# Table of Contents

Preface ........................................................................................................................................... xlvi

1. What is PostgreSQL? .................................................................................................................. xlviii

2. A Brief History of PostgreSQL ................................................................................................. xlix
   2.1. The Berkeley POSTGRES Project ....................................................................................... xlix
   2.2. Postgres95 .......................................................................................................................... xlix
   2.3. PostgreSQL ........................................................................................................................ 1

3. Conventions.................................................................................................................................. 1

4. Further Information ..................................................................................................................... li

5. Bug Reporting Guidelines ............................................................................................................. li
   5.1. Identifying Bugs .................................................................................................................. lii
   5.2. What to report ...................................................................................................................... lii
   5.3. Where to report bugs .......................................................................................................... liiv

I. Tutorial.......................................................................................................................................... 1

1. Getting Started ........................................................................................................................... 1
   1.1. Installation .......................................................................................................................... 1
   1.2. Architectural Fundamentals ............................................................................................. 1
   1.3. Creating a Database ......................................................................................................... 2
   1.4. Accessing a Database ....................................................................................................... 3

2. The SQL Language .................................................................................................................... 5
   2.1. Introduction ....................................................................................................................... 5
   2.2. Concepts ............................................................................................................................ 5
   2.3. Creating a New Table ......................................................................................................... 5
   2.4. Populating a Table With Rows ......................................................................................... 6
   2.5. Querying a Table .............................................................................................................. 7
   2.6. Joins Between Tables ....................................................................................................... 9
   2.7. Aggregate Functions ....................................................................................................... 11
   2.8. Updates ............................................................................................................................. 12
   2.9. Deletions ........................................................................................................................... 13

3. Advanced Features...................................................................................................................... 14
   3.1. Introduction ....................................................................................................................... 14
   3.2. Views ................................................................................................................................. 14
   3.3. Foreign Keys ....................................................................................................................... 14
   3.4. Transactions ....................................................................................................................... 15
   3.5. Window Functions ........................................................................................................... 17
   3.6. Inheritance ......................................................................................................................... 20
   3.7. Conclusion ......................................................................................................................... 21

II. The SQL Language ................................................................................................................... 22

4. SQL Syntax ................................................................................................................................ 24
   4.1. Lexical Structure ................................................................................................................. 24
   4.1.1. Identifiers and Key Words ............................................................................................. 24
   4.1.2. Constants ....................................................................................................................... 26
   4.1.2.1. String Constants ........................................................................................................ 26
   4.1.2.2. String Constants with C-Style Escapes ................................................................. 26
   4.1.2.3. String Constants with Unicode Escapes ............................................................... 27
   4.1.2.4. Dollar-Quoted String Constants ............................................................................. 28
   4.1.2.5. Bit-String Constants ................................................................................................. 29
   4.1.2.6. Numeric Constants .................................................................................................... 29
   4.1.2.7. Constants of Other Types ....................................................................................... 30
15.8.3. HP-UX ................................................................. 353
15.8.4. IRIX ................................................................. 354
15.8.5. MinGW/Native Windows ........................................... 355
15.8.6. SCO OpenServer and SCO UnixWare ................................. 355
15.8.6.1. Skunkware .................................................. 355
15.8.6.2. GNU Make .................................................. 355
15.8.6.3. Readline ..................................................... 355
15.8.6.4. Using the UDK on OpenServer ................................. 356
15.8.6.5. Reading the PostgreSQL man pages .......................... 356
15.8.6.6. C99 Issues with the 7.1.1b Feature Supplement .............. 356
15.8.6.7. --enable-thread-safety and UnixWare ........................ 356
15.8.7. Solaris ......................................................... 356
15.8.7.1. Required tools ............................................. 357
15.8.7.2. Problems with OpenSSL ...................................... 357
15.8.7.3. configure complains about a failed test program .............. 357
15.8.7.4. 64-bit build sometimes crashes ................................. 357
15.8.7.5. Compiling for optimal performance ............................. 358
15.8.7.6. Using DTrace for tracing PostgreSQL .......................... 358
16. Installation from Source Code on Windows ......................... 359
16.1.1. Requirements ..................................................... 359
16.1.2. Building ............................................................ 360
16.1.3. Cleaning and installing ............................................ 361
16.1.4. Running the regression tests ....................................... 361
16.1.5. Building the documentation ........................................ 362
16.2. Building libpq with Visual C++ or Borland C++ .................... 362
16.2.1. Generated files ................................................... 363
17. Server Setup and Operation ............................................. 364
17.1. The PostgreSQL User Account ........................................ 364
17.2. Creating a Database Cluster ........................................... 364
17.2.1. Network File Systems ............................................ 365
17.3. Starting the Database Server ........................................... 365
17.3.1. Server Start-up Failures ............................................ 367
17.3.2. Client Connection Problems ...................................... 367
17.4. Managing Kernel Resources .......................................... 368
17.4.1. Shared Memory and Semaphores .................................. 368
17.4.2. Resource Limits ................................................... 374
17.4.3. Linux Memory Overcommit ........................................ 375
17.5. Shutting Down the Server ............................................. 375
17.6. Preventing Server Spoofing ............................................ 376
17.7. Encryption Options .................................................. 377
17.8. Secure TCP/IP Connections with SSL ............................... 378
17.8.1. Using client certificates ........................................... 378
17.8.2. SSL Server File Usage ........................................... 379
17.8.3. Creating a Self-Signed Certificate ................................. 379
17.9. Secure TCP/IP Connections with SSH Tunnels ..................... 380
18. Server Configuration .................................................... 382
18.1. Setting Parameters .................................................... 382
18.2. File Locations ........................................................ 383
18.3. Connections and Authentication ...................................... 384
18.3.1. Connection Settings .............................................. 384
18.3.2. Security and Authentication ........................................ 386
V. Server Programming ................................................................................................................. 694

34. Extending SQL .................................................................................................................. 696

34.1. How Extensibility Works............................................................................................. 696

34.2. The PostgreSQL Type System .................................................................................... 696

34.2.1. Base Types ........................................................................................................... 696

34.2.2. Composite Types ................................................................................................. 696

34.2.3. Domains ................................................................................................................ 697

34.2.4. Pseudo-Types ....................................................................................................... 697

34.2.5. Polymorphic Types ............................................................................................... 697

34.3. User-Defined Functions ............................................................................................... 698

34.4. Query Language (SQL) Functions .............................................................................. 698

34.4.1. SQL Functions on Base Types .............................................................................. 699

34.4.2. SQL Functions on Composite Types ...................................................................... 701

34.4.3. SQL Functions with Output Parameters ............................................................. 703

34.4.4. SQL Functions with Variable Numbers of Arguments ......................................... 704

34.4.5. SQL Functions with Default Values for Arguments ............................................. 705

34.4.6. SQL Functions as Table Sources ......................................................................... 706

34.4.7. SQL Functions Returning Sets ............................................................................ 706

34.4.8. SQL Functions Returning TABLE ....................................................................... 708

34.4.9. Polymorphic SQL Functions ................................................................................ 708

34.5. Function Overloading .................................................................................................. 710

34.6. Function Volatility Categories .................................................................................... 711

34.7. Procedural Language Functions ................................................................................... 712
34.8. Internal Functions ................................................................. 712
34.9. C-Language Functions .............................................................. 713
  34.9.1. Dynamic Loading ................................................................. 713
  34.9.2. Base Types in C-Language Functions ................................. 714
  34.9.3. Version 0 Calling Conventions ........................................... 717
  34.9.4. Version 1 Calling Conventions ........................................... 719
  34.9.5. Writing Code ................................................................. 721
  34.9.6. Compiling and Linking Dynamically-Loaded Functions ........ 722
  34.9.7. Extension Building Infrastructure ....................................... 724
  34.9.8. Composite-Type Arguments ............................................... 726
  34.9.9. Returning Rows (Composite Types) ................................. 728
  34.9.10. Returning Sets .............................................................. 730
  34.9.11. Polymorphic Arguments and Return Types ....................... 734
  34.9.12. Shared Memory and LWLocks .......................................... 736
  34.9.13. Operator Optimization Information ................................... 743
    34.9.13.1. COMMUTATOR .......................................................... 743
    34.9.13.2. NEGATOR ............................................................... 744
    34.9.13.3. RESTRICT ............................................................... 744
    34.9.13.4. JOIN ................................................................. 745
    34.9.13.5. HASHES ................................................................. 746
    34.9.13.6. MERGES ................................................................. 746
  34.9.14. Interfacing Extensions To Indexes .................................... 747
    34.9.14.1. Index Methods and Operator Classes ......................... 747
    34.9.14.2. Index Method Strategies ........................................... 748
    34.9.14.3. Index Method Support Routines ................................... 749
    34.9.14.4. An Example ........................................................... 751
    34.9.14.5. Operator Classes and Operator Families ..................... 753
    34.9.14.6. System Dependencies on Operator Classes .................. 756
    34.9.14.7. Special Features of Operator Classes ......................... 756
  35. Triggers .................................................................................. 758
    35.1. Overview of Trigger Behavior ............................................ 758
    35.2. Visibility of Data Changes ................................................ 759
    35.3. Writing Trigger Functions in C ......................................... 760
    35.4. A Complete Example ....................................................... 762
  36. The Rule System ..................................................................... 766
    36.1. The Query Tree .............................................................. 766
    36.2. Views and the Rule System ................................................ 768
      36.2.1. How SELECT Rules Work ............................................ 768
      36.2.2. View Rules in Non-SELECT Statements ....................... 773
      36.2.3. The Power of Views in PostgreSQL ............................... 774
      36.2.4. Updating a View ......................................................... 774
    36.3. Rules on INSERT, UPDATE, and DELETE ............................. 774
      36.3.1. How Update Rules Work ............................................. 775
        36.3.1.1. A First Rule Step by Step ...................................... 776
      36.3.2. Cooperation with Views .............................................. 779
    36.4. Rules and Privileges ......................................................... 785
    36.5. Rules and Command Status .............................................. 786
    36.6. Rules versus Triggers ....................................................... 786
  37. Procedural Languages ............................................................ 790
VII. Internals ................................................................................................................................. 1366

43. Overview of PostgreSQL Internals .......................................................................................... 1368
   43.1. The Path of a Query .................................................................................................................. 1368
   43.2. How Connections are Established ......................................................................................... 1368
   43.3. The Parser Stage .................................................................................................................... 1369
       43.3.1. Parser ............................................................................................................................ 1369
       43.3.2. Transformation Process ................................................................................................. 1370
   43.4. The PostgreSQL Rule System ............................................................................................... 1370
   43.5. Planner/Optimizer .................................................................................................................. 1370
       43.5.1. Generating Possible Plans ............................................................................................ 1370
   43.6. Executor ............................................................................................................................... 1372
44. System Catalogs ........................................................................................................................ 1374
   44.1. Overview .............................................................................................................................. 1374
   44.2. pg_aggregate ......................................................................................................................... 1375
   44.3. pg_am ................................................................................................................................. 1376

Preface

This book is the official documentation of PostgreSQL. It has been written by the PostgreSQL developers and other volunteers in parallel to the development of the PostgreSQL software. It describes all the functionality that the current version of PostgreSQL officially supports.

To make the large amount of information about PostgreSQL manageable, this book has been organized in several parts. Each part is targeted at a different class of users, or at users in different stages of their PostgreSQL experience:

• Part I is an informal introduction for new users.
• Part II documents the SQL query language environment, including data types and functions, as well as user-level performance tuning. Every PostgreSQL user should read this.
• Part III describes the installation and administration of the server. Everyone who runs a PostgreSQL server, be it for private use or for others, should read this part.
• Part IV describes the programming interfaces for PostgreSQL client programs.
• Part V contains information for advanced users about the extensibility capabilities of the server. Topics include user-defined data types and functions.
• Part VI contains reference information about SQL commands, client and server programs. This part supports the other parts with structured information sorted by command or program.
• Part VII contains assorted information that might be of use to PostgreSQL developers.

1. What is PostgreSQL?

PostgreSQL is an object-relational database management system (ORDBMS) based on POSTGRES, Version 4.2, developed at the University of California at Berkeley Computer Science Department. POSTGRES pioneered many concepts that only became available in some commercial database systems much later.

PostgreSQL is an open-source descendant of this original Berkeley code. It supports a large part of the SQL standard and offers many modern features:

• complex queries
• foreign keys
• triggers
• views
• transactional integrity
• multiversion concurrency control

Also, PostgreSQL can be extended by the user in many ways, for example by adding new

• data types
• functions
• operators
• aggregate functions
• index methods

And because of the liberal license, PostgreSQL can be used, modified, and distributed by anyone free of charge for any purpose, be it private, commercial, or academic.

2. A Brief History of PostgreSQL

The object-relational database management system now known as PostgreSQL is derived from the POSTGRES package written at the University of California at Berkeley. With over two decades of development behind it, PostgreSQL is now the most advanced open-source database available anywhere.

2.1. The Berkeley POSTGRES Project

The POSTGRES project, led by Professor Michael Stonebraker, was sponsored by the Defense Advanced Research Projects Agency (DARPA), the Army Research Office (ARO), the National Science Foundation (NSF), and ESL, Inc. The implementation of POSTGRES began in 1986. The initial concepts for the system were presented in *The design of POSTGRES*, and the definition of the initial data model appeared in *The POSTGRES data model*. The design of the rule system at that time was described in *The design of the POSTGRES rules system*. The rationale and architecture of the storage manager were detailed in *The design of the POSTGRES storage system*.

POSTGRES has undergone several major releases since then. The first “demoware” system became operational in 1987 and was shown at the 1988 ACM-SIGMOD Conference. Version 1, described in *The implementation of POSTGRES*, was released to a few external users in June 1989. In response to a critique of the first rule system (*A commentary on the POSTGRES rules system*), the rule system was redesigned (*On Rules, Procedures, Caching and Views in Database Systems*), and Version 2 was released in June 1990 with the new rule system. Version 3 appeared in 1991 and added support for multiple storage managers, an improved query executor, and a rewritten rule system. For the most part, subsequent releases until Postgres95 (see below) focused on portability and reliability.

POSTGRES has been used to implement many different research and production applications. These include: a financial data analysis system, a jet engine performance monitoring package, an asteroid tracking database, a medical information database, and several geographic information systems. POSTGRES has also been used as an educational tool at several universities. Finally, Illustra Information Technologies (later merged into Informix2, which is now owned by IBM3) picked up the code and commercialized it. In late 1992, POSTGRES became the primary data manager for the Sequoia 2000 scientific computing project4.

The size of the external user community nearly doubled during 1993. It became increasingly obvious that maintenance of the prototype code and support was taking up large amounts of time that should have been devoted to database research. In an effort to reduce this support burden, the Berkeley POSTGRES project officially ended with Version 4.2.

---

4. http://meteora.ucsd.edu/s2k/s2k_home.html
2.2. Postgres95

In 1994, Andrew Yu and Jolly Chen added an SQL language interpreter to POSTGRES. Under a new name, Postgres95 was subsequently released to the web to find its own way in the world as an open-source descendant of the original POSTGRES Berkeley code.

Postgres95 code was completely ANSI C and trimmed in size by 25%. Many internal changes improved performance and maintainability. Postgres95 release 1.0.x ran about 30-50% faster on the Wisconsin Benchmark compared to POSTGRES, Version 4.2. Apart from bug fixes, the following were the major enhancements:

- The query language PostQUEL was replaced with SQL (implemented in the server). Subqueries were not supported until PostgreSQL (see below), but they could be imitated in Postgres95 with user-defined SQL functions. Aggregate functions were re-implemented. Support for the GROUP BY query clause was also added.
- A new program (psql) was provided for interactive SQL queries, which used GNU Readline. This largely superseded the old monitor program.
- A new front-end library, libpgtcl, supported Tcl-based clients. A sample shell, pgtclsh, provided new Tcl commands to interface Tcl programs with the Postgres95 server.
- The large-object interface was overhauled. The inversion large objects were the only mechanism for storing large objects. (The inversion file system was removed.)
- The instance-level rule system was removed. Rules were still available as rewrite rules.
- A short tutorial introducing regular SQL features as well as those of Postgres95 was distributed with the source code.
- GNU make (instead of BSD make) was used for the build. Also, Postgres95 could be compiled with an unpatched GCC (data alignment of doubles was fixed).

2.3. PostgreSQL

By 1996, it became clear that the name “Postgres95” would not stand the test of time. We chose a new name, PostgreSQL, to reflect the relationship between the original POSTGRES and the more recent versions with SQL capability. At the same time, we set the version numbering to start at 6.0, putting the numbers back into the sequence originally begun by the Berkeley POSTGRES project.

Many people continue to refer to PostgreSQL as “Postgres” (now rarely in all capital letters) because of tradition or because it is easier to pronounce. This usage is widely accepted as a nickname or alias.

The emphasis during development of Postgres95 was on identifying and understanding existing problems in the server code. With PostgreSQL, the emphasis has shifted to augmenting features and capabilities, although work continues in all areas.

Details about what has happened in PostgreSQL since then can be found in Appendix E.

3. Conventions

This book uses the following typographical conventions to mark certain portions of text: new terms, foreign phrases, and other important passages are emphasized in *italics*. Everything that represents
input or output of the computer, in particular commands, program code, and screen output, is shown in a monospaced font (example). Within such passages, italics (example) indicate placeholders; you must insert an actual value instead of the placeholder. On occasion, parts of program code are emphasized in bold face (example), if they have been added or changed since the preceding example.

The following conventions are used in the synopsis of a command: brackets ([ and ]) indicate optional parts. (In the synopsis of a Tcl command, question marks (?) are used instead, as is usual in Tcl.) Braces ( { and } ) and vertical lines ( | ) indicate that you must choose one alternative. Dots ( . . . ) mean that the preceding element can be repeated.

Where it enhances the clarity, SQL commands are preceded by the prompt =>, and shell commands are preceded by the prompt $ . Normally, prompts are not shown, though.

An administrator is generally a person who is in charge of installing and running the server. A user could be anyone who is using, or wants to use, any part of the PostgreSQL system. These terms should not be interpreted too narrowly; this book does not have fixed presumptions about system administration procedures.

4. Further Information

Besides the documentation, that is, this book, there are other resources about PostgreSQL:

Wiki

The PostgreSQL wiki5 contains the project’s FAQ6 (Frequently Asked Questions) list, TODO7 list, and detailed information about many more topics.

Web Site

The PostgreSQL web site8 carries details on the latest release and other information to make your work or play with PostgreSQL more productive.

Mailing Lists

The mailing lists are a good place to have your questions answered, to share experiences with other users, and to contact the developers. Consult the PostgreSQL web site for details.

Yourself!

PostgreSQL is an open-source project. As such, it depends on the user community for ongoing support. As you begin to use PostgreSQL, you will rely on others for help, either through the documentation or through the mailing lists. Consider contributing your knowledge back. Read the mailing lists and answer questions. If you learn something which is not in the documentation, write it up and contribute it. If you add features to the code, contribute them.

5. Bug Reporting Guidelines

When you find a bug in PostgreSQL we want to hear about it. Your bug reports play an important part in making PostgreSQL more reliable because even the utmost care cannot guarantee that every part

---

of PostgreSQL will work on every platform under every circumstance.

The following suggestions are intended to assist you in forming bug reports that can be handled in an effective fashion. No one is required to follow them but doing so tends to be to everyone’s advantage.

We cannot promise to fix every bug right away. If the bug is obvious, critical, or affects a lot of users, chances are good that someone will look into it. It could also happen that we tell you to update to a newer version to see if the bug happens there. Or we might decide that the bug cannot be fixed before some major rewrite we might be planning is done. Or perhaps it is simply too hard and there are more important things on the agenda. If you need help immediately, consider obtaining a commercial support contract.

5.1. Identifying Bugs

Before you report a bug, please read and re-read the documentation to verify that you can really do whatever it is you are trying. If it is not clear from the documentation whether you can do something or not, please report that too; it is a bug in the documentation. If it turns out that a program does something different from what the documentation says, that is a bug. That might include, but is not limited to, the following circumstances:

- A program terminates with a fatal signal or an operating system error message that would point to a problem in the program. (A counterexample might be a “disk full” message, since you have to fix that yourself.)
- A program produces the wrong output for any given input.
- A program refuses to accept valid input (as defined in the documentation).
- A program accepts invalid input without a notice or error message. But keep in mind that your idea of invalid input might be our idea of an extension or compatibility with traditional practice.
- PostgreSQL fails to compile, build, or install according to the instructions on supported platforms.

Here “program” refers to any executable, not only the backend server.

Being slow or resource-hogging is not necessarily a bug. Read the documentation or ask on one of the mailing lists for help in tuning your applications. Failing to comply to the SQL standard is not necessarily a bug either, unless compliance for the specific feature is explicitly claimed.

Before you continue, check on the TODO list and in the FAQ to see if your bug is already known. If you cannot decode the information on the TODO list, report your problem. The least we can do is make the TODO list clearer.

5.2. What to report

The most important thing to remember about bug reporting is to state all the facts and only facts. Do not speculate what you think went wrong, what “it seemed to do”, or which part of the program has a fault. If you are not familiar with the implementation you would probably guess wrong and not help us a bit. And even if you are, educated explanations are a great supplement to but no substitute for facts. If we are going to fix the bug we still have to see it happen for ourselves first. Reporting the bare facts is relatively straightforward (you can probably copy and paste them from the screen) but all too often important details are left out because someone thought it does not matter or the report would be understood anyway.

The following items should be contained in every bug report:
• The exact sequence of steps from program start-up necessary to reproduce the problem. This should be self-contained; it is not enough to send in a bare SELECT statement without the preceding CREATE TABLE and INSERT statements, if the output should depend on the data in the tables. We do not have the time to reverse-engineer your database schema, and if we are supposed to make up our own data we would probably miss the problem.

The best format for a test case for SQL-related problems is a file that can be run through the psql frontend that shows the problem. (Be sure to not have anything in your ~/.psqlrc start-up file.) An easy way to create this file is to use pg_dump to dump out the table declarations and data needed to set the scene, then add the problem query. You are encouraged to minimize the size of your example, but this is not absolutely necessary. If the bug is reproducible, we will find it either way.

If your application uses some other client interface, such as PHP, then please try to isolate the offending queries. We will probably not set up a web server to reproduce your problem. In any case remember to provide the exact input files; do not guess that the problem happens for “large files” or “midsize databases”, etc. since this information is too inexact to be of use.

• The output you got. Please do not say that it “didn’t work” or “crashed”. If there is an error message, show it, even if you do not understand it. If the program terminates with an operating system error, say which. If nothing at all happens, say so. Even if the result of your test case is a program crash or otherwise obvious it might not happen on our platform. The easiest thing is to copy the output from the terminal, if possible.

Note: If you are reporting an error message, please obtain the most verbose form of the message. In psql, say \set VERBOSITY verbose beforehand. If you are extracting the message from the server log, set the run-time parameter log_error_verbosity to verbose so that all details are logged.

Note: In case of fatal errors, the error message reported by the client might not contain all the information available. Please also look at the log output of the database server. If you do not keep your server’s log output, this would be a good time to start doing so.

• The output you expected is very important to state. If you just write “This command gives me that output.” or “This is not what I expected.”, we might run it ourselves, scan the output, and think it looks OK and is exactly what we expected. We should not have to spend the time to decode the exact semantics behind your commands. Especially refrain from merely saying that “This is not what SQL says/Oracle does.” Digging out the correct behavior from SQL is not a fun undertaking, nor do we all know how all the other relational databases out there behave. (If your problem is a program crash, you can obviously omit this item.)

• Any command line options and other start-up options, including any relevant environment variables or configuration files that you changed from the default. Again, please provide exact information. If you are using a prepackaged distribution that starts the database server at boot time, you should try to find out how that is done.

• Anything you did at all differently from the installation instructions.

• The PostgreSQL version. You can run the command SELECT version(); to find out the version of the server you are connected to. Most executable programs also support a --version option; at least postgres --version and psql --version should work. If the function or the options do
not exist then your version is more than old enough to warrant an upgrade. If you run a prepackaged version, such as RPMs, say so, including any subversion the package might have. If you are talking about a Git snapshot, mention that, including the commit hash.

If your version is older than 8.4.22 we will almost certainly tell you to upgrade. There are many bug fixes and improvements in each new release, so it is quite possible that a bug you have encountered in an older release of PostgreSQL has already been fixed. We can only provide limited support for sites using older releases of PostgreSQL; if you require more than we can provide, consider acquiring a commercial support contract.

- Platform information. This includes the kernel name and version, C library, processor, memory information, and so on. In most cases it is sufficient to report the vendor and version, but do not assume everyone knows what exactly “Debian” contains or that everyone runs on i386s. If you have installation problems then information about the toolchain on your machine (compiler, make, and so on) is also necessary.

Do not be afraid if your bug report becomes rather lengthy. That is a fact of life. It is better to report everything the first time than us having to squeeze the facts out of you. On the other hand, if your input files are huge, it is fair to ask first whether somebody is interested in looking into it. Here is an article\(^9\) that outlines some more tips on reporting bugs.

Do not spend all your time to figure out which changes in the input make the problem go away. This will probably not help solving it. If it turns out that the bug cannot be fixed right away, you will still have time to find and share your work-around. Also, once again, do not waste your time guessing why the bug exists. We will find that out soon enough.

When writing a bug report, please avoid confusing terminology. The software package in total is called “PostgreSQL”, sometimes “Postgres” for short. If you are specifically talking about the backend server, mention that, do not just say “PostgreSQL crashes”. A crash of a single backend server process is quite different from crash of the parent “postgres” process; please don’t say “the server crashed” when you mean a single backend process went down, nor vice versa. Also, client programs such as the interactive frontend “psql” are completely separate from the backend. Please try to be specific about whether the problem is on the client or server side.

### 5.3. Where to report bugs

In general, send bug reports to the bug report mailing list at <pgsql-bugs@postgresql.org>. You are requested to use a descriptive subject for your email message, perhaps parts of the error message.

Another method is to fill in the bug report web-form available at the project’s web site\(^10\). Entering a bug report this way causes it to be mailed to the <pgsql-bugs@postgresql.org> mailing list.

If your bug report has security implications and you’d prefer that it not become immediately visible in public archives, don’t send it to psql-bugs. Security issues can be reported privately to <security@postgresql.org>.

Do not send bug reports to any of the user mailing lists, such as <pgsql-sql@postgresql.org> or <pgsql-general@postgresql.org>. These mailing lists are for answering user questions, and their subscribers normally do not wish to receive bug reports. More importantly, they are unlikely to fix them.

Also, please do not send reports to the developers’ mailing list <pgsql-hackers@postgresql.org>. This list is for discussing the development of PostgreSQL.

---

\(^10\) [http://www.postgresql.org/](http://www.postgresql.org/)
and it would be nice if we could keep the bug reports separate. We might choose to take up a
discussion about your bug report on `pgsql-hackers`, if the problem needs more review.

If you have a problem with the documentation, the best place to report it is the documentation mailing
list `<pgsql-docs@postgresql.org>`. Please be specific about what part of the documentation you
are unhappy with.

If your bug is a portability problem on a non-supported platform, send mail to
`<pgsql-hackers@postgresql.org>`, so we (and you) can work on porting PostgreSQL to your
platform.

**Note:** Due to the unfortunate amount of spam going around, all of the above email addresses
are closed mailing lists. That is, you need to be subscribed to a list to be allowed to post on it.
(You need not be subscribed to use the bug-report web form, however.) If you would like to send
mail but do not want to receive list traffic, you can subscribe and set your subscription option to
`nomail`. For more information send mail to `<majordomo@postgresql.org>` with the single word
`help` in the body of the message.
I. Tutorial

Welcome to the PostgreSQL Tutorial. The following few chapters are intended to give a simple introduction to PostgreSQL, relational database concepts, and the SQL language to those who are new to any one of these aspects. We only assume some general knowledge about how to use computers. No particular Unix or programming experience is required. This part is mainly intended to give you some hands-on experience with important aspects of the PostgreSQL system. It makes no attempt to be a complete or thorough treatment of the topics it covers.

After you have worked through this tutorial you might want to move on to reading Part II to gain a more formal knowledge of the SQL language, or Part IV for information about developing applications for PostgreSQL. Those who set up and manage their own server should also read Part III.
Chapter 1. Getting Started

1.1. Installation

Before you can use PostgreSQL you need to install it, of course. It is possible that PostgreSQL is already installed at your site, either because it was included in your operating system distribution or because the system administrator already installed it. If that is the case, you should obtain information from the operating system documentation or your system administrator about how to access PostgreSQL.

If you are not sure whether PostgreSQL is already available or whether you can use it for your experimentation then you can install it yourself. Doing so is not hard and it can be a good exercise. PostgreSQL can be installed by any unprivileged user; no superuser (root) access is required.

If you are installing PostgreSQL yourself, then refer to Chapter 15 for instructions on installation, and return to this guide when the installation is complete. Be sure to follow closely the section about setting up the appropriate environment variables.

If your site administrator has not set things up in the default way, you might have some more work to do. For example, if the database server machine is a remote machine, you will need to set the `PGHOST` environment variable to the name of the database server machine. The environment variable `PGPORT` might also have to be set. The bottom line is this: if you try to start an application program and it complains that it cannot connect to the database, you should consult your site administrator or, if that is you, the documentation to make sure that your environment is properly set up. If you did not understand the preceding paragraph then read the next section.

1.2. Architectural Fundamentals

Before we proceed, you should understand the basic PostgreSQL system architecture. Understanding how the parts of PostgreSQL interact will make this chapter somewhat clearer.

In database jargon, PostgreSQL uses a client/server model. A PostgreSQL session consists of the following cooperating processes (programs):

- A server process, which manages the database files, accepts connections to the database from client applications, and performs database actions on behalf of the clients. The database server program is called `postgres`.
- The user’s client (frontend) application that wants to perform database operations. Client applications can be very diverse in nature: a client could be a text-oriented tool, a graphical application, a web server that accesses the database to display web pages, or a specialized database maintenance tool. Some client applications are supplied with the PostgreSQL distribution; most are developed by users.

As is typical of client/server applications, the client and the server can be on different hosts. In that case they communicate over a TCP/IP network connection. You should keep this in mind, because the files that can be accessed on a client machine might not be accessible (or might only be accessible using a different file name) on the database server machine.

The PostgreSQL server can handle multiple concurrent connections from clients. To achieve this it starts (“forks”) a new process for each connection. From that point on, the client and the new
server process communicate without intervention by the original postgres process. Thus, the master server process is always running, waiting for client connections, whereas client and associated server processes come and go. (All of this is of course invisible to the user. We only mention it here for completeness.)

1.3. Creating a Database

The first test to see whether you can access the database server is to try to create a database. A running PostgreSQL server can manage many databases. Typically, a separate database is used for each project or for each user.

Possibly, your site administrator has already created a database for your use. He should have told you what the name of your database is. In that case you can omit this step and skip ahead to the next section.

To create a new database, in this example named mydb, you use the following command:

```
$ createdb mydb
```

If this produces no response then this step was successful and you can skip over the remainder of this section.

If you see a message similar to:

```
createdb: command not found
```

then PostgreSQL was not installed properly. Either it was not installed at all or your shell’s search path was not set to include it. Try calling the command with an absolute path instead:

```
$ /usr/local/pgsql/bin/createdb mydb
```

The path at your site might be different. Contact your site administrator or check the installation instructions to correct the situation.

Another response could be this:

```
createdb: could not connect to database postgres: could not connect to server: No such file or directory
```

Is the server running locally and accepting connections on Unix domain socket "/tmp/.s.PGSQL.5432"?

This means that the server was not started, or it was not started where createdb expected it. Again, check the installation instructions or consult the administrator.

Another response could be this:

```
createdb: could not connect to database postgres: FATAL: role "joe" does not exist
```

where your own login name is mentioned. This will happen if the administrator has not created a PostgreSQL user account for you. (PostgreSQL user accounts are distinct from operating system user accounts.) If you are the administrator, see Chapter 20 for help creating accounts. You will need to become the operating system user under which PostgreSQL was installed (usually postgres) to create the first user account. It could also be that you were assigned a PostgreSQL user name that is different from your operating system user name; in that case you need to use the -U switch or set the PGUSER environment variable to specify your PostgreSQL user name.

If you have a user account but it does not have the privileges required to create a database, you will see the following:
createdb: database creation failed: ERROR: permission denied to create database

Not every user has authorization to create new databases. If PostgreSQL refuses to create databases for you then the site administrator needs to grant you permission to create databases. Consult your site administrator if this occurs. If you installed PostgreSQL yourself then you should log in for the purposes of this tutorial under the user account that you started the server as. ¹

You can also create databases with other names. PostgreSQL allows you to create any number of databases at a given site. Database names must have an alphabetic first character and are limited to 63 bytes in length. A convenient choice is to create a database with the same name as your current user name. Many tools assume that database name as the default, so it can save you some typing. To create that database, simply type:

```
$ createdb
```

If you do not want to use your database anymore you can remove it. For example, if you are the owner (creator) of the database `mydb`, you can destroy it using the following command:

```
$ dropdb mydb
```

(For this command, the database name does not default to the user account name. You always need to specify it.) This action physically removes all files associated with the database and cannot be undone, so this should only be done with a great deal of forethought.

More about `createdb` and `dropdb` can be found in `createdb` and `dropdb` respectively.

## 1.4. Accessing a Database

Once you have created a database, you can access it by:

- Running the PostgreSQL interactive terminal program, called `psql`, which allows you to interactively enter, edit, and execute SQL commands.
- Using an existing graphical frontend tool like pgAdmin or an office suite with ODBC or JDBC support to create and manipulate a database. These possibilities are not covered in this tutorial.
- Writing a custom application, using one of the several available language bindings. These possibilities are discussed further in Part IV.

You probably want to start up `psql` to try the examples in this tutorial. It can be activated for the `mydb` database by typing the command:

```
$ psql mydb
```

If you do not supply the database name then it will default to your user account name. You already discovered this scheme in the previous section using `createdb`.

In `psql`, you will be greeted with the following message:

---

¹ As an explanation for why this works: PostgreSQL user names are separate from operating system user accounts. When you connect to a database, you can choose what PostgreSQL user name to connect as; if you don’t, it will default to the same name as your current operating system account. As it happens, there will always be a PostgreSQL user account that has the same name as the operating system user that started the server, and it also happens that that user always has permission to create databases. Instead of logging in as that user you can also specify the `-U` option everywhere to select a PostgreSQL user name to connect as.
Chapter 1. Getting Started

```plaintext
psql (8.4.22)
Type *"help"* for help.

mydb=>

The last line could also be:

mydb=#

That would mean you are a database superuser, which is most likely the case if you installed PostgresQL yourself. Being a superuser means that you are not subject to access controls. For the purposes of this tutorial that is not important.

If you encounter problems starting `psql` then go back to the previous section. The diagnostics of `createdb` and `psql` are similar, and if the former worked the latter should work as well.

The last line printed out by `psql` is the prompt, and it indicates that `psql` is listening to you and that you can type SQL queries into a work space maintained by `psql`. Try out these commands:

```plaintext
mydb=> SELECT version();

version
PostgreSQL 8.4.22 on i586-pc-linux-gnu, compiled by GCC 2.96, 32-bit
(1 row)

mydb=> SELECT current_date;

date
2002-08-31
(1 row)

mydb=> SELECT 2 + 2;

?column?
4
(1 row)
```

The `psql` program has a number of internal commands that are not SQL commands. They begin with the backslash character, \\
Some of these commands were listed in the welcome message. For example, you can get help on the syntax of various PostgreSQL SQL commands by typing:

```plaintext
mydb=> \h
```

To get out of `psql`, type:

```plaintext
mydb=> \q
```

and `psql` will quit and return you to your command shell. (For more internal commands, type `\?` at the `psql` prompt.) The full capabilities of `psql` are documented in `psql`. If PostgreSQL is installed correctly you can also type `man psql` at the operating system shell prompt to see the documentation. In this tutorial we will not use these features explicitly, but you can use them yourself when it is helpful.

4
Chapter 2. The SQL Language

2.1. Introduction

This chapter provides an overview of how to use SQL to perform simple operations. This tutorial is only intended to give you an introduction and is in no way a complete tutorial on SQL. Numerous books have been written on SQL, including Understanding the New SQL and A Guide to the SQL Standard. You should be aware that some PostgreSQL language features are extensions to the standard.

In the examples that follow, we assume that you have created a database named mydb, as described in the previous chapter, and have been able to start psql.

Examples in this manual can also be found in the PostgreSQL source distribution in the directory src/tutorial/. To use those files, first change to that directory and run make:

```bash
$ cd .../src/tutorial
$ make
```

This creates the scripts and compiles the C files containing user-defined functions and types. (If you installed a pre-packaged version of PostgreSQL rather than building from source, look for a directory named tutorial within the PostgreSQL distribution. The “make” part should already have been done for you.) Then, to start the tutorial, do the following:

```bash
$ cd .../tutorial
$ psql -s mydb
...
```

mydb=> \i basics.sql

The \i command reads in commands from the specified file. psql's -s option puts you in single step mode which pauses before sending each statement to the server. The commands used in this section are in the file basics.sql.

2.2. Concepts

PostgreSQL is a relational database management system (RDBMS). That means it is a system for managing data stored in relations. Relation is essentially a mathematical term for table. The notion of storing data in tables is so commonplace today that it might seem inherently obvious, but there are a number of other ways of organizing databases. Files and directories on Unix-like operating systems form an example of a hierarchical database. A more modern development is the object-oriented database.

Each table is a named collection of rows. Each row of a given table has the same set of named columns, and each column is of a specific data type. Whereas columns have a fixed order in each row, it is important to remember that SQL does not guarantee the order of the rows within the table in any way (although they can be explicitly sorted for display).

Tables are grouped into databases, and a collection of databases managed by a single PostgreSQL server instance constitutes a database cluster.
2.3. Creating a New Table

You can create a new table by specifying the table name, along with all column names and their types:

```sql
CREATE TABLE weather (
  city varchar(80),
  temp_lo int, -- low temperature
  temp_hi int, -- high temperature
  prcp real, -- precipitation
  date date
);
```

You can enter this into `psql` with the line breaks. `psql` will recognize that the command is not terminated until the semicolon.

White space (i.e., spaces, tabs, and newlines) can be used freely in SQL commands. That means you can type the command aligned differently than above, or even all on one line. Two dashes ("--") introduce comments. Whatever follows them is ignored up to the end of the line. SQL is case insensitive about key words and identifiers, except when identifiers are double-quoted to preserve the case (not done above).

`varchar(80)` specifies a data type that can store arbitrary character strings up to 80 characters in length. `int` is the normal integer type. `real` is a type for storing single precision floating-point numbers. `date` should be self-explanatory. (Yes, the column of type `date` is also named `date`. This might be convenient or confusing — you choose.)

PostgreSQL supports the standard SQL types `int`, `smallint`, `real`, `double precision`, `char(N)`, `varchar(N)`, `date`, `time`, `timestamp`, and `interval`, as well as other types of general utility and a rich set of geometric types. PostgreSQL can be customized with an arbitrary number of user-defined data types. Consequently, type names are not key words in the syntax, except where required to support special cases in the SQL standard.

The second example will store cities and their associated geographical location:

```sql
CREATE TABLE cities {
  name varchar(80),
  location point
};
```

The `point` type is an example of a PostgreSQL-specific data type.

Finally, it should be mentioned that if you don’t need a table any longer or want to recreate it differently you can remove it using the following command:

```sql
DROP TABLE tablename;
```

2.4. Populating a Table With Rows

The `INSERT` statement is used to populate a table with rows:

```sql
INSERT INTO weather VALUES ('San Francisco', 46, 50, 0.25, '1994-11-27');
```
Chapter 2. The SQL Language

Note that all data types use rather obvious input formats. Constants that are not simple numeric values usually must be surrounded by single quotes (‘), as in the example. The date type is actually quite flexible in what it accepts, but for this tutorial we will stick to the unambiguous format shown here.

The point type requires a coordinate pair as input, as shown here:

```
INSERT INTO cities VALUES ('San Francisco', '(-194.0, 53.0)');
```

The syntax used so far requires you to remember the order of the columns. An alternative syntax allows you to list the columns explicitly:

```
INSERT INTO weather (city, temp_lo, temp_hi, prcp, date)
    VALUES ('San Francisco', 43, 57, 0.0, '1994-11-29');
```

You can list the columns in a different order if you wish or even omit some columns, e.g., if the precipitation is unknown:

```
INSERT INTO weather (date, city, temp_hi, temp_lo)
    VALUES ('1994-11-29', 'Hayward', 54, 37);
```

Many developers consider explicitly listing the columns better style than relying on the order implicitly.

Please enter all the commands shown above so you have some data to work with in the following sections.

You could also have used COPY to load large amounts of data from flat-text files. This is usually faster because the COPY command is optimized for this application while allowing less flexibility than INSERT. An example would be:

```
COPY weather FROM '/home/user/weather.txt';
```

where the file name for the source file must be available to the backend server machine, not the client, since the backend server reads the file directly. You can read more about the COPY command in COPY.

2.5. Querying a Table

To retrieve data from a table, the table is queried. An SQL SELECT statement is used to do this. The statement is divided into a select list (the part that lists the columns to be returned), a table list (the part that lists the tables from which to retrieve the data), and an optional qualification (the part that specifies any restrictions). For example, to retrieve all the rows of table weather, type:

```
SELECT * FROM weather;
```

Here * is a shorthand for “all columns”. So the same result would be had with:

```
SELECT city, temp_lo, temp_hi, prcp, date FROM weather;
```

The output should be:

```
city | temp_lo | temp_hi | prcp | date
-----------------+---------+---------+------+---------
```

1. While SELECT * is useful for off-the-cuff queries, it is widely considered bad style in production code, since adding a column to the table would change the results.
You can write expressions, not just simple column references, in the select list. For example, you can do:

```sql
SELECT city, (temp_hi+temp_lo)/2 AS temp_avg, date FROM weather;
```

This should give:

<table>
<thead>
<tr>
<th>city</th>
<th>temp_avg</th>
<th>date</th>
</tr>
</thead>
<tbody>
<tr>
<td>San Francisco</td>
<td>48</td>
<td>1994-11-27</td>
</tr>
<tr>
<td>San Francisco</td>
<td>50</td>
<td>1994-11-29</td>
</tr>
<tr>
<td>Hayward</td>
<td>45</td>
<td>1994-11-29</td>
</tr>
</tbody>
</table>

(3 rows)

Notice how the `AS` clause is used to relabel the output column. (The `AS` clause is optional.)

A query can be “qualified” by adding a `WHERE` clause that specifies which rows are wanted. The `WHERE` clause contains a Boolean (truth value) expression, and only rows for which the Boolean expression is true are returned. The usual Boolean operators (`AND`, `OR`, and `NOT`) are allowed in the qualification. For example, the following retrieves the weather of San Francisco on rainy days:

```sql
SELECT * FROM weather
WHERE city = 'San Francisco' AND prcp > 0.0;
```

Result:

<table>
<thead>
<tr>
<th>city</th>
<th>temp_lo</th>
<th>temp_hi</th>
<th>prcp</th>
<th>date</th>
</tr>
</thead>
<tbody>
<tr>
<td>San Francisco</td>
<td>46</td>
<td>50</td>
<td>0.25</td>
<td>1994-11-27</td>
</tr>
</tbody>
</table>

(1 row)

You can request that the results of a query be returned in sorted order:

```sql
SELECT * FROM weather
ORDER BY city;
```

Result:

<table>
<thead>
<tr>
<th>city</th>
<th>temp_lo</th>
<th>temp_hi</th>
<th>prcp</th>
<th>date</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hayward</td>
<td>37</td>
<td>54</td>
<td></td>
<td>1994-11-29</td>
</tr>
<tr>
<td>San Francisco</td>
<td>43</td>
<td>57</td>
<td>0</td>
<td>1994-11-29</td>
</tr>
<tr>
<td>San Francisco</td>
<td>46</td>
<td>50</td>
<td>0.25</td>
<td>1994-11-27</td>
</tr>
</tbody>
</table>

In this example, the sort order isn’t fully specified, and so you might get the San Francisco rows in either order. But you’d always get the results shown above if you do:

```sql
SELECT * FROM weather
ORDER BY city, temp_lo;
```

You can request that duplicate rows be removed from the result of a query:
SELECT DISTINCT city
FROM weather;

---

<table>
<thead>
<tr>
<th>city</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hayward</td>
</tr>
<tr>
<td>San Francisco</td>
</tr>
</tbody>
</table>
(2 rows)

Here again, the result row ordering might vary. You can ensure consistent results by using `DISTINCT` and `ORDER BY` together:

```sql
SELECT DISTINCT city
FROM weather
ORDER BY city;
```

### 2.6. Joins Between Tables

Thus far, our queries have only accessed one table at a time. Queries can access multiple tables at once, or access the same table in such a way that multiple rows of the table are being processed at the same time. A query that accesses multiple rows of the same or different tables at one time is called a join query. As an example, say you wish to list all the weather records together with the location of the associated city. To do that, we need to compare the `city` column of each row of the `weather` table with the `name` column of all rows in the `cities` table, and select the pairs of rows where these values match.

**Note:** This is only a conceptual model. The join is usually performed in a more efficient manner than actually comparing each possible pair of rows, but this is invisible to the user.

This would be accomplished by the following query:

```sql
SELECT *
FROM weather, cities
WHERE city = name;
```

<table>
<thead>
<tr>
<th>city</th>
<th>temp_lo</th>
<th>temp_hi</th>
<th>prcp</th>
<th>date</th>
<th>name</th>
<th>location</th>
</tr>
</thead>
<tbody>
<tr>
<td>San Francisco</td>
<td>46</td>
<td>50</td>
<td>0.25</td>
<td>1994-11-27</td>
<td>San Francisco</td>
<td>(-194,53)</td>
</tr>
<tr>
<td>San Francisco</td>
<td>43</td>
<td>57</td>
<td>0</td>
<td>1994-11-29</td>
<td>San Francisco</td>
<td>(-194,53)</td>
</tr>
</tbody>
</table>
(2 rows)

Observe two things about the result set:

- There is no result row for the city of Hayward. This is because there is no matching entry in the `cities` table for Hayward, so the join ignores the unmatched rows in the `weather` table. We will see shortly how this can be fixed.

---

2. In some database systems, including older versions of PostgreSQL, the implementation of `DISTINCT` automatically orders the rows and so `ORDER BY` is unnecessary. But this is not required by the SQL standard, and current PostgreSQL does not guarantee that `DISTINCT` causes the rows to be ordered.
• There are two columns containing the city name. This is correct because the lists of columns from the
weather and cities tables are concatenated. In practice this is undesirable, though, so you
will probably want to list the output columns explicitly rather than using *:

```
SELECT city, temp_lo, temp_hi, prcp, date, location
FROM weather, cities
WHERE city = name;
```

**Exercise:** Attempt to determine the semantics of this query when the `WHERE` clause is omitted.

Since the columns all had different names, the parser automatically found which table they belong to.
If there were duplicate column names in the two tables you’d need to *qualify* the column names to
show which one you meant, as in:

```
SELECT weather.city, weather.temp_lo, weather.temp_hi,
       weather.prcp, weather.date, cities.location
FROM weather, cities
WHERE cities.name = weather.city;
```

It is widely considered good style to qualify all column names in a join query, so that the query won’t
fail if a duplicate column name is later added to one of the tables.

Join queries of the kind seen thus far can also be written in this alternative form:

```
SELECT *
FROM weather INNER JOIN cities ON (weather.city = cities.name);
```

This syntax is not as commonly used as the one above, but we show it here to help you understand the
following topics.

Now we will figure out how we can get the Hayward records back in. What we want the query to do
is to scan the `weather` table and for each row to find the matching `cities` row(s). If no matching
row is found we want some “empty values” to be substituted for the `cities` table’s columns. This
kind of query is called an *outer join*. (The joins we have seen so far are *inner joins*.) The command
looks like this:

```
SELECT *
FROM weather LEFT OUTER JOIN cities ON (weather.city = cities.name);
```

This query is called a *left outer join* because the table mentioned on the left of the join operator will
have each of its rows in the output at least once, whereas the table on the right will only have those
rows output that match some row of the left table. When outputting a left-table row for which there is
no right-table match, empty (null) values are substituted for the right-table columns.

**Exercise:** There are also right outer joins and full outer joins. Try to find out what those do.

We can also join a table against itself. This is called a *self join*. As an example, suppose we wish to
find all the weather records that are in the temperature range of other weather records. So we need to
compare the `temp_lo` and `temp_hi` columns of each `weather` row to the `temp_lo` and `temp_hi`
columns of all other `weather` rows. We can do this with the following query:

```
SELECT *
FROM weather
INNER JOIN weather AS weather2
ON (weather.city = weather2.city AND weather.temp_lo < weather2.temp_hi
    AND weather2.temp_lo < weather.temp_hi);
```

<table>
<thead>
<tr>
<th>city</th>
<th>low</th>
<th>high</th>
<th>city</th>
<th>low</th>
<th>high</th>
</tr>
</thead>
<tbody>
<tr>
<td>San Francisco</td>
<td>43</td>
<td>57</td>
<td>San Francisco</td>
<td>46</td>
<td>50</td>
</tr>
<tr>
<td>Hayward</td>
<td>37</td>
<td>54</td>
<td>San Francisco</td>
<td>46</td>
<td>50</td>
</tr>
</tbody>
</table>

Here we have relabeled the weather table as W1 and W2 to be able to distinguish the left and right side of the join. You can also use these kinds of aliases in other queries to save some typing, e.g.:

SELECT *
FROM weather w, cities c
WHERE w.city = c.name;

You will encounter this style of abbreviating quite frequently.

### 2.7. Aggregate Functions

Like most other relational database products, PostgreSQL supports aggregate functions. An aggregate function computes a single result from multiple input rows. For example, there are aggregates to compute the count, sum, avg (average), max (maximum) and min (minimum) over a set of rows.

As an example, we can find the highest low-temperature reading anywhere with:

SELECT max(temp_lo) FROM weather;

```
max
-----
46
(1 row)
```

If we wanted to know what city (or cities) that reading occurred in, we might try:

SELECT city FROM weather WHERE temp_lo = max(temp_lo);

```
WRONG
```

but this will not work since the aggregate `max` cannot be used in the `WHERE` clause. (This restriction exists because the `WHERE` clause determines which rows will be included in the aggregate calculation; so obviously it has to be evaluated before aggregate functions are computed.) However, as is often the case the query can be restated to accomplish the desired result, here by using a subquery:

```
SELECT city FROM weather
WHERE temp_lo = (SELECT max(temp_lo) FROM weather);
```

```
<table>
<thead>
<tr>
<th>city</th>
</tr>
</thead>
<tbody>
<tr>
<td>San Francisco</td>
</tr>
</tbody>
</table>
```

(1 row)
This is OK because the subquery is an independent computation that computes its own aggregate separately from what is happening in the outer query.

Aggregates are also very useful in combination with GROUP BY clauses. For example, we can get the maximum low temperature observed in each city with:

```sql
SELECT city, max(temp_lo)
FROM weather
GROUP BY city;
```

<table>
<thead>
<tr>
<th>city</th>
<th>max</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hayward</td>
<td>37</td>
</tr>
<tr>
<td>San Francisco</td>
<td>46</td>
</tr>
</tbody>
</table>

(2 rows)

which gives us one output row per city. Each aggregate result is computed over the table rows matching that city. We can filter these grouped rows using HAVING:

```sql
SELECT city, max(temp_lo)
FROM weather
GROUP BY city
HAVING max(temp_lo) < 40;
```

<table>
<thead>
<tr>
<th>city</th>
<th>max</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hayward</td>
<td>37</td>
</tr>
</tbody>
</table>

(1 row)

which gives us the same results for only the cities that have all temp_lo values below 40. Finally, if we only care about cities whose names begin with “S”, we might do:

```sql
SELECT city, max(temp_lo)
FROM weather
WHERE city LIKE 'S%'
GROUP BY city
HAVING max(temp_lo) < 40;
```

1 The LIKE operator does pattern matching and is explained in Section 9.7.

It is important to understand the interaction between aggregates and SQL’s WHERE and HAVING clauses. The fundamental difference between WHERE and HAVING is this: WHERE selects input rows before groups and aggregates are computed (thus, it controls which rows go into the aggregate computation), whereas HAVING selects group rows after groups and aggregates are computed. Thus, the WHERE clause must not contain aggregate functions; it makes no sense to try to use an aggregate to determine which rows will be inputs to the aggregates. On the other hand, the HAVING clause always contains aggregate functions. (Strictly speaking, you are allowed to write a HAVING clause that doesn’t use aggregates, but it’s seldom useful. The same condition could be used more efficiently at the WHERE stage.)

In the previous example, we can apply the city name restriction in WHERE, since it needs no aggregate. This is more efficient than adding the restriction to HAVING, because we avoid doing the grouping and aggregate calculations for all rows that fail the WHERE check.
2.8. Updates

You can update existing rows using the **UPDATE** command. Suppose you discover the temperature readings are all off by 2 degrees after November 28. You can correct the data as follows:

```
UPDATE weather
SET temp_hi = temp_hi - 2, temp_lo = temp_lo - 2
WHERE date > '1994-11-28';
```

Look at the new state of the data:

```
SELECT * FROM weather;
```

```
city | temp_lo | temp_hi | prcp | date
--- | ------- | ------- | ---- | ---
San Francisco | 46 | 50 | 0.25 | 1994-11-27
San Francisco | 41 | 55 | 0 | 1994-11-29
Hayward | 35 | 52 | | 1994-11-29
```

(3 rows)

2.9. Deletions

Rows can be removed from a table using the **DELETE** command. Suppose you are no longer interested in the weather of Hayward. Then you can do the following to delete those rows from the table:

```
DELETE FROM weather WHERE city = 'Hayward';
```

All weather records belonging to Hayward are removed.

