted, the foreign table's name is used.

column_name (string)

This option, which can be specified for a column of a foreign table, gives the column name to use for the column on the remote server. If this option is omitted, the column's name is used.

F.38.1.3. Cost Estimation Options

postgres_fdw retrieves remote data by executing queries against remote servers, so ideally the estimated cost of scanning a foreign table should be whatever it costs to be done on the remote server, plus some overhead for communication. The most reliable way to get such an estimate is to ask the remote server and then add something for overhead — but for simple queries, it may not be worth the
cost of an additional remote query to get a cost estimate. So postgres_fdw provides the following options to control how cost estimation is done:

**use_remote_estimate (boolean)**

This option, which can be specified for a foreign table or a foreign server, controls whether postgres_fdw issues remote EXPLAIN commands to obtain cost estimates. A setting for a foreign table overrides any setting for its server, but only for that table. The default is false.

**fdw_startup_cost (floating point)**

This option, which can be specified for a foreign server, is a floating point value that is added to the estimated startup cost of any foreign-table scan on that server. This represents the additional overhead of establishing a connection, parsing and planning the query on the remote side, etc. The default value is 100.

**fdw_tuple_cost (floating point)**

This option, which can be specified for a foreign server, is a floating point value that is used as extra cost per-tuple for foreign-table scans on that server. This represents the additional overhead of data transfer between servers. You might increase or decrease this number to reflect higher or lower network delay to the remote server. The default value is 0.01.

When use_remote_estimate is true, postgres_fdw obtains row count and cost estimates from the remote server and then adds fdw_startup_cost and fdw_tuple_cost to the cost estimates. When use_remote_estimate is false, postgres_fdw performs local row count and cost estimation and then adds fdw_startup_cost and fdw_tuple_cost to the cost estimates. This local estimation is unlikely to be very accurate unless local copies of the remote table's statistics are available. Running ANALYZE on the foreign table is the way to update the local statistics; this will perform a scan of the remote table and then calculate and store statistics just as though the table were local. Keeping local statistics can be a useful way to reduce per-query planning overhead for a remote table — but if the remote table is frequently updated, the local statistics will soon be obsolete.

The following option controls how such an ANALYZE operation behaves:

**analyze_sampling (string)**

This option, which can be specified for a foreign table or a foreign server, determines if ANALYZE on a foreign table samples the data on the remote side, or reads and transfers all data and performs the sampling locally. The supported values are off, random, system, bernoulli and auto. off disables remote sampling, so all data are transferred and sampled locally. random performs remote sampling using the random() function to choose returned rows, while system and bernoulli rely on the built-in TABLESAMPLE methods of those names. random works on all remote server versions, while TABLESAMPLE is supported only since 9.5. auto (the default) picks the recommended sampling method automatically; currently it means either bernoulli or random depending on the remote server version.

### F.38.1.4. Remote Execution Options

By default, only WHERE clauses using built-in operators and functions will be considered for execution on the remote server. Clauses involving non-built-in functions are checked locally after rows are fetched. If such functions are available on the remote server and can be relied on to produce the same results as they do locally, performance can be improved by sending such WHERE clauses for remote execution. This behavior can be controlled using the following option:

**extensions (string)**

This option is a comma-separated list of names of PostgreSQL extensions that are installed, in compatible versions, on both the local and remote servers. Functions and operators that are immutable and belong to a listed extension will be considered shippable to the remote server. This option can only be specified for foreign servers, not per-table.
When using the `extensions` option, it is the user's responsibility that the listed extensions exist and behave identically on both the local and remote servers. Otherwise, remote queries may fail or behave unexpectedly.

`fetch_size(integer)`

This option specifies the number of rows `postgres_fdw` should get in each fetch operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 100.

`batch_size(integer)`

This option specifies the number of rows `postgres_fdw` should insert in each insert operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 1.

Note the actual number of rows `postgres_fdw` inserts at once depends on the number of columns and the provided `batch_size` value. The batch is executed as a single query, and the libpq protocol (which `postgres_fdw` uses to connect to a remote server) limits the number of parameters in a single query to 65535. When the number of columns * `batch_size` exceeds the limit, the `batch_size` will be adjusted to avoid an error.

This option also applies when copying into foreign tables. In that case the actual number of rows `postgres_fdw` copies at once is determined in a similar way to the insert case, but it is limited to at most 1000 due to implementation restrictions of the `COPY` command.

**F.38.1.5. Asynchronous Execution Options**

`postgres_fdw` supports asynchronous execution, which runs multiple parts of an `Append` node concurrently rather than serially to improve performance. This execution can be controlled using the following option:

`async_capable(boolean)`

This option controls whether `postgres_fdw` allows foreign tables to be scanned concurrently for asynchronous execution. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `false`.

In order to ensure that the data being returned from a foreign server is consistent, `postgres_fdw` will only open one connection for a given foreign server and will run all queries against that server sequentially even if there are multiple foreign tables involved, unless those tables are subject to different user mappings. In such a case, it may be more performant to disable this option to eliminate the overhead associated with running queries asynchronously.

Asynchronous execution is applied even when an `Append` node contains subplan(s) executed synchronously as well as subplan(s) executed asynchronously. In such a case, if the asynchronous subplans are ones processed using `postgres_fdw`, tuples from the asynchronous subplans are not returned until after at least one synchronous subplan returns all tuples, as that subplan is executed while the asynchronous subplans are waiting for the results of asynchronous queries sent to foreign servers. This behavior might change in a future release.

**F.38.1.6. Transaction Management Options**

As described in the Transaction Management section, in `postgres_fdw` transactions are managed by creating corresponding remote transactions, and subtransactions are managed by creating corresponding remote subtransactions. When multiple remote transactions are involved in the current local transaction, by default `postgres_fdw` commits or aborts those remote transactions serially when the local transaction is committed or aborted. When multiple remote subtransactions are involved in the current local subtransaction, by default `postgres_fdw` commits or aborts those remote sub-
transactions serially when the local subtransaction is committed or aborted. Performance can be improved with the following options:

```plaintext
parallel_commit (boolean)
```

This option controls whether `postgres_fdw` commits, in parallel, remote transactions opened on a foreign server in a local transaction when the local transaction is committed. This setting also applies to remote and local subtransactions. This option can only be specified for foreign servers, not per-table. The default is `false`.

```plaintext
parallel_abort (boolean)
```

This option controls whether `postgres_fdw` aborts, in parallel, remote transactions opened on a foreign server in a local transaction when the local transaction is aborted. This setting also applies to remote and local subtransactions. This option can only be specified for foreign servers, not per-table. The default is `false`.

If multiple foreign servers with these options enabled are involved in a local transaction, multiple remote transactions on those foreign servers are committed or aborted in parallel across those foreign servers when the local transaction is committed or aborted.

When these options are enabled, a foreign server with many remote transactions may see a negative performance impact when the local transaction is committed or aborted.

F.38.1.7. Updatability Options

By default all foreign tables using `postgres_fdw` are assumed to be updatable. This may be overridden using the following option:

```plaintext
updatable (boolean)
```

This option controls whether `postgres_fdw` allows foreign tables to be modified using `INSERT`, `UPDATE` and `DELETE` commands. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact updatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server. Note however that the `information_schema` views will report a `postgres_fdw` foreign table to be updatable (or not) according to the setting of this option, without any check of the remote server.

F.38.1.8. Truncatability Options

By default all foreign tables using `postgres_fdw` are assumed to be truncatable. This may be overridden using the following option:

```plaintext
truncatable (boolean)
```

This option controls whether `postgres_fdw` allows foreign tables to be truncated using the `TRUNCATE` command. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact truncatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server.

F.38.1.9. Importing Options

`postgres_fdw` is able to import foreign table definitions using `IMPORT FOREIGN SCHEMA`. This command creates foreign table definitions on the local server that match tables or views present on the remote server. If the remote tables to be imported have columns of user-defined data types, the local server must have compatible types of the same names.
Importing behavior can be customized with the following options (given in the IMPORT FOREIGN SCHEMA command):

import_collate (boolean)

This option controls whether column COLLATE options are included in the definitions of foreign tables imported from a foreign server. The default is true. You might need to turn this off if the remote server has a different set of collation names than the local server does, which is likely to be the case if it's running on a different operating system. If you do so, however, there is a very severe risk that the imported table columns' collations will not match the underlying data, resulting in anomalous query behavior.

Even when this parameter is set to true, importing columns whose collation is the remote server's default can be risky. They will be imported with COLLATE "default", which will select the local server's default collation, which could be different.

import_default (boolean)

This option controls whether column DEFAULT expressions are included in the definitions of foreign tables imported from a foreign server. The default is false. If you enable this option, be wary of defaults that might get computed differently on the local server than they would on the remote server; nextval() is a common source of problems. The IMPORT will fail altogether if an imported default expression uses a function or operator that does not exist locally.

import_generated (boolean)

This option controls whether column GENERATED expressions are included in the definitions of foreign tables imported from a foreign server. The default is true. The IMPORT will fail altogether if an imported generated expression uses a function or operator that does not exist locally.

import_not_null (boolean)

This option controls whether column NOT NULL constraints are included in the definitions of foreign tables imported from a foreign server. The default is true.

Note that constraints other than NOT NULL will never be imported from the remote tables. Although PostgreSQL does support check constraints on foreign tables, there is no provision for importing them automatically, because of the risk that a constraint expression could evaluate differently on the local and remote servers. Any such inconsistency in the behavior of a check constraint could lead to hard-to-detect errors in query optimization. So if you wish to import check constraints, you must do so manually, and you should verify the semantics of each one carefully. For more detail about the treatment of check constraints on foreign tables, see CREATE FOREIGN TABLE.

Tables or foreign tables which are partitions of some other table are imported only when they are explicitly specified in LIMIT TO clause. Otherwise they are automatically excluded from IMPORT FOREIGN SCHEMA. Since all data can be accessed through the partitioned table which is the root of the partitioning hierarchy, importing only partitioned tables should allow access to all the data without creating extra objects.

F.38.1.10. Connection Management Options

By default, all connections that postgres_fdw establishes to foreign servers are kept open in the local session for re-use.

keep_connections (boolean)

This option controls whether postgres_fdw keeps the connections to the foreign server open so that subsequent queries can re-use them. It can only be specified for a foreign server. The default is on. If set to off, all connections to this foreign server will be discarded at the end of each transaction.
F.38.2. Functions

postgres_fdw_get_connections(OUT server_name text, OUT valid boolean) returns setof record

This function returns the foreign server names of all the open connections that postgres_fdw established from the local session to the foreign servers. It also returns whether each connection is valid or not. false is returned if the foreign server connection is used in the current local transaction but its foreign server or user mapping is changed or dropped (Note that server name of an invalid connection will be NULL if the server is dropped), and then such invalid connection will be closed at the end of that transaction. true is returned otherwise. If there are no open connections, no record is returned. Example usage of the function:

postgres=# SELECT * FROM postgres_fdw_get_connections() ORDER BY 1;
server_name | valid
-------------+-------
loopback1    | t
loopback2    | f

postgres_fdw_disconnect(server_name text) returns boolean

This function discards the open connections that are established by postgres_fdw from the local session to the foreign server with the given name. Note that there can be multiple connections to the given server using different user mappings. If the connections are used in the current local transaction, they are not disconnected and warning messages are reported. This function returns true if it disconnects at least one connection, otherwise false. If no foreign server with the given name is found, an error is reported. Example usage of the function:

postgres=# SELECT postgres_fdw_disconnect('loopback1');
postgres_fdw_disconnect
-------------------------
t

postgres_fdw_disconnect_all() returns boolean

This function discards all the open connections that are established by postgres_fdw from the local session to foreign servers. If the connections are used in the current local transaction, they are not disconnected and warning messages are reported. This function returns true if it disconnects at least one connection, otherwise false. Example usage of the function:

postgres=# SELECT postgres_fdw_disconnect_all();
postgres_fdw_disconnect_all
---------------------------
t

F.38.3. Connection Management

postgres_fdw establishes a connection to a foreign server during the first query that uses a foreign table associated with the foreign server. By default this connection is kept and re-used for subsequent queries in the same session. This behavior can be controlled using keep_connections option for a foreign server. If multiple user identities (user mappings) are used to access the foreign server, a connection is established for each user mapping.

When changing the definition of or removing a foreign server or a user mapping, the associated connections are closed. But note that if any connections are in use in the current local transaction, they are
Additional Supplied Modules and Extensions

kept until the end of the transaction. Closed connections will be re-established when they are necessary by future queries using a foreign table.

Once a connection to a foreign server has been established, it’s by default kept until the local or corresponding remote session exits. To disconnect a connection explicitly, keep_connections option for a foreign server may be disabled, or postgres_fdw_disconnect and postgres_fdw_disconnect_all functions may be used. For example, these are useful to close connections that are no longer necessary, thereby releasing connections on the foreign server.

F.38.4. Transaction Management

During a query that references any remote tables on a foreign server, postgres_fdw opens a transaction on the remote server if one is not already open corresponding to the current local transaction. The remote transaction is committed or aborted when the local transaction commits or aborts. Savepoints are similarly managed by creating corresponding remote savepoints.

The remote transaction uses SERIALIZE isolation level when the local transaction has SERIALIZE isolation level; otherwise it uses REPEATABLE READ isolation level. This choice ensures that if a query performs multiple table scans on the remote server, it will get snapshot-consistent results for all the scans. A consequence is that successive queries within a single transaction will see the same data from the remote server, even if concurrent updates are occurring on the remote server due to other activities. That behavior would be expected anyway if the local transaction uses SERIALIZE or REPEATABLE READ isolation level, but it might be surprising for a READ COMMITTED local transaction. A future PostgreSQL release might modify these rules.

Note that it is currently not supported by postgres_fdw to prepare the remote transaction for two-phase commit.

F.38.5. Remote Query Optimization

postgres_fdw attempts to optimize remote queries to reduce the amount of data transferred from foreign servers. This is done by sending query WHERE clauses to the remote server for execution, and by not retrieving table columns that are not needed for the current query. To reduce the risk of misexecution of queries, WHERE clauses are not sent to the remote server unless they use only data types, operators, and functions that are built-in or belong to an extension that’s listed in the foreign server’s extensions option. Operators and functions in such clauses must be IMMUTABLE as well.

For an UPDATE or DELETE query, postgres_fdw attempts to optimize the query execution by sending the whole query to the remote server if there are no query WHERE clauses that cannot be sent to the remote server, no local joins for the query, no row-level local BEFORE or AFTER triggers or stored generated columns on the target table, and no CHECK OPTION constraints from parent views. In UPDATE, expressions to assign to target columns must use only built-in data types, IMMUTABLE operators, or IMMUTABLE functions, to reduce the risk of misexecution of the query.

When postgres_fdw encounters a join between foreign tables on the same foreign server, it sends the entire join to the foreign server, unless for some reason it believes that it will be more efficient to fetch rows from each table individually, or unless the table references involved are subject to different user mappings. While sending the JOIN clauses, it takes the same precautions as mentioned above for the WHERE clauses.

The query that is actually sent to the remote server for execution can be examined using EXPLAIN VERSE.

F.38.6. Remote Query Execution Environment

In the remote sessions opened by postgres_fdw, the search_path parameter is set to just pg_catalog, so that only built-in objects are visible without schema qualification. This is not an issue for queries generated by postgres_fdw itself, because it always supplies such qualification. However, this can pose a hazard for functions that are executed on the remote server via triggers or rules on
remote tables. For example, if a remote table is actually a view, any functions used in that view will be executed with the restricted search path. It is recommended to schema-qualify all names in such functions, or else attach \texttt{SET search\_path} options (see \texttt{CREATE FUNCTION}) to such functions to establish their expected search path environment.

\texttt{postgres\_fdw} likewise establishes remote session settings for various parameters:

- TimeZone is set to UTC
- DateStyle is set to ISO
- IntervalStyle is set to postgres
- extra\_float\_digits is set to 3 for remote servers 9.0 and newer and is set to 2 for older versions

These are less likely to be problematic than search\_path, but can be handled with function \texttt{SET} options if the need arises.

It is \textit{not} recommended that you override this behavior by changing the session-level settings of these parameters; that is likely to cause \texttt{postgres\_fdw} to malfunction.

**F.38.7. Cross-Version Compatibility**

\texttt{postgres\_fdw} can be used with remote servers dating back to PostgreSQL 8.3. Read-only capability is available back to 8.1. A limitation however is that \texttt{postgres\_fdw} generally assumes that immutable built-in functions and operators are safe to send to the remote server for execution, if they appear in a \texttt{WHERE} clause for a foreign table. Thus, a built-in function that was added since the remote server’s release might be sent to it for execution, resulting in “function does not exist” or a similar error. This type of failure can be worked around by rewriting the query, for example by embedding the foreign table reference in a \texttt{sub-SELECT} with \texttt{OFFSET 0} as an optimization fence, and placing the problematic function or operator outside the sub-\texttt{SELECT}.

**F.38.8. Configuration Parameters**

\texttt{postgres\_fdw.application\_name(string)}

Specifies a value for application\_name configuration parameter used when \texttt{postgres\_fdw} establishes a connection to a foreign server. This overrides application\_name option of the server object. Note that change of this parameter doesn’t affect any existing connections until they are re-established.

\texttt{postgres\_fdw.application\_name} can be any string of any length and contain even non-ASCII characters. However when it’s passed to and used as application\_name in a foreign server, note that it will be truncated to less than NAMEDATALEN characters. Anything other than printable ASCII characters are replaced with C-style hexadecimal escapes. See application\_name for details.

% characters begin “escape sequences” that are replaced with status information as outlined below. Unrecognized escapes are ignored. Other characters are copied straight to the application name. Note that it’s not allowed to specify a plus/minus sign or a numeric literal after the % and before the option, for alignment and padding.

<table>
<thead>
<tr>
<th>Escape</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>%a</td>
<td>Application name on local server</td>
</tr>
<tr>
<td>%c</td>
<td>Session ID on local server (see log_line_prefix for details)</td>
</tr>
<tr>
<td>%C</td>
<td>Cluster name on local server (see cluster_name for details)</td>
</tr>
<tr>
<td>%u</td>
<td>User name on local server</td>
</tr>
<tr>
<td>%d</td>
<td>Database name on local server</td>
</tr>
</tbody>
</table>
Additional Supplied
Modules and Extensions

<table>
<thead>
<tr>
<th>Escape</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>%p</td>
<td>Process ID of backend on local server</td>
</tr>
<tr>
<td>%</td>
<td>Literal %</td>
</tr>
</tbody>
</table>

For example, suppose user `local_user` establishes a connection from database `local_db` to `foreign_db` as user `foreign_user`, the setting 'db=%d, user=%u' is replaced with 'db=local_db, user=local_user'.

**F.38.9. Examples**

Here is an example of creating a foreign table with `postgres_fdw`. First install the extension:

```
CREATE EXTENSION postgres_fdw;
```

Then create a foreign server using `CREATE SERVER`. In this example we wish to connect to a PostgreSQL server on host `192.83.123.89` listening on port `5432`. The database to which the connection is made is named `foreign_db` on the remote server:

```
CREATE SERVER foreign_server
    FOREIGN DATA WRAPPER postgres_fdw
    OPTIONS (host '192.83.123.89', port '5432', dbname 'foreign_db');
```

A user mapping, defined with `CREATE USER MAPPING`, is needed as well to identify the role that will be used on the remote server:

```
CREATE USER MAPPING FOR local_user
    SERVER foreign_server
    OPTIONS (user 'foreign_user', password 'password');
```

Now it is possible to create a foreign table with `CREATE FOREIGN TABLE`. In this example we wish to access the table named `some_schema.some_table` on the remote server. The local name for it will be `foreign_table`:

```
CREATE FOREIGN TABLE foreign_table (id integer NOT NULL, data text)
    SERVER foreign_server
    OPTIONS (schema_name 'some_schema', table_name 'some_table');
```

It's essential that the data types and other properties of the columns declared in `CREATE FOREIGN TABLE` match the actual remote table. Column names must match as well, unless you attach `column_name` options to the individual columns to show how they are named in the remote table. In many cases, use of `IMPORT FOREIGN SCHEMA` is preferable to constructing foreign table definitions manually.

**F.38.10. Author**

Shigeru Hanada <shigeru.hanada@gmail.com>
F.39. seg — a datatype for line segments or floating point intervals

This module implements a data type `seg` for representing line segments, or floating point intervals. `seg` can represent uncertainty in the interval endpoints, making it especially useful for representing laboratory measurements.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.39.1. Rationale

The geometry of measurements is usually more complex than that of a point in a numeric continuum. A measurement is usually a segment of that continuum with somewhat fuzzy limits. The measurements come out as intervals because of uncertainty and randomness, as well as because the value being measured may naturally be an interval indicating some condition, such as the temperature range of stability of a protein.

Using just common sense, it appears more convenient to store such data as intervals, rather than pairs of numbers. In practice, it even turns out more efficient in most applications.

Further along the line of common sense, the fuzziness of the limits suggests that the use of traditional numeric data types leads to a certain loss of information. Consider this: your instrument reads 6.50, and you input this reading into the database. What do you get when you fetch it? Watch:

```
test=> select 6.50 :: float8 as "pH";
pH
---
6.5
(1 row)
```

In the world of measurements, 6.50 is not the same as 6.5. It may sometimes be critically different. The experimenters usually write down (and publish) the digits they trust. 6.50 is actually a fuzzy interval contained within a bigger and even fuzzier interval, 6.5, with their center points being (probably) the only common feature they share. We definitely do not want such different data items to appear the same.

Conclusion? It is nice to have a special data type that can record the limits of an interval with arbitrarily variable precision. Variable in the sense that each data element records its own precision.

Check this out:

```
 test=> select '6.25 .. 6.50'::seg as "pH";
pH
--------
6.25 .. 6.50
(1 row)
```

F.39.2. Syntax

The external representation of an interval is formed using one or two floating-point numbers joined by the range operator (`..` or `...`). Alternatively, it can be specified as a center point plus or minus a deviation. Optional certainty indicators (`<`, `>` or `~`) can be stored as well. (Certainty indicators are ignored by all the built-in operators, however.) Table F.28 gives an overview of allowed representations; Table F.29 shows some examples.
In Table F.28, \( x, y \), and \( \delta \) denote floating-point numbers. \( x \) and \( y \), but not \( \delta \), can be preceded by a certainty indicator.

**Table F.28. \texttt{seg} External Representations**

| \( x \) | Single value (zero-length interval) |
| \( x .. y \) | Interval from \( x \) to \( y \) |
| \( x (\pm) \delta \) | Interval from \( x - \delta \) to \( x + \delta \) |
| \( x .. \) | Open interval with lower bound \( x \) |
| \( .. x \) | Open interval with upper bound \( x \) |

**Table F.29. Examples of Valid \texttt{seg} Input**

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.0</td>
<td>Creates a zero-length segment (a point, if you will)</td>
</tr>
<tr>
<td>(~5.0)</td>
<td>Creates a zero-length segment and records (<del>) in the data. (</del>) is ignored by \texttt{seg} operations, but is preserved as a comment.</td>
</tr>
<tr>
<td>&lt;5.0</td>
<td>Creates a point at 5.0. &lt; is ignored but is preserved as a comment.</td>
</tr>
<tr>
<td>&gt;5.0</td>
<td>Creates a point at 5.0. &gt; is ignored but is preserved as a comment.</td>
</tr>
<tr>
<td>5(\pm)0.3</td>
<td>Creates an interval 4.7 .. 5.3. Note that the (\pm) notation isn’t preserved.</td>
</tr>
<tr>
<td>50 ..</td>
<td>Everything that is greater than or equal to 50</td>
</tr>
<tr>
<td>.. 0</td>
<td>Everything that is less than or equal to 0</td>
</tr>
<tr>
<td>1.5e-2 .. 2e-2</td>
<td>Creates an interval 0.015 .. 0.02</td>
</tr>
<tr>
<td>1 .. 2</td>
<td>The same as 1 ... 2, or 1 .. 2, or 1 .. 2 (spaces around the range operator are ignored)</td>
</tr>
</tbody>
</table>

Because the \( ... \) operator is widely used in data sources, it is allowed as an alternative spelling of the \( .. \) operator. Unfortunately, this creates a parsing ambiguity: it is not clear whether the upper bound in 0 ... 23 is meant to be 23 or 0.23. This is resolved by requiring at least one digit before the decimal point in all numbers in \texttt{seg} input.

As a sanity check, \texttt{seg} rejects intervals with the lower bound greater than the upper, for example 5 .. 2.

**F.39.3. Precision**

\texttt{seg} values are stored internally as pairs of 32-bit floating point numbers. This means that numbers with more than 7 significant digits will be truncated.

Numbers with 7 or fewer significant digits retain their original precision. That is, if your query returns 0.00, you will be sure that the trailing zeroes are not the artifacts of formatting; they reflect the precision of the original data. The number of leading zeroes does not affect precision: the value 0.0067 is considered to have just 2 significant digits.

**F.39.4. Usage**

The \texttt{seg} module includes a GiST index operator class for \texttt{seg} values. The operators supported by the GiST operator class are shown in Table F.30.

**Table F.30. Seg GiST Operators**

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{seg &lt;&lt; seg} \rightarrow \texttt{boolean}</td>
<td></td>
</tr>
</tbody>
</table>
### Additional Supplied Modules and Extensions

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>seg &gt;&gt; seg → boolean</td>
<td>Is the first seg entirely to the right of the second? [a, b] &gt;&gt; [c, d] is true if a &gt; d.</td>
</tr>
<tr>
<td>seg &amp;&lt; seg → boolean</td>
<td>Does the first seg not extend to the right of the second? [a, b] &amp;&lt; [c, d] is true if b &lt;= d.</td>
</tr>
<tr>
<td>seg &amp;&gt; seg → boolean</td>
<td>Does the first seg not extend to the left of the second? [a, b] &amp;&gt; [c, d] is true if a &gt;= c.</td>
</tr>
<tr>
<td>seg = seg → boolean</td>
<td>Are the two segs equal?</td>
</tr>
<tr>
<td>seg &amp;&amp; seg → boolean</td>
<td>Do the two segs overlap?</td>
</tr>
<tr>
<td>seg @&gt; seg → boolean</td>
<td>Does the first seg contain the second?</td>
</tr>
<tr>
<td>seg &lt;@ seg → boolean</td>
<td>Is the first seg contained in the second?</td>
</tr>
</tbody>
</table>

In addition to the above operators, the usual comparison operators shown in Table 9.1 are available for type seg. These operators first compare (a) to (c), and if these are equal, compare (b) to (d). That results in reasonably good sorting in most cases, which is useful if you want to use ORDER BY with this type.

**F.39.5. Notes**

For examples of usage, see the regression test sql/seg.sql.

The mechanism that converts (+-) to regular ranges isn't completely accurate in determining the number of significant digits for the boundaries. For example, it adds an extra digit to the lower boundary if the resulting interval includes a power of ten:

```
postgres=> select '10(+-)1'::seg as seg;
seg
---------
9.0 .. 11             -- should be: 9 .. 11
```

The performance of an R-tree index can largely depend on the initial order of input values. It may be very helpful to sort the input table on the seg column; see the script sort-segments.pl for an example.

**F.39.6. Credits**

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (https://dsf.berkeley.edu/jmh/) for elucidating the gist of the GiST (http://gist.cs.berkeley.edu/). I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.
Additional Supplied
Modules and Extensions

F.40. sepgsql — SELinux-, label-based mandatory access control (MAC) security module

sepgsql is a loadable module that supports label-based mandatory access control (MAC) based on SELinux security policy.

Warning

The current implementation has significant limitations, and does not enforce mandatory access control for all actions. See Section F.40.7.

F.40.1. Overview

This module integrates with SELinux to provide an additional layer of security checking above and beyond what is normally provided by PostgreSQL. From the perspective of SELinux, this module allows PostgreSQL to function as a user-space object manager. Each table or function access initiated by a DML query will be checked against the system security policy. This check is in addition to the usual SQL permissions checking performed by PostgreSQL.

SELinux access control decisions are made using security labels, which are represented by strings such as system_u:object_r:sepgsql_table_t:s0. Each access control decision involves two labels: the label of the subject attempting to perform the action, and the label of the object on which the operation is to be performed. Since these labels can be applied to any sort of object, access control decisions for objects stored within the database can be (and, with this module, are) subjected to the same general criteria used for objects of any other type, such as files. This design is intended to allow a centralized security policy to protect information assets independent of the particulars of how those assets are stored.

The SECURITY LABEL statement allows assignment of a security label to a database object.

F.40.2. Installation

sepgsql can only be used on Linux 2.6.28 or higher with SELinux enabled. It is not available on any other platform. You will also need libselinux 2.1.10 or higher and selinux-policy 3.9.13 or higher (although some distributions may backport the necessary rules into older policy versions).

The sestatus command allows you to check the status of SELinux. A typical display is:

```
$ sestatus
SELinux status:                           enabled
SELinuxfs mount:                          /selinux
Current mode:                             enforcing
Mode from config file:                    enforcing
Policy version:                           24
Policy from config file:                  targeted
```

If SELinux is disabled or not installed, you must set that product up first before installing this module.

To build this module, include the option --with-selinux in your PostgreSQL configure command. Be sure that the libselinux-devel RPM is installed at build time.
To use this module, you must include `sepgsql` in the `shared_preload_libraries` parameter in `postgresql.conf`. The module will not function correctly if loaded in any other manner. Once the module is loaded, you should execute `sepgsql.sql` in each database. This will install functions needed for security label management, and assign initial security labels.

Here is an example showing how to initialize a fresh database cluster with `sepgsql` functions and security labels installed. Adjust the paths shown as appropriate for your installation:

```
$ export PGDATA=/path/to/data/directory
$ initdb
$ vi $PGDATA/postgresql.conf
change
  #shared_preload_libraries = ''                # (change
requires restart)
to
  shared_preload_libraries = 'sepgsql'          # (change
requires restart)
$ for DBNAME in template0 template1 postgres; do
  postgres --single -F -c exit_on_error=true $DBNAME \<
  /usr/local/pgsql/share/contrib/sepgsql.sql >/dev/null
done
```

Please note that you may see some or all of the following notifications depending on the particular versions you have of libselinux and selinux-policy:

```
/etc/selinux/targeted/contexts/sepgsql_contexts: line 33 has
invalid object type db_blobs
/etc/selinux/targeted/contexts/sepgsql_contexts: line 36 has
invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 37 has
invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 38 has
invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 39 has
invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 40 has
invalid object type db_language
```

These messages are harmless and should be ignored.

If the installation process completes without error, you can now start the server normally.

### F.40.3. Regression Tests

Due to the nature of SELinux, running the regression tests for `sepgsql` requires several extra configuration steps, some of which must be done as root. The regression tests will not be run by an ordinary `make check` or `make installcheck` command; you must set up the configuration and then invoke the test script manually. The tests must be run in the `contrib/sepgsql` directory of a configured PostgreSQL build tree. Although they require a build tree, the tests are designed to be executed against an installed server, that is they are comparable to `make installcheck` not `make check`.

First, set up `sepgsql` in a working database according to the instructions in Section F.40.2. Note that the current operating system user must be able to connect to the database as superuser without password authentication.

Second, build and install the policy package for the regression test. The `sepgsql-regtest` policy is a special purpose policy package which provides a set of rules to be allowed during the regression
tests. It should be built from the policy source file sepgsql-regtest.te, which is done using
make with a Makefile supplied by SELinux. You will need to locate the appropriate Makefile on your
system; the path shown below is only an example. (This Makefile is usually supplied by the selinux-policy-devel or selinux-policy RPM.) Once built, install this policy package using
the semodule command, which loads supplied policy packages into the kernel. If the package is
correctly installed, semodule -l should list sepgsql-regtest as an available policy package:

```
$ cd ../contrib/sepgsql
$ make -f /usr/share/selinux/devel/Makefile
$ sudo semodule -u sepgsql-regtest.pp
$ sudo semodule -l | grep sepgsql
sepgsql-regtest 1.07
```

Third, turn on `sepgsql_regression_test_mode`. For security reasons, the rules in
sepgsql-regtest are not enabled by default; the `sepgsql_regression_test_mode` pa-
rameter enables the rules needed to launch the regression tests. It can be turned on using the `setse-
bool` command:

```
$ sudo setsebool sepgsql_regression_test_mode on
$ getsebool sepgsql_regression_test_mode
sepgsql_regression_test_mode --> on
```

Fourth, verify your shell is operating in the `unconfined_t` domain:

```
$ id -Z
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
```

See Section F.40.8 for details on adjusting your working domain, if necessary.

Finally, run the regression test script:

```
$ ./test_sepgsql
```

This script will attempt to verify that you have done all the configuration steps correctly, and then it
will run the regression tests for the sepgsql module.

After completing the tests, it’s recommended you disable the `sepgsql_regression_test_mode` parameter:

```
$ sudo setsebool sepgsql_regression_test_mode off
```

You might prefer to remove the sepgsql-regtest policy entirely:

```
$ sudo semodule -r sepgsql-regtest
```

### F.40.4. GUC Parameters

`sepgsql.permissive` (boolean)

This parameter enables sepgsql to function in permissive mode, regardless of the system setting. The default is off. This parameter can only be set in the `postgresql.conf` file or on
the server command line.

When this parameter is on, sepgsql functions in permissive mode, even if SELinux in general
is working in enforcing mode. This parameter is primarily useful for testing purposes.
sepgsql.debug_audit (boolean)

This parameter enables the printing of audit messages regardless of the system policy settings. The default is off, which means that messages will be printed according to the system settings.

The security policy of SELinux also has rules to control whether or not particular accesses are logged. By default, access violations are logged, but allowed accesses are not.

This parameter forces all possible logging to be turned on, regardless of the system policy.

F.40.5. Features

F.40.5.1. Controlled Object Classes

The security model of SELinux describes all the access control rules as relationships between a subject entity (typically, a client of the database) and an object entity (such as a database object), each of which is identified by a security label. If access to an unlabeled object is attempted, the object is treated as if it were assigned the label unlabeled_t.

Currently, sepgsql allows security labels to be assigned to schemas, tables, columns, sequences, views, and functions. When sepgsql is in use, security labels are automatically assigned to supported database objects at creation time. This label is called a default security label, and is decided according to the system security policy, which takes as input the creator's label, the label assigned to the new object's parent object and optionally name of the constructed object.

A new database object basically inherits the security label of the parent object, except when the security policy has special rules known as type-transition rules, in which case a different label may be applied. For schemas, the parent object is the current database; for tables, sequences, views, and functions, it is the containing schema; for columns, it is the containing table.

F.40.5.2. DML Permissions

For tables, db_table:select, db_table:insert, db_table:update or db_table:delete are checked for all the referenced target tables depending on the kind of statement; in addition, db_table:select is also checked for all the tables that contain columns referenced in the WHERE or RETURNING clause, as a data source for UPDATE, and so on.

Column-level permissions will also be checked for each referenced column. db_column:select is checked on not only the columns being read using SELECT, but those being referenced in other DML statements; db_column:update or db_column:insert will also be checked for columns being modified by UPDATE or INSERT.

For example, consider:

```
UPDATE t1 SET x = 2, y = func1(y) WHERE z = 100;
```

Here, db_column:update will be checked for t1.x, since it is being updated, db_column:{select update} will be checked for t1.y, since it is both updated and referenced, and db_column:select will be checked for t1.z, since it is only referenced. db_table:{select update} will also be checked at the table level.

For sequences, db_sequence:get_value is checked when we reference a sequence object using SELECT; however, note that we do not currently check permissions on execution of corresponding functions such as lastval().

For views, db_view:expand will be checked, then any other required permissions will be checked on the objects being expanded from the view, individually.
Additional Supplied
Modules and Extensions

For functions, `db_procedure:{execute}` will be checked when user tries to execute a function as a part of query, or using fast-path invocation. If this function is a trusted procedure, it also checks `db_procedure:{entrypoint}` permission to check whether it can perform as entry point of trusted procedure.

In order to access any schema object, `db_schema:search` permission is required on the containing schema. When an object is referenced without schema qualification, schemas on which this permission is not present will not be searched (just as if the user did not have `USAGE` privilege on the schema). If an explicit schema qualification is present, an error will occur if the user does not have the requisite permission on the named schema.

The client must be allowed to access all referenced tables and columns, even if they originated from views which were then expanded, so that we apply consistent access control rules independent of the manner in which the table contents are referenced.

The default database privilege system allows database superusers to modify system catalogs using DML commands, and reference or modify toast tables. These operations are prohibited when `sepgsql` is enabled.