```
SELECT * FROM weather;
```

```
city | temp_lo | temp_hi | prcp | date
--- | ------- | ------- | ---- | ---
San Francisco | 46 | 50 | 0.25 | 1994-11-27
San Francisco | 41 | 55 | 0 | 1994-11-29
```

(2 rows)

One should be wary of statements of the form

```
DELETE FROM tablename;
```

Without a qualification, **DELETE** will remove all rows from the given table, leaving it empty. The system will not request confirmation before doing this!
Chapter 3. Advanced Features

3.1. Introduction

In the previous chapter we have covered the basics of using SQL to store and access your data in PostgreSQL. We will now discuss some more advanced features of SQL that simplify management and prevent loss or corruption of your data. Finally, we will look at some PostgreSQL extensions.

This chapter will on occasion refer to examples found in Chapter 2 to change or improve them, so it will be useful to have read that chapter. Some examples from this chapter can also be found in advanced.sql in the tutorial directory. This file also contains some sample data to load, which is not repeated here. (Refer to Section 2.1 for how to use the file.)

3.2. Views

Refer back to the queries in Section 2.6. Suppose the combined listing of weather records and city location is of particular interest to your application, but you do not want to type the query each time you need it. You can create a view over the query, which gives a name to the query that you can refer to like an ordinary table:

```sql
CREATE VIEW myview AS
    SELECT city, temp_lo, temp_hi, prcp, date, location
    FROM weather, cities
    WHERE city = name;

SELECT * FROM myview;
```

Making liberal use of views is a key aspect of good SQL database design. Views allow you to encapsulate the details of the structure of your tables, which might change as your application evolves, behind consistent interfaces.

Views can be used in almost any place a real table can be used. Building views upon other views is not uncommon.

3.3. Foreign Keys

Recall the weather and cities tables from Chapter 2. Consider the following problem: You want to make sure that no one can insert rows in the weather table that do not have a matching entry in the cities table. This is called maintaining the referential integrity of your data. In simplistic database systems this would be implemented (if at all) by first looking at the cities table to check if a matching record exists, and then inserting or rejecting the new weather records. This approach has a number of problems and is very inconvenient, so PostgreSQL can do this for you.

The new declaration of the tables would look like this:

```sql
CREATE TABLE cities {
    city varchar(80) primary key,
    location point
};
```
CREATE TABLE weather (  
city varchar(80) references cities(city),  
temp_lo int,  
temp_hi int,  
prcp real,  
date date  
);

Now try inserting an invalid record:

INSERT INTO weather VALUES ('Berkeley', 45, 53, 0.0, '1994-11-28');

ERROR: insert or update on table "weather" violates foreign key constraint "weather_city_fkey"
DETAIL: Key (city)=(Berkeley) is not present in table "cities".

The behavior of foreign keys can be finely tuned to your application. We will not go beyond this simple example in this tutorial, but just refer you to Chapter 5 for more information. Making correct use of foreign keys will definitely improve the quality of your database applications, so you are strongly encouraged to learn about them.

3.4. Transactions

Transactions are a fundamental concept of all database systems. The essential point of a transaction is that it bundles multiple steps into a single, all-or-nothing operation. The intermediate states between the steps are not visible to other concurrent transactions, and if some failure occurs that prevents the transaction from completing, then none of the steps affect the database at all.

For example, consider a bank database that contains balances for various customer accounts, as well as total deposit balances for branches. Suppose that we want to record a payment of $100.00 from Alice’s account to Bob’s account. Simplifying outrageously, the SQL commands for this might look like:

```sql
UPDATE accounts SET balance = balance - 100.00  
    WHERE name = 'Alice';
UPDATE branches SET balance = balance - 100.00  
    WHERE name = (SELECT branch_name FROM accounts WHERE name = 'Alice');
UPDATE accounts SET balance = balance + 100.00  
    WHERE name = 'Bob';
UPDATE branches SET balance = balance + 100.00  
    WHERE name = (SELECT branch_name FROM accounts WHERE name = 'Bob');
```

The details of these commands are not important here; the important point is that there are several separate updates involved to accomplish this rather simple operation. Our bank’s officers will want to be assured that either all these updates happen, or none of them happen. It would certainly not do for a system failure to result in Bob receiving $100.00 that was not debited from Alice. Nor would Alice long remain a happy customer if she was debited without Bob being credited. We need a guarantee that if something goes wrong partway through the operation, none of the steps executed so far will take effect. Grouping the updates into a transaction gives us this guarantee. A transaction is said to be atomic: from the point of view of other transactions, it either happens completely or not at all.
We also want a guarantee that once a transaction is completed and acknowledged by the database system, it has indeed been permanently recorded and won’t be lost even if a crash ensues shortly thereafter. For example, if we are recording a cash withdrawal by Bob, we do not want any chance that the debit to his account will disappear in a crash just after he walks out the bank door. A transactional database guarantees that all the updates made by a transaction are logged in permanent storage (i.e., on disk) before the transaction is reported complete.

Another important property of transactional databases is closely related to the notion of atomic updates: when multiple transactions are running concurrently, each one should not be able to see the incomplete changes made by others. For example, if one transaction is busy totalling all the branch balances, it would not do for it to include the debit from Alice’s branch but not the credit to Bob’s branch, nor vice versa. So transactions must be all-or-nothing not only in terms of their permanent effect on the database, but also in terms of their visibility as they happen. The updates made so far by an open transaction are invisible to other transactions until the transaction completes, whereupon all the updates become visible simultaneously.

In PostgreSQL, a transaction is set up by surrounding the SQL commands of the transaction with `BEGIN` and `COMMIT` commands. So our banking transaction would actually look like:

```
BEGIN;
UPDATE accounts SET balance = balance - 100.00
    WHERE name = 'Alice';
-- etc etc
COMMIT;
```

If, partway through the transaction, we decide we do not want to commit (perhaps we just noticed that Alice’s balance went negative), we can issue the command `ROLLBACK` instead of `COMMIT`, and all our updates so far will be canceled.

PostgreSQL actually treats every SQL statement as being executed within a transaction. If you do not issue a `BEGIN` command, then each individual statement has an implicit `BEGIN` and (if successful) `COMMIT` wrapped around it. A group of statements surrounded by `BEGIN` and `COMMIT` is sometimes called a transaction block.

Note: Some client libraries issue `BEGIN` and `COMMIT` commands automatically, so that you might get the effect of transaction blocks without asking. Check the documentation for the interface you are using.

It’s possible to control the statements in a transaction in a more granular fashion through the use of savepoints. Savepoints allow you to selectively discard parts of the transaction, while committing the rest. After defining a savepoint with `SAVEPOINT`, you can if needed roll back to the savepoint with `ROLLBACK TO`. All the transaction’s database changes between defining the savepoint and rolling back to it are discarded, but changes earlier than the savepoint are kept.

After rolling back to a savepoint, it continues to be defined, so you can roll back to it several times. Conversely, if you are sure you won’t need to roll back to a particular savepoint again, it can be released, so the system can free some resources. Keep in mind that either releasing or rolling back to a savepoint will automatically release all savepoints that were defined after it.

All this is happening within the transaction block, so none of it is visible to other database sessions. When and if you commit the transaction block, the committed actions become visible as a unit to other sessions, while the rolled-back actions never become visible at all.
Remembering the bank database, suppose we debit $100.00 from Alice’s account, and credit Bob’s account, only to find later that we should have credited Wally’s account. We could do it using savepoints like this:

BEGIN;
UPDATE accounts SET balance = balance - 100.00
    WHERE name = 'Alice';
SAVEPOINT my_savepoint;
UPDATE accounts SET balance = balance + 100.00
    WHERE name = 'Bob';
-- oops ... forget that and use Wally’s account
ROLLBACK TO my_savepoint;
UPDATE accounts SET balance = balance + 100.00
    WHERE name = 'Wally';
COMMIT;

This example is, of course, oversimplified, but there’s a lot of control possible in a transaction block through the use of savepoints. Moreover, ROLLBACK TO is the only way to regain control of a transaction block that was put in aborted state by the system due to an error, short of rolling it back completely and starting again.

3.5. Window Functions

A window function performs a calculation across a set of table rows that are somehow related to the current row. This is comparable to the type of calculation that can be done with an aggregate function. But unlike regular aggregate functions, use of a window function does not cause rows to become grouped into a single output row — the rows retain their separate identities. Behind the scenes, the window function is able to access more than just the current row of the query result.

Here is an example that shows how to compare each employee’s salary with the average salary in his or her department:

```
SELECT depname, empno, salary, avg(salary) OVER (PARTITION BY depname) FROM empsalary;
```

<table>
<thead>
<tr>
<th>depname</th>
<th>empno</th>
<th>salary</th>
<th>avg</th>
</tr>
</thead>
<tbody>
<tr>
<td>develop</td>
<td>11</td>
<td>5200</td>
<td>5020.0000000000000000</td>
</tr>
<tr>
<td>develop</td>
<td>7</td>
<td>4200</td>
<td>5020.0000000000000000</td>
</tr>
<tr>
<td>develop</td>
<td>9</td>
<td>4500</td>
<td>5020.0000000000000000</td>
</tr>
<tr>
<td>develop</td>
<td>8</td>
<td>6000</td>
<td>5020.0000000000000000</td>
</tr>
<tr>
<td>develop</td>
<td>10</td>
<td>5200</td>
<td>5020.0000000000000000</td>
</tr>
<tr>
<td>personnel</td>
<td>5</td>
<td>3500</td>
<td>3700.0000000000000000</td>
</tr>
<tr>
<td>personnel</td>
<td>2</td>
<td>3900</td>
<td>3700.0000000000000000</td>
</tr>
<tr>
<td>sales</td>
<td>3</td>
<td>4800</td>
<td>4866.6666666666666667</td>
</tr>
<tr>
<td>sales</td>
<td>1</td>
<td>5000</td>
<td>4866.6666666666666667</td>
</tr>
<tr>
<td>sales</td>
<td>4</td>
<td>4800</td>
<td>4866.6666666666666667</td>
</tr>
</tbody>
</table>
(10 rows)

The first three output columns come directly from the table empsalary, and there is one output row for each row in the table. The fourth column represents an average taken across all the table rows that have the same depname value as the current row. (This actually is the same function as the regular avg aggregate function, but the OVER clause causes it to be treated as a window function and computed across an appropriate set of rows.)
A window function call always contains an **OVER** clause following the window function’s name and argument(s). This is what syntactically distinguishes it from a regular function or aggregate function. The **OVER** clause determines exactly how the rows of the query are split up for processing by the window function. The **PARTITION BY** list within **OVER** specifies dividing the rows into groups, or partitions, that share the same values of the **PARTITION BY** expression(s). For each row, the window function is computed across the rows that fall into the same partition as the current row.

Although `avg` will produce the same result no matter what order it processes the partition’s rows in, this is not true of all window functions. When needed, you can control that order using **ORDER BY** within **OVER**. Here is an example:

```sql
SELECT depname, empno, salary, rank() OVER (PARTITION BY depname ORDER BY salary DESC) FROM empsalary;
```

<table>
<thead>
<tr>
<th>depname</th>
<th>empno</th>
<th>salary</th>
<th>rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>develop</td>
<td>8</td>
<td>6000</td>
<td>1</td>
</tr>
<tr>
<td>develop</td>
<td>10</td>
<td>5200</td>
<td>2</td>
</tr>
<tr>
<td>develop</td>
<td>11</td>
<td>5200</td>
<td>2</td>
</tr>
<tr>
<td>develop</td>
<td>9</td>
<td>4500</td>
<td>4</td>
</tr>
<tr>
<td>develop</td>
<td>7</td>
<td>4200</td>
<td>5</td>
</tr>
<tr>
<td>personnel</td>
<td>2</td>
<td>3900</td>
<td>1</td>
</tr>
<tr>
<td>personnel</td>
<td>5</td>
<td>3500</td>
<td>2</td>
</tr>
<tr>
<td>sales</td>
<td>1</td>
<td>5000</td>
<td>1</td>
</tr>
<tr>
<td>sales</td>
<td>4</td>
<td>4800</td>
<td>2</td>
</tr>
<tr>
<td>sales</td>
<td>3</td>
<td>4800</td>
<td>2</td>
</tr>
</tbody>
</table>

(10 rows)

As shown here, the `rank` function produces a numerical rank within the current row’s partition for each distinct **ORDER BY** value, in the order defined by the **ORDER BY** clause. `rank` needs no explicit parameter, because its behavior is entirely determined by the **OVER** clause.

The rows considered by a window function are those of the “virtual table” produced by the query’s **FROM** clause as filtered by its **WHERE**, **GROUP BY**, and **HAVING** clauses if any. For example, a row removed because it does not meet the **WHERE** condition is not seen by any window function. A query can contain multiple window functions that slice up the data in different ways by means of different **OVER** clauses, but they all act on the same collection of rows defined by this virtual table.

We already saw that **ORDER BY** can be omitted if the ordering of rows is not important. It is also possible to omit **PARTITION BY**, in which case there is just one partition containing all the rows.

There is another important concept associated with window functions: for each row, there is a set of rows within its partition called its **window frame**. Many (but not all) window functions act only on the rows of the window frame, rather than of the whole partition. By default, if **ORDER BY** is supplied then the frame consists of all rows from the start of the partition up through the current row, plus any following rows that are equal to the current row according to the **ORDER BY** clause. When **ORDER BY** is omitted the default frame consists of all rows in the partition. ¹ Here is an example using `sum`:

```sql
SELECT salary, sum(salary) OVER () FROM empsalary;
```

<table>
<thead>
<tr>
<th>salary</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>5200</td>
<td>47100</td>
</tr>
<tr>
<td>5000</td>
<td>47100</td>
</tr>
<tr>
<td>3500</td>
<td>47100</td>
</tr>
<tr>
<td>4800</td>
<td>47100</td>
</tr>
</tbody>
</table>

¹ There are options to define the window frame in other ways, but this tutorial does not cover them. See Section 4.2.8 for details.
Above, since there is no `ORDER BY` in the `OVER` clause, the window frame is the same as the partition, which for lack of `PARTITION BY` is the whole table; in other words each sum is taken over the whole table and so we get the same result for each output row. But if we add an `ORDER BY` clause, we get very different results:

```sql
SELECT salary, sum(salary) OVER (ORDER BY salary) FROM empsalary;
```

<table>
<thead>
<tr>
<th>salary</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>3500</td>
<td>3500</td>
</tr>
<tr>
<td>3900</td>
<td>7400</td>
</tr>
<tr>
<td>4200</td>
<td>11600</td>
</tr>
<tr>
<td>4500</td>
<td>16100</td>
</tr>
<tr>
<td>4800</td>
<td>25700</td>
</tr>
<tr>
<td>4800</td>
<td>25700</td>
</tr>
<tr>
<td>5000</td>
<td>30700</td>
</tr>
<tr>
<td>5200</td>
<td>41100</td>
</tr>
<tr>
<td>5200</td>
<td>41100</td>
</tr>
<tr>
<td>6000</td>
<td>47100</td>
</tr>
</tbody>
</table>

(10 rows)

Here the sum is taken from the first (lowest) salary up through the current one, including any duplicates of the current one (notice the results for the duplicated salaries).

Window functions are permitted only in the `SELECT` list and the `ORDER BY` clause of the query. They are forbidden elsewhere, such as in `GROUP BY`, `HAVING` and `WHERE` clauses. This is because they logically execute after the processing of those clauses. Also, window functions execute after regular aggregate functions. This means it is valid to include an aggregate function call in the arguments of a window function, but not vice versa.

If there is a need to filter or group rows after the window calculations are performed, you can use a sub-select. For example:

```sql
SELECT depname, empno, salary, enroll_date
FROM
  (SELECT depname, empno, salary, enroll_date,
   rank() OVER (PARTITION BY depname ORDER BY salary DESC, empno) AS pos
   FROM empsalary
  ) AS ss
WHERE pos < 3;
```

The above query only shows the rows from the inner query having `rank` less than 3.

When a query involves multiple window functions, it is possible to write out each one with a separate `OVER` clause, but this is duplicative and error-prone if the same windowing behavior is wanted for several functions. Instead, each windowing behavior can be named in a `WINDOW` clause and then referenced in `OVER`. For example:

```sql
SELECT sum(salary) OVER w, avg(salary) OVER w
FROM empsalary
```
Chapter 3. Advanced Features

WINDOW w AS (PARTITION BY depname ORDER BY salary DESC);

More details about window functions can be found in Section 4.2.8, Section 7.2.4, and the SELECT reference page.

3.6. Inheritance

Inheritance is a concept from object-oriented databases. It opens up interesting new possibilities of database design.

Let’s create two tables: A table cities and a table capitals. Naturally, capitals are also cities, so you want some way to show the capitals implicitly when you list all cities. If you’re really clever you might invent some scheme like this:

```sql
CREATE TABLE capitals {
    name text,
    population real,
    altitude int, -- (in ft)
    state char(2)
};

CREATE TABLE non_capitals {
    name text,
    population real,
    altitude int -- (in ft)
};

CREATE VIEW cities AS
    SELECT name, population, altitude FROM capitals
    UNION
    SELECT name, population, altitude FROM non_capitals;
```

This works OK as far as querying goes, but it gets ugly when you need to update several rows, for one thing.

A better solution is this:

```sql
CREATE TABLE cities {
    name text,
    population real,
    altitude int -- (in ft)
};

CREATE TABLE capitals {
    state char(2)
} INHERITS (cities);
```

In this case, a row of capitals inherits all columns (name, population, and altitude) from its parent, cities. The type of the column name is text, a native PostgreSQL type for variable length character strings. State capitals have an extra column, state, that shows their state. In PostgreSQL, a table can inherit from zero or more other tables.
For example, the following query finds the names of all cities, including state capitals, that are located at an altitude over 500 feet:

```sql
SELECT name, altitude
FROM cities
WHERE altitude > 500;
```

which returns:

<table>
<thead>
<tr>
<th>name</th>
<th>altitude</th>
</tr>
</thead>
<tbody>
<tr>
<td>Las Vegas</td>
<td>2174</td>
</tr>
<tr>
<td>Mariposa</td>
<td>1953</td>
</tr>
<tr>
<td>Madison</td>
<td>845</td>
</tr>
</tbody>
</table>

(3 rows)

On the other hand, the following query finds all the cities that are not state capitals and are situated at an altitude of 500 feet or higher:

```sql
SELECT name, altitude
FROM ONLY cities
WHERE altitude > 500;
```

<table>
<thead>
<tr>
<th>name</th>
<th>altitude</th>
</tr>
</thead>
<tbody>
<tr>
<td>Las Vegas</td>
<td>2174</td>
</tr>
<tr>
<td>Mariposa</td>
<td>1953</td>
</tr>
</tbody>
</table>

(2 rows)

Here the `ONLY` before `cities` indicates that the query should be run over only the `cities` table, and not tables below `cities` in the inheritance hierarchy. Many of the commands that we have already discussed — `SELECT`, `UPDATE`, and `DELETE` — support this `ONLY` notation.

Note: Although inheritance is frequently useful, it has not been integrated with unique constraints or foreign keys, which limits its usefulness. See Section 5.8 for more detail.

### 3.7. Conclusion

PostgreSQL has many features not touched upon in this tutorial introduction, which has been oriented toward newer users of SQL. These features are discussed in more detail in the remainder of this book.

If you feel you need more introductory material, please visit the PostgreSQL web site\(^2\) for links to more resources.

\(^2\) http://www.postgresql.org
II. The SQL Language

This part describes the use of the SQL language in PostgreSQL. We start with describing the general syntax of SQL, then explain how to create the structures to hold data, how to populate the database, and how to query it. The middle part lists the available data types and functions for use in SQL commands. The rest treats several aspects that are important for tuning a database for optimal performance.

The information in this part is arranged so that a novice user can follow it start to end to gain a full understanding of the topics without having to refer forward too many times. The chapters are intended to be self-contained, so that advanced users can read the chapters individually as they choose. The information in this part is presented in a narrative fashion in topical units. Readers looking for a complete description of a particular command should see Part VI.

Readers of this part should know how to connect to a PostgreSQL database and issue SQL commands. Readers that are unfamiliar with these issues are encouraged to read Part I first. SQL commands are typically entered using the PostgreSQL interactive terminal psql, but other programs that have similar functionality can be used as well.
Chapter 4. SQL Syntax

This chapter describes the syntax of SQL. It forms the foundation for understanding the following chapters which will go into detail about how SQL commands are applied to define and modify data.

We also advise users who are already familiar with SQL to read this chapter carefully because it contains several rules and concepts that are implemented inconsistently among SQL databases or that are specific to PostgreSQL.

4.1. Lexical Structure

SQL input consists of a sequence of commands. A command is composed of a sequence of tokens, terminated by a semicolon (";"). The end of the input stream also terminates a command. Which tokens are valid depends on the syntax of the particular command.

A token can be a key word, an identifier, a quoted identifier, a literal (or constant), or a special character symbol. Tokens are normally separated by whitespace (space, tab, newline), but need not be if there is no ambiguity (which is generally only the case if a special character is adjacent to some other token type).

Additionally, comments can occur in SQL input. They are not tokens, they are effectively equivalent to whitespace.

For example, the following is (syntactically) valid SQL input:

```
SELECT * FROM MY_TABLE;
UPDATE MY_TABLE SET A = 5;
INSERT INTO MY_TABLE VALUES (3, 'hi there');
```

This is a sequence of three commands, one per line (although this is not required; more than one command can be on a line, and commands can usefully be split across lines).

The SQL syntax is not very consistent regarding what tokens identify commands and which are operands or parameters. The first few tokens are generally the command name, so in the above example we would usually speak of a “SELECT”, an “UPDATE”, and an “INSERT” command. But for instance the UPDATE command always requires a SET token to appear in a certain position, and this particular variation of INSERT also requires a VALUES in order to be complete. The precise syntax rules for each command are described in Part VI.

4.1.1. Identifiers and Key Words

Tokens such as SELECT, UPDATE, or VALUES in the example above are examples of key words, that is, words that have a fixed meaning in the SQL language. The tokens MY_TABLE and A are examples of identifiers. They identify names of tables, columns, or other database objects, depending on the command they are used in. Therefore they are sometimes simply called “names”. Key words and identifiers have the same lexical structure, meaning that one cannot know whether a token is an identifier or a key word without knowing the language. A complete list of key words can be found in Appendix C.

SQL identifiers and key words must begin with a letter (a-z, but also letters with diacritical marks and non-Latin letters) or an underscore (_). Subsequent characters in an identifier or key word can be letters, underscores, digits (0-9), or dollar signs ($). Note that dollar signs are not allowed in identifiers according to the letter of the SQL standard, so their use might render applications less portable. The
SQL standard will not define a key word that contains digits or starts or ends with an underscore, so identifiers of this form are safe against possible conflict with future extensions of the standard.

The system uses no more than \texttt{NAMEDATALEN}-1 bytes of an identifier; longer names can be written in commands, but they will be truncated. By default, \texttt{NAMEDATALEN} is 64 so the maximum identifier length is 63 bytes. If this limit is problematic, it can be raised by changing the \texttt{NAMEDATALEN} constant in \texttt{src/include/pg_config_manual.h}.

Identifier and key word names are case insensitive. Therefore:

\begin{verbatim}
UPDATE MY_TABLE SET A = 5;
\end{verbatim}

can equivalently be written as:

\begin{verbatim}
uPDaTE my_TabLE SeT a = 5;
\end{verbatim}

A convention often used is to write key words in upper case and names in lower case, e.g.:

\begin{verbatim}
UPDATE my_table SET a = 5;
\end{verbatim}

There is a second kind of identifier: the delimited identifier or quoted identifier. It is formed by enclosing an arbitrary sequence of characters in double-quotes ("). A delimited identifier is always an identifier, never a key word. So "select" could be used to refer to a column or table named “select”, whereas an unquoted select would be taken as a key word and would therefore provoke a parse error when used where a table or column name is expected. The example can be written with quoted identifiers like this:

\begin{verbatim}
UPDATE "my_table" SET "a" = 5;
\end{verbatim}

Quoted identifiers can contain any character, except the character with code zero. (To include a double quote, write two double quotes.) This allows constructing table or column names that would otherwise not be possible, such as ones containing spaces or ampersands. The length limitation still applies.

A variant of quoted identifiers allows including escaped Unicode characters identified by their code points. This variant starts with \texttt{U&} (upper or lower case U followed by ampersand) immediately before the opening double quote, without any spaces in between, for example \texttt{U&"foo"}. (Note that this creates an ambiguity with the operator \texttt{&}. Use spaces around the operator to avoid this problem.) Inside the quotes, Unicode characters can be specified in escaped form by writing a backslash followed by the four-digit hexadecimal code point number or alternatively a backslash followed by a plus sign followed by a six-digit hexadecimal code point number. For example, the identifier "data" could be written as

\begin{verbatim}
U&"d\0061t\+000061"
\end{verbatim}

The following less trivial example writes the Russian word “слон” (elephant) in Cyrillic letters:

\begin{verbatim}
U&"\0441\043B\043E\043D"
\end{verbatim}

If a different escape character than backslash is desired, it can be specified using the \texttt{UESCAPE} clause after the string, for example:

\begin{verbatim}
U&"d\0061t\+000061" UESCAPE '\'
\end{verbatim}
Chapter 4. SQL Syntax

The escape character can be any single character other than a hexadecimal digit, the plus sign, a single quote, a double quote, or a whitespace character. Note that the escape character is written in single quotes, not double quotes.

To include the escape character in the identifier literally, write it twice.

The Unicode escape syntax works only when the server encoding is UTF8. When other server encodings are used, only code points in the ASCII range (up to \007F) can be specified.

Quoting an identifier also makes it case-sensitive, whereas unquoted names are always folded to lower case. For example, the identifiers FOO, foo, and "foo" are considered the same by PostgreSQL, but "Foo" and "FOO" are different from these three and each other. (The folding of unquoted names to lower case in PostgreSQL is incompatible with the SQL standard, which says that unquoted names should be folded to upper case. Thus, foo should be equivalent to "FOO" not "foo" according to the standard. If you want to write portable applications you are advised to always quote a particular name or never quote it.)

4.1.2. Constants

There are three kinds of implicitly-typed constants in PostgreSQL: strings, bit strings, and numbers. Constants can also be specified with explicit types, which can enable more accurate representation and more efficient handling by the system. These alternatives are discussed in the following subsections.

4.1.2.1. String Constants

A string constant in SQL is an arbitrary sequence of characters bounded by single quotes ('), for example 'This is a string'. To include a single-quote character within a string constant, write two adjacent single quotes, e.g., 'Dianne''s horse'. Note that this is not the same as a double-quote character (").

Two string constants that are only separated by whitespace with at least one newline are concatenated and effectively treated as if the string had been written as one constant. For example:

SELECT 'foo'
     'bar';

is equivalent to:

SELECT 'foobar';

but:

SELECT 'foo'    'bar';

is not valid syntax. (This slightly bizarre behavior is specified by SQL; PostgreSQL is following the standard.)

4.1.2.2. String Constants with C-Style Escapes

PostgreSQL also accepts "escape" string constants, which are an extension to the SQL standard. An escape string constant is specified by writing the letter E (upper or lower case) just before the opening single quote, e.g., E'foo'. (When continuing an escape string constant across lines, write E only before the first opening quote.) Within an escape string, a backslash character (\) begins a
C-like *backslash escape* sequence, in which the combination of backslash and following character(s) represent a special byte value, as shown in Table 4-1.

### Table 4-1. Backslash Escape Sequences

<table>
<thead>
<tr>
<th>Backslash Escape Sequence</th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td>\b</td>
<td>backspace</td>
</tr>
<tr>
<td>\f</td>
<td>form feed</td>
</tr>
<tr>
<td>\n</td>
<td>newline</td>
</tr>
<tr>
<td>\r</td>
<td>carriage return</td>
</tr>
<tr>
<td>\t</td>
<td>tab</td>
</tr>
<tr>
<td>\a, \oo, \ooo (a = 0 - 7)</td>
<td>octal byte value</td>
</tr>
<tr>
<td>\xb, \xbb (h = 0 - 9, A - F)</td>
<td>hexadecimal byte value</td>
</tr>
</tbody>
</table>

Any other character following a backslash is taken literally. Thus, to include a backslash character, write two backslashes (\`). Also, a single quote can be included in an escape string by writing `\'`, in addition to the normal way of “”.

It is your responsibility that the byte sequences you create are valid characters in the server character set encoding. When the server encoding is UTF-8, then the alternative Unicode escape syntax, explained in Section 4.1.2.3, should be used instead. (The alternative would be doing the UTF-8 encoding by hand and writing out the bytes, which would be very cumbersome.)

---

**Caution**

If the configuration parameter `standard_conforming_strings` is off, then PostgreSQL recognizes backslash escapes in both regular and escape string constants. This is for backward compatibility with the historical behavior, where backslash escapes were always recognized. Although `standard_conforming_strings` currently defaults to off, the default will change to on in a future release for improved standards compliance. Applications are therefore encouraged to migrate away from using backslash escapes. If you need to use a backslash escape to represent a special character, write the string constant with an E to be sure it will be handled the same way in future releases.

In addition to `standard_conforming_strings`, the configuration parameters `escape_string_warning` and `backslash_quote` govern treatment of backslashes in string constants.

The character with the code zero cannot be in a string constant.

### 4.1.2.3. String Constants with Unicode Escapes

PostgreSQL also supports another type of escape syntax for strings that allows specifying arbitrary Unicode characters by code point. A Unicode escape string constant starts with `U&` (upper or lower case letter U followed by ampersand) immediately before the opening quote, without any spaces in between, for example `U&’foo’`. (Note that this creates an ambiguity with the operator &. Use spaces around the operator to avoid this problem.) Inside the quotes, Unicode characters can be specified in escaped form by writing a backslash followed by the four-digit hexadecimal code point number or alternatively a backslash followed by a plus sign followed by a six-digit hexadecimal code point number.
number. For example, the string ‘data’ could be written as

U$'d\0061t\+000061$

The following less trivial example writes the Russian word “slon” (elephant) in Cyrillic letters:

U$'\0441\043B\043E\043D'$

If a different escape character than backslash is desired, it can be specified using the \texttt{UESCAPE} clause after the string, for example:

U$'d!0061t!+000061$ UESCAPE ‘!’

The escape character can be any single character other than a hexadecimal digit, the plus sign, a single quote, a double quote, or a whitespace character.

The Unicode escape syntax works only when the server encoding is UTF8. When other server encodings are used, only code points in the ASCII range (up to \texttt{\007F}) can be specified.

Also, the Unicode escape syntax for string constants only works when the configuration parameter \texttt{standard_conforming_strings} is turned on. This is because otherwise this syntax could confuse clients that parse the SQL statements to the point that it could lead to SQL injections and similar security issues. If the parameter is set to off, this syntax will be rejected with an error message.

To include the escape character in the string literally, write it twice.

4.1.2.4. Dollar-Quoted String Constants

While the standard syntax for specifying string constants is usually convenient, it can be difficult to understand when the desired string contains many single quotes or backslashes, since each of those must be doubled. To allow more readable queries in such situations, PostgreSQL provides another way, called “dollar quoting”, to write string constants. A dollar-quoted string constant consists of a dollar sign ($), an optional “tag” of zero or more characters, another dollar sign, an arbitrary sequence of characters that makes up the string content, a dollar sign, the same tag that began this dollar quote, and a dollar sign. For example, here are two different ways to specify the string “Dianne’s horse” using dollar quoting:

$$Dianne’s horse$$

$SomeTag$Dianne’s horse$SomeTag$

Notice that inside the dollar-quoted string, single quotes can be used without needing to be escaped. Indeed, no characters inside a dollar-quoted string are ever escaped: the string content is always written literally. Backslashes are not special, and neither are dollar signs, unless they are part of a sequence matching the opening tag.

It is possible to nest dollar-quoted string constants by choosing different tags at each nesting level. This is most commonly used in writing function definitions. For example:

$\texttt{function}$

BEGIN
  RETURN ($1 \sim $q$\[	\r\n\v\\$]q$);
END;
$\texttt{function}$
Here, the sequence $q$ represents a dollar-quoted literal string \$(\text{\textbackslash t\textbackslash r\textbackslash n\textbackslash v\textbackslash n})q\$, which will be recognized when the function body is executed by PostgreSQL. But since the sequence does not match the outer dollar quoting delimiter $function$, it is just some more characters within the constant so far as the outer string is concerned.

The tag, if any, of a dollar-quoted string follows the same rules as an unquoted identifier, except that it cannot contain a dollar sign. Tags are case sensitive, so $tag$String content$tag$ is correct, but $TAG$String content$tag$ is not.

A dollar-quoted string that follows a keyword or identifier must be separated from it by whitespace; otherwise the dollar quoting delimiter would be taken as part of the preceding identifier.

Dollar quoting is not part of the SQL standard, but it is often a more convenient way to write complicated string literals than the standard-compliant single quote syntax. It is particularly useful when representing string constants inside other constants, as is often needed in procedural function definitions. With single-quote syntax, each backslash in the above example would have to be written as four backslashes, which would be reduced to two backslashes in parsing the original string constant, and then to one when the inner string constant is re-parsed during function execution.

### 4.1.2.5. Bit-String Constants

Bit-string constants look like regular string constants with a B (upper or lower case) immediately before the opening quote (no intervening whitespace), e.g., B'1001'. The only characters allowed within bit-string constants are 0 and 1.

Alternatively, bit-string constants can be specified in hexadecimal notation, using a leading X (upper or lower case), e.g., X'1FF'. This notation is equivalent to a bit-string constant with four binary digits for each hexadecimal digit.

Both forms of bit-string constant can be continued across lines in the same way as regular string constants. Dollar quoting cannot be used in a bit-string constant.

### 4.1.2.6. Numeric Constants

Numeric constants are accepted in these general forms:

\[
\begin{align*}
\text{digits} \\
\text{digits}.\text{ digits}[\text{e}{+\text{-}}\text{ digits}]
\end{align*}
\]

\[
\begin{align*}
[\text{ digits}].\text{ digits}[\text{e}{+\text{-}}\text{ digits}]
\end{align*}
\]

\[
\begin{align*}
\text{ digits}\text{ e}{+\text{-}}\text{ digits}
\end{align*}
\]

where \text{ digits} is one or more decimal digits (0 through 9). At least one digit must be before or after the decimal point, if one is used. At least one digit must follow the exponent marker (e), if one is present. There cannot be any spaces or other characters embedded in the constant. Note that any leading plus or minus sign is not actually considered part of the constant; it is an operator applied to the constant.

These are some examples of valid numeric constants:

42
3.5
.4
.001
5e2
1.925e-3
A numeric constant that contains neither a decimal point nor an exponent is initially presumed to be type \texttt{integer} if its value fits in type \texttt{integer} (32 bits); otherwise it is presumed to be type \texttt{bigint} if its value fits in type \texttt{bigint} (64 bits); otherwise it is taken to be type \texttt{numeric}. Constants that contain decimal points and/or exponents are always initially presumed to be type \texttt{numeric}.

The initially assigned data type of a numeric constant is just a starting point for the type resolution algorithms. In most cases the constant will be automatically coerced to the most appropriate type depending on context. When necessary, you can force a numeric value to be interpreted as a specific data type by casting it. For example, you can force a numeric value to be treated as type \texttt{real} (\texttt{float4}) by writing:

\begin{verbatim}
REAL '1.23' -- string style
1.23::REAL -- PostgreSQL (historical) style
\end{verbatim}

These are actually just special cases of the general casting notations discussed next.

### 4.1.2.7. Constants of Other Types

A constant of an \textit{arbitrary} type can be entered using any one of the following notations:

- \texttt{type 'string'}
- \texttt{string'::type}
- \texttt{CAST ( 'string' AS type )}

The string constant’s text is passed to the input conversion routine for the type called \texttt{type}. The result is a constant of the indicated type. The explicit type cast can be omitted if there is no ambiguity as to the type the constant must be (for example, when it is assigned directly to a table column), in which case it is automatically coerced.

The string constant can be written using either regular SQL notation or dollar-quoting.

It is also possible to specify a type coercion using a function-like syntax:

\begin{verbatim}
typename ( 'string' )
\end{verbatim}

but not all type names can be used in this way; see Section 4.2.9 for details.

The ::, \texttt{CAST()}, and function-call syntaxes can also be used to specify run-time type conversions of arbitrary expressions, as discussed in Section 4.2.9. To avoid syntactic ambiguity, the \texttt{type 'string'} syntax can only be used to specify the type of a simple literal constant. Another restriction on the \texttt{type 'string'} syntax is that it does not work for array types; use :: or \texttt{CAST()} to specify the type of an array constant.

The \texttt{CAST()} syntax conforms to SQL. The \texttt{type 'string'} syntax is a generalization of the standard: SQL specifies this syntax only for a few data types, but PostgreSQL allows it for all types. The syntax with :: is historical PostgreSQL usage, as is the function-call syntax.

### 4.1.3. Operators

An operator name is a sequence of up to \texttt{NAMEDATALEN-1} (63 by default) characters from the following list:

\begin{verbatim}
+ - * / < > = ~ ! @ # % ^ & | '
\end{verbatim}
There are a few restrictions on operator names, however:

- `--` and `/*` cannot appear anywhere in an operator name, since they will be taken as the start of a comment.
- A multiple-character operator name cannot end in `+` or `-`, unless the name also contains at least one of these characters:
  
  ~ ! @ # % ^ & | ' ?

  For example, `@@` is an allowed operator name, but `*` is not. This restriction allows PostgreSQL to parse SQL-compliant queries without requiring spaces between tokens.

When working with non-SQL-standard operator names, you will usually need to separate adjacent operators with spaces to avoid ambiguity. For example, if you have defined a left unary operator named `@`, you cannot write `X*@Y`; you must write `X* @Y` to ensure that PostgreSQL reads it as two operator names not one.

### 4.1.4. Special Characters

Some characters that are not alphanumeric have a special meaning that is different from being an operator. Details on the usage can be found at the location where the respective syntax element is described. This section only exists to advise the existence and summarize the purposes of these characters.

- A dollar sign (`$`) followed by digits is used to represent a positional parameter in the body of a function definition or a prepared statement. In other contexts the dollar sign can be part of an identifier or a dollar-quoted string constant.
- Parentheses (`()`) have their usual meaning to group expressions and enforce precedence. In some cases parentheses are required as part of the fixed syntax of a particular SQL command.
- Brackets (`[]`) are used to select the elements of an array. See Section 8.14 for more information on arrays.
- Commas (`,`) are used in some syntactical constructs to separate the elements of a list.
- The semicolon (`;`) terminates an SQL command. It cannot appear anywhere within a command, except within a string constant or quoted identifier.
- The colon (`:`) is used to select “slices” from arrays. (See Section 8.14.) In certain SQL dialects (such as Embedded SQL), the colon is used to prefix variable names.
- The asterisk (`*`) is used in some contexts to denote all the fields of a table row or composite value. It also has a special meaning when used as the argument of an aggregate function, namely that the aggregate does not require any explicit parameter.
- The period (`.`) is used in numeric constants, and to separate schema, table, and column names.
4.1.5. Comments

A comment is a sequence of characters beginning with double dashes and extending to the end of the line, e.g.:

```
-- This is a standard SQL comment
```

Alternatively, C-style block comments can be used:

```
/* multiline comment
with nesting: /* nested block comment */
*/
```

where the comment begins with `/*` and extends to the matching occurrence of `*/`. These block comments nest, as specified in the SQL standard but unlike C, so that one can comment out larger blocks of code that might contain existing block comments.

A comment is removed from the input stream before further syntax analysis and is effectively replaced by whitespace.

4.1.6. Lexical Precedence

Table 4-2 shows the precedence and associativity of the operators in PostgreSQL. Most operators have the same precedence and are left-associative. The precedence and associativity of the operators is hard-wired into the parser. This can lead to non-intuitive behavior; for example the Boolean operators `<` and `>` have a different precedence than the Boolean operators `<=` and `>=`. Also, you will sometimes need to add parentheses when using combinations of binary and unary operators. For instance:

```
SELECT 5 ! - 6;
```

will be parsed as:

```
SELECT 5 ! (- 6);
```

because the parser has no idea — until it is too late — that `!` is defined as a postfix operator, not an infix one. To get the desired behavior in this case, you must write:

```
SELECT (5 !) - 6;
```

This is the price one pays for extensibility.

Table 4-2. Operator Precedence (decreasing)

<table>

</tr>
</tbody>
</table>

Note that the operator precedence rules also apply to user-defined operators that have the same names as the built-in operators mentioned above. For example, if you define a “+” operator for some custom data type it will have the same precedence as the built-in “+” operator, no matter what yours does.

When a schema-qualified operator name is used in the OPERATOR syntax, as for example in:

```
SELECT 3 OPERATOR(pg_catalog.+) 4;
```

the OPERATOR construct is taken to have the default precedence shown in Table 4-2 for “any other” operator. This is true no matter which specific operator appears inside OPERATOR().

### 4.2. Value Expressions

Value expressions are used in a variety of contexts, such as in the target list of the SELECT command, as new column values in INSERT or UPDATE, or in search conditions in a number of commands. The result of a value expression is sometimes called a scalar, to distinguish it from the result of a table expression (which is a table). Value expressions are therefore also called scalar expressions (or even simply expressions). The expression syntax allows the calculation of values from primitive parts using arithmetic, logical, set, and other operations.

A value expression is one of the following:

- A constant or literal value
- A column reference
- A positional parameter reference, in the body of a function definition or prepared statement
- A subexpressed selection
- A field selection expression
- An operator invocation
- A function call
• An aggregate expression
• A window function call
• A type cast
• A scalar subquery
• An array constructor
• A row constructor
• Another value expression in parentheses (used to group subexpressions and override precedence)

In addition to this list, there are a number of constructs that can be classified as an expression but do not follow any general syntax rules. These generally have the semantics of a function or operator and are explained in the appropriate location in Chapter 9. An example is the IS NULL clause.

We have already discussed constants in Section 4.1.2. The following sections discuss the remaining options.

### 4.2.1. Column References

A column can be referenced in the form:

```
correlation.columnname
```

`correlation` is the name of a table (possibly qualified with a schema name), or an alias for a table defined by means of a `FROM` clause, or one of the key words `NEW` or `OLD`. (`NEW` and `OLD` can only appear in rewrite rules, while other correlation names can be used in any SQL statement.) The correlation name and separating dot can be omitted if the column name is unique across all the tables being used in the current query. (See also Chapter 7.)

### 4.2.2. Positional Parameters

A positional parameter reference is used to indicate a value that is supplied externally to an SQL statement. Parameters are used in SQL function definitions and in prepared queries. Some client libraries also support specifying data values separately from the SQL command string, in which case parameters are used to refer to the out-of-line data values. The form of a parameter reference is:

```
$number
```

For example, consider the definition of a function, `dept`, as:

```sql
CREATE FUNCTION dept(text) RETURNS dept
    AS $$ SELECT * FROM dept WHERE name = $1 $$
    LANGUAGE SQL;
```

Here the `$1` references the value of the first function argument whenever the function is invoked.
4.2.3. Subscripts

If an expression yields a value of an array type, then a specific element of the array value can be extracted by writing

\[ \text{expression}[\text{subscript}] \]

or multiple adjacent elements (an “array slice”) can be extracted by writing

\[ \text{expression}[\text{lower_subscript} : \text{upper_subscript}] \]

(Here, the brackets \([\ ]\) are meant to appear literally.) Each \textit{subscript} is itself an expression, which must yield an integer value.

In general the array \textit{expression} must be parenthesized, but the parentheses can be omitted when the expression to be subscripted is just a column reference or positional parameter. Also, multiple subscripts can be concatenated when the original array is multidimensional. For example:

- \texttt{mytable.arraycolumn[4]}
- \texttt{mytable.two_d_column[17][34]}
- \texttt{$1[10:42]}
- \texttt{(arrayfunction(a,b))[42]}

The parentheses in the last example are required. See Section 8.14 for more about arrays.

4.2.4. Field Selection

If an expression yields a value of a composite type (row type), then a specific field of the row can be extracted by writing

\[ \text{expression}.\text{fieldname} \]

In general the row \textit{expression} must be parenthesized, but the parentheses can be omitted when the expression to be selected from is just a table reference or positional parameter. For example:

- \texttt{mytable.mycolumn}
- \texttt{$1.somecolumn}
- \texttt{(rowfunction(a,b)).col3}

(Thus, a qualified column reference is actually just a special case of the field selection syntax.) An important special case is extracting a field from a table column that is of a composite type:

- \texttt{(compositecol).somefield}
- \texttt{(mytable.compositecol).somefield}

The parentheses are required here to show that \texttt{compositecol} is a column name not a table name, or that \texttt{mytable} is a table name not a schema name in the second case.

4.2.5. Operator Invocations

There are three possible syntaxes for an operator invocation:

\[ \text{expression} \text{ operator} \text{ expression} \] (binary infix operator)
Chapter 4. SQL Syntax

operator expression (unary prefix operator)

expression operator (unary postfix operator)

where the operator token follows the syntax rules of Section 4.1.3, or is one of the key words AND, OR, and NOT, or is a qualified operator name in the form:

OPERATOR(schema, operatorname)

Which particular operators exist and whether they are unary or binary depends on what operators have been defined by the system or the user. Chapter 9 describes the built-in operators.

4.2.6. Function Calls

The syntax for a function call is the name of a function (possibly qualified with a schema name), followed by its argument list enclosed in parentheses:

function_name ([expression [, expression ... ]])

For example, the following computes the square root of 2:

sqrt(2)

The list of built-in functions is in Chapter 9. Other functions can be added by the user.

4.2.7. Aggregate Expressions

An aggregate expression represents the application of an aggregate function across the rows selected by a query. An aggregate function reduces multiple inputs to a single output value, such as the sum or average of the inputs. The syntax of an aggregate expression is one of the following:

aggregate_name (expression [ , ... ])
aggregate_name (ALL expression [ , ... ])
aggregate_name (DISTINCT expression)
aggregate_name ( *)

where aggregate_name is a previously defined aggregate (possibly qualified with a schema name), and expression is any value expression that does not itself contain an aggregate expression or a window function call.

The first form of aggregate expression invokes the aggregate across all input rows for which the given expression(s) yield non-null values. (Actually, it is up to the aggregate function whether to ignore null values or not — but all the standard ones do.) The second form is the same as the first, since ALL is the default. The third form invokes the aggregate for all distinct non-null values of the expressions found in the input rows. The last form invokes the aggregate once for each input row regardless of null or non-null values; since no particular input value is specified, it is generally only useful for the count(*) aggregate function.

For example, count(*) yields the total number of input rows; count(f1) yields the number of input rows in which f1 is non-null; count(different f1) yields the number of distinct non-null values of f1.
The predefined aggregate functions are described in Section 9.18. Other aggregate functions can be added by the user.

An aggregate expression can only appear in the result list or HAVING clause of a SELECT command. It is forbidden in other clauses, such as WHERE, because those clauses are logically evaluated before the results of aggregates are formed.

When an aggregate expression appears in a subquery (see Section 4.2.10 and Section 9.20), the aggregate is normally evaluated over the rows of the subquery. But an exception occurs if the aggregate’s arguments contain only outer-level variables: the aggregate then belongs to the nearest such outer level, and is evaluated over the rows of that query. The aggregate expression as a whole is then an outer reference for the subquery it appears in, and acts as a constant over any one evaluation of that subquery. The restriction about appearing only in the result list or HAVING clause applies with respect to the query level that the aggregate belongs to.

Note: PostgreSQL currently does not support DISTINCT with more than one input expression.

### 4.2.8. Window Function Calls

A window function call represents the application of an aggregate-like function over some portion of the rows selected by a query. Unlike regular aggregate function calls, this is not tied to grouping of the selected rows into a single output row — each row remains separate in the query output. However the window function is able to scan all the rows that would be part of the current row’s group according to the grouping specification (PARTITION BY list) of the window function call. The syntax of a window function call is one of the following:

```
function_name ([expression [, expression ... ]]) OVER window_name
function_name ([expression [, expression ... ]]) OVER (window_definition)
function_name ( * ) OVER window_name
function_name ( * ) OVER (window_definition)
```

where window_definition has the syntax

```
[ existing_window_name ]
[ PARTITION BY expression [, ...] ]
[ ORDER BY expression [ASC | DESC | USING operator] [NULLS {FIRST | LAST }] [, ...]]
[ frame_clause ]
```

and the optional frame_clause can be one of

- RANGE UNBOUNDED PRECEDING
- RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW
- RANGE BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING
- ROWS UNBOUNDED PRECEDING
- ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW
- ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING

Here, expression represents any value expression that does not itself contain window function calls. The PARTITION BY and ORDER BY lists have essentially the same syntax and semantics as GROUP BY and ORDER BY clauses of the whole query, except that their expressions are always just expressions and cannot be output-column names or numbers. window_name is a reference to a named window specification defined in the query’s WINDOW clause. Alternatively, a full window_definition can be given within parentheses, using the same syntax as for defining a named window in the WINDOW
clause; see the SELECT reference page for details. It’s worth pointing out that `OVER (wname)` is not exactly equivalent to `OVER wname`; the latter implies copying and modifying the window definition, and will be rejected if the referenced window specification includes a frame clause.

The frame clause specifies the set of rows constituting the window frame, for those window functions that act on the frame instead of the whole partition. The default framing option is RANGE UNBOUNDED PRECEDING, which is the same as RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW; it selects rows up through the current row’s last peer in the ORDER BY ordering (which means all rows if there is no ORDER BY). The options RANGE BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING and ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING are also equivalent: they always select all rows in the partition. Lastly, ROWS UNBOUNDED PRECEDING or its verbose equivalent ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW select all rows up through the current row (regardless of duplicates). Beware that this option can produce implementation-dependent results if the ORDER BY ordering does not order the rows uniquely.

The built-in window functions are described in Table 9-44. Other window functions can be added by the user. Also, any built-in or user-defined aggregate function can be used as a window function.

The syntaxes using `*` are used for calling parameter-less aggregate functions as window functions, for example `count(*) OVER (PARTITION BY x ORDER BY y)`. `*` is customarily not used for non-aggregate window functions. Aggregate window functions, unlike normal aggregate functions, do not allow `DISTINCT` to be used within the function argument list.

Window function calls are permitted only in the SELECT list and the ORDER BY clause of the query.

More information about window functions can be found in Section 3.5 and Section 7.2.4.

### 4.2.9. Type Casts

A type cast specifies a conversion from one data type to another. PostgreSQL accepts two equivalent syntaxes for type casts:

```
CAST ( expression AS type )
```

```
expression::type
```

The CAST syntax conforms to SQL; the syntax with '::' is historical PostgreSQL usage.

When a cast is applied to a value expression of a known type, it represents a run-time type conversion. The cast will succeed only if a suitable type conversion operation has been defined. Notice that this is subtly different from the use of casts with constants, as shown in Section 4.1.2.7. A cast applied to an unadorned string literal represents the initial assignment of a type to a literal constant value, and so it will succeed for any type (if the contents of the string literal are acceptable input syntax for the data type).

An explicit type cast can usually be omitted if there is no ambiguity as to the type that a value expression must produce (for example, when it is assigned to a table column); the system will automatically apply a type cast in such cases. However, automatic casting is only done for casts that are marked “OK to apply implicitly” in the system catalogs. Other casts must be invoked with explicit casting syntax. This restriction is intended to prevent surprising conversions from being applied silently.

It is also possible to specify a type cast using a function-like syntax:

```
typename ( expression )
```

However, this only works for types whose names are also valid as function names. For example, `double precision` cannot be used this way, but the equivalent `float8` can. Also, the names
interval, time, and timestamp can only be used in this fashion if they are double-quoted, because of syntactic conflicts. Therefore, the use of the function-like cast syntax leads to inconsistencies and should probably be avoided.

**Note:** The function-like syntax is in fact just a function call. When one of the two standard cast syntaxes is used to do a run-time conversion, it will internally invoke a registered function to perform the conversion. By convention, these conversion functions have the same name as their output type, and thus the “function-like syntax” is nothing more than a direct invocation of the underlying conversion function. Obviously, this is not something that a portable application should rely on. For further details see `CREATE CAST`.

### 4.2.10. Scalar Subqueries

A scalar subquery is an ordinary `SELECT` query in parentheses that returns exactly one row with one column. (See Chapter 7 for information about writing queries.) The `SELECT` query is executed and the single returned value is used in the surrounding value expression. It is an error to use a query that returns more than one row or more than one column as a scalar subquery. (But if, during a particular execution, the subquery returns no rows, there is no error; the scalar result is taken to be null.) The subquery can refer to variables from the surrounding query, which will act as constants during any one evaluation of the subquery. See also Section 9.20 for other expressions involving subqueries.

For example, the following finds the largest city population in each state:

```sql
SELECT name, (SELECT max(pop) FROM cities WHERE cities.state = states.name) 
FROM states;
```

### 4.2.11. Array Constructors

An array constructor is an expression that builds an array value using values for its member elements. A simple array constructor consists of the key word `ARRAY`, a left square bracket `[`, a list of expressions (separated by commas) for the array element values, and finally a right square bracket `]`. For example:

```sql
SELECT ARRAY[1,2,3+4];
array
----
{1,2,7}
(1 row)
```

By default, the array element type is the common type of the member expressions, determined using the same rules as for `UNION` or `CASE` constructs (see Section 10.5). You can override this by explicitly casting the array constructor to the desired type, for example:

```sql
SELECT ARRAY[1,2,22.7]::integer[];
array
----------
{1,2,23}
(1 row)
```
This has the same effect as casting each expression to the array element type individually. For more on casting, see Section 4.2.9.

Multidimensional array values can be built by nesting array constructors. In the inner constructors, the key word ARRAY can be omitted. For example, these produce the same result:

```sql
SELECT ARRAY[ARRAY[1, 2], ARRAY[3, 4]];
  array
     ------------
    (1 row)

SELECT ARRAY[[1, 2], [3, 4]];
  array
     ------------
    (1 row)
```

Since multidimensional arrays must be rectangular, inner constructors at the same level must produce sub-arrays of identical dimensions. Any cast applied to the outer ARRAY constructor propagates automatically to all the inner constructors.

Multidimensional array constructor elements can be anything yielding an array of the proper kind, not only a sub-ARRAY construct. For example:

```sql
CREATE TABLE arr(f1 int[], f2 int[]);

INSERT INTO arr VALUES (ARRAY[[1, 2], [3, 4]], ARRAY[[5, 6], [7, 8]]);

SELECT ARRAY[f1, f2, '{{9,10},{11,12}}::int[]] FROM arr;
  array
    ----------------------------
   {{1,2},{3,4}},{{5,6},{7,8}},{{9,10},{11,12}}
 (1 row)
```

You can construct an empty array, but since it’s impossible to have an array with no type, you must explicitly cast your empty array to the desired type. For example:

```sql
SELECT ARRAY[]::integer[];
  array
    -----
   ()
 (1 row)
```

It is also possible to construct an array from the results of a subquery. In this form, the array constructor is written with the key word ARRAY followed by a parenthesized (not bracketed) subquery. For example:

```sql
SELECT ARRAY(SELECT oid FROM pg_proc WHERE proname LIKE 'bytea%');
  ?column?
   -----------------------------------------------
 (1 row)
```
The subquery must return a single column. The resulting one-dimensional array will have an element for each row in the subquery result, with an element type matching that of the subquery’s output column.

The subscripts of an array value built with `ARRAY` always begin with one. For more information about arrays, see Section 8.14.

### 4.2.12. Row Constructors

A row constructor is an expression that builds a row value (also called a composite value) using values for its member fields. A row constructor consists of the key word `ROW`, a left parenthesis, zero or more expressions (separated by commas) for the row field values, and finally a right parenthesis. For example:

```sql
SELECT ROW(1,2.5,'this is a test');
```

The key word `ROW` is optional when there is more than one expression in the list.

A row constructor can include the syntax `rowvalue.*`, which will be expanded to a list of the elements of the row value, just as occurs when the `.=` syntax is used at the top level of a `SELECT` list. For example, if table `t` has columns `f1` and `f2`, these are the same:

```sql
SELECT ROW(t.*, 42) FROM t;
SELECT ROW(t.f1, t.f2, 42) FROM t;
```

**Note:** Before PostgreSQL 8.2, the `.*` syntax was not expanded, so that writing `ROW(t.*, 42)` created a two-field row whose first field was another row value. The new behavior is usually more useful. If you need the old behavior of nested row values, write the inner row value without `.*`, for instance `ROW(t, 42).

By default, the value created by a `ROW` expression is of an anonymous record type. If necessary, it can be cast to a named composite type — either the row type of a table, or a composite type created with `CREATE TYPE AS`. An explicit cast might be needed to avoid ambiguity. For example:

```sql
CREATE TABLE mytable(f1 int, f2 float, f3 text);
CREATE FUNCTION getf1(mytable) RETURNS int AS 'SELECT $1.f1' LANGUAGE SQL;
-- No cast needed since only one getf1() exists
SELECT getf1(ROW(1,2.5,'this is a test'));
```

```sql
getf1
-----
1
(1 row)
CREATE TYPE myrowtype AS (f1 int, f2 text, f3 numeric);
CREATE FUNCTION getf1(myrowtype) RETURNS int AS 'SELECT $1.f1' LANGUAGE SQL;
-- Now we need a cast to indicate which function to call:
SELECT getf1(ROW(1,2.5,'this is a test'));
```

**ERROR:** function getf1(record) is not unique

41
Row constructors can be used to build composite values to be stored in a composite-type table column, or to be passed to a function that accepts a composite parameter. Also, it is possible to compare two row values or test a row with IS NULL or IS NOT NULL, for example:

```sql
SELECT ROW(1,2.5,'this is a test') = ROW(1, 3, 'not the same');
SELECT ROW(table.*) IS NULL FROM table; -- detect all-null rows
```

For more detail see Section 9.21. Row constructors can also be used in connection with subqueries, as discussed in Section 9.20.

### 4.2.13. Expression Evaluation Rules

The order of evaluation of subexpressions is not defined. In particular, the inputs of an operator or function are not necessarily evaluated left-to-right or in any other fixed order.

Furthermore, if the result of an expression can be determined by evaluating only some parts of it, then other subexpressions might not be evaluated at all. For instance, if one wrote:

```sql
SELECT true OR somefunc();
```

then `somefunc()` would (probably) not be called at all. The same would be the case if one wrote:

```sql
SELECT somefunc() OR true;
```

Note that this is not the same as the left-to-right “short-circuiting” of Boolean operators that is found in some programming languages.

As a consequence, it is unwise to use functions with side effects as part of complex expressions. It is particularly dangerous to rely on side effects or evaluation order in WHERE and HAVING clauses, since those clauses are extensively reprocessed as part of developing an execution plan. Boolean expressions (AND/OR/NOT combinations) in those clauses can be reorganized in any manner allowed by the laws of Boolean algebra.

When it is essential to force evaluation order, a CASE construct (see Section 9.16) can be used. For example, this is an untrustworthy way of trying to avoid division by zero in a WHERE clause:

```sql
SELECT ... WHERE x > 0 AND y/x > 1.5;
```

But this is safe:

```sql
SELECT ... WHERE CASE WHEN x > 0 THEN y/x > 1.5 ELSE false END;
```
A `CASE` construct used in this fashion will defeat optimization attempts, so it should only be done when necessary. (In this particular example, it would be better to sidestep the problem by writing $y > 1.5 \cdot x$ instead.)
Chapter 5. Data Definition

This chapter covers how one creates the database structures that will hold one’s data. In a relational database, the raw data is stored in tables, so the majority of this chapter is devoted to explaining how tables are created and modified and what features are available to control what data is stored in the tables. Subsequently, we discuss how tables can be organized into schemas, and how privileges can be assigned to tables. Finally, we will briefly look at other features that affect the data storage, such as inheritance, views, functions, and triggers.

5.1. Table Basics

A table in a relational database is much like a table on paper: It consists of rows and columns. The number and order of the columns is fixed, and each column has a name. The number of rows is variable — it reflects how much data is stored at a given moment. SQL does not make any guarantees about the order of the rows in a table. When a table is read, the rows will appear in random order, unless sorting is explicitly requested. This is covered in Chapter 7. Furthermore, SQL does not assign unique identifiers to rows, so it is possible to have several completely identical rows in a table. This is a consequence of the mathematical model that underlies SQL but is usually not desirable. Later in this chapter we will see how to deal with this issue.

Each column has a data type. The data type constrains the set of possible values that can be assigned to a column and assigns semantics to the data stored in the column so that it can be used for computations. For instance, a column declared to be of a numerical type will not accept arbitrary text strings, and the data stored in such a column can be used for mathematical computations. By contrast, a column declared to be of a character string type will accept almost any kind of data but it does not lend itself to mathematical calculations, although other operations such as string concatenation are available.

PostgreSQL includes a sizable set of built-in data types that fit many applications. Users can also define their own data types. Most built-in data types have obvious names and semantics, so we defer a detailed explanation to Chapter 8. Some of the frequently used data types are integer for whole numbers, numeric for possibly fractional numbers, text for character strings, date for dates, time for time-of-day values, and timestamp for values containing both date and time.

To create a table, you use the aptly named CREATE TABLE command. In this command you specify at least a name for the new table, the names of the columns and the data type of each column. For example:

```sql
CREATE TABLE my_first_table (  
    first_column text,  
    second_column integer
);  
```

This creates a table named `my_first_table` with two columns. The first column is named `first_column` and has a data type of `text`; the second column has the name `second_column` and the type `integer`. The table and column names follow the identifier syntax explained in Section 4.1.1. The type names are usually also identifiers, but there are some exceptions. Note that the column list is comma-separated and surrounded by parentheses.

Of course, the previous example was heavily contrived. Normally, you would give names to your tables and columns that convey what kind of data they store. So let’s look at a more realistic example:

```sql
CREATE TABLE products {  
```
Chapter 5. Data Definition

```sql
CREATE TABLE products (  
    product_no integer,  
    name text,  
    price numeric
);
```

(The `numeric` type can store fractional components, as would be typical of monetary amounts.)

**Tip:** When you create many interrelated tables it is wise to choose a consistent naming pattern for the tables and columns. For instance, there is a choice of using singular or plural nouns for table names, both of which are favored by some theorist or other.

There is a limit on how many columns a table can contain. Depending on the column types, it is between 250 and 1600. However, defining a table with anywhere near this many columns is highly unusual and often a questionable design.

If you no longer need a table, you can remove it using the `DROP TABLE` command. For example:

```sql
DROP TABLE my_first_table;
DROP TABLE products;
```

Attempting to drop a table that does not exist is an error. Nevertheless, it is common in SQL script files to unconditionally try to drop each table before creating it, ignoring any error messages, so that the script works whether or not the table exists. (If you like, you can use the `DROP TABLE IF EXISTS` variant to avoid the error messages, but this is not standard SQL.)

If you need to modify a table that already exists, see Section 5.5 later in this chapter.

With the tools discussed so far you can create fully functional tables. The remainder of this chapter is concerned with adding features to the table definition to ensure data integrity, security, or convenience. If you are eager to fill your tables with data now you can skip ahead to Chapter 6 and read the rest of this chapter later.

### 5.2. Default Values

A column can be assigned a default value. When a new row is created and no values are specified for some of the columns, those columns will be filled with their respective default values. A data manipulation command can also request explicitly that a column be set to its default value, without having to know what that value is. (Details about data manipulation commands are in Chapter 6.)

If no default value is declared explicitly, the default value is the null value. This usually makes sense because a null value can be considered to represent unknown data.

In a table definition, default values are listed after the column data type. For example:

```sql
CREATE TABLE products {  
    product_no integer,  
    name text,  
    price numeric DEFAULT 9.99
};
```

The default value can be an expression, which will be evaluated whenever the default value is inserted (not when the table is created). A common example is for a `timestamp` column to have a default of...
Chapter 5. Data Definition

CURRENT_TIMESTAMP, so that it gets set to the time of row insertion. Another common example is generating a "serial number" for each row. In PostgreSQL this is typically done by something like:

```sql
CREATE TABLE products {
    product_no integer DEFAULT nextval('products_product_no_seq'),
    ...;
}
```

where the `nextval()` function supplies successive values from a sequence object (see Section 9.15). This arrangement is sufficiently common that there’s a special shorthand for it:

```sql
CREATE TABLE products {
    product_no SERIAL,
    ...;
}
```

The `SERIAL` shorthand is discussed further in Section 8.1.4.

5.3. Constraints

Data types are a way to limit the kind of data that can be stored in a table. For many applications, however, the constraint they provide is too coarse. For example, a column containing a product price should probably only accept positive values. But there is no standard data type that accepts only positive numbers. Another issue is that you might want to constrain column data with respect to other columns or rows. For example, in a table containing product information, there should be only one row for each product number.

To that end, SQL allows you to define constraints on columns and tables. Constraints give you as much control over the data in your tables as you wish. If a user attempts to store data in a column that would violate a constraint, an error is raised. This applies even if the value came from the default value definition.

5.3.1. Check Constraints

A check constraint is the most generic constraint type. It allows you to specify that the value in a certain column must satisfy a Boolean (truth-value) expression. For instance, to require positive product prices, you could use:

```sql
CREATE TABLE products {
    product_no integer,
    name text,
    price numeric CHECK (price > 0)
};
```

As you see, the constraint definition comes after the data type, just like default value definitions. Default values and constraints can be listed in any order. A check constraint consists of the key word `CHECK` followed by an expression in parentheses. The check constraint expression should involve the column thus constrained, otherwise the constraint would not make too much sense.

You can also give the constraint a separate name. This clarifies error messages and allows you to refer to the constraint when you need to change it. The syntax is:
CREATE TABLE products {
    product_no integer,
    name text,
    price numeric CONSTRAINT positive_price CHECK (price > 0)
};

So, to specify a named constraint, use the key word CONSTRAINT followed by an identifier followed by the constraint definition. (If you don’t specify a constraint name in this way, the system chooses a name for you.)

A check constraint can also refer to several columns. Say you store a regular price and a discounted price, and you want to ensure that the discounted price is lower than the regular price:

CREATE TABLE products {
    product_no integer,
    name text,
    price numeric CHECK (price > 0),
    discounted_price numeric CHECK (discounted_price > 0),
    CHECK (price > discounted_price)
};

The first two constraints should look familiar. The third one uses a new syntax. It is not attached to a particular column, instead it appears as a separate item in the comma-separated column list. Column definitions and these constraint definitions can be listed in mixed order.

We say that the first two constraints are column constraints, whereas the third one is a table constraint because it is written separately from any one column definition. Column constraints can also be written as table constraints, while the reverse is not necessarily possible, since a column constraint is supposed to refer to only the column it is attached to. (PostgreSQL doesn’t enforce that rule, but you should follow it if you want your table definitions to work with other database systems.) The above example could also be written as:

CREATE TABLE products {
    product_no integer,
    name text,
    price numeric,
    CHECK (price > 0),
    discounted_price numeric,
    CHECK (discounted_price > 0),
    CHECK (price > discounted_price)
};

or even:

CREATE TABLE products {
    product_no integer,
    name text,
    price numeric CHECK (price > 0),
    discounted_price numeric,
    CHECK (discounted_price > 0 AND price > discounted_price)
};

It’s a matter of taste.

Names can be assigned to table constraints in the same way as column constraints:

CREATE TABLE products {

product_no integer,
name text,
price numeric,
CHECK (price > 0),
discounted_price numeric,
CHECK (discounted_price > 0),
CONSTRAINT valid_discount CHECK (price > discounted_price)
);

It should be noted that a check constraint is satisfied if the check expression evaluates to true or the null value. Since most expressions will evaluate to the null value if any operand is null, they will not prevent null values in the constrained columns. To ensure that a column does not contain null values, the not-null constraint described in the next section can be used.

5.3.2. Not-Null Constraints

A not-null constraint simply specifies that a column must not assume the null value. A syntax example:

CREATE TABLE products {
    product_no integer NOT NULL,
    name text NOT NULL,
    price numeric
};

A not-null constraint is always written as a column constraint. A not-null constraint is functionally equivalent to creating a check constraint \( \text{CHECK (column}\_\text{name IS NOT NULL)} \), but in PostgreSQL creating an explicit not-null constraint is more efficient. The drawback is that you cannot give explicit names to not-null constraints created this way.

Of course, a column can have more than one constraint. Just write the constraints one after another:

CREATE TABLE products {
    product_no integer NOT NULL,
    name text NOT NULL,
    price numeric NOT NULL CHECK (price > 0)
};

The order doesn’t matter. It does not necessarily determine in which order the constraints are checked.

The NOT NULL constraint has an inverse: the NULL constraint. This does not mean that the column must be null, which would surely be useless. Instead, this simply selects the default behavior that the column might be null. The NULL constraint is not present in the SQL standard and should not be used in portable applications. (It was only added to PostgreSQL to be compatible with some other database systems.) Some users, however, like it because it makes it easy to toggle the constraint in a script file. For example, you could start with:

CREATE TABLE products {
    product_no integer NULL,
    name text NULL,
    price numeric NULL
};

and then insert the NOT key word where desired.
Tip: In most database designs the majority of columns should be marked not null.

5.3.3. Unique Constraints

Unique constraints ensure that the data contained in a column or a group of columns is unique with respect to all the rows in the table. The syntax is:

```sql
CREATE TABLE products (
    product_no integer UNIQUE,
    name text,
    price numeric
);
```

when written as a column constraint, and:

```sql
CREATE TABLE products (
    product_no integer,
    name text,
    price numeric,
    UNIQUE (product_no)
);
```

when written as a table constraint.

If a unique constraint refers to a group of columns, the columns are listed separated by commas:

```sql
CREATE TABLE example (
    a integer,
    b integer,
    c integer,
    UNIQUE (a, c)
);
```

This specifies that the combination of values in the indicated columns is unique across the whole table, though any one of the columns need not be (and ordinarily isn’t) unique.

You can assign your own name for a unique constraint, in the usual way:

```sql
CREATE TABLE products (
    product_no integer CONSTRAINT must_be_different UNIQUE,
    name text,
    price numeric
);
```

In general, a unique constraint is violated when there is more than one row in the table where the values of all of the columns included in the constraint are equal. However, two null values are not considered equal in this comparison. That means even in the presence of a unique constraint it is possible to store duplicate rows that contain a null value in at least one of the constrained columns. This behavior conforms to the SQL standard, but we have heard that other SQL databases might not follow this rule. So be careful when developing applications that are intended to be portable.
5.3.4. Primary Keys

Technically, a primary key constraint is simply a combination of a unique constraint and a not-null constraint. So, the following two table definitions accept the same data:

```sql
CREATE TABLE products {
    product_no integer UNIQUE NOT NULL,
    name text,
    price numeric
};

CREATE TABLE products {
    product_no integer PRIMARY KEY,
    name text,
    price numeric
};
```

Primary keys can also constrain more than one column; the syntax is similar to unique constraints:

```sql
CREATE TABLE example {
    a integer,
    b integer,
    c integer,
    PRIMARY KEY (a, c)
};
```

A primary key indicates that a column or group of columns can be used as a unique identifier for rows in the table. (This is a direct consequence of the definition of a primary key. Note that a unique constraint does not, by itself, provide a unique identifier because it does not exclude null values.) This is useful both for documentation purposes and for client applications. For example, a GUI application that allows modifying row values probably needs to know the primary key of a table to be able to identify rows uniquely.

A table can have at most one primary key. (There can be any number of unique and not-null constraints, which are functionally the same thing, but only one can be identified as the primary key.) Relational database theory dictates that every table must have a primary key. This rule is not enforced by PostgreSQL, but it is usually best to follow it.

5.3.5. Foreign Keys

A foreign key constraint specifies that the values in a column (or a group of columns) must match the values appearing in some row of another table. We say this maintains the referential integrity between two related tables.

Say you have the product table that we have used several times already:

```sql
CREATE TABLE products {
    product_no integer PRIMARY KEY,
    name text,
    price numeric
};
```
Let’s also assume you have a table storing orders of those products. We want to ensure that the orders table only contains orders of products that actually exist. So we define a foreign key constraint in the orders table that references the products table:

```sql
CREATE TABLE orders (
    order_id integer PRIMARY KEY,
    product_no integer REFERENCES products (product_no),
    quantity integer
);
```

Now it is impossible to create orders with `product_no` entries that do not appear in the products table.

We say that in this situation the orders table is the referencing table and the products table is the referenced table. Similarly, there are referencing and referenced columns.

You can also shorten the above command to:

```sql
CREATE TABLE orders (
    order_id integer PRIMARY KEY,
    product_no integer REFERENCES products,
    quantity integer
);
```

because in absence of a column list the primary key of the referenced table is used as the referenced column(s).

A foreign key can also constrain and reference a group of columns. As usual, it then needs to be written in table constraint form. Here is a contrived syntax example:

```sql
CREATE TABLE t1 (
    a integer PRIMARY KEY,
    b integer,
    c integer,
    FOREIGN KEY (b, c) REFERENCES other_table (c1, c2)
);
```

Of course, the number and type of the constrained columns need to match the number and type of the referenced columns.

You can assign your own name for a foreign key constraint, in the usual way.

A table can contain more than one foreign key constraint. This is used to implement many-to-many relationships between tables. Say you have tables about products and orders, but now you want to allow one order to contain possibly many products (which the structure above did not allow). You could use this table structure:

```sql
CREATE TABLE products {
    product_no integer PRIMARY KEY,
    name text,
    price numeric
};
```

```sql
CREATE TABLE orders {
    order_id integer PRIMARY KEY,
    shipping_address text,
    ...
};
```
Chapter 5. Data Definition

CREATE TABLE order_items (  
  product_no integer REFERENCES products,  
  order_id integer REFERENCES orders,  
  quantity integer,  
  PRIMARY KEY (product_no, order_id) 
);

Notice that the primary key overlaps with the foreign keys in the last table.

We know that the foreign keys disallow creation of orders that do not relate to any products. But what if a product is removed after an order is created that references it? SQL allows you to handle that as well. Intuitively, we have a few options:

- Disallow deleting a referenced product
- Delete the orders as well
- Something else?

To illustrate this, let’s implement the following policy on the many-to-many relationship example above: when someone wants to remove a product that is still referenced by an order (via order_items), we disallow it. If someone removes an order, the order items are removed as well:

CREATE TABLE products (  
  product_no integer PRIMARY KEY,  
  name text,  
  price numeric 
);

CREATE TABLE orders (  
  order_id integer PRIMARY KEY,  
  shipping_address text,  
  ... 
);

CREATE TABLE order_items (  
  product_no integer REFERENCES products ON DELETE RESTRICT,  
  order_id integer REFERENCES orders ON DELETE CASCADE,  
  quantity integer,  
  PRIMARY KEY (product_no, order_id) 
);

Restricting and cascading deletes are the two most common options. RESTRICT prevents deletion of a referenced row. NO ACTION means that if any referencing rows still exist when the constraint is checked, an error is raised; this is the default behavior if you do not specify anything. (The essential difference between these two choices is that NO ACTION allows the check to be deferred until later in the transaction, whereas RESTRICT does not.) CASCADE specifies that when a referenced row is deleted, row(s) referencing it should be automatically deleted as well. There are two other options: SET NULL and SET DEFAULT. These cause the referencing columns to be set to nulls or default values, respectively, when the referenced row is deleted. Note that these do not excuse you from observing any constraints. For example, if an action specifies SET DEFAULT but the default value would not satisfy the foreign key, the operation will fail.

Analogous to ON DELETE there is also ON UPDATE which is invoked when a referenced column is changed (updated). The possible actions are the same.
More information about updating and deleting data is in Chapter 6.

Finally, we should mention that a foreign key must reference columns that either are a primary key or form a unique constraint. If the foreign key references a unique constraint, there are some additional possibilities regarding how null values are matched. These are explained in the reference documentation for `CREATE TABLE`.

### 5.4. System Columns

Every table has several system columns that are implicitly defined by the system. Therefore, these names cannot be used as names of user-defined columns. (Note that these restrictions are separate from whether the name is a key word or not; quoting a name will not allow you to escape these restrictions.) You do not really need to be concerned about these columns; just know they exist.

**oid**

The object identifier (object ID) of a row. This column is only present if the table was created using `WITH OIDS`, or if the `default_with_oids` configuration variable was set at the time. This column is of type `oid` (same name as the column); see Section 8.16 for more information about the type.

**tableoid**

The OID of the table containing this row. This column is particularly handy for queries that select from inheritance hierarchies (see Section 5.8), since without it, it’s difficult to tell which individual table a row came from. The `tableoid` can be joined against the `oid` column of `pg_class` to obtain the table name.

**xmin**

The identity (transaction ID) of the inserting transaction for this row version. (A row version is an individual state of a row; each update of a row creates a new row version for the same logical row.)

**cmin**

The command identifier (starting at zero) within the inserting transaction.

**xmax**

The identity (transaction ID) of the deleting transaction, or zero for an undeleted row version. It is possible for this column to be nonzero in a visible row version. That usually indicates that the deleting transaction hasn’t committed yet, or that an attempted deletion was rolled back.

**cmax**

The command identifier within the deleting transaction, or zero.

**ctid**

The physical location of the row version within its table. Note that although the `ctid` can be used to locate the row version very quickly, a row’s `ctid` will change if it is updated or moved by `VACUUM FULL`. Therefore `ctid` is useless as a long-term row identifier. The OID, or even better a user-defined serial number, should be used to identify logical rows.

OIDs are 32-bit quantities and are assigned from a single cluster-wide counter. In a large or long-lived database, it is possible for the counter to wrap around. Hence, it is bad practice to assume that OIDs are unique, unless you take steps to ensure that this is the case. If you need to identify the rows in
a table, using a sequence generator is strongly recommended. However, OIDs can be used as well, provided that a few additional precautions are taken:

- A unique constraint should be created on the OID column of each table for which the OID will be used to identify rows. When such a unique constraint (or unique index) exists, the system takes care not to generate an OID matching an already-existing row. (Of course, this is only possible if the table contains fewer than $2^{32}$ (4 billion) rows, and in practice the table size had better be much less than that, or performance might suffer.)

- OIDs should never be assumed to be unique across tables; use the combination of tableoid and row OID if you need a database-wide identifier.

- Of course, the tables in question must be created with OIDS. As of PostgreSQL 8.1, WITHOUT OIDS is the default.

Transaction identifiers are also 32-bit quantities. In a long-lived database it is possible for transaction IDs to wrap around. This is not a fatal problem given appropriate maintenance procedures; see Chapter 23 for details. It is unwise, however, to depend on the uniqueness of transaction IDs over the long term (more than one billion transactions).

Command identifiers are also 32-bit quantities. This creates a hard limit of $2^{32}$ (4 billion) SQL commands within a single transaction. In practice this limit is not a problem — note that the limit is on the number of SQL commands, not the number of rows processed. Also, as of PostgreSQL 8.3, only commands that actually modify the database contents will consume a command identifier.

### 5.5. Modifying Tables

When you create a table and you realize that you made a mistake, or the requirements of the application change, you can drop the table and create it again. But this is not a convenient option if the table is already filled with data, or if the table is referenced by other database objects (for instance a foreign key constraint). Therefore PostgreSQL provides a family of commands to make modifications to existing tables. Note that this is conceptually distinct from altering the data contained in the table: here we are interested in altering the definition, or structure, of the table.

You can:

- Add columns
- Remove columns
- Add constraints
- Remove constraints
- Change default values
- Change column data types
- Rename columns
- Rename tables

All these actions are performed using the `ALTER TABLE` command, whose reference page contains details beyond those given here.
5.5.1. Adding a Column

To add a column, use a command like:

```
ALTER TABLE products ADD COLUMN description text;
```

The new column is initially filled with whatever default value is given (null if you don’t specify a `DEFAULT` clause).

You can also define constraints on the column at the same time, using the usual syntax:

```
ALTER TABLE products ADD COLUMN description text CHECK (description <> '');
```

In fact all the options that can be applied to a column description in `CREATE TABLE` can be used here. Keep in mind however that the default value must satisfy the given constraints, or the `ADD` will fail. Alternatively, you can add constraints later (see below) after you’ve filled in the new column correctly.

Tip: Adding a column with a default requires updating each row of the table (to store the new column value). However, if no default is specified, PostgreSQL is able to avoid the physical update. So if you intend to fill the column with mostly nondefault values, it’s best to add the column with no default, insert the correct values using `UPDATE`, and then add any desired default as described below.

5.5.2. Removing a Column

To remove a column, use a command like:

```
ALTER TABLE products DROP COLUMN description;
```

Whatever data was in the column disappears. Table constraints involving the column are dropped, too. However, if the column is referenced by a foreign key constraint of another table, PostgreSQL will not silently drop that constraint. You can authorize dropping everything that depends on the column by adding `CASCADE`:

```
ALTER TABLE products DROP COLUMN description CASCADE;
```

See Section 5.11 for a description of the general mechanism behind this.

5.5.3. Adding a Constraint

To add a constraint, the table constraint syntax is used. For example:

```
ALTER TABLE products ADD CHECK (name <> '');
ALTER TABLE products ADD CONSTRAINT some_name UNIQUE (product_no);
ALTER TABLE products ADD FOREIGN KEY (product_group_id) REFERENCES product_groups;
```

To add a not-null constraint, which cannot be written as a table constraint, use this syntax:

```
ALTER TABLE products ALTER COLUMN product_no SET NOT NULL;
```
The constraint will be checked immediately, so the table data must satisfy the constraint before it can be added.

5.5.4. Removing a Constraint

To remove a constraint you need to know its name. If you gave it a name then that’s easy. Otherwise the system assigned a generated name, which you need to find out. The psql command `\d tablename` can be helpful here; other interfaces might also provide a way to inspect table details. Then the command is:

```
ALTER TABLE products DROP CONSTRAINT some_name;
```

(If you are dealing with a generated constraint name like $2, don’t forget that you’ll need to double-quote it to make it a valid identifier.)

As with dropping a column, you need to add `CASCADE` if you want to drop a constraint that something else depends on. An example is that a foreign key constraint depends on a unique or primary key constraint on the referenced column(s).

This works the same for all constraint types except not-null constraints. To drop a not null constraint use:

```
ALTER TABLE products ALTER COLUMN product_no DROP NOT NULL;
```

(Recall that not-null constraints do not have names.)

5.5.5. Changing a Column’s Default Value

To set a new default for a column, use a command like:

```
ALTER TABLE products ALTER COLUMN price SET DEFAULT 7.77;
```

Note that this doesn’t affect any existing rows in the table, it just changes the default for future `INSERT` commands.

To remove any default value, use:

```
ALTER TABLE products ALTER COLUMN price DROP DEFAULT;
```

This is effectively the same as setting the default to null. As a consequence, it is not an error to drop a default where one hadn’t been defined, because the default is implicitly the null value.

5.5.6. Changing a Column’s Data Type

To convert a column to a different data type, use a command like:

```
ALTER TABLE products ALTER COLUMN price TYPE numeric(10,2);
```

This will succeed only if each existing entry in the column can be converted to the new type by an implicit cast. If a more complex conversion is needed, you can add a `USING` clause that specifies how to compute the new values from the old.

PostgreSQL will attempt to convert the column’s default value (if any) to the new type, as well as any constraints that involve the column. But these conversions might fail, or might produce surprising
results. It’s often best to drop any constraints on the column before altering its type, and then add back suitably modified constraints afterwards.

### 5.5.7. Renaming a Column

To rename a column:

```
ALTER TABLE products RENAME COLUMN product_no TO product_number;
```

### 5.5.8. Renaming a Table

To rename a table:

```
ALTER TABLE products RENAME TO items;
```

### 5.6. Privileges

When you create a database object, you become its owner. By default, only the owner of an object can do anything with the object. In order to allow other users to use it, privileges must be granted. (However, users that have the superuser attribute can always access any object.)

There are several different privileges: `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, `REFERENCES`, `TRIGGER`, `CREATE`, `CONNECT`, `TEMPORARY`, `EXECUTE`, and `USAGE`. The privileges applicable to a particular object vary depending on the object’s type (table, function, etc). For complete information on the different types of privileges supported by PostgreSQL, refer to the `GRANT` reference page. The following sections and chapters will also show you how those privileges are used.

The right to modify or destroy an object is always the privilege of the owner only.

**Note:** To change the owner of a table, index, sequence, or view, use the `ALTER TABLE` command. There are corresponding `ALTER` commands for other object types.

To assign privileges, the `GRANT` command is used. For example, if `joe` is an existing user, and `accounts` is an existing table, the privilege to update the table can be granted with:

```
GRANT UPDATE ON accounts TO joe;
```

Writing `ALL` in place of a specific privilege grants all privileges that are relevant for the object type.

The special "user" name `PUBLIC` can be used to grant a privilege to every user on the system. Also, "group" roles can be set up to help manage privileges when there are many users of a database — for details see Chapter 20.

To revoke a privilege, use the fittingly named `REVOKE` command:

```
REVOKE ALL ON accounts FROM PUBLIC;
```
The special privileges of the object owner (i.e., the right to do `DROP`, `GRANT`, `REVOKE`, etc.) are always implicit in being the owner, and cannot be granted or revoked. But the object owner can choose to revoke his own ordinary privileges, for example to make a table read-only for himself as well as others.

Ordinarily, only the object’s owner (or a superuser) can grant or revoke privileges on an object. However, it is possible to grant a privilege “with grant option”, which gives the recipient the right to grant it in turn to others. If the grant option is subsequently revoked then all who received the privilege from that recipient (directly or through a chain of grants) will lose the privilege. For details see the `GRANT` and `REVOKE` reference pages.

5.7. Schemas

A PostgreSQL database cluster contains one or more named databases. Users and groups of users are shared across the entire cluster, but no other data is shared across databases. Any given client connection to the server can access only the data in a single database, the one specified in the connection request.

Note: Users of a cluster do not necessarily have the privilege to access every database in the cluster. Sharing of user names means that there cannot be different users named, say, joe in two databases in the same cluster; but the system can be configured to allow joe access to only some of the databases.

A database contains one or more named schemas, which in turn contain tables. Schemas also contain other kinds of named objects, including data types, functions, and operators. The same object name can be used in different schemas without conflict; for example, both `schema1` and `myschema` can contain tables named `mytable`. Unlike databases, schemas are not rigidly separated: a user can access objects in any of the schemas in the database he is connected to, if he has privileges to do so.

There are several reasons why one might want to use schemas:

- To allow many users to use one database without interfering with each other.
- To organize database objects into logical groups to make them more manageable.
- Third-party applications can be put into separate schemas so they do not collide with the names of other objects.

Schemas are analogous to directories at the operating system level, except that schemas cannot be nested.

5.7.1. Creating a Schema

To create a schema, use the `CREATE SCHEMA` command. Give the schema a name of your choice. For example:

```
CREATE SCHEMA myschema;
```

To create or access objects in a schema, write a qualified name consisting of the schema name and table name separated by a dot:
This works anywhere a table name is expected, including the table modification commands and the
data access commands discussed in the following chapters. (For brevity we will speak of tables only,
but the same ideas apply to other kinds of named objects, such as types and functions.)

Actually, the even more general syntax

```
database.schema.table
```

can be used too, but at present this is just for *pro forma* compliance with the SQL standard. If you
write a database name, it must be the same as the database you are connected to.

So to create a table in the new schema, use:

```
CREATE TABLE myschema.mytable ( ...
);
```

To drop a schema if it’s empty (all objects in it have been dropped), use:

```
DROP SCHEMA myschema;
```

To drop a schema including all contained objects, use:

```
DROP SCHEMA myschema CASCADE;
```

See Section 5.11 for a description of the general mechanism behind this.

Often you will want to create a schema owned by someone else (since this is one of the ways to
restrict the activities of your users to well-defined namespaces). The syntax for that is:

```
CREATE SCHEMA schemaname AUTHORIZATION username;
```

You can even omit the schema name, in which case the schema name will be the same as the user
name. See Section 5.7.6 for how this can be useful.

Schema names beginning with `pg_` are reserved for system purposes and cannot be created by users.

### 5.7.2. The Public Schema

In the previous sections we created tables without specifying any schema names. By default such
tables (and other objects) are automatically put into a schema named “public”. Every new database
contains such a schema. Thus, the following are equivalent:

```
CREATE TABLE products { ... };
```

and:

```
CREATE TABLE public.products { ... };
```
5.7.3. The Schema Search Path

Qualified names are tedious to write, and it’s often best not to wire a particular schema name into applications anyway. Therefore tables are often referred to by *unqualified names*, which consist of just the table name. The system determines which table is meant by following a *search path*, which is a list of schemas to look in. The first matching table in the search path is taken to be the one wanted. If there is no match in the search path, an error is reported, even if matching table names exist in other schemas in the database.

The first schema named in the search path is called the current schema. Aside from being the first schema searched, it is also the schema in which new tables will be created if the `CREATE TABLE` command does not specify a schema name.

To show the current search path, use the following command:

```
SHOW search_path;
```

In the default setup this returns:

```
  search_path
  ------------
    "$user",public
```

The first element specifies that a schema with the same name as the current user is to be searched. If no such schema exists, the entry is ignored. The second element refers to the public schema that we have seen already.

The first schema in the search path that exists is the default location for creating new objects. That is the reason that by default objects are created in the public schema. When objects are referenced in any other context without schema qualification (table modification, data modification, or query commands) the search path is traversed until a matching object is found. Therefore, in the default configuration, any unqualified access again can only refer to the public schema.

To put our new schema in the path, we use:

```
SET search_path TO myschema,public;
```

(We omit the `$user` here because we have no immediate need for it.) And then we can access the table without schema qualification:

```
DROP TABLE mytable;
```

Also, since `myschema` is the first element in the path, new objects would by default be created in it. We could also have written:

```
SET search_path TO myschema;
```

Then we no longer have access to the public schema without explicit qualification. There is nothing special about the public schema except that it exists by default. It can be dropped, too.

See also Section 9.23 for other ways to manipulate the schema search path.

The search path works in the same way for data type names, function names, and operator names as it does for table names. Data type and function names can be qualified in exactly the same way as table names. If you need to write a qualified operator name in an expression, there is a special provision: you must write

```
OPERATOR(schema,operator)
```
This is needed to avoid syntactic ambiguity. An example is:

\[
\text{SELECT 3 OPERATOR(pg_catalog.+) 4;}
\]

In practice one usually relies on the search path for operators, so as not to have to write anything so ugly as that.

### 5.7.4. Schemas and Privileges

By default, users cannot access any objects in schemas they do not own. To allow that, the owner of the schema must grant the `USAGE` privilege on the schema. To allow users to make use of the objects in the schema, additional privileges might need to be granted, as appropriate for the object.

A user can also be allowed to create objects in someone else’s schema. To allow that, the `CREATE` privilege on the schema needs to be granted. Note that by default, everyone has `CREATE` and `USAGE` privileges on the schema `public`. This allows all users that are able to connect to a given database to create objects in its `public` schema. If you do not want to allow that, you can revoke that privilege:

```sql
REVOKE CREATE ON SCHEMA public FROM PUBLIC;
```

(The first “public” is the schema, the second “public” means “every user”. In the first sense it is an identifier, in the second sense it is a key word, hence the different capitalization; recall the guidelines from Section 4.1.1.)

### 5.7.5. The System Catalog Schema

In addition to `public` and user-created schemas, each database contains a `pg_catalog` schema, which contains the system tables and all the built-in data types, functions, and operators. `pg_catalog` is always effectively part of the search path. If it is not named explicitly in the path then it is implicitly searched before searching the path’s schemas. This ensures that built-in names will always be findable. However, you can explicitly place `pg_catalog` at the end of your search path if you prefer to have user-defined names override built-in names.

In PostgreSQL versions before 7.3, table names beginning with `pg_` were reserved. This is no longer true: you can create such a table name if you wish, in any non-system schema. However, it’s best to continue to avoid such names, to ensure that you won’t suffer a conflict if some future version defines a system table named the same as your table. (With the default search path, an unqualified reference to your table name would then be resolved as the system table instead.) System tables will continue to follow the convention of having names beginning with `pg_`, so that they will not conflict with unqualified user-table names so long as users avoid the `pg_` prefix.

### 5.7.6. Usage Patterns

Schemas can be used to organize your data in many ways. There are a few usage patterns that are recommended and are easily supported by the default configuration:

- If you do not create any schemas then all users access the public schema implicitly. This simulates the situation where schemas are not available at all. This setup is mainly recommended when there is only a single user or a few cooperating users in a database. This setup also allows smooth transition from the non-schema-aware world.
• You can create a schema for each user with the same name as that user. Recall that the default search path starts with $user, which resolves to the user name. Therefore, if each user has a separate schema, they access their own schemas by default. If you use this setup then you might also want to revoke access to the public schema (or drop it altogether), so users are truly constrained to their own schemas.

• To install shared applications (tables to be used by everyone, additional functions provided by third parties, etc.), put them into separate schemas. Remember to grant appropriate privileges to allow the other users to access them. Users can then refer to these additional objects by qualifying the names with a schema name, or they can put the additional schemas into their search path, as they choose.

5.7.7. Portability
In the SQL standard, the notion of objects in the same schema being owned by different users does not exist. Moreover, some implementations do not allow you to create schemas that have a different name than their owner. In fact, the concepts of schema and user are nearly equivalent in a database system that implements only the basic schema support specified in the standard. Therefore, many users consider qualified names to really consist of $username.$tablename. This is how PostgreSQL will effectively behave if you create a per-user schema for every user.

Also, there is no concept of a public schema in the SQL standard. For maximum conformance to the standard, you should not use (perhaps even remove) the public schema.

Of course, some SQL database systems might not implement schemas at all, or provide namespace support by allowing (possibly limited) cross-database access. If you need to work with those systems, then maximum portability would be achieved by not using schemas at all.

5.8. Inheritance
PostgreSQL implements table inheritance, which can be a useful tool for database designers. (SQL:1999 and later define a type inheritance feature, which differs in many respects from the features described here.)

Let’s start with an example: suppose we are trying to build a data model for cities. Each state has many cities, but only one capital. We want to be able to quickly retrieve the capital city for any particular state. This can be done by creating two tables, one for state capitals and one for cities that are not capitals. However, what happens when we want to ask for data about a city, regardless of whether it is a capital or not? The inheritance feature can help to resolve this problem. We define the capitals table so that it inherits from cities:

```
CREATE TABLE cities {
    name text,
    population float,
    altitude int -- in feet
};

CREATE TABLE capitals {
    state char(2)
} INHERITS (cities);
```
In this case, the capitals table inherits all the columns of its parent table, cities. State capitals also have an extra column, state, that shows their state.

In PostgreSQL, a table can inherit from zero or more other tables, and a query can reference either all rows of a table or all rows of a table plus all of its descendant tables. The latter behavior is the default. For example, the following query finds the names of all cities, including state capitals, that are located at an altitude over 500 feet:

```sql
SELECT name, altitude
FROM cities
WHERE altitude > 500;
```

Given the sample data from the PostgreSQL tutorial (see Section 2.1), this returns:

<table>
<thead>
<tr>
<th>name</th>
<th>altitude</th>
</tr>
</thead>
<tbody>
<tr>
<td>Las Vegas</td>
<td>2174</td>
</tr>
<tr>
<td>Mariposa</td>
<td>1953</td>
</tr>
<tr>
<td>Madison</td>
<td>845</td>
</tr>
</tbody>
</table>

On the other hand, the following query finds all the cities that are not state capitals and are situated at an altitude over 500 feet:

```sql
SELECT name, altitude
FROM ONLY cities
WHERE altitude > 500;
```

Here the ONLY keyword indicates that the query should apply only to cities, and not any tables below cities in the inheritance hierarchy. Many of the commands that we have already discussed — SELECT, UPDATE and DELETE — support the ONLY keyword.

You can also write the table name with a trailing * to explicitly specify that descendant tables are included:

```sql
SELECT name, altitude
FROM cities*
WHERE altitude > 500;
```

Writing * is not necessary, since this behavior is the default (unless you have changed the setting of the sql_inheritance configuration option). However writing * might be useful to emphasize that additional tables will be searched.

In some cases you might wish to know which table a particular row originated from. There is a system column called tableoid in each table which can tell you the originating table:

```sql
SELECT c.tableoid, c.name, c.altitude
FROM cities c
WHERE c.altitude > 500;
```

which returns:
Chapter 5. Data Definition

<table>
<thead>
<tr>
<th>tableoid</th>
<th>name</th>
<th>altitude</th>
</tr>
</thead>
<tbody>
<tr>
<td>139793</td>
<td>Las Vegas</td>
<td>2174</td>
</tr>
<tr>
<td>139793</td>
<td>Mariposa</td>
<td>1953</td>
</tr>
<tr>
<td>139798</td>
<td>Madison</td>
<td>845</td>
</tr>
</tbody>
</table>

(If you try to reproduce this example, you will probably get different numeric OIDs.) By doing a join with `pg_class` you can see the actual table names:

```sql
SELECT p.relname, c.name, c.altitude
FROM cities c, pg_class p
WHERE c.altitude > 500 AND c.tableoid = p.oid;
```

which returns:

<table>
<thead>
<tr>
<th>relname</th>
<th>name</th>
<th>altitude</th>
</tr>
</thead>
<tbody>
<tr>
<td>cities</td>
<td>Las Vegas</td>
<td>2174</td>
</tr>
<tr>
<td>cities</td>
<td>Mariposa</td>
<td>1953</td>
</tr>
<tr>
<td>capitals</td>
<td>Madison</td>
<td>845</td>
</tr>
</tbody>
</table>

Inheritance does not automatically propagate data from `INSERT` or `COPY` commands to other tables in the inheritance hierarchy. In our example, the following `INSERT` statement will fail:

```sql
INSERT INTO cities (name, population, altitude, state)
VALUES ('New York', NULL, NULL, 'NY');
```

We might hope that the data would somehow be routed to the `capitals` table, but this does not happen: `INSERT` always inserts into exactly the table specified. In some cases it is possible to redirect the insertion using a rule (see Chapter 36). However that does not help for the above case because the `cities` table does not contain the column `state`, and so the command will be rejected before the rule can be applied.

All check constraints and not-null constraints on a parent table are automatically inherited by its children. Other types of constraints (unique, primary key, and foreign key constraints) are not inherited.

A table can inherit from more than one parent table, in which case it has the union of the columns defined by the parent tables. Any columns declared in the child table’s definition are added to these. If the same column name appears in multiple parent tables, or in both a parent table and the child’s definition, then these columns are “merged” so that there is only one such column in the child table. To be merged, columns must have the same data types, else an error is raised. The merged column will have copies of all the check constraints coming from any one of the column definitions it came from, and will be marked not-null if any of them are.

Table inheritance is typically established when the child table is created, using the `INHERITS` clause of the `CREATE TABLE` statement. Alternatively, a table which is already defined in a compatible way can have a new parent relationship added, using the `INHERIT` variant of `ALTER TABLE`. To do this the new child table must already include columns with the same names and types as the columns of the parent. It must also include check constraints with the same names and check expressions as those of the parent. Similarly an inheritance link can be removed from a child using the `NO INHERIT` variant of `ALTER TABLE`. Dynamically adding and removing inheritance links like this can be useful when the inheritance relationship is being used for table partitioning (see Section 5.9).

One convenient way to create a compatible table that will later be made a new child is to use the `LIKE` clause in `CREATE TABLE`. This creates a new table with the same columns as the source table. If there are any `CHECK` constraints defined on the source table, the `INCLUDING CONSTRAINTS` option to
LIKE should be specified, as the new child must have constraints matching the parent to be considered compatible.

A parent table cannot be dropped while any of its children remain. Neither can columns or check constraints of child tables be dropped or altered if they are inherited from any parent tables. If you wish to remove a table and all of its descendants, one easy way is to drop the parent table with the CASCADE option.

ALTER TABLE will propagate any changes in column data definitions and check constraints down the inheritance hierarchy. Again, dropping columns that are depended on by other tables is only possible when using the CASCADE option. ALTER TABLE follows the same rules for duplicate column merging and rejection that apply during CREATE TABLE.

### 5.8.1. Caveats

Table access permissions are not automatically inherited. Therefore, a user attempting to access a parent table must either have permissions to do the same operation on all its child tables as well, or must use the ONLY notation. When adding a new child table to an existing inheritance hierarchy, be careful to grant all the needed permissions on it.

More generally, note that not all SQL commands are able to work on inheritance hierarchies. Commands that are used for data querying, data modification, or schema modification (e.g., SELECT, UPDATE, DELETE, most variants of ALTER TABLE, but not INSERT or ALTER TABLE ... RENAME) typically default to including child tables and support the ONLY notation to exclude them. Commands that do database maintenance and tuning (e.g., REINDEX, VACUUM) typically only work on individual, physical tables and do not support recursing over inheritance hierarchies. The respective behavior of each individual command is documented in its reference page (Reference I, SQL Commands).

A serious limitation of the inheritance feature is that indexes (including unique constraints) and foreign key constraints only apply to single tables, not to their inheritance children. This is true on both the referencing and referenced sides of a foreign key constraint. Thus, in the terms of the above example:

- If we declared cities.name to be UNIQUE or a PRIMARY KEY, this would not stop the capitals table from having rows with names duplicating rows in cities. And those duplicate rows would by default show up in queries from cities. In fact, by default capitals would have no unique constraint at all, and so could contain multiple rows with the same name. You could add a unique constraint to capitals, but this would not prevent duplication compared to cities.
- Similarly, if we were to specify that cities.name REFERENCES some other table, this constraint would not automatically propagate to capitals. In this case you could work around it by manually adding the same REFERENCES constraint to capitals.
- Specifying that another table’s column REFERENCES cities(name) would allow the other table to contain city names, but not capital names. There is no good workaround for this case.

These deficiencies will probably be fixed in some future release, but in the meantime considerable care is needed in deciding whether inheritance is useful for your application.

### 5.9. Partitioning

PostgreSQL supports basic table partitioning. This section describes why and how to implement partitioning as part of your database design.
5.9.1. Overview

Partitioning refers to splitting what is logically one large table into smaller physical pieces. Partitioning can provide several benefits:

- Query performance can be improved dramatically in certain situations, particularly when most of the heavily accessed rows of the table are in a single partition or a small number of partitions. The partitioning substitutes for leading columns of indexes, reducing index size and making it more likely that the heavily-used parts of the indexes fit in memory.
- When queries or updates access a large percentage of a single partition, performance can be improved by taking advantage of sequential scan of that partition instead of using an index and random access reads scattered across the whole table.
- Bulk loads and deletes can be accomplished by adding or removing partitions, if that requirement is planned into the partitioning design. ALTER TABLE is far faster than a bulk operation. It also entirely avoids the VACUUM overhead caused by a bulk DELETE.
- Seldom-used data can be migrated to cheaper and slower storage media.

The benefits will normally be worthwhile only when a table would otherwise be very large. The exact point at which a table will benefit from partitioning depends on the application, although a rule of thumb is that the size of the table should exceed the physical memory of the database server.

Currently, PostgreSQL supports partitioning via table inheritance. Each partition must be created as a child table of a single parent table. The parent table itself is normally empty; it exists just to represent the entire data set. You should be familiar with inheritance (see Section 5.8) before attempting to set up partitioning.

The following forms of partitioning can be implemented in PostgreSQL:

Range Partitioning

The table is partitioned into “ranges” defined by a key column or set of columns, with no overlap between the ranges of values assigned to different partitions. For example one might partition by date ranges, or by ranges of identifiers for particular business objects.

List Partitioning

The table is partitioned by explicitly listing which key values appear in each partition.

5.9.2. Implementing Partitioning

To set up a partitioned table, do the following:

1. Create the “master” table, from which all of the partitions will inherit.

   This table will contain no data. Do not define any check constraints on this table, unless you intend them to be applied equally to all partitions. There is no point in defining any indexes or unique constraints on it, either.

2. Create several “child” tables that each inherit from the master table. Normally, these tables will not add any columns to the set inherited from the master.

   We will refer to the child tables as partitions, though they are in every way normal PostgreSQL tables.
3. Add table constraints to the partition tables to define the allowed key values in each partition.

   Typical examples would be:
   
   CHECK ( x = 1 )
   CHECK ( county IN ( 'Oxfordshire', 'Buckinghamshire', 'Warwickshire' ) )
   CHECK ( outletID >= 100 AND outletID < 200 )

   Ensure that the constraints guarantee that there is no overlap between the key values permitted in
different partitions. A common mistake is to set up range constraints like:
   
   CHECK ( outletID BETWEEN 100 AND 200 )
   CHECK ( outletID BETWEEN 200 AND 300 )

   This is wrong since it is not clear which partition the key value 200 belongs in.

   Note that there is no difference in syntax between range and list partitioning; those terms are
descriptive only.

4. For each partition, create an index on the key column(s), as well as any other indexes you might
want. (The key index is not strictly necessary, but in most scenarios it is helpful. If you intend
the key values to be unique then you should always create a unique or primary-key constraint for
each partition.)

5. Optionally, define a trigger or rule to redirect data inserted into the master table to the appropriate
partition.

6. Ensure that the constraint_exclusion configuration parameter is not disabled in
postgresql.conf. If it is, queries will not be optimized as desired.

For example, suppose we are constructing a database for a large ice cream company. The company
measures peak temperatures every day as well as ice cream sales in each region. Conceptually, we
want a table like:

```
CREATE TABLE measurement (
    city_id int not null,
    logdate date not null,
    peaktemp int,
    unitsales int
);
```

We know that most queries will access just the last week’s, month’s or quarter’s data, since the main
use of this table will be to prepare online reports for management. To reduce the amount of old data
that needs to be stored, we decide to only keep the most recent 3 years worth of data. At the beginning
of each month we will remove the oldest month’s data.

In this situation we can use partitioning to help us meet all of our different requirements for the
measurements table. Following the steps outlined above, partitioning can be set up as follows:

1. The master table is the `measurement` table, declared exactly as above.
2. Next we create one partition for each active month:
   
   CREATE TABLE measurement_y2006m02 ( ) INHERITS (measurement);
   CREATE TABLE measurement_y2006m03 ( ) INHERITS (measurement);
   ...
   CREATE TABLE measurement_y2007m11 ( ) INHERITS (measurement);
   CREATE TABLE measurement_y2007m12 ( ) INHERITS (measurement);
   CREATE TABLE measurement_y2008m01 ( ) INHERITS (measurement);

   Each of the partitions are complete tables in their own right, but they inherit their definitions from
   the `measurement` table.
Chapter 5. Data Definition

3. We must provide non-overlapping table constraints. Rather than just creating the partition tables as above, the table creation script should really be:

```sql
CREATE TABLE measurement_y2006m02 (
    CHECK ( logdate >= DATE '2006-02-01' AND logdate < DATE '2006-03-01' )
) INHERITS (measurement);
CREATE TABLE measurement_y2006m03 (
    CHECK ( logdate >= DATE '2006-03-01' AND logdate < DATE '2006-04-01' )
) INHERITS (measurement);
... CREATE TABLE measurement_y2007m11 (
    CHECK ( logdate >= DATE '2007-11-01' AND logdate < DATE '2007-12-01' )
) INHERITS (measurement);
CREATE TABLE measurement_y2007m12 (
    CHECK ( logdate >= DATE '2007-12-01' AND logdate < DATE '2008-01-01' )
) INHERITS (measurement);
CREATE TABLE measurement_y2008m01 (
    CHECK ( logdate >= DATE '2008-01-01' AND logdate < DATE '2008-02-01' )
) INHERITS (measurement);
```

4. We probably need indexes on the key columns too:

```sql
CREATE INDEX measurement_y2006m02_logdate ON measurement_y2006m02 (logdate);
CREATE INDEX measurement_y2006m03_logdate ON measurement_y2006m03 (logdate);
... CREATE INDEX measurement_y2007m11_logdate ON measurement_y2007m11 (logdate);
CREATE INDEX measurement_y2007m12_logdate ON measurement_y2007m12 (logdate);
CREATE INDEX measurement_y2008m01_logdate ON measurement_y2008m01 (logdate);
```

5. We want our application to be able to say `INSERT INTO measurement ...` and have the data be redirected into the appropriate partition table. We can arrange that by attaching a suitable trigger function to the master table. If data will be added only to the latest partition, we can use a very simple trigger function:

```sql
CREATE OR REPLACE FUNCTION measurement_insert_trigger()
RETURNS TRIGGER AS $$
BEGIN
    INSERT INTO measurement_y2008m01 VALUES (NEW.*);
    RETURN NULL;
END;
$$
LANGUAGE plpgsql;
```

After creating the function, we create a trigger which calls the trigger function:

```sql
CREATE TRIGGER insert_measurement_trigger
BEFORE INSERT ON measurement
FOR EACH ROW EXECUTE PROCEDURE measurement_insert_trigger();
```

We must redefine the trigger function each month so that it always points to the current partition. The trigger definition does not need to be updated, however.

We might want to insert data and have the server automatically locate the partition into which the row should be added. We could do this with a more complex trigger function, for example:

```sql
CREATE OR REPLACE FUNCTION measurement_insert_trigger()
RETURNS TRIGGER AS $$
BEGIN
    IF ( NEW.logdate >= DATE '2006-02-01' AND
        NEW.logdate < DATE '2006-03-01' ) THEN
      INSERT INTO measurement_y2006m02 VALUES (NEW.*);
    END IF;
    RETURN NULL;
END;
$$
LANGUAGE plpgsql;
```

6. We might want to insert data and have the server automatically locate the partition into which the row should be added. We could do this with a more complex trigger function, for example:
Chapter 5. Data Definition

```
INSERT INTO measurement_y2006m02 VALUES (NEW.*);
ELSIF ( NEW.logdate >= DATE '2006-03-01' AND
       NEW.logdate < DATE '2006-04-01' ) THEN
  INSERT INTO measurement_y2006m03 VALUES (NEW.*);
...
ELSIF ( NEW.logdate >= DATE '2008-01-01' AND
       NEW.logdate < DATE '2008-02-01' ) THEN
  INSERT INTO measurement_y2008m01 VALUES (NEW.*);
ELSE
  RAISE EXCEPTION 'Date out of range. Fix the measurement_insert_trigger() function!';
END IF;
RETURN NULL;
END;
$$
LANGUAGE plpgsql;
```

The trigger definition is the same as before. Note that each IF test must exactly match the CHECK constraint for its partition.

While this function is more complex than the single-month case, it doesn’t need to be updated as often, since branches can be added in advance of being needed.

**Note:** In practice it might be best to check the newest partition first, if most inserts go into that partition. For simplicity we have shown the trigger’s tests in the same order as in other parts of this example.

As we can see, a complex partitioning scheme could require a substantial amount of DDL. In the above example we would be creating a new partition each month, so it might be wise to write a script that generates the required DDL automatically.

### 5.9.3. Managing Partitions

Normally the set of partitions established when initially defining the table are not intended to remain static. It is common to want to remove old partitions of data and periodically add new partitions for new data. One of the most important advantages of partitioning is precisely that it allows this otherwise painful task to be executed nearly instantaneously by manipulating the partition structure, rather than physically moving large amounts of data around.

The simplest option for removing old data is simply to drop the partition that is no longer necessary:

```
DROP TABLE measurement_y2006m02;
```

This can very quickly delete millions of records because it doesn’t have to individually delete every record.

Another option that is often preferable is to remove the partition from the partitioned table but retain access to it as a table in its own right:

```
ALTER TABLE measurement_y2006m02 NO INHERIT measurement;
```
This allows further operations to be performed on the data before it is dropped. For example, this is often a useful time to back up the data using COPY, pg_dump, or similar tools. It might also be a useful time to aggregate data into smaller formats, perform other data manipulations, or run reports.

Similarly we can add a new partition to handle new data. We can create an empty partition in the partitioned table just as the original partitions were created above:

```sql
CREATE TABLE measurement_y2008m02 (
    CHECK ( logdate >= DATE '2008-02-01' AND logdate < DATE '2008-03-01' )
) INHERITS (measurement);
```

As an alternative, it is sometimes more convenient to create the new table outside the partition structure, and make it a proper partition later. This allows the data to be loaded, checked, and transformed prior to it appearing in the partitioned table:

```sql
CREATE TABLE measurement_y2008m02
    (LIKE measurement INCLUDING DEFAULTS INCLUDING CONSTRAINTS);
ALTER TABLE measurement_y2008m02 ADD CONSTRAINT y2008m02
    CHECK ( logdate >= DATE '2008-02-01' AND logdate < DATE '2008-03-01' );
\copy measurement_y2008m02 from 'measurement_y2008m02'
    -- possibly some other data preparation work
ALTER TABLE measurement_y2008m02 INHERIT measurement;
```

### 5.9.4. Partitioning and Constraint Exclusion

**Constraint exclusion** is a query optimization technique that improves performance for partitioned tables defined in the fashion described above. As an example:

```sql
SET constraint_exclusion = on;
SELECT count(*) FROM measurement WHERE logdate >= DATE '2008-01-01';
```

Without constraint exclusion, the above query would scan each of the partitions of the `measurement` table. With constraint exclusion enabled, the planner will examine the constraints of each partition and try to prove that the partition need not be scanned because it could not contain any rows meeting the query’s `WHERE` clause. When the planner can prove this, it excludes the partition from the query plan.

You can use the `EXPLAIN` command to show the difference between a plan with `constraint_exclusion` on and a plan with it off. A typical unoptimized plan for this type of table setup is:

```sql
SET constraint_exclusion = off;
EXPLAIN SELECT count(*) FROM measurement WHERE logdate >= DATE '2008-01-01';
```

```
QUERY PLAN
--------------------------------------------------------
Aggregate (cost=158.66..158.68 rows=1 width=0)
  ->  Append (cost=0.00..151.88 rows=2715 width=0)
      ->  Seq Scan on measurement (cost=0.00..30.38 rows=543 width=0)
          Filter: (logdate >= '2008-01-01'::date)
      ->  Seq Scan on measurement_y2006m02 measurement (cost=0.00..30.38 rows=543 width=0)
          Filter: (logdate >= '2008-01-01'::date)
      ->  Seq Scan on measurement_y2006m03 measurement (cost=0.00..30.38 rows=543 width=0)
          Filter: (logdate >= '2008-01-01'::date)
```
Chapter 5. Data Definition

...  

-> Seq Scan on measurement_y2007m12 measurement  (cost=0.00..30.38 rows=543 width=0)  
Filter: (logdate >= '2008-01-01'::date)  

-> Seq Scan on measurement_y2008m01 measurement  (cost=0.00..30.38 rows=543 width=0)  
Filter: (logdate >= '2008-01-01'::date)  

Some or all of the partitions might use index scans instead of full-table sequential scans, but the point here is that there is no need to scan the older partitions at all to answer this query. When we enable constraint exclusion, we get a significantly cheaper plan that will deliver the same answer:

```sql
SET constraint_exclusion = on;
EXPLAIN SELECT count(*) FROM measurement WHERE logdate >= DATE '2008-01-01';
```

```
QUERY PLAN  
Aggregate (cost=63.47..63.48 rows=1 width=0)  
  ->  Append (cost=0.00..60.75 rows=1086 width=0)  
    ->  Seq Scan on measurement (cost=0.00..30.38 rows=543 width=0)  
        Filter: (logdate >= '2008-01-01'::date)  
    ->  Seq Scan on measurement_y2008m01 measurement (cost=0.00..30.38 rows=543 width=0)  
        Filter: (logdate >= '2008-01-01'::date)  
```

Note that constraint exclusion is driven only by CHECK constraints, not by the presence of indexes. Therefore it isn’t necessary to define indexes on the key columns. Whether an index needs to be created for a given partition depends on whether you expect that queries that scan the partition will generally scan a large part of the partition or just a small part. An index will be helpful in the latter case but not the former.

The default (and recommended) setting of constraint_exclusion is actually neither on nor off, but an intermediate setting called partition, which causes the technique to be applied only to queries that are likely to be working on partitioned tables. The on setting causes the planner to examine CHECK constraints in all queries, even simple ones that are unlikely to benefit.

### 5.9.5. Alternative Partitioning Methods

A different approach to redirecting inserts into the appropriate partition table is to set up rules, instead of a trigger, on the master table. For example:

```sql
CREATE RULE measurement_insert_y2006m02 AS  
ON INSERT TO measurement WHERE  
  (logdate >= DATE '2006-02-01' AND logdate < DATE '2006-03-01')  
DO INSTEAD  
  INSERT INTO measurement_y2006m02 VALUES (NEW.*);
...
CREATE RULE measurement_insert_y2008m01 AS  
ON INSERT TO measurement WHERE  
  (logdate >= DATE '2008-01-01' AND logdate < DATE '2008-02-01')  
DO INSTEAD  
  INSERT INTO measurement_y2008m01 VALUES (NEW.*);
```

A rule has significantly more overhead than a trigger, but the overhead is paid once per query rather than once per row, so this method might be advantageous for bulk-insert situations. In most cases, however, the trigger method will offer better performance.
Be aware that \texttt{COPY} ignores rules. If you want to use \texttt{COPY} to insert data, you’ll need to copy into the correct partition table rather than into the master. \texttt{COPY} does fire triggers, so you can use it normally if you use the trigger approach.

Another disadvantage of the rule approach is that there is no simple way to force an error if the set of rules doesn’t cover the insertion date; the data will silently go into the master table instead.

Partitioning can also be arranged using a \texttt{UNION ALL} view, instead of table inheritance. For example,

\begin{verbatim}
CREATE VIEW measurement AS
    SELECT * FROM measurement_y2006m02
UNION ALL SELECT * FROM measurement_y2006m03
    ...
UNION ALL SELECT * FROM measurement_y2007m11
UNION ALL SELECT * FROM measurement_y2007m12
UNION ALL SELECT * FROM measurement_y2008m01;
\end{verbatim}

However, the need to recreate the view adds an extra step to adding and dropping individual partitions of the data set. In practice this method has little to recommend it compared to using inheritance.

\section*{5.9.6. Caveats}

The following caveats apply to partitioned tables:

- There is no automatic way to verify that all of the \texttt{CHECK} constraints are mutually exclusive. It is safer to create code that generates partitions and creates and/or modifies associated objects than to write each by hand.

- The schemes shown here assume that the partition key column(s) of a row never change, or at least do not change enough to require it to move to another partition. An \texttt{UPDATE} that attempts to do that will fail because of the \texttt{CHECK} constraints. If you need to handle such cases, you can put suitable update triggers on the partition tables, but it makes management of the structure much more complicated.

- If you are using manual \texttt{VACUUM} or \texttt{ANALYZE} commands, don’t forget that you need to run them on each partition individually. A command like:

\begin{verbatim}
ANALYZE measurement;
\end{verbatim}

will only process the master table.

The following caveats apply to constraint exclusion:

- Constraint exclusion only works when the query’s \texttt{WHERE} clause contains constants. A parameterized query will not be optimized, since the planner cannot know which partitions the parameter value might select at run time. For the same reason, "stable" functions such as \texttt{CURRENT_DATE} must be avoided.

- Keep the partitioning constraints simple, else the planner may not be able to prove that partitions don’t need to be visited. Use simple equality conditions for list partitioning, or simple range tests for range partitioning, as illustrated in the preceding examples. A good rule of thumb is that partitioning constraints should contain only comparisons of the partitioning column(s) to constants using B-tree-indexable operators.

- All constraints on all partitions of the master table are examined during constraint exclusion, so large numbers of partitions are likely to increase query planning time considerably. Partitioning
using these techniques will work well with up to perhaps a hundred partitions; don’t try to use many thousands of partitions.

5.10. Other Database Objects

Tables are the central objects in a relational database structure, because they hold your data. But they are not the only objects that exist in a database. Many other kinds of objects can be created to make the use and management of the data more efficient or convenient. They are not discussed in this chapter, but we give you a list here so that you are aware of what is possible:

- Views
- Functions and operators
- Data types and domains
- Triggers and rewrite rules

Detailed information on these topics appears in Part V.

5.11. Dependency Tracking

When you create complex database structures involving many tables with foreign key constraints, views, triggers, functions, etc. you implicitly create a net of dependencies between the objects. For instance, a table with a foreign key constraint depends on the table it references.

To ensure the integrity of the entire database structure, PostgreSQL makes sure that you cannot drop objects that other objects still depend on. For example, attempting to drop the products table we had considered in Section 5.3.5, with the orders table depending on it, would result in an error message such as this:

```
DROP TABLE products;
```

```
NOTICE: constraint orders_product_no_fkey on table orders depends on table products
ERROR: cannot drop table products because other objects depend on it
HINT: Use DROP ... CASCADE to drop the dependent objects too.
```

The error message contains a useful hint: if you do not want to bother deleting all the dependent objects individually, you can run:

```
DROP TABLE products CASCADE;
```

and all the dependent objects will be removed. In this case, it doesn’t remove the orders table, it only removes the foreign key constraint. (If you want to check what DROP ... CASCADE will do, run DROP without CASCADE and read the NOTICE messages.)

All drop commands in PostgreSQL support specifying CASCADE. Of course, the nature of the possible dependencies varies with the type of the object. You can also write RESTRICT instead of CASCADE to get the default behavior, which is to prevent the dropping of objects that other objects depend on.
Note: According to the SQL standard, specifying either **RESTRICT** or **CASCADE** is required. No database system actually enforces that rule, but whether the default behavior is **RESTRICT** or **CASCADE** varies across systems.

Note: Foreign key constraint dependencies and serial column dependencies from PostgreSQL versions prior to 7.3 are *not* maintained or created during the upgrade process. All other dependency types will be properly created during an upgrade from a pre-7.3 database.
Chapter 6. Data Manipulation

The previous chapter discussed how to create tables and other structures to hold your data. Now it is time to fill the tables with data. This chapter covers how to insert, update, and delete table data. We also introduce ways to effect automatic data changes when certain events occur: triggers and rewrite rules. The chapter after this will finally explain how to extract your long-lost data from the database.

6.1. Inserting Data

When a table is created, it contains no data. The first thing to do before a database can be of much use is to insert data. Data is conceptually inserted one row at a time. Of course you can also insert more than one row, but there is no way to insert less than one row. Even if you know only some column values, a complete row must be created.

To create a new row, use the `INSERT` command. The command requires the table name and column values. For example, consider the products table from Chapter 5:

```sql
CREATE TABLE products (
    product_no integer,
    name text,
    price numeric
);
```

An example command to insert a row would be:

```sql
INSERT INTO products VALUES (1, 'Cheese', 9.99);
```

The data values are listed in the order in which the columns appear in the table, separated by commas. Usually, the data values will be literals (constants), but scalar expressions are also allowed.

The above syntax has the drawback that you need to know the order of the columns in the table. To avoid this you can also list the columns explicitly. For example, both of the following commands have the same effect as the one above:

```sql
INSERT INTO products (product_no, name, price) VALUES (1, 'Cheese', 9.99);
INSERT INTO products (name, price, product_no) VALUES ('Cheese', 9.99, 1);
```

Many users consider it good practice to always list the column names.

If you don’t have values for all the columns, you can omit some of them. In that case, the columns will be filled with their default values. For example:

```sql
INSERT INTO products (product_no, name) VALUES (1, 'Cheese');
INSERT INTO products VALUES (1, 'Cheese');
```

The second form is a PostgreSQL extension. It fills the columns from the left with as many values as are given, and the rest will be defaulted.

For clarity, you can also request default values explicitly, for individual columns or for the entire row:

```sql
INSERT INTO products (product_no, name, price) VALUES (1, 'Cheese', DEFAULT);
INSERT INTO products DEFAULT VALUES;
```

You can insert multiple rows in a single command:
Chapter 6. Data Manipulation

INSERT INTO products (product_no, name, price) VALUES
(1, 'Cheese', 9.99),
(2, 'Bread', 1.99),
(3, 'Milk', 2.99);

**Tip:** When inserting a lot of data at the same time, considering using the *COPY* command. It is not as flexible as the *INSERT* command, but is more efficient. Refer to Section 14.4 for more information on improving bulk loading performance.

### 6.2. Updating Data

The modification of data that is already in the database is referred to as updating. You can update individual rows, all the rows in a table, or a subset of all rows. Each column can be updated separately; the other columns are not affected.

To update existing rows, use the *UPDATE* command. This requires three pieces of information:

1. The name of the table and column to update
2. The new value of the column
3. Which row(s) to update

Recall from Chapter 5 that SQL does not, in general, provide a unique identifier for rows. Therefore it is not always possible to directly specify which row to update. Instead, you specify which conditions a row must meet in order to be updated. Only if you have a primary key in the table (independent of whether you declared it or not) can you reliably address individual rows by choosing a condition that matches the primary key. Graphical database access tools rely on this fact to allow you to update rows individually.

For example, this command updates all products that have a price of 5 to have a price of 10:

```
UPDATE products SET price = 10 WHERE price = 5;
```

This might cause zero, one, or many rows to be updated. It is not an error to attempt an update that does not match any rows.

Let’s look at that command in detail. First is the key word *UPDATE* followed by the table name. As usual, the table name can be schema-qualified, otherwise it is looked up in the path. Next is the key word *SET* followed by the column name, an equal sign, and the new column value. The new column value can be any scalar expression, not just a constant. For example, if you want to raise the price of all products by 10% you could use:

```
UPDATE products SET price = price * 1.10;
```

As you see, the expression for the new value can refer to the existing value(s) in the row. We also left out the *WHERE* clause. If it is omitted, it means that all rows in the table are updated. If it is present, only those rows that match the *WHERE* condition are updated. Note that the equals sign in the *SET* clause is an assignment while the one in the *WHERE* clause is a comparison, but this does not create any ambiguity. Of course, the *WHERE* condition does not have to be an equality test. Many other operators are available (see Chapter 9). But the expression needs to evaluate to a Boolean result.
You can update more than one column in an UPDATE command by listing more than one assignment in the SET clause. For example:

```
UPDATE mytable SET a = 5, b = 3, c = 1 WHERE a > 0;
```

### 6.3. Deleting Data

So far we have explained how to add data to tables and how to change data. What remains is to discuss how to remove data that is no longer needed. Just as adding data is only possible in whole rows, you can only remove entire rows from a table. In the previous section we explained that SQL does not provide a way to directly address individual rows. Therefore, removing rows can only be done by specifying conditions that the rows to be removed have to match. If you have a primary key in the table then you can specify the exact row. But you can also remove groups of rows matching a condition, or you can remove all rows in the table at once.

You use the DELETE command to remove rows; the syntax is very similar to the UPDATE command. For instance, to remove all rows from the products table that have a price of 10, use:

```
DELETE FROM products WHERE price = 10;
```

If you simply write:

```
DELETE FROM products;
```

then all rows in the table will be deleted! Caveat programmer.
Chapter 7. Queries

The previous chapters explained how to create tables, how to fill them with data, and how to manipulate that data. Now we finally discuss how to retrieve the data from the database.

7.1. Overview

The process of retrieving or the command to retrieve data from a database is called a query. In SQL the SELECT command is used to specify queries. The general syntax of the SELECT command is:

\[
\text{WITH with_queries] SELECT select_list FROM table_expression [sort_specification]}
\]

The following sections describe the details of the select list, the table expression, and the sort specification. WITH queries are treated last since they are an advanced feature.

A simple kind of query has the form:

\[
\text{SELECT * FROM table1;}
\]

Assuming that there is a table called table1, this command would retrieve all rows and all columns from table1. (The method of retrieval depends on the client application. For example, the psql program will display an ASCII-art table on the screen, while client libraries will offer functions to extract individual values from the query result.) The select list specification * means all columns that the table expression happens to provide. A select list can also select a subset of the available columns or make calculations using the columns. For example, if table1 has columns named a, b, and c (and perhaps others) you can make the following query:

\[
\text{SELECT a, b + c FROM table1;}
\]

(assuming that b and c are of a numerical data type). See Section 7.3 for more details.

FROM table1 is a simple kind of table expression: it reads just one table. In general, table expressions can be complex constructs of base tables, joins, and subqueries. But you can also omit the table expression entirely and use the SELECT command as a calculator:

\[
\text{SELECT 3 * 4;}
\]

This is more useful if the expressions in the select list return varying results. For example, you could call a function this way:

\[
\text{SELECT random();}
\]

7.2. Table Expressions

A table expression computes a table. The table expression contains a FROM clause that is optionally followed by WHERE, GROUP BY, and HAVING clauses. Trivial table expressions simply refer to a table on disk, a so-called base table, but more complex expressions can be used to modify or combine base tables in various ways.

The optional WHERE, GROUP BY, and HAVING clauses in the table expression specify a pipeline of successive transformations performed on the table derived in the FROM clause. All these transforma-
7.2.1. The FROM Clause

The FROM Clause derives a table from one or more other tables given in a comma-separated table reference list.

```
FROM table_reference [, table_reference [, ...]]
```

A table reference can be a table name (possibly schema-qualified), or a derived table such as a sub-query, a table join, or complex combinations of these. If more than one table reference is listed in the FROM clause they are cross-joined (see below) to form the intermediate virtual table that can then be subject to transformations by the WHERE, GROUP BY, and HAVING clauses and is finally the result of the overall table expression.

When a table reference names a table that is the parent of a table inheritance hierarchy, the table reference produces rows of not only that table but all of its descendant tables, unless the key word ONLY precedes the table name. However, the reference produces only the columns that appear in the named table — any columns added in subtables are ignored.

Instead of writing ONLY before the table name, you can write * after the table name to explicitly specify that descendant tables are included. Writing * is not necessary since that behavior is the default (unless you have changed the setting of the sql_inheritance configuration option). However writing * might be useful to emphasize that additional tables will be searched.

7.2.1.1. Joined Tables

A joined table is a table derived from two other (real or derived) tables according to the rules of the particular join type. Inner, outer, and cross-joins are available.

Join Types

Cross join

```
T1 CROSS JOIN T2
```

For every possible combination of rows from T1 and T2 (i.e., a Cartesian product), the joined table will contain a row consisting of all columns in T1 followed by all columns in T2. If the tables have N and M rows respectively, the joined table will have N * M rows.

```
FROM T1 CROSS JOIN T2
```

is equivalent to

```
FROM T1, T2. It is also equivalent to FROM T1 INNER JOIN T2 ON TRUE (see below).
```

Qualified joins

```
T1 { [INNER] | { LEFT | RIGHT | FULL } [OUTER] } JOIN T2 ON boolean_expression
T1 { [INNER] | { LEFT | RIGHT | FULL } [OUTER] } JOIN T2 USING ( join column list )
T1 NATURAL { [INNER] | { LEFT | RIGHT | FULL } [OUTER] } JOIN T2
```

The words INNER and OUTER are optional in all forms. INNER is the default; LEFT, RIGHT, and FULL imply an outer join.

The join condition is specified in the ON or USING clause, or implicitly by the word NATURAL. The join condition determines which rows from the two source tables are considered to “match”, as explained in detail below.
The **ON** clause is the most general kind of join condition: it takes a Boolean value expression of the same kind as is used in a **WHERE** clause. A pair of rows from \( T_1 \) and \( T_2 \) match if the **ON** expression evaluates to true for them.

**USING** is a shorthand notation: it takes a comma-separated list of column names, which the joined tables must have in common, and forms a join condition specifying equality of each of these pairs of columns. Furthermore, the output of **JOIN USING** has one column for each of the equated pairs of input columns, followed by the remaining columns from each table. Thus, **USING** \((a, b, c)\) is equivalent to **ON** \((t_1.a = t_2.a \land t_1.b = t_2.b \land t_1.c = t_2.c)\) with the exception that if **ON** is used there will be two columns \(a, b, c\) in the result, whereas with **USING** there will be only one of each (and they will appear first if **SELECT *\) is used).

Finally, **NATURAL** is a shorthand form of **USING**: it forms a **USING** list consisting of all column names that appear in both input tables. As with **USING**, these columns appear only once in the output table.

The possible types of qualified join are:

**INNER JOIN**

For each row \( R_1 \) of \( T_1 \), the joined table has a row for each row in \( T_2 \) that satisfies the join condition with \( R_1 \).

**LEFT OUTER JOIN**

First, an inner join is performed. Then, for each row in \( T_1 \) that does not satisfy the join condition with any row in \( T_2 \), a joined row is added with null values in columns of \( T_2 \). Thus, the joined table always has at least one row for each row in \( T_1 \).

**RIGHT OUTER JOIN**

First, an inner join is performed. Then, for each row in \( T_2 \) that does not satisfy the join condition with any row in \( T_1 \), a joined row is added with null values in columns of \( T_1 \). This is the converse of a left join: the result table will always have a row for each row in \( T_2 \).

**FULL OUTER JOIN**

First, an inner join is performed. Then, for each row in \( T_1 \) that does not satisfy the join condition with any row in \( T_2 \), a joined row is added with null values in columns of \( T_2 \). Also, for each row of \( T_2 \) that does not satisfy the join condition with any row in \( T_1 \), a joined row with null values in the columns of \( T_1 \) is added.

Joins of all types can be chained together or nested: either or both \( T_1 \) and \( T_2 \) can be joined tables. Parentheses can be used around **JOIN** clauses to control the join order. In the absence of parentheses, **JOIN** clauses nest left-to-right.

To put this together, assume we have tables \( t_1 \):

<table>
<thead>
<tr>
<th>num</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>a</td>
</tr>
<tr>
<td>2</td>
<td>b</td>
</tr>
<tr>
<td>3</td>
<td>c</td>
</tr>
</tbody>
</table>

and \( t_2 \):

<table>
<thead>
<tr>
<th>num</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>xxx</td>
</tr>
</tbody>
</table>
then we get the following results for the various joins:

```sql
-> SELECT * FROM t1 CROSS JOIN t2;
num | name | num | value
-----+------+-----+-------
 1 | a  | 1 | xxx
 1 | a  | 3 | yyy
 1 | a  | 5 | zzz
 2 | b  | 1 | xxx
 2 | b  | 3 | yyy
 2 | b  | 5 | zzz
 3 | c  | 1 | xxx
 3 | c  | 3 | yyy
 3 | c  | 5 | zzz
(9 rows)
```

```sql
-> SELECT * FROM t1 INNER JOIN t2 ON t1.num = t2.num;
num | name | num | value
-----+------+-----+-------
 1 | a  | 1 | xxx
 3 | c  | 3 | yyy
(2 rows)
```

```sql
-> SELECT * FROM t1 INNER JOIN t2 USING (num);
num | name | value
-----+------+-------
 1 | a  | xxx
 3 | c  | yyy
(2 rows)
```

```sql
-> SELECT * FROM t1 NATURAL INNER JOIN t2;
num | name | value
-----+------+-------
 1 | a  | xxx
 3 | c  | yyy
(2 rows)
```

```sql
-> SELECT * FROM t1 LEFT JOIN t2 ON t1.num = t2.num;
num | name | num | value
-----+------+-----+-------
 1 | a  | 1 | xxx
 2 | b  | | 
 3 | c  | 3 | yyy
(3 rows)
```

```sql
-> SELECT * FROM t1 LEFT JOIN t2 USING (num);
num | name | value
-----+------+-------
 1 | a  | xxx
 2 | b  | 
 3 | c  | yyy
(3 rows)
```

```sql
-> SELECT * FROM t1 RIGHT JOIN t2 ON t1.num = t2.num;
```
Chapter 7. Queries

<table>
<thead>
<tr>
<th>num</th>
<th>name</th>
<th>num</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>a</td>
<td>1</td>
<td>xxx</td>
</tr>
<tr>
<td>3</td>
<td>c</td>
<td>3</td>
<td>yyy</td>
</tr>
</tbody>
</table>

(3 rows)

=> SELECT * FROM t1 FULL JOIN t2 ON t1.num = t2.num;

<table>
<thead>
<tr>
<th>num</th>
<th>name</th>
<th>num</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>a</td>
<td>1</td>
<td>xxx</td>
</tr>
<tr>
<td>2</td>
<td>b</td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>c</td>
<td>3</td>
<td>yyy</td>
</tr>
<tr>
<td></td>
<td></td>
<td>5</td>
<td>zzz</td>
</tr>
</tbody>
</table>

(4 rows)

The join condition specified with ON can also contain conditions that do not relate directly to the join. This can prove useful for some queries but needs to be thought out carefully. For example:

=> SELECT * FROM t1 LEFT JOIN t2 ON t1.num = t2.num AND t2.value = 'xxx';

<table>
<thead>
<tr>
<th>num</th>
<th>name</th>
<th>num</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>a</td>
<td>1</td>
<td>xxx</td>
</tr>
</tbody>
</table>

(3 rows)

Notice that placing the restriction in the WHERE clause produces a different result:

=> SELECT * FROM t1 LEFT JOIN t2 ON t1.num = t2.num WHERE t2.value = 'xxx';

<table>
<thead>
<tr>
<th>num</th>
<th>name</th>
<th>num</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>a</td>
<td>1</td>
<td>xxx</td>
</tr>
</tbody>
</table>

(1 row)

This is because a restriction placed in the ON clause is processed before the join, while a restriction placed in the WHERE clause is processed after the join.

7.2.1.2. Table and Column Aliases

A temporary name can be given to tables and complex table references to be used for references to the derived table in the rest of the query. This is called a table alias.

To create a table alias, write

FROM table_reference AS alias

or

FROM table_reference alias

The AS key word is optional noise. alias can be any identifier.

A typical application of table aliases is to assign short identifiers to long table names to keep the join clauses readable. For example:
SELECT * FROM some_very_long_table_name s JOIN another_fairly_long_name a ON s.id = a.num;

The alias becomes the new name of the table reference for the current query — it is no longer possible
to refer to the table by the original name. Thus:

SELECT * FROM my_table AS m WHERE my_table.a > 5;

is not valid according to the SQL standard. In PostgreSQL this will draw an error, assuming the
add_missing_from configuration variable is off (as it is by default). If it is on, an implicit table
reference will be added to the FROM clause, so the query is processed as if it were written as:

SELECT * FROM my_table AS m, my_table AS my_table WHERE my_table.a > 5;

That will result in a cross join, which is usually not what you want.

Table aliases are mainly for notational convenience, but it is necessary to use them when joining a
table to itself, e.g.:

SELECT * FROM people AS mother JOIN people AS child ON mother.id = child.mother_id;

Additionally, an alias is required if the table reference is a subquery (see Section 7.2.1.3).

Parentheses are used to resolve ambiguities. In the following example, the first statement assigns the
alias b to the second instance of my_table, but the second statement assigns the alias to the result of
the join:

SELECT * FROM my_table AS a CROSS JOIN my_table AS b ...
SELECT * FROM (my_table AS a CROSS JOIN my_table) AS b ...

Another form of table aliasing gives temporary names to the columns of the table, as well as the table
itself:

FROM table_reference [AS] alias (column1 [, column2 [, ...]])

If fewer column aliases are specified than the actual table has columns, the remaining columns are not
renamed. This syntax is especially useful for self-joins or subqueries.

When an alias is applied to the output of a JOIN clause, the alias hides the original name(s) within the
JOIN. For example:

SELECT a.* FROM my_table AS a JOIN your_table AS b ON ...

is valid SQL. but:

SELECT a.* FROM (my_table AS a JOIN your_table AS b ON ...) AS c

is not valid; the table alias a is not visible outside the alias c.

### 7.2.1.3. Subqueries

Subqueries specifying a derived table must be enclosed in parentheses and must be assigned a table
alias name. (See Section 7.2.1.2.) For example:

FROM (SELECT * FROM table1) AS alias_name
Chapter 7. Queries

This example is equivalent to `FROM table1 AS alias_name`. More interesting cases, which cannot be reduced to a plain join, arise when the subquery involves grouping or aggregation.

A subquery can also be a `VALUES` list:

```
FROM (VALUES ('anne', 'smith'), ('bob', 'jones'), ('joe', 'blow'))
    AS names(first, last)
```

Again, a table alias is required. Assigning alias names to the columns of the `VALUES` list is optional, but is good practice. For more information see Section 7.7.

### 7.2.1.4. Table Functions

Table functions are functions that produce a set of rows, made up of either base data types (scalar types) or composite data types (table rows). They are used like a table, view, or subquery in the `FROM` clause of a query. Columns returned by table functions can be included in `SELECT`, `JOIN`, or `WHERE` clauses in the same manner as a table, view, or subquery column.

If a table function returns a base data type, the single result column name matches the function name. If the function returns a composite type, the result columns get the same names as the individual attributes of the type.

A table function can be aliased in the `FROM` clause, but it also can be left unaliased. If a function is used in the `FROM` clause with no alias, the function name is used as the resulting table name.

Some examples:

```
CREATE TABLE foo (fooid int, foosubid int, fooname text);

CREATE FUNCTION getfoo(int) RETURNS SETOF foo AS $$
    SELECT * FROM foo WHERE fooid = $1;
$$ LANGUAGE SQL;

SELECT * FROM getfoo(1) AS t1;

SELECT * FROM foo
WHERE foosubid IN (SELECT foosubid
    FROM getfoo(foo.fooid) z
    WHERE z.fooid = foo.fooid);

CREATE VIEW vw_getfoo AS SELECT * FROM getfoo(1);

SELECT * FROM vw_getfoo;
```

In some cases it is useful to define table functions that can return different column sets depending on how they are invoked. To support this, the table function can be declared as returning the pseudotype `record`. When such a function is used in a query, the expected row structure must be specified in the query itself, so that the system can know how to parse and plan the query. Consider this example:

```
SELECT *
FROM dblink('dbname=mydb', 'SELECT proname, prosrc FROM pg_proc')
    AS t1(proname name, prosrc text)
```

84
WHERE proname LIKE 'bytea%';

The `dblink` function executes a remote query (see `contrib/dblink`). It is declared to return `record` since it might be used for any kind of query. The actual column set must be specified in the calling query so that the parser knows, for example, what `*` should expand to.

### 7.2.2. The `WHERE` Clause

The syntax of the `WHERE` Clause is

```
WHERE search_condition
```

where `search_condition` is any value expression (see Section 4.2) that returns a value of type `boolean`.

After the processing of the `FROM` clause is done, each row of the derived virtual table is checked against the search condition. If the result of the condition is true, the row is kept in the output table, otherwise (i.e., if the result is false or null) it is discarded. The search condition typically references at least one column of the table generated in the `FROM` clause; this is not required, but otherwise the `WHERE` clause will be fairly useless.

**Note:** The join condition of an inner join can be written either in the `WHERE` clause or in the `JOIN` clause. For example, these table expressions are equivalent:

```
FROM a, b WHERE a.id = b.id AND b.val > 5
```

and:

```
FROM a INNER JOIN b ON (a.id = b.id) WHERE b.val > 5
```

or perhaps even:

```
FROM a NATURAL JOIN b WHERE b.val > 5
```

Which one of these you use is mainly a matter of style. The `JOIN` syntax in the `FROM` clause is probably not as portable to other SQL database management systems, even though it is in the SQL standard. For outer joins there is no choice: they must be done in the `FROM` clause. The `ON` or `USING` clause of an outer join is *not* equivalent to a `WHERE` condition, because it results in the addition of rows (for unmatched input rows) as well as the removal of rows in the final result.

Here are some examples of `WHERE` clauses:

```
SELECT ... FROM fdt WHERE c1 > 5

SELECT ... FROM fdt WHERE c1 IN (1, 2, 3)

SELECT ... FROM fdt WHERE c1 IN (SELECT c1 FROM t2)

SELECT ... FROM fdt WHERE c1 IN (SELECT c3 FROM t2 WHERE c2 = fdt.c1 + 10)

SELECT ... FROM fdt WHERE c1 BETWEEN (SELECT c3 FROM t2 WHERE c2 = fdt.c1 + 10) AND 100
```
Chapter 7. Queries

SELECT ... FROM fdt WHERE EXISTS (SELECT c1 FROM t2 WHERE c2 > fdt.c1)

fdt is the table derived in the FROM clause. Rows that do not meet the search condition of the WHERE clause are eliminated from fdt. Notice the use of scalar subqueries as value expressions. Just like any other query, the subqueries can employ complex table expressions. Notice also how fdt is referenced in the subqueries. Qualifying c1 as fdt.c1 is only necessary if c1 is also the name of a column in the derived input table of the subquery. But qualifying the column name adds clarity even when it is not needed. This example shows how the column naming scope of an outer query extends into its inner queries.

7.2.3. The GROUP BY and HAVING Clauses

After passing the WHERE filter, the derived input table might be subject to grouping, using the GROUP BY clause, and elimination of group rows using the HAVING clause.

```sql
SELECT select_list
FROM ...
[WHERE ...]
GROUP BY grouping_column_reference [, grouping_column_reference]...
```

The GROUP BY Clause is used to group together those rows in a table that have the same values in all the columns listed. The order in which the columns are listed does not matter. The effect is to combine each set of rows having common values into one group row that represents all rows in the group. This is done to eliminate redundancy in the output and/or compute aggregates that apply to these groups.

For instance:

```sql
=> SELECT * FROM test1;
 x | y
---+---
a | 3
b | 5
a | 1
(4 rows)
```

```sql
=> SELECT x FROM test1 GROUP BY x;
x
---
a
b
(3 rows)
```

In the second query, we could not have written SELECT * FROM test1 GROUP BY x, because there is no single value for the column y that could be associated with each group. The grouped-by columns can be referenced in the select list since they have a single value in each group.

In general, if a table is grouped, columns that are not listed in GROUP BY cannot be referenced except in aggregate expressions. An example with aggregate expressions is:

```sql
=> SELECT x, sum(y) FROM test1 GROUP BY x;
x | sum
---+-----
a | 4
```
Here \( \text{sum} \) is an aggregate function that computes a single value over the entire group. More information about the available aggregate functions can be found in Section 9.18.

**Tip:** Grouping without aggregate expressions effectively calculates the set of distinct values in a column. This can also be achieved using the \text{DISTINCT} clause (see Section 7.3.3).

Here is another example: it calculates the total sales for each product (rather than the total sales of all products):

```
SELECT product_id, p.name, (sum(s.units) * p.price) AS sales
FROM products p LEFT JOIN sales s USING (product_id)
GROUP BY product_id, p.name, p.price;
```

In this example, the columns \text{product_id}, \text{p.name}, and \text{p.price} must be in the \text{GROUP BY} clause since they are referenced in the query select list. (Depending on how the products table is set up, name and price might be fully dependent on the product ID, so the additional groupings could theoretically be unnecessary, though this is not implemented.) The column \text{s.units} does not have to be in the \text{GROUP BY} list since it is only used in an aggregate expression (\text{sum(...)}), which represents the sales of a product. For each product, the query returns a summary row about all sales of the product.

In strict SQL, \text{GROUP BY} can only group by columns of the source table but PostgreSQL extends this to also allow \text{GROUP BY} to group by columns in the select list. Grouping by value expressions instead of simple column names is also allowed.

If a table has been grouped using \text{GROUP BY}, but only certain groups are of interest, the \text{HAVING} clause can be used, much like a \text{WHERE} clause, to eliminate groups from the result. The syntax is:

```
SELECT select_list FROM ... [WHERE ...] GROUP BY ... HAVING boolean_expression
```

Expressions in the \text{HAVING} clause can refer both to grouped expressions and to ungrouped expressions (which necessarily involve an aggregate function).

Example:

```
=> SELECT x, sum(y) FROM test1 GROUP BY x HAVING sum(y) > 3;
    x | sum
-----+-----
    a |  4
    b |  5
(2 rows)
```

```
=> SELECT x, sum(y) FROM test1 GROUP BY x HAVING x < 'c';
    x | sum
-----+-----
    a |  4
    b |  5
(2 rows)
```

Again, a more realistic example:

```
SELECT product_id, p.name, (sum(s.units) * (p.price - p.cost)) AS profit
```
FROM products p LEFT JOIN sales s USING (product_id)
WHERE s.date > CURRENT_DATE - INTERVAL '4 weeks'
GROUP BY product_id, p.name, p.price, p.cost
HAVING sum(p.price * s.units) > 5000;

In the example above, the WHERE clause is selecting rows by a column that is not grouped (the expression is only true for sales during the last four weeks), while the HAVING clause restricts the output to groups with total gross sales over 5000. Note that the aggregate expressions do not necessarily need to be the same in all parts of the query.

If a query contains aggregate function calls, but no GROUP BY clause, grouping still occurs: the result is a single group row (or perhaps no rows at all, if the single row is then eliminated by HAVING). The same is true if it contains a HAVING clause, even without any aggregate function calls or GROUP BY clause.

7.2.4. Window Function Processing

If the query contains any window functions (see Section 3.5 and Section 4.2.8), these functions are evaluated after any grouping, aggregation, and HAVING filtering is performed. That is, if the query uses any aggregates, GROUP BY, or HAVING, then the rows seen by the window functions are the group rows instead of the original table rows from FROM/WHERE.

When multiple window functions are used, all the window functions having syntactically equivalent PARTITION BY and ORDER BY clauses in their window definitions are guaranteed to be evaluated in a single pass over the data. Therefore they will see the same sort ordering, even if the ORDER BY does not uniquely determine an ordering. However, no guarantees are made about the evaluation of functions having different PARTITION BY or ORDER BY specifications. (In such cases a sort step is typically required between the passes of window function evaluations, and the sort is not guaranteed to preserve ordering of rows that its ORDER BY sees as equivalent.)

Currently, window functions always require presorted data, and so the query output will be ordered according to one or another of the window functions’ PARTITION BY/ORDER BY clauses. It is not recommendable to rely on this, however. Use an explicit top-level ORDER BY clause if you want to be sure the results are sorted in a particular way.

7.3. Select Lists

As shown in the previous section, the table expression in the SELECT command constructs an intermediate virtual table by possibly combining tables, views, eliminating rows, grouping, etc. This table is finally passed on to processing by the select list. The select list determines which columns of the intermediate table are actually output.

7.3.1. Select-List Items

The simplest kind of select list is * which emits all columns that the table expression produces. Otherwise, a select list is a comma-separated list of value expressions (as defined in Section 4.2). For instance, it could be a list of column names:

SELECT a, b, c FROM ...
The columns names a, b, and c are either the actual names of the columns of tables referenced in the FROM clause, or the aliases given to them as explained in Section 7.2.1.2. The name space available in the select list is the same as in the WHERE clause, unless grouping is used, in which case it is the same as in the HAVING clause.

If more than one table has a column of the same name, the table name must also be given, as in:

```sql
SELECT tbl1.a, tbl2.a, tbl1.b FROM ...
```

When working with multiple tables, it can also be useful to ask for all the columns of a particular table:

```sql
SELECT tbl1.*, tbl2.a FROM ...
```

(See also Section 7.2.2.)

If an arbitrary value expression is used in the select list, it conceptually adds a new virtual column to the returned table. The value expression is evaluated once for each result row, with the row’s values substituted for any column references. But the expressions in the select list do not have to reference any columns in the table expression of the FROM clause; they can be constant arithmetic expressions, for instance.

### 7.3.2. Column Labels

The entries in the select list can be assigned names for subsequent processing, such as for use in an ORDER BY clause or for display by the client application. For example:

```sql
SELECT a AS value, b + c AS sum FROM ...
```

If no output column name is specified using AS, the system assigns a default column name. For simple column references, this is the name of the referenced column. For function calls, this is the name of the function. For complex expressions, the system will generate a generic name.

The AS keyword is optional, but only if the new column name does not match any PostgreSQL keyword (see Appendix C). To avoid an accidental match to a keyword, you can double-quote the column name. For example, VALUE is a keyword, so this does not work:

```sql
SELECT a value, b + c AS sum FROM ...
```

but this does:

```sql
SELECT a "value", b + c AS sum FROM ...
```

For protection against possible future keyword additions, it is recommended that you always either write AS or double-quote the output column name.

**Note:** The naming of output columns here is different from that done in the FROM clause (see Section 7.2.1.2). It is possible to rename the same column twice, but the name assigned in the select list is the one that will be passed on.
7.3.3. DISTINCT

After the select list has been processed, the result table can optionally be subject to the elimination of duplicate rows. The DISTINCT key word is written directly after SELECT to specify this:

```
SELECT DISTINCT select_list ...
```

(Instead of DISTINCT the key word ALL can be used to specify the default behavior of retaining all rows.)

Obviously, two rows are considered distinct if they differ in at least one column value. Null values are considered equal in this comparison.

Alternatively, an arbitrary expression can determine what rows are to be considered distinct:

```
SELECT DISTINCT ON (expression [, expression ...]) select_list ...
```

Here expression is an arbitrary value expression that is evaluated for all rows. A set of rows for which all the expressions are equal are considered duplicates, and only the first row of the set is kept in the output. Note that the “first row” of a set is unpredictable unless the query is sorted on enough columns to guarantee a unique ordering of the rows arriving at the DISTINCT filter. (DISTINCT ON processing occurs after ORDER BY sorting.)

The DISTINCT ON clause is not part of the SQL standard and is sometimes considered bad style because of the potentially indeterminate nature of its results. With judicious use of GROUP BY and subqueries in FROM, this construct can be avoided, but it is often the most convenient alternative.

7.4. Combining Queries

The results of two queries can be combined using the set operations union, intersection, and difference. The syntax is

```
query1 UNION [ALL] query2
query1 INTERSECT [ALL] query2
query1 EXCEPT [ALL] query2
```

query1 and query2 are queries that can use any of the features discussed up to this point. Set operations can also be nested and chained, for example

```
query1 UNION query2 UNION query3
```

which is executed as:

```
(query1 UNION query2) UNION query3
```

UNION effectively appends the result of query2 to the result of query1 (although there is no guarantee that this is the order in which the rows are actually returned). Furthermore, it eliminates duplicate rows from its result, in the same way as DISTINCT, unless UNION ALL is used.

INTERSECT returns all rows that are both in the result of query1 and in the result of query2. Duplicate rows are eliminated unless INTERSECT ALL is used.
EXCEPT returns all rows that are in the result of `query1` but not in the result of `query2`. (This is sometimes called the difference between two queries.) Again, duplicates are eliminated unless `EXCEPT ALL` is used.

In order to calculate the union, intersection, or difference of two queries, the two queries must be “union compatible”, which means that they return the same number of columns and the corresponding columns have compatible data types, as described in Section 10.5.

### 7.5. Sorting Rows

After a query has produced an output table (after the select list has been processed) it can optionally be sorted. If sorting is not chosen, the rows will be returned in an unspecified order. The actual order in that case will depend on the scan and join plan types and the order on disk, but it must not be relied on. A particular output ordering can only be guaranteed if the sort step is explicitly chosen.

The `ORDER BY` clause specifies the sort order:

```sql
SELECT select_list
FROM table_expression
ORDER BY sort_expression1 [ASC | DESC] [NULLS { FIRST | LAST }]
[, sort_expression2 [ASC | DESC] [NULLS { FIRST | LAST }]] ...
```

The sort expression(s) can be any expression that would be valid in the query’s select list. An example is:

```sql
SELECT a, b FROM table1 ORDER BY a + b, c;
```

When more than one expression is specified, the later values are used to sort rows that are equal according to the earlier values. Each expression can be followed by an optional `ASC` or `DESC` keyword to set the sort direction to ascending or descending. `ASC` order is the default. Ascending order puts smaller values first, where “smaller” is defined in terms of the `<` operator. Similarly, descending order is determined with the `>` operator.  

The `NULLS FIRST` and `NULLS LAST` options can be used to determine whether nulls appear before or after non-null values in the sort ordering. By default, null values sort as if larger than any non-null value; that is, `NULLS FIRST` is the default for `DESC` order, and `NULLS LAST` otherwise.

Note that the ordering options are considered independently for each sort column. For example `ORDER BY x, y DESC` means `ORDER BY x ASC, y DESC`, which is not the same as `ORDER BY x DESC, y DESC`.

A `sort_expression` can also be the column label or number of an output column, as in:

```sql
SELECT a + b AS sum, c FROM table1 ORDER BY sum;
SELECT a, max(b) FROM table1 GROUP BY a ORDER BY 1;
```

both of which sort by the first output column. Note that an output column name has to stand alone, that is, it cannot be used in an expression — for example, this is not correct:

```sql
SELECT a + b AS sum, c FROM table1 ORDER BY sum + c;   -- wrong
```

This restriction is made to reduce ambiguity. There is still ambiguity if an `ORDER BY` item is a simple name that could match either an output column name or a column from the table expression. The

---

1. Actually, PostgreSQL uses the default B-tree operator class for the expression’s data type to determine the sort ordering for `ASC` and `DESC`. Conventionally, data types will be set up so that the `<` and `>` operators correspond to this sort ordering, but a user-defined data type’s designer could choose to do something different.
output column is used in such cases. This would only cause confusion if you use AS to rename an
output column to match some other table column’s name.

ORDER BY can be applied to the result of a UNION, INTERSECT, or EXCEPT combination, but in this
case it is only permitted to sort by output column names or numbers, not by expressions.

7.6. LIMIT and OFFSET

LIMIT and OFFSET allow you to retrieve just a portion of the rows that are generated by the rest of
the query:

```sql
SELECT select_list
    FROM table_expression
    [ ORDER BY ... ]
    [ LIMIT { number | ALL } ] [ OFFSET number ]
```

If a limit count is given, no more than that many rows will be returned (but possibly less, if the query
itself yields less rows). LIMIT ALL is the same as omitting the LIMIT clause.

OFFSET says to skip that many rows before beginning to return rows. OFFSET 0 is the same as
omitting the OFFSET clause, and LIMIT NULL is the same as omitting the LIMIT clause. If both
OFFSET and LIMIT appear, then OFFSET rows are skipped before starting to count the LIMIT rows
that are returned.

When using LIMIT, it is important to use an ORDER BY clause that constrains the result rows into a
unique order. Otherwise you will get an unpredictable subset of the query’s rows. You might be asking
for the tenth through twentieth rows, but tenth through twentieth in what ordering? The ordering is
unknown, unless you specified ORDER BY.

The query optimizer takes LIMIT into account when generating query plans, so you are very likely
to get different plans (yielding different row orders) depending on what you give for LIMIT and
OFFSET. Thus, using different LIMIT/OFFSET values to select different subsets of a query result will
give inconsistent results unless you enforce a predictable result ordering with ORDER BY. This is not
a bug; it is an inherent consequence of the fact that SQL does not promise to deliver the results of a
query in any particular order unless ORDER BY is used to constrain the order.

The rows skipped by an OFFSET clause still have to be computed inside the server; therefore a large
OFFSET might be inefficient.

7.7. VALUES Lists

VALUES provides a way to generate a “constant table” that can be used in a query without having to
actually create and populate a table on-disk. The syntax is

```sql
VALUES ( expression [, ...] ) [, ...]
```

Each parenthesized list of expressions generates a row in the table. The lists must all have the same
number of elements (i.e., the number of columns in the table), and corresponding entries in each
list must have compatible data types. The actual data type assigned to each column of the result is
determined using the same rules as for UNION (see Section 10.5).

As an example:
VALUES (1, 'one'), (2, 'two'), (3, 'three');

will return a table of two columns and three rows. It’s effectively equivalent to:

SELECT 1 AS column1, 'one' AS column2
UNION ALL
SELECT 2, 'two'
UNION ALL
SELECT 3, 'three';

By default, PostgreSQL assigns the names column1, column2, etc. to the columns of a VALUES table. The column names are not specified by the SQL standard and different database systems do it differently, so it’s usually better to override the default names with a table alias list.

Syntactically, VALUES followed by expression lists is treated as equivalent to:

SELECT select_list FROM table_expression

and can appear anywhere a SELECT can. For example, you can use it as part of a UNION, or attach a sort_specification (ORDER BY, LIMIT, and/or OFFSET) to it. VALUES is most commonly used as the data source in an INSERT command, and next most commonly as a subquery.

For more information see VALUES.

7.8. WITH Queries (Common Table Expressions)

WITH provides a way to write subqueries for use in a larger SELECT query. The subqueries, which are often referred to as Common Table Expressions or CTEs, can be thought of as defining temporary tables that exist just for this query. One use of this feature is to break down complicated queries into simpler parts. An example is:

WITH regional_sales AS (
    SELECT region, SUM(amount) AS total_sales
    FROM orders
    GROUP BY region
), top_regions AS (
    SELECT region
    FROM regional_sales
    WHERE total_sales > (SELECT SUM(total_sales)/10 FROM regional_sales)
)

SELECT region,
    product,
    SUM(quantity) AS product_units,
    SUM(amount) AS product_sales
FROM orders
WHERE region IN (SELECT region FROM top_regions)
GROUP BY region, product;

which displays per-product sales totals in only the top sales regions. This example could have been written without WITH, but we’d have needed two levels of nested sub-SELECTs. It’s a bit easier to follow this way.

The optional RECURSIVE modifier changes WITH from a mere syntactic convenience into a feature that accomplishes things not otherwise possible in standard SQL. Using RECURSIVE, a WITH query can refer to its own output. A very simple example is this query to sum the integers from 1 through 100:
Chapter 7. Queries

WITH RECURSIVE t(n) AS (
    VALUES (1)
    UNION ALL
    SELECT n+1 FROM t WHERE n < 100
)
SELECT sum(n) FROM t;

The general form of a recursive WITH query is always a non-recursive term, then UNION (or UNION ALL), then a recursive term, where only the recursive term can contain a reference to the query’s own output. Such a query is executed as follows:

Recursive Query Evaluation

1. Evaluate the non-recursive term. For UNION (but not UNION ALL), discard duplicate rows. Include all remaining rows in the result of the recursive query, and also place them in a temporary working table.
2. So long as the working table is not empty, repeat these steps:
   a. Evaluate the recursive term, substituting the current contents of the working table for the recursive self-reference. For UNION (but not UNION ALL), discard duplicate rows and rows that duplicate any previous result row. Include all remaining rows in the result of the recursive query, and also place them in a temporary intermediate table.
   b. Replace the contents of the working table with the contents of the intermediate table, then empty the intermediate table.

Note: Strictly speaking, this process is iteration not recursion, but RECURSIVE is the terminology chosen by the SQL standards committee.

In the example above, the working table has just a single row in each step, and it takes on the values from 1 through 100 in successive steps. In the 100th step, there is no output because of the WHERE clause, and so the query terminates.

Recursive queries are typically used to deal with hierarchical or tree-structured data. A useful example is this query to find all the direct and indirect sub-parts of a product, given only a table that shows immediate inclusions:

WITH RECURSIVE included_parts(sub_part, part, quantity) AS (
    SELECT sub_part, part, quantity FROM parts WHERE part = 'our_product'
    UNION ALL
    SELECT p.sub_part, p.part, p.quantity
    FROM included_parts pr, parts p
    WHERE p.part = pr.sub_part
)
SELECT sub_part, SUM(quantity) as total_quantity
FROM included_parts
GROUP BY sub_part

When working with recursive queries it is important to be sure that the recursive part of the query will eventually return no tuples, or else the query will loop indefinitely. Sometimes, using UNION instead of UNION ALL can accomplish this by discarding rows that duplicate previous output rows. However, often a cycle does not involve output rows that are completely duplicate: it may be necessary to check
just one or a few fields to see if the same point has been reached before. The standard method for handling such situations is to compute an array of the already-visited values. For example, consider the following query that searches a table graph using a link field:

```
WITH RECURSIVE search_graph(id, link, data, depth) AS (
    SELECT g.id, g.link, g.data, 1
    FROM graph g
    UNION ALL
    SELECT g.id, g.link, g.data, sg.depth + 1
    FROM graph g, search_graph sg
    WHERE g.id = sg.link
)
SELECT * FROM search_graph;
```

This query will loop if the link relationships contain cycles. Because we require a “depth” output, just changing UNION ALL to UNION would not eliminate the looping. Instead we need to recognize whether we have reached the same row again while following a particular path of links. We add two columns path and cycle to the loop-prone query:

```
WITH RECURSIVE search_graph(id, link, data, depth, path, cycle) AS (
    SELECT g.id, g.link, g.data, 1,
    ARRAY[g.id],
    false
    FROM graph g
    UNION ALL
    SELECT g.id, g.link, g.data, sg.depth + 1,
    path || g.id,
    g.id = ANY(path)
    FROM graph g, search_graph sg
    WHERE g.id = sg.link AND NOT cycle
)
SELECT * FROM search_graph;
```

Aside from preventing cycles, the array value is often useful in its own right as representing the “path” taken to reach any particular row.

In the general case where more than one field needs to be checked to recognize a cycle, use an array of rows. For example, if we needed to compare fields \( f_1 \) and \( f_2 \):

```
WITH RECURSIVE search_graph(id, link, data, depth, path, cycle) AS (
    SELECT g.id, g.link, g.data, 1,
    ARRAY[ROW(g.f1, g.f2)],
    false
    FROM graph g
    UNION ALL
    SELECT g.id, g.link, g.data, sg.depth + 1,
    path || ROW(g.f1, g.f2),
    ROW(g.f1, g.f2) = ANY(path)
    FROM graph g, search_graph sg
    WHERE g.id = sg.link AND NOT cycle
)
SELECT * FROM search_graph;
```
Chapter 7. Queries

**Tip:** Omit the `ROW()` syntax in the common case where only one field needs to be checked to recognize a cycle. This allows a simple array rather than a composite-type array to be used, gaining efficiency.

**Tip:** The recursive query evaluation algorithm produces its output in breadth-first search order. You can display the results in depth-first search order by making the outer query `ORDER BY` a “path” column constructed in this way.

A helpful trick for testing queries when you are not certain if they might loop is to place a `LIMIT` in the parent query. For example, this query would loop forever without the `LIMIT`:

```sql
WITH RECURSIVE t(n) AS (  
  SELECT 1  
  UNION ALL  
  SELECT n+1 FROM t  
)  
SELECT n FROM t LIMIT 100;
```

This works because PostgreSQL’s implementation evaluates only as many rows of a `WITH` query as are actually fetched by the parent query. Using this trick in production is not recommended, because other systems might work differently. Also, it usually won’t work if you make the outer query sort the recursive query’s results or join them to some other table.

A useful property of `WITH` queries is that they are evaluated only once per execution of the parent query, even if they are referred to more than once by the parent query or sibling `WITH` queries. Thus, expensive calculations that are needed in multiple places can be placed within a `WITH` query to avoid redundant work. Another possible application is to prevent unwanted multiple evaluations of functions with side-effects. However, the other side of this coin is that the optimizer is less able to push restrictions from the parent query down into a `WITH` query than an ordinary sub-query. The `WITH` query will generally be evaluated as stated, without suppression of rows that the parent query might discard afterwards. (But, as mentioned above, evaluation might stop early if the reference(s) to the query demand only a limited number of rows.)
Chapter 8. Data Types

PostgreSQL has a rich set of native data types available to users. Users can add new types to Postgres using the `CREATE TYPE` command.

Table 8-1 shows all the built-in general-purpose data types. Most of the alternative names listed in the “Aliases” column are the names used internally by PostgreSQL for historical reasons. In addition, some internally used or deprecated types are available, but are not listed here.

Table 8-1. Data Types

<table>
<thead>
<tr>
<th>Name</th>

</tr>
<tr>
<td>xml</td>
<td></td>
<td>XML data</td>
</tr>
</tbody>
</table>

**Compatibility:** The following types (or spellings thereof) are specified by SQL: bigint, bit, bit varying, boolean, char, character varying, character, varchar, date, double precision, integer, interval, numeric, decimal, real, smallint, time (with or without time zone), timestamp (with or without time zone), xml.

Each data type has an external representation determined by its input and output functions. Many of the built-in types have obvious external formats. However, several types are either unique to PostgreSQL, such as geometric paths, or have several possible formats, such as the date and time types. Some of the input and output functions are not invertible, i.e., the result of an output function might lose accuracy when compared to the original input.

### 8.1. Numeric Types

Numeric types consist of two-, four-, and eight-byte integers, four- and eight-byte floating-point numbers, and selectable-precision decimals. Table 8-2 lists the available types.

<table>
<thead>
<tr>
<th>Name</th>
<th>Storage Size</th>

<td>1 to 9223372036854775807</td>
</tr>
</tbody>
</table>

The syntax of constants for the numeric types is described in Section 4.1.2. The numeric types have a full set of corresponding arithmetic operators and functions. Refer to Chapter 9 for more information. The following sections describe the types in detail.

### 8.1.1. Integer Types

The types `smallint`, `integer`, and `bigint` store whole numbers, that is, numbers without fractional components, of various ranges. Attempts to store values outside of the allowed range will result in an error.

The type `integer` is the common choice, as it offers the best balance between range, storage size, and performance. The `smallint` type is generally only used if disk space is at a premium. The `bigint` type should only be used if the `integer` range is insufficient, because the latter is definitely faster.

On very minimal operating systems the `bigint` type might not function correctly, because it relies on compiler support for eight-byte integers. On such machines, `bigint` acts the same as `integer`, but still takes up eight bytes of storage. (We are not aware of any modern platform where this is the case.)

SQL only specifies the integer types `integer` (or `int`), `smallint`, and `bigint`. The type names `int2`, `int4`, and `int8` are extensions, which are also used by some other SQL database systems.

### 8.1.2. Arbitrary Precision Numbers

The type `numeric` can store numbers with up to 1000 digits of precision and perform calculations exactly. It is especially recommended for storing monetary amounts and other quantities where exactness is required. However, arithmetic on `numeric` values is very slow compared to the integer types, or to the floating-point types described in the next section.

We use the following terms below: The *scale* of a `numeric` is the count of decimal digits in the fractional part, to the right of the decimal point. The *precision* of a `numeric` is the total count of
significant digits in the whole number, that is, the number of digits to both sides of the decimal point. So the number 23.5141 has a precision of 6 and a scale of 4. Integers can be considered to have a scale of zero.

Both the maximum precision and the maximum scale of a numeric column can be configured. To declare a column of type numeric use the syntax:

\[ \text{NUMERIC}(\text{precision}, \text{scale}) \]

The precision must be positive, the scale zero or positive. Alternatively:

\[ \text{NUMERIC}(\text{precision}) \]

selects a scale of 0. Specifying:

\[ \text{NUMERIC} \]

without any precision or scale creates a column in which numeric values of any precision and scale can be stored, up to the implementation limit on precision. A column of this kind will not coerce input values to any particular scale, whereas numeric columns with a declared scale will coerce input values to that scale. (The SQL standard requires a default scale of 0, i.e., coercion to integer precision. We find this a bit useless. If you’re concerned about portability, always specify the precision and scale explicitly.)

If the scale of a value to be stored is greater than the declared scale of the column, the system will round the value to the specified number of fractional digits. Then, if the number of digits to the left of the decimal point exceeds the declared precision minus the declared scale, an error is raised.

Numeric values are physically stored without any extra leading or trailing zeroes. Thus, the declared precision and scale of a column are maximums, not fixed allocations. (In this sense the numeric type is more akin to varchar\(n\) than to char\(n\).) The actual storage requirement is two bytes for each group of four decimal digits, plus five to eight bytes overhead.

In addition to ordinary numeric values, the numeric type allows the special value NaN, meaning “not-a-number”. Any operation on NaN yields another NaN. When writing this value as a constant in an SQL command, you must put quotes around it, for example UPDATE table SET x = ‘NaN’.

On input, the string NaN is recognized in a case-insensitive manner.

Note: In most implementations of the “not-a-number” concept, NaN is not considered equal to any other numeric value (including NaN). In order to allow numeric values to be sorted and used in tree-based indexes, PostgreSQL treats NaN values as equal, and greater than all non-NaN values.

The types decimal and numeric are equivalent. Both types are part of the SQL standard.

### 8.1.3. Floating-Point Types

The data types real and double precision are inexact, variable-precision numeric types. In practice, these types are usually implementations of IEEE Standard 754 for Binary Floating-Point Arithmetic (single and double precision, respectively), to the extent that the underlying processor, operating system, and compiler support it.

Inexact means that some values cannot be converted exactly to the internal format and are stored as approximations, so that storing and retrieving a value might show slight discrepancies. Managing these
errors and how they propagate through calculations is the subject of an entire branch of mathematics
and computer science and will not be discussed here, except for the following points:

- If you require exact storage and calculations (such as for monetary amounts), use the numeric
type instead.
- If you want to do complicated calculations with these types for anything important, especially
  if you rely on certain behavior in boundary cases (infinity, underflow), you should evaluate the
  implementation carefully.
- Comparing two floating-point values for equality might not always work as expected.

On most platforms, the real type has a range of at least 1E-37 to 1E+37 with a precision of at least 6
decimal digits. The double precision type typically has a range of around 1E-307 to 1E+308 with
a precision of at least 15 digits. Values that are too large or too small will cause an error. Rounding
might take place if the precision of an input number is too high. Numbers too close to zero that are
not representable as distinct from zero will cause an underflow error.

**Note:** The extra_float_digits setting controls the number of extra significant digits included when
a floating point value is converted to text for output. With the default value of 0, the output is the
same on every platform supported by PostgreSQL. Increasing it will produce output that more
accurately represents the stored value, but may be unportable.

In addition to ordinary numeric values, the floating-point types have several special values:

Infinity
-Infinity
NaN

These represent the IEEE 754 special values “infinity”, “negative infinity”, and “not-a-number”, re-
spectively. (On a machine whose floating-point arithmetic does not follow IEEE 754, these values
will probably not work as expected.) When writing these values as constants in an SQL command,
you must put quotes around them, for example **UPDATE table SET x = ‘Infinity’**. On input,
these strings are recognized in a case-insensitive manner.

**Note:** IEEE754 specifies that NaN should not compare equal to any other floating-point value
(including NaN). In order to allow floating-point values to be sorted and used in tree-based indexes,
PostgreSQL treats NaN values as equal, and greater than all non-NaN values.

PostgreSQL also supports the SQL-standard notations float and float (p) for specifying inexact
numeric types. Here, p specifies the minimum acceptable precision in binary digits. PostgreSQL
accepts float (1) to float (24) as selecting the real type, while float (25) to float (53) select
double precision. Values of p outside the allowed range draw an error. float with no precision
specified is taken to mean double precision.

**Note:** Prior to PostgreSQL 7.4, the precision in float (p) was taken to mean so many decimal
digits. This has been corrected to match the SQL standard, which specifies that the precision is
measured in binary digits. The assumption that real and double precision have exactly 24 and
53 bits in the mantissa respectively is correct for IEEE-standard floating point implementations.
On non-IEEE platforms it might be off a little, but for simplicity the same ranges of p are used on
all platforms.
8.1.4. Serial Types

The data types `serial` and `bigserial` are not true types, but merely a notational convenience for creating unique identifier columns (similar to the `AUTO_INCREMENT` property supported by some other databases). In the current implementation, specifying:

```sql
CREATE TABLE tablename (  
  colname SERIAL  
);  
```

is equivalent to specifying:

```sql
CREATE SEQUENCE tablename_colname_seq;  
CREATE TABLE tablename (  
  colname integer NOT NULL DEFAULT nextval('tablename_colname_seq')  
);  
ALTER SEQUENCE tablename_colname_seq OWNED BY tablename.colname;  
```

Thus, we have created an integer column and arranged for its default values to be assigned from a sequence generator. A `NOT NULL` constraint is applied to ensure that a null value cannot be inserted. (In most cases you would also want to attach a `UNIQUE` or `PRIMARY KEY` constraint to prevent duplicate values from being inserted by accident, but this is not automatic.) Lastly, the sequence is marked as “owned by” the column, so that it will be dropped if the column or table is dropped.

**Note:** Prior to PostgreSQL 7.3, `serial` implied `UNIQUE`. This is no longer automatic. If you wish a `serial` column to have a unique constraint or be a primary key, it must now be specified, just like any other data type.

To insert the next value of the sequence into the `serial` column, specify that the `serial` column should be assigned its default value. This can be done either by excluding the column from the list of columns in the `INSERT` statement, or through the use of the `DEFAULT` keyword.

The type names `serial` and `serial4` are equivalent: both create `integer` columns. The type names `bigserial` and `serial8` work the same way, except that they create a `bigint` column. `bigserial` should be used if you anticipate the use of more than $2^{31}$ identifiers over the lifetime of the table.

The sequence created for a `serial` column is automatically dropped when the owning column is dropped. You can drop the sequence without dropping the column, but this will force removal of the column default expression.

8.2. Monetary Types

The `money` type stores a currency amount with a fixed fractional precision; see Table 8-3. The fractional precision is determined by the database’s `lc_monetary` setting. Input is accepted in a variety of formats, including integer and floating-point literals, as well as typical currency formatting, such as
Chapter 8. Data Types

'\$1,000.00'. Output is generally in the latter form but depends on the locale. Non-quoted numeric values can be converted to money by casting the numeric value to text and then money, for example:

```
SELECT 1234::text::money;
```

There is no simple way of doing the reverse in a locale-independent manner, namely casting a money value to a numeric type. If you know the currency symbol and thousands separator you can use `regexp_replace()`:

```
SELECT regexp_replace('52093.89'::money::text, '[,$]', ',', 'g')::numeric;
```

Since the output of this data type is locale-sensitive, it might not work to load money data into a database that has a different setting of `lc_monetary`. To avoid problems, before restoring a dump into a new database make sure `lc_monetary` has the same or equivalent value as in the database that was dumped.

Table 8-3. Monetary Types

<table>
<thead>
<tr>
<th>Name</th>
<th>Storage Size</th>
<th>Description</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>money</td>
<td>8 bytes</td>
<td>currency amount</td>
<td>-9,223,372,036,854,775,808 to +9,223,372,036,854,775,807</td>
</tr>
</tbody>
</table>

8.3. Character Types

Table 8-4. Character Types

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>character varying(n), varchar(n)</td>
<td>variable-length with limit</td>
</tr>
<tr>
<td>character(n), char(n)</td>
<td>fixed-length, blank padded</td>
</tr>
<tr>
<td>text</td>
<td>variable unlimited length</td>
</tr>
</tbody>
</table>

Table 8-4 shows the general-purpose character types available in PostgreSQL.

SQL defines two primary character types: character varying(n) and character(n), where n is a positive integer. Both of these types can store strings up to n characters (not bytes) in length. An attempt to store a longer string into a column of these types will result in an error, unless the excess characters are all spaces, in which case the string will be truncated to the maximum length. (This somewhat bizarre exception is required by the SQL standard.) If the string to be stored is shorter than the declared length, values of type character will be space-padded; values of type character varying will simply store the shorter string.

If one explicitly casts a value to character varying(n) or character(n), then an over-length value will be truncated to n characters without raising an error. (This too is required by the SQL standard.)

The notations varchar(n) and char(n) are aliases for character varying(n) and character(n), respectively. character without length specifier is equivalent to character(1).
If `character varying` is used without length specifier, the type accepts strings of any size. The latter is a PostgreSQL extension.

In addition, PostgreSQL provides the `text` type, which stores strings of any length. Although the type `text` is not in the SQL standard, several other SQL database management systems have it as well.

Values of type `character` are physically padded with spaces to the specified width `n`, and are stored and displayed that way. However, the padding spaces are treated as semantically insignificant. Trailing spaces are disregarded when comparing two values of type `character`, and they will be removed when converting a `character` value to one of the other string types. Note that trailing spaces are semantically significant in `character varying` and `text` values.

The storage requirement for a short string (up to 126 bytes) is 1 byte plus the actual string, which includes the space padding in the case of `character`. Longer strings have 4 bytes of overhead instead of 1. Long strings are compressed by the system automatically, so the physical requirement on disk might be less. Very long values are also stored in background tables so that they do not interfere with rapid access to shorter column values. In any case, the longest possible character string that can be stored is about 1 GB. (The maximum value that will be allowed for `n` in the data type declaration is less than that. It wouldn’t be useful to change this because with multibyte character encodings the number of characters and bytes can be quite different. If you desire to store long strings with no specific upper limit, use `text` or `character varying` without a length specifier, rather than making up an arbitrary length limit.)

**Tip:** There is no performance difference among these three types, apart from increased storage space when using the blank-padded type, and a few extra CPU cycles to check the length when storing into a length-constrained column. While `character(n)` has performance advantages in some other database systems, there is no such advantage in PostgreSQL; in fact `character(n)` is usually the slowest of the three because of its additional storage costs. In most situations `text` or `character varying` should be used instead.

Refer to Section 4.1.2.1 for information about the syntax of string literals, and to Chapter 9 for information about available operators and functions. The database character set determines the character set used to store textual values; for more information on character set support, refer to Section 22.2.

**Example 8-1. Using the character types**

```
CREATE TABLE test1 (a character(4));
INSERT INTO test1 VALUES ('ok');
SELECT a, char_length(a) FROM test1; -- 1
  a | char_length
----+-------------
  ok | 2

CREATE TABLE test2 (b varchar(5));
INSERT INTO test2 VALUES ('ok');
INSERT INTO test2 VALUES ('good ');
INSERT INTO test2 VALUES ('too long');
ERROR: value too long for type character varying(5)
INSERT INTO test2 VALUES ('too long'::varchar(5)); -- explicit truncation
SELECT b, char_length(b) FROM test2;
  b | char_length
-----+-------------
  ok | 2
  good | 5
```

104
Chapter 8. Data Types

The `char_length` function is discussed in Section 9.4.

There are two other fixed-length character types in PostgreSQL, shown in Table 8-5. The `name` type exists only for the storage of identifiers in the internal system catalogs and is not intended for use by the general user. Its length is currently defined as 64 bytes (63 usable characters plus terminator) but should be referenced using the constant `NAMEDATALEN` in C source code. The length is set at compile time (and is therefore adjustable for special uses); the default maximum length might change in a future release. The type "char" (note the quotes) is different from `char(1)` in that it only uses one byte of storage. It is internally used in the system catalogs as a simplistic enumeration type.

### Table 8-5. Special Character Types

<table>
<thead>
<tr>
<th>Name</th>
<th>Storage Size</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;char&quot;</td>
<td>1 byte</td>
<td>single-byte internal type</td>
</tr>
<tr>
<td>name</td>
<td>64 bytes</td>
<td>internal type for object names</td>
</tr>
</tbody>
</table>

### 8.4. Binary Data Types

The `bytea` data type allows storage of binary strings; see Table 8-6.

### Table 8-6. Binary Data Types

<table>
<thead>
<tr>
<th>Name</th>
<th>Storage Size</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bytea</td>
<td>1 or 4 bytes plus the actual binary string</td>
<td>variable-length binary string</td>
</tr>
</tbody>
</table>

A binary string is a sequence of octets (or bytes). Binary strings are distinguished from character strings in two ways: First, binary strings specifically allow storing octets of value zero and other “non-printable” octets (usually, octets outside the range 32 to 126). Character strings disallow zero octets, and also disallow any other octet values and sequences of octet values that are invalid according to the database’s selected character set encoding. Second, operations on binary strings process the actual bytes, whereas the processing of character strings depends on locale settings. In short, binary strings are appropriate for storing data that the programmer thinks of as “raw bytes”, whereas character strings are appropriate for storing text.

When entering `bytea` values, octets of certain values must be escaped (but all octet values can be escaped) when used as part of a string literal in an SQL statement. In general, to escape an octet, convert it into its three-digit octal value and precede it by two backslashes. Table 8-7 shows the characters that must be escaped, and gives the alternative escape sequences where applicable.

### Table 8-7. `bytea` Literal Escaped Octets

<table>
<thead>
<tr>
<th>Decimal Octet Value</th>
<th>Description</th>
<th>Escaped Input Representation</th>
<th>Example</th>
<th>Output Representation</th>
</tr>
</thead>
</table>

105
Table 8-7. Decimal Octets

<table>
<thead>
<tr>
<th>Decimal Octet Value</th>
<th>Description</th>
<th>Escaped Input Representation</th>
<th>Example</th>
<th>Output Representation</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>zero octet</td>
<td>\E'\000'</td>
<td>SELECT E'\000':bytea;</td>
<td>\000</td>
</tr>
<tr>
<td>39</td>
<td>single quote</td>
<td>&quot;&quot; or \E'\047'</td>
<td>SELECT E'&quot;:bytea;</td>
<td>'</td>
</tr>
<tr>
<td>92</td>
<td>backslash</td>
<td>\E'\134'</td>
<td>SELECT E'\134':bytea;</td>
<td>\</td>
</tr>
<tr>
<td>0 to 31 and 127 to 255</td>
<td>&quot;non-printable&quot; octets</td>
<td>\E'\xxx' (octal value)</td>
<td>SELECT E'\001':bytea;</td>
<td>\001</td>
</tr>
</tbody>
</table>

The requirement to escape *non-printable* octets varies depending on locale settings. In some instances you can get away with leaving them unescaped. Note that the result in each of the examples in Table 8-7 was exactly one octet in length, even though the output representation is sometimes more than one character.

The reason multiple backslashes are required, as shown in Table 8-7, is that an input string written as a string literal must pass through two parse phases in the PostgreSQL server. The first backslash of each pair is interpreted as an escape character by the string-literal parser (assuming escape string syntax is used) and is therefore consumed, leaving the second backslash of the pair. (Dollar-quoted strings can be used to avoid this level of escaping.) The remaining backslash is then recognized by the bytea input function as starting either a three digit octal value or escaping another backslash. For example, a string literal passed to the server as \E'\001' becomes \001 after passing through the escape string parser. The \001 is then sent to the bytea input function, where it is converted to a single octet with a decimal value of 1. Note that the single-quote character is not treated specially by bytea, so it follows the normal rules for string literals. (See also Section 4.1.2.1.)

Bytea octets are sometimes escaped when output. In general, each “non-printable” octet is converted into its equivalent three-digit octal value and preceded by one backslash. Most “printable” octets are represented by their standard representation in the client character set. The octet with decimal value 92 (backslash) is doubled in the output. Details are in Table 8-8.

Table 8-8. bytea Output Escaped Octets

<table>
<thead>
<tr>
<th>Decimal Octet Value</th>
<th>Description</th>
<th>Escaped Output Representation</th>
<th>Example</th>
<th>Output Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>92</td>
<td>backslash</td>
<td>\</td>
<td>SELECT E'\134':bytea;</td>
<td>\</td>
</tr>
<tr>
<td>0 to 31 and 127 to 255</td>
<td>&quot;non-printable&quot; octets</td>
<td>\xxx (octal value)</td>
<td>SELECT E'\001':bytea;</td>
<td>\001</td>
</tr>
<tr>
<td>32 to 126</td>
<td>“printable” octets</td>
<td>client character set representation</td>
<td>SELECT E'\176':bytea;</td>
<td>~</td>
</tr>
</tbody>
</table>
Depending on the front end to PostgreSQL you use, you might have additional work to do in terms of escaping and unescaping bytea strings. For example, you might also have to escape line feeds and carriage returns if your interface automatically translates these.

The SQL standard defines a different binary string type, called BLOB or BINARY LARGE OBJECT. The input format is different from bytea, but the provided functions and operators are mostly the same.

## 8.5. Date/Time Types

PostgreSQL supports the full set of SQL date and time types, shown in Table 8-9. The operations available on these data types are described in Section 9.9.

### Table 8-9. Date/Time Types

<table>
<thead>
<tr>
<th>Name</th>
<th>Storage Size</th>
<th>Description</th>
<th>Low Value</th>
<th>High Value</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>timestamp [ (p) ] [ without time zone ]</td>
<td>8 bytes</td>
<td>both date and time (no time zone)</td>
<td>4713 BC</td>
<td>294276 AD</td>
<td>1 microsecond / 14 digits</td>
</tr>
<tr>
<td>timestamp [ (p) ] with time zone</td>
<td>8 bytes</td>
<td>both date and time, with time zone</td>
<td>4713 BC</td>
<td>294276 AD</td>
<td>1 microsecond / 14 digits</td>
</tr>
<tr>
<td>date</td>
<td>4 bytes</td>
<td>date (no time of day)</td>
<td>4713 BC</td>
<td>5874897 AD</td>
<td>1 day</td>
</tr>
<tr>
<td>time [ (p) ] [ without time zone ]</td>
<td>8 bytes</td>
<td>time of day (no date)</td>
<td>00:00:00</td>
<td>24:00:00</td>
<td>1 microsecond / 14 digits</td>
</tr>
<tr>
<td>time [ (p) ] with time zone</td>
<td>12 bytes</td>
<td>times of day only, with time zone</td>
<td>00:00:00+1459</td>
<td>24:00:00-1459</td>
<td>1 microsecond / 14 digits</td>
</tr>
<tr>
<td>interval [ fields ] [ (p) ]</td>
<td>16 bytes</td>
<td>time interval</td>
<td>-178000000 years</td>
<td>178000000 years</td>
<td>1 microsecond / 14 digits</td>
</tr>
</tbody>
</table>

**Note:** Prior to PostgreSQL 7.3, writing just `timestamp` was equivalent to `timestamp with time zone`. This was changed for SQL compliance.

*Note:* `time`, `timestamp`, and `interval` accept an optional precision value `p` which specifies the number of fractional digits retained in the seconds field. By default, there is no explicit bound on precision. The allowed range of `p` is from 0 to 6 for the `timestamp` and `interval` types.

*Note:* When `timestamp` values are stored as eight-byte integers (currently the default), microsecond precision is available over the full range of values. When `timestamp` values are stored as double precision floating-point numbers instead (a deprecated compile-time option), the effective
Chapter 8. Data Types

The limit of precision might be less than 6. `timestamp` values are stored as seconds before or after midnight 2000-01-01. When `timestamp` values are implemented using floating-point numbers, microsecond precision is achieved for dates within a few years of 2000-01-01, but the precision degrades for dates further away. Note that using floating-point datetimes allows a larger range of `timestamp` values to be represented than shown above: from 4713 BC up to 5874897 AD.

The same compile-time option also determines whether `time` and `interval` values are stored as floating-point numbers or eight-byte integers. In the floating-point case, large `interval` values degrade in precision as the size of the interval increases.

For the `time` types, the allowed range of $p$ is from 0 to 6 when eight-byte integer storage is used, or from 0 to 10 when floating-point storage is used.

The `interval` type has an additional option, which is to restrict the set of stored fields by writing one of these phrases:

```
YEAR
MONTH
DAY
HOUR
MINUTE
SECOND
YEAR TO MONTH
DAY TO HOUR
DAY TO MINUTE
DAY TO SECOND
HOUR TO MINUTE
HOUR TO SECOND
MINUTE TO SECOND
```

Note that if both `fields` and $p$ are specified, the `fields` must include `SECOND`, since the precision applies only to the seconds.

The type `time with time zone` is defined by the SQL standard, but the definition exhibits properties which lead to questionable usefulness. In most cases, a combination of `date`, `time`, `timestamp without time zone`, and `timestamp with time zone` should provide a complete range of date/time functionality required by any application.

The types `abstime` and `reltime` are lower precision types which are used internally. You are discouraged from using these types in applications; these internal types might disappear in a future release.

### 8.5.1. Date/Time Input

Date and time input is accepted in almost any reasonable format, including ISO 8601, SQL-compatible, traditional POSTGRES, and others. For some formats, ordering of day, month, and year in date input is ambiguous and there is support for specifying the expected ordering of these fields. Set the `DateStyle` parameter to `MDY` to select month-day-year interpretation, `DMY` to select day-month-year interpretation, or `YMD` to select year-month-day interpretation.

PostgreSQL is more flexible in handling date/time input than the SQL standard requires. See Appendix B for the exact parsing rules of date/time input and for the recognized text fields including months, days of the week, and time zones.

Remember that any date or time literal input needs to be enclosed in single quotes, like text strings. Refer to Section 4.1.2.7 for more information. SQL requires the following syntax
Chapter 8. Data Types

type [ (p) ] 'value'

where p is an optional precision specification giving the number of fractional digits in the seconds field. Precision can be specified for time, timestamp, and interval types. The allowed values are mentioned above. If no precision is specified in a constant specification, it defaults to the precision of the literal value.

8.5.1.1. Dates

Table 8-10 shows some possible inputs for the date type.

Table 8-10. Date Input

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1999-01-08</td>
<td>ISO 8601; January 8 in any mode (recommended format)</td>
</tr>
<tr>
<td>January 8, 1999</td>
<td>unambiguous in any datestyle input mode</td>
</tr>
<tr>
<td>1/8/1999</td>
<td>January 8 in MDY mode; August 1 in DMY mode</td>
</tr>
<tr>
<td>1/18/1999</td>
<td>January 18 in MDY mode; rejected in other modes</td>
</tr>
<tr>
<td>01/02/03</td>
<td>January 2, 2003 in MDY mode; February 1, 2003 in DMY mode</td>
</tr>
<tr>
<td>1999-Jan-08</td>
<td>January 8 in any mode</td>
</tr>
<tr>
<td>Jan-08-1999</td>
<td>January 8 in any mode</td>
</tr>
<tr>
<td>08-Jan-1999</td>
<td>January 8 in any mode</td>
</tr>
<tr>
<td>99-Jan-08</td>
<td>January 8 in YMD mode, else error</td>
</tr>
<tr>
<td>08-Jan-99</td>
<td>January 8, except error in YMD mode</td>
</tr>
<tr>
<td>Jan-08-99</td>
<td>January 8, except error in YMD mode</td>
</tr>
<tr>
<td>19990108</td>
<td>ISO 8601; January 8, 1999 in any mode</td>
</tr>
<tr>
<td>990108</td>
<td>ISO 8601; January 8, 1999 in any mode</td>
</tr>
<tr>
<td>1999.008</td>
<td>year and day of year</td>
</tr>
<tr>
<td>J2451187</td>
<td>Julian day</td>
</tr>
<tr>
<td>January 8, 99 BC</td>
<td>year 99 BC</td>
</tr>
</tbody>
</table>

8.5.1.2. Times

The time-of-day types are time [ (p) ] without time zone and time [ (p) ] with time zone. time alone is equivalent to time without time zone.

Valid input for these types consists of a time of day followed by an optional time zone. (See Table 8-11 and Table 8-12.) If a time zone is specified in the input for time without time zone, it is silently ignored. You can also specify a date but it will be ignored, except when you use a time zone name that involves a daylight-savings rule, such as America/New_York. In this case specifying the date is required in order to determine whether standard or daylight-savings time applies. The appropriate time zone offset is recorded in the time with time zone value.

Table 8-11. Time Input
Example | Description
--- | ---
04:05:06.789 | ISO 8601
04:05:06 | ISO 8601
04:05 | ISO 8601
040506 | ISO 8601
04:05 AM | same as 04:05; AM does not affect value
04:05 PM | same as 16:05; input hour must be <= 12
04:05:06.789-8 | ISO 8601
04:05:06-08:00 | ISO 8601
04:05-08:00 | ISO 8601
040506-08 | ISO 8601
04:05:06 PST | time zone specified by abbreviation
2003-04-12 04:05:06 America/New_York | time zone specified by full name

Table 8-12. Time Zone Input

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
</table>
PST | Abbreviation (for Pacific Standard Time) |
America/New_York | Full time zone name |
PST8PDT | POSIX-style time zone specification |
-8:00 | ISO-8601 offset for PST |
-800 | ISO-8601 offset for PST |
-8 | ISO-8601 offset for PST |
zulu | Military abbreviation for UTC |
z | Short form of zulu |

Refer to Section 8.5.3 for more information on how to specify time zones.

8.5.1.3. Time Stamps

Valid input for the time stamp types consists of the concatenation of a date and a time, followed by an optional time zone, followed by an optional AD or BC. (Alternatively, AD/BC can appear before the time zone, but this is not the preferred ordering.) Thus:

1999-01-08 04:05:06

and:

1999-01-08 04:05:06 -8:00

are valid values, which follow the ISO 8601 standard. In addition, the common format:

January 8 04:05:06 1999 PST

is supported.
The SQL standard differentiates `timestamp without time zone` and `timestamp with time zone` literals by the presence of a “+” or “-” symbol and time zone offset after the time. Hence, according to the standard,

```
TIMESTAMP '2004-10-19 10:23:54'
```

is a `timestamp without time zone`, while

```
TIMESTAMP '2004-10-19 10:23:54+02'
```

is a `timestamp with time zone`. PostgreSQL never examines the content of a literal string before determining its type, and therefore will treat both of the above as `timestamp without time zone`. To ensure that a literal is treated as `timestamp with time zone`, give it the correct explicit type:

```
TIMESTAMP WITH TIME ZONE '2004-10-19 10:23:54+02'
```

In a literal that has been determined to be `timestamp without time zone`, PostgreSQL will silently ignore any time zone indication. That is, the resulting value is derived from the date/time fields in the input value, and is not adjusted for time zone.

For `timestamp with time zone`, the internally stored value is always in UTC (Universal Coordinated Time, traditionally known as Greenwich Mean Time, GMT). An input value that has an explicit time zone specified is converted to UTC using the appropriate offset for that time zone. If no time zone is stated in the input string, then it is assumed to be in the time zone indicated by the system’s timezone parameter, and is converted to UTC using the offset for the timezone zone.

When a `timestamp with time zone` value is output, it is always converted from UTC to the current timezone zone, and displayed as local time in that zone. To see the time in another time zone, either change timezone or use the AT TIME ZONE construct (see Section 9.9.3).

Conversions between `timestamp without time zone` and `timestamp with time zone` normally assume that the `timestamp without time zone` value should be taken or given as timezone local time. A different time zone can be specified for the conversion using AT TIME ZONE.

### 8.5.1.4. Special Values

PostgreSQL supports several special date/time input values for convenience, as shown in Table 8-13. The values `infinity` and `-infinity` are specially represented inside the system and will be displayed unchanged; but the others are simply notational shorthands that will be converted to ordinary date/time values when read. (In particular, `now` and related strings are converted to a specific time value as soon as they are read.) All of these values need to be enclosed in single quotes when used as constants in SQL commands.

<table>
<thead>
<tr>
<th>Input String</th>
<th>Valid Types</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>epoch</code></td>
<td><code>date,timestamp</code></td>
<td>1970-01-01 00:00:00+00 (Unix system time zero)</td>
</tr>
<tr>
<td><code>infinity</code></td>
<td><code>date,timestamp</code></td>
<td>later than all other time stamps</td>
</tr>
<tr>
<td><code>-infinity</code></td>
<td><code>date,timestamp</code></td>
<td>earlier than all other time stamps</td>
</tr>
<tr>
<td><code>now</code></td>
<td><code>date,time,timestamp</code></td>
<td>current transaction’s start time</td>
</tr>
</tbody>
</table>
Chapter 8. Data Types

<table>
<thead>
<tr>
<th>Input String</th>
<th>Valid Types</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>today</td>
<td>date, timestamp</td>
<td>midnight today</td>
</tr>
<tr>
<td>tomorrow</td>
<td>date, timestamp</td>
<td>midnight tomorrow</td>
</tr>
<tr>
<td>yesterday</td>
<td>date, timestamp</td>
<td>midnight yesterday</td>
</tr>
<tr>
<td>allballs</td>
<td>time</td>
<td>00:00:00.00 UTC</td>
</tr>
</tbody>
</table>

The following SQL-compatible functions can also be used to obtain the current time value for the corresponding data type: CURRENT_DATE, CURRENT_TIME, CURRENT_TIMESTAMP, LOCALTIME, LOCALTIMESTAMP. The latter four accept an optional subsecond precision specification. (See Section 9.9.4.) Note that these are SQL functions and are not recognized in data input strings.

8.5.2. Date/Time Output

The output format of the date/time types can be set to one of the four styles ISO 8601, SQL (Ingres), traditional POSTGRES (Unix date format), or German. The default is the ISO format. (The SQL standard requires the use of the ISO 8601 format. The name of the “SQL” output format is a historical accident.) Table 8-14 shows examples of each output style. The output of the date and time types is of course only the date or time part in accordance with the given examples.

Table 8-14. Date/Time Output Styles

<table>
<thead>
<tr>
<th>Style Specification</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO</td>
<td>ISO 8601/SQL standard</td>
<td>1997-12-17 07:37:16-08</td>
</tr>
<tr>
<td>SQL</td>
<td>traditional style</td>
<td>12/17/1997 07:37:16.00 PST</td>
</tr>
<tr>
<td>POSTGRES</td>
<td>original style</td>
<td>Wed Dec 17 07:37:16 1997 PST</td>
</tr>
<tr>
<td>German</td>
<td>regional style</td>
<td>17.12.1997 07:37:16.00 PST</td>
</tr>
</tbody>
</table>

In the SQL and POSTGRES styles, day appears before month if DMY field ordering has been specified, otherwise month appears before day. (See Section 8.5.1 for how this setting also affects interpretation of input values.) Table 8-15 shows an example.

Table 8-15. Date Order Conventions

<table>
<thead>
<tr>
<th>datestyle Setting</th>
<th>Input Ordering</th>
<th>Example Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL, DMY</td>
<td>day/month/year</td>
<td>17/12/1997 15:37:16:00 CET</td>
</tr>
<tr>
<td>SQL, MDY</td>
<td>month/day/year</td>
<td>12/17/1997 07:37:16.00 PST</td>
</tr>
<tr>
<td>Postgres, DMY</td>
<td>day/month/year</td>
<td>Wed 17 Dec 07:37:16 1997 PST</td>
</tr>
</tbody>
</table>

The date/time styles can be selected by the user using the SET datestyle command, the DateStyle parameter in the postgresql.conf configuration file, or the PGDATESTYLE environment variable on the server or client. The formatting function to_char (see Section 9.8) is also available as a more flexible way to format date/time output.
8.5.3. Time Zones

Time zones, and time-zone conventions, are influenced by political decisions, not just earth geometry. Time zones around the world became somewhat standardized during the 1900’s, but continue to be prone to arbitrary changes, particularly with respect to daylight-savings rules. PostgreSQL uses the widely-used zoneinfo time zone database for information about historical time zone rules. For times in the future, the assumption is that the latest known rules for a given time zone will continue to be observed indefinitely far into the future.

PostgreSQL endeavors to be compatible with the SQL standard definitions for typical usage. However, the SQL standard has an odd mix of date and time types and capabilities. Two obvious problems are:

• Although the date type cannot have an associated time zone, the time type can. Time zones in the real world have little meaning unless associated with a date as well as a time, since the offset can vary through the year with daylight-saving time boundaries.
• The default time zone is specified as a constant numeric offset from UTC. It is therefore impossible to adapt to daylight-saving time when doing date/time arithmetic across DST boundaries.

To address these difficulties, we recommend using date/time types that contain both date and time when using time zones. We do not recommend using the type time with time zone (though it is supported by PostgreSQL for legacy applications and for compliance with the SQL standard). PostgreSQL assumes your local time zone for any type containing only date or time.

All timezone-aware dates and times are stored internally in UTC. They are converted to local time in the zone specified by the timezone configuration parameter before being displayed to the client.

PostgreSQL allows you to specify time zones in three different forms:

• A full time zone name, for example America/New_York. The recognized time zone names are listed in the pg_timezone_names view (see Section 44.58). PostgreSQL uses the widely-used zoneinfo time zone data for this purpose, so the same names are also recognized by much other software.
• A time zone abbreviation, for example PST. Such a specification merely defines a particular offset from UTC, in contrast to full time zone names which can imply a set of daylight savings transition-date rules as well. The recognized abbreviations are listed in the pg_timezone_abbrevs view (see Section 44.57). You cannot set the configuration parameters timezone or log_timezone to a time zone abbreviation, but you can use abbreviations in date/time input values and with the AT TIME ZONE operator.
• In addition to the timezone names and abbreviations, PostgreSQL will accept POSIX-style time zone specifications of the form STDoffset or STDoffsetDST, where STD is a zone abbreviation, offset is a numeric offset in hours west from UTC, and DST is an optional daylight-savings zone abbreviation, assumed to stand for one hour ahead of the given offset. For example, if EST5EDT were not already a recognized zone name, it would be accepted and would be functionally equivalent to United States East Coast time. When a daylight-savings zone name is present, it is assumed to be used according to the same daylight-savings transition rules used in the zoneinfo time zone database’s posixrules entry. In a standard PostgreSQL installation, posixrules is the same as US/Eastern, so that POSIX-style time zone specifications follow USA daylight-savings rules. If needed, you can adjust this behavior by replacing the posixrules file.

In short, this is the difference between abbreviations and full names: abbreviations always represent a fixed offset from UTC, whereas most of the full names imply a local daylight-savings time rule, and
so have two possible UTC offsets.

One should be wary that the POSIX-style time zone feature can lead to silently accepting bogus input, since there is no check on the reasonableness of the zone abbreviations. For example, \texttt{SET TIMEZONE TO FOOBAR} will work, leaving the system effectively using a rather peculiar abbreviation for UTC. Another issue to keep in mind is that in POSIX time zone names, positive offsets are used for locations \textit{west} of Greenwich. Everywhere else, PostgreSQL follows the ISO-8601 convention that positive timezone offsets are \textit{east} of Greenwich.

In all cases, timezone names are recognized case-insensitively. (This is a change from PostgreSQL versions prior to 8.2, which were case-sensitive in some contexts but not others.)

Neither full names nor abbreviations are hard-wired into the server; they are obtained from configuration files stored under \texttt{.../share/timezone/} and \texttt{.../share/timezonesets/} of the installation directory (see Section B.3).

The timezone configuration parameter can be set in the file \texttt{postgresql.conf}, or in any of the other standard ways described in Chapter 18. There are also several special ways to set it:

- If \texttt{timezone} is not specified in \texttt{postgresql.conf} or as a server command-line option, the server attempts to use the value of the \texttt{TZ} environment variable as the default time zone. If \texttt{TZ} is not defined or is not any of the time zone names known to PostgreSQL, the server attempts to determine the operating system’s default time zone by checking the behavior of the C library function \texttt{localtime()}. The default time zone is selected as the closest match among PostgreSQL’s known time zones. (These rules are also used to choose the default value of log\_timezone, if not specified.)

- The SQL command \texttt{SET TIME ZONE} sets the time zone for the session. This is an alternative spelling of \texttt{SET TIMEZONE TO} with a more SQL-spec-compatible syntax.

- The \texttt{PGTZ} environment variable is used by libpq clients to send a \texttt{SET TIME ZONE} command to the server upon connection.

### 8.5.4. Interval Input

\texttt{interval} values can be written using the following verbose syntax:

\begin{verbatim}
[@] quantity unit [quantity unit...] [direction]
\end{verbatim}

where \texttt{quantity} is a number (possibly signed); \texttt{unit} is \texttt{microsecond}, \texttt{millisecond}, \texttt{second}, \texttt{minute}, \texttt{hour}, \texttt{day}, \texttt{week}, \texttt{month}, \texttt{year}, \texttt{decade}, \texttt{century}, \texttt{millennium}, or abbreviations or plurals of these units; \texttt{direction} can be \texttt{ago} or empty. The at sign (@) is optional noise. The amounts of the different units are implicitly added with appropriate sign accounting. \texttt{ago} negates all the fields. This syntax is also used for interval output, if IntervalStyle is set to \texttt{postgres\_verbose}.

Quantities of days, hours, minutes, and seconds can be specified without explicit unit markings. For example, ‘1 12:59:10’ is read the same as ‘1 day 12 hours 59 min 10 sec’. Also, a combination of years and months can be specified with a dash; for example ‘200-10’ is read the same as ‘200 years 10 months’. (These shorter forms are in fact the only ones allowed by the SQL standard, and are used for output when IntervalStyle is set to \texttt{sql\_standard}.)

Interval values can also be written as ISO 8601 time intervals, using either the “format with designators” of the standard’s section 4.4.3.2 or the “alternative format” of section 4.4.3.3. The format with designators looks like this:

\begin{verbatim}
P quantity unit [ quantity unit ...] [ T [ quantity unit ...]]
\end{verbatim}
The string must start with a P, and may include a T that introduces the time-of-day units. The available unit abbreviations are given in Table 8-16. Units may be omitted, and may be specified in any order, but units smaller than a day must appear after T. In particular, the meaning of M depends on whether it is before or after T.

Table 8-16. ISO 8601 interval unit abbreviations

<table>
<thead>
<tr>
<th>Abbreviation</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Y</td>
<td>Years</td>
</tr>
<tr>
<td>M</td>
<td>Months (in the date part)</td>
</tr>
<tr>
<td>W</td>
<td>Weeks</td>
</tr>
<tr>
<td>D</td>
<td>Days</td>
</tr>
<tr>
<td>H</td>
<td>Hours</td>
</tr>
<tr>
<td>M</td>
<td>Minutes (in the time part)</td>
</tr>
<tr>
<td>S</td>
<td>Seconds</td>
</tr>
</tbody>
</table>

In the alternative format:

P [ years-months-days ] [ T hours:minutes:seconds ]

the string must begin with P, and a T separates the date and time parts of the interval. The values are given as numbers similar to ISO 8601 dates.

When writing an interval constant with a fields specification, or when assigning a string to an interval column that was defined with a fields specification, the interpretation of unmarked quantities depends on the fields. For example INTERVAL ‘1’ YEAR is read as 1 year, whereas INTERVAL ‘1’ means 1 second. Also, field values “to the right” of the least significant field allowed by the fields specification are silently discarded. For example, writing INTERVAL ‘1 day 2:03:04’ HOUR TO MINUTE results in dropping the seconds field, but not the day field.

According to the SQL standard all fields of an interval value must have the same sign, so a leading negative sign applies to all fields; for example the negative sign in the interval literal ‘-1 2:03:04’ applies to both the days and hour/minute/second parts. PostgreSQL allows the fields to have different signs, and traditionally treats each field in the textual representation as independently signed, so that the hour/minute/second part is considered positive in this example. If IntervalStyle is set to sql_standard then a leading sign is considered to apply to all fields (but only if no additional signs appear). Otherwise the traditional PostgreSQL interpretation is used. To avoid ambiguity, it’s recommended to attach an explicit sign to each field if any field is negative.

Internally interval values are stored as months, days, and seconds. This is done because the number of days in a month varies, and a day can have 23 or 25 hours if a daylight savings time adjustment is involved. The months and days fields are integers while the seconds field can store fractions. Because intervals are usually created from constant strings or timestamp subtraction, this storage method works well in most cases. Functions justify_days and justify_hours are available for adjusting days and hours that overflow their normal ranges.

In the verbose input format, and in some fields of the more compact input formats, field values can have fractional parts; for example ‘1.5 week’ or ‘01:02:03.45’. Such input is converted to the appropriate number of months, days, and seconds for storage. When this would result in a fractional number of months or days, the fraction is added to the lower-order fields using the conversion factors 1 month = 30 days and 1 day = 24 hours. For example, ‘1.5 month’ becomes 1 month and 15 days. Only seconds will ever be shown as fractional on output.

Table 8-17 shows some examples of valid interval input.
Table 8-17. Interval Input

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-2</td>
<td>SQL standard format: 1 year 2 months</td>
</tr>
<tr>
<td>3 4:05:06</td>
<td>SQL standard format: 3 days 4 hours 5 minutes 6 seconds</td>
</tr>
<tr>
<td>1 year 2 months 3 days 4 hours 5 minutes 6 seconds</td>
<td>Traditional Postgres format: 1 year 2 months 3 days 4 hours 5 minutes 6 seconds</td>
</tr>
<tr>
<td>P1Y2M3DT4H5M6S</td>
<td>ISO 8601 “format with designators”: same meaning as above</td>
</tr>
<tr>
<td>P0001-02-03T04:05:06</td>
<td>ISO 8601 “alternative format”: same meaning as above</td>
</tr>
</tbody>
</table>

8.5.5. Interval Output

The output format of the interval type can be set to one of the four styles `sql_standard`, `postgres`, `postgres_verbose`, or `iso_8601`, using the command `SET intervalstyle`. The default is the `postgres` format. Table 8-18 shows examples of each output style.

The `sql_standard` style produces output that conforms to the SQL standard’s specification for interval literal strings, if the interval value meets the standard’s restrictions (either year-month only or day-time only, with no mixing of positive and negative components). Otherwise the output looks like a standard year-month literal string followed by a day-time literal string, with explicit signs added to disambiguate mixed-sign intervals.

The output of the `postgres` style matches the output of PostgreSQL releases prior to 8.4 when the `DateStyle` parameter was set to `ISO`.

The output of the `postgres_verbose` style matches the output of PostgreSQL releases prior to 8.4 when the `DateStyle` parameter was set to non-`ISO` output.

The output of the `iso_8601` style matches the “format with designators” described in section 4.4.3.2 of the ISO 8601 standard.

Table 8-18. Interval Output Style Examples

<table>
<thead>
<tr>
<th>Style Specification</th>
<th>Year-Month Interval</th>
<th>Day-Time Interval</th>
<th>Mixed Interval</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sql_standard</code></td>
<td>1-2</td>
<td>3 4:05:06</td>

<td>P1Y2M</td>
<td>P3DT4H5M6S</td>
<td>P-1Y-2M3DT-4H-5M-6S</td>
</tr>
</tbody>
</table>
8.5.6. Internals

PostgreSQL uses Julian dates for all date/time calculations. This has the useful property of correctly calculating dates from 4713 BC to far into the future, using the assumption that the length of the year is 365.2425 days.

Date conventions before the 19th century make for interesting reading, but are not consistent enough to warrant coding into a date/time handler.

8.6. Boolean Type

PostgreSQL provides the standard SQL type `boolean`. `boolean` can have one of only two states: “true” or “false”. A third state, “unknown”, is represented by the SQL null value.

Valid literal values for the “true” state are:

```sql
TRUE
't'
'true'
'y'
'yes'
'on'
'1'
```

For the “false” state, the following values can be used:

```sql
FALSE
'f'
'false'
'n'
'no'
'off'
'0'
```

Leading or trailing whitespace is ignored, and case does not matter. The key words `TRUE` and `FALSE` are the preferred (SQL-compliant) usage.

Example 8-2. Using the `boolean` type

```sql
CREATE TABLE test1 (a boolean, b text);
INSERT INTO test1 VALUES (TRUE, 'sic est');
INSERT INTO test1 VALUES (FALSE, 'non est');
SELECT * FROM test1;
```

```
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
<td>sic est</td>
</tr>
<tr>
<td>f</td>
<td>non est</td>
</tr>
</tbody>
</table>
```

```sql
SELECT * FROM test1 WHERE a;
```

```
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
<td>sic est</td>
</tr>
</tbody>
</table>
```

Example 8-2 shows that `boolean` values are output using the letters `t` and `f`. 
8.7. Enumerated Types

Enumerated (enum) types are data types that comprise a static, ordered set of values. They are equivalent to the `enum` types supported in a number of programming languages. An example of an enum type might be the days of the week, or a set of status values for a piece of data.

8.7.1. Declaration of Enumerated Types

Enum types are created using the `CREATE TYPE` command, for example:

```sql
CREATE TYPE mood AS ENUM ('sad', 'ok', 'happy');
```

Once created, the enum type can be used in table and function definitions much like any other type:

**Example 8-3. Basic Enum Usage**

```sql
CREATE TYPE mood AS ENUM ('sad', 'ok', 'happy');
CREATE TABLE person (  
    name text,
    current_mood mood
);
INSERT INTO person VALUES ('Moe', 'happy');
SELECT * FROM person WHERE current_mood = 'happy';
```

<table>
<thead>
<tr>
<th>name</th>
<th>current_mood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Moe</td>
<td>happy</td>
</tr>
</tbody>
</table>

(1 row)

8.7.2. Ordering

The ordering of the values in an enum type is the order in which the values were listed when the type was created. All standard comparison operators and related aggregate functions are supported for enums. For example:

**Example 8-4. Enum Ordering**

```sql
INSERT INTO person VALUES ('Larry', 'sad');
INSERT INTO person VALUES ('Curly', 'ok');
SELECT * FROM person WHERE current_mood > 'sad';
```

<table>
<thead>
<tr>
<th>name</th>
<th>current_mood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Moe</td>
<td>happy</td>
</tr>
<tr>
<td>Curly</td>
<td>ok</td>
</tr>
</tbody>
</table>

(2 rows)

```sql
SELECT * FROM person WHERE current_mood > 'sad' ORDER BY current_mood;
```

<table>
<thead>
<tr>
<th>name</th>
<th>current_mood</th>
</tr>
</thead>
<tbody>
<tr>
<td>Curly</td>
<td>ok</td>
</tr>
</tbody>
</table>
8.7.3. Type Safety

Each enumerated data type is separate and cannot be compared with other enumerated types.

Example 8-5. Lack of Casting

CREATE TYPE happiness AS ENUM ('happy', 'very happy', 'ecstatic');
CREATE TABLE holidays (
    num_weeks integer,
    happiness happiness
);
INSERT INTO holidays(num_weeks,happiness) VALUES (4, 'happy');
INSERT INTO holidays(num_weeks,happiness) VALUES (6, 'very happy');
INSERT INTO holidays(num_weeks,happiness) VALUES (8, 'ecstatic');
INSERT INTO holidays(num_weeks,happiness) VALUES (2, 'sad');
ERROR: invalid input value for enum happiness: "sad"
SELECT person.name, holidays.num_weeks FROM person, holidays
WHERE person.current_mood = holidays.happiness;
ERROR: operator does not exist: mood = happiness

If you really need to do something like that, you can either write a custom operator or add explicit casts to your query:

Example 8-6. Comparing Different Enums by Casting to Text

SELECT person.name, holidays.num_weeks FROM person, holidays
    WHERE person.current_mood::text = holidays.happiness::text;

8.7.4. Implementation Details

An enum value occupies four bytes on disk. The length of an enum value’s textual label is limited by the NAMEDATALEN setting compiled into PostgreSQL; in standard builds this means at most 63 bytes. Enum labels are case sensitive, so ‘happy’ is not the same as ‘HAPPY’. White space in the labels is significant too.

The translations from internal enum values to textual labels are kept in the system catalog pg_enum. Querying this catalog directly can be useful.
8.8. Geometric Types

Geometric data types represent two-dimensional spatial objects. Table 8-19 shows the geometric types available in PostgreSQL. The most fundamental type, the point, forms the basis for all of the other types.

Table 8-19. Geometric Types

<table>
<thead>
<tr>
<th>Name</th>
<th>Storage Size</th>
<th>Representation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>point</td>
<td>16 bytes</td>
<td>Point on a plane</td>
<td>(x,y)</td>
</tr>
<tr>
<td>line</td>
<td>32 bytes</td>
<td>Infinite line (not fully implemented)</td>
<td>((x1,y1),(x2,y2))</td>
</tr>
<tr>
<td>lseg</td>
<td>32 bytes</td>
<td>Finite line segment</td>
<td>((x1,y1),(x2,y2))</td>
</tr>
<tr>
<td>box</td>
<td>32 bytes</td>
<td>Rectangular box</td>
<td>((x1,y1),(x2,y2))</td>
</tr>
<tr>
<td>path</td>
<td>16+16n bytes</td>
<td>Closed path (similar to polygon)</td>
<td>((x1,y1),...)</td>
</tr>
<tr>
<td>path</td>
<td>16+16n bytes</td>
<td>Open path</td>
<td>[(x1,y1),...]</td>
</tr>
<tr>
<td>polygon</td>
<td>40+16n bytes</td>
<td>Polygon (similar to closed path)</td>
<td>((x1,y1),...)</td>
</tr>
<tr>
<td>circle</td>
<td>24 bytes</td>
<td>Circle</td>
<td>&lt;(x,y),r&gt; (center point and radius)</td>
</tr>
</tbody>
</table>

A rich set of functions and operators is available to perform various geometric operations such as scaling, translation, rotation, and determining intersections. They are explained in Section 9.11.

8.8.1. Points

Points are the fundamental two-dimensional building block for geometric types. Values of type point are specified using either of the following syntaxes:

\[
( x , y ) \\
\text{x , y}
\]

where \(x\) and \(y\) are the respective coordinates, as floating-point numbers.

Points are output using the first syntax.

8.8.2. Line Segments

Line segments (lseg) are represented by pairs of points. Values of type lseg are specified using any of the following syntaxes:

\[
[ ( x1 , y1 ) , ( x2 , y2 ) ] \\
( ( x1 , y1 ) , ( x2 , y2 ) ) \\
( x1 , y1 ) , ( x2 , y2 ) \\
x1 , y1 , x2 , y2
\]

where \((x1,y1)\) and \((x2,y2)\) are the end points of the line segment.

Line segments are output using the first syntax.
8.8.3. Boxes

Boxes are represented by pairs of points that are opposite corners of the box. Values of type `box` are specified using any of the following syntaxes:

\[
( (x_1, y_1), (x_2, y_2) ) \\
( x_1, y_1 ), ( x_2, y_2 ) \\
x_1, y_1, x_2, y_2
\]

where \((x_1, y_1)\) and \((x_2, y_2)\) are any two opposite corners of the box.

Boxes are output using the second syntax.

Any two opposite corners can be supplied on input, but the values will be reordered as needed to store the upper right and lower left corners, in that order.

8.8.4. Paths

Paths are represented by lists of connected points. Paths can be open, where the first and last points in the list are considered not connected, or closed, where the first and last points are considered connected.

Values of type `path` are specified using any of the following syntaxes:

\[
[ (x_1, y_1), \ldots, (x_n, y_n) ] \\
( (x_1, y_1), \ldots, (x_n, y_n) ) \\
( x_1, y_1), \ldots, (x_n, y_n) \\
( x_1, y_1), \ldots, x_n, y_n \\
x_1, y_1, \ldots, x_n, y_n
\]

where the points are the end points of the line segments comprising the path. Square brackets `[ ]` indicate an open path, while parentheses `( )` indicate a closed path. When the outermost parentheses are omitted, as in the third through fifth syntaxes, a closed path is assumed.

Paths are output using the first or second syntax, as appropriate.

8.8.5. Polygons

Polygons are represented by lists of points (the vertexes of the polygon). Polygons are very similar to closed paths, but are stored differently and have their own set of support routines.

Values of type `polygon` are specified using any of the following syntaxes:

\[
( (x_1, y_1), \ldots, (x_n, y_n) ) \\
( x_1, y_1), \ldots, (x_n, y_n) \\
( x_1, y_1), \ldots, x_n, y_n \\
x_1, y_1, \ldots, x_n, y_n
\]

where the points are the end points of the line segments comprising the boundary of the polygon.

Polygons are output using the first syntax.
8.8.6. Circles

Circles are represented by a center point and radius. Values of type `circle` are specified using any of the following syntaxes:

\[
\begin{align*}
&< (x, y), r > \\
&( (x, y), r ) \\
&( x, y ), r \\
& x, y , r
\end{align*}
\]

where \((x, y)\) is the center point and \(r\) is the radius of the circle.

Circles are output using the first syntax.

8.9. Network Address Types

PostgreSQL offers data types to store IPv4, IPv6, and MAC addresses, as shown in Table 8-20. It is better to use these types instead of plain text types to store network addresses, because these types offer input error checking and specialized operators and functions (see Section 9.12).

Table 8-20. Network Address Types

<table>
<thead>
<tr>
<th>Name</th>
<th>Storage Size</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cidr</td>
<td>7 or 19 bytes</td>
<td>IPv4 and IPv6 networks</td>
</tr>
<tr>
<td>inet</td>
<td>7 or 19 bytes</td>
<td>IPv4 and IPv6 hosts and networks</td>
</tr>
<tr>
<td>macaddr</td>
<td>6 bytes</td>
<td>MAC addresses</td>
</tr>
</tbody>
</table>

When sorting `inet` or `cidr` data types, IPv4 addresses will always sort before IPv6 addresses, including IPv4 addresses encapsulated or mapped to IPv6 addresses, such as ::10.2.3.4 or ::ffff:10.4.3.2.

8.9.1. inet

The `inet` type holds an IPv4 or IPv6 host address, and optionally its subnet, all in one field. The subnet is represented by the number of network address bits present in the host address (the “netmask”). If the netmask is 32 and the address is IPv4, then the value does not indicate a subnet, only a single host. In IPv6, the address length is 128 bits, so 128 bits specify a unique host address. Note that if you want to accept only networks, you should use the `cidr` type rather than `inet`.

The input format for this type is `address/y` where `address` is an IPv4 or IPv6 address and \(y\) is the number of bits in the netmask. If the /\(y\) portion is missing, the netmask is 32 for IPv4 and 128 for IPv6, so the value represents just a single host. On display, the /\(y\) portion is suppressed if the netmask specifies a single host.

8.9.2. cidr

The `cidr` type holds an IPv4 or IPv6 network specification. Input and output formats follow Classless Internet Domain Routing conventions. The format for specifying networks is `address/y` where `address` is the network represented as an IPv4 or IPv6 address, and \(y\) is the number of bits in the netmask. If \(y\) is omitted, it is calculated using assumptions from the older classful network numbering
system, except it will be at least large enough to include all of the octets written in the input. It is an error to specify a network address that has bits set to the right of the specified netmask.

Table 8-21 shows some examples.

### Table 8-21. cidr Type Input Examples

<table>
<thead>
<tr>
<th>cidr Input</th>
<th>cidr Output</th>
<th>abbrev(cidr)</th>
</tr>
</thead>
<tbody>

<td>::ffff:1.2.3.0/120</td>
</tr>
<tr>
<td>::ffff:1.2.3.0/128</td>
<td>::ffff:1.2.3.0/128</td>
<td>::ffff:1.2.3.0/128</td>
</tr>
</tbody>
</table>

### 8.9.3. inet VS. cidr

The essential difference between inet and cidr data types is that inet accepts values with nonzero bits to the right of the netmask, whereas cidr does not.

**Tip:** If you do not like the output format for inet or cidr values, try the functions host, text, and abbrev.

### 8.9.4. macaddr

The macaddr type stores MAC addresses, known for example from Ethernet card hardware addresses (although MAC addresses are used for other purposes as well). Input is accepted in the following formats:

- ‘08:00:2b:01:02:03’
- ‘08-00-2b-01-02-03’
- ‘08002b:010203’
- ‘08002b-010203’
- ‘0800.2b01.0203’
Chapter 8. Data Types

These examples would all specify the same address. Upper and lower case is accepted for the digits a through f. Output is always in the first of the forms shown.

IEEE Std 802-2001 specifies the second shown form (with hyphens) as the canonical form for MAC addresses, and specifies the first form (with colons) as the bit-reversed notation, so that 08-00-2b-01-02-03 = 01:00:4D:08:04:0C. This convention is widely ignored nowadays, and it is only relevant for obsolete network protocols (such as Token Ring). PostgreSQL makes no provisions for bit reversal, and all accepted formats use the canonical LSB order.

The remaining four input formats are not part of any standard.

8.10. Bit String Types

Bit strings are strings of 1’s and 0’s. They can be used to store or visualize bit masks. There are two SQL bit types: \texttt{bit(n)} and \texttt{bit varying(n)}, where \( n \) is a positive integer.

\texttt{bit} type data must match the length \( n \) exactly; it is an error to attempt to store shorter or longer bit strings. \texttt{bit varying} data is of variable length up to the maximum length \( n \); longer strings will be rejected. Writing \texttt{bit} without a length is equivalent to \texttt{bit(1)}, while \texttt{bit varying} without a length specification means unlimited length.

\textbf{Note:} If one explicitly casts a bit-string value to \texttt{bit(n)}, it will be truncated or zero-padded on the right to be exactly \( n \) bits, without raising an error. Similarly, if one explicitly casts a bit-string value to \texttt{bit varying(n)}, it will be truncated on the right if it is more than \( n \) bits.

Refer to Section 4.1.2.5 for information about the syntax of bit string constants. Bit-logical operators and string manipulation functions are available; see Section 9.6.

\textbf{Example 8-7. Using the bit string types}

\begin{verbatim}
CREATE TABLE test (a BIT(3), b BIT VARYING(5));
INSERT INTO test VALUES (B'101', B'00');
INSERT INTO test VALUES (B'10', B'101');
ERROR: bit string length 2 does not match type bit(3)
INSERT INTO test VALUES (B'10'::bit(3), B'101');
SELECT * FROM test;
   a | b
-----+-----
   101 | 00
   100 | 101
\end{verbatim}

A bit string value requires 1 byte for each group of 8 bits, plus 5 or 8 bytes overhead depending on the length of the string (but long values may be compressed or moved out-of-line, as explained in Section 8.3 for character strings).
8.11. Text Search Types

PostgreSQL provides two data types that are designed to support full text search, which is the activity of searching through a collection of natural-language documents to locate those that best match a query. The \texttt{tsvector} type represents a document in a form optimized for text search; the \texttt{tsquery} type similarly represents a text query. Chapter 12 provides a detailed explanation of this facility, and Section 9.13 summarizes the related functions and operators.

8.11.1. \texttt{tsvector}

A \texttt{tsvector} value is a sorted list of distinct lexemes, which are words that have been normalized to merge different variants of the same word (see Chapter 12 for details). Sorting and duplicate-elimination are done automatically during input, as shown in this example:

\begin{verbatim}
SELECT 'a fat cat sat on a mat and ate a fat rat':tsvector;
tsvector
----------------------------------------------------
'a' 'and' 'ate' 'cat' 'fat' 'mat' 'on' 'rat' 'sat'
\end{verbatim}

To represent lexemes containing whitespace or punctuation, surround them with quotes:

\begin{verbatim}
SELECT $$the lexeme ' ' contains spaces$$::tsvector;
tsvector
-------------------------------------------
' ' 'contains' 'lexeme' 'spaces' 'the'
\end{verbatim}

(We use dollar-quoted string literals in this example and the next one to avoid the confusion of having to double quote marks within the literals.) Embedded quotes and backslashes must be doubled:

\begin{verbatim}
SELECT $$the lexeme 'Joe"s' contains a quote$$::tsvector;
tsvector
------------------------------------------------
'Joe"s' 'a' 'contains' 'lexeme' 'quote' 'the'
\end{verbatim}

Optionally, integer positions can be attached to lexemes:

\begin{verbatim}
SELECT 'a:1 fat:2 cat:3 sat:4 on:5 a:6 mat:7 and:8 ate:9 a:10 fat:11 rat:12':tsvector;
tsvector
-------------------------------------------------------------------------------
'a':1,6,10 'and':8 'ate':9 'cat':3 'fat':2,11 'mat':7 'on':5 'rat':12 'sat':4
\end{verbatim}

A position normally indicates the source word’s location in the document. Positional information can be used for proximity ranking. Position values can range from 1 to 16383; larger numbers are silently set to 16383. Duplicate positions for the same lexeme are discarded.

Lexemes that have positions can further be labeled with a weight, which can be A, B, C, or D. D is the default and hence is not shown on output:

\begin{verbatim}
SELECT 'a:1A fat:2B,4C cat:5D':tsvector;
tsvector
----------------------------
'a':1A 'cat':5 'fat':2B,4C
\end{verbatim}

Weights are typically used to reflect document structure, for example by marking title words differently from body words. Text search ranking functions can assign different priorities to the different weight markers.
It is important to understand that the `tsvector` type itself does not perform any normalization; it assumes the words it is given are normalized appropriately for the application. For example,

```
select 'The Fat Rats'::tsvector;
```

```
---------------------
'Fat' 'Rats' 'The'
```

For most English-text-searching applications the above words would be considered non-normalized, but `tsvector` doesn’t care. Raw document text should usually be passed through `to_tsvector` to normalize the words appropriately for searching:

```
SELECT to_tsvector('english', 'The Fat Rats');
```

```
-----------------
'fat':2 'rat':3
```

Again, see Chapter 12 for more detail.

### 8.11.2. tsquery

A `tsquery` value stores lexemes that are to be searched for, and combines them honoring the boolean operators & (AND), | (OR), and ! (NOT). Parentheses can be used to enforce grouping of the operators:

```
SELECT 'fat & rat'::tsquery;
```

```
--------------
'fat' & 'rat'
```

```
SELECT 'fat & (rat | cat)'::tsquery;
```

```
----------------------
'fat' & ( 'rat' | 'cat' )
```

```
SELECT 'fat & rat & ! cat'::tsquery;
```

```
---------------------
'fat' & 'rat' & '!cat'
```

In the absence of parentheses, ! (NOT) binds most tightly, and & (AND) binds more tightly than | (OR).

Optionally, lexemes in a `tsquery` can be labeled with one or more weight letters, which restricts them to match only `tsvector` lexemes with matching weights:

```
SELECT 'fat:ab & cat'::tsquery;
```

```
----------
'fat':AB & 'cat'
```

Also, lexemes in a `tsquery` can be labeled with * to specify prefix matching:

```
SELECT 'super:*'::tsquery;
```

```
   `
```
Chapter 8. Data Types

8.12. UUID Type

The data type `uuid` stores Universally Unique Identifiers (UUID) as defined by RFC 4122, ISO/IEC 9834-8:2005, and related standards. (Some systems refer to this data type as a globally unique identifier, or GUID, instead.) This identifier is a 128-bit quantity that is generated by an algorithm chosen to make it very unlikely that the same identifier will be generated by anyone else in the known universe using the same algorithm. Therefore, for distributed systems, these identifiers provide a better uniqueness guarantee than sequence generators, which are only unique within a single database.

A UUID is written as a sequence of lower-case hexadecimal digits, in several groups separated by hyphens, specifically a group of 8 digits followed by three groups of 4 digits followed by a group of 12 digits, for a total of 32 digits representing the 128 bits. An example of a UUID in this standard form is:

```
a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
```

PostgreSQL also accepts the following alternative forms for input: use of upper-case digits, the standard format surrounded by braces, omitting some or all hyphens, adding a hyphen after any group of four digits. Examples are:

```
{a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11}
a0eebc99-c0b-4ef8-bb6d-6bb9bd380a11
a0ee-bc99-9c0b-4ef8-bb6d-6bb9-bd38-0a11
{a0eebc99-9c0b4ef8-bb6d6bb9-bd380a11}
```

Output is always in the standard form.

PostgreSQL provides storage and comparison functions for UUIDs, but the core database does not include any function for generating UUIDs, because no single algorithm is well suited for every application. The contrib module `contrib/uuid-ossp` provides functions that implement several standard algorithms. Alternatively, UUIDs could be generated by client applications or other libraries invoked through a server-side function.
8.13. XML Type

The xml data type can be used to store XML data. Its advantage over storing XML data in a text field is that it checks the input values for well-formedness, and there are support functions to perform type-safe operations on it; see Section 9.14. Use of this data type requires the installation to have been built with configure --with-libxml.

The xml type can store well-formed “documents”, as defined by the XML standard, as well as “content” fragments, which are defined by the production XMLDecl? content in the XML standard. Roughly, this means that content fragments can have more than one top-level element or character node. The expression xmlvalue IS DOCUMENT can be used to evaluate whether a particular xml value is a full document or only a content fragment.

8.13.1. Creating XML Values

To produce a value of type xml from character data, use the function xmlparse:

XMLPARSE ( { DOCUMENT | CONTENT } value)

Examples:

XMLPARSE (DOCUMENT '<?xml version="1.0"?><book><title>Manual</title><chapter>...</chapter></book>')
XMLPARSE (CONTENT 'abc<foo>bar</foo><bar>foo</bar>')

While this is the only way to convert character strings into XML values according to the SQL standard, the PostgreSQL-specific syntaxes:

xml '<foo>bar</foo>'
'<foo>bar</foo>::xml

can also be used.

The xml type does not validate input values against a document type declaration (DTD), even when the input value specifies a DTD.

The inverse operation, producing a character string value from xml, uses the function xmlserialize:

XMLSERIALIZE ( { DOCUMENT | CONTENT } value AS type)

type can be character, character varying, or text (or an alias for one of those). Again, according to the SQL standard, this is the only way to convert between type xml and character types, but PostgreSQL also allows you to simply cast the value.

When a character string value is cast to or from type xml without going through XMLPARSE or XMLSERIALIZE, respectively, the choice of DOCUMENT versus CONTENT is determined by the “XML option” session configuration parameter, which can be set using the standard command:

SET XML OPTION { DOCUMENT | CONTENT };

or the more PostgreSQL-like syntax

SET xmloption TO { DOCUMENT | CONTENT };

The default is CONTENT, so all forms of XML data are allowed.
8.13.2. Encoding Handling

Care must be taken when dealing with multiple character encodings on the client, server, and in the XML data passed through them. When using the text mode to pass queries to the server and query results to the client (which is the normal mode), PostgreSQL converts all character data passed between the client and the server and vice versa to the character encoding of the respective end; see Section 22.2. This includes string representations of XML values, such as in the above examples. This would ordinarily mean that encoding declarations contained in XML data can become invalid as the character data is converted to other encodings while travelling between client and server, because the embedded encoding declaration is not changed. To cope with this behavior, encoding declarations contained in character strings presented for input to the `xml` type are ignored, and content is assumed to be in the current server encoding. Consequently, for correct processing, character strings of XML data must be sent from the client in the current client encoding. It is the responsibility of the client to either convert documents to the current client encoding before sending them to the server, or to adjust the client encoding appropriately. On output, values of type `xml` will not have an encoding declaration, and clients should assume all data is in the current client encoding.

When using binary mode to pass query parameters to the server and query results back to the client, no character set conversion is performed, so the situation is different. In this case, an encoding declaration in the XML data will be observed, and if it is absent, the data will be assumed to be in UTF-8 (as required by the XML standard; note that PostgreSQL does not support UTF-16). On output, data will have an encoding declaration specifying the client encoding, unless the client encoding is UTF-8, in which case it will be omitted.

Needless to say, processing XML data with PostgreSQL will be less error-prone and more efficient if the XML data encoding, client encoding, and server encoding are the same. Since XML data is internally processed in UTF-8, computations will be most efficient if the server encoding is also UTF-8.

Caution

Some XML-related functions may not work at all on non-ASCII data when the server encoding is not UTF-8. This is known to be an issue for `xpath()` in particular.

8.13.3. Accessing XML Values

The `xml` data type is unusual in that it does not provide any comparison operators. This is because there is no well-defined and universally useful comparison algorithm for XML data. One consequence of this is that you cannot retrieve rows by comparing an `xml` column against a search value. XML values should therefore typically be accompanied by a separate key field such as an ID. An alternative solution for comparing XML values is to convert them to character strings first, but note that character string comparison has little to do with a useful XML comparison method.

Since there are no comparison operators for the `xml` data type, it is not possible to create an index directly on a column of this type. If speedy searches in XML data are desired, possible workarounds include casting the expression to a character string type and indexing that, or indexing an XPath expression. Of course, the actual query would have to be adjusted to search by the indexed expression.

The text-search functionality in PostgreSQL can also be used to speed up full-document searches of XML data. The necessary preprocessing support is, however, not yet available in the PostgreSQL distribution.

PostgreSQL allows columns of a table to be defined as variable-length multidimensional arrays. Arrays of any built-in or user-defined base type, enum type, or composite type can be created. Arrays of domains are not yet supported.

8.14.1. Declaration of Array Types

To illustrate the use of array types, we create this table:

```sql
CREATE TABLE sal_emp (  
  name text,  
  pay_by_quarter integer[],  
  schedule text[][]  
);
```

As shown, an array data type is named by appending square brackets ([]) to the data type name of the array elements. The above command will create a table named `sal_emp` with a column of type `text` (name), a one-dimensional array of type `integer` (pay_by_quarter), which represents the employee’s salary by quarter, and a two-dimensional array of `text` (schedule), which represents the employee’s weekly schedule.

The syntax for `CREATE TABLE` allows the exact size of arrays to be specified, for example:

```sql
CREATE TABLE tictactoe (  
  squares integer[3][3]  
);
```

However, the current implementation ignores any supplied array size limits, i.e., the behavior is the same as for arrays of unspecified length.

The current implementation does not enforce the declared number of dimensions either. Arrays of a particular element type are all considered to be of the same type, regardless of size or number of dimensions. So, declaring the array size or number of dimensions in `CREATE TABLE` is simply documentation; it does not affect run-time behavior.

An alternative syntax, which conforms to the SQL standard by using the keyword `ARRAY`, can be used for one-dimensional arrays. `pay_by_quarter` could have been defined as:

```sql
pay_by_quarter integer ARRAY[4],
```

Or, if no array size is to be specified:

```sql
pay_by_quarter integer ARRAY,
```

As before, however, PostgreSQL does not enforce the size restriction in any case.

8.14.2. Array Value Input

To write an array value as a literal constant, enclose the element values within curly braces and separate them by commas. (If you know C, this is not unlike the C syntax for initializing structures.) You can put double quotes around any element value, and must do so if it contains commas or curly braces. (More details appear below.) Thus, the general format of an array constant is the following:

'\{ val1 delim val2 delim ... }'
where *delim* is the delimiter character for the type, as recorded in its *pg_type* entry. Among the standard data types provided in the PostgreSQL distribution, all use a comma (,), except for type *box* which uses a semicolon (;). Each *val* is either a constant of the array element type, or a subarray. An example of an array constant is:

```
'{{1,2,3},{4,5,6},{7,8,9}}'
```

This constant is a two-dimensional, 3-by-3 array consisting of three subarrays of integers.

To set an element of an array constant to NULL, write NULL for the element value. (Any upper- or lower-case variant of NULL will do.) If you want an actual string value “NULL”, you must put double quotes around it.

(These kinds of array constants are actually only a special case of the generic type constants discussed in Section 4.1.2.7. The constant is initially treated as a string and passed to the array input conversion routine. An explicit type specification might be necessary.)

Now we can show some INSERT statements:

```sql
INSERT INTO sal_emp
VALUES ('Bill',
    '{10000, 10000, 10000, 10000}',
    '{"meeting", "lunch"}, {"training", "presentation"})');
```

```sql
INSERT INTO sal_emp
VALUES ('Carol',
    '{20000, 25000, 25000, 25000}',
    '{"breakfast", "consulting"}, {"meeting", "lunch"})');
```

The result of the previous two inserts looks like this:

```
SELECT * FROM sal_emp;
name | pay_by_quarter | schedule
-------+-----------------+-------------------------------------------
Bill | {10000,10000,10000,10000} | {{meeting,lunch},{training,presentation}}
Carol | {20000,25000,25000,25000} | {{breakfast,consulting},{meeting,lunch}}
(2 rows)
```

Multidimensional arrays must have matching extents for each dimension. A mismatch causes an error, for example:

```sql
INSERT INTO sal_emp
VALUES ('Bill',
    '{10000, 10000, 10000, 10000}',
    '{"meeting", "lunch"}, {"meeting"})');
```

```
ERROR: multidimensional arrays must have array expressions with matching dimensions
```

The *ARRAY* constructor syntax can also be used:

```sql
INSERT INTO sal_emp
VALUES ('Bill',
    ARRAY[10000, 10000, 10000, 10000],
    ARRAY[['meeting', 'lunch'], ['training', 'presentation']]);
```
Chapter 8. Data Types

INSERT INTO sal_emp
VALUES ('Carol',
ARRAY[20000, 25000, 25000, 25000],
ARRAY[['breakfast', 'consulting'], ['meeting', 'lunch']]);

Notice that the array elements are ordinary SQL constants or expressions; for instance, string literals are single quoted, instead of double quoted as they would be in an array literal. The ARRAY constructor syntax is discussed in more detail in Section 4.2.11.

8.14.3. Accessing Arrays

Now, we can run some queries on the table. First, we show how to access a single element of an array. This query retrieves the names of the employees whose pay changed in the second quarter:

```
SELECT name FROM sal_emp WHERE pay_by_quarter[1] <> pay_by_quarter[2];
```

```
name
-------
Carol
(1 row)
```

The array subscript numbers are written within square brackets. By default PostgreSQL uses a one-based numbering convention for arrays, that is, an array of \( n \) elements starts with \( \text{array}[1] \) and ends with \( \text{array}[n] \).

This query retrieves the third quarter pay of all employees:

```
SELECT pay_by_quarter[3] FROM sal_emp;
```

```
pay_by_quarter
-----------------
    10000
    25000
(2 rows)
```

We can also access arbitrary rectangular slices of an array, or subarrays. An array slice is denoted by writing \( \text{lower-bound:upper-bound} \) for one or more array dimensions. For example, this query retrieves the first item on Bill’s schedule for the first two days of the week:

```
SELECT schedule[1:2][1:1] FROM sal_emp WHERE name = 'Bill';
```

```
schedule
------------------------
{{meeting},{training}}
(1 row)
```

If any dimension is written as a slice, i.e., contains a colon, then all dimensions are treated as slices. Any dimension that has only a single number (no colon) is treated as being from 1 to the number specified. For example, \[2\] is treated as \[1:2\], as in this example:

```
SELECT schedule[1:2][2] FROM sal_emp WHERE name = 'Bill';
```

```
schedule
------------------------
```

132
To avoid confusion with the non-slice case, it’s best to use slice syntax for all dimensions, e.g.,
\[[1:2][1:1]\), not \[[2][1:1]\).

An array subscript expression will return null if either the array itself or any of the subscript expressions are null. Also, null is returned if a subscript is outside the array bounds (this case does not raise an error). For example, if \(\text{schedule}\) currently has the dimensions \([1:3][1:2]\) then referencing \(\text{schedule}[3][3]\) yields NULL. Similarly, an array reference with the wrong number of subscripts yields a null rather than an error.

An array slice expression likewise yields null if the array itself or any of the subscript expressions are null. However, in other cases such as selecting an array slice that is completely outside the current array bounds, a slice expression yields an empty (zero-dimensional) array instead of null. (This does not match non-slice behavior and is done for historical reasons.) If the requested slice partially overlaps the array bounds, then it is silently reduced to just the overlapping region instead of returning null.

The current dimensions of any array value can be retrieved with the \text{array_dims} function:

\[
\text{SELECT array_dims(schedule) FROM sal_emp WHERE name = 'Carol';}
\]

\[
\text{array_dims}
\]

\[
\text{[1:2][1:2]}
\]

(1 row)

\text{array_dims} produces a text result, which is convenient for people to read but perhaps inconvenient for programs. Dimensions can also be retrieved with \text{array_upper} and \text{array_lower}, which return the upper and lower bound of a specified array dimension, respectively:

\[
\text{SELECT array_upper(schedule, 1) FROM sal_emp WHERE name = 'Carol';}
\]

\[
\text{array_upper}
\]

\[
2
\]

(1 row)

\text{array_upper} will return the length of a specified array dimension:

\[
\text{SELECT array_length(schedule, 1) FROM sal_emp WHERE name = 'Carol';}
\]

\[
\text{array_length}
\]

\[
2
\]

(1 row)

### 8.14.4. Modifying Arrays

An array value can be replaced completely:

\[
\text{UPDATE sal_emp SET pay_by_quarter = '{25000,25000,27000,27000}' WHERE name = 'Carol';}
\]
or using the `ARRAY` expression syntax:

```sql
UPDATE sal_emp SET pay_by_quarter = ARRAY[25000,25000,27000,27000]
   WHERE name = 'Carol';
```

An array can also be updated at a single element:

```sql
   WHERE name = 'Bill';
```

or updated in a slice:

```sql
UPDATE sal_emp SET pay_by_quarter[1:2] = '{27000,27000}'
   WHERE name = 'Carol';
```

A stored array value can be enlarged by assigning to elements not already present. Any positions between those previously present and the newly assigned elements will be filled with nulls. For example, if array `myarray` currently has 4 elements, it will have six elements after an update that assigns to `myarray[6]:myarray[5]` will contain null. Currently, enlargement in this fashion is only allowed for one-dimensional arrays, not multidimensional arrays.

Subscripted assignment allows creation of arrays that do not use one-based subscripts. For example one might assign to `myarray[-2:7]` to create an array with subscript values from -2 to 7.

New array values can also be constructed using the concatenation operator, `||`:

```sql
SELECT ARRAY[1,2] || ARRAY[3,4];
   ?column?
  -----------
     {1,2,3,4}
(1 row)
```

```sql
SELECT ARRAY[5,6] || ARRAY[[1,2],[3,4]];
   ?column?
  ---------------------
    {{5,6},{1,2},{3,4}}
(1 row)
```

The concatenation operator allows a single element to be pushed onto the beginning or end of a one-dimensional array. It also accepts two `N`-dimensional arrays, or an `N`-dimensional and an `N+1`-dimensional array.

When a single element is pushed onto either the beginning or end of a one-dimensional array, the result is an array with the same lower bound subscript as the array operand. For example:

```sql
SELECT array_dims(1 || '{0:1}={2,3}':int[]);
array_dims
  -----------
    [0:2]
(1 row)
```

```sql
SELECT array_dims(ARRAY[1,2] || 3);
array_dims
  -----------
    [1:3]
(1 row)
```
When two arrays with an equal number of dimensions are concatenated, the result retains the lower bound subscript of the left-hand operand’s outer dimension. The result is an array comprising every element of the left-hand operand followed by every element of the right-hand operand. For example:

```sql
SELECT array_dims(ARRAY[1,2] || ARRAY[3,4,5]);
array_dims
-----------
[1:5]
(1 row)
```

```sql
SELECT array_dims(ARRAY[[1,2],[3,4]] || ARRAY[[5,6],[7,8],[9,0]]);
array_dims
-----------
[1:5][1:2]
(1 row)
```

When an \(N\)-dimensional array is pushed onto the beginning or end of an \(N+1\)-dimensional array, the result is analogous to the element-array case above. Each \(N\)-dimensional sub-array is essentially an element of the \(N+1\)-dimensional array’s outer dimension. For example:

```sql
SELECT array_dims(ARRAY[1,2] || ARRAY[[3,4],[5,6]]);
array_dims
-----------
[1:3][1:2]
(1 row)
```

An array can also be constructed by using the functions `array_prepend`, `array_append`, or `array_cat`. The first two only support one-dimensional arrays, but `array_cat` supports multidimensional arrays. Note that the concatenation operator discussed above is preferred over direct use of these functions. In fact, these functions primarily exist for use in implementing the concatenation operator. However, they might be directly useful in the creation of user-defined aggregates. Some examples:

```sql
SELECT array_prepend(1, ARRAY[2,3]);
array_prepend
-------------
{1,2,3}
(1 row)
```

```sql
SELECT array_append(ARRAY[1,2], 3);
array_append
-------------
{1,2,3}
(1 row)
```

```sql
SELECT array_cat(ARRAY[1,2], ARRAY[3,4]);
array_cat
---------
{1,2,3,4}
(1 row)
```

```sql
SELECT array_cat(ARRAY[[1,2],[3,4]], ARRAY[5,6]);
```
Chapter 8. Data Types

8.14.5. Searching in Arrays

To search for a value in an array, each value must be checked. This can be done manually, if you know the size of the array. For example:

```
```

However, this quickly becomes tedious for large arrays, and is not helpful if the size of the array is unknown. An alternative method is described in Section 9.21. The above query could be replaced by:

```
SELECT * FROM sal_emp WHERE 10000 = ANY (pay_by_quarter);
```

In addition, you can find rows where the array has all values equal to 10000 with:

```
SELECT * FROM sal_emp WHERE 10000 = ALL (pay_by_quarter);
```

Alternatively, the `generate_subscripts` function can be used. For example:

```
SELECT * FROM sal_emp
WHERE 10000 = (SELECT pay_by_quarter,
               generate_subscripts(pay_by_quarter, 1) AS s
               FROM sal_emp) AS foo
WHERE pay_by_quarter[s] = 10000;
```

This function is described in Table 9-46.

**Tip:** Arrays are not sets; searching for specific array elements can be a sign of database misde-sign. Consider using a separate table with a row for each item that would be an array element. This will be easier to search, and is likely to scale better for a large number of elements.

8.14.6. Array Input and Output Syntax

The external text representation of an array value consists of items that are interpreted according to the I/O conversion rules for the array’s element type, plus decoration that indicates the array structure. The decoration consists of curly braces ({ and }) around the array value plus delimiter characters between adjacent items. The delimiter character is usually a comma (,) but can be something else:
it is determined by the typdelim setting for the array’s element type. Among the standard data types provided in the PostgreSQL distribution, all use a comma, except for type box, which uses a semicolon (;). In a multidimensional array, each dimension (row, plane, cube, etc.) gets its own level of curly braces, and delimiters must be written between adjacent curly-braced entities of the same level.

The array output routine will put double quotes around element values if they are empty strings, contain curly braces, delimeter characters, double quotes, backslashes, or white space, or match the word NULL. Double quotes and backslashes embedded in element values will be backslash-escaped. For numeric data types it is safe to assume that double quotes will never appear, but for textual data types one should be prepared to cope with either the presence or absence of quotes.

By default, the lower bound index value of an array’s dimensions is set to one. To represent arrays with other lower bounds, the array subscript ranges can be specified explicitly before writing the array contents. This decoration consists of square brackets ([]) around each array dimension’s lower and upper bounds, with a colon (:) delimiter character in between. The array dimension decoration is followed by an equal sign (=). For example:

```sql
SELECT f1[1][-2][3] AS e1, f1[1][-1][5] AS e2
FROM (SELECT '[1:1][-2:-1][3:5]={{1,2,3},{4,5,6}}'::int[] AS f1) AS ss;
```

```
+----+----+
| e1 | e2 |
+----+----+
| 1  | 6  |
+----+----+
```

The array output routine will include explicit dimensions in its result only when there are one or more lower bounds different from one.

If the value written for an element is NULL (in any case variant), the element is taken to be NULL. The presence of any quotes or backslashes disables this and allows the literal string value “NULL” to be entered. Also, for backwards compatibility with pre-8.2 versions of PostgreSQL, the array_nulls configuration parameter can be turned off to suppress recognition of NULL as a NULL.

As shown previously, when writing an array value you can use double quotes around any individual array element. You must do so if the element value would otherwise confuse the array-value parser. For example, elements containing curly braces, commas (or the data type’s delimiter character), double quotes, backslashes, or leading or trailing whitespace must be double-quoted. Empty strings and strings matching the word NULL must be quoted, too. To put a double quote or backslash in a quoted array element value, use escape string syntax and precede it with a backslash. Alternatively, you can avoid quotes and use backslash-escaping to protect all data characters that would otherwise be taken as array syntax.

You can add whitespace before a left brace or after a right brace. You can also add whitespace before or after any individual item string. In all of these cases the whitespace will be ignored. However, whitespace within double-quoted elements, or surrounded on both sides by non-whitespace characters of an element, is not ignored.

**Note:** Remember that what you write in an SQL command will first be interpreted as a string literal, and then as an array. This doubles the number of backslashes you need. For example, to insert a text array value containing a backslash and a double quote, you’d need to write:

```sql
INSERT ... VALUES (E'"\\","\"');
```

The escape string processor removes one level of backslashes, so that what arrives at the array-value parser looks like ("", "). In turn, the strings fed to the text data type’s input routine become \ and " respectively. (If we were working with a data type whose input routine also treated
backslashes specially, for example, we might need as many as eight backslashes in the command to get one backslash into the stored array element.) Dollar quoting (see Section 4.1.2.4) can be used to avoid the need to double backslashes.

**Tip:** The `ARRAY` constructor syntax (see Section 4.2.11) is often easier to work with than the array-literal syntax when writing array values in SQL commands. In `ARRAY`, individual element values are written the same way they would be written when not members of an array.

## 8.15. Composite Types

A composite type represents the structure of a row or record; it is essentially just a list of field names and their data types. PostgreSQL allows composite types to be used in many of the same ways that simple types can be used. For example, a column of a table can be declared to be of a composite type.

### 8.15.1. Declaration of Composite Types

Here are two simple examples of defining composite types:

```sql
CREATE TYPE complex AS (  
   r  double precision,  
   i  double precision;
);

CREATE TYPE inventory_item AS (  
   name  text,  
   supplier_id  integer,  
   price  numeric;
);
```

The syntax is comparable to `CREATE TABLE`, except that only field names and types can be specified; no constraints (such as `NOT NULL`) can presently be included. Note that the `AS` keyword is essential; without it, the system will think a different kind of `CREATE TYPE` command is meant, and you will get odd syntax errors.

Having defined the types, we can use them to create tables:

```sql
CREATE TABLE on_hand (  
   item  inventory_item,  
   count  integer;
);

INSERT INTO on_hand VALUES (ROW('fuzzy dice', 42, 1.99), 1000);
```

or functions:

```sql
CREATE FUNCTION price_extension(inventory_item, integer) RETURNS numeric  
AS 'SELECT $1.price * $2' LANGUAGE SQL;

SELECT price_extension(item, 10) FROM on_hand;
```
Whenever you create a table, a composite type is also automatically created, with the same name as the table, to represent the table’s row type. For example, had we said:

```sql
CREATE TABLE inventory_item (
  name text,
  supplier_id integer REFERENCES suppliers,
  price numeric CHECK (price > 0)
);
```

then the same `inventory_item` composite type shown above would come into being as a byproduct, and could be used just as above. Note however an important restriction of the current implementation: since no constraints are associated with a composite type, the constraints shown in the table definition do not apply to values of the composite type outside the table. (A partial workaround is to use domain types as members of composite types.)

### 8.15.2. Composite Value Input

To write a composite value as a literal constant, enclose the field values within parentheses and separate them by commas. You can put double quotes around any field value, and must do so if it contains commas or parentheses. (More details appear below.) Thus, the general format of a composite constant is the following:

```
' ( val1 , val2 , ... ) '
```

An example is:

```
' ("fuzzy dice",42,1.99) '
```

which would be a valid value of the `inventory_item` type defined above. To make a field be NULL, write no characters at all in its position in the list. For example, this constant specifies a NULL third field:

```
' ("fuzzy dice",42,) '
```

If you want an empty string rather than NULL, write double quotes:

```
' ("",42,) '
```

Here the first field is a non-NULL empty string, the third is NULL.

(These constants are actually only a special case of the generic type constants discussed in Section 4.1.2.7. The constant is initially treated as a string and passed to the composite-type input conversion routine. An explicit type specification might be necessary.)

The `ROW` expression syntax can also be used to construct composite values. In most cases this is considerably simpler to use than the string-literal syntax since you don’t have to worry about multiple layers of quoting. We already used this method above:

```sql
ROW('fuzzy dice', 42, 1.99)
ROW(' ', 42, NULL)
```

The `ROW` keyword is actually optional as long as you have more than one field in the expression, so these can simplify to:

```
('fuzzy dice', 42, 1.99)
```
8.15.3. Accessing Composite Types

To access a field of a composite column, one writes a dot and the field name, much like selecting a field from a table name. In fact, it’s so much like selecting from a table name that you often have to use parentheses to keep from confusing the parser. For example, you might try to select some subfields from our `on_hand` example table with something like:

```sql
SELECT item.name FROM on_hand WHERE item.price > 9.99;
```

This will not work since the name `item` is taken to be a table name, not a column name of `on_hand`, per SQL syntax rules. You must write it like this:

```sql
SELECT (item).name FROM on_hand WHERE (item).price > 9.99;
```

or if you need to use the table name as well (for instance in a multitable query), like this:

```sql
SELECT (on_hand.item).name FROM on_hand WHERE (on_hand.item).price > 9.99;
```

Now the parenthesized object is correctly interpreted as a reference to the `item` column, and then the subfield can be selected from it.

Similar syntactic issues apply whenever you select a field from a composite value. For instance, to select just one field from the result of a function that returns a composite value, you’d need to write something like:

```sql
SELECT (my_func(...)).field FROM ...
```

Without the extra parentheses, this will generate a syntax error.

8.15.4. Modifying Composite Types

Here are some examples of the proper syntax for inserting and updating composite columns. First, inserting or updating a whole column:

```sql
INSERT INTO mytab (complex_col) VALUES((1.1,2.2));
UPDATE mytab SET complex_col = ROW(1.1,2.2) WHERE ...;
```

The first example omits `ROW`, the second uses it; we could have done it either way.

We can update an individual subfield of a composite column:

```sql
UPDATE mytab SET complex_col.r = (complex_col).r + 1 WHERE ...;
```

Notice here that we don’t need to (and indeed cannot) put parentheses around the column name appearing just after `SET`, but we do need parentheses when referencing the same column in the expression to the right of the equal sign.

And we can specify subfields as targets for `INSERT`, too:

```sql
INSERT INTO mytab (complex_col.r, complex_col.i) VALUES(1.1, 2.2);
```
Had we not supplied values for all the subfields of the column, the remaining subfields would have been filled with null values.

8.15.5. Composite Type Input and Output Syntax

The external text representation of a composite value consists of items that are interpreted according to the I/O conversion rules for the individual field types, plus decoration that indicates the composite structure. The decoration consists of parentheses ( and ) around the whole value, plus commas (,) between adjacent items. Whitespace outside the parentheses is ignored, but within the parentheses it is considered part of the field value, and might or might not be significant depending on the input conversion rules for the field data type. For example, in:

' ( 42 )'

the whitespace will be ignored if the field type is integer, but not if it is text.

As shown previously, when writing a composite value you can write double quotes around any individual field value. You must do so if the field value would otherwise confuse the composite-value parser. In particular, fields containing parentheses, commas, double quotes, or backslashes must be double-quoted. To put a double quote or backslash in a quoted composite field value, precede it with a backslash. (Also, a pair of double quotes within a double-quoted field value is taken to represent a double quote character, analogously to the rules for single quotes in SQL literal strings.) Alternatively, you can avoid quoting and use backslash-escaping to protect all data characters that would otherwise be taken as composite syntax.

A completely empty field value (no characters at all between the commas or parentheses) represents a NULL. To write a value that is an empty string rather than NULL, write "".

The composite output routine will put double quotes around field values if they are empty strings or contain parentheses, commas, double quotes, backslashes, or white space. (Doing so for white space is not essential, but aids legibility.) Double quotes and backslashes embedded in field values will be doubled.

Note: Remember that what you write in an SQL command will first be interpreted as a string literal, and then as a composite. This doubles the number of backslashes you need (assuming escape string syntax is used). For example, to insert a text field containing a double quote and a backslash in a composite value, you’d need to write:

```
INSERT ... VALUES (E'("\\")');
```

The string-literal processor removes one level of backslashes, so that what arrives at the composite-value parser looks like "\. In turn, the string fed to the text data type’s input routine becomes ". (If we were working with a data type whose input routine also treated backslashes specially, bytes for example, we might need as many as eight backslashes in the command to get one backslash into the stored composite field.) Dollar quoting (see Section 4.1.2.4) can be used to avoid the need to double backslashes.

Tip: The ROW constructor syntax is usually easier to work with than the composite-literal syntax when writing composite values in SQL commands. In ROW, individual field values are written the same way they would be written when not members of a composite.
8.16. Object Identifier Types

Object identifiers (OIDs) are used internally by PostgreSQL as primary keys for various system tables. OIDs are not added to user-created tables, unless WITH OIDS is specified when the table is created, or the default with_oids configuration variable is enabled. Type oid represents an object identifier. There are also several alias types for oid: regproc, regprocedure, regoper, regoperator, regclass, regtype, regconfig, and regdictionary. Table 8-22 shows an overview.

The **oid** type is currently implemented as an unsigned four-byte integer. Therefore, it is not large enough to provide database-wide uniqueness in large databases, or even in large individual tables. So, using a user-created table’s OID column as a primary key is discouraged. OIDs are best used only for references to system tables.

The **oid** type itself has few operations beyond comparison. It can be cast to integer, however, and then manipulated using the standard integer operators. (Beware of possible signed-versus-unsigned confusion if you do this.)

The OID alias types have no operations of their own except for specialized input and output routines. These routines are able to accept and display symbolic names for system objects, rather than the raw numeric value that type **oid** would use. The alias types allow simplified lookup of OID values for objects. For example, to examine the **pg_attribute** rows related to a table **mytable**, one could write:

```sql
SELECT * FROM pg_attribute WHERE attrelid = 'mytable':regclass;
```

rather than:

```sql
SELECT * FROM pg_attribute
  WHERE attrelid = (SELECT oid FROM pg_class WHERE relname = 'mytable');
```

While that doesn’t look all that bad by itself, it’s still oversimplified. A far more complicated subselect would be needed to select the right OID if there are multiple tables named **mytable** in different schemas. The **regclass** input converter handles the table lookup according to the schema path setting, and so it does the “right thing” automatically. Similarly, casting a table’s OID to **regclass** is handy for symbolic display of a numeric OID.

**Table 8-22. Object Identifier Types**

<table>
<thead>
<tr>
<th>Name</th>
<th>References</th>
<th>Description</th>
<th>Value Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>any</td>
<td>numeric object identifier</td>
<td>564182</td>
</tr>
<tr>
<td>regproc</td>
<td>pg_proc</td>
<td>function name</td>
<td>sum</td>
</tr>
<tr>
<td>regprocedure</td>
<td>pg_proc</td>
<td>function with argument types</td>
<td>sum(int4)</td>
</tr>
<tr>
<td>regoper</td>
<td>pg_operator</td>
<td>operator name</td>
<td>+</td>
</tr>
<tr>
<td>regoperator</td>
<td>pg_operator</td>
<td>operator with argument types</td>
<td>*(integer,integer) or -(NONE,integer)</td>
</tr>
<tr>
<td>regclass</td>
<td>pg_class</td>
<td>relation name</td>
<td>pg_type</td>
</tr>
<tr>
<td>regtype</td>
<td>pg_type</td>
<td>data type name</td>
<td>integer</td>
</tr>
<tr>
<td>regconfig</td>
<td>pg_ts_config</td>
<td>text search configuration</td>
<td>english</td>
</tr>
<tr>
<td>regdictionary</td>
<td>pg_ts_dict</td>
<td>text search dictionary</td>
<td>simple</td>
</tr>
</tbody>
</table>
All of the OID alias types accept schema-qualified names, and will display schema-qualified names on output if the object would not be found in the current search path without being qualified. The \texttt{regproc} and \texttt{regoper} alias types will only accept input names that are unique (not overloaded), so they are of limited use; for most uses \texttt{regprocedure} or \texttt{regoperator} are more appropriate. For \texttt{regoperator}, unary operators are identified by writing \texttt{NONE} for the unused operand.

An additional property of the OID alias types is the creation of dependencies. If a constant of one of these types appears in a stored expression (such as a column default expression or view), it creates a dependency on the referenced object. For example, if a column has a default expression \texttt{nextval('my_seq'::regclass)}, PostgreSQL understands that the default expression depends on the sequence \texttt{my_seq}; the system will not let the sequence be dropped without first removing the default expression.

Another identifier type used by the system is \texttt{xid}, or transaction (abbreviated xact) identifier. This is the data type of the system columns \texttt{xmin} and \texttt{xmax}. Transaction identifiers are 32-bit quantities.

A third identifier type used by the system is \texttt{cid}, or command identifier. This is the data type of the system columns \texttt{cmin} and \texttt{cmax}. Command identifiers are also 32-bit quantities.

A final identifier type used by the system is \texttt{tid}, or tuple identifier (row identifier). This is the data type of the system column \texttt{ctid}. A tuple ID is a pair (block number, tuple index within block) that identifies the physical location of the row within its table.

(The system columns are further explained in Section 5.4.)

### 8.17. Pseudo-Types

The PostgreSQL type system contains a number of special-purpose entries that are collectively called \textit{pseudo-types}. A pseudo-type cannot be used as a column data type, but it can be used to declare a function’s argument or result type. Each of the available pseudo-types is useful in situations where a function’s behavior does not correspond to simply taking or returning a value of a specific SQL data type. Table 8-23 lists the existing pseudo-types.

**Table 8-23. Pseudo-Types**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>any</td>
<td>Indicates that a function accepts any input data type.</td>
</tr>
<tr>
<td>anyarray</td>
<td>Indicates that a function accepts any array data type (see Section 34.2.5).</td>
</tr>
<tr>
<td>anyelement</td>
<td>Indicates that a function accepts any data type (see Section 34.2.5).</td>
</tr>
<tr>
<td>anyenum</td>
<td>Indicates that a function accepts any enum data type (see Section 34.2.5 and Section 8.7).</td>
</tr>
<tr>
<td>anynonarray</td>
<td>Indicates that a function accepts any non-array data type (see Section 34.2.5).</td>
</tr>
<tr>
<td>cstring</td>
<td>Indicates that a function accepts or returns a null-terminated C string.</td>
</tr>
<tr>
<td>internal</td>
<td>Indicates that a function accepts or returns a server-internal data type.</td>
</tr>
</tbody>
</table>
Chapter 8. Data Types

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>language_handler</td>
<td>A procedural language call handler is declared to return language_handler.</td>
</tr>
<tr>
<td>record</td>
<td>Identifies a function returning an unspecified row type.</td>
</tr>
<tr>
<td>trigger</td>
<td>A trigger function is declared to return trigger.</td>
</tr>
<tr>
<td>void</td>
<td>Indicates that a function returns no value.</td>
</tr>
<tr>
<td>opaque</td>
<td>An obsolete type name that formerly served all the above purposes.</td>
</tr>
</tbody>
</table>

Functions coded in C (whether built-in or dynamically loaded) can be declared to accept or return any of these pseudo data types. It is up to the function author to ensure that the function will behave safely when a pseudo-type is used as an argument type.

Functions coded in procedural languages can use pseudo-types only as allowed by their implementation languages. At present the procedural languages all forbid use of a pseudo-type as argument type, and allow only `void` and `record` as a result type (plus `trigger` when the function is used as a trigger). Some also support polymorphic functions using the types `anyarray`, `aneyelement`, `anyenum`, and `anynonarray`.

The `internal` pseudo-type is used to declare functions that are meant only to be called internally by the database system, and not by direct invocation in an SQL query. If a function has at least one `internal`-type argument then it cannot be called from SQL. To preserve the type safety of this restriction it is important to follow this coding rule: do not create any function that is declared to return `internal` unless it has at least one `internal` argument.
Chapter 9. Functions and Operators

PostgreSQL provides a large number of functions and operators for the built-in data types. Users can also define their own functions and operators, as described in Part V. The psql commands \df and \do can be used to list all available functions and operators, respectively.

If you are concerned about portability then note that most of the functions and operators described in this chapter, with the exception of the most trivial arithmetic and comparison operators and some explicitly marked functions, are not specified by the SQL standard. Some of this extended functionality is present in other SQL database management systems, and in many cases this functionality is compatible and consistent between the various implementations. This chapter is also not exhaustive; additional functions appear in relevant sections of the manual.

9.1. Logical Operators

The usual logical operators are available:

- AND
- OR
- NOT

SQL uses a three-valued Boolean logic where the null value represents “unknown”. Observe the following truth tables:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th>a AND b</th>
<th>a OR b</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRUE</td>
<td>TRUE</td>
<td>TRUE</td>
<td>TRUE</td>
</tr>
<tr>
<td>TRUE</td>
<td>FALSE</td>
<td>FALSE</td>
<td>TRUE</td>
</tr>
<tr>
<td>TRUE</td>
<td>NULL</td>
<td>NULL</td>
<td>TRUE</td>
</tr>
<tr>
<td>FALSE</td>
<td>FALSE</td>
<td>FALSE</td>
<td>FALSE</td>
</tr>
<tr>
<td>FALSE</td>
<td>NULL</td>
<td>FALSE</td>
<td>NULL</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th></th>
<th></th>
<th>NOT a</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRUE</td>
<td>FALSE</td>
<td></td>
</tr>
<tr>
<td>FALSE</td>
<td>TRUE</td>
<td></td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td></td>
</tr>
</tbody>
</table>

The operators AND and OR are commutative, that is, you can switch the left and right operand without affecting the result. But see Section 4.2.13 for more information about the order of evaluation of subexpressions.

9.2. Comparison Operators

The usual comparison operators are available, shown in Table 9-1.
Table 9-1. Comparison Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;</td>
<td>less than</td>
</tr>
<tr>
<td>&gt;</td>
<td>greater than</td>
</tr>
<tr>
<td>&lt;=</td>
<td>less than or equal to</td>
</tr>
<tr>
<td>&gt;=</td>
<td>greater than or equal to</td>
</tr>
<tr>
<td>=</td>
<td>equal</td>
</tr>
<tr>
<td>&lt;&gt; or !=</td>
<td>not equal</td>
</tr>
</tbody>
</table>

Note: The != operator is converted to <> in the parser stage. It is not possible to implement != and <> operators that do different things.

Comparison operators are available for all relevant data types. All comparison operators are binary operators that return values of type boolean; expressions like 1 < 2 < 3 are not valid (because there is no < operator to compare a Boolean value with 3).

In addition to the comparison operators, the special BETWEEN construct is available:

\[ a \text{ BETWEEN } x \text{ AND } y \]

is equivalent to

\[ a \geq x \text{ AND } a \leq y \]

Notice that BETWEEN treats the endpoint values as included in the range. NOT BETWEEN does the opposite comparison:

\[ a \text{ NOT BETWEEN } x \text{ AND } y \]

is equivalent to

\[ a < x \text{ OR } a > y \]

BETWEEN SYMMETRIC is the same as BETWEEN except there is no requirement that the argument to the left of AND be less than or equal to the argument on the right. If it is not, those two arguments are automatically swapped, so that a nonempty range is always implied.

To check whether a value is or is not null, use the constructs:

\[ \text{expression IS NULL} \]
\[ \text{expression IS NOT NULL} \]

or the equivalent, but nonstandard, constructs:

\[ \text{expression ISNULL} \]
\[ \text{expression NOTNULL} \]

Do not write \[ \text{expression = NULL} \] because NULL is not “equal to” NULL. (The null value represents an unknown value, and it is not known whether two unknown values are equal.) This behavior conforms to the SQL standard.
Chapter 9. Functions and Operators

Tip: Some applications might expect that `expression = NULL` returns true if `expression` evaluates to the null value. It is highly recommended that these applications be modified to comply with the SQL standard. However, if that cannot be done the `transform_null_equals` configuration variable is available. If it is enabled, PostgreSQL will convert `x = NULL` clauses to `x IS NULL`.

Note: If the `expression` is row-valued, then `IS NULL` is true when the row expression itself is null or when all the row's fields are null, while `IS NOT NULL` is true when the row expression itself is non-null and all the row's fields are non-null. Because of this behavior, `IS NULL` and `IS NOT NULL` do not always return inverse results for row-valued expressions, i.e., a row-valued expression that contains both NULL and non-null values will return false for both tests. This definition conforms to the SQL standard, and is a change from the inconsistent behavior exhibited by PostgreSQL versions prior to 8.2.

Ordinary comparison operators yield null (signifying “unknown”), not true or false, when either input is null. For example, `7 = NULL` yields null. When this behavior is not suitable, use the `IS [ NOT ] DISTINCT FROM` constructs:

```
expression IS DISTINCT FROM expression
expression IS NOT DISTINCT FROM expression
```

For non-null inputs, `IS DISTINCT FROM` is the same as the `<>` operator. However, if both inputs are null it returns false, and if only one input is null it returns true. Similarly, `IS NOT DISTINCT FROM` is identical to `=` for non-null inputs, but it returns true when both inputs are null, and false when only one input is null. Thus, these constructs effectively act as though null were a normal data value, rather than “unknown”.

Boolean values can also be tested using the constructs

```
expression IS TRUE
expression IS NOT TRUE
expression IS FALSE
expression IS NOT FALSE
expression IS UNKNOWN
expression IS NOT UNKNOWN
```

These will always return true or false, never a null value, even when the operand is null. A null input is treated as the logical value “unknown”. Notice that `IS UNKNOWN` and `IS NOT UNKNOWN` are effectively the same as `IS NULL` and `IS NOT NULL`, respectively, except that the input expression must be of Boolean type.

9.3. Mathematical Functions and Operators

Mathematical operators are provided for many PostgreSQL types. For types without standard mathematical conventions (e.g., date/time types) we describe the actual behavior in subsequent sections.

Table 9-2 shows the available mathematical operators.

Table 9-2. Mathematical Operators

### 9.4. String Functions and Operators

This section describes functions and operators for examining and manipulating string values. Strings in this context include values of the types `character`, `character varying`, and `text`. Unless otherwise noted, all of the functions listed below work on all of these types, but be wary of potential effects of automatic space-padding when using the `character` type. Some functions also exist natively for the bit-string types.

SQL defines some string functions that use key words, rather than commas, to separate arguments. Details are in Table 9-5. PostgreSQL also provides versions of these functions that use the regular function invocation syntax (see Table 9-6).
Chapter 9. Functions and Operators

Note: Before PostgreSQL 8.3, these functions would silently accept values of several non-string data types as well, due to the presence of implicit coercions from those data types to text. Those coercions have been removed because they frequently caused surprising behaviors. However, the string concatenation operator (||) still accepts non-string input, so long as at least one input is of a string type, as shown in Table 9-5. For other cases, insert an explicit coercion to text if you need to duplicate the previous behavior.

Table 9-5. SQL String Functions and Operators

<td>text</td>
<td>Extract substring matching POSIX regular expression. See Section 9.7 for more information on pattern matching.</td>
<td>substring('Thomas from ‘...$’)</td>
<td></td>
</tr>
</tbody>
</table>
### Chapter 9. Functions and Operators

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>substring(string from pattern for escape)</td>
<td>text</td>
<td>Extract substring matching SQL regular expression. See Section 9.7 for more information on pattern matching.</td>
<td>substring('Thomas' from '%#o_a#_%' for '#')</td>
<td>oma</td>
</tr>
<tr>
<td>trim([leading</td>
<td>trailing</td>
<td>both] [characters] from string)</td>
<td>text</td>
<td>Remove the longest string containing only the characters (a space by default) from the start/end/both ends of the string</td>
</tr>
<tr>
<td>upper(string)</td>
<td>text</td>
<td>Convert string to uppercase</td>
<td>upper('tom')</td>
<td>TOM</td>
</tr>
</tbody>
</table>

Additional string manipulation functions are available and are listed in Table 9-6. Some of them are used internally to implement the SQL-standard string functions listed in Table 9-5.

### Table 9-6. Other String Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>ascii(string)</td>
<td>int</td>
<td>ASCII code of the first character of the argument. For UTF8 returns the Unicode code point of the character. For other multibyte encodings, the argument must be an ASCII character.</td>
<td>ascii('x')</td>
<td>120</td>
</tr>
<tr>
<td>btrim(string text [, characters text])</td>
<td>text</td>
<td>Remove the longest string consisting only of characters in characters (a space by default) from the start and end of string</td>
<td>btrim('xyxtrimxy')</td>
<td>yxtrim</td>
</tr>
</tbody>
</table>

<td>EUC_JIS_2004</td>
<td>SHIFT_JIS_2004</td>
</tr>
<tr>
<td>shift_jis_2004_to_euc_jis</td>
<td>EUC_JIS_2004</td>
<td>EUC_JIS_2004</td>
</tr>
</tbody>
</table>

**Notes:**

a. The conversion names follow a standard naming scheme: The official name of the source encoding with all non-alphanumeric characters replaced by underscores, followed by `to_`, followed by the similarly processed destination encoding name. Therefore, the names might deviate from the customary encoding names.

---

### 9.5. Binary String Functions and Operators

This section describes functions and operators for examining and manipulating values of type `bytea`.

SQL defines some string functions that use key words, rather than commas, to separate arguments. Details are in Table 9-8. PostgreSQL also provides versions of these functions that use the regular function invocation syntax (see Table 9-9).
### Table 9-8. SQL Binary String Functions and Operators

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>

<td>string</td>
<td>bytea</td>
<td>String concatenation</td>
</tr>
<tr>
<td>get_bit(string, offset)</td>
<td>int</td>
<td>Extract bit from string</td>
<td>get_bit(E'Thomas'::bytea, 45)</td>
<td></td>
</tr>
<tr>
<td>get_byte(string, offset)</td>
<td>int</td>
<td>Extract byte from string</td>
<td>get_byte(E'Thomas'::bytea, 4)</td>
<td></td>
</tr>
<tr>
<td>octet_length(string)</td>
<td>int</td>
<td>Number of bytes in binary string</td>
<td>octet_length(E'Jo\000se'::bytea)</td>
<td></td>
</tr>
<tr>
<td>position(substring in string)</td>
<td>int</td>
<td>Location of specified substring</td>
<td>position(E'\000om'::bytea in E'Thomas'::bytea)</td>
<td></td>
</tr>
<tr>
<td>set_bit(string, offset, newvalue)</td>
<td>bytea</td>
<td>Set bit in string</td>
<td>set_bit(E'Thomas'::bytea, 45, 0)</td>
<td></td>
</tr>
<tr>
<td>set_byte(string, offset, newvalue)</td>
<td>bytea</td>
<td>Set byte in string</td>
<td>set_byte(E'Thomas'::bytea, 4, 64)</td>
<td></td>
</tr>
<tr>
<td>substring(string [from int] [for int])</td>
<td>bytea</td>
<td>Extract substring</td>
<td>substring(E'Thomas'::bytea from 2 for 3)</td>
<td></td>
</tr>
<tr>
<td>trim([both] bytes from string)</td>
<td>bytea</td>
<td>Remove the longest string containing only the bytes in bytes from the start and end of string</td>
<td>trim(E'\0000Tom\0000'::bytea)</td>
<td></td>
</tr>
</tbody>
</table>

Additional binary string manipulation functions are available and are listed in Table 9-9. Some of them are used internally to implement the SQL-standard string functions listed in Table 9-8.

### Table 9-9. Other Binary String Functions

<table>

</tr>
</tbody>
</table>

#### 9.6. Bit String Functions and Operators

This section describes functions and operators for examining and manipulating bit strings, that is values of the types `bit` and `bit varying`. Aside from the usual comparison operators, the operators shown in Table 9-10 can be used. Bit string operands of `&`, `|`, and `#` must be of equal length. When bit shifting, the original length of the string is preserved, as shown in the examples.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>`</td>
<td></td>
<td>`</td>
<td>concatenation</td>
</tr>
<tr>
<td><code>&amp;</code></td>
<td>bitwise AND</td>
<td><code>B'10001' &amp; B'01101'</code></td>
<td><code>00001</code></td>
</tr>
<tr>
<td>`</td>
<td>`</td>
<td>bitwise OR</td>
<td>`B'10001'</td>
</tr>
<tr>
<td><code>#</code></td>
<td>bitwise XOR</td>
<td><code>B'10001' # B'01101'</code></td>
<td><code>11100</code></td>
</tr>
</tbody>
</table>
### Chapter 9. Functions and Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>~</td>
<td>bitwise NOT</td>
<td>~ B'10001'</td>
<td>01110</td>
</tr>
<tr>
<td>&lt;&lt;</td>
<td>bitwise shift left</td>
<td>B'10001' &lt;&lt; 3</td>
<td>01000</td>
</tr>
<tr>
<td>&gt;&gt;</td>
<td>bitwise shift right</td>
<td>B'10001' &gt;&gt; 2</td>
<td>00100</td>
</tr>
</tbody>
</table>

The following SQL-standard functions work on bit strings as well as character strings: `length`, `bit_length`, `octet_length`, `position`, `substring`.

In addition, it is possible to cast integral values to and from type `bit`. Some examples:

- `44::bit(10)`
- `44::bit(3)`
- `cast(-44 as bit(12))`
- `'1110'::bit(4)::integer`

Note that casting to just “bit” means casting to `bit(1)`, and so will deliver only the least significant bit of the integer.

Note: Prior to PostgreSQL 8.0, casting an integer to `bit(n)` would copy the leftmost `n` bits of the integer, whereas now it copies the rightmost `n` bits. Also, casting an integer to a bit string width wider than the integer itself will sign-extend on the left.

### 9.7. Pattern Matching

There are three separate approaches to pattern matching provided by PostgreSQL: the traditional SQL `LIKE` operator, the more recent `SIMILAR TO` operator (added in SQL:1999), and POSIX-style regular expressions. Aside from the basic “does this string match this pattern?” operators, functions are available to extract or replace matching substrings and to split a string at matching locations.

**Tip:** If you have pattern matching needs that go beyond this, consider writing a user-defined function in Perl or Tcl.

#### 9.7.1. LIKE

```
string LIKE pattern [ESCAPE escape-character]
string NOT LIKE pattern [ESCAPE escape-character]
```

The `LIKE` expression returns true if the `string` matches the supplied `pattern`. (As expected, the `NOT LIKE` expression returns false if `LIKE` returns true, and vice versa. An equivalent expression is `NOT (string LIKE pattern).`)

If `pattern` does not contain percent signs or underscores, then the pattern only represents the string itself; in that case `LIKE` acts like the equals operator. An underscore (_) in `pattern` stands for (matches) any single character; a percent sign (%) matches any sequence of zero or more characters.

Some examples:

- `'abc' LIKE 'abc'`  true
- `'abc' LIKE 'a%'`  true
LIKE pattern matching always covers the entire string. Therefore, to match a sequence anywhere within a string, the pattern must start and end with a percent sign.

To match a literal underscore or percent sign without matching other characters, the respective character in pattern must be preceded by the escape character. The default escape character is the backslash but a different one can be selected by using the ESCAPE clause. To match the escape character itself, write two escape characters.

Note that the backslash already has a special meaning in string literals, so to write a pattern constant that contains a backslash you must write two backslashes in an SQL statement (assuming escape string syntax is used, see Section 4.1.2.1). Thus, writing a pattern that actually matches a literal backslash means writing four backslashes in the statement. You can avoid this by selecting a different escape character with ESCAPE; then a backslash is not special to LIKE anymore. (But backslash is still special to the string literal parser, so you still need two of them to match a backslash.)

It’s also possible to select no escape character by writing ESCAPE "". This effectively disables the escape mechanism, which makes it impossible to turn off the special meaning of underscore and percent signs in the pattern.

The key word ILIKE can be used instead of LIKE to make the match case-insensitive according to the active locale. This is not in the SQL standard but is a PostgreSQL extension.

The operator ~~ is equivalent to LIKE, and ~~* corresponds to ILIKE. There are also !~~ and !~~* operators that represent NOT LIKE and NOT ILIKE, respectively. All of these operators are PostgreSQL-specific.

**9.7.2. SIMILAR TO Regular Expressions**

\[ \text{string SIMILAR TO pattern[ESCAPE escape-character]} \]
\[ \text{string NOT SIMILAR TO pattern[ESCAPE escape-character]} \]

The SIMILAR TO operator returns true or false depending on whether its pattern matches the given string. It is similar to LIKE, except that it interprets the pattern using the SQL standard’s definition of a regular expression. SQL regular expressions are a curious cross between LIKE notation and common regular expression notation.

Like LIKE, the SIMILAR TO operator succeeds only if its pattern matches the entire string; this is unlike common regular expression behavior where the pattern can match any part of the string. Also like LIKE, SIMILAR TO uses _ and % as wildcard characters denoting any single character and any string, respectively (these are comparable to . and .* in POSIX regular expressions).

In addition to these facilities borrowed from LIKE, SIMILAR TO supports these pattern-matching metacharacters borrowed from POSIX regular expressions:

- | denotes alternation (either of two alternatives).
- * denotes repetition of the previous item zero or more times.
- + denotes repetition of the previous item one or more times.
- Parentheses () can be used to group items into a single logical item.
- A bracket expression [ . . . ] specifies a character class, just as in POSIX regular expressions.
Notice that bounded repetition operators (?) and {...}) are not provided, though they exist in POSIX. Also, the period (.) is not a metacharacter.

As with `LIKE`, a backslash disables the special meaning of any of these metacharacters; or a different escape character can be specified with `ESCAPE`.

Some examples:

```
'abc' SIMILAR TO 'abc'   true
'abc' SIMILAR TO 'a'     false
'abc' SIMILAR TO 'b(d)'  true
'abc' SIMILAR TO 'b(c)'  false
```

The `substring` function with three parameters, `substring(string from pattern for escape-character)`, provides extraction of a substring that matches an SQL regular expression pattern. As with `SIMILAR TO`, the specified pattern must match the entire data string, or else the function fails and returns null. To indicate the part of the pattern that should be returned on success, the pattern must contain two occurrences of the escape character followed by a double quote ("). The text matching the portion of the pattern between these markers is returned.

Some examples, with "*" delimiting the return string:

```
substring('foobar' from '%"o_b"%' for '#')   oob
substring('foobar' from '#"o_b"%' for '#')   NULL
```

### 9.7.3. POSIX Regular Expressions

Table 9-11 lists the available operators for pattern matching using POSIX regular expressions.

#### Table 9-11. Regular Expression Match Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>~</td>
<td>Matches regular expression, case sensitive</td>
<td>'thomas' ~ '.<em>thomas.</em>'</td>
</tr>
<tr>
<td>~*</td>
<td>Matches regular expression, case insensitive</td>
<td>'thomas' ~* '.<em>Thomas.</em>'</td>
</tr>
<tr>
<td>!~</td>
<td>Does not match regular expression, case sensitive</td>
<td>'thomas' !~ '.<em>Thomas.</em>'</td>
</tr>
<tr>
<td>!~*</td>
<td>Does not match regular expression, case insensitive</td>
<td>'thomas' !~* '.<em>vadim.</em>'</td>
</tr>
</tbody>
</table>

POSIX regular expressions provide a more powerful means for pattern matching than the `LIKE` and `SIMILAR TO` operators. Many Unix tools such as `grep`, `sed`, or `awk` use a pattern matching language that is similar to the one described here.

A regular expression is a character sequence that is an abbreviated definition of a set of strings (a regular set). A string is said to match a regular expression if it is a member of the regular set described by the regular expression. As with `LIKE`, pattern characters match string characters exactly unless they are special characters in the regular expression language — but regular expressions use different special characters than `LIKE` does. Unlike `LIKE` patterns, a regular expression is allowed to match anywhere within a string, unless the regular expression is explicitly anchored to the beginning or end.
of the string.

Some examples:

\lit{abc’} ~ \lit{abc’} \quad \text{true}
\lit{abc’} ~ \lit{’}a\lit{’} \quad \text{true}
\lit{abc’} ~ \lit{(}b\lit{|}d\lit{)}’ \quad \text{true}
\lit{abc’} ~ \lit{’}^\lit{(}b\lit{|}c\lit{)}\lit{’} \quad \text{false}

The POSIX pattern language is described in much greater detail below.

The \texttt{substring} function with two parameters, \texttt{substring(string from pattern)}, provides extraction of a substring that matches a POSIX regular expression pattern. It returns null if there is no match, otherwise the portion of the text that matched the pattern. But if the pattern contains any parentheses, the portion of the text that matched the first parenthesized subexpression (the one whose left parenthesis comes first) is returned. You can put parentheses around the whole expression if you want to use parentheses within it without triggering this exception. If you need parentheses in the pattern before the subexpression you want to extract, see the non-capturing parentheses described below.

Some examples:

\begin{verbatim}
substring('foobar' from 'o.b') \quad oob
substring('foobar' from 'o(.)b') \quad o
\end{verbatim}

The \texttt{regexp_replace} function provides substitution of new text for substrings that match POSIX regular expression patterns. It has the syntax \texttt{regexp_replace(source, pattern, replacement [, flags ])}). The \texttt{source} string is returned unchanged if there is no match to the \texttt{pattern}. If there is a match, the \texttt{source} string is returned with the \texttt{replacement} string substituted for the matching substring. The \texttt{replacement} string can contain \texttt{\textbackslash n}, where \texttt{n} is 1 through 9, to indicate that the source substring matching the \texttt{n}'th parenthesized subexpression of the pattern should be inserted, and it can contain \texttt{\textbackslash a} to indicate that the substring matching the entire pattern should be inserted. Write \texttt{\textbackslash \textbackslash} if you need to put a literal backslash in the replacement text. (As always, remember to double backslashes written in literal constant strings, assuming escape string syntax is used.) The \texttt{flags} parameter is an optional text string containing zero or more single-letter flags that change the function’s behavior. Flag \texttt{i} specifies case-insensitive matching, while flag \texttt{g} specifies replacement of each matching substring rather than only the first one. Other supported flags are described in Table 9-19.

Some examples:

\begin{verbatim}
regexp_replace('foobazbar', 'b..', 'X') \quad foobXbar
regexp_replace('foobazbar', 'b..', 'X', 'g') \quad foobXX
regexp_replace('foobazbar', 'b(..)', E'X\textbackslash\textbackslashY', 'g') \quad foobXarYXazY
\end{verbatim}

The \texttt{regexp_matches} function returns all of the captured substrings resulting from matching a POSIX regular expression pattern. It has the syntax \texttt{regexp_matches(string, pattern [, flags ]). If there is no match to the pattern, the function returns no rows. If there is a match, the function returns a text array whose \texttt{n}'th element is the substring matching the \texttt{n}'th parenthesized subexpression of the pattern (not counting “non-capturing” parentheses; see below for details). If the pattern does not contain any parenthesized subexpressions, then the result is a single-element text array containing
the substring matching the whole pattern. The flags parameter is an optional text string containing zero or more single-letter flags that change the function’s behavior. Flag g causes the function to find each match in the string, not only the first one, and return a row for each such match. Other supported flags are described in Table 9-19.

Some examples:

```sql
SELECT regexp_matches('foobarbequebaz', '(bar)(beque)');
+------------------+
| {bar,beque}      |
+------------------+
(1 row)

SELECT regexp_matches('foobarbequebazilbarfbonk', '(b[^b]+)(b[^b]+)', 'g');
+------------------+
| {bar,beque}      |
| {bazil,barf}     |
+------------------+
(2 rows)

SELECT regexp_matches('foobarbequebaz', 'barbeque');
+------------------+
| {barbeque}       |
+------------------+
(1 row)
```

The `regexp_split_to_table` function splits a string using a POSIX regular expression pattern as a delimiter. It has the syntax `regexp_split_to_table(string, pattern [, flags ])`. If there is no match to the pattern, the function returns the string. If there is at least one match, for each match it returns the text from the end of the last match (or the beginning of the string) to the beginning of the match. When there are no more matches, it returns the text from the end of the last match to the end of the string. The flags parameter is an optional text string containing zero or more single-letter flags that change the function’s behavior. `regexp_split_to_table` supports the flags described in Table 9-19.

The `regexp_split_to_array` function behaves the same as `regexp_split_to_table`, except that `regexp_split_to_array` returns its result as an array of text. It has the syntax `regexp_split_to_array(string, pattern [, flags ])`. The parameters are the same as for `regexp_split_to_table`.

Some examples:

```sql
SELECT foo FROM regexp_split_to_table('the quick brown fox jumped over the lazy dog', E'\s+');
   foo
--------
   the
   quick
   brown
   fox
   jumped
   over
   the
   lazy
   dog
(9 rows)
```
As the last example demonstrates, the regexp split functions ignore zero-length matches that occur at the start or end of the string or immediately after a previous match. This is contrary to the strict definition of regexp matching that is implemented by \texttt{regexp\_matches}, but is usually the most convenient behavior in practice. Other software systems such as Perl use similar definitions.

### 9.7.3.1. Regular Expression Details

PostgreSQL’s regular expressions are implemented using a software package written by Henry Spencer. Much of the description of regular expressions below is copied verbatim from his manual.

Regular expressions (REs), as defined in POSIX 1003.2, come in two forms: extended REs or EREs (roughly those of \texttt{egrep}), and basic REs or BREs (roughly those of \texttt{ed}). PostgreSQL supports both forms, and also implements some extensions that are not in the POSIX standard, but have become widely used due to their availability in programming languages such as Perl and Tcl. REs using these non-POSIX extensions are called advanced REs or AREs in this documentation. AREs are almost an exact superset of EREs, but BREs have several notational incompatibilities (as well as being much more limited). We first describe the ARE and ERE forms, noting features that apply only to AREs, and then describe how BREs differ.

\textbf{Note:} The form of regular expressions accepted by PostgreSQL can be chosen by setting the \texttt{regex\_flavor} run-time parameter. The usual setting is advanced, but one might choose extended for backwards compatibility with pre-7.4 releases of PostgreSQL.

A regular expression is defined as one or more \textit{branches}, separated by |. It matches anything that matches one of the branches.
A branch is zero or more quantified atoms or constraints, concatenated. It matches a match for the first, followed by a match for the second, etc; an empty branch matches the empty string.

A quantified atom is an atom possibly followed by a single quantifier. Without a quantifier, it matches a match for the atom. With a quantifier, it can match some number of matches of the atom. An atom can be any of the possibilities shown in Table 9-12. The possible quantifiers and their meanings are shown in Table 9-13.

A constraint matches an empty string, but matches only when specific conditions are met. A constraint can be used where an atom could be used, except it cannot be followed by a quantifier. The simple constraints are shown in Table 9-14; some more constraints are described later.

### Table 9-12. Regular Expression Atoms

<table>
<thead>
<tr>
<th>Atom</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(re)</td>
<td>(where re is any regular expression) matches a match for re, with the match noted for possible reporting</td>
</tr>
<tr>
<td>(?:re)</td>
<td>as above, but the match is not noted for reporting (a “non-capturing” set of parentheses) (AREs only)</td>
</tr>
<tr>
<td>.</td>
<td>matches any single character</td>
</tr>
<tr>
<td>[chars]</td>
<td>a bracket expression, matching any one of the chars (see Section 9.7.3.2 for more detail)</td>
</tr>
<tr>
<td>\k</td>
<td>(where k is a non-alphanumeric character) matches that character taken as an ordinary character, e.g., \ matches a backslash character</td>
</tr>
<tr>
<td>\c</td>
<td>where c is alphanumeric (possibly followed by other characters) is an escape, see Section 9.7.3.3 (AREs only; in EREs and BREs, this matches c)</td>
</tr>
<tr>
<td>{</td>
<td>when followed by a character other than a digit, matches the left-brace character ; when followed by a digit, it is the beginning of a bound (see below)</td>
</tr>
<tr>
<td>x</td>
<td>where x is a single character with no other significance, matches that character</td>
</tr>
</tbody>
</table>

An RE cannot end with \\.

**Note:** Remember that the backslash (\) already has a special meaning in PostgreSQL string literals. To write a pattern constant that contains a backslash, you must write two backslashes in the statement, assuming escape string syntax is used (see Section 4.1.2.1).

### Table 9-13. Regular Expression Quantifiers

<table>
<thead>
<tr>
<th>Quantifier</th>
<th>Matches</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>a sequence of 0 or more matches of the atom</td>
</tr>
</tbody>
</table>
Chapter 9. Functions and Operators

<table>
<thead>
<tr>
<th>Quantifier</th>
<th>Matches</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>a sequence of 1 or more matches of the atom</td>
</tr>
<tr>
<td>?</td>
<td>a sequence of 0 or 1 matches of the atom</td>
</tr>
<tr>
<td>{m}</td>
<td>a sequence of exactly m matches of the atom</td>
</tr>
<tr>
<td>{m,}</td>
<td>a sequence of m or more matches of the atom</td>
</tr>
<tr>
<td>{m, n}</td>
<td>a sequence of m through n (inclusive) matches of the atom; m cannot exceed n</td>
</tr>
<tr>
<td>*?</td>
<td>non-greedy version of *</td>
</tr>
<tr>
<td>+?</td>
<td>non-greedy version of +</td>
</tr>
<tr>
<td>??</td>
<td>non-greedy version of ?</td>
</tr>
<tr>
<td>{m}??</td>
<td>non-greedy version of {m}</td>
</tr>
<tr>
<td>{m,}??</td>
<td>non-greedy version of {m,}</td>
</tr>
<tr>
<td>{m, n}??</td>
<td>non-greedy version of {m, n}</td>
</tr>
</tbody>
</table>

The forms using {...} are known as *bounds*. The numbers m and n within a bound are unsigned decimal integers with permissible values from 0 to 255 inclusive.

*Non-greedy* quantifiers (available in AREs only) match the same possibilities as their corresponding normal (greedy) counterparts, but prefer the smallest number rather than the largest number of matches. See Section 9.7.3.5 for more detail.

**Note:** A quantifier cannot immediately follow another quantifier, e.g., * * is invalid. A quantifier cannot begin an expression or subexpression or follow ^ or |.

<table>
<thead>
<tr>
<th>Table 9-14. Regular Expression Constraints</th>
</tr>
</thead>
<tbody>
<tr>
<td>Constraint</td>
</tr>
<tr>
<td>^</td>
</tr>
<tr>
<td>$</td>
</tr>
<tr>
<td>(?=re)</td>
</tr>
<tr>
<td>(?!re)</td>
</tr>
</tbody>
</table>

Lookahead constraints cannot contain *back references* (see Section 9.7.3.3), and all parentheses within them are considered non-capturing.

### 9.7.3.2. Bracket Expressions

A *bracket expression* is a list of characters enclosed in [ ]. It normally matches any single character from the list (but see below). If the list begins with ^, it matches any single character not from the rest of the list. If two characters in the list are separated by -, this is shorthand for the full range of characters between those two (inclusive) in the collating sequence, e.g., [0-9] in ASCII matches any decimal digit. It is illegal for two ranges to share an endpoint, e.g., a-c-e. Ranges are very collating-sequence-dependent, so portable programs should avoid relying on them.

To include a literal ] in the list, make it the first character (after ^, if that is used). To include a literal -, make it the first or last character, or the second endpoint of a range. To use a literal - as
the first endpoint of a range, enclose it in [. and .] to make it a collating element (see below). With the exception of these characters, some combinations using [ (see next paragraphs), and escapes (AREs only), all other special characters lose their special significance within a bracket expression. In particular, \ is not special when following ERE or BRE rules, though it is special (as introducing an escape) in AREs.

Within a bracket expression, a collating element (a character, a multiple-character sequence that collates as if it were a single character, or a collating-sequence name for either) enclosed in [. and .] stands for the sequence of characters of that collating element. The sequence is treated as a single element of the bracket expression’s list. This allows a bracket expression containing a multiple-character collating element to match more than one character, e.g., if the collating sequence includes a ch collating element, then the RE [[.ch.]]*c matches the first five characters of chchcc.

Note: PostgreSQL currently does not support multi-character collating elements. This information describes possible future behavior.

Within a bracket expression, a collating element enclosed in [ and ] is an equivalence class, standing for the sequences of characters of all collating elements equivalent to that one, including itself. (If there are no other equivalent collating elements, the treatment is as if the enclosing delimiters were [. and .].) For example, if o and ^ are the members of an equivalence class, then [[:o=]], [[:^=]], and [o^*] are all synonymous. An equivalence class cannot be an endpoint of a range.

Within a bracket expression, the name of a character class enclosed in [: and :] stands for the list of all characters belonging to that class. Standard character class names are: alnum, alpha, blank, cntrl, digit, graph, lower, print, punct, space, upper,xdigit. These stand for the character classes defined in ctype. A locale can provide others. A character class cannot be used as an endpoint of a range.

There are two special cases of bracket expressions: the bracket expressions [:<:] and [:>:] are constraints, matching empty strings at the beginning and end of a word respectively. A word is defined as a sequence of word characters that is neither preceded nor followed by word characters. A word character is an alnum character (as defined by ctype) or an underscore. This is an extension, compatible with but not specified by POSIX 1003.2, and should be used with caution in software intended to be portable to other systems. The constraint escapes described below are usually preferable; they are no more standard, but are easier to type.

9.7.3.3. Regular Expression Escapes

Escapes are special sequences beginning with \ followed by an alphanumeric character. Escapes come in several varieties: character entry, class shorthands, constraint escapes, and back references. A \ followed by an alphanumeric character but not constituting a valid escape is illegal in AREs. In EREs, there are no escapes: outside a bracket expression, a \ followed by an alphanumeric character merely stands for that character as an ordinary character, and inside a bracket expression, \ is an ordinary character. (The latter is the one actual incompatibility between EREs and AREs.)

Character-entry escapes exist to make it easier to specify non-printing and other inconvenient characters in REs. They are shown in Table 9-15.

Class-shorthand escapes provide shorthands for certain commonly-used character classes. They are shown in Table 9-16.

A constraint escape is a constraint, matching the empty string if specific conditions are met, written as an escape. They are shown in Table 9-17.
A back reference (\n) matches the same string matched by the previous parenthesized subexpression specified by the number n (see Table 9-18). For example, ([bc])\1 matches bb or cc but not bc or cb. The subexpression must entirely precede the back reference in the RE. Subexpressions are numbered in the order of their leading parentheses. Non-capturing parentheses do not define subexpressions.

**Note:** Keep in mind that an escape’s leading \ will need to be doubled when entering the pattern as an SQL string constant. For example:

'123' ~ E'^\d{3}' true

### Table 9-15. Regular Expression Character-Entry Escapes

<table>
<thead>
<tr>
<th>Escape</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\a</td>
<td>alert (bell) character, as in C</td>
</tr>
<tr>
<td>\b</td>
<td>backspace, as in C</td>
</tr>
<tr>
<td>\B</td>
<td>synonym for backslash () to help reduce the need for backslash doubling</td>
</tr>
<tr>
<td>\cX</td>
<td>(where X is any character) the character whose low-order 5 bits are the same as those of X, and whose other bits are all zero</td>
</tr>
<tr>
<td>\e</td>
<td>the character whose collating-sequence name is ESC, or failing that, the character with octal value 033</td>
</tr>
<tr>
<td>\f</td>
<td>form feed, as in C</td>
</tr>
<tr>
<td>\n</td>
<td>newline, as in C</td>
</tr>
<tr>
<td>\r</td>
<td>carriage return, as in C</td>
</tr>
<tr>
<td>\t</td>
<td>horizontal tab, as in C</td>
</tr>
<tr>
<td>\uwxxyz</td>
<td>(where wxyz is exactly four hexadecimal digits) the UTF16 (Unicode, 16-bit) character U+wxyz in the local byte ordering</td>
</tr>
<tr>
<td>\Ustuvwxyz</td>
<td>(where stuvwxyz is exactly eight hexadecimal digits) reserved for a hypothetical Unicode extension to 32 bits</td>
</tr>
<tr>
<td>\v</td>
<td>vertical tab, as in C</td>
</tr>
<tr>
<td>\xhxxx</td>
<td>(where hhhh is any sequence of hexadecimal digits) the character whose hexadecimal value is 0xhxxx (a single character no matter how many hexadecimal digits are used)</td>
</tr>
<tr>
<td>\0</td>
<td>the character whose value is 0 (the null byte)</td>
</tr>
<tr>
<td>\xy</td>
<td>(where xy is exactly two octal digits, and is not a back reference) the character whose octal value is 0xy</td>
</tr>
</tbody>
</table>
Chapter 9. Functions and Operators

**Escape** | **Description**
--- | ---
\( \text{	exttt{xyz}} \) | (where \( \text{xyz} \) is exactly three octal digits, and is not a back reference) the character whose octal value is \( 0\text{xyz} \)

Hexadecimal digits are 0-9, a-f, and A-F. Octal digits are 0-7.

The character-entry escapes are always taken as ordinary characters. For example, \( \text{	exttt{\textbackslash 135}} \) is ] in ASCII, but \( \text{	exttt{\textbackslash 135}} \) does not terminate a bracket expression.

### Table 9-16. Regular Expression Class-Shorthand Escapes

<table>
<thead>
<tr>
<th>Escape</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{	exttt{\textbackslash d}} )</td>
<td>[[[:digit:]]]</td>
</tr>
<tr>
<td>( \text{	exttt{\textbackslash s}} )</td>
<td>[[[:space:]]]</td>
</tr>
<tr>
<td>( \text{	exttt{\textbackslash w}} )</td>
<td>[[[:alnum:]]_] (note underscore is included)</td>
</tr>
<tr>
<td>( \text{	exttt{\textbackslash D}} )</td>
<td>^[[:digit:]]]</td>
</tr>
<tr>
<td>( \text{	exttt{\textbackslash S}} )</td>
<td>^[[:space:]]]</td>
</tr>
<tr>
<td>( \text{	exttt{\textbackslash W}} )</td>
<td>^[[:alnum:]]_] (note underscore is included)</td>
</tr>
</tbody>
</table>

Within bracket expressions, \( \text{	exttt{\textbackslash d}}, \text{	exttt{\textbackslash s}}, \text{ and } \text{	exttt{\textbackslash w}} \) lose their outer brackets, and \( \text{	exttt{\textbackslash d}}, \text{	exttt{\textbackslash s}}, \text{ and } \text{	exttt{\textbackslash w}} \) are illegal. (So, for example, \( \text{	exttt{[a-c\textbackslash d]}} \) is equivalent to \( \text{	exttt{[a-c[:digit:]]}} \). Also, \( \text{	exttt{[a-c\textbackslash D]}} \), which is equivalent to \( \text{	exttt{[a-c^[[:digit:]]]}} \), is illegal.)

### Table 9-17. Regular Expression Constraint Escapes

<table>
<thead>
<tr>
<th>Escape</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{	exttt{\textbackslash A}} )</td>
<td>matches only at the beginning of the string (see Section 9.7.3.5 for how this differs from ( ^{} ))</td>
</tr>
<tr>
<td>( \text{	exttt{\textbackslash m}} )</td>
<td>matches only at the beginning of a word</td>
</tr>
<tr>
<td>( \text{	exttt{\textbackslash M}} )</td>
<td>matches only at the end of a word</td>
</tr>
<tr>
<td>( \text{	exttt{\textbackslash y}} )</td>
<td>matches only at the beginning or end of a word</td>
</tr>
<tr>
<td>( \text{	exttt{\textbackslash Y}} )</td>
<td>matches only at a point that is not the beginning or end of a word</td>
</tr>
<tr>
<td>( \text{	exttt{\textbackslash Z}} )</td>
<td>matches only at the end of the string (see Section 9.7.3.5 for how this differs from ( $ ))</td>
</tr>
</tbody>
</table>

A word is defined as in the specification of \( [[<:]] \) and \( [[>:]] \) above. Constraint escapes are illegal within bracket expressions.

### Table 9-18. Regular Expression Back References

<table>
<thead>
<tr>
<th>Escape</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{	exttt{\textbackslash m}} )</td>
<td>(where ( m ) is a nonzero digit) a back reference to the ( m )’th subexpression</td>
</tr>
</tbody>
</table>
### Chapter 9. Functions and Operators

#### 9.7. Functions and Operators

<table>
<thead>
<tr>
<th>Escape</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\mnn</td>
<td>(where ( m ) is a nonzero digit, and ( nn ) is some more digits, and the decimal value ( mnn ) is not greater than the number of closing capturing parentheses seen so far) a back reference to the ( mnn )th subexpression</td>
</tr>
</tbody>
</table>

**Note:** There is an inherent ambiguity between octal character-entry escapes and back references, which is resolved by the following heuristics, as hinted at above. A leading zero always indicates an octal escape. A single non-zero digit, not followed by another digit, is always taken as a back reference. A multi-digit sequence not starting with a zero is taken as a back reference if it comes after a suitable subexpression (i.e., the number is in the legal range for a back reference), and otherwise is taken as octal.

#### 9.7.3.4. Regular Expression Metasyntax

In addition to the main syntax described above, there are some special forms and miscellaneous syntactic facilities available.

Normally the flavor of RE being used is determined by `regex_flavor`. However, this can be overridden by a `director` prefix. If an RE begins with `***`, the rest of the RE is taken as an ARE regardless of `regex_flavor`. If an RE begins with `***=`, the rest of the RE is taken to be a literal string, with all characters considered ordinary characters.

An ARE can begin with *embedded options*: a sequence `(?!xyz)` (where `xyz` is one or more alphabetic characters) specifies options affecting the rest of the RE. These options override any previously determined options (including both the RE flavor and case sensitivity). The available option letters are shown in Table 9-19.

**Table 9-19. ARE Embedded-Option Letters**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>b</td>
<td>rest of RE is a BRE</td>
</tr>
<tr>
<td>c</td>
<td>case-sensitive matching (overrides operator type)</td>
</tr>
<tr>
<td>e</td>
<td>rest of RE is an ERE</td>
</tr>
<tr>
<td>i</td>
<td>case-insensitive matching (see Section 9.7.3.5) (overrides operator type)</td>
</tr>
<tr>
<td>m</td>
<td>historical synonym for ( n )</td>
</tr>
<tr>
<td>n</td>
<td>newline-sensitive matching (see Section 9.7.3.5)</td>
</tr>
<tr>
<td>p</td>
<td>partial newline-sensitive matching (see Section 9.7.3.5)</td>
</tr>
<tr>
<td>q</td>
<td>rest of RE is a literal (“quoted”) string, all ordinary characters</td>
</tr>
<tr>
<td>s</td>
<td>non-newline-sensitive matching (default)</td>
</tr>
<tr>
<td>t</td>
<td>tight syntax (default; see below)</td>
</tr>
</tbody>
</table>
Chapter 9. Functions and Operators

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>w</td>
<td>inverse partial newline-sensitive (&quot;weird&quot;) matching (see Section 9.7.3.5)</td>
</tr>
<tr>
<td>x</td>
<td>expanded syntax (see below)</td>
</tr>
</tbody>
</table>

Embedded options take effect at the ) terminating the sequence. They can appear only at the start of an ARE (after the ***: director if any).

In addition to the usual (tight) RE syntax, in which all characters are significant, there is an expanded syntax, available by specifying the embedded x option. In the expanded syntax, white-space characters in the RE are ignored, as are all characters between a # and the following newline (or the end of the RE). This permits paragraphing and commenting a complex RE. There are three exceptions to that basic rule:

- a white-space character or # preceded by \ is retained
- white space or # within a bracket expression is retained
- white space and comments cannot appear within multi-character symbols, such as (?:

For this purpose, white-space characters are blank, tab, newline, and any character that belongs to the space character class.

Finally, in an ARE, outside bracket expressions, the sequence (?#ttt) (where ttt is any text not containing a ) is a comment, completely ignored. Again, this is not allowed between the characters of multi-character symbols, like (?:. Such comments are more a historical artifact than a useful facility, and their use is deprecated; use the expanded syntax instead.

None of these metasyntax extensions is available if an initial ***= director has specified that the user’s input be treated as a literal string rather than as an RE.

9.7.3.5. Regular Expression Matching Rules

In the event that an RE could match more than one substring of a given string, the RE matches the one starting earliest in the string. If the RE could match more than one substring starting at that point, either the longest possible match or the shortest possible match will be taken, depending on whether the RE is greedy or non-greedy.

Whether an RE is greedy or not is determined by the following rules:

- Most atoms, and all constraints, have no greediness attribute (because they cannot match variable amounts of text anyway).
- Adding parentheses around an RE does not change its greediness.
- A quantified atom with a fixed-repetition quantifier (\{m\} or \{m\}? has the same greediness (possibly none) as the atom itself.
- A quantified atom with other normal quantifiers (including \{m, n\} with m equal to n) is greedy (prefers longest match).
- A quantified atom with a non-greedy quantifier (including \{m, n\}? with m equal to n) is non-greedy (prefers shortest match).
- A branch — that is, an RE that has no top-level | operator — has the same greediness as the first quantified atom in it that has a greediness attribute.
- An RE consisting of two or more branches connected by the | operator is always greedy.
The above rules associate greediness attributes not only with individual quantified atoms, but with branches and entire REs that contain quantified atoms. What that means is that the matching is done in such a way that the branch, or whole RE, matches the longest or shortest possible substring as a whole. Once the length of the entire match is determined, the part of it that matches any particular subexpression is determined on the basis of the greediness attribute of that subexpression, with subexpressions starting earlier in the RE taking priority over ones starting later.

An example of what this means:

```
SELECT SUBSTRING('XY1234Z', 'Y*([0-9]{1,3})');
Result: 123
```

```
SELECT SUBSTRING('XY1234Z', 'Y*?([0-9]{1,3})');
Result: 1
```

In the first case, the RE as a whole is greedy because $Y*$ is greedy. It can match beginning at the $Y$, and it matches the longest possible string starting there, i.e., $Y123$. The output is the parenthesized part of that, or $123$. In the second case, the RE as a whole is non-greedy because $Y*$? is non-greedy. It can match beginning at the $Y$, and it matches the shortest possible string starting there, i.e., $Y1$. The subexpression $[0-9]{1,3}$ is greedy but it cannot change the decision as to the overall match length; so it is forced to match just $1$.

In short, when an RE contains both greedy and non-greedy subexpressions, the total match length is either as long as possible or as short as possible, according to the attribute assigned to the whole RE. The attributes assigned to the subexpressions only affect how much of that match they are allowed to “eat” relative to each other.

The quantifiers $\{1,1\}$ and $\{1,1\}?\] can be used to force greediness or non-greediness, respectively, on a subexpression or a whole RE.

Match lengths are measured in characters, not collating elements. An empty string is considered longer than no match at all. For example: $bb*$ matches the three middle characters of $abbbc$; $(week|wee)(night|knights)$ matches all ten characters of $weeknights$; when $().*.$ is matched against $abc$ the parenthesized subexpression matches all three characters; and when $(a*)*$ is matched against $bc$ both the whole RE and the parenthesized subexpression match an empty string.

If case-independent matching is specified, the effect is much as if all case distinctions had vanished from the alphabet. When an alphabetic that exists in multiple cases appears as an ordinary character outside a bracket expression, it is effectively transformed into a bracket expression containing both cases, e.g., $x$ becomes $[xX]$. When it appears inside a bracket expression, all case counterparts of it are added to the bracket expression, e.g., $[x]$ becomes $[xX]$ and $[^x]$ becomes $[^xX]$.

If newline-sensitive matching is specified, $.$ and bracket expressions using $^$ will never match the newline character (so that matches will never cross newlines unless the RE explicitly arranges it) and $^$and $\$ will match the empty string after and before a newline respectively, in addition to matching at beginning and end of string respectively. But the ARE escapes $\A$ and $\Z$ continue to match beginning or end of string only.

If partial newline-sensitive matching is specified, this affects $.$ and bracket expressions as with newline-sensitive matching, but not $^$ and $\$.

If inverse partial newline-sensitive matching is specified, this affects $^$ and $\$ as with newline-sensitive matching, but not $.$ and bracket expressions. This isn’t very useful but is provided for symmetry.
9.7.3.6. Limits and Compatibility

No particular limit is imposed on the length of REs in this implementation. However, programs intended to be highly portable should not employ REs longer than 256 bytes, as a POSIX-compliant implementation can refuse to accept such REs.

The only feature of AREs that is actually incompatible with POSIX EREs is that \ does not lose its special significance inside bracket expressions. All other ARE features use syntax which is illegal or has undefined or unspecified effects in POSIX EREs; the \* syntax of directors likewise is outside the POSIX syntax for both BREs and EREs.

Many of the ARE extensions are borrowed from Perl, but some have been changed to clean them up, and a few Perl extensions are not present. Incompatibilities of note include \b, \B, the lack of special treatment for a trailing newline, the addition of complemented bracket expressions to the things affected by newline-sensitive matching, the restrictions on parentheses and back references in lookahead constraints, and the longest/shortest-match (rather than first-match) matching semantics.

Two significant incompatibilities exist between AREs and the ERE syntax recognized by pre-7.4 releases of PostgreSQL:

- In AREs, \ followed by an alphanumeric character is either an escape or an error, while in previous releases, it was just another way of writing the alphanumeric. This should not be much of a problem because there was no reason to write such a sequence in earlier releases.
- In AREs, \ remains a special character within [], so a literal \ within a bracket expression must be written \. \\

While these differences are unlikely to create a problem for most applications, you can avoid them if necessary by setting regex_flavor to extended.

9.7.3.7. Basic Regular Expressions

BREs differ from EREs in several respects. In BREs, |, +, and ? are ordinary characters and there is no equivalent for their functionality. The delimiters for bounds are {}, with { and } by themselves ordinary characters. The parentheses for nested subexpressions are (), with () by themselves ordinary characters. ^ is an ordinary character except at the beginning of the RE or the beginning of a parenthesized subexpression, $ is an ordinary character except at the end of the RE or the end of a parenthesized subexpression, and * is an ordinary character if it appears at the beginning of the RE or the beginning of a parenthesized subexpression (after a possible leading ^). Finally, single-digit back references are available, and \< and \> are synonyms for [[:<:]] and [[:>:]] respectively; no other escapes are available in BREs.

9.8. Data Type Formatting Functions

The PostgreSQL formatting functions provide a powerful set of tools for converting various data types (date/time, integer, floating point, numeric) to formatted strings and for converting from formatted strings to specific data types. Table 9-20 lists them. These functions all follow a common calling convention: the first argument is the value to be formatted and the second argument is a template that defines the output or input format.
A single-argument \texttt{to_timestamp} function is also available; it accepts a double precision argument and converts from Unix epoch (seconds since 1970-01-01 00:00:00+00) to timestamp with time zone. (Integer Unix epochs are implicitly cast to double precision.)

Table 9-20. Formatting Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{to_char(timestamp, text)}</td>
<td>text</td>
<td>convert time stamp to string</td>
<td>\texttt{to_char(current_timestamp, 'HH12:MI:SS')}</td>
</tr>
<tr>
<td>\texttt{to_char(interval, text)}</td>
<td>text</td>
<td>convert interval to string</td>
<td>\texttt{to_char(interval '15h 2m 12s', 'HH24:MI:SS')}</td>
</tr>
<tr>
<td>\texttt{to_char(int, text)}</td>
<td>text</td>
<td>convert integer to string</td>
<td>\texttt{to_char(125, '999')}</td>
</tr>
<tr>
<td>\texttt{to_char(double precision, text)}</td>
<td>text</td>
<td>convert real/double precision to string</td>
<td>\texttt{to_char(125.8::real, '999D9')}</td>
</tr>
<tr>
<td>\texttt{to_char(numeric, text)}</td>
<td>text</td>
<td>convert numeric to string</td>
<td>\texttt{to_char(-125.8, '999D999')}</td>
</tr>
<tr>
<td>\texttt{to_date(text, text)}</td>
<td>date</td>
<td>convert string to date</td>
<td>\texttt{to_date('05 Dec 2000', 'DD Mon YYYY')}</td>
</tr>
<tr>
<td>\texttt{to_number(text, text)}</td>
<td>numeric</td>
<td>convert string to numeric</td>
<td>\texttt{to_number('12,454.8-', '99G999D9S')}</td>
</tr>
<tr>
<td>\texttt{to_timestamp(text, text)}</td>
<td>timestamp with time zone</td>
<td>convert string to timestamp</td>
<td>\texttt{to_timestamp('05 Dec 2000', 'DD Mon YYYY')}</td>
</tr>
<tr>
<td>\texttt{to_timestamp(double precision)}</td>
<td>timestamp with time zone</td>
<td>convert Unix epoch to timestamp</td>
<td>\texttt{to_timestamp(1284352323)}</td>
</tr>
</tbody>
</table>

In a \texttt{to_char} output template string, there are certain patterns that are recognized and replaced with appropriately-formatted data based on the given value. Any text that is not a template pattern is simply copied verbatim. Similarly, in an input template string (for the other functions), template patterns identify the values to be supplied by the input data string.

Table 9-21 shows the template patterns available for formatting date and time values.

Table 9-21. Template Patterns for Date/Time Formatting

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Description</th>

</tr>
</tbody>
</table>

Modifiers can be applied to any template pattern to alter its behavior. For example, FMMonth is the Month pattern with the FM modifier. Table 9-22 shows the modifier patterns for date/time formatting.

### Table 9-22. Template Pattern Modifiers for Date/Time Formatting

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>FM prefix</td>

</tr>
<tr>
<td>TM prefix</td>
<td>translation mode (print localized day and month names based on lc_time)</td>
<td>TMMonth</td>
</tr>
<tr>
<td>SP suffix</td>
<td>spell mode (not implemented)</td>
<td>DDSP</td>
</tr>
</tbody>
</table>

Usage notes for date/time formatting:

- **FM** suppresses leading zeroes and trailing blanks that would otherwise be added to make the output of a pattern be fixed-width.
- **TM** does not include trailing blanks.
- **to_timestamp** and **to_date** skip multiple blank spaces in the input string unless the **FX** option is used. For example, `to_timestamp('2000 JUN', 'YYYY MON')` works, but `to_timestamp('2000 JUN', 'FXYYYY MON')` returns an error because `to_timestamp` expects one space only. **FX** must be specified as the first item in the template.
- Ordinary text is allowed in **to_char** templates and will be output literally. You can put a substring
in double quotes to force it to be interpreted as literal text even if it contains pattern key words. For example, in "Hello Year "YYYY", the YYYY will be replaced by the year data, but the single Y in Year will not be.

- If you want to have a double quote in the output you must precede it with a backslash, for example E\"YYYY Month\". (Two backslashes are necessary because the backslash has special meaning when using the escape string syntax.)

- The YYYY conversion from string to timestamp or date has a restriction when processing years with more than 4 digits. You must use some non-digit character or template after YYYY, otherwise the year is always interpreted as 4 digits. For example (with the year 20000):
  - `to_date('200001131', 'YYYYMMDD')` will be interpreted as a 4-digit year; instead use a non-digit separator after the year, like `to_date('20000-1131', 'YYYY-MMDD')` or `to_date('20000Nov31', 'YYYYMonDD')`.

- In conversions from string to timestamp or date, the CC (century) field is ignored if there is a YYYY, YY or Y field. If CC is used with YY or Y then the year is computed as (CC-1)*100+YY.

- An ISO week date (as distinct from a Gregorian date) can be specified to `to_timestamp` and `to_date` in one of two ways:
  - Year, week, and weekday: for example `to_date('2006-42-4', 'IYYY-IW-ID')` returns the date 2006-10-19. If you omit the weekday it is assumed to be 1 (Monday).
  - Year and day of year: for example `to_date('2006-291', 'IYYY-IDDD')` also returns 2006-10-19.

Attempting to construct a date using a mixture of ISO week and Gregorian date fields is nonsensical, and will cause an “error. In the context of an ISO year, the concept of a “month” or “day of month” has no meaning. In the context of a Gregorian year, the ISO week has no meaning. Users should avoid mixing Gregorian and ISO date specifications.

- In a conversion from string to timestamp, millisecond (MS) or microsecond (US) values are used as the seconds digits after the decimal point. For example `to_timestamp('12:3', 'SS:MS')` is not 3 milliseconds, but 300, because the conversion counts it as 12 + 0.3 seconds. This means for the format SS:MS, the input values 12:3, 12:30, and 12:300 specify the same number of milliseconds. To get three milliseconds, one must use 12:003, which the conversion counts as 12 + 0.003 = 12.003 seconds.

Here is a more complex example: `to_timestamp('15:12:02.020.001230', 'HH:MI:SS.MS.US')` is 15 hours, 12 minutes, and 2 seconds + 20 milliseconds + 1230 microseconds = 2.021230 seconds.

- `to_char(..., 'ID')`’s day of the week numbering matches the `extract(isodow from ...)` function, but `to_char(..., 'D')`’s does not match `extract(dow from ...)’s day numbering.

- `to_char(interval)` formats HH and HH12 as hours in a single day, while HH24 can output hours exceeding a single day, e.g., >24.

Table 9-23 shows the template patterns available for formatting numeric values.

### Table 9-23. Template Patterns for Numeric Formatting

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>9</td>
<td>value with the specified number of digits</td>
</tr>
</tbody>
</table>
Chapter 9. Functions and Operators

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>value with leading zeros</td>
</tr>
<tr>
<td>, (period)</td>
<td>decimal point</td>
</tr>
<tr>
<td>, (comma)</td>
<td>group (thousand) separator</td>
</tr>
<tr>
<td>PR</td>
<td>negative value in angle brackets</td>
</tr>
<tr>
<td>S</td>
<td>sign anchored to number (uses locale)</td>
</tr>
<tr>
<td>L</td>
<td>currency symbol (uses locale)</td>
</tr>
<tr>
<td>D</td>
<td>decimal point (uses locale)</td>
</tr>
<tr>
<td>G</td>
<td>group separator (uses locale)</td>
</tr>
<tr>
<td>MI</td>
<td>minus sign in specified position (if number &lt; 0)</td>
</tr>
<tr>
<td>PL</td>
<td>plus sign in specified position (if number &gt; 0)</td>
</tr>
<tr>
<td>SG</td>
<td>plus/minus sign in specified position</td>
</tr>
<tr>
<td>RN</td>
<td>Roman numeral (input between 1 and 3999)</td>
</tr>
<tr>
<td>TH or th</td>
<td>ordinal number suffix</td>
</tr>
<tr>
<td>V</td>
<td>shift specified number of digits (see notes)</td>
</tr>
<tr>
<td>EEEE</td>
<td>scientific notation (not implemented)</td>
</tr>
</tbody>
</table>

Usage notes for numeric formatting:

- A sign formatted using SG, PL, or MI is not anchored to the number; for example, `to_char(-12, 'MI9999')` produces ‘- 12’ but `to_char(-12, 'S9999')` produces ‘-12’. The Oracle implementation does not allow the use of MI before 9, but rather requires that 9 precede MI.
- 9 results in a value with the same number of digits as there are 9s. If a digit is not available it outputs a space.
- TH does not convert values less than zero and does not convert fractional numbers.
- PL, SG, and TH are PostgreSQL extensions.
- V effectively multiplies the input values by $10^n$, where $n$ is the number of digits following V. `to_char` does not support the use of V combined with a decimal point (e.g., 99.9V99 is not allowed).

Certain modifiers can be applied to any template pattern to alter its behavior. For example, FM9999 is the 9999 pattern with the FM modifier. Table 9-24 shows the modifier patterns for numeric formatting.

### Table 9-24. Template Pattern Modifiers for Numeric Formatting

<table>
<thead>
<tr>
<th>Modifier</th>

</tbody>
</table>
9.9. Date/Time Functions and Operators

Table 9-27 shows the available functions for date/time value processing, with details appearing in the following subsections. Table 9-26 illustrates the behaviors of the basic arithmetic operators (+, *, etc.). For formatting functions, refer to Section 9.8. You should be familiar with the background information on date/time data types from Section 8.5.

All the functions and operators described below that take time or timestamp inputs actually come in two variants: one that takes time with time zone or timestamp with time zone, and one that takes time without time zone or timestamp without time zone. For brevity, these variants are not shown separately. Also, the + and * operators come in commutative pairs (for example both date + integer and integer + date); we show only one of each such pair.

Table 9-26. Date/Time Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>date ‘2001-09-28’ + integer ‘7’</td>
<td>date ‘2001-10-05’</td>
</tr>
<tr>
<td>+</td>
<td>date ‘2001-09-28’ + interval ‘1 hour’</td>
<td>timestamp ‘2001-09-28 01:00:00’</td>
</tr>
<tr>
<td>+</td>
<td>date ‘2001-09-28’ + time ‘03:00’</td>
<td>timestamp ‘2001-09-28 03:00:00’</td>
</tr>
<tr>

</tbody>
</table>
In addition to these functions, the SQL `OVERLAPS` operator is supported:

\[
\text{(start1, end1)} \text{ OVERLAPS (start2, end2)}
\]
\[
\text{(start1, length1)} \text{ OVERLAPS (start2, length2)}
\]

This expression yields true when two time periods (defined by their endpoints) overlap, false when they do not overlap. The endpoints can be specified as pairs of dates, times, or time stamps; or as a date, time, or time stamp followed by an interval.

```
SELECT (DATE '2001-02-16', DATE '2001-12-21') OVERLAPS
       (DATE '2001-10-30', DATE '2002-10-30');
Result: true
```

```
SELECT (DATE '2001-02-16', INTERVAL '100 days') OVERLAPS
       (DATE '2001-10-30', DATE '2002-10-30');
Result: false
```

When adding an interval value to (or subtracting an interval value from) a timestamp with time zone value, the days component advances (or decrements) the date of the timestamp with time zone by the indicated number of days. Across daylight saving time changes (with the session time zone set to a time zone that recognizes DST), this means interval ‘1 day’ does not necessarily equal interval ‘24 hours’. For example, with the session time zone set to CST7CDT, `timestamp with time zone '2005-04-02 12:00-07' + interval '1 day'` will produce timestamp with time zone '2005-04-03 12:00-06', while adding interval ‘24 hours’ to the same initial timestamp with time zone produces timestamp with time zone '2005-04-03 13:00-06', as there is a change in daylight saving time at 2005-04-03 02:00 in time zone CST7CDT.

Note there can be ambiguity in the months returned by `age` because different months have a different number of days. PostgreSQL’s approach uses the month from the earlier of the two dates when calculating partial months. For example, `age('2004-06-01', '2004-04-30')` uses April to yield 1 mon 1 day, while using May would yield 1 mon 2 days because May has 31 days, while April has only 30.
### 9.9.1. EXTRACT, date_part

**EXTRACT (field FROM source)**

The `extract` function retrieves subfields such as year or hour from date/time values. `source` must be a value expression of type `timestamp`, `time`, or `interval`. (Expressions of type `date` are cast to `timestamp` and can therefore be used as well.) `field` is an identifier or string that selects what field to extract from the source value. The `extract` function returns values of type `double precision`. The following are valid field names:

- **century**
  - The century
    
    ```sql
    SELECT EXTRACT(CENTURY FROM TIMESTAMP '2000-12-16 12:21:13');
    Result: 20
    
    SELECT EXTRACT(CENTURY FROM TIMESTAMP '2001-02-16 20:38:40');
    Result: 21
    
    The first century starts at 0001-01-01 00:00:00 AD, although they did not know it at the time. This definition applies to all Gregorian calendar countries. There is no century number 0, you go from -1 century to 1 century. If you disagree with this, please write your complaint to: Pope, Cathedral Saint-Peter of Roma, Vatican.
    
    PostgreSQL releases before 8.0 did not follow the conventional numbering of centuries, but just returned the year field divided by 100.
    ```

- **day**
  - The day (of the month) field (1 - 31)
    
    ```sql
    SELECT EXTRACT(DAY FROM TIMESTAMP '2001-02-16 20:38:40');
    Result: 16
    
    decade
    - The year field divided by 10
      
      ```sql
      SELECT EXTRACT(DECADE FROM TIMESTAMP '2001-02-16 20:38:40');
      Result: 200
      ```

- **dow**
  - The day of the week as Sunday(0) to Saturday(6)
    
    ```sql
    SELECT EXTRACT(DOW FROM TIMESTAMP '2001-02-16 20:38:40');
    Result: 5
    
    Note that `extract`'s day of the week numbering differs from that of the `to_char(..., 'D')` function.
    ```

- **doy**
  - The day of the year (1 - 365/366)
    
    ```sql
    SELECT EXTRACT(DOY FROM TIMESTAMP '2001-02-16 20:38:40');
    Result: 47
    ```

- **epoch**
  - For `date` and `timestamp` values, the number of seconds since 1970-01-01 00:00:00 UTC (can be negative); for `interval` values, the total number of seconds in the interval
    
    ```sql
    SELECT EXTRACT(EPOCH FROM TIMESTAMP WITH TIME ZONE '2001-02-16 20:38:40-08');
    Result: 982384720
    ```
SELECT EXTRACT(EPOCH FROM INTERVAL '5 days 3 hours');
Result: 442800

Here is how you can convert an epoch value back to a time stamp:
SELECT TIMESTAMPTZ WITH TIME ZONE 'epoch' + 982384720 * INTERVAL '1 second';

**hour**

The hour field (0 - 23)

SELECT EXTRACT(HOUR FROM TIMESTAMPTZ '2001-02-16 20:38:40');
Result: 20

**isodow**

The day of the week as Monday(1) to Sunday(7)

SELECT EXTRACT(ISODOW FROM TIMESTAMPTZ '2001-02-18 20:38:40');
Result: 7

This is identical to **dow** except for Sunday. This matches the ISO 8601 day of the week numbering.

**isoyear**

The ISO 8601 year that the date falls in (not applicable to intervals)

SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-01');
Result: 2005
SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-02');
Result: 2006

Each ISO year begins with the Monday of the week containing the 4th of January, so in early January or late December the ISO year may be different from the Gregorian year. See the **week** field for more information.

This field is not available in PostgreSQL releases prior to 8.3.

**microseconds**

The seconds field, including fractional parts, multiplied by 1 000 000; note that this includes full seconds

SELECT EXTRACT(MICROSECONDS FROM TIME '17:12:28.5');
Result: 28500000

**millennium**

The millennium

SELECT EXTRACT(MILLENNIUM FROM TIMESTAMPTZ '2001-02-16 20:38:40');
Result: 3

Years in the 1900s are in the second millennium. The third millennium started January 1, 2001. PostgreSQL releases before 8.0 did not follow the conventional numbering of millennia, but just returned the year field divided by 1000.

**milliseconds**

The seconds field, including fractional parts, multiplied by 1000. Note that this includes full seconds.

SELECT EXTRACT(MILLISECONDS FROM TIME '17:12:28.5');
Result: 28500
minute

The minutes field (0 - 59)

SELECT EXTRACT(MINUTE FROM TIMESTAMP '2001-02-16 20:38:40');
Result: 38

month

For timestamp values, the number of the month within the year (1 - 12); for interval values
the number of months, modulo 12 (0 - 11)

SELECT EXTRACT(MONTH FROM TIMESTAMP '2001-02-16 20:38:40');
Result: 2

SELECT EXTRACT(MONTH FROM INTERVAL '2 years 3 months');
Result: 3

SELECT EXTRACT(MONTH FROM INTERVAL '2 years 13 months');
Result: 1

quarter

The quarter of the year (1 - 4) that the date is in

SELECT EXTRACT(QUARTER FROM TIMESTAMP '2001-02-16 20:38:40');
Result: 1

second

The seconds field, including fractional parts (0 - 59)

SELECT EXTRACT(SECOND FROM TIMESTAMP '2001-02-16 20:38:40');
Result: 40

SELECT EXTRACT(SECOND FROM TIME '17:12:28.5');
Result: 28.5

timezone

The time zone offset from UTC, measured in seconds. Positive values correspond to time zones
east of UTC, negative values to zones west of UTC.

timezone_hour

The hour component of the time zone offset

timezone_minute

The minute component of the time zone offset

week

The number of the week of the year that the day is in. By definition (ISO 8601),
weeks start on Mondays and the first week of a year contains January 4 of that year. In other words,
the first Thursday of a year is in week 1 of that year.

In the ISO definition, it is possible for early-January dates to be part of the 52nd or 53rd week of
the previous year, and for late-December dates to be part of the first week of the next year. For
example, 2005-01-01 is part of the 53rd week of year 2004, and 2006-01-01 is part of the
52nd week of year 2005, while 2012-12-31 is part of the first week of 2013. It’s recommended
to use the isoyear field together with week to get consistent results.

SELECT EXTRACT(WEEK FROM TIMESTAMP '2001-02-16 20:38:40');
Result: 7

60 if leap seconds are implemented by the operating system
The year field. Keep in mind there is no 0 AD, so subtracting BC years from AD years should be done with care.

```sql
SELECT EXTRACT(YEAR FROM TIMESTAMP '2001-02-16 20:38:40');
Result: 2001
```

The `extract` function is primarily intended for computational processing. For formatting date/time values for display, see Section 9.8.

The `date_part` function is modeled on the traditional Ingres equivalent to the SQL-standard function `extract`:

```sql
date_part('field', source)
```

Note that here the `field` parameter needs to be a string value, not a name. The valid field names for `date_part` are the same as for `extract`.

```sql
SELECT date_part('day', TIMESTAMP '2001-02-16 20:38:40');
Result: 16
```

```sql
SELECT date_part('hour', INTERVAL '4 hours 3 minutes');
Result: 4
```

### 9.9.2. `date_trunc`

The function `date_trunc` is conceptually similar to the `trunc` function for numbers.

```sql
date_trunc('field', source)
```

`source` is a value expression of type `timestamp` or `interval`. (Values of type `date` and `time` are cast automatically to `timestamp` or `interval`, respectively.) `field` selects to which precision to truncate the input value. The return value is of type `timestamp` or `interval` with all fields that are less significant than the selected one set to zero (or one, for day and month).

Valid values for `field` are:

- microseconds
- milliseconds
- second
- minute
- hour
- day
- week
- month
- quarter
- year
- decade
- century
- millennium

Examples:
Chapter 9. Functions and Operators

SELECT date_trunc('hour', TIMESTAMP '2001-02-16 20:38:40');
Result: 2001-02-16 20:00:00

SELECT date_trunc('year', TIMESTAMP '2001-02-16 20:38:40');
Result: 2001-01-01 00:00:00

9.9.3. AT TIME ZONE

The AT TIME ZONE construct allows conversions of time stamps to different time zones. Table 9-28 shows its variants.

Table 9-28. AT TIME ZONE Variants

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timestamp without time zone AT TIME ZONE zone</td>
<td>timestamp with time zone</td>
<td>Treat given time stamp without time zone as located in the specified time zone</td>
</tr>
<tr>
<td>timestamp with time zone AT TIME ZONE zone</td>
<td>timestamp without time zone</td>
<td>Convert given time stamp with time zone to the new time zone, with no time zone designation</td>
</tr>
<tr>
<td>time with time zone AT TIME ZONE zone</td>
<td>time with time zone</td>
<td>Convert given time with time zone to the new time zone</td>
</tr>
</tbody>
</table>

In these expressions, the desired time zone zone can be specified either as a text string (e.g., 'PST') or as an interval (e.g., INTERVAL '-08:00'). In the text case, a time zone name can be specified in any of the ways described in Section 8.5.3.

Examples (assuming the local time zone is PST8PDT):

SELECT TIMESTAMP '2001-02-16 20:38:40' AT TIME ZONE 'MST';
Result: 2001-02-16 19:38:40-08

SELECT TIMESTAMP WITH TIME ZONE '2001-02-16 20:38:40-05' AT TIME ZONE 'MST';
Result: 2001-02-16 18:38:40

The first example takes a time stamp without time zone and interprets it as MST time (UTC-7), which is then converted to PST (UTC-8) for display. The second example takes a time stamp specified in EST (UTC-5) and converts it to local time in MST (UTC-7).

The function timezone(zone, timestamp) is equivalent to the SQL-conforming construct timestamp AT TIME ZONE zone.

9.9.4. Current Date/Time

PostgreSQL provides a number of functions that return values related to the current date and time. These SQL-standard functions all return values based on the start time of the current transaction:

CURRENT_DATE
CURRENT_TIME
CURRENT_TIMESTAMP
CURRENT_TIME(precision)
Chapter 9. Functions and Operators

CURRENT_TIMESTAMP (precision)
LOCALTIME
LOCALTIMESTAMP
LOCALTIME (precision)
LOCALTIMESTAMP (precision)

CURRENT_TIME and CURRENT_TIMESTAMP deliver values with time zone; LOCALTIME and LOCALTIMESTAMP deliver values without time zone.

CURRENT_TIME, CURRENT_TIMESTAMP, LOCALTIME, and LOCALTIMESTAMP can optionally take a precision parameter, which causes the result to be rounded to that many fractional digits in the seconds field. Without a precision parameter, the result is given to the full available precision.

Some examples:

SELECT CURRENT_TIME;
Result: 14:39:53.662522-05

SELECT CURRENT_DATE;
Result: 2001-12-23

SELECT CURRENT_TIMESTAMP;
Result: 2001-12-23 14:39:53.662522-05

SELECT CURRENT_TIMESTAMP (2);
Result: 2001-12-23 14:39:53.66-05

SELECT LOCALTIMESTAMP;
Result: 2001-12-23 14:39:53.662522

Since these functions return the start time of the current transaction, their values do not change during the transaction. This is considered a feature: the intent is to allow a single transaction to have a consistent notion of the “current” time, so that multiple modifications within the same transaction bear the same time stamp.

Note: Other database systems might advance these values more frequently.

PostgreSQL also provides functions that return the start time of the current statement, as well as the actual current time at the instant the function is called. The complete list of non-SQL-standard time functions is:

transaction_timestamp()
statement_timestamp()
clock_timestamp()
timeofday()
now()

transaction_timestamp() is equivalent to CURRENT_TIMESTAMP, but is named to clearly reflect what it returns. statement_timestamp() returns the start time of the current statement (more specifically, the time of receipt of the latest command message from the client). statement_timestamp() and transaction_timestamp() return the same value
during the first command of a transaction, but might differ during subsequent commands. clock_timestamp() returns the actual current time, and therefore its value changes even within a single SQL command. timeofday() is a historical PostgreSQL function. Like clock_timestamp(), it returns the actual current time, but as a formatted text string rather than a timestamp with time zone value. now() is a traditional PostgreSQL equivalent to transaction_timestamp().

All the date/time data types also accept the special literal value now to specify the current date and time (again, interpreted as the transaction start time). Thus, the following three all return the same result:

```
SELECT CURRENT_TIMESTAMP;
SELECT now();
SELECT TIMESTAMP 'now';  -- incorrect for use with DEFAULT
```

Tip: You do not want to use the third form when specifying a DEFAULT clause while creating a table. The system will convert now to a timestamp as soon as the constant is parsed, so that when the default value is needed, the time of the table creation would be used! The first two forms will not be evaluated until the default value is used, because they are function calls. Thus they will give the desired behavior of defaulting to the time of row insertion.

### 9.9.5. Delaying Execution

The following function is available to delay execution of the server process:

```
pg_sleep(seconds)
```

`pg_sleep` makes the current session’s process sleep until `seconds` seconds have elapsed. `seconds` is a value of type `double precision`, so fractional-second delays can be specified. For example:

```
SELECT pg_sleep(1.5);
```

**Note:** The effective resolution of the sleep interval is platform-specific; 0.01 seconds is a common value. The sleep delay will be at least as long as specified. It might be longer depending on factors such as server load.

**Warning**

Make sure that your session does not hold more locks than necessary when calling `pg_sleep`. Otherwise other sessions might have to wait for your sleeping process, slowing down the entire system.
Chapter 9. Functions and Operators

9.10. Enum Support Functions

For enum types (described in Section 8.7), there are several functions that allow cleaner programming without hard-coding particular values of an enum type. These are listed in Table 9-29. The examples assume an enum type created as:

```
CREATE TYPE rainbow AS ENUM ('red', 'orange', 'yellow', 'green', 'blue', 'purple');
```

Table 9-29. Enum Support Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Example</th>
<th>Example Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>enum_first(anyenum)</td>
<td>Returns the first value of the input enum type</td>
<td>enum_first(null::rainbow)</td>
<td>red</td>
</tr>
<tr>
<td>enum_last(anyenum)</td>
<td>Returns the last value of the input enum type</td>
<td>enum_last(null::rainbow)</td>
<td>purple</td>
</tr>
<tr>
<td>enum_range(anyenum)</td>
<td>Returns all values of the input enum type in an ordered array</td>
<td>enum_range(null::rainbow,orange,yellow,green,blue,purple)</td>
<td>{red,orange,yellow,green,blue,purple}</td>
</tr>
<tr>
<td>enum_range(anyenum, anyenum)</td>
<td>Returns the range between the two given enum values, as an ordered array. The values must be from the same enum type. If the first parameter is null, the result will start with the first value of the enum type. If the second parameter is null, the result will end with the last value of the enum type.</td>
<td>enum_range('orange'::rainbow,'green'::rainbow)</td>
<td>{orange,yellow,green}</td>
</tr>
<tr>
<td></td>
<td></td>
<td>enum_range(NULL,'green'::rainbow)</td>
<td>{red,orange,yellow,green}</td>
</tr>
<tr>
<td></td>
<td></td>
<td>enum_range('orange'::rainbow,NULL)</td>
<td>{orange,yellow,green,blue,purple}</td>
</tr>
</tbody>
</table>

Notice that except for the two-argument form of `enum_range`, these functions disregard the specific value passed to them; they care only about its declared data type. Either null or a specific value of the type can be passed, with the same result. It is more common to apply these functions to a table column or function argument than to a hardwired type name as suggested by the examples.

9.11. Geometric Functions and Operators

The geometric types `point`, `box`, `lseg`, `line`, `path`, `polygon`, and `circle` have a large set of native support functions and operators, shown in Table 9-30, Table 9-31, and Table 9-32.
Caution

Note that the “same as” operator, \(~=\), represents the usual notion of equality for the `point`, `box`, `polygon`, and `circle` types. Some of these types also have an `=` operator, but `=` compares for equal *areas* only. The other scalar comparison operators (\(<\)- and so on) likewise compare areas for these types.

Table 9-30. Geometric Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Translation</td>
<td><code>box '((0,0),(1,1))' + point '(2.0,0)'</code></td>

</tbody>
</table>
Chapter 9. Functions and Operators

### Operator

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;^</code></td>
<td>Is below (allows touching)?</td>
<td><code>circle '((0,0),1)' </code>&lt;^` circle '((0,5),1)'</td>
</tr>
<tr>
<td><code>&gt;^</code></td>
<td>Is above (allows touching)?</td>
<td><code>circle '((0,5),1)' </code>&gt;^` circle '((0,0),1)'</td>
</tr>
<tr>
<td><code>?#</code></td>
<td>Intersects?</td>
<td><code>lseg '((-1,0),(1,0))' </code># box '(((-2,-2),(2,2))'</td>
</tr>
<tr>
<td><code>?-</code></td>
<td>Is horizontal?</td>
<td><code>?- lseg '((-1,0),(1,0))'</code></td>
</tr>
<tr>
<td><code>?-</code></td>
<td>Are horizontally aligned?</td>
<td><code>point '(1,0)' </code>?- point '(0,0)'</td>
</tr>
<tr>
<td>`?</td>
<td>`</td>
<td>Is vertical?</td>
</tr>
<tr>
<td>`?</td>
<td>`</td>
<td>Are vertically aligned?</td>
</tr>
<tr>
<td>`?-</td>
<td>`</td>
<td>Is perpendicular?</td>
</tr>
<tr>
<td>`?</td>
<td></td>
<td>`</td>
</tr>
<tr>
<td><code>@&gt;</code></td>
<td>Contains?</td>
<td><code>circle '((0,0),2)' </code>@&gt; point '(1,1)'</td>
</tr>
<tr>
<td><code>&lt;@</code></td>
<td>Contained in or on?</td>
<td><code>point '(1,1)' </code>&lt;@ circle '((0,0),2)'</td>
</tr>
<tr>
<td><code>~=</code></td>
<td>Same as?</td>
<td><code>polygon '((0,0),(1,1))' </code>~=` polygon '((1,1),(0,0))'</td>
</tr>
</tbody>
</table>

**Note:** Before PostgreSQL 8.2, the containment operators `@>` and `<@` were respectively called `~` and `@`. These names are still available, but are deprecated and will eventually be removed.

<td>construct point</td>
<td>point(23.4, -44.5)</td>
</tr>
<tr>
<td>point(box)</td>
<td>point</td>
<td>center of box</td>
<td>point(box '((-1,0),(1,0))')</td>
</tr>
<tr>
<td>point(circle)</td>
<td>point</td>
<td>center of circle</td>
<td>point(circle '((0,0),2.0)')</td>
</tr>
<tr>
<td>point(lseg)</td>
<td>point</td>
<td>center of line segment</td>
<td>point(lseg '((-1,0),(1,0))')</td>
</tr>
<tr>
<td>point(polygon)</td>
<td>point</td>
<td>center of polygon</td>
<td>point(polygon '((0,0),(1,1),(2,0))')</td>
</tr>
<tr>
<td>polygon(box)</td>
<td>polygon</td>
<td>box to 4-point polygon</td>
<td>polygon(box '((0,0),(1,1))')</td>
</tr>
<tr>
<td>polygon(circle)</td>
<td>polygon</td>
<td>circle to 12-point polygon</td>
<td>polygon(circle '((0,0),2.0)')</td>
</tr>
<tr>
<td>polygon(npts, circle)</td>
<td>polygon</td>
<td>circle to npts-point polygon</td>
<td>polygon(12, circle '((0,0),2.0)')</td>
</tr>
<tr>
<td>polygon(path)</td>
<td>polygon</td>
<td>path to polygon</td>
<td>polygon(path '((0,0),(1,1),(2,0))')</td>
</tr>
</tbody>
</table>

It is possible to access the two component numbers of a `point` as though the point were an array with indexes 0 and 1. For example, if `t.p` is a `point` column then `SELECT p[0] FROM t` retrieves the X coordinate and `UPDATE t SET p[1] = ...` changes the Y coordinate. In the same way, a value of type `box` or `lseg` can be treated as an array of two `point` values.

The `area` function works for the types `box`, `circle`, and `path`. The `area` function only works on the `path` data type if the points in the `path` are non-intersecting. For example, the `path '((0,0),(0,1),(1,2),(1,2),(2,2),(1,2),(1,0),(0,0),(0,0))'::PATH` will not work; however, the following visually identical `path '((0,0),(0,1),(1,1),(1,2),(2,2),(2,1),(1,1),(1,0),(0,0))'::PATH` will work. If the concept of an intersecting versus non-intersecting `path` is confusing, draw both of the above `paths` side by side on a piece of graph paper.

### 9.12. Network Address Functions and Operators

Table 9-33 shows the operators available for the `cidr` and `inet` types. The operators `<<`, `<<=`, `>>`, and `>>=`, test for subnet inclusion. They consider only the network parts of the two addresses (ignoring any host part) and determine whether one network is identical to or a subnet of the other.

---

201
Table 9-33. `cidr` and `inet` Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
</tr>

</tr>
<tr>
<td>netmask/inet</td>
<td>inet</td>
<td>construct netmask for network</td>
<td>netmask('192.168.1.5/24')</td>
<td></td>
</tr>
<tr>
<td>network/inet</td>
<td>cidr</td>
<td>extract network part of address</td>
<td>network('192.168.1.5/24')</td>
<td></td>
</tr>
<tr>
<td>set_masklen/inet</td>
<td>inet</td>
<td>set netmask length for inet value</td>
<td>set_masklen('192.168.1.5/24', 16)</td>
<td></td>
</tr>
<tr>
<td>set_masklen/cidr</td>
<td>cidr</td>
<td>set netmask length for cidr value</td>
<td>set_masklen('192.168.1.5/24', 16)</td>
<td></td>
</tr>
<tr>
<td>text/inet</td>
<td>text</td>
<td>extract IP address and netmask length as text</td>
<td>text(inet '192.168.1.5')</td>
<td>192.168.1.5/32</td>
</tr>
</tbody>
</table>

Any cidr value can be cast to inet implicitly or explicitly; therefore, the functions shown above as operating on inet also work on cidr values. (Where there are separate functions for inet and cidr, it is because the behavior should be different for the two cases.) Also, it is permitted to cast an inet value to cidr. When this is done, any bits to the right of the netmask are silently zeroed to create a valid cidr value. In addition, you can cast a text value to inet or cidr using normal casting syntax: for example, inet(expression) or colname::cidr.

Table 9-35 shows the functions available for use with the macaddr type. The function trunc(macaddr) returns a MAC address with the last 3 bytes set to zero. This can be used to associate the remaining prefix with a manufacturer.

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>trunc(macaddr)</td>
<td>macaddr</td>
<td>set last 3 bytes to zero</td>
<td>trunc(macaddr '12:34:56:78:90:ab')</td>
<td>12:34:56:00:00:00 00</td>
</tr>
</tbody>
</table>

The macaddr type also supports the standard relational operators (> , < , etc.) for lexicographical ordering.

9.13. Text Search Functions and Operators

Table 9-36, Table 9-37 and Table 9-38 summarize the functions and operators that are provided for full text searching. See Chapter 12 for a detailed explanation of PostgreSQL’s text search facility.
Table 9-36. Text Search Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>@@</td>
<td>tsvector matches tsquery ?</td>
<td>to_tsvector('fat cats ate rats') @@ to_tsquery('cat &amp; rat')</td>
<td>t</td>
</tr>
<tr>
<td>@@@</td>
<td>deprecated synonym for @@</td>
<td>to_tsvector('fat cats ate rats') @@@ to_tsquery('cat &amp; rat')</td>
<td>t</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>concatenate tsvectors</td>
</tr>
<tr>
<td>&amp;&amp;</td>
<td>AND tsquerys together</td>
<td>'fat</td>
<td>rat':tsquery &amp;&amp; 'cat':tsquery</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>OR tsquerys together</td>
</tr>
<tr>
<td>!!!</td>
<td>negate a tsquery</td>
<td>!!! 'cat':tsquery !!!</td>
<td>'cat'</td>
</tr>
<tr>
<td>@&gt;</td>
<td>tsquery contains another ?</td>
<td>'cat':tsquery @&gt; 'cat'</td>
<td>f</td>
</tr>
<tr>
<td>&lt;@</td>
<td>tsquery is contained in ?</td>
<td>'cat':tsquery &lt;@ 'cat &amp; rat':tsquery</td>
<td>t</td>
</tr>
</tbody>
</table>

Note: The tsquery containment operators consider only the lexemes listed in the two queries, ignoring the combining operators.

In addition to the operators shown in the table, the ordinary B-tree comparison operators (\(=\), \(<\), etc) are defined for types tsvector and tsquery. These are not very useful for text searching but allow, for example, unique indexes to be built on columns of these types.

Table 9-37. Text Search Functions

<tr>
<td>regconfig, ] document text, query tsquery [, options text ])</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>ts_rewrite(query tsquery, target tsquery, substitute tsquery)</td>
<td>tsquery</td>
<td>replace target with substitute within query</td>
<td>ts_rewrite('a &amp; b':tsquery, 'a':tsquery, 'foo</td>
<td>bar':tsquery)</td>
</tr>
<tr>
<td>ts_rewrite(query tsquery, select text)</td>
<td>tsquery</td>
<td>replace using targets and substitutes from a SELECT command</td>
<td>SELECT ts_rewrite('a &amp; b':tsquery, 'SELECT t,s FROM aliases')</td>
<td>'b' &amp; ( 'foo'</td>
</tr>
<tr>
<td>get_current_ts_config()</td>
<td>regconfig</td>
<td>get default text search configuration</td>
<td>get_current_ts_config()</td>
<td></td>
</tr>
<tr>
<td>tsvector_update_trigger()</td>
<td>trigger</td>
<td>trigger function for automatic tsvector column update</td>
<td>CREATE TRIGGER ... tsvector_update_trigger(tsvcol, 'pg_catalog.swedish', title, body)</td>
<td></td>
</tr>
<tr>
<td>tsvector_update_trigger_column()</td>
<td>trigger</td>
<td>trigger function for automatic tsvector column update</td>
<td>CREATE TRIGGER ... tsvector_update_trigger_column(tsvcol, configcol, title, body)</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** All the text search functions that accept an optional `regconfig` argument will use the configuration specified by `default_text_search_config` when that argument is omitted.

The functions in Table 9-38 are listed separately because they are not usually used in everyday text searching operations. They are helpful for development and debugging of new text search configurations.

**Table 9-38. Text Search Debugging Functions**

</tbody>
</table>
### 9.14. XML Functions

The functions and function-like expressions described in this section operate on values of type `xml`. Check Section 8.13 for information about the `xml` type. The function-like expressions `xmlparse` and `xmlserialize` for converting to and from type `xml` are not repeated here. Use of many of these functions requires the installation to have been built with `configure --with-libxml`.

#### 9.14.1. Producing XML Content

A set of functions and function-like expressions are available for producing XML content from SQL data. As such, they are particularly suitable for formatting query results into XML documents for processing in client applications.

##### 9.14.1.1. `xmlcomment`

xmlcomment(text)

The function `xmlcomment` creates an XML value containing an XML comment with the specified text as content. The text cannot contain “--” or end with a “-” so that the resulting construct is a valid XML comment. If the argument is null, the result is null.

Example:

```sql
SELECT xmlcomment('hello');
```

```xml
<!--hello-->
```

##### 9.14.1.2. `xmlconcat`

xmlconcat(xml[, ...])

The function `xmlconcat` concatenates a list of individual XML values to create a single value containing an XML content fragment. Null values are omitted; the result is only null if there are no nonnull arguments.
Chapter 9. Functions and Operators
Example:
SELECT xmlconcat(’<abc/>’, ’<bar>foo</bar>’);
xmlconcat
---------------------<abc/><bar>foo</bar>

XML declarations, if present, are combined as follows. If all argument values have the same XML
version declaration, that version is used in the result, else no version is used. If all argument values
have the standalone declaration value “yes”, then that value is used in the result. If all argument
values have a standalone declaration value and at least one is “no”, then that is used in the result.
Else the result will have no standalone declaration. If the result is determined to require a standalone
declaration but no version declaration, a version declaration with version 1.0 will be used because
XML requires an XML declaration to contain a version declaration. Encoding declarations are ignored
and removed in all cases.
Example:

SELECT xmlconcat(’<?xml version="1.1"?><foo/>’, ’<?xml version="1.1" standalone="no"?><ba
xmlconcat
----------------------------------<?xml version="1.1"?><foo/><bar/>

9.14.1.3. xmlelement
xmlelement(name name [, xmlattributes(value [AS attname] [, ... ])] [, content, ...])

The xmlelement expression produces an XML element with the given name, attributes, and content.
Examples:
SELECT xmlelement(name foo);
xmlelement
-----------<foo/>
SELECT xmlelement(name foo, xmlattributes(’xyz’ as bar));
xmlelement
-----------------<foo bar="xyz"/>
SELECT xmlelement(name foo, xmlattributes(current_date as bar), ’cont’, ’ent’);
xmlelement
------------------------------------<foo bar="2007-01-26">content</foo>

209


Element and attribute names that are not valid XML names are escaped by replacing the offending characters by the sequence \_xHHHH\_, where \HHHH\ is the character’s Unicode codepoint in hexadecimal notation. For example:

```sql
SELECT xmlelement(name "foo$bar", xmlattributes('xyz' as 'a&b'));
```

An explicit attribute name need not be specified if the attribute value is a column reference, in which case the column’s name will be used as the attribute name by default. In other cases, the attribute must be given an explicit name. So this example is valid:

```sql
CREATE TABLE test (a xml, b xml);
SELECT xmlelement(name test, xmlattributes(a, b)) FROM test;
```

But these are not:

```sql
SELECT xmlelement(name test, xmlattributes('constant'), a, b) FROM test;
SELECT xmlelement(name test, xmlattributes(func(a, b))) FROM test;
```

Element content, if specified, will be formatted according to its data type. If the content is itself of type \textit{xml}, complex XML documents can be constructed. For example:

```sql
SELECT xmlelement(name foo, xmlattributes('xyz' as bar),
                   xmlelement(name abc),
                   xmlcomment('test'),
                   xmlelement(name xyz));
```

Content of other types will be formatted into valid XML character data. This means in particular that the characters <, >, and & will be converted to entities. Binary data (data type \textit{bytea}) will be represented in base64 or hex encoding, depending on the setting of the configuration parameter \texttt{xmlbinary}. The particular behavior for individual data types is expected to evolve in order to align the SQL and PostgreSQL data types with the XML Schema specification, at which point a more precise description will appear.

### 9.14.1.4. \texttt{xmlforest}

\texttt{xmlforest(content [AS name] [, ...])}

The \texttt{xmlforest} expression produces an XML forest (sequence) of elements using the given names and content.

Examples:

```sql
SELECT xmlforest('abc' AS foo, 123 AS bar);
```
As seen in the second example, the element name can be omitted if the content value is a column reference, in which case the column name is used by default. Otherwise, a name must be specified.

Element names that are not valid XML names are escaped as shown for `xmlelement` above. Similarly, content data is escaped to make valid XML content, unless it is already of type `xml`.

Note that XML forests are not valid XML documents if they consist of more than one element, so it might be useful to wrap `xmlforest` expressions in `xmlelement`.

### 9.14.1.5. xmlpi

```
xmlpi(name target [, content])
```

The `xmlpi` expression creates an XML processing instruction. The content, if present, must not contain the character sequence `?>`.

Example:
```
SELECT xmlpi(name php, 'echo "hello world";');
```

```
<?php echo "hello world";?>
```

### 9.14.1.6. xmlroot

```
xmlroot(xml, version text | no value [, standalone yes|no|no value])
```

The `xmlroot` expression alters the properties of the root node of an XML value. If a version is specified, it replaces the value in the root node’s version declaration; if a standalone setting is specified, it replaces the value in the root node’s standalone declaration.

```
SELECT xmlroot(xmlparse(document '<?xml version="1.1"?><content>abc</content>'),
             version '1.0', standalone yes);
```
9.14.1.7. xmlagg

xmlagg(xml)

The function `xmlagg` is, unlike the other functions described here, an aggregate function. It concatenates the input values to the aggregate function call, like `xmlconcat` does. See Section 9.18 for additional information about aggregate functions.

Example:

```sql
CREATE TABLE test (y int, x xml);
INSERT INTO test VALUES (1, '<foo>abc</foo>');
INSERT INTO test VALUES (2, '<bar/>');
SELECT xmlagg(x) FROM test;
```

```
xmlagg----------------------
<foo>abc</foo><bar/>
```

To determine the order of the concatenation, something like the following approach can be used:

```sql
SELECT xmlagg(x) FROM (SELECT * FROM test ORDER BY y DESC) AS tab;
```

```
xmlagg----------------------
<bar/><foo>abc</foo>
```

Again, see Section 9.18 for additional information.

9.14.1.8. XML Predicates

`xml IS DOCUMENT`

The expression `IS DOCUMENT` returns true if the argument XML value is a proper XML document, false if it is not (that is, it is a content fragment), or null if the argument is null. See Section 8.13 about the difference between documents and content fragments.

9.14.2. Processing XML

To process values of data type `xml`, PostgreSQL offers the function `xpath`, which evaluates XPath 1.0 expressions.

```sql
xpath(xpath, xml[, nsarray])
```

The function `xpath` evaluates the XPath expression `xpath` against the XML value `xml`. It returns an array of XML values corresponding to the node set produced by the XPath expression.
The second argument must be a well formed XML document. In particular, it must have a single root node element.

The third argument of the function is an array of namespace mappings. This array should be a two-dimensional array with the length of the second axis being equal to 2 (i.e., it should be an array of arrays, each of which consists of exactly 2 elements). The first element of each array entry is the namespace name, the second the namespace URI.

Example:

```sql
ARRAY[ARRAY['my', 'http://example.com']]);
```

```
xpath
-------
{test}
(1 row)
```

### 9.14.3. Mapping Tables to XML

The following functions map the contents of relational tables to XML values. They can be thought of as XML export functionality:

- `table_to_xml(tbl regclass, nulls boolean, tableforest boolean, targetns text)`
- `query_to_xml(query text, nulls boolean, tableforest boolean, targetns text)`
- `cursor_to_xml(cursor refcursor, count int, nulls boolean, tableforest boolean, targetns text)`

The return type of each function is `xml`.

`table_to_xml` maps the content of the named table, passed as parameter `tbl`. The `regclass` type accepts strings identifying tables using the usual notation, including optional schema qualifications and double quotes. `query_to_xml` executes the query whose text is passed as parameter `query` and maps the result set. `cursor_to_xml` fetches the indicated number of rows from the cursor specified by the parameter `cursor`. This variant is recommended if large tables have to be mapped, because the result value is built up in memory by each function.

If `tableforest` is false, then the resulting XML document looks like this:

```
<tablename>
  <row>
    <columnname1>data</columnname1>
    <columnname2>data</columnname2>
  </row>
  ...
</tablename>
```

If `tableforest` is true, the result is an XML content fragment that looks like this:

```
<tablename>
  ...
</tablename>
```
If no table name is available, that is, when mapping a query or a cursor, the string `table` is used in the first format, `row` in the second format.

The choice between these formats is up to the user. The first format is a proper XML document, which will be important in many applications. The second format tends to be more useful in the `cursor_to_xml` function if the result values are to be reassembled into one document later on. The functions for producing XML content discussed above, in particular `xmlelement`, can be used to alter the results to taste.

The data values are mapped in the same way as described for the function `xmlelement` above.

The parameter `nulls` determines whether null values should be included in the output. If true, null values in columns are represented as:

```xml
<columnname xsi:nil="true"/>
```

where `xsi` is the XML namespace prefix for XML Schema Instance. An appropriate namespace declaration will be added to the result value. If false, columns containing null values are simply omitted from the output.

The parameter `targetns` specifies the desired XML namespace of the result. If no particular namespace is wanted, an empty string should be passed.

The following functions return XML Schema documents describing the mappings performed by the corresponding functions above:

```sql
table_to_xmlschema(tbl regclass, nulls boolean, tableforest boolean, targetns text)
query_to_xmlschema(query text, nulls boolean, tableforest boolean, targetns text)
cursor_to_xmlschema(cursor refcursor, nulls boolean, tableforest boolean, targetns text)
```

It is essential that the same parameters are passed in order to obtain matching XML data mappings and XML Schema documents.

The following functions produce XML data mappings and the corresponding XML Schema in one document (or forest), linked together. They can be useful where self-contained and self-describing results are wanted:

```sql
table_to_xml_and_xmlschema(tbl regclass, nulls boolean, tableforest boolean, targetns text)
query_to_xml_and_xmlschema(query text, nulls boolean, tableforest boolean, targetns text)
```

In addition, the following functions are available to produce analogous mappings of entire schemas or the entire current database:

```sql
schema_to_xml(schema name, nulls boolean, tableforest boolean, targetns text)
schema_to_xmlschema(schema name, nulls boolean, tableforest boolean, targetns text)
schema_to_xml_and_xmlschema(schema name, nulls boolean, tableforest boolean, targetns text)
database_to_xml(nulls boolean, tableforest boolean, targetns text)
```
Chapter 9. Functions and Operators

database_to_xmlschema(nulls boolean, tableforest boolean, targetns text)
database_to_xml_and_xmlschema(nulls boolean, tableforest boolean, targetns text)

Note that these potentially produce a lot of data, which needs to be built up in memory. When request-
ing content mappings of large schemas or databases, it might be worthwhile to consider mapping the
tables separately instead, possibly even through a cursor.

The result of a schema content mapping looks like this:

<schemaname>
  table1-mapping
  table2-mapping
  ...
</schemaname>

where the format of a table mapping depends on the tableforest parameter as explained above.

The result of a database content mapping looks like this:

<dbname>
  <schema1name>
    ...
  </schema1name>
  <schema2name>
    ...
  </schema2name>
  ...
</dbname>

where the schema mapping is as above.

As an example of using the output produced by these functions, Figure 9-1 shows an XSLT stylesheet
that converts the output of table_to_xml_and_xmlschema to an HTML document containing a
tabular rendition of the table data. In a similar manner, the results from these functions can be con-
verted into other XML-based formats.

**Figure 9-1. XSLT stylesheet for converting SQL/XML output to HTML**

```xml
<?xml version="1.0"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns="http://www.w3.org/1999/xhtml">
  <xsl:output method="xml"
    doctype-system="http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd"
    doctype-public="-//W3C//DTD XHTML 1.0 Strict//EN"
    indent="yes"/>
</xsl:stylesheet>
```
9.15. Sequence Manipulation Functions

This section describes functions for operating on sequence objects, also called sequence generators or just sequences. Sequence objects are special single-row tables created with `CREATE SEQUENCE`. Sequence objects are commonly used to generate unique identifiers for rows of a table. The sequence functions, listed in Table 9-39, provide simple, multiuser-safe methods for obtaining successive sequence values from sequence objects.

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>currval</code></td>
<td>bigint</td>
<td>Return value most recently obtained with <code>nextval</code> for specified sequence</td>
</tr>
<tr>
<td><code>lastval</code></td>
<td>bigint</td>
<td>Return value most recently obtained with <code>nextval</code> for any sequence</td>
</tr>
</tbody>
</table>

Table 9-39. Sequence Functions
Chapter 9. Functions and Operators
Function

Return Type

Description

nextval(regclass)

bigint

Advance sequence and return
new value

setval(regclass, bigint)

bigint

Set sequence’s current value

setval(regclass, bigint,

bigint

Set sequence’s current value
and is_called flag

boolean)

The sequence to be operated on by a sequence function is specified by a regclass argument, which is
simply the OID of the sequence in the pg_class system catalog. You do not have to look up the OID
by hand, however, since the regclass data type’s input converter will do the work for you. Just write
the sequence name enclosed in single quotes so that it looks like a literal constant. For compatibility
with the handling of ordinary SQL names, the string will be converted to lowercase unless it contains
double quotes around the sequence name. Thus:
nextval(’foo’)
nextval(’FOO’)
nextval(’"Foo"’)

operates on sequence foo
operates on sequence foo
operates on sequence Foo

The sequence name can be schema-qualified if necessary:
nextval(’myschema.foo’)
nextval(’"myschema".foo’)
nextval(’foo’)

operates on myschema.foo
same as above
searches search path for foo

See Section 8.16 for more information about regclass.
Note: Before PostgreSQL 8.1, the arguments of the sequence functions were of type text, not
regclass, and the above-described conversion from a text string to an OID value would happen
at run time during each call. For backwards compatibility, this facility still exists, but internally it is
now handled as an implicit coercion from text to regclass before the function is invoked.
When you write the argument of a sequence function as an unadorned literal string, it becomes
a constant of type regclass. Since this is really just an OID, it will track the originally identified
sequence despite later renaming, schema reassignment, etc. This “early binding” behavior is
usually desirable for sequence references in column defaults and views. But sometimes you might
want “late binding” where the sequence reference is resolved at run time. To get late-binding
behavior, force the constant to be stored as a text constant instead of regclass:
nextval(’foo’::text)

foo is looked up at runtime

Note that late binding was the only behavior supported in PostgreSQL releases before 8.1, so you
might need to do this to preserve the semantics of old applications.
Of course, the argument of a sequence function can be an expression as well as a constant. If it
is a text expression then the implicit coercion will result in a run-time lookup.

The available sequence functions are:

nextval

Advance the sequence object to its next value and return that value. This is done atomically: even
if multiple sessions execute nextval concurrently, each will safely receive a distinct sequence
value.

217


currval

Return the value most recently obtained by nextval for this sequence in the current session. (An error is reported if nextval has never been called for this sequence in this session.) Because this is returning a session-local value, it gives a predictable answer whether or not other sessions have executed nextval since the current session did.

lastval

Return the value most recently returned by nextval in the current session. This function is identical to currval, except that instead of taking the sequence name as an argument it fetches the value of the last sequence used by nextval in the current session. It is an error to call lastval if nextval has not yet been called in the current session.

setval

Reset the sequence object’s counter value. The two-parameter form sets the sequence’s last_value field to the specified value and sets its is_called field to true, meaning that the next nextval will advance the sequence before returning a value. The value reported by currval is also set to the specified value. In the three-parameter form, is_called can be set to either true or false. true has the same effect as the two-parameter form. If it is set to false, the next nextval will return exactly the specified value, and sequence advancement commences with the following nextval. Furthermore, the value reported by currval is not changed in this case (this is a change from pre-8.3 behavior). For example,