F.40.5.3. DDL Permissions

SELinux defines several permissions to control common operations for each object type; such as creation, alter, drop and relabel of security label. In addition, several object types have special permissions to control their characteristic operations; such as addition or deletion of name entries within a particular schema.

Creating a new database object requires `create` permission. SELinux will grant or deny this permission based on the client's security label and the proposed security label for the new object. In some cases, additional privileges are required:

- **CREATE DATABASE** additionally requires `getattr` permission for the source or template database.
- Creating a schema object additionally requires `add_name` permission on the parent schema.
- Creating a table additionally requires permission to create each individual table column, just as if each table column were a separate top-level object.
- Creating a function marked as `LEAKPROOF` additionally requires `install` permission. (This permission is also checked when `LEAKPROOF` is set for an existing function.)

When `DROP` command is executed, `drop` will be checked on the object being removed. Permissions will be also checked for objects dropped indirectly via `CASCADE`. Deletion of objects contained within a particular schema (tables, views, sequences and procedures) additionally requires `remove_name` on the schema.

When `ALTER` command is executed, `setattr` will be checked on the object being modified for each object types, except for subsidiary objects such as the indexes or triggers of a table, where permissions are instead checked on the parent object. In some cases, additional permissions are required:

- Moving an object to a new schema additionally requires `remove_name` permission on the old schema and `add_name` permission on the new one.
- Setting the `LEAKPROOF` attribute on a function requires `install` permission.
- Using `SECURITY LABEL` on an object additionally requires `relabelfrom` permission for the object in conjunction with its old security label and `relabelto` permission for the object in conjunction with its new security label. (In cases where multiple label providers are installed and the user tries to set a security label, but it is not managed by SELinux, only `setattr` should be checked here. This is currently not done due to implementation restrictions.)
**F.40.5.4. Trusted Procedures**

Trusted procedures are similar to security definer functions or setuid commands. SELinux provides a feature to allow trusted code to run using a security label different from that of the client, generally for the purpose of providing highly controlled access to sensitive data (e.g., rows might be omitted, or the precision of stored values might be reduced). Whether or not a function acts as a trusted procedure is controlled by its security label and the operating system security policy. For example:

```sql
CREATE TABLE customer (cid int primary key, cname text, credit text);

CREATE TABLE
postgres=# SECURITY LABEL ON COLUMN customer.credit IS 'system_u:object_r:sepgsql_secret_table_t:s0';

postgres=# CREATE FUNCTION show_credit(int) RETURNS text AS 'SELECT regexp_replace(credit, '-[0-9]+$', '-xxxx', 'g') FROM customer WHERE cid = $1' LANGUAGE sql;

postgres=# SECURITY LABEL ON FUNCTION show_credit(int) IS 'system_u:object_r:sepgsql_trusted_proc_exec_t:s0';

The above operations should be performed by an administrative user.

```sql
postgres=# SELECT * FROM customer;
ERROR:  SELinux: security policy violation

postgres=# SELECT cid, cname, show_credit(cid) FROM customer;

<table>
<thead>
<tr>
<th>cid</th>
<th>cname</th>
<th>show_credit</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>taro</td>
<td>1111-2222-3333-xxxx</td>
</tr>
<tr>
<td>2</td>
<td>hanako</td>
<td>5555-6666-7777-xxxx</td>
</tr>
</tbody>
</table>

(2 rows)

In this case, a regular user cannot reference `customer.credit` directly, but a trusted procedure `show_credit` allows the user to print the credit card numbers of customers with some of the digits masked out.

**F.40.5.5. Dynamic Domain Transitions**

It is possible to use SELinux's dynamic domain transition feature to switch the security label of the client process, the client domain, to a new context, if that is allowed by the security policy. The client domain needs the `setcurrent` permission and also `dyntransition` from the old to the new domain.

Dynamic domain transitions should be considered carefully, because they allow users to switch their label, and therefore their privileges, at their option, rather than (as in the case of a trusted procedure) as mandated by the system. Thus, the `dyntransition` permission is only considered safe when used to switch to a domain with a smaller set of privileges than the original one. For example:

```sql
regression=# select sepgsql_getcon();
```
In this example above we were allowed to switch from the larger MCS range `c1.c1023` to the smaller range `c1.c4`, but switching back was denied.

A combination of dynamic domain transition and trusted procedure enables an interesting use case that fits the typical process life-cycle of connection pooling software. Even if your connection pooling software is not allowed to run most of SQL commands, you can allow it to switch the security label of the client using the `sepgsql_setcon()` function from within a trusted procedure; that should take some credential to authorize the request to switch the client label. After that, this session will have the privileges of the target user, rather than the connection pooler. The connection pooler can later revert the security label change by again using `sepgsql_setcon()` with NULL argument, again invoked from within a trusted procedure with appropriate permissions checks. The point here is that only the trusted procedure actually has permission to change the effective security label, and only does so when given proper credentials. Of course, for secure operation, the credential store (table, procedure definition, or whatever) must be protected from unauthorized access.

**F.40.5.6. Miscellaneous**

We reject the `LOAD` command across the board, because any module loaded could easily circumvent security policy enforcement.

**F.40.6. Sepgsql Functions**

Table F.31 shows the available functions.

**Table F.31. Sepgsql Functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sepgsql_getcon()</code> → text</td>
<td>Returns the client domain, the current security label of the client.</td>
</tr>
<tr>
<td><code>sepgsql_setcon(text) → boolean</code></td>
<td>Switches the client domain of the current session to the new domain, if allowed by the security policy. It also accepts NULL as a request to transition to the client’s original domain.</td>
</tr>
<tr>
<td><code>sepgsql_mcstrans_in(text) → text</code></td>
<td>Translates the given qualified MLS/MCS range into raw format if the mcstrans daemon is running.</td>
</tr>
</tbody>
</table>
Additional Supplied
Modules and Extensions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sepgsql_mcstrans_out(text) → text</code></td>
<td>Translates the given raw MLS/MCS range into qualified format if the mcstrans daemon is running.</td>
</tr>
<tr>
<td><code>sepgsql_restorecon(text) → boolean</code></td>
<td>Sets up initial security labels for all objects within the current database. The argument may be <code>NULL</code>, or the name of a specfile to be used as alternative of the system default.</td>
</tr>
</tbody>
</table>

F.40.7. Limitations

Data Definition Language (DDL) Permissions

Due to implementation restrictions, some DDL operations do not check permissions.

Data Control Language (DCL) Permissions

Due to implementation restrictions, DCL operations do not check permissions.

Row-level access control

PostgreSQL supports row-level access, but `sepgsql` does not.

Covert channels

`sepgsql` does not try to hide the existence of a certain object, even if the user is not allowed to reference it. For example, we can infer the existence of an invisible object as a result of primary key conflicts, foreign key violations, and so on, even if we cannot obtain the contents of the object. The existence of a top secret table cannot be hidden; we only hope to conceal its contents.

F.41. spi — Server Programming Interface
features/examples

The spi module provides several workable examples of using the Server Programming Interface (SPI) and triggers. While these functions are of some value in their own right, they are even more useful as examples to modify for your own purposes. The functions are general enough to be used with any table, but you have to specify table and field names (as described below) while creating a trigger.

Each of the groups of functions described below is provided as a separately-installable extension.

F.41.1. refint — Functions for Implementing Referential Integrity

check_primary_key() and check_foreign_key() are used to check foreign key constraints. (This functionality is long since superseded by the built-in foreign key mechanism, of course, but the module is still useful as an example.)

check_primary_key() checks the referencing table. To use, create a BEFORE INSERT OR UPDATE trigger using this function on a table referencing another table. Specify as the trigger arguments: the referencing table’s column name(s) which form the foreign key, the referenced table name, and the column names in the referenced table which form the primary/unique key. To handle multiple foreign keys, create a trigger for each reference.

check_foreign_key() checks the referenced table. To use, create a BEFORE DELETE OR UPDATE trigger using this function on a table referenced by other table(s). Specify as the trigger arguments: the number of referencing tables for which the function has to perform checking, the action if a referencing key is found (cascade — to delete the referencing row, restrict — to abort transaction if referencing keys exist, setnull — to set referencing key fields to null), the triggered table’s column names which form the primary/unique key, then the referencing table name and column names (repeated for as many referencing tables as were specified by first argument). Note that the primary/unique key columns should be marked NOT NULL and should have a unique index.

There are examples in refint.example.

F.41.2. autoinc — Functions for Autoincrementing Fields

autoinc() is a trigger that stores the next value of a sequence into an integer field. This has some overlap with the built-in “serial column” feature, but it is not the same: autoinc() will override attempts to substitute a different field value during inserts, and optionally it can be used to increment the field during updates, too.

To use, create a BEFORE INSERT (or optionally BEFORE INSERT OR UPDATE) trigger using this function. Specify two trigger arguments: the name of the integer column to be modified, and the name of the sequence object that will supply values. (Actually, you can specify any number of pairs of such names, if you’d like to update more than one autoincrementing column.)

There is an example in autoinc.example.

F.41.3. insert_username — Functions for Tracking Who Changed a Table

insert_username() is a trigger that stores the current user’s name into a text field. This can be useful for tracking who last modified a particular row within a table.
To use, create a BEFORE INSERT and/or UPDATE trigger using this function. Specify a single trigger argument: the name of the text column to be modified.

There is an example in insert_username.example.

F.41.4. moddatetime — Functions for Tracking Last Modification Time

moddatetime() is a trigger that stores the current time into a timestamp field. This can be useful for tracking the last modification time of a particular row within a table.

To use, create a BEFORE UPDATE trigger using this function. Specify a single trigger argument: the name of the column to be modified. The column must be of type timestamp or timestamp with time zone.

There is an example in moddatetime.example.
F.42. sslinfo — obtain client SSL information

The sslinfo module provides information about the SSL certificate that the current client provided when connecting to PostgreSQL. The module is useless (most functions will return NULL) if the current connection does not use SSL.

Some of the information available through this module can also be obtained using the built-in system view `pg_stat_ssl`.

This extension won't build at all unless the installation was configured with `--with-ssl=openssl`.

F.42.1. Functions Provided

ssl_is_used() returns boolean

Returns true if current connection to server uses SSL, and false otherwise.

ssl_version() returns text

Returns the name of the protocol used for the SSL connection (e.g., TLSv1.0, TLSv1.1, TLSv1.2 or TLSv1.3).

ssl_cipher() returns text

Returns the name of the cipher used for the SSL connection (e.g., DHE-RSA-AES256-SHA).

ssl_client_cert_present() returns boolean

Returns true if current client has presented a valid SSL client certificate to the server, and false otherwise. (The server might or might not be configured to require a client certificate.)

ssl_client_serial() returns numeric

Returns serial number of current client certificate. The combination of certificate serial number and certificate issuer is guaranteed to uniquely identify a certificate (but not its owner — the owner ought to regularly change their keys, and get new certificates from the issuer).

So, if you run your own CA and allow only certificates from this CA to be accepted by the server, the serial number is the most reliable (albeit not very mnemonic) means to identify a user.

ssl_client_dn() returns text

Returns the full subject of the current client certificate, converting character data into the current database encoding. It is assumed that if you use non-ASCII characters in the certificate names, your database is able to represent these characters, too. If your database uses the SQL_ASCII encoding, non-ASCII characters in the name will be represented as UTF-8 sequences.

The result looks like `/CN=Someone /C=Some country/O=Some organization`.

ssl_issuer_dn() returns text

Returns the full issuer name of the current client certificate, converting character data into the current database encoding. Encoding conversions are handled the same as for `ssl_client_dn`.

The combination of the return value of this function with the certificate serial number uniquely identifies the certificate.

This function is really useful only if you have more than one trusted CA certificate in your server's certificate authority file, or if this CA has issued some intermediate certificate authority certificates.
ssl_client_dn_field(fieldname text) returns text

This function returns the value of the specified field in the certificate subject, or NULL if the field is not present. Field names are string constants that are converted into ASN1 object identifiers using the OpenSSL object database. The following values are acceptable:

- commonName (alias CN)
- surname (alias SN)
- givenName (alias GN)
- countryName (alias C)
- localityName (alias L)
- stateOrProvinceName (alias ST)
- organizationName (alias O)
- organizationalUnitName (alias OU)
- title
- description
- initials
- postalCode
- streetAddress
- generationQualifier
- description
- dnQualifier
- x500UniqueIdentifier
- pseudonym
- role
- emailAddress

All of these fields are optional, except commonName. It depends entirely on your CA's policy which of them would be included and which wouldn't. The meaning of these fields, however, is strictly defined by the X.500 and X.509 standards, so you cannot just assign arbitrary meaning to them.

ssl_issuer_field(fieldname text) returns text

Same as ssl_client_dn_field, but for the certificate issuer rather than the certificate subject.

ssl_extension_info() returns setof record

Provide information about extensions of client certificate: extension name, extension value, and if it is a critical extension.

Additional Supplied
Modules and Extensions

F.43. tablefunc — functions that return tables (crosstab and others)

The tablefunc module includes various functions that return tables (that is, multiple rows). These functions are useful both in their own right and as examples of how to write C functions that return multiple rows.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.43.1. Functions Provided

Table F.32 summarizes the functions provided by the tablefunc module.

Table F.32. tablefunc Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>normal_rand(int numvals, float mean, float stddev) → setof float8</td>
<td>Produces a set of normally distributed random values.</td>
</tr>
<tr>
<td>crosstab(text) → setof record</td>
<td>Produces a “pivot table” containing row names plus N value columns, where N is determined by the row type specified in the calling query.</td>
</tr>
<tr>
<td>crosstabN(text) → setof table_crosstab_N</td>
<td>Produces a “pivot table” containing row names plus N value columns. crosstab2, crosstab3, and crosstab4 are predefined, but you can create additional crosstabN functions as described below.</td>
</tr>
<tr>
<td>crosstab(source_sql text, category_sql text) → setof record</td>
<td>Produces a “pivot table” with the value columns specified by a second query.</td>
</tr>
<tr>
<td>crosstab(text, N integer) → setof record</td>
<td>Obsolete version of crosstab(text). The parameter N is now ignored, since the number of value columns is always determined by the calling query.</td>
</tr>
<tr>
<td>connectby(relname text, keyid_fld text, parent_keyid_fld text [, orderby_fld text ], start_with text, max_depth integer [, branch_delim text ] ) → setof record</td>
<td>Produces a representation of a hierarchical tree structure.</td>
</tr>
</tbody>
</table>

F.43.1.1. normal_rand

normal_rand(int numvals, float mean, float stddev) returns setof float8

normal_rand produces a set of normally distributed random values (Gaussian distribution).

numvals is the number of values to be returned from the function. mean is the mean of the normal distribution of values and stddev is the standard deviation of the normal distribution of values.

For example, this call requests 1000 values with a mean of 5 and a standard deviation of 3:
F.43.1.2. crosstab (text)

crosstab(text sql)
crosstab(text sql, int N)

The crosstab function is used to produce “pivot” displays, wherein data is listed across the page rather than down. For example, we might have data like

row1    val11
row1    val12
row1    val13
...
row2    val21
row2    val22
row2    val23
...

which we wish to display like

row1    val11   val12   val13   ...
row2    val21   val22   val23   ...
...

The crosstab function takes a text parameter that is an SQL query producing raw data formatted in the first way, and produces a table formatted in the second way.

The sql parameter is an SQL statement that produces the source set of data. This statement must return one row_name column, one category column, and one value column. N is an obsolete parameter, ignored if supplied (formerly this had to match the number of output value columns, but now that is determined by the calling query).

For example, the provided query might produce a set something like:

row_name    cat     value
----------+-------+-------
row1       cat1    val1
row1       cat2    val2
row1       cat3    val3
row1       cat4    val4
The crosstab function is declared to return setof record, so the actual names and types of the output columns must be defined in the FROM clause of the calling SELECT statement, for example:

```
SELECT * FROM crosstab('...') AS ct(row_name text, category_1 text, category_2 text);
```

This example produces a set something like:

```
<== value columns ==>
row_name   category_1   category_2
----------+------------+------------
row1        val1         val2
row2        val5         val6
```

The FROM clause must define the output as one row_name column (of the same data type as the first result column of the SQL query) followed by N value columns (all of the same data type as the third result column of the SQL query). You can set up as many output value columns as you wish. The names of the output columns are up to you.

The crosstab function produces one output row for each consecutive group of input rows with the same row_name value. It fills the output value columns, left to right, with the value fields from these rows. If there are fewer rows in a group than there are output value columns, the extra output columns are filled with nulls; if there are more rows, the extra input rows are skipped.

In practice the SQL query should always specify ORDER BY 1,2 to ensure that the input rows are properly ordered, that is, values with the same row_name are brought together and correctly ordered within the row. Notice that crosstab itself does not pay any attention to the second column of the query result; it's just there to be ordered by, to control the order in which the third-column values appear across the page.

Here is a complete example:

```
CREATE TABLE ct(id SERIAL, rowid TEXT, attribute TEXT, value TEXT);
INSERT INTO ct(rowid, attribute, value)
VALUES('test1','att1','val1');
INSERT INTO ct(rowid, attribute, value)
VALUES('test1','att2','val2');
INSERT INTO ct(rowid, attribute, value)
VALUES('test1','att3','val3');
INSERT INTO ct(rowid, attribute, value)
VALUES('test1','att4','val4');
INSERT INTO ct(rowid, attribute, value)
VALUES('test2','att1','val5');
INSERT INTO ct(rowid, attribute, value)
VALUES('test2','att2','val6');
INSERT INTO ct(rowid, attribute, value)
VALUES('test2','att3','val7');
INSERT INTO ct(rowid, attribute, value)
VALUES('test2','att4','val8');
SELECT *
```
FROM crosstab(
    'select rowid, attribute, value
    from ct
    where attribute = ''att2'' or attribute = ''att3''
    order by 1,2'
) AS ct(row_name text, category_1 text, category_2 text, category_3 text);

<table>
<thead>
<tr>
<th>row_name</th>
<th>category_1</th>
<th>category_2</th>
<th>category_3</th>
</tr>
</thead>
<tbody>
<tr>
<td>test1</td>
<td>val2</td>
<td>val3</td>
<td></td>
</tr>
<tr>
<td>test2</td>
<td>val6</td>
<td>val7</td>
<td></td>
</tr>
</tbody>
</table>

(2 rows)

You can avoid always having to write out a FROM clause to define the output columns, by setting up a custom crosstab function that has the desired output row type wired into its definition. This is described in the next section. Another possibility is to embed the required FROM clause in a view definition.

Note

See also the \crosstabview command in psql, which provides functionality similar to crosstab().

F.43.1.3. crosstabN(text)

crosstabN(text sql)

The crosstabN functions are examples of how to set up custom wrappers for the general crosstab function, so that you need not write out column names and types in the calling SELECT query. The tablefunc module includes crosstab2, crosstab3, and crosstab4, whose output row types are defined as

CREATE TYPE tablefunc_crosstab_N AS (
    row_name TEXT,
    category_1 TEXT,
    category_2 TEXT,
    .
    .
    .
    category_N TEXT
);

Thus, these functions can be used directly when the input query produces row_name and value columns of type text, and you want 2, 3, or 4 output values columns. In all other ways they behave exactly as described above for the general crosstab function.

For instance, the example given in the previous section would also work as

SELECT *
FROM crosstab3(
    'select rowid, attribute, value
    from ct
    where attribute = ''att2'' or attribute = ''att3''
) AS ct(row_name text, category_1 text, category_2 text, category_3 text);

<table>
<thead>
<tr>
<th>row_name</th>
<th>category_1</th>
<th>category_2</th>
<th>category_3</th>
</tr>
</thead>
<tbody>
<tr>
<td>test1</td>
<td>val2</td>
<td>val3</td>
<td></td>
</tr>
<tr>
<td>test2</td>
<td>val6</td>
<td>val7</td>
<td></td>
</tr>
</tbody>
</table>

(2 rows)
These functions are provided mostly for illustration purposes. You can create your own return types and functions based on the underlying `crosstab()` function. There are two ways to do it:

- Create a composite type describing the desired output columns, similar to the examples in `contrib/tablefunc/tablefunc--1.0.sql`. Then define a unique function name accepting one text parameter and returning `setof your_type_name`, but linking to the same underlying `crosstab` C function. For example, if your source data produces row names that are `text`, and values that are `float8`, and you want 5 value columns:

  ```sql
  CREATE TYPE my_crosstab_float8_5_cols AS (  
    my_row_name text,
    my_category_1 float8,
    my_category_2 float8,
    my_category_3 float8,
    my_category_4 float8,
    my_category_5 float8
  );
  CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(text)  
  RETURNS setof my_crosstab_float8_5_cols
  AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;
  ```

- Use `OUT` parameters to define the return type implicitly. The same example could also be done this way:

  ```sql
  CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(  
    IN text,
    OUT my_row_name text,
    OUT my_category_1 float8,
    OUT my_category_2 float8,
    OUT my_category_3 float8,
    OUT my_category_4 float8,
    OUT my_category_5 float8)
  RETURNS setof record
  AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;
  ```

### F.43.1.4. `crosstab(text, text)`

`crosstab(text source_sql, text category_sql)`

The main limitation of the single-parameter form of `crosstab` is that it treats all values in a group alike, inserting each value into the first available column. If you want the value columns to correspond to specific categories of data, and some groups might not have data for some of the categories, that doesn't work well. The two-parameter form of `crosstab` handles this case by providing an explicit list of the categories corresponding to the output columns.

`source_sql` is an SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. It may also have one or more “extra” columns. The `row_name` column must be first. The `category` and `value` columns must be the last two columns, in that order. Any columns between `row_name` and `category` are treated as “extra”. The “extra” columns are expected to be the same for all rows with the same `row_name` value.

For example, `source_sql` might produce a set something like:
SELECT row_name, extra_col, cat, value FROM foo ORDER BY 1;

row_name | extra_col | cat | value
----------+------------+-----+---------
row1      | extra1     | cat1 | val1    
row1      | extra1     | cat2 | val2    
row1      | extra1     | cat4 | val4    
row2      | extra2     | cat1 | val5    
row2      | extra2     | cat2 | val6    
row2      | extra2     | cat3 | val7    
row2      | extra2     | cat4 | val8    

category_sql is an SQL statement that produces the set of categories. This statement must return only one column. It must produce at least one row, or an error will be generated. Also, it must not produce duplicate values, or an error will be generated. category_sql might be something like:

SELECT DISTINCT cat FROM foo ORDER BY 1;

cat
-------
cat1
cat2
cat3
cat4

The crosstab function is declared to return setof record, so the actual names and types of the output columns must be defined in the FROM clause of the calling SELECT statement, for example:

SELECT * FROM crosstab('...', '...')
    AS ct(row_name text, extra text, cat1 text, cat2 text, cat3 text, cat4 text);

This will produce a result something like:

<== value columns ==>  
row_name | extra | cat1 | cat2 | cat3 | cat4
----------+-------+------+------+------+
row1      | extra1| val1 |      |      | val4
row2      | extra2| val5 | val6 | val7 | val8

The FROM clause must define the proper number of output columns of the proper data types. If there are \(N\) columns in the source_sql query's result, the first \(N-2\) of them must match up with the first \(N-2\) output columns. The remaining output columns must have the type of the last column of the source_sql query's result, and there must be exactly as many of them as there are rows in the category_sql query's result.

The crosstab function produces one output row for each consecutive group of input rows with the same row_name value. The output row_name column, plus any "extra" columns, are copied from the first row of the group. The output value columns are filled with the value fields from rows having matching category values. If a row's category does not match any output of the category_sql query, its value is ignored. Output columns whose matching category is not present in any input row of the group are filled with nulls.

In practice the source_sql query should always specify ORDER BY 1 to ensure that values with the same row_name are brought together. However, ordering of the categories within a group is not important. Also, it is essential to be sure that the order of the category_sql query's output matches the specified output column order.
Here are two complete examples:

```sql
create table sales(year int, month int, qty int);
insert into sales values(2007, 1, 1000);
insert into sales values(2007, 2, 1500);
insert into sales values(2007, 7, 500);
insert into sales values(2007, 11, 1500);
insert into sales values(2007, 12, 2000);
insert into sales values(2008, 1, 1000);
select * from crosstab('select year, month, qty from sales order by 1',
'select m from generate_series(1,12) m')
) as (
  year int,
  "Jan" int,
  "Feb" int,
  "Mar" int,
  "Apr" int,
  "May" int,
  "Jun" int,
  "Jul" int,
  "Aug" int,
  "Sep" int,
  "Oct" int,
  "Nov" int,
  "Dec" int
);
```

```
year | Jan  | Feb  | Mar | Apr | May | Jun | Jul | Aug | Sep | Oct
-----|------|------|-----|-----|-----|-----|-----|-----|-----|-----
  2007 | 1000 | 1500 |    |    |    |    | 500 |    |    |
  2008 | 1000 |      |    |    |    |    |     |    |    |
|      | | 2000
(2 rows)
```

```sql
CREATE TABLE cth(rowid text, rowdt timestamp, attribute text, val text);
INSERT INTO cth VALUES('test1','01 March 2003','temperature','42');
INSERT INTO cth VALUES('test1','01 March 2003','test_result','PASS');
INSERT INTO cth VALUES('test1','01 March 2003','volts','2.6987');
INSERT INTO cth VALUES('test2','02 March 2003','temperature','53');
INSERT INTO cth VALUES('test2','02 March 2003','test_result','FAIL');
INSERT INTO cth VALUES('test2','02 March 2003','test_startdate','01 March 2003');
INSERT INTO cth VALUES('test2','02 March 2003','volts','3.1234');
SELECT * FROM crosstab('SELECT rowid, rowdt, attribute, val FROM cth ORDER BY 1',
'SELECT DISTINCT attribute FROM cth ORDER BY 1')
```
Additional Supplied
Modules and Extensions

(2 rows)

You can create predefined functions to avoid having to write out the result column names and types in each query. See the examples in the previous section. The underlying C function for this form of crosstab is named crosstab_hash.

F.43.1.5. connectby

connectby(text relname, text keyid_fld, text parent_keyid_fld
[, text orderby_fld ], text start_with, int max_depth
[, text branch_delim ])

The connectby function produces a display of hierarchical data that is stored in a table. The table must have a key field that uniquely identifies rows, and a parent-key field that references the parent (if any) of each row. connectby can display the sub-tree descending from any row.

Table F.33 explains the parameters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>relname</td>
<td>Name of the source relation</td>
</tr>
<tr>
<td>keyid_fld</td>
<td>Name of the key field</td>
</tr>
<tr>
<td>parent_keyid_fld</td>
<td>Name of the parent-key field</td>
</tr>
<tr>
<td>orderby_fld</td>
<td>Name of the field to order siblings by (optional)</td>
</tr>
<tr>
<td>start_with</td>
<td>Key value of the row to start at</td>
</tr>
<tr>
<td>max_depth</td>
<td>Maximum depth to descend to, or zero for unlimited depth</td>
</tr>
<tr>
<td>branch_delim</td>
<td>String to separate keys with in branch output (optional)</td>
</tr>
</tbody>
</table>

The key and parent-key fields can be any data type, but they must be the same type. Note that the start_with value must be entered as a text string, regardless of the type of the key field.

The connectby function is declared to return setof record, so the actual names and types of the output columns must be defined in the FROM clause of the calling SELECT statement, for example:
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0, '-')
AS t(keyid text, parent_keyid text, level int, branch text, pos int);

The first two output columns are used for the current row's key and its parent row's key; they must match the type of the table's key field. The third output column is the depth in the tree and must be of type integer. If a branch_delim parameter was given, the next output column is the branch display and must be of type text. Finally, if an orderby fld parameter was given, the last output column is a serial number, and must be of type integer.

The “branch” output column shows the path of keys taken to reach the current row. The keys are separated by the specified branch_delim string. If no branch display is wanted, omit both the branch_delim parameter and the branch column in the output column list.

If the ordering of siblings of the same parent is important, include the orderby fld parameter to specify which field to order siblings by. This field can be of any sortable data type. The output column list must include a final integer serial-number column, if and only if orderby fld is specified.

The parameters representing table and field names are copied as-is into the SQL queries that connectby generates internally. Therefore, include double quotes if the names are mixed-case or contain special characters. You may also need to schema-qualify the table name.

In large tables, performance will be poor unless there is an index on the parent-key field.

It is important that the branch_delim string not appear in any key values, else connectby may incorrectly report an infinite-recursion error. Note that if branch_delim is not provided, a default value of ~ is used for recursion detection purposes.

Here is an example:

CREATE TABLE connectby_tree(keyid text, parent_keyid text, pos int);

INSERT INTO connectby_tree VALUES('row1', NULL, 0);
INSERT INTO connectby_tree VALUES('row2', 'row1', 0);
INSERT INTO connectby_tree VALUES('row3', 'row1', 0);
INSERT INTO connectby_tree VALUES('row4', 'row2', 1);
INSERT INTO connectby_tree VALUES('row5', 'row2', 0);
INSERT INTO connectby_tree VALUES('row6', 'row4', 0);
INSERT INTO connectby_tree VALUES('row7', 'row3', 0);
INSERT INTO connectby_tree VALUES('row8', 'row6', 0);
INSERT INTO connectby_tree VALUES('row9', 'row5', 0);

-- with branch, without orderby fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0, '-')
AS t(keyid text, parent_keyid text, level int, branch text);

keyid | parent_keyid | level | branch
-------+--------------+-------+---------------------
row2  |              |     0 | row2
row4  | row2         |     1 | row2~row4
row6  | row4         |     2 | row2~row4~row6
row8  | row6         |     3 | row2~row4~row6~row8
row5  | row2         |     1 | row2~row5
row9  | row5         |     2 | row2~row5~row9

(6 rows)
-- without branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0)
AS t(keyid text, parent_keyid text, level int);
keyid | parent_keyid | level |
-------+--------------+-------|
row2   |              |   0   |
row4   | row2         |   1   |
row6   | row4         |   2   |
row8   | row6         |   3   |
row5   | row2         |   1   |
row9   | row5         |   2   |
(6 rows)

-- with branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0, '-')
AS t(keyid text, parent_keyid text, level int, branch text, pos int);
keyid | parent_keyid | level |       branch       | pos |
-------+--------------+-------+-------------------+-----|
row2   |              |   0   | row2             |   1 |
row5   | row2         |   1   | row2~row5        |   2 |
row9   | row5         |   2   | row2~row5~row9   |   3 |
row4   | row2         |   1   | row2~row4        |   4 |
row6   | row4         |   2   | row2~row4~row6   |   5 |
row8   | row6         |   3   | row2~row4~row6~row8 |   6 |
(6 rows)

-- without branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0)
AS t(keyid text, parent_keyid text, level int, pos int);
keyid | parent_keyid | level | pos |
-------+--------------+-------+-----|
row2   |              |   0   |   1 |
row5   | row2         |   1   |   2 |
row9   | row5         |   2   |   3 |
row4   | row2         |   1   |   4 |
row6   | row4         |   2   |   5 |
row8   | row6         |   3   |   6 |
(6 rows)

F.43.2. Author

Joe Conway
F.44. tcn — a trigger function to notify listeners of changes to table content

The tcn module provides a trigger function that notifies listeners of changes to any table on which it is attached. It must be used as an AFTER trigger FOR EACH ROW.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

Only one parameter may be supplied to the function in a CREATE TRIGGER statement, and that is optional. If supplied it will be used for the channel name for the notifications. If omitted tcn will be used for the channel name.

The payload of the notifications consists of the table name, a letter to indicate which type of operation was performed, and column name/value pairs for primary key columns. Each part is separated from the next by a comma. For ease of parsing using regular expressions, table and column names are always wrapped in double quotes, and data values are always wrapped in single quotes. Embedded quotes are doubled.

A brief example of using the extension follows.

```sql
test=# create table tcndata
    a int not null,
    b date not null,
    c text,
    primary key (a, b)
);
CREATE TABLE

test=# create trigger tcndata_tcn_trigger
    after insert or update or delete on tcndata
    for each row execute function
    triggered_change_notification();
CREATE TRIGGER

test=# listen tcn;
LISTEN

test=# insert into tcndata values (1, date '2012-12-22', 'one'),
    (1, date '2012-12-23',
     'another'),
    (2, date '2012-12-23', 'two');
INSERT 0 3

Asynchronous notification "tcn" with payload
    "tcndata",I,"a"='1',"b"='2012-12-22' received from server
    process with PID 22770.

Asynchronous notification "tcn" with payload
    "tcndata",I,"a"='1',"b"='2012-12-23' received from server
    process with PID 22770.

Asynchronous notification "tcn" with payload
    "tcndata",I,"a"='2',"b"='2012-12-23' received from server
    process with PID 22770.

test=# update tcndata set c = 'uno' where a = 1;
UPDATE 2

Asynchronous notification "tcn" with payload
    "tcndata",U,"a"='1',"b"='2012-12-22' received from server
    process with PID 22770.
```
Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1','b'='2012-12-23'" received from server process with PID 22770.

```
test=# delete from tcndata where a = 1 and b = date '2012-12-22';
DELETE 1
```

Asynchronous notification "tcn" with payload ""tcndata",D,"a"='1','b'='2012-12-22'" received from server process with PID 22770.
test_decoding is an example of a logical decoding output plugin. It doesn't do anything especially useful, but can serve as a starting point for developing your own output plugin.

test_decoding receives WAL through the logical decoding mechanism and decodes it into text representations of the operations performed.

Typical output from this plugin, used over the SQL logical decoding interface, might be:

```sql
postgres=# SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'include-xids', '0');

 | lsn     | xid |                       data          |
+----------+-----+-------------------------------+
0/16D30F8 | 691 | BEGIN                         |
0/16D32A0 | 691 | table public.data: INSERT: id[int4]:2 data[text]: 'arg' |
0/16D32A0 | 691 | table public.data: INSERT: id[int4]:3 data[text]: 'demo' |
0/16D32A0 | 691 | COMMIT                        |
0/16D328 | 692 | BEGIN                         |
0/16D3398 | 692 | table public.data: DELETE: id[int4]:2 |
0/16D3398 | 692 | table public.data: DELETE: id[int4]:3 |
0/16D3398 | 692 | COMMIT                        |
```

We can also get the changes of the in-progress transaction, and the typical output might be:

```sql
postgres[33712]=# SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'stream-changes', '1');

 | lsn     | xid |                       data                                  |
+----------+-----+----------------------------------------------------------+
0/16B21F8 | 503 | opening a streamed block for transaction TXN 503          |
0/16B21F8 | 503 | streaming change for TXN 503                             |
0/16B2300 | 503 | streaming change for TXN 503                             |
0/16B2408 | 503 | streaming change for TXN 503                             |
0/16BEBA0 | 503 | closing a streamed block for transaction TXN 503          |
0/16B21F8 | 503 | opening a streamed block for transaction TXN 503          |
0/16BEC08 | 503 | streaming change for TXN 503                             |
0/16BEDB0 | 503 | streaming change for TXN 503                             |
0/16BEBA0 | 503 | closing a streamed block for transaction TXN 503          |
```

F.46. tsm_system_rows — the SYSTEM_ROWS sampling method for TABLESAMPLE

The tsm_system_rows module provides the table sampling method SYSTEM_ROWS, which can be used in the TABLESAMPLE clause of a SELECT command.

This table sampling method accepts a single integer argument that is the maximum number of rows to read. The resulting sample will always contain exactly that many rows, unless the table does not contain enough rows, in which case the whole table is selected.

Like the built-in SYSTEM sampling method, SYSTEM_ROWS performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are requested.

SYSTEM_ROWS does not support the REPEATABLE clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.46.1. Examples

Here is an example of selecting a sample of a table with SYSTEM_ROWS. First install the extension:

```
CREATE EXTENSION tsm_system_rows;
```

Then you can use it in a SELECT command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_ROWS(100);
```

This command will return a sample of 100 rows from the table my_table (unless the table does not have 100 visible rows, in which case all its rows are returned).
F.47. tsm_system_time — the SYSTEM_TIME sampling method for TABLESAMPLE

The tsm_system_time module provides the table sampling method SYSTEM_TIME, which can be used in the TABLESAMPLE clause of a SELECT command.

This table sampling method accepts a single floating-point argument that is the maximum number of milliseconds to spend reading the table. This gives you direct control over how long the query takes, at the price that the size of the sample becomes hard to predict. The resulting sample will contain as many rows as could be read in the specified time, unless the whole table has been read first.

Like the built-in SYSTEM sampling method, SYSTEM_TIME performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are selected.

SYSTEM_TIME does not support the REPEATABLE clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.47.1. Examples

Here is an example of selecting a sample of a table with SYSTEM_TIME. First install the extension:

```
CREATE EXTENSION tsm_system_time;
```

Then you can use it in a SELECT command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_TIME(1000);
```

This command will return as large a sample of my_table as it can read in 1 second (1000 milliseconds). Of course, if the whole table can be read in under 1 second, all its rows will be returned.
F.48. unaccent — a text search dictionary which removes diacritics

unaccent is a text search dictionary that removes accents (diacritic signs) from lexemes. It's a filtering dictionary, which means its output is always passed to the next dictionary (if any), unlike the normal behavior of dictionaries. This allows accent-insensitive processing for full text search.

The current implementation of unaccent cannot be used as a normalizing dictionary for the thesaurus dictionary.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.48.1. Configuration

An unaccent dictionary accepts the following options:

- RULES is the base name of the file containing the list of translation rules. This file must be stored in $SHAREDIR/tsearch_data/ (where $SHAREDIR means the PostgreSQL installation's shared-data directory). Its name must end in .rules (which is not to be included in the RULES parameter).

The rules file has the following format:

- Each line represents one translation rule, consisting of a character with accent followed by a character without accent. The first is translated into the second. For example,

```
À        A
Ä        A
Å        A
Æ        AE
Æ        AE
```

The two characters must be separated by whitespace, and any leading or trailing whitespace on a line is ignored.

- Alternatively, if only one character is given on a line, instances of that character are deleted; this is useful in languages where accents are represented by separate characters.

- Actually, each “character” can be any string not containing whitespace, so unaccent dictionaries could be used for other sorts of substring substitutions besides diacritic removal.

- As with other PostgreSQL text search configuration files, the rules file must be stored in UTF-8 encoding. The data is automatically translated into the current database's encoding when loaded. Any lines containing untranslatable characters are silently ignored, so that rules files can contain rules that are not applicable in the current encoding.

A more complete example, which is directly useful for most European languages, can be found in unaccent.rules, which is installed in $SHAREDIR/tsearch_data/ when the unaccent module is installed. This rules file translates characters with accents to the same characters without accents, and it also expands ligatures into the equivalent series of simple characters (for example, Å to AE).
F.48.2. Usage

Installing the unaccent extension creates a text search template unaccent and a dictionary unaccent based on it. The unaccent dictionary has the default parameter setting RULES='unaccent', which makes it immediately usable with the standard unaccent.rules file. If you wish, you can alter the parameter, for example

mydb=# ALTER TEXT SEARCH DICTIONARY unaccent (RULES='my_rules');

or create new dictionaries based on the template.

To test the dictionary, you can try:

mydb=# select ts_lexize('unaccent','Hôtel');
s\n
ts_lexize
---------
{Hotel}
(1 row)

Here is an example showing how to insert the unaccent dictionary into a text search configuration:

mydb=# CREATE TEXT SEARCH CONFIGURATION fr ( COPY = french );
mydb=# ALTER TEXT SEARCH CONFIGURATION fr
    ALTER MAPPING FOR hword, hword_part, word
    WITH unaccent, french_stem;
mydb=# select to_tsvector('fr','Hôtels de la Mer');
to_tsvector
----------
'hôtel':1 'mer':4
(1 row)

mydb=# select to_tsvector('fr','Hôtel de la Mer') @@
to_tsquery('fr','Hotels');
?column?
--------
t
(1 row)

mydb=# select ts_headline('fr','Hôtel de la Mer',to_tsquery('fr','Hotels'));
ts_headline
------------------------
<b>Hôtel</b> de la Mer
(1 row)

F.48.3. Functions

The unaccent() function removes accents (diacritic signs) from a given string. Basically, it's a wrapper around unaccent-type dictionaries, but it can be used outside normal text search contexts.

unaccent([dictionary regdictionary, ] string text) returns text

If the dictionary argument is omitted, the text search dictionary named unaccent and appearing in the same schema as the unaccent() function itself is used.

2870
For example:

```sql
SELECT unaccent('unaccent', 'Hôtel');
SELECT unaccent('Hôtel');
```
F.49. uuid-ossp — a UUID generator

The uuid-ossp module provides functions to generate universally unique identifiers (UUIDs) using one of several standard algorithms. There are also functions to produce certain special UUID constants. This module is only necessary for special requirements beyond what is available in core PostgreSQL. See Section 9.14 for built-in ways to generate UUIDs.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

F.49.1. uuid-ossp Functions

Table F.34 shows the functions available to generate UUIDs. The relevant standards ITU-T Rec. X.667, ISO/IEC 9834-8:2005, and RFC 4122\(^9\) specify four algorithms for generating UUIDs, identified by the version numbers 1, 3, 4, and 5. (There is no version 2 algorithm.) Each of these algorithms could be suitable for a different set of applications.

Table F.34. Functions for UUID Generation

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>uuid_generate_v1()</code> → <code>uuid</code></td>
<td>Generates a version 1 UUID. This involves the MAC address of the computer and a time stamp. Note that UUIDs of this kind reveal the identity of the computer that created the identifier and the time at which it did so, which might make it unsuitable for certain security-sensitive applications.</td>
</tr>
<tr>
<td><code>uuid_generate_v1mc()</code> → <code>uuid</code></td>
<td>Generates a version 1 UUID, but uses a random multicast MAC address instead of the real MAC address of the computer.</td>
</tr>
<tr>
<td><code>uuid_generate_v3(namespace uuid, name text)</code> → <code>uuid</code></td>
<td>Generates a version 3 UUID in the given namespace using the specified input name. The namespace should be one of the special constants produced by the <code>uuid_ns_*()</code> functions shown in Table F.35. (It could be any UUID in theory.) The name is an identifier in the selected namespace. For example:</td>
</tr>
<tr>
<td></td>
<td><code>SELECT uuid_generate_v3(uuid_ns_url(), 'http://www.postgresql.org');</code></td>
</tr>
<tr>
<td></td>
<td>The name parameter will be MD5-hashed, so the cleartext cannot be derived from the generated UUID. The generation of UUIDs by this method has no random or environment-dependent element and is therefore reproducible.</td>
</tr>
<tr>
<td><code>uuid_generate_v4()</code> → <code>uuid</code></td>
<td>Generates a version 4 UUID, which is derived entirely from random numbers.</td>
</tr>
<tr>
<td><code>uuid_generate_v5(namespace uuid, name text)</code> → <code>uuid</code></td>
<td>Generates a version 5 UUID, which works like a version 3 UUID except that SHA-1 is used as a hashing method. Version 5 should be preferred over version 3 because SHA-1 is thought to be more secure than MD5.</td>
</tr>
</tbody>
</table>

Additional Supplied
Modules and Extensions

Table F.35. Functions Returning UUID Constants

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uuid_nil() → uuid</td>
<td>Returns a “nil” UUID constant, which does not occur as a real UUID.</td>
</tr>
<tr>
<td>uuid_ns_dns() → uuid</td>
<td>Returns a constant designating the DNS namespace for UUIDs.</td>
</tr>
<tr>
<td>uuid_ns_url() → uuid</td>
<td>Returns a constant designating the URL namespace for UUIDs.</td>
</tr>
<tr>
<td>uuid_ns_oid() → uuid</td>
<td>Returns a constant designating the ISO object identifier (OID) namespace for UUIDs. (This pertains to ASN.1 OIDs, which are unrelated to the OIDs used in PostgreSQL.)</td>
</tr>
<tr>
<td>uuid_ns_x500() → uuid</td>
<td>Returns a constant designating the X.500 distinguished name (DN) namespace for UUIDs.</td>
</tr>
</tbody>
</table>

F.49.2. Building uuid-ossp

Historically this module depended on the OSSP UUID library, which accounts for the module’s name. While the OSSP UUID library can still be found at http://www.ossp.org/pkg/lib/uuid/, it is not well maintained, and is becoming increasingly difficult to port to newer platforms. uuid-ossp can now be built without the OSSP library on some platforms. On FreeBSD and some other BSD-derived platforms, suitable UUID creation functions are included in the core libc library. On Linux, macOS, and some other platforms, suitable functions are provided in the libuuid library, which originally came from the e2fsprogs project (though on modern Linux it is considered part of util-linux-ng). When invoking configure, specify --with-uuid=bsd to use the BSD functions, or --with-uuid=e2fs to use e2fsprogs' libuuid, or --with-uuid=ossp to use the OSSP UUID library. More than one of these libraries might be available on a particular machine, so configure does not automatically choose one.

F.49.3. Author

Peter Eisentraut <peter_e@gmx.net>
F.50. xml2 — XPath querying and XSLT functionality

The xml2 module provides XPath querying and XSLT functionality.

F.50.1. Deprecation Notice

From PostgreSQL 8.3 on, there is XML-related functionality based on the SQL/XML standard in the core server. That functionality covers XML syntax checking and XPath queries, which is what this module does, and more, but the API is not at all compatible. It is planned that this module will be removed in a future version of PostgreSQL in favor of the newer standard API, so you are encouraged to try converting your applications. If you find that some of the functionality of this module is not available in an adequate form with the newer API, please explain your issue to <pgsql-hackers@lists.postgresql.org> so that the deficiency can be addressed.

F.50.2. Description of Functions

Table F.36 shows the functions provided by this module. These functions provide straightforward XML parsing and XPath queries.

Table F.36. xml2 Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml_valid(document text) → boolean</td>
<td>Parses the given document and returns true if the document is well-formed XML. (Note: this is an alias for the standard PostgreSQL function xml_is_well_formed(). The name xml_valid() is technically incorrect since validity and well-formedness have different meanings in XML.)</td>
</tr>
<tr>
<td>xpath_string(document text, query text) → text</td>
<td>Evaluates the XPath query on the supplied document, and casts the result to text.</td>
</tr>
<tr>
<td>xpath_number(document text, query text) → real</td>
<td>Evaluates the XPath query on the supplied document, and casts the result to real.</td>
</tr>
<tr>
<td>xpath_bool(document text, query text) → boolean</td>
<td>Evaluates the XPath query on the supplied document, and casts the result to boolean.</td>
</tr>
</tbody>
</table>
| xpath_nodeset(document text, query text, toptag text, itemtag text) → text | Evaluates the query on the document and wraps the result in XML tags. If the result is multivalued, the output will look like:  

```
<toptag>
<itemtag>Value 1 which could be an XML fragment</itemtag>
<itemtag>Value 2....</itemtag>
</toptag>
```

If either toptag or itemtag is an empty string, the relevant tag is omitted.

| xpath_nodeset(document text, query text, itemtag text) → text | Like xpath_nodeset(document, query, toptag, itemtag) but result omits toptag. |
| xpath_nodeset(document text, query text) → text | |
## Additional Supplied Modules and Extensions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Like</td>
<td>xpath_nodeset(document, query, toptag, itemtag) but result omits both tags.</td>
</tr>
<tr>
<td>xpath_list(document text, query text, separator text) → text</td>
<td>Evaluates the query on the document and returns multiple values separated by the specified separator, for example Value 1, Value 2, Value 3 if separator is,.</td>
</tr>
<tr>
<td>xpath_list(document text, query text) → text</td>
<td>This is a wrapper for the above function that uses , as the separator.</td>
</tr>
</tbody>
</table>

### F.50.3. xpath_table

xpath_table(text key, text document, text relation, text xpaths, text criteria) returns setof record

xpath_table is a table function that evaluates a set of XPath queries on each of a set of documents and returns the results as a table. The primary key field from the original document table is returned as the first column of the result so that the result set can readily be used in joins. The parameters are described in Table F.37.

#### Table F.37. xpath_table Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>the name of the “key” field — this is just a field to be used as the first column of the output table, i.e., it identifies the record from which each output row came (see note below about multiple values)</td>
</tr>
<tr>
<td>document</td>
<td>the name of the field containing the XML document</td>
</tr>
<tr>
<td>relation</td>
<td>the name of the table or view containing the documents</td>
</tr>
<tr>
<td>xpaths</td>
<td>one or more XPath expressions, separated by</td>
</tr>
<tr>
<td>criteria</td>
<td>the contents of the WHERE clause. This cannot be omitted, so use true or 1=1 if you want to process all the rows in the relation</td>
</tr>
</tbody>
</table>

These parameters (except the XPath strings) are just substituted into a plain SQL SELECT statement, so you have some flexibility — the statement is

SELECT <key>, <document> FROM <relation> WHERE <criteria>

so those parameters can be anything valid in those particular locations. The result from this SELECT needs to return exactly two columns (which it will unless you try to list multiple fields for key or document). Beware that this simplistic approach requires that you validate any user-supplied values to avoid SQL injection attacks.

The function has to be used in a FROM expression, with an AS clause to specify the output columns; for example

SELECT * FROM xpath_table('article_id', 'article_xml', 'articles', '/article/author|/article/pages|/article/title', 2875
Additional Supplied
Modules and Extensions

'date_entered > '2003-01-01' ')
AS t(article_id integer, author text, page_count integer, title text);

The AS clause defines the names and types of the columns in the output table. The first is the “key” field and the rest correspond to the XPath queries. If there are more XPath queries than result columns, the extra queries will be ignored. If there are more result columns than XPath queries, the extra columns will be NULL.

Notice that this example defines the page_count result column as an integer. The function deals internally with string representations, so when you say you want an integer in the output, it will take the string representation of the XPath result and use PostgreSQL input functions to transform it into an integer (or whatever type the AS clause requests). An error will result if it can’t do this — for example if the result is empty — so you may wish to just stick to text as the column type if you think your data has any problems.

The calling SELECT statement doesn’t necessarily have to be just SELECT * — it can reference the output columns by name or join them to other tables. The function produces a virtual table with which you can perform any operation you wish (e.g., aggregation, joining, sorting etc.). So we could also have:

```
SELECT t.title, p.fullname, p.email
FROM xpath_table('article_id', 'article_xml', 'articles',
    '/article/title|/article/author/@id',
    'xpath_string(article_xml,''/article/@date'') > ''2003-03-20'' ')
AS t(article_id integer, title text, author_id integer),
    tblPeopleInfo AS p
WHERE t.author_id = p.person_id;
```

as a more complicated example. Of course, you could wrap all of this in a view for convenience.

**F.50.3.1. Multivalued Results**

The xpath_table function assumes that the results of each XPath query might be multivalued, so the number of rows returned by the function may not be the same as the number of input documents. The first row returned contains the first result from each query, the second row the second result from each query. If one of the queries has fewer values than the others, null values will be returned instead.

In some cases, a user will know that a given XPath query will return only a single result (perhaps a unique document identifier) — if used alongside an XPath query returning multiple results, the single-valued result will appear only on the first row of the result. The solution to this is to use the key field as part of a join against a simpler XPath query. As an example:

```
CREATE TABLE test (id int PRIMARY KEY,
    xml text);

INSERT INTO test VALUES (1, '<doc num="C1">
    <line num="L1"><a>1</a><b>2</b><c>3</c></line>
    <line num="L2"><a>11</a><b>22</b><c>33</c></line>
</doc>');

INSERT INTO test VALUES (2, '<doc num="C2">
    <line num="L1"><a>111</a><b>222</b><c>333</c></line>
    <line num="L2"><a>111</a><b>222</b><c>333</c></line>
</doc>');
```

```
SELECT * FROM
xpath_table('id','xml','test',
'/doc/@num|/doc/line/@num|/doc/line/a|/doc/line/b|/
doc/line/c',
'true')
AS t(id int, doc_num varchar(10), line_num varchar(10), val1 int,
val2 int, val3 int)
WHERE id = 1 ORDER BY doc_num, line_num

<table>
<thead>
<tr>
<th>id</th>
<th>doc_num</th>
<th>line_num</th>
<th>val1</th>
<th>val2</th>
<th>val3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>C1</td>
<td>L1</td>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>1</td>
<td></td>
<td>L2</td>
<td>11</td>
<td>22</td>
<td>33</td>
</tr>
</tbody>
</table>

To get `doc_num` on every line, the solution is to use two invocations of `xpath_table` and join the results:

SELECT t.*,i.doc_num FROM
xpath_table('id', 'xml', 'test',
'/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
'true')
AS t(id int, line_num varchar(10), val1 int, val2 int, val3 int),
xpath_table('id', 'xml', 'test', '/doc/@num', 'true')
AS i(id int, doc_num varchar(10))
WHERE i.id=t.id AND i.id=1
ORDER BY doc_num, line_num;

<table>
<thead>
<tr>
<th>id</th>
<th>line_num</th>
<th>val1</th>
<th>val2</th>
<th>val3</th>
<th>doc_num</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>L1</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>C1</td>
</tr>
<tr>
<td>1</td>
<td>L2</td>
<td>11</td>
<td>22</td>
<td>33</td>
<td>C1</td>
</tr>
</tbody>
</table>
(2 rows)

### F.50.4. XSLT Functions

The following functions are available if libxslt is installed:

#### F.50.4.1. `xslt_process`

```plaintext
xslt_process(text document, text stylesheet, text paramlist)
returns text
```

This function applies the XSL stylesheet to the document and returns the transformed result. The `paramlist` is a list of parameter assignments to be used in the transformation, specified in the form `a=1,b=2`. Note that the parameter parsing is very simple-minded: parameter values cannot contain commas!

There is also a two-parameter version of `xslt_process` which does not pass any parameters to the transformation.

### F.50.5. Author

John Gray <jgray@azuli.co.uk>
Development of this module was sponsored by Torchbox Ltd. (www.torchbox.com). It has the same BSD license as PostgreSQL.
Appendix G. Additional Supplied Programs

This appendix and the previous one contain information regarding the modules that can be found in the contrib directory of the PostgreSQL distribution. See Appendix F for more information about the contrib section in general and server extensions and plug-ins found in contrib specifically.

This appendix covers utility programs found in contrib. Once installed, either from source or a packaging system, they are found in the bin directory of the PostgreSQL installation and can be used like any other program.

G.1. Client Applications

This section covers PostgreSQL client applications in contrib. They can be run from anywhere, independent of where the database server resides. See also PostgreSQL Client Applications for information about client applications that are part of the core PostgreSQL distribution.
oid2name

oid2name — resolve OIDs and file nodes in a PostgreSQL data directory

Synopsis

oid2name[option...]

Description

oid2name is a utility program that helps administrators to examine the file structure used by PostgreSQL. To make use of it, you need to be familiar with the database file structure, which is described in Chapter 73.

Note

The name "oid2name" is historical, and is actually rather misleading, since most of the time when you use it, you will really be concerned with tables' filenode numbers (which are the file names visible in the database directories). Be sure you understand the difference between table OIDs and table filenodes!

oid2name connects to a target database and extracts OID, filenode, and/or table name information. You can also have it show database OIDs or tablespace OIDs.

Options

oid2name accepts the following command-line arguments:

- \(-f \) filenode
  --filenode=filenode
    show info for table with filenode filenode.

- \(-i \)  --indexes
    include indexes and sequences in the listing.

- \(-o \) oid
  --oid=oid
    show info for table with OID oid.

- \(-q \)  --quiet
    omit headers (useful for scripting).

- \(-s \)  --tablespaces
    show tablespace OIDs.

- \(-S \)  --system-objects
    include system objects (those in information_schema, pg_toast and pg_catalog schemas).
Additional Supplied Programs

-t  tablename_pattern
--table=tablename_pattern

    show info for table(s) matching tablename_pattern.

-V
--version

    Print the oid2name version and exit.

-x
--extended

    display more information about each object shown: tablespace name, schema name, and OID.

-?
--help

    Show help about oid2name command line arguments, and exit.

oid2name also accepts the following command-line arguments for connection parameters:

-d  database
--dbname=database

    database to connect to.

-h  host
--host=host

    database server's host.

-H  host

    database server's host. Use of this parameter is deprecated as of PostgreSQL 12.

-p  port
--port=port

    database server's port.

-U  username
--username=username

    user name to connect as.

To display specific tables, select which tables to show by using -o, -f and/or -t. -o takes an OID, -f takes a filenode, and -t takes a table name (actually, it's a LIKE pattern, so you can use things like foo%). You can use as many of these options as you like, and the listing will include all objects matched by any of the options. But note that these options can only show objects in the database given by -d.

If you don't give any of -o, -f or -t, but do give -d, it will list all tables in the database named by -d. In this mode, the -S and -i options control what gets listed.

If you don't give -d either, it will show a listing of database OIDs. Alternatively you can give -s to get a tablespace listing.

Environment

PGHOST
PGPORT
PGUSER

    Default connection parameters.
This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 34.15).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

oid2name requires a running database server with non-corrupt system catalogs. It is therefore of only limited use for recovering from catastrophic database corruption situations.

Examples

```
$ # what's in this database server, anyway?
$ oid2name
All databases:
                     Oid  Database Name  Tablespace
----------------------------------
  17228       alvherre  pg_default
  17255     regression  pg_default
  17227      template0  pg_default
         1      template1  pg_default

$ oid2name -s
All tablespaces:
                     Oid  Tablespace Name
-------------------------
     1663       pg_default
     1664        pg_global
  155151         fastdisk
  155152          bigdisk

$ # OK, let's look into database alvherre
$ cd $PGDATA/base/17228

$ # get top 10 db objects in the default tablespace, ordered by size
$ ls -lS * | head -10
   -rw-------  1 alvherre alvherre 136536064 sep 14 09:51 155173
   -rw-------  1 alvherre alvherre 17965056 sep 14 09:51 1155291
   -rw-------  1 alvherre alvherre 1204224 sep 14 09:51 16717

B. Palmer <bpalmer@crimelabs.net>
vacuumlo

vacuumlo — remove orphaned large objects from a PostgreSQL database

Synopsis

vacuumlo [option...] dbname...

Description

vacuumlo is a simple utility program that will remove any “orphaned” large objects from a PostgreSQL database. An orphaned large object (LO) is considered to be any LO whose OID does not appear in any \texttt{oid} or \texttt{lo} data column of the database.

If you use this, you may also be interested in the \texttt{lo_manage} trigger in the \texttt{lo} module. \texttt{lo_manage} is useful to try to avoid creating orphaned LOs in the first place.

All databases named on the command line are processed.

Options

vacuumlo accepts the following command-line arguments:

- \texttt{-l limit}  
  \texttt{--limit=limit}

  Remove no more than \texttt{limit} large objects per transaction (default 1000). Since the server acquires a lock per LO removed, removing too many LOs in one transaction risks exceeding \texttt{max_locks_per_transaction}. Set the limit to zero if you want all removals done in a single transaction.

- \texttt{-n}  
  \texttt{--dry-run}

  Don’t remove anything, just show what would be done.

- \texttt{-v}  
  \texttt{--verbose}

  Write a lot of progress messages.

- \texttt{-V}  
  \texttt{--version}

  Print the vacuumlo version and exit.

- \texttt{-?}  
  \texttt{--help}

  Show help about vacuumlo command line arguments, and exit.

vacuumlo also accepts the following command-line arguments for connection parameters:

- \texttt{-h host}  
  \texttt{--host=host}

  Database server’s host.
-p  port
--port=port

    Database server's port.

-U  username
--username=username

    User name to connect as.

-w
--no-password

    Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W
--password

    Force vacuumlo to prompt for a password before connecting to a database.

This option is never essential, since vacuumlo will automatically prompt for a password if the server demands password authentication. However, vacuumlo will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

Environment

PGHOST
PGPORT
PGUSER

    Default connection parameters.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 34.15).

The environment variable PG_COLOR specifies whether to use color in diagnostic messages. Possible values are always, auto and never.

Notes

vacuumlo works by the following method: First, vacuumlo builds a temporary table which contains all of the OIDs of the large objects in the selected database. It then scans through all columns in the database that are of type oid or lo, and removes matching entries from the temporary table. (Note: Only types with these names are considered; in particular, domains over them are not considered.) The remaining entries in the temporary table identify orphaned LOs. These are removed.

Author

Peter Mount <peter@retep.org.uk>

G.2. Server Applications

Some applications run on the PostgreSQL server itself. Currently, no such applications are included in the contrib directory. See also PostgreSQL Server Applications for information about server applications that are part of the core PostgreSQL distribution.
Appendix H. External Projects

PostgreSQL is a complex software project, and managing the project is difficult. We have found that many enhancements to PostgreSQL can be more efficiently developed separately from the core project.

H.1. Client Interfaces

There are only two client interfaces included in the base PostgreSQL distribution:

- libpq is included because it is the primary C language interface, and because many other client interfaces are built on top of it.

- ECPG is included because it depends on the server-side SQL grammar, and is therefore sensitive to changes in PostgreSQL itself.

All other language interfaces are external projects and are distributed separately. A list of language interfaces is maintained on the PostgreSQL wiki. Note that some of these packages are not released under the same license as PostgreSQL. For more information on each language interface, including licensing terms, refer to its website and documentation.

https://wiki.postgresql.org/wiki/List_of_drivers

H.2. Administration Tools

There are several administration tools available for PostgreSQL. The most popular is pgAdmin², and there are several commercially available ones as well.

H.3. Procedural Languages

PostgreSQL includes several procedural languages with the base distribution: PL/pgSQL, PL/Tcl, PL/Perl, and PL/Python.

In addition, there are a number of procedural languages that are developed and maintained outside the core PostgreSQL distribution. A list of procedural languages is maintained on the PostgreSQL wiki. Note that some of these projects are not released under the same license as PostgreSQL. For more information on each procedural language, including licensing information, refer to its website and documentation.

https://wiki.postgresql.org/wiki/PL_Matrix

H.4. Extensions

PostgreSQL is designed to be easily extensible. For this reason, extensions loaded into the database can function just like features that are built in. The contrib/ directory shipped with the source code contains several extensions, which are described in Appendix F. Other extensions are developed independently, like PostGIS⁴. Even PostgreSQL replication solutions can be developed externally. For example, Slony-I⁵ is a popular primary/standby replication solution that is developed independently from the core project.

---

¹ https://wiki.postgresql.org/wiki/List_of_drivers
² https://www.pgadmin.org/
³ https://wiki.postgresql.org/wiki/PL_Matrix
⁴ https://postgis.net/
⁵ https://www.slony.info
Appendix I. The Source Code Repository

The PostgreSQL source code is stored and managed using the Git version control system. A public mirror of the master repository is available; it is updated within a minute of any change to the master repository.

Our wiki, https://wiki.postgresql.org/wiki/Working_with_Git, has some discussion on working with Git.

Note that building PostgreSQL from the source repository requires reasonably up-to-date versions of bison, flex, and Perl. These tools are not needed to build from a distribution tarball, because the files generated with these tools are included in the tarball. Other tool requirements are the same as shown in Section 17.1.

I.1. Getting the Source via Git

With Git you will make a copy of the entire code repository on your local machine, so you will have access to all history and branches offline. This is the fastest and most flexible way to develop or test patches.

Git

1. You will need an installed version of Git, which you can get from https://git-scm.com. Many systems already have a recent version of Git installed by default, or available in their package distribution system.

2. To begin using the Git repository, make a clone of the official mirror:

        git clone https://git.postgresql.org/git/postgresql.git

This will copy the full repository to your local machine, so it may take a while to complete, especially if you have a slow Internet connection. The files will be placed in a new subdirectory postgresql of your current directory.

The Git mirror can also be reached via the Git protocol. Just change the URL prefix to git, as in:

        git clone git://git.postgresql.org/git/postgresql.git

3. Whenever you want to get the latest updates in the system, cd into the repository, and run:

        git fetch

Git can do a lot more things than just fetch the source. For more information, consult the Git man pages, or see the website at https://git-scm.com.
Appendix J. Documentation

PostgreSQL has four primary documentation formats:

- Plain text, for pre-installation information
- HTML, for on-line browsing and reference
- PDF, for printing
- man pages, for quick reference.

Additionally, a number of plain-text README files can be found throughout the PostgreSQL source tree, documenting various implementation issues.

HTML documentation and man pages are part of a standard distribution and are installed by default. PDF format documentation is available separately for download.

J.1. DocBook

The documentation sources are written in DocBook, which is a markup language defined in XML. In what follows, the terms DocBook and XML are both used, but technically they are not interchangeable.

DocBook allows an author to specify the structure and content of a technical document without worrying about presentation details. A document style defines how that content is rendered into one of several final forms. DocBook is maintained by the OASIS group. The official DocBook site has good introductory and reference documentation and a complete O'Reilly book for your online reading pleasure. The NewbieDoc Docbook Guide is very helpful for beginners. The FreeBSD Documentation Project also uses DocBook and has some good information, including a number of style guidelines that might be worth considering.

J.2. Tool Sets

The following tools are used to process the documentation. Some might be optional, as noted.

DocBook DTD

This is the definition of DocBook itself. We currently use version 4.5; you cannot use later or earlier versions. You need the XML variant of the DocBook DTD, not the SGML variant.

DocBook XSL Stylesheets

These contain the processing instructions for converting the DocBook sources to other formats, such as HTML.

The minimum required version is currently 1.77.0, but it is recommended to use the latest available version for best results.

Libxml2 for xmllint

This library and the xmllint tool it contains are used for processing XML. Many developers will already have Libxml2 installed, because it is also used when building the PostgreSQL code. Note, however, that xmllint might need to be installed from a separate subpackage.

1 https://www.oasis-open.org
2 https://www.oasis-open.org/docbook/
4 https://www.freebsd.org/docproj/
5 https://www.oasis-open.org/docbook/
7 http://xmlsoft.org/
Libxslt\(^8\) for \texttt{xsltproc}

\texttt{xsltproc} is an XSLT processor, that is, a program to convert XML to other formats using XSLT stylesheets.

\textbf{FOP}\(^9\)

This is a program for converting, among other things, XML to PDF. It is needed only if you want to build the documentation in PDF format.

We have documented experience with several installation methods for the various tools that are needed to process the documentation. These will be described below. There might be some other packaged distributions for these tools. Please report package status to the documentation mailing list, and we will include that information here.

\textbf{J.2.1. Installation on Fedora, RHEL, and Derivatives}

To install the required packages, use:

\begin{verbatim}
yum install docbook-dtds docbook-style-xsl libxslt fop
\end{verbatim}

\textbf{J.2.2. Installation on FreeBSD}

To install the required packages with \texttt{pkg}, use:

\begin{verbatim}
 pkg install docbook-xml docbook-xsl libxslt fop
\end{verbatim}

When building the documentation from the \texttt{doc} directory you'll need to use \texttt{gmake}, because the makefile provided is not suitable for FreeBSD's \texttt{make}.

\textbf{J.2.3. Debian Packages}

There is a full set of packages of the documentation tools available for Debian GNU/Linux. To install, simply use:

\begin{verbatim}
 apt-get install docbook-xml docbook-xsl libxml2-utils xsltproc fop
\end{verbatim}

\textbf{J.2.4. macOS}

If you use MacPorts, the following will get you set up:

\begin{verbatim}
 sudo port install docbook-xml docbook-xsl-nons libxslt fop
\end{verbatim}

If you use Homebrew, use this:

\begin{verbatim}
 brew install docbook docbook-xsl libxslt fop
\end{verbatim}

The Homebrew-supplied programs require the following environment variable to be set. For Intel based machines, use this:

\(^8\)\ http://xmlsoft.org/XSLT/
\(^9\)\ https://xmlgraphics.apache.org/fop/
export XML_CATALOG_FILES=/usr/local/etc/xml/catalog

On Apple Silicon based machines, use this:

export XML_CATALOG_FILES=/opt/homebrew/etc/xml/catalog

Without it, xsltproc will throw errors like this:

I/O error : Attempt to load network entity http://www.oasis-open.org/docbook/xml/4.5/docbookx.dtd
...

While it is possible to use the Apple-provided versions of xmllint and xsltproc instead of those from MacPorts or Homebrew, you'll still need to install the DocBook DTD and stylesheets, and set up a catalog file that points to them.

J.2.5. Detection by configure

Before you can build the documentation you need to run the configure script, as you would when building the PostgreSQL programs themselves. Check the output near the end of the run; it should look something like this:

checking for xmllint... xmllint
checking for xsltproc... xsltproc
checking for fop... fop
checking for dbtoepub... dbtoepub

If xmllint or xsltproc is not found, you will not be able to build any of the documentation. fop is only needed to build the documentation in PDF format. dbtoepub is only needed to build the documentation in EPUB format.

If necessary, you can tell configure where to find these programs, for example

./configure ... XMLLINT=/opt/local/bin/xmllint ...

If you prefer to build PostgreSQL using Meson, instead run meson setup as described in Section 17.4, and then see Section J.4.

J.3. Building the Documentation with Make

Once you have everything set up, change to the directory doc/src/sgml and run one of the commands described in the following subsections to build the documentation. (Remember to use GNU make.)

J.3.1. HTML

To build the HTML version of the documentation:

doc/src/sgml$ make html
This is also the default target. The output appears in the subdirectory `html`.

To produce HTML documentation with the stylesheet used on postgresql.org\(^{10}\) instead of the default simple style use:

```
doc/src/sgml$ make STYLE=website html
```

If the `STYLE=website` option is used, the generated HTML files include references to stylesheets hosted on postgresql.org\(^{11}\) and require network access to view.

### J.3.2. Manpages

We use the DocBook XSL stylesheets to convert DocBook refentry pages to *roff output suitable for man pages. To create the man pages, use the command:

```
doc/src/sgml$ make man
```

### J.3.3. PDF

To produce a PDF rendition of the documentation using FOP, you can use one of the following commands, depending on the preferred paper format:

- For A4 format:
  
  ```
doc/src/sgml$ make postgres-A4.pdf
  ```

- For U.S. letter format:
  
  ```
doc/src/sgml$ make postgres-US.pdf
  ```

Because the PostgreSQL documentation is fairly big, FOP will require a significant amount of memory. Because of that, on some systems, the build will fail with a memory-related error message. This can usually be fixed by configuring Java heap settings in the configuration file `~/.foprc`, for example:

```
# FOP binary distribution
FOP_OPTS='--Xmx1500m'
# Debian
JAVA_ARGS='--Xmx1500m'
# Red Hat
ADDITIONAL_FLAGS='--Xmx1500m'
```

There is a minimum amount of memory that is required, and to some extent more memory appears to make things a bit faster. On systems with very little memory (less than 1 GB), the build will either be very slow due to swapping or will not work at all.

In its default configuration FOP will emit an INFO message for each page. The log level can be changed via `~/.foprc`:

```
LOGCHOICE=-Dorg.apache.commons.logging.Log=org.apache.commons.logging.impl.SimpleLog
LOGLEVEL=-Dorg.apache.commons.logging.simplelog.defaultlog=WARN
```

---

\(^{10}\) [https://www.postgresql.org/docs/current/](https://www.postgresql.org/docs/current/)

\(^{11}\) [https://www.postgresql.org/docs/current/](https://www.postgresql.org/docs/current/)
Other XSL-FO processors can also be used manually, but the automated build process only supports FOP.

**J.3.4. Plain Text Files**

The installation instructions are also distributed as plain text, in case they are needed in a situation where better reading tools are not available. The INSTALL file corresponds to Chapter 17, with some minor changes to account for the different context. To recreate the file, change to the directory doc/src/sgml and enter `make INSTALL`. Building text output requires Pandoc version 1.13 or newer as an additional build tool.

In the past, the release notes and regression testing instructions were also distributed as plain text, but this practice has been discontinued.

**J.3.5. Syntax Check**

Building the documentation can take very long. But there is a method to just check the correct syntax of the documentation files, which only takes a few seconds:

```
doc/src/sgml$ make check
```

**J.4. Building the Documentation with Meson**

Two options are provided for building the documentation using Meson. Change to the `build` directory before running one of these commands, or add `-C build` to the command.

To build just the HTML version of the documentation:

```
build$ ninja docs
```

To build all forms of the documentation:

```
build$ ninja alldocs
```

The output appears in the subdirectory `build/doc/src/sgml`.

**J.5. Documentation Authoring**

The documentation sources are most conveniently modified with an editor that has a mode for editing XML, and even more so if it has some awareness of XML schema languages so that it can know about DocBook syntax specifically.

Note that for historical reasons the documentation source files are named with an extension `.sgml` even though they are now XML files. So you might need to adjust your editor configuration to set the correct mode.

**J.5.1. Emacs**

nXML Mode, which ships with Emacs, is the most common mode for editing XML documents with Emacs. It will allow you to use Emacs to insert tags and check markup consistency, and it supports DocBook out of the box. Check the nXML manual\(^\text{12}\) for detailed documentation.

```
src/tools/editors/emacs.samples
```

J.6. Style Guide

J.6.1. Reference Pages

Reference pages should follow a standard layout. This allows users to find the desired information more quickly, and it also encourages writers to document all relevant aspects of a command. Consistency is not only desired among PostgreSQL reference pages, but also with reference pages provided by the operating system and other packages. Hence the following guidelines have been developed. They are for the most part consistent with similar guidelines established by various operating systems.

Reference pages that describe executable commands should contain the following sections, in this order. Sections that do not apply can be omitted. Additional top-level sections should only be used in special circumstances; often that information belongs in the “Usage” section.

Name

This section is generated automatically. It contains the command name and a half-sentence summary of its functionality.

Synopsis

This section contains the syntax diagram of the command. The synopsis should normally not list each command-line option; that is done below. Instead, list the major components of the command line, such as where input and output files go.

Description

Several paragraphs explaining what the command does.

Options

A list describing each command-line option. If there are a lot of options, subsections can be used.

Exit Status

If the program uses 0 for success and non-zero for failure, then you do not need to document it. If there is a meaning behind the different non-zero exit codes, list them here.

Usage

Describe any sublanguage or run-time interface of the program. If the program is not interactive, this section can usually be omitted. Otherwise, this section is a catch-all for describing run-time features. Use subsections if appropriate.

Environment

List all environment variables that the program might use. Try to be complete; even seemingly trivial variables like SHELL might be of interest to the user.

Files

List any files that the program might access implicitly. That is, do not list input and output files that were specified on the command line, but list configuration files, etc.

Diagnostics

Explain any unusual output that the program might create. Refrain from listing every possible error message. This is a lot of work and has little use in practice. But if, say, the error messages have a standard format that the user can parse, this would be the place to explain it.
Notes

Anything that doesn't fit elsewhere, but in particular bugs, implementation flaws, security considerations, compatibility issues.

Examples

Examples

History

If there were some major milestones in the history of the program, they might be listed here. Usually, this section can be omitted.

Author

Author (only used in the contrib section)

See Also

Cross-references, listed in the following order: other PostgreSQL command reference pages, PostgreSQL SQL command reference pages, citation of PostgreSQL manuals, other reference pages (e.g., operating system, other packages), other documentation. Items in the same group are listed alphabetically.

Reference pages describing SQL commands should contain the following sections: Name, Synopsis, Description, Parameters, Outputs, Notes, Examples, Compatibility, History, See Also. The Parameters section is like the Options section, but there is more freedom about which clauses of the command can be listed. The Outputs section is only needed if the command returns something other than a default command-completion tag. The Compatibility section should explain to what extent this command conforms to the SQL standard(s), or to which other database system it is compatible. The See Also section of SQL commands should list SQL commands before cross-references to programs.
Appendix K. PostgreSQL Limits

Table K.1 describes various hard limits of PostgreSQL. However, practical limits, such as performance limitations or available disk space may apply before absolute hard limits are reached.

Table K.1. PostgreSQL Limitations

<table>
<thead>
<tr>
<th>Item</th>
<th>Upper Limit</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>database size</td>
<td>unlimited</td>
<td></td>
</tr>
<tr>

<td>63 bytes</td>
<td>can be increased by recompiling PostgreSQL</td>
</tr>
<tr>
<td>function arguments</td>
<td>100</td>
<td>can be increased by recompiling PostgreSQL</td>
</tr>
<tr>
<td>query parameters</td>
<td>65,535</td>
<td></td>
</tr>
</tbody>
</table>

The maximum number of columns for a table is further reduced as the tuple being stored must fit in a single 8192-byte heap page. For example, excluding the tuple header, a tuple made up of 1,600 int columns would consume 6400 bytes and could be stored in a heap page, but a tuple of 1,600 bigint columns would consume 12800 bytes and would therefore not fit inside a heap page. Variable-length fields of types such as text, varchar, and char can have their values stored out of line in the table's TOAST table when the values are large enough to require it. Only an 18-byte pointer must remain inside the tuple in the table's heap. For shorter length variable-length fields, either a 4-byte or 1-byte field header is used and the value is stored inside the heap tuple.

Columns that have been dropped from the table also contribute to the maximum column limit. Moreover, although the dropped column values for newly created tuples are internally marked as null in the tuple's null bitmap, the null bitmap also occupies space.

Acronyms

MCF
Most Common Frequency, that is the frequency associated with some Most Common Value

MCV
Most Common Value, one of the values appearing most often within a particular table column

MITM
Man-in-the-middle attack\textsuperscript{30}

MSVC
Microsoft Visual C\textsuperscript{31}

MVCC
Multi-Version Concurrency Control

NLS
National Language Support\textsuperscript{32}

ODBC
Open Database Connectivity\textsuperscript{33}

OID
Object Identifier

OLAP
Online Analytical Processing\textsuperscript{34}

OLTP
Online Transaction Processing\textsuperscript{35}

ORDBMS
Object-Relational Database Management System\textsuperscript{36}

PAM
Pluggable Authentication Modules\textsuperscript{37}

PGSQL
PostgreSQL

PGXS
PostgreSQL Extension System

# Appendix M. Glossary

This is a list of terms and their meaning in the context of PostgreSQL and relational database systems in general.

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACID</td>
<td>Atomicity, Consistency, Isolation, and Durability. This set of properties of database transactions is intended to guarantee validity in concurrent operation and even in event of errors, power failures, etc.</td>
</tr>
<tr>
<td>Aggregate function (routine)</td>
<td>A function that combines (aggregates) multiple input values, for example by counting, averaging or adding, yielding a single output value. For more information, see Section 9.21. See Also Window function (routine).</td>
</tr>
<tr>
<td>Analytic function</td>
<td>See Window function (routine).</td>
</tr>
<tr>
<td>Analyze (operation)</td>
<td>The act of collecting statistics from data in tables and other relations to help the query planner to make decisions about how to execute queries. (Don't confuse this term with the ANALYZE option to the EXPLAIN command.) For more information, see ANALYZE.</td>
</tr>
<tr>
<td>Atomic</td>
<td>In reference to a datum: the fact that its value cannot be broken down into smaller components. In reference to a database transaction: see atomicity.</td>
</tr>
<tr>
<td>Atomicity</td>
<td>The property of a transaction that either all its operations complete as a single unit or none do. In addition, if a system failure occurs during the execution of a transaction, no partial results are visible after recovery. This is one of the ACID properties.</td>
</tr>
<tr>
<td>Attribute</td>
<td>An element with a certain name and data type found within a tuple.</td>
</tr>
<tr>
<td>Autovacuum (process)</td>
<td>A set of background processes that routinely perform vacuum and analyze operations. The auxiliary process that coordinates the work and is always present (unless autovacuum is disabled) is known as the autovacuum launcher, and the processes that carry out the tasks are known as the autovacuum workers. For more information, see Section 25.1.6.</td>
</tr>
<tr>
<td>Auxiliary process</td>
<td>A process within an instance that is in charge of some specific background task for the instance. The auxiliary processes consist of the autovacuum launcher (but not the autovacuum workers), the background writer, the checkpointer, the logger, the startup process, the WAL archiver, the WAL receiver (but not the WAL senders), and the WAL writer.</td>
</tr>
<tr>
<td>Backend (process)</td>
<td>Process of an instance which acts on behalf of a client session and handles its requests. (Don't confuse this term with the similar terms Background Worker or Background Writer).</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>------</td>
<td>------------</td>
</tr>
<tr>
<td>Background worker (process)</td>
<td>Process within an <em>instance</em>, which runs system- or user-supplied code. Serves as infrastructure for several features in PostgreSQL, such as <em>logical replication</em> and <em>parallel queries</em>. In addition, <em>Extensions</em> can add custom background worker processes. For more information, see Chapter 48.</td>
</tr>
<tr>
<td>Background writer (process)</td>
<td><em>An auxiliary process</em> that writes dirty <em>data pages</em> from <em>shared memory</em> to the file system. It wakes up periodically, but works only for a short period in order to distribute its expensive I/O activity over time to avoid generating larger I/O peaks which could block other processes. For more information, see Section 20.4.5.</td>
</tr>
<tr>
<td>Base Backup</td>
<td>A binary copy of all <em>database cluster</em> files. It is generated by the tool <em>pg_basebackup</em>. In combination with WAL files it can be used as the starting point for recovery, log shipping, or streaming replication.</td>
</tr>
<tr>
<td>Bloat</td>
<td>Space in data pages which does not contain current row versions, such as unused (free) space or outdated row versions.</td>
</tr>
<tr>
<td>Bootstrap superuser</td>
<td>The first <em>user</em> initialized in a <em>database cluster</em>. This user owns all system catalog tables in each database. It is also the role from which all granted permissions originate. Because of these things, this role may not be dropped. This role also behaves as a normal <em>database superuser</em>.</td>
</tr>
<tr>
<td>Buffer Access Strategy</td>
<td>Some operations will access a large number of <em>pages</em>. <em>A Buffer Access Strategy</em> helps to prevent these operations from evicting too many pages from <em>shared buffers</em>. A Buffer Access Strategy sets up references to a limited number of <em>shared buffers</em> and reuses them circularly. When the operation requires a new page, a victim buffer is chosen from the buffers in the strategy ring, which may require flushing the page's dirty data and possibly also unflushed <em>WAL</em> to permanent storage. Buffer Access Strategies are used for various operations such as sequential scans of large tables, VACUUM, COPY, CREATE TABLE AS SELECT, ALTER TABLE, CREATE DATABASE, CREATE INDEX, and CLUSTER.</td>
</tr>
<tr>
<td>Cast</td>
<td>A conversion of a <em>datum</em> from its current data type to another data type. For more information, see CREATE CAST.</td>
</tr>
<tr>
<td>Catalog</td>
<td>The SQL standard uses this term to indicate what is called a <em>database</em> in PostgreSQL's terminology. <em>(Don't confuse this term with system catalog).</em> For more information, see Section 23.1.</td>
</tr>
<tr>
<td>Check constraint</td>
<td>A type of <em>constraint</em> defined on a <em>relation</em> which restricts the values allowed in one or more <em>attributes</em>. The check constraint can</td>
</tr>
</tbody>
</table>
make reference to any attribute of the same row in the relation, but
cannot reference other rows of the same relation or other relations.

For more information, see Section 5.4.

Checkpointer (process) An auxiliary process that is responsible for executing checkpoints.

Class (archaic) See Relation.

Client (process) Any process, possibly remote, that establishes a session by connecting to an instance to interact with a database.

Cluster owner The operating system user that owns the data directory and under which the postgres process is run. It is required that this user exist prior to creating a new database cluster.

On operating systems with a root user, said user is not allowed to be the cluster owner.

Column An attribute found in a table or view.

Commit The act of finalizing a transaction within the database, which makes it visible to other transactions and assures its durability.

For more information, see COMMIT.

Concurrency The concept that multiple independent operations happen within the database at the same time. In PostgreSQL, concurrency is controlled by the multiversion concurrency control mechanism.

Connection An established line of communication between a client process and a backend process, usually over a network, supporting a session. This term is sometimes used as a synonym for session.

For more information, see Section 20.3.

Consistency The property that the data in the database is always in compliance with integrity constraints. Transactions may be allowed to violate some of the constraints transiently before it commits, but if such violations are not resolved by the time it commits, such a transaction is automatically rolled back. This is one of the ACID properties.

Constraint A restriction on the values of data allowed within a table, or in attributes of a domain.

For more information, see Section 5.4.
Cumulative Statistics System
A system which, if enabled, accumulates statistical information about the instance's activities.
For more information, see Section 28.2.

Data area
See Data directory.

Database
A named collection of local SQL objects.
For more information, see Section 23.1.

Database cluster
A collection of databases and global SQL objects, and their common static and dynamic metadata. Sometimes referred to as a cluster. A database cluster is created using the initdb program.

In PostgreSQL, the term cluster is also sometimes used to refer to an instance. (Don't confuse this term with the SQL command CLUSTER.)

See also cluster owner, the operating-system owner of a cluster, and bootstrap superuser, the PostgreSQL owner of a cluster.

Database server
See Instance.

Database superuser
A role having superuser status (see Section 22.2).
Frequently referred to as superuser.

Data directory
The base directory on the file system of a server that contains all data files and subdirectories associated with a database cluster (with the exception of tablespaces, and optionally WAL). The environment variable PGDATA is commonly used to refer to the data directory.

A cluster's storage space comprises the data directory plus any additional tablespaces.
For more information, see Section 73.1.

Data page
The basic structure used to store relation data. All pages are of the same size. Data pages are typically stored on disk, each in a specific file, and can be read to shared buffers where they can be modified, becoming dirty. They become clean when written to disk. New pages, which initially exist in memory only, are also dirty until written.

Datum
The internal representation of one value of an SQL data type.

Delete
An SQL command which removes rows from a given table or relation.
For more information, see DELETE.

Domain
A user-defined data type that is based on another underlying data type. It acts the same as the underlying type except for possibly restricting the set of allowed values.
For more information, see Section 8.18.

Durability
The assurance that once a transaction has been committed, the changes remain even after a system failure or crash. This is one of the ACID properties.
Glossary

Epoch
See Transaction ID.

Extension
A software add-on package that can be installed on an instance to get extra features.

For more information, see Section 38.17.

File segment
A physical file which stores data for a given relation. File segments are limited in size by a configuration value (typically 1 gigabyte), so if a relation exceeds that size, it is split into multiple segments.

For more information, see Section 73.1.

(Don’t confuse this term with the similar term WAL segment).

Foreign data wrapper
A means of representing data that is not contained in the local database so that it appears as if were in local table(s). With a foreign data wrapper it is possible to define a foreign server and foreign tables.

For more information, see CREATE FOREIGN DATA WRAPPER.

Foreign key
A type of constraint defined on one or more columns in a table which requires the value(s) in those columns to identify zero or one row in another (or, infrequently, the same) table.

Foreign server
A named collection of foreign tables which all use the same foreign data wrapper and have other configuration values in common.

For more information, see CREATE SERVER.

Foreign table (relation)
A relation which appears to have rows and columns similar to a regular table, but will forward requests for data through its foreign data wrapper, which will return result sets structured according to the definition of the foreign table.

For more information, see CREATE FOREIGN TABLE.

Fork
Each of the separate segmented file sets in which a relation is stored. The main fork is where the actual data resides. There also exist two secondary forks for metadata: the free space map and the visibility map. Unlogged relations also have an init fork.

Free space map (fork)
A storage structure that keeps metadata about each data page of a table’s main fork. The free space map entry for each page stores the amount of free space that’s available for future tuples, and is structured to be efficiently searched for available space for a new tuple of a given size.

For more information, see Section 73.3.

Function (routine)
A type of routine that receives zero or more arguments, returns zero or more output values, and is constrained to run within one transaction. Functions are invoked as part of a query, for example via SELECT. Certain functions can return sets; those are called set-returning functions.

Functions can also be used for triggers to invoke.
Glossary

For more information, see CREATE FUNCTION.

Grant
An SQL command that is used to allow a user or role to access specific objects within the database.

For more information, see GRANT.

Heap
Contains the values of row attributes (i.e., the data) for a relation. The heap is realized within one or more file segments in the relation's main fork.

Host
A computer that communicates with other computers over a network. This is sometimes used as a synonym for server. It is also used to refer to a computer where client processes run.

Index (relation)
A relation that contains data derived from a table or materialized view. Its internal structure supports fast retrieval of and access to the original data.

For more information, see CREATE INDEX.

Insert
An SQL command used to add new data into a table.

For more information, see INSERT.

Instance
A group of backend and auxiliary processes that communicate using a common shared memory area. One postmaster process manages the instance; one instance manages exactly one database cluster with all its databases. Many instances can run on the same server as long as their TCP ports do not conflict.

The instance handles all key features of a DBMS: read and write access to files and shared memory, assurance of the ACID properties, connections to client processes, privilege verification, crash recovery, replication, etc.

Isolation
The property that the effects of a transaction are not visible to concurrent transactions before it commits. This is one of the ACID properties.

For more information, see Section 13.2.

Join
An operation and SQL keyword used in queries for combining data from multiple relations.

Key
A means of identifying a row within a table or other relation by values contained within one or more attributes in that relation.

Lock
A mechanism that allows a process to limit or prevent simultaneous access to a resource.

Log file
Log files contain human-readable text lines about events. Examples include login failures, long-running queries, etc.

For more information, see Section 25.3.

Logged
A table is considered logged if changes to it are sent to the WAL. By default, all regular tables are logged. A table can be specified as unlogged either at creation time or via the ALTER TABLE command.
<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Logger (process)</td>
<td>An auxiliary process which, if enabled, writes information about database events into the current log file. When reaching certain time- or volume-dependent criteria, a new log file is created. Also called syslogger. For more information, see Section 20.8.</td>
</tr>
<tr>
<td>Log record</td>
<td>Archaic term for a WAL record.</td>
</tr>
<tr>
<td>Log sequence number (LSN)</td>
<td>Byte offset into the WAL, increasing monotonically with each new WAL record. For more information, see pg_lsn and Section 30.6.</td>
</tr>
<tr>
<td>LSN</td>
<td>See Log sequence number.</td>
</tr>
<tr>
<td>Master (server)</td>
<td>See Primary (server).</td>
</tr>
<tr>
<td>Materialized</td>
<td>The property that some information has been pre-computed and stored for later use, rather than computing it on-the-fly. This term is used in materialized view, to mean that the data derived from the view's query is stored on disk separately from the sources of that data. This term is also used to refer to some multi-step queries to mean that the data resulting from executing a given step is stored in memory (with the possibility of spilling to disk), so that it can be read multiple times by another step.</td>
</tr>
<tr>
<td>Materialized view (relation)</td>
<td>A relation that is defined by a SELECT statement (just like a view), but stores data in the same way that a table does. It cannot be modified via INSERT, UPDATE, DELETE, or MERGE operations. For more information, see CREATE MATERIALIZED VIEW.</td>
</tr>
<tr>
<td>Merge</td>
<td>An SQL command used to conditionally add, modify, or remove rows in a given table, using data from a source relation. For more information, see MERGE.</td>
</tr>
<tr>
<td>Multi-version concurrency control (MVCC)</td>
<td>A mechanism designed to allow several transactions to be reading and writing the same rows without one process causing other processes to stall. In PostgreSQL, MVCC is implemented by creating copies (versions) of tuples as they are modified; after transactions that can see the old versions terminate, those old versions need to be removed.</td>
</tr>
<tr>
<td>Null</td>
<td>A concept of non-existence that is a central tenet of relational database theory. It represents the absence of a definite value.</td>
</tr>
<tr>
<td>Optimizer</td>
<td>See Query planner.</td>
</tr>
<tr>
<td>Parallel query</td>
<td>The ability to handle parts of executing a query to take advantage of parallel processes on servers with multiple CPUs.</td>
</tr>
<tr>
<td>Partition</td>
<td>One of several disjoint (not overlapping) subsets of a larger set. In reference to a partitioned table: One of the tables that each contain part of the data of the partitioned table, which is said to be the parent. The partition is itself a table, so it can also be queried di-</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Directly</td>
<td>At the same time, a partition can sometimes be a partitioned table, allowing hierarchies to be created.</td>
</tr>
<tr>
<td>window function</td>
<td>In reference to a window function in a query, a partition is a user-defined criterion that identifies which neighboring rows of the query's result set can be considered by the function.</td>
</tr>
<tr>
<td>Partitioned table (relation)</td>
<td>A relation that is in semantic terms the same as a table, but whose storage is distributed across several partitions.</td>
</tr>
<tr>
<td>Postmaster (process)</td>
<td>The very first process of an instance. It starts and manages the auxiliary processes and creates backend processes on demand.</td>
</tr>
<tr>
<td>Primary key</td>
<td>A special case of a unique constraint defined on a table or other relation that also guarantees that all of the attributes within the primary key do not have null values. As the name implies, there can be only one primary key per table, though it is possible to have multiple unique constraints that also have no null-capable attributes.</td>
</tr>
<tr>
<td>Primary (server)</td>
<td>When two or more databases are linked via replication, the server that is considered the authoritative source of information is called the primary, also known as a master.</td>
</tr>
<tr>
<td>Procedure (routine)</td>
<td>A type of routine. Their distinctive qualities are that they do not return values, and that they are allowed to make transactional statements such as COMMIT and ROLLBACK. They are invoked via the CALL command. For more information, see CREATE PROCEDURE.</td>
</tr>
<tr>
<td>Query</td>
<td>A request sent by a client to a backend, usually to return results or to modify data on the database.</td>
</tr>
<tr>
<td>Query planner</td>
<td>The part of PostgreSQL that is devoted to determining (planning) the most efficient way to execute queries. Also known as query optimizer, optimizer, or simply planner.</td>
</tr>
<tr>
<td>Record</td>
<td>See Tuple.</td>
</tr>
<tr>
<td>Recycling</td>
<td>See WAL file.</td>
</tr>
<tr>
<td>Referential integrity</td>
<td>A means of restricting data in one relation by a foreign key so that it must have matching data in another relation.</td>
</tr>
<tr>
<td>Relation</td>
<td>The generic term for all objects in a database that have a name and a list of attributes defined in a specific order. Tables, sequences, views, foreign tables, materialized views, composite types, and indexes are all relations. More generically, a relation is a set of tuples; for example, the result of a query is also a relation. In PostgreSQL, Class is an archaic synonym for relation.</td>
</tr>
<tr>
<td>Replica (server)</td>
<td>A database that is paired with a primary database and is maintaining a copy of some or all of the primary database's data. The foremost reasons for doing this are to allow for greater access to that data, and to maintain availability of the data in the event that the primary becomes unavailable.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Replication</td>
<td>The act of reproducing data on one server onto another server called a replica. This can take the form of physical replication, where all file changes from one server are copied verbatim, or logical replication where a defined subset of data changes are conveyed using a higher-level representation.</td>
</tr>
<tr>
<td>Restartpoint</td>
<td>A variant of a checkpoint performed on a replica.</td>
</tr>
<tr>
<td>Result set</td>
<td>A relation transmitted from a backend process to a client upon the completion of an SQL command, usually a SELECT but it can be an INSERT, UPDATE, or DELETE command if the RETURNING clause is specified. The fact that a result set is a relation means that a query can be used in the definition of another query, becoming a subquery.</td>
</tr>
<tr>
<td>Revoke</td>
<td>A command to prevent access to a named set of database objects for a named list of roles.</td>
</tr>
<tr>
<td>Role</td>
<td>A collection of access privileges to the instance. Roles are themselves a privilege that can be granted to other roles. This is often done for convenience or to ensure completeness when multiple users need the same privileges.</td>
</tr>
<tr>
<td>Rollback</td>
<td>A command to undo all of the operations performed since the beginning of a transaction.</td>
</tr>
<tr>
<td>Routine</td>
<td>A defined set of instructions stored in the database system that can be invoked for execution. A routine can be written in a variety of programming languages. Routines can be functions (including set-returning functions and trigger functions), aggregate functions, and procedures. Many routines are already defined within PostgreSQL itself, but user-defined ones can also be added.</td>
</tr>
<tr>
<td>Row</td>
<td>See Tuple.</td>
</tr>
<tr>
<td>Savepoint</td>
<td>A special mark in the sequence of steps in a transaction. Data modifications after this point in time may be reverted to the time of the savepoint.</td>
</tr>
<tr>
<td>Schema</td>
<td>A schema is a namespace for SQL objects, which all reside in the same database. Each SQL object must reside in exactly one schema. All system-defined SQL objects reside in schema <code>pg_catalog</code>. More generically, the term schema is used to mean all data descriptions (table definitions, constraints, comments, etc.) for a given database or subset thereof.</td>
</tr>
<tr>
<td><strong>Glossary</strong></td>
<td></td>
</tr>
<tr>
<td>------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td><strong>Segment</strong></td>
<td>See File segment.</td>
</tr>
<tr>
<td><strong>Select</strong></td>
<td>The SQL command used to request data from a <em>database</em>. Normally, <em>SELECT</em> commands are not expected to modify the <em>database</em> in any way, but it is possible that <em>functions</em> invoked within the query could have side effects that do modify data. For more information, see <em>SELECT</em>.</td>
</tr>
<tr>
<td><strong>Sequence (relation)</strong></td>
<td>A type of relation that is used to generate values. Typically the generated values are sequential non-repeating numbers. They are commonly used to generate surrogate <em>primary key</em> values.</td>
</tr>
<tr>
<td><strong>Server</strong></td>
<td>A computer on which PostgreSQL <em>instances</em> run. The term <em>server</em> denotes real hardware, a container, or a <em>virtual machine</em>. This term is sometimes used to refer to an instance or to a host.</td>
</tr>
<tr>
<td><strong>Session</strong></td>
<td>A state that allows a client and a backend to interact, communicating over a <em>connection</em>.</td>
</tr>
<tr>
<td><strong>Shared memory</strong></td>
<td>RAM which is used by the processes common to an <em>instance</em>. It mirrors parts of <em>database</em> files, provides a transient area for <em>WAL records</em>, and stores additional common information. Note that shared memory belongs to the complete instance, not to a single database. The largest part of shared memory is known as <em>shared buffers</em> and is used to mirror part of data files, organized into pages. When a page is modified, it is called a dirty page until it is written back to the file system. For more information, see Section 20.4.1.</td>
</tr>
<tr>
<td><strong>SQL object</strong></td>
<td>Any object that can be created with a <em>CREATE</em> command. Most objects are specific to one database, and are commonly known as <em>local objects</em>. Most local objects reside in a specific <em>schema</em> in their containing database, such as <em>relations</em> (all types), <em>routines</em> (all types), data types, etc. The names of such objects of the same type in the same schema are enforced to be unique. There also exist local objects that do not reside in schemas; some examples are <em>extensions</em>, <em>data type casts</em>, and <em>foreign data wrappers</em>. The names of such objects of the same type are enforced to be unique within the database. Other object types, such as <em>roles</em>, <em>tablespaces</em>, replication origins, subscriptions for logical replication, and databases themselves are not local SQL objects since they exist entirely outside of any specific database; they are called <em>global objects</em>. The names of such objects are enforced to be unique within the whole database cluster. For more information, see Section 23.1.</td>
</tr>
<tr>
<td><strong>SQL standard</strong></td>
<td>A series of documents that define the SQL language.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Standby (server)</td>
<td>See Replica (server).</td>
</tr>
<tr>
<td>Startup process</td>
<td>An auxiliary process that replays WAL during crash recovery and in a physical replica. (The name is historical: the startup process was named before replication was implemented; the name refers to its task as it relates to the server startup following a crash.)</td>
</tr>
<tr>
<td>Superuser</td>
<td>As used in this documentation, it is a synonym for database superuser.</td>
</tr>
<tr>
<td>System catalog</td>
<td>A collection of tables which describe the structure of all SQL objects of the instance. The system catalog resides in the schema pg_catalog. These tables contain data in internal representation and are not typically considered useful for user examination; a number of user-friendly views, also in schema pg_catalog, offer more convenient access to some of that information, while additional tables and views exist in schema information_schema (see Chapter 37) that expose some of the same and additional information as mandated by the SQL standard. For more information, see Section 5.9.</td>
</tr>
<tr>
<td>Table</td>
<td>A collection of tuples having a common data structure (the same number of attributes, in the same order, having the same name and type per position). A table is the most common form of relation in PostgreSQL. For more information, see CREATE TABLE.</td>
</tr>
<tr>
<td>Tablespace</td>
<td>A named location on the server file system. All SQL objects which require storage beyond their definition in the system catalog must belong to a single tablespace. Initially, a database cluster contains a single usable tablespace which is used as the default for all SQL objects, called pg_default. For more information, see Section 23.6.</td>
</tr>
<tr>
<td>Temporary table</td>
<td>Tables that exist either for the lifetime of a session or a transaction, as specified at the time of creation. The data in them is not visible to other sessions, and is not logged. Temporary tables are often used to store intermediate data for a multi-step operation. For more information, see CREATE TABLE.</td>
</tr>
<tr>
<td>TOAST</td>
<td>A mechanism by which large attributes of table rows are split and stored in a secondary table, called the TOAST table. Each relation with large attributes has its own TOAST table. For more information, see Section 73.2.</td>
</tr>
<tr>
<td>Transaction</td>
<td>A combination of commands that must act as a single atomic command: they all succeed or all fail as a single unit, and their effects are not visible to other sessions until the transaction is complete, and possibly even later, depending on the isolation level. For more information, see Section 13.2.</td>
</tr>
<tr>
<td>Transaction ID</td>
<td>The numerical, unique, sequentially-assigned identifier that each transaction receives when it first causes a database modification.</td>
</tr>
</tbody>
</table>
Frequently abbreviated as xid. When stored on disk, xids are only 32-bits wide, so only approximately four billion write transaction IDs can be generated; to permit the system to run for longer than that, epochs are used, also 32 bits wide. When the counter reaches the maximum xid value, it starts over at 3 (values under that are reserved) and the epoch value is incremented by one. In some contexts, the epoch and xid values are considered together as a single 64-bit value; see Section 74.1 for more details.

For more information, see Section 8.19.

Transactions per second (TPS) Average number of transactions that are executed per second, totaled across all sessions active for a measured run. This is used as a measure of the performance characteristics of an instance.

Trigger A function which can be defined to execute whenever a certain operation (INSERT, UPDATE, DELETE, TRUNCATE) is applied to a relation. A trigger executes within the same transaction as the statement which invoked it, and if the function fails, then the invoking statement also fails.

For more information, see CREATE TRIGGER.

Tuple A collection of attributes in a fixed order. That order may be defined by the table (or other relation) where the tuple is contained, in which case the tuple is often called a row. It may also be defined by the structure of a result set, in which case it is sometimes called a record.

Unique constraint A type of constraint defined on a relation which restricts the values allowed in one or a combination of columns so that each value or combination of values can only appear once in the relation — that is, no other row in the relation contains values that are equal to those.

Because null values are not considered equal to each other, multiple rows with null values are allowed to exist without violating the unique constraint.

Unlogged The property of certain relations that the changes to them are not reflected in the WAL. This disables replication and crash recovery for these relations.

The primary use of unlogged tables is for storing transient work data that must be shared across processes.

Temporary tables are always unlogged.

Update An SQL command used to modify rows that may already exist in a specified table. It cannot create or remove rows.

For more information, see UPDATE.

User A role that has the login privilege (see Section 22.2).

User mapping The translation of login credentials in the local database to credentials in a remote data system defined by a foreign data wrapper.

For more information, see CREATE USER MAPPING.
Glossary

Vacuum
The process of removing outdated tuple versions from tables or materialized views, and other closely related processing required by PostgreSQL's implementation of MVCC. This can be initiated through the use of the VACUUM command, but can also be handled automatically via autovacuum processes.

For more information, see Section 25.1.

View
A relation that is defined by a SELECT statement, but has no storage of its own. Any time a query references a view, the definition of the view is substituted into the query as if the user had typed it as a subquery instead of the name of the view.

For more information, see CREATE VIEW.

Visibility map (fork)
A storage structure that keeps metadata about each data page of a table's main fork. The visibility map entry for each page stores two bits: the first one (all-visible) indicates that all tuples in the page are visible to all transactions. The second one (all-frozen) indicates that all tuples in the page are marked frozen.

WAL
See Write-ahead log.

WAL archiver (process)
An auxiliary process which, if enabled, saves copies of WAL files for the purpose of creating backups or keeping replicas current.

For more information, see Section 26.3.

WAL file
Also known as WAL segment or WAL segment file. Each of the sequentially-numbered files that provide storage space for WAL. The files are all of the same predefined size and are written in sequential order, interspersing changes as they occur in multiple simultaneous sessions. If the system crashes, the files are read in order, and each of the changes is replayed to restore the system to the state it was in before the crash.

Each WAL file can be released after a checkpoint writes all the changes in it to the corresponding data files. Releasing the file can be done either by deleting it, or by changing its name so that it will be used in the future, which is called recycling.

For more information, see Section 30.6.

WAL record
A low-level description of an individual data change. It contains sufficient information for the data change to be re-executed (replayed) in case a system failure causes the change to be lost. WAL records use a non-printable binary format.

For more information, see Section 30.6.

WAL receiver (process)
An auxiliary process that runs on a replica to receive WAL from the primary server for replay by the startup process.

For more information, see Section 27.2.

WAL segment
See WAL file.

WAL sender (process)
A special backend process that streams WAL over a network. The receiving end can be a WAL receiver in a replica, pg_receivewal, or any other client program that speaks the replication protocol.
<table>
<thead>
<tr>
<th>Glossary</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>WAL writer (process)</td>
<td>A process that writes WAL records from shared memory to WAL files. For more information, see Section 20.5.</td>
</tr>
<tr>
<td>Window function (routine)</td>
<td>A type of function used in a query that applies to a partition of the query’s result set; the function’s result is based on values found in rows of the same partition or frame. All aggregate functions can be used as window functions, but window functions can also be used to, for example, give ranks to each of the rows in the partition. Also known as analytic functions. For more information, see Section 3.5.</td>
</tr>
<tr>
<td>Write-ahead log</td>
<td>The journal that keeps track of the changes in the database cluster as user- and system-invoked operations take place. It comprises many individual WAL records written sequentially to WAL files.</td>
</tr>
</tbody>
</table>
Appendix N. Color Support

Most programs in the PostgreSQL package can produce colorized console output. This appendix describes how that is configured.

N.1. When Color is Used

To use colorized output, set the environment variable `PG_COLOR` as follows:

1. If the value is `always`, then color is used.
2. If the value is `auto` and the standard error stream is associated with a terminal device, then color is used.
3. Otherwise, color is not used.

N.2. Configuring the Colors

The actual colors to be used are configured using the environment variable `PG_COLORS` (note plural). The value is a colon-separated list of `key=value` pairs. The keys specify what the color is to be used for. The values are SGR (Select Graphic Rendition) specifications, which are interpreted by the terminal.

The following keys are currently in use:

- `error`
  used to highlight the text “error” in error messages
- `warning`
  used to highlight the text “warning” in warning messages
- `note`
  used to highlight the text “detail” and “hint” in such messages
- `locus`
  used to highlight location information (e.g., program name and file name) in messages

The default value is `error=01;31:warning=01;35:note=01;36:locus=01` (01;31 = bold red, 01;35 = bold magenta, 01;36 = bold cyan, 01 = bold default color).

Tip

This color specification format is also used by other software packages such as GCC, GNU coreutils, and GNU grep.
Appendix O. Obsolete or Renamed Features

Functionality is sometimes removed from PostgreSQL, feature, setting and file names sometimes change, or documentation moves to different places. This section directs users coming from old versions of the documentation or from external links to the appropriate new location for the information they need.

O.1. recovery.conf file merged into postgresql.conf

PostgreSQL 11 and below used a configuration file named recovery.conf to manage replicas and standbys. Support for this file was removed in PostgreSQL 12. See the release notes for PostgreSQL 12 for details on this change.

On PostgreSQL 12 and above, archive recovery, streaming replication, and PITR are configured using normal server configuration parameters. These are set in postgresql.conf or via ALTER SYSTEM like any other parameter.

The server will not start if a recovery.conf exists.

PostgreSQL 15 and below had a setting promote_trigger_file, or trigger_file before 12. Use pg_ctl promote or call pg_promote() to promote a standby instead.

The standby_mode setting has been removed. A standby.signal file in the data directory is used instead. See Standby Server Operation for details.

O.2. Default Roles Renamed to Predefined Roles

PostgreSQL 13 and below used the term “Default Roles”. However, as these roles are not able to actually be changed and are installed as part of the system at initialization time, the more appropriate term to use is “Predefined Roles”. See Section 22.5 for current documentation regarding Predefined Roles, and the release notes for PostgreSQL 14 for details on this change.

O.3. pg_xlogdump renamed to pg_waldump

PostgreSQL 9.6 and below provided a command named pg_xlogdump to read write-ahead-log (WAL) files. This command was renamed to pg_waldump, see pg_waldump for documentation of pg_waldump and see the release notes for PostgreSQL 10 for details on this change.

O.4. pg_resetxlog renamed to pg_resetwal

PostgreSQL 9.6 and below provided a command named pg_resetxlog to reset the write-ahead-log (WAL) files. This command was renamed to pg_resetwal, see pg_resetwal for documentation of pg_resetwal and see the release notes for PostgreSQL 10 for details on this change.

O.5. pg_receivexlog renamed to pg_receivewal
PostgreSQL 9.6 and below provided a command named `pg_receivexlog` to fetch write-ahead-log (WAL) files. This command was renamed to `pg_receivewal`, see `pg_receivewal` for documentation of `pg_receivewal` and see the release notes for PostgreSQL 10 for details on this change.