```
SELECT setval('foo', 42);       // Next nextval will return 43
SELECT setval('foo', 42, true); // Same as above
SELECT setval('foo', 42, false); // Next nextval will return 42
```

The result returned by setval is just the value of its second argument.

If a sequence object has been created with default parameters, successive nextval calls will return successive values beginning with 1. Other behaviors can be obtained by using special parameters in the CREATE SEQUENCE command; see its command reference page for more information.

Important: To avoid blocking concurrent transactions that obtain numbers from the same sequence, a nextval operation is never rolled back; that is, once a value has been fetched it is considered used, even if the transaction that did the nextval later aborts. This means that aborted transactions might leave unused “holes” in the sequence of assigned values. setval operations are never rolled back, either.

### 9.16. Conditional Expressions

This section describes the SQL-compliant conditional expressions available in PostgreSQL.

Tip: If your needs go beyond the capabilities of these conditional expressions, you might want to consider writing a stored procedure in a more expressive programming language.
9.16.1. CASE

The SQL CASE expression is a generic conditional expression, similar to if/else statements in other programming languages:

```
CASE WHEN condition THEN result
    [WHEN ...]
    [ELSE result]
END
```

CASE clauses can be used wherever an expression is valid. Each condition is an expression that returns a boolean result. If the condition’s result is true, the value of the CASE expression is the result that follows the condition, and the remainder of the CASE expression is not processed. If the condition’s result is not true, any subsequent WHEN clauses are examined in the same manner. If no WHEN condition yields true, the value of the CASE expression is the result of the ELSE clause. If the ELSE clause is omitted and no condition is true, the result is null.

An example:

```
SELECT * FROM test;
```

```
a
---
1
2
3
```

```
SELECT a,
    CASE WHEN a=1 THEN 'one'
        WHEN a=2 THEN 'two'
        ELSE 'other'
    END
FROM test;
```

```
a | case
---+-----
1 | one
2 | two
3 | other
```

The data types of all the result expressions must be convertible to a single output type. See Section 10.5 for more details.

There is a “simple” form of CASE expression that is a variant of the general form above:

```
CASE expression
    WHEN value THEN result
    [WHEN ...]
    [ELSE result]
END
```

The first expression is computed, then compared to each of the value expressions in the WHEN clauses until one is found that is equal to it. If no match is found, the result of the ELSE clause (or a null value) is returned. This is similar to the switch statement in C.

The example above can be written using the simple CASE syntax:
SELECT a,
    CASE a WHEN 1 THEN 'one'
           WHEN 2 THEN 'two'
           ELSE 'other'
    END
FROM test;

<table>
<thead>
<tr>
<th>a</th>
<th>case</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>one</td>
</tr>
<tr>
<td>2</td>
<td>two</td>
</tr>
<tr>
<td>3</td>
<td>other</td>
</tr>
</tbody>
</table>

A **CASE** expression does not evaluate any subexpressions that are not needed to determine the result. For example, this is a possible way of avoiding a division-by-zero failure:

SELECT ... WHERE CASE WHEN x <> 0 THEN y/x > 1.5 ELSE false END;

**Note:** As described in Section 34.6, functions and operators marked **IMMUTABLE** can be evaluated when the query is planned rather than when it is executed. This means that constant parts of a subexpression that is not evaluated during query execution might still be evaluated during query planning.

### 9.16.2. COALESCE

COALESCE(value [, ...])

The **COALESCE** function returns the first of its arguments that is not null. Null is returned only if all arguments are null. It is often used to substitute a default value for null values when data is retrieved for display, for example:

SELECT COALESCE(description, short_description, '(none)') ... 

Like a **CASE** expression, **COALESCE** only evaluates the arguments that are needed to determine the result; that is, arguments to the right of the first non-null argument are not evaluated. This SQL-standard function provides capabilities similar to **NVL** and **IFNULL**, which are used in some other database systems.

### 9.16.3. NULLIF

NULLIF(value1, value2)

The **NULLIF** function returns a null value if **value1** equals **value2**; otherwise it returns **value1**. This can be used to perform the inverse operation of the **COALESCE** example given above:

SELECT NULLIF(value, '(none)') ...
If \( \text{value1} \) is (none), return a null, otherwise return \( \text{value1} \).

### 9.16.4. GREATEST and LEAST

**GREATEST(value [, ...])**

**LEAST(value [, ...])**

The \texttt{GREATEST} and \texttt{LEAST} functions select the largest or smallest value from a list of any number of expressions. The expressions must all be convertible to a common data type, which will be the type of the result (see Section 10.5 for details). NULL values in the list are ignored. The result will be NULL only if all the expressions evaluate to NULL.

Note that \texttt{GREATEST} and \texttt{LEAST} are not in the SQL standard, but are a common extension. Some other databases make them return NULL if any argument is NULL, rather than only when all are NULL.

### 9.17. Array Functions and Operators

Table 9-40 shows the operators available for array types.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>(-)</td>
<td>equal</td>
<td>\texttt{ARRAY[1.1,2.1,3.1]}::\texttt{int[]} = \texttt{ARRAY[1,2,3]}</td>
<td></td>
</tr>
<tr>
<td>(&lt;\gt)</td>
<td>not equal</td>
<td>\texttt{ARRAY[1,2,3]} &lt;\gt&gt; \texttt{ARRAY[1,2,4]}</td>
<td>\texttt{t}</td>
</tr>
<tr>
<td>(&lt;)</td>
<td>less than</td>
<td>\texttt{ARRAY[1,2,3]} &lt;&gt; \texttt{ARRAY[1,2,4]}</td>
<td>\texttt{t}</td>
</tr>
<tr>
<td>(&gt;)</td>
<td>greater than</td>
<td>\texttt{ARRAY[1,4,3]} &gt;&gt; \texttt{ARRAY[1,2,4]}</td>
<td>\texttt{t}</td>
</tr>
<tr>
<td>(&lt;\leq)</td>
<td>less than or equal</td>
<td>\texttt{ARRAY[1,2,3]} &lt;\leq&gt; \texttt{ARRAY[1,2,3]}</td>
<td>\texttt{t}</td>
</tr>
<tr>
<td>(\geq)</td>
<td>greater than or equal</td>
<td>\texttt{ARRAY[1,4,3]} &gt;\geq&gt; \texttt{ARRAY[1,4,3]}</td>
<td>\texttt{t}</td>
</tr>
<tr>
<td>(\emptyset\gt)</td>
<td>contains</td>
<td>\texttt{ARRAY[1,4,3]} (\emptyset\gt) \texttt{ARRAY[3,1]}</td>
<td>\texttt{t}</td>
</tr>
<tr>
<td>(&lt;\emptyset)</td>
<td>is contained by</td>
<td>\texttt{ARRAY[2,7]} (&lt;\emptyset) \texttt{ARRAY[1,7,4,2,6]}</td>
<td>\texttt{t}</td>
</tr>
<tr>
<td>(&amp;&amp;)</td>
<td>overlap (have elements in common)</td>
<td>\texttt{ARRAY[1,4,3]} (&amp;&amp;) \texttt{ARRAY[2,1]}</td>
<td>\texttt{t}</td>
</tr>
<tr>
<td>(\mid\mid)</td>
<td>array-to-array concatenation</td>
<td>\texttt{ARRAY[1,2,3]} (\mid\mid) \texttt{ARRAY[4,5,6]}</td>
<td>{1,2,3,4,5,6}</td>
</tr>
</tbody>
</table>
## Chapter 9. Functions and Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>array-to-array concatenation</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>element-to-array concatenation</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>array-to-element concatenation</td>
</tr>
</tbody>
</table>

Array comparisons compare the array contents element-by-element, using the default B-Tree comparison function for the element data type. In multidimensional arrays the elements are visited in row-major order (last subscript varies most rapidly). If the contents of two arrays are equal but the dimensionality is different, the first difference in the dimensionality information determines the sort order. (This is a change from versions of PostgreSQL prior to 8.2: older versions would claim that two arrays with the same contents were equal, even if the number of dimensions or subscript ranges were different.)

See Section 8.14 for more details about array operator behavior.

Table 9-41 shows the functions available for use with array types. See Section 8.14 for more information and examples of the use of these functions.

### Table 9-41. Array Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>array_append</td>
<td>anyarray</td>
<td>append an element to the end of an array</td>
<td>array_append(ARRAY[1,2], 3)</td>
<td>ARRAY[1,2,3]</td>
</tr>
<tr>
<td>array_cat</td>
<td>anyarray</td>
<td>concatenate two arrays</td>
<td>array_cat(ARRAY[1,2,3], ARRAY[4,5])</td>
<td>{1,2,3,4,5}</td>
</tr>
<tr>
<td>array_ndims</td>
<td>int</td>
<td>returns the number of dimensions of the array</td>
<td>array_ndims(ARRAY[1,2,3], [4,5,6])</td>
<td>3</td>
</tr>
<tr>
<td>array_dims</td>
<td>text</td>
<td>returns a text representation of array’s dimensions</td>
<td>array_dims(ARRAY[1,2,3], [4,5,6])</td>
<td>{1,2,3}</td>
</tr>
<tr>
<td>array_fill</td>
<td>anyarray</td>
<td>returns an array initialized with supplied value and dimensions, optionally with lower bounds other than 1</td>
<td>array_fill(7, ARRAY[3], ARRAY[2])</td>
<td>[2:4]={7,7,7}</td>
</tr>
<tr>
<td>array_length</td>
<td>int</td>
<td>returns the length of the requested array dimension</td>
<td>array_length(ARRAY[1,2,3])</td>
<td>ARRAY[1]</td>
</tr>
</tbody>
</table>
### Chapter 9. Functions and Operators

#### 9.18. Aggregate Functions

*Aggregate functions* compute a single result from a set of input values. The built-in aggregate functions are listed in Table 9-42 and Table 9-43. The special syntax considerations for aggregate functions are explained in Section 4.2.7. Consult Section 2.7 for additional introductory information.

#### Table 9-42. General-Purpose Aggregate Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Argument Type</th>
<th>Return Type</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>array_agg(expression)</td>
<td>any</td>
<td>array of the argument type</td>
<td>input values concatenated into an array</td>
<td></td>
<td></td>
</tr>
<tr>
<td>avg(expression)</td>
<td>smallint, int, bigint, real, double precision, numeric, or interval</td>
<td>numeric for any integer-type argument, double precision for a floating-point argument, otherwise the same as the argument data type</td>
<td>the average (arithmetic mean) of all input values</td>
<td></td>
<td></td>
</tr>
<tr>
<td>bit_and(expression)</td>
<td>smallint, int, bigint, or bit</td>
<td>same as argument data type</td>
<td>the bitwise AND of all non-null input values, or null if none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
## Chapter 9. Functions and Operators

<table>
<thead>
<tr>
<th>Function</th>
<th>Argument Type</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bit_or(expression)</code></td>
<td><code>smallint, int, bigint, or bit</code></td>
<td>same as argument data type</td>
<td>the bitwise OR of all non-null input values, or null if none</td>
</tr>
<tr>
<td><code>bool_and(expression)</code></td>
<td><code>bool</code></td>
<td><code>bool</code></td>
<td>true if all input values are true, otherwise false</td>
</tr>
<tr>
<td><code>bool_or(expression)</code></td>
<td><code>bool</code></td>
<td><code>bool</code></td>
<td>true if at least one input value is true, otherwise false</td>
</tr>
<tr>
<td><code>count(*)</code></td>
<td></td>
<td><code>bigint</code></td>
<td>number of input rows</td>
</tr>
<tr>
<td><code>count(expression)</code></td>
<td><code>any</code></td>
<td><code>bigint</code></td>
<td>number of input rows for which the value of <code>expression</code> is not null</td>
</tr>
<tr>
<td><code>every(expression)</code></td>
<td><code>bool</code></td>
<td><code>bool</code></td>
<td>equivalent to <code>bool_and</code></td>
</tr>
<tr>
<td><code>max(expression)</code></td>
<td><code>any array, numeric, string, or date/time type</code></td>
<td>same as argument type</td>
<td>maximum value of <code>expression</code> across all input values</td>
</tr>
<tr>
<td><code>min(expression)</code></td>
<td><code>any array, numeric, string, or date/time type</code></td>
<td>same as argument type</td>
<td>minimum value of <code>expression</code> across all input values</td>
</tr>
<tr>
<td><code>sum(expression)</code></td>
<td><code>smallint, int, bigint, real, double precision, numeric, or interval</code></td>
<td><code>bigint</code> for <code>smallint</code> or <code>int</code> arguments, numeric for <code>bigint</code> arguments, double precision for floating-point arguments, otherwise the same as the argument data type</td>
<td>sum of <code>expression</code> across all input values</td>
</tr>
<tr>
<td><code>xmlagg(expression)</code></td>
<td><code>xml</code></td>
<td><code>xml</code></td>
<td>concatenation of XML values (see also Section 9.14.1.7)</td>
</tr>
</tbody>
</table>

It should be noted that except for `count`, these functions return a null value when no rows are selected. In particular, `sum` of no rows returns null, not zero as one might expect, and `array_agg` returns null rather than an empty array when there are no input rows. The `coalesce` function can be used to substitute zero or an empty array for null when necessary.

**Note:** Boolean aggregates `bool_and` and `bool_or` correspond to standard SQL aggregates `every` and `any` or `some`. As for `any` and `some`, it seems that there is an ambiguity built into the standard syntax:

```
SELECT b1 = ANY((SELECT b2 FROM t2 ...)) FROM t1 ...;
```

Here `ANY` can be considered either as introducing a subquery, or as being an aggregate function, if the sub-select returns one row with a boolean value. Thus the standard name cannot be given to these aggregates.
**Note:** Users accustomed to working with other SQL database management systems might be disappointed by the performance of the `count` aggregate when it is applied to the entire table. A query like:

```sql
SELECT count(*) FROM sometable;
```

will be executed by PostgreSQL using a sequential scan of the entire table.

The aggregate functions `array_agg` and `xmlagg`, as well as similar user-defined aggregate functions, produce meaningfully different result values depending on the order of the input values. In the current implementation, the order of the input is in principle unspecified. Supplying the input values from a sorted subquery will usually work, however. For example:

```sql
SELECT xmlagg(x) FROM (SELECT x FROM test ORDER BY y DESC) AS tab;
```

But this syntax is not allowed in the SQL standard, and is not portable to other database systems. A future version of PostgreSQL might provide an additional feature to control the order in a better-defined way (`xmlagg(expr ORDER BY expr, expr, ...)`).

Table 9-43 shows aggregate functions typically used in statistical analysis. (These are separated out merely to avoid cluttering the listing of more-commonly-used aggregates.) Where the description mentions \( N \), it means the number of input rows for which all the input expressions are non-null. In all cases, null is returned if the computation is meaningless, for example when \( N \) is zero.

<table>
<thead>
<tr>
<th>Function</th>
<th>Argument Type</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>corr(Y, X)</code></td>
<td>double precision</td>

<td>double precision</td>
<td>double precision</td>
<td>average of the dependent variable ( \frac{\sum(Y)}{N} )</td>
</tr>
<tr>
<td><code>regr_count(Y, X)</code></td>
<td>double precision</td>
<td>bigint</td>
<td>number of input rows in which both expressions are nonnull</td>
</tr>
<tr>
<td><code>regr_intercept(Y, X)</code></td>
<td>double precision</td>
<td>double precision</td>
<td>y-intercept of the least-squares-fit linear equation determined by the ( (X, Y) ) pairs</td>
</tr>
<tr>
<td><code>regr_r2(Y, X)</code></td>
<td>double precision</td>
<td>double precision</td>
<td>square of the correlation coefficient</td>
</tr>
</tbody>
</table>
## 9.19. Window Functions

*Window functions* provide the ability to perform calculations across sets of rows that are related to the current query row. See Section 3.5 for an introduction to this feature.

<table>
<thead>
<tr>
<th>Function</th>
<th>Argument Type</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>regr_slope(Y, X)</td>
<td>double precision</td>
<td>double precision</td>
<td>slope of the least-squares-fit linear equation determined by the ((X, Y)) pairs</td>
</tr>
<tr>
<td>regr_sxx(Y, X)</td>
<td>double precision</td>
<td>double precision</td>
<td>(\sum(X^2) - \frac{\sum(X)^2}{N}) (&quot;sum of squares&quot; of the independent variable)</td>
</tr>
<tr>
<td>regr_sxy(Y, X)</td>
<td>double precision</td>
<td>double precision</td>
<td>(\sum(X \times Y) - \frac{\sum(X) \times \sum(Y)}{N}) (&quot;sum of products&quot; of independent times dependent variable)</td>
</tr>
<tr>
<td>regr_syy(Y, X)</td>
<td>double precision</td>
<td>double precision</td>
<td>(\sum(Y^2) - \frac{\sum(Y)^2}{N}) (&quot;sum of squares&quot; of the dependent variable)</td>
</tr>
<tr>
<td>stddev(expression)</td>
<td>smallint, int, bigint, real, double precision, or numeric</td>
<td>double precision</td>
<td>historical alias for stddev_samp</td>
</tr>
<tr>
<td>stddev_pop(expression)</td>
<td>smallint, int, bigint, real, double precision, or numeric</td>
<td>double precision</td>
<td>population standard deviation of the input values</td>
</tr>
<tr>
<td>stddev_samp(expression)</td>
<td>smallint, int, bigint, real, double precision, or numeric</td>
<td>double precision</td>
<td>sample standard deviation of the input values</td>
</tr>
<tr>
<td>variance(expression)</td>
<td>smallint, int, bigint, real, double precision, or numeric</td>
<td>double precision</td>
<td>historical alias for var_samp</td>
</tr>
<tr>
<td>var_pop(expression)</td>
<td>smallint, int, bigint, real, double precision, or numeric</td>
<td>double precision</td>
<td>population variance of the input values (square of the population standard deviation)</td>
</tr>
<tr>
<td>var_samp(expression)</td>
<td>smallint, int, bigint, real, double precision, or numeric</td>
<td>double precision</td>
<td>sample variance of the input values (square of the sample standard deviation)</td>
</tr>
</tbody>
</table>
The built-in window functions are listed in Table 9-44. Note that these functions must be invoked using window function syntax; that is an OVER clause is required.

In addition to these functions, any built-in or user-defined aggregate function can be used as a window function (see Section 9.18 for a list of the built-in aggregates). Aggregate functions act as window functions only when an OVER clause follows the call; otherwise they act as regular aggregates.

Table 9-44. General-Purpose Window Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row_number()</td>
<td>bigint</td>
<td>number of the current row within its partition, counting from 1</td>
</tr>
<tr>
<td>rank()</td>
<td>bigint</td>
<td>rank of the current row with gaps; same as row_number of its first peer</td>
</tr>
<tr>
<td>dense_rank()</td>
<td>bigint</td>
<td>rank of the current row without gaps; this function counts peer groups</td>
</tr>
<tr>
<td>percent_rank()</td>
<td>double precision</td>
<td>relative rank of the current row: (rank - 1) / (total rows - 1)</td>
</tr>
<tr>
<td>cume_dist()</td>
<td>double precision</td>
<td>relative rank of the current row: (number of rows preceding or peer with current row) / (total rows)</td>
</tr>
<tr>
<td>ntile(num_buckets integer)</td>
<td>integer</td>
<td>integer ranging from 1 to the argument value, dividing the partition as equally as possible</td>
</tr>
<tr>
<td>lag(value any [, offset integer [, default any ]])</td>
<td>same type as value</td>
<td>returns value evaluated at the row that is offset rows before the current row within the partition; if there is no such row, instead return default. Both offset and default are evaluated with respect to the current row. If omitted, offset defaults to 1 and default to null</td>
</tr>
<tr>
<td>lead(value any [, offset integer [, default any ]])</td>
<td>same type as value</td>
<td>returns value evaluated at the row that is offset rows after the current row within the partition; if there is no such row, instead return default. Both offset and default are evaluated with respect to the current row. If omitted, offset defaults to 1 and default to null</td>
</tr>
<tr>
<td>Function</td>
<td>Return Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>------------------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>first_value (value any)</td>
<td>same type as value</td>
<td>returns value evaluated at the row that is the first row of the window frame</td>
</tr>
<tr>
<td>last_value (value any)</td>
<td>same type as value</td>
<td>returns value evaluated at the row that is the last row of the window frame</td>
</tr>
<tr>
<td>nth_value (value any, nth integer)</td>
<td>same type as value</td>
<td>returns value evaluated at the row that is the nth row of the window frame (counting from 1); null if no such row</td>
</tr>
</tbody>
</table>

All of the functions listed in Table 9-44 depend on the sort ordering specified by the ORDER BY clause of the associated window definition. Rows that are not distinct in the ORDER BY ordering are said to be peers; the four ranking functions are defined so that they give the same answer for any two peer rows.

Note that first_value, last_value, and nth_value consider only the rows within the “window frame”, which by default contains the rows from the start of the partition through the last peer of the current row. This is likely to give unhelpful results for nth_value and particularly last_value. You can redefine the frame as being the whole partition by adding ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING to the OVER clause. See Section 4.2.8 for more information.

When an aggregate function is used as a window function, it aggregates over the rows within the current row’s window frame. To obtain aggregation over the whole partition, omit ORDER BY or use ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING. An aggregate used with ORDER BY and the default window frame definition produces a “running sum” type of behavior, which may or may not be what’s wanted.

Note: The SQL standard defines a RESPECT NULLS or IGNORE NULLS option for lead, lag, first_value, last_value, and nth_value. This is not implemented in PostgreSQL: the behavior is always the same as the standard’s default, namely RESPECT NULLS. Likewise, the standard’s FROM FIRST or FROM LAST option for nth_value is not implemented: only the default FROM FIRST behavior is supported. (You can achieve the result of FROM LAST by reversing the ORDER BY ordering.)

## 9.20. Subquery Expressions

This section describes the SQL-compliant subquery expressions available in PostgreSQL. All of the expression forms documented in this section return Boolean (true/false) results.

### 9.20.1. EXISTS

**EXISTS (subquery)**

The argument of EXISTS is an arbitrary SELECT statement, or subquery. The subquery is evaluated to determine whether it returns any rows. If it returns at least one row, the result of EXISTS is “true”; if the subquery returns no rows, the result of EXISTS is “false”. 

---

228
Chapter 9. Functions and Operators

The subquery can refer to variables from the surrounding query, which will act as constants during any one evaluation of the subquery.

The subquery will generally only be executed long enough to determine whether at least one row is returned, not all the way to completion. It is unwise to write a subquery that has side effects (such as calling sequence functions); whether the side effects occur might be unpredictable.

Since the result depends only on whether any rows are returned, and not on the contents of those rows, the output list of the subquery is normally unimportant. A common coding convention is to write all EXISTS tests in the form EXISTS(SELECT 1 WHERE ...). There are exceptions to this rule however, such as subqueries that use INTERSECT.

This simple example is like an inner join on col2, but it produces at most one output row for each tab1 row, even if there are several matching tab2 rows:

```sql
SELECT col1
FROM tab1
WHERE EXISTS (SELECT 1 FROM tab2 WHERE col2 = tab1.col2);
```

### 9.20.2. IN

expression IN (subquery)

The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result. The result of IN is “true” if any equal subquery row is found. The result is “false” if no equal row is found (including the case where the subquery returns no rows).

Note that if the left-hand expression yields null, or if there are no equal right-hand values and at least one right-hand row yields null, the result of the IN construct will be null, not false. This is in accordance with SQL’s normal rules for Boolean combinations of null values.

As usual, null values in the rows are combined per the normal rules of SQL Boolean expressions. Two rows are considered equal if all their corresponding members are non-null and equal; the rows are unequal if any corresponding members are non-null and unequal; otherwise the result of that row comparison is unknown (null). If all the per-row results are either unequal or null, with at least one null, then the result of IN is null.

### 9.20.3. NOT IN

expression NOT IN (subquery)

The left-hand side of this form of IN is a row constructor, as described in Section 4.2.12. The right-hand side is a parenthesized subquery, which must return exactly as many columns as there are expressions in the left-hand row. The left-hand expressions are evaluated and compared row-wise to each row of the subquery result. The result of IN is “true” if any equal subquery row is found. The result is “false” if no equal row is found (including the case where the subquery returns no rows).

As usual, null values in the rows are combined per the normal rules of SQL Boolean expressions. Two rows are considered equal if all their corresponding members are non-null and equal; the rows are unequal if any corresponding members are non-null and unequal; otherwise the result of that row comparison is unknown (null). If all the per-row results are either unequal or null, with at least one null, then the result of IN is null.
Chapter 9. Functions and Operators

The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result. The result of \texttt{NOT IN} is “true” if only unequal subquery rows are found (including the case where the subquery returns no rows). The result is “false” if any equal row is found.

Note that if the left-hand expression yields null, or if there are no equal right-hand values and at least one right-hand row yields null, the result of the \texttt{NOT IN} construct will be null, not true. This is in accordance with SQL’s normal rules for Boolean combinations of null values.

As with \texttt{EXISTS}, it’s unwise to assume that the subquery will be evaluated completely.

\begin{verbatim}
row_constructor NOT IN (subquery)
\end{verbatim}

The left-hand side of this form of \texttt{NOT IN} is a row constructor, as described in Section 4.2.12. The right-hand side is a parenthesized subquery, which must return exactly as many columns as there are expressions in the left-hand row. The left-hand expressions are evaluated and compared row-wise to each row of the subquery result. The result of \texttt{NOT IN} is “true” if only unequal subquery rows are found (including the case where the subquery returns no rows). The result is “false” if any equal row is found.

As usual, null values in the rows are combined per the normal rules of SQL Boolean expressions. Two rows are considered equal if all their corresponding members are non-null and equal; the rows are unequal if any corresponding members are non-null and unequal; otherwise the result of that row comparison is unknown (null). If all the per-row results are either unequal or null, with at least one null, then the result of \texttt{NOT IN} is null.

9.20.4. ANY/SOME

\begin{verbatim}
expression operator ANY (subquery)
expression operator SOME (subquery)
\end{verbatim}

The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result using the given \texttt{operator}, which must yield a Boolean result. The result of \texttt{ANY} is “true” if any true result is obtained. The result is “false” if no true result is found (including the case where the subquery returns no rows).

\texttt{SOME} is a synonym for \texttt{ANY}. \texttt{IN} is equivalent to = \texttt{ANY}.

Note that if there are no successes and at least one right-hand row yields null for the operator’s result, the result of the \texttt{ANY} construct will be null, not false. This is in accordance with SQL’s normal rules for Boolean combinations of null values.

As with \texttt{EXISTS}, it’s unwise to assume that the subquery will be evaluated completely.

\begin{verbatim}
row_constructor operator ANY (subquery)
row_constructor operator SOME (subquery)
\end{verbatim}

The left-hand side of this form of \texttt{ANY} is a row constructor, as described in Section 4.2.12. The right-hand side is a parenthesized subquery, which must return exactly as many columns as there are expressions in the left-hand row. The left-hand expressions are evaluated and compared row-wise to each row of the subquery result, using the given \texttt{operator}. The result of \texttt{ANY} is “true” if the comparison returns true for any subquery row. The result is “false” if the comparison returns false for every subquery row (including the case where the subquery returns no rows). The result is NULL if the comparison does not return true for any row, and it returns NULL for at least one row.

See Section 9.21.5 for details about the meaning of a row-wise comparison.
Chapter 9. Functions and Operators

9.20.5. ALL

expression operator ALL (subquery)

The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand
expression is evaluated and compared to each row of the subquery result using the given operator,
which must yield a Boolean result. The result of \texttt{ALL} is “true” if all rows yield true (including the case
where the subquery returns no rows). The result is “false” if any false result is found. The result is
NULL if the comparison does not return false for any row, and it returns NULL for at least one row.

\texttt{NOT IN} is equivalent to \texttt{<> ALL}.

As with \texttt{EXISTS}, it’s unwise to assume that the subquery will be evaluated completely.

row_constructor operator ALL (subquery)

The left-hand side of this form of \texttt{ALL} is a row constructor, as described in Section 4.2.12. The
right-hand side is a parenthesized subquery, which must return exactly as many columns as there
are expressions in the left-hand row. The left-hand expressions are evaluated and compared row-wise
to each row of the subquery result, using the given operator. The result of \texttt{ALL} is “true” if the
comparison returns true for all subquery rows (including the case where the subquery returns no
rows). The result is “false” if the comparison returns false for any subquery row. The result is NULL
if the comparison does not return false for any subquery row, and it returns NULL for at least one row.

See Section 9.21.5 for details about the meaning of a row-wise comparison.

9.20.6. Row-wise Comparison

row_constructor operator (subquery)

The left-hand side is a row constructor, as described in Section 4.2.12. The right-hand side is a paren-
thesized subquery, which must return exactly as many columns as there are expressions in the left-
hand row. Furthermore, the subquery cannot return more than one row. (If it returns zero rows, the
result is taken to be null.) The left-hand side is evaluated and compared row-wise to the single sub-
query result row.

See Section 9.21.5 for details about the meaning of a row-wise comparison.

9.21. Row and Array Comparisons

This section describes several specialized constructs for making multiple comparisons between groups
of values. These forms are syntactically related to the subquery forms of the previous section, but do
not involve subqueries. The forms involving array subexpressions are PostgreSQL extensions; the rest
are SQL-compliant. All of the expression forms documented in this section return Boolean (true/false)
results.

9.21.1. IN

expression IN \{value [, ...]\}

The right-hand side is a parenthesized list of scalar expressions. The result is “true” if the left-hand expression’s result is equal to any of the right-hand expressions. This is a shorthand notation for

```
expression = value1
OR
expression = value2
OR
...
```

Note that if the left-hand expression yields null, or if there are no equal right-hand values and at least one right-hand expression yields null, the result of the \texttt{IN} construct will be null, not false. This is in accordance with SQL’s normal rules for Boolean combinations of null values.

### 9.21.2. \texttt{NOT IN}

```
expression \texttt{NOT IN} (value [, ...])
```

The right-hand side is a parenthesized list of scalar expressions. The result is “true” if the left-hand expression’s result is unequal to all of the right-hand expressions. This is a shorthand notation for

```
expression <> value1
AND
expression <> value2
AND
...
```

Note that if the left-hand expression yields null, or if there are no equal right-hand values and at least one right-hand expression yields null, the result of the \texttt{NOT IN} construct will be null, not true as one might naively expect. This is in accordance with SQL’s normal rules for Boolean combinations of null values.

**Tip:** \(x \text{ NOT IN } y\) is equivalent to \(\text{NOT (x IN y)}\) in all cases. However, null values are much more likely to trip up the novice when working with \texttt{NOT IN} than when working with \texttt{IN}. It is best to express your condition positively if possible.

### 9.21.3. \texttt{ANY/SOME (array)}

```
expression \texttt{operator ANY} (array expression)
```

The right-hand side is a parenthesized expression, which must yield an array value. The left-hand expression is evaluated and compared to each element of the array using the given \texttt{operator}, which must yield a Boolean result. The result of \texttt{ANY} is “true” if any true result is obtained. The result is “false” if no true result is found (including the case where the array has zero elements).

If the array expression yields a null array, the result of \texttt{ANY} will be null. If the left-hand expression yields null, the result of \texttt{ANY} is ordinarily null (though a non-strict comparison operator could possibly...
yield a different result). Also, if the right-hand array contains any null elements and no true comparison result is obtained, the result of \texttt{ANY} will be null, not false (again, assuming a strict comparison operator). This is in accordance with SQL’s normal rules for Boolean combinations of null values. \texttt{SOME} is a synonym for \texttt{ANY}.

9.21.4. \texttt{ALL} (array)

expression \texttt{operator} \texttt{ALL} (array expression)

The right-hand side is a parenthesized expression, which must yield an array value. The left-hand expression is evaluated and compared to each element of the array using the given \texttt{operator}, which must yield a Boolean result. The result of \texttt{ALL} is “true” if all comparisons yield true (including the case where the array has zero elements). The result is “false” if any false result is found.

If the array expression yields a null array, the result of \texttt{ALL} will be null. If the left-hand expression yields null, the result of \texttt{ALL} is ordinarily null (though a non-strict comparison operator could possibly yield a different result). Also, if the right-hand array contains any null elements and no false comparison result is obtained, the result of \texttt{ALL} will be null, not true (again, assuming a strict comparison operator). This is in accordance with SQL’s normal rules for Boolean combinations of null values.

9.21.5. Row-wise Comparison

row_constructor \texttt{operator} row_constructor

Each side is a row constructor, as described in Section 4.2.12. The two row values must have the same number of fields. Each side is evaluated and they are compared row-wise. Row comparisons are allowed when the \texttt{operator} is \(=\), \(<\), \(\leq\), \(\langle\), \(\geq\) or \(\rangle\), or has semantics similar to one of these. (To be specific, an operator can be a row comparison operator if it is a member of a B-Tree operator class, or is the negator of the \(=\) member of a B-Tree operator class.)

The \(=\) and \(<\) cases work slightly differently from the others. Two rows are considered equal if all their corresponding members are non-null and equal; the rows are unequal if any corresponding members are non-null and unequal; otherwise the result of the row comparison is unknown (null).

For the \(=\), \(\langle\), \(\rangle\) cases, the row elements are compared left-to-right, stopping as soon as an unequal or null pair of elements is found. If either of this pair of elements is null, the result of the row comparison is unknown (null); otherwise comparison of this pair of elements determines the result. For example, \(\text{ROW}(1,2,\text{NULL}) \text{<} \text{ROW}(1,3,0)\) yields true, not null, because the third pair of elements are not considered.

\textbf{Note:} Prior to PostgreSQL 8.2, the \(=\), \(\langle\), \(\rangle\) cases were not handled per SQL specification. A comparison \(\text{ROW}(a,b) \text{<} \text{ROW}(c,d)\) was implemented as \(a < c \text{ AND } b < d\) whereas the correct behavior is equivalent to \(a < c \text{ OR } (a = c \text{ AND } b < d)\).

row_constructor \texttt{IS DISTINCT FROM} row_constructor

This construct is similar to a \(<\) row comparison, but it does not yield null for null inputs. Instead, any null value is considered unequal to (distinct from) any non-null value, and any two nulls are considered equal (not distinct). Thus the result will either be true or false, never null.

row_constructor \texttt{IS NOT DISTINCT FROM} row_constructor
This construct is similar to a <= row comparison, but it does not yield null for null inputs. Instead, any null value is considered unequal to (distinct from) any non-null value, and any two nulls are considered equal (not distinct). Thus the result will always be either true or false, never null.

**Note:** The SQL specification requires row-wise comparison to return NULL if the result depends on comparing two NULL values or a NULL and a non-NULL. PostgreSQL does this only when comparing the results of two row constructors or comparing a row constructor to the output of a subquery (as in Section 9.20). In other contexts where two composite-type values are compared, two NULL field values are considered equal, and a NULL is considered larger than a non-NULL. This is necessary in order to have consistent sorting and indexing behavior for composite types.

### 9.22. Set Returning Functions

This section describes functions that possibly return more than one row. Currently the only functions in this class are series generating functions, as detailed in Table 9-45 and Table 9-46.

**Table 9-45. Series Generating Functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Argument Type</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>generate_series(start, stop)</td>
<td>int or bigint</td>
<td>setof int or setof bigint (same as argument type)</td>
<td>Generate a series of values, from start to stop with a step size of one</td>
</tr>
<tr>
<td>generate_series(start, stop, step)</td>
<td>int or bigint</td>
<td>setof int or setof bigint (same as argument type)</td>
<td>Generate a series of values, from start to stop with a step size of step</td>
</tr>
<tr>
<td>generate_series(start, stop, step interval)</td>
<td>timestamp or timestamp with time zone</td>
<td>setof timestamp or setof timestamp with time zone (same as argument type)</td>
<td>Generate a series of values, from start to stop with a step size of step</td>
</tr>
</tbody>
</table>

When `step` is positive, zero rows are returned if `start` is greater than `stop`. Conversely, when `step` is negative, zero rows are returned if `start` is less than `stop`. Zero rows are also returned for NULL inputs. It is an error for `step` to be zero. Some examples follow:

```
SELECT * FROM generate_series(2,4);
generate_series
-----------------
  2
  3
  4
(3 rows)

SELECT * FROM generate_series(5,1,-2);
generate_series
-----------------
  5
```

234

```sql
SELECT * FROM generate_series(4,3);
generate_series
-----------------
(0 rows)
```

-- this example relies on the date-plus-integer operator
SELECT current_date + s.a AS dates FROM generate_series(0,14,7) AS s(a);
dates
---------
2004-02-05
2004-02-12
2004-02-19
(3 rows)

SELECT * FROM generate_series(’2008-03-01 00:00’::timestamp,
’2008-03-04 12:00’, ’10 hours’);
generate_series
---------------------
2008-03-01 00:00:00
2008-03-01 10:00:00
2008-03-01 20:00:00
2008-03-02 06:00:00
2008-03-02 16:00:00
2008-03-03 02:00:00
2008-03-03 12:00:00
2008-03-03 22:00:00
2008-03-04 08:00:00
(9 rows)

Table 9-46. Subscript Generating Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>generate_subscripts(array anyarray, dim int)</td>
<td>setof int</td>
<td>Generate a series comprising the given array’s subscripts.</td>
</tr>
<tr>
<td>generate_subscripts(array anyarray, dim int, reverse boolean)</td>
<td>setof int</td>
<td>Generate a series comprising the given array’s subscripts. When reverse is true, the series is returned in reverse order.</td>
</tr>
</tbody>
</table>

generate_subscripts is a convenience function that generates the set of valid subscripts for the specified dimension of the given array. Zero rows are returned for arrays that do not have the requested dimension, or for NULL arrays (but valid subscripts are returned for NULL array elements). Some examples follow:

-- basic usage
select generate_subscripts(’{NULL,1,NULL,2}’::int[], 1) as s;
s
---
Chapter 9. Functions and Operators

9.23. System Information Functions

Table 9-47 shows several functions that extract session and system information.

In addition to the functions listed in this section, there are a number of functions related to the statistics system that also provide system information. See Section 26.2.2 for more information.
<table>
<thead>
<tr>
<th>Name</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>current_catalog</td>
<td>name</td>
<td>name of current database (called “catalog” in the SQL standard)</td>
</tr>
<tr>
<td>current_database()</td>
<td>name</td>
<td>name of current database</td>
</tr>
<tr>
<td>current_schema[]</td>
<td>name</td>
<td>name of current schema</td>
</tr>
<tr>
<td>current_schemas(boolean)</td>
<td>name[]</td>
<td>names of schemas in search path, optionally including implicit schemas</td>
</tr>
<tr>
<td>current_user</td>
<td>name</td>
<td>user name of current execution context</td>
</tr>
<tr>
<td>current_query()</td>
<td>text</td>
<td>text of the currently executing query, as submitted by the client (might contain more than one statement)</td>
</tr>
<tr>
<td>pg_backend_pid()</td>
<td>int</td>
<td>Process ID of the server process attached to the current session</td>
</tr>
<tr>
<td>inet_client_addr()</td>
<td>inet</td>
<td>address of the remote connection</td>
</tr>
<tr>
<td>inet_client_port()</td>
<td>int</td>
<td>port of the remote connection</td>
</tr>
<tr>
<td>inet_server_addr()</td>
<td>inet</td>
<td>address of the local connection</td>
</tr>
<tr>
<td>inet_server_port()</td>
<td>int</td>
<td>port of the local connection</td>
</tr>
<tr>
<td>pg_my_temp_schema()</td>
<td>oid</td>
<td>OID of session’s temporary schema, or 0 if none</td>
</tr>
<tr>
<td>pg_is_other_temp_schema(oid)</td>
<td>Boolean</td>
<td>is schema another session’s temporary schema?</td>
</tr>
<tr>
<td>pg_postmaster_start_time()</td>
<td>timestamp with time zone</td>
<td>server start time</td>
</tr>
<tr>
<td>pg_conf_load_time()</td>
<td>timestamp with time zone</td>
<td>configuration load time</td>
</tr>
<tr>
<td>session_user</td>
<td>name</td>
<td>session user name</td>
</tr>
<tr>
<td>user</td>
<td>name</td>
<td>equivalent to current_user</td>
</tr>
<tr>
<td>version()</td>
<td>text</td>
<td>PostgreSQL version information</td>
</tr>
</tbody>
</table>

**Note:** current_catalog, current_schema, current_user, session_user, and user have special syntactic status in SQL: they must be called without trailing parentheses. (In PostgreSQL, parentheses can optionally be used with current_schema, but not with the others.)

The session_user is normally the user who initiated the current database connection; but superusers can change this setting with SET SESSION AUTHORIZATION. The current_user is the user identifier that is applicable for permission checking. Normally it is equal to the session user, but
Chapter 9. Functions and Operators

it can be changed with `SET ROLE`. It also changes during the execution of functions with the attribute
`SECURITY DEFINER`. In Unix parlance, the session user is the “real user” and the current user is the
“effective user”.

current_schema returns the name of the schema that is first in the search path (or a null value if the
search path is empty). This is the schema that will be used for any tables or other named objects that
are created without specifying a target schema. current_schemas(boolean) returns an array of
the names of all schemas presently in the search path. The Boolean option determines whether or not
implicitly included system schemas such as `pg_catalog` are included in the returned search path.

**Note:** The search path can be altered at run time. The command is:

```sql
SET search_path TO schema [, schema, ...]
```

`inet_client_addr` returns the IP address of the current client, and `inet_client_port` returns
the port number. `inet_server_addr` returns the IP address on which the server accepted the current
connection, and `inet_server_port` returns the port number. All these functions return NULL if the
current connection is via a Unix-domain socket.

`pg_my_temp_schema` returns the OID of the current session’s temporary schema, or zero if it has
none (because it has not created any temporary tables). `pg_is_other_temp_schema` returns true if
the given OID is the OID of another session’s temporary schema. (This can be useful, for example, to
exclude other sessions’ temporary tables from a catalog display.)

`pg_postmaster_start_time` returns the `timestamp with time zone` when the server started.

`pg_conf_load_time` returns the `timestamp with time zone` when the server configuration
files were last loaded. (If the current session was alive at the time, this will be the time when the
session itself re-read the configuration files, so the reading will vary a little in different sessions.
Otherwise it is the time when the postmaster process re-read the configuration files.)

`version` returns a string describing the PostgreSQL server’s version.

Table 9-48 lists functions that allow the user to query object access privileges programmatically. See
Section 5.6 for more information about privileges.

### Table 9-48. Access Privilege Inquiry Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>has_any_column_privilege(user, table, privilege)</code></td>
<td><code>boolean</code></td>
<td>does user have privilege for any column of table</td>
</tr>
<tr>
<td><code>has_any_column_privilege(table)</code></td>
<td><code>boolean</code></td>
<td>does current user have privilege for any column of table</td>
</tr>
<tr>
<td><code>has_column_privilege(user, table, column, privilege)</code></td>
<td><code>boolean</code></td>
<td>does user have privilege for column</td>
</tr>
<tr>
<td><code>has_column_privilege(table, column, privilege)</code></td>
<td><code>boolean</code></td>
<td>does current user have privilege for column</td>
</tr>
<tr>
<td><code>has_database privilege(user, database, privilege)</code></td>
<td><code>boolean</code></td>
<td>does user have privilege for database</td>
</tr>
</tbody>
</table>
## Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>has_database_privilege</code> (database, privilege)</td>
<td>boolean</td>
<td>does current user have privilege for database</td>
</tr>
<tr>
<td><code>has_foreign_data_wrapper_privilege</code> (user, fdw, privilege)</td>
<td>boolean</td>
<td>does user have privilege for foreign-data wrapper</td>
</tr>
<tr>
<td><code>has_foreign_data_wrapper_privilege</code> (fdw, privilege)</td>
<td>boolean</td>
<td>does current user have privilege for foreign-data wrapper</td>
</tr>
<tr>
<td><code>has_function_privilege</code> (user, function, privilege)</td>
<td>boolean</td>
<td>does user have privilege for function</td>
</tr>
<tr>
<td><code>has_function_privilege</code> (function, privilege)</td>
<td>boolean</td>
<td>does current user have privilege for function</td>
</tr>
<tr>
<td><code>has_language_privilege</code> (user, language, privilege)</td>
<td>boolean</td>
<td>does user have privilege for language</td>
</tr>
<tr>
<td><code>has_language_privilege</code> (language, privilege)</td>
<td>boolean</td>
<td>does current user have privilege for language</td>
</tr>
<tr>
<td><code>has_schema_privilege</code> (user, schema, privilege)</td>
<td>boolean</td>
<td>does user have privilege for schema</td>
</tr>
<tr>
<td><code>has_schema_privilege</code> (schema, privilege)</td>
<td>boolean</td>
<td>does current user have privilege for schema</td>
</tr>
<tr>
<td><code>has_server_privilege</code> (user, server, privilege)</td>
<td>boolean</td>
<td>does user have privilege for foreign server</td>
</tr>
<tr>
<td><code>has_server_privilege</code> (server, privilege)</td>
<td>boolean</td>
<td>does current user have privilege for foreign server</td>
</tr>
<tr>
<td><code>has_table_privilege</code> (user, table, privilege)</td>
<td>boolean</td>
<td>does user have privilege for table</td>
</tr>
<tr>
<td><code>has_table_privilege</code> (table, privilege)</td>
<td>boolean</td>
<td>does current user have privilege for table</td>
</tr>
<tr>
<td><code>has_tablespace_privilege</code> (user, tablespace, privilege)</td>
<td>boolean</td>
<td>does user have privilege for tablespace</td>
</tr>
<tr>
<td><code>has_tablespace_privilege</code> (tablespace, privilege)</td>
<td>boolean</td>
<td>does current user have privilege for tablespace</td>
</tr>
<tr>
<td><code>pg_has_role</code> (user, role, privilege)</td>
<td>boolean</td>
<td>does user have privilege for role</td>
</tr>
<tr>
<td><code>pg_has_role</code> (role, privilege)</td>
<td>boolean</td>
<td>does current user have privilege for role</td>
</tr>
</tbody>
</table>

`has_table_privilege` checks whether a user can access a table in a particular way. The user can be specified by name or by OID (`pg_authid.oid`), or if the argument is omitted `current_user` is assumed. The table can be specified by name or by OID. (Thus, there are actually six variants of `has_table_privilege`, which can be distinguished by the number and types of their arguments.) When specifying by name, the name can be schema-qualified if necessary. The desired access privilege type is specified by a text string, which must evaluate to one of the values `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, `REFERENCES`, or `TRIGGER`. Optionally, `WITH GRANT OPTION` can be added to a privilege type to test whether the privilege is held with grant option. Also, multiple privilege types can be listed separated by commas, in which case the result will be `true` if any of the listed privileges is held. (Case of the privilege string is not significant, and extra whitespace is allowed between but not within privilege names.) Some examples:

```sql
SELECT has_table_privilege('myschema.mytable', 'select');
```
has_any_column_privilege checks whether a user can access any column of a table in a particular way. Its argument possibilities are analogous to has_table_privilege, except that the desired access privilege type must evaluate to some combination of SELECT, INSERT, UPDATE, or REFERENCES. Note that having any of these privileges at the table level implicitly grants it for each column of the table, so has_any_column_privilege will always return true if has_table_privilege does for the same arguments. But has_any_column_privilege also succeeds if there is a column-level grant of the privilege for at least one column.

has_column_privilege checks whether a user can access a column in a particular way. Its argument possibilities are analogous to has_table_privilege, with the addition that the column can be specified either by name or attribute number. The desired access privilege type must evaluate to some combination of SELECT, INSERT, UPDATE, or REFERENCES. Note that having any of these privileges at the table level implicitly grants it for each column of the table.

has_database_privilege checks whether a user can access a database in a particular way. Its argument possibilities are analogous to has_table_privilege. The desired access privilege type must evaluate to some combination of CREATE, CONNECT, TEMPORARY, or TEMP (which is equivalent to TEMPORARY).

has_function_privilege checks whether a user can access a function in a particular way. Its argument possibilities are analogous to has_table_privilege. When specifying a function by a text string rather than by OID, the allowed input is the same as for the regprocedure data type (see Section 8.16). The desired access privilege type must evaluate to EXECUTE. An example is:

```
SELECT has_function_privilege('joeuser', 'myfunc(int, text)', 'execute');
```

has_foreign_data_wrapper_privilege checks whether a user can access a foreign-data wrapper in a particular way. Its argument possibilities are analogous to has_table_privilege. The desired access privilege type must evaluate to USAGE.

has_language_privilege checks whether a user can access a procedural language in a particular way. Its argument possibilities are analogous to has_table_privilege. The desired access privilege type must evaluate to USAGE.

has_schema_privilege checks whether a user can access a schema in a particular way. Its argument possibilities are analogous to has_table_privilege. The desired access privilege type must evaluate to some combination of CREATE or USAGE.

has_server_privilege checks whether a user can access a foreign server in a particular way. Its argument possibilities are analogous to has_table_privilege. The desired access privilege type must evaluate to USAGE.

has_tablespace_privilege checks whether a user can access a tablespace in a particular way. Its argument possibilities are analogous to has_table_privilege. The desired access privilege type must evaluate to CREATE.

pg_has_role checks whether a user can access a role in a particular way. Its argument possibilities are analogous to has_table_privilege. The desired access privilege type must evaluate to some combination of MEMBER or USAGE. MEMBER denotes direct or indirect membership in the role (that is, the right to do SET ROLE), while USAGE denotes whether the privileges of the role are immediately available without doing SET ROLE.
Chapter 9. Functions and Operators

Table 9-49 shows functions that determine whether a certain object is visible in the current schema search path. For example, a table is said to be visible if its containing schema is in the search path and no table of the same name appears earlier in the search path. This is equivalent to the statement that the table can be referenced by name without explicit schema qualification. To list the names of all visible tables:

```
SELECT relname FROM pg_class WHERE pg_table_is_visible(oid);
```

<table>
<thead>
<tr>
<th>Name</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pg_conversion_is_visible</td>
<td>boolean</td>
<td>is conversion visible in search path</td>
</tr>
<tr>
<td>pg_function_is_visible</td>
<td>boolean</td>
<td>is function visible in search path</td>
</tr>
<tr>
<td>pg_operator_is_visible</td>
<td>boolean</td>
<td>is operator visible in search path</td>
</tr>
<tr>
<td>pg_opclass_is_visible</td>
<td>boolean</td>
<td>is operator class visible in search path</td>
</tr>
<tr>
<td>pg_table_is_visible</td>
<td>boolean</td>
<td>is table visible in search path</td>
</tr>
<tr>
<td>pg_ts_config_is_visible</td>
<td>boolean</td>
<td>is text search configuration visible in search path</td>
</tr>
<tr>
<td>pg_ts_dict_is_visible</td>
<td>boolean</td>
<td>is text search dictionary visible in search path</td>
</tr>
<tr>
<td>pg_ts_parser_is_visible</td>
<td>boolean</td>
<td>is text search parser visible in search path</td>
</tr>
<tr>
<td>pg_ts_template_is_visible</td>
<td>boolean</td>
<td>is text search template visible in search path</td>
</tr>
<tr>
<td>pg_type_is_visible</td>
<td>boolean</td>
<td>is type (or domain) visible in search path</td>
</tr>
</tbody>
</table>

Each function performs the visibility check for one type of database object. Note that `pg_table_is_visible` can also be used with views, indexes and sequences; `pg_type_is_visible` can also be used with domains. For functions and operators, an object in the search path is visible if there is no object of the same name and argument data type(s) earlier in the path. For operator classes, both name and associated index access method are considered.

All these functions require object OIDs to identify the object to be checked. If you want to test an object by name, it is convenient to use the OID alias types (`regclass`, `regtype`, `regprocedure`, `regoperator`, `regconfig`, or `regdictionary`), for example:

```
SELECT pg_type_is_visible('myschema.widget'::regtype);
```

Note that it would not make much sense to test a non-schema-qualified type name in this way — if the name can be recognized at all, it must be visible.

Table 9-50 lists functions that extract information from the system catalogs.

</tr>
</tbody>
</table>

format_type returns the SQL name of a data type that is identified by its type OID and possibly a type modifier. Pass NULL for the type modifier if no specific modifier is known.

pg_get_keywords returns a set of records describing the SQL keywords recognized by the server. The word column contains the keyword. The catcode column contains a category code: U for unreserved, C for column name, T for type or function name, or R for reserved. The catdesc column contains a possibly-localized string describing the category.

pg_get_constraintdef, pg_get_indexdef, pg_get_ruledef, and pg_get_triggerdef, respectively reconstruct the creating command for a constraint, index, rule, or trigger. (Note that this is a decompiled reconstruction, not the original text of the command.) pg_get_expr decompiles the internal form of an individual expression, such as the default value for a column. It can be useful when examining the contents of system catalogs. If the expression might contain Vars, specify the OID of the relation they refer to as the second parameter; if no Vars are expected, zero is sufficient.

pg_get_viewdef reconstructs the SELECT query that defines a view. Most of these functions come in two variants, one of which can optionally “pretty-print” the result. The pretty-printed format is more readable, but the default format is more likely to be interpreted the same way by future versions of PostgreSQL; avoid using pretty-printed output for dump purposes. Passing false for the pretty-print parameter yields the same result as the variant that does not have the parameter at all.

pg_get_functiondef returns a complete CREATE OR REPLACE FUNCTION statement for a function. pg_get_function_arguments returns the argument list of a function, in the form it would need to appear in within CREATE FUNCTION. pg_get_function_result similarly returns the appropriate RETURNS clause for the function. pg_get_function_identity_arguments returns the argument list necessary to identify a function, in the form it would need to appear in within ALTER FUNCTION, for instance. This form omits default values.

pg_get_serial_sequence returns the name of the sequence associated with a column, or NULL if no sequence is associated with the column. The first input parameter is a table name with optional schema, and the second parameter is a column name. Because the first parameter is potentially a schema and table, it is not treated as a double-quoted identifier, meaning it is lowercased by default, while the second parameter, being just a column name, is treated as double-quoted and has its case preserved. The function returns a value suitably formatted for passing to sequence functions (see Section 9.15). This association can be modified or removed with ALTER SEQUENCE OWNED BY. (The function probably should have been called pg_get_owned_sequence; its current name reflects the fact that it’s typically used with serial or bigserial columns.)
Chapter 9. Functions and Operators

pg_get_userbyid extracts a role's name given its OID.

pg_tablespace_databases allows a tablespace to be examined. It returns the set of OIDs of databases that have objects stored in the tablespace. If this function returns any rows, the tablespace is not empty and cannot be dropped. To display the specific objects populating the tablespace, you will need to connect to the databases identified by pg_tablespace_databases and query their pg_class catalogs.

pg_typeof returns the OID of the data type of the value that is passed to it. This can be helpful for troubleshooting or dynamically constructing SQL queries. The function is declared as returning regtype, which is an OID alias type (see Section 8.16); this means that it is the same as an OID for comparison purposes but displays as a type name. For example:

```sql
SELECT pg_typeof(33);
```

```
pg_typeof
-------------
integer
(1 row)
```

```sql
SELECT typlen FROM pg_type WHERE oid = pg_typeof(33);
```

```
typlen
--------
   4
(1 row)
```

The functions shown in Table 9-51 extract comments previously stored with the COMMENT command. A null value is returned if no comment could be found for the specified parameters.

### Table 9-51. Comment Information Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>col_description(table_oid, column_number)</td>
<td>text</td>
<td>get comment for a table column</td>
</tr>
<tr>
<td>obj_description(object_oid, catalog_name)</td>
<td>text</td>
<td>get comment for a database object</td>
</tr>
<tr>
<td>obj_description(object_oid)</td>
<td>text</td>
<td>get comment for a database object (deprecated)</td>
</tr>
<tr>
<td>shobj_description(object_oid, catalog_name)</td>
<td>text</td>
<td>get comment for a shared database object</td>
</tr>
</tbody>
</table>

col_description returns the comment for a table column, which is specified by the OID of its table and its column number. obj_description cannot be used for table columns since columns do not have OIDs of their own.

The two-parameter form of obj_description returns the comment for a database object specified by its OID and the name of the containing system catalog. For example, obj_description(123456,'pg_class') would retrieve the comment for the table with OID 123456. The one-parameter form of obj_description requires only the object OID. It is deprecated since there is no guarantee that OIDs are unique across different system catalogs; therefore, the wrong comment might be returned.

shobj_description is used just like obj_description except it is used for retrieving comments on shared objects. Some system catalogs are global to all databases within each cluster and their
Chapter 9. Functions and Operators

descriptions are stored globally as well.

The functions shown in Table 9-52 provide server transaction information in an exportable form. The main use of these functions is to determine which transactions were committed between two snapshots.

Table 9-52. Transaction IDs and snapshots

<table>
<thead>
<tr>
<th>Name</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>txid_current()</td>
<td>bigint</td>
<td>get current transaction ID</td>
</tr>
<tr>
<td>txid_current_snapshot()</td>
<td>txid_snapshot</td>
<td>get current snapshot</td>
</tr>
<tr>
<td>txid_snapshot_xmin(txid_snap)</td>
<td>bigint</td>
<td>get xmin of snapshot</td>
</tr>
<tr>
<td>txid_snapshot_xmax(txid_snap)</td>
<td>bigint</td>
<td>get xmax of snapshot</td>
</tr>
<tr>
<td>txid_snapshot_xip(txid_snap)</td>
<td>setof bigint</td>
<td>get in-progress transaction IDs in snapshot</td>
</tr>
<tr>
<td>txid_visible_in_snapshot(txid_snap)</td>
<td>boolean</td>
<td>is transaction ID visible in snapshot? (do not use with subtransaction ids)</td>
</tr>
</tbody>
</table>

The internal transaction ID type (xid) is 32 bits wide and wraps around every 4 billion transactions. However, these functions export a 64-bit format that is extended with an “epoch” counter so it will not wrap around during the life of an installation. The data type used by these functions, txid_snapshot, stores information about transaction ID visibility at a particular moment in time. Its components are described in Table 9-53.

Table 9-53. Snapshot components

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xmin</td>
<td>Earliest transaction ID (txid) that is still active. All earlier transactions will either be committed and visible, or rolled back and dead.</td>
</tr>
<tr>
<td>xmax</td>
<td>First as-yet-unassigned txid. All txids greater than or equal to this are not yet started as of the time of the snapshot, and thus invisible.</td>
</tr>
<tr>
<td>xip_list</td>
<td>Active txids at the time of the snapshot. The list includes only those active txids between xmin and xmax; there might be active txids higher than xmax. A txid that is xmin &lt;= txid &lt; xmax and not in this list was already completed at the time of the snapshot, and thus either visible or dead according to its commit status. The list does not include txids of subtransactions.</td>
</tr>
</tbody>
</table>

txid_snapshot’s textual representation is xmin:xmax:xip_list. For example 10:20:10,14,15 means xmin=10, xmax=20, xip_list=10, 14, 15.
Table 9-54 shows the functions available to query and alter run-time configuration parameters.

**Table 9-54. Configuration Settings Functions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>current_setting(setting_name)</td>
<td>text</td>
<td>get current value of setting</td>
</tr>
<tr>
<td>set_config(setting_name, new_value, is_local)</td>
<td>text</td>
<td>set parameter and return new value</td>
</tr>
</tbody>
</table>

The function `current_setting` yields the current value of the setting `setting_name`. It corresponds to the SQL command `SHOW`. An example:

```sql
SELECT current_setting('datestyle');
```

```
current_setting
-----------------
ISO, MDY
(1 row)
```

`set_config` sets the parameter `setting_name` to `new_value`. If `is_local` is `true`, the new value will only apply to the current transaction. If you want the new value to apply for the current session, use `false` instead. The function corresponds to the SQL command `SET`. An example:

```sql
SELECT set_config('log_statement_stats', 'off', false);
```

```
set_config
----------
off
(1 row)
```

The functions shown in Table 9-55 send control signals to other server processes. Use of these functions is restricted to superusers.

**Table 9-55. Server Signalling Functions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pg_cancel_backend(pid int)</td>
<td>boolean</td>
<td>Cancel a backend’s current query</td>
</tr>
<tr>
<td>pg_terminate_backend(pid int)</td>
<td>boolean</td>
<td>Terminate a backend</td>
</tr>
<tr>
<td>pg_reload_conf()</td>
<td>boolean</td>
<td>Cause server processes to reload their configuration files</td>
</tr>
<tr>
<td>pg_rotate_logfile()</td>
<td>boolean</td>
<td>Rotate server’s log file</td>
</tr>
</tbody>
</table>

Each of these functions returns `true` if successful and `false` otherwise.

`pg_cancel_backend` and `pg_terminate_backend` send signals (SIGINT or SIGTERM respec-
tively) to backend processes identified by process ID. The process ID of an active backend can be found from the `procpid` column of the `pg_stat_activity` view, or by listing the `postgres` processes on the server (using `ps` on Unix or the Task Manager on Windows).

`pg_reload_conf` sends a SIGHUP signal to the server, causing configuration files to be reloaded by all server processes.

`pg_rotate_logfile` signals the log-file manager to switch to a new output file immediately. This works only when the built-in log collector is running, since otherwise there is no log-file manager subprocess.

The functions shown in Table 9-56 assist in making on-line backups. Use of the first three functions is restricted to superusers.

### Table 9-56. Backup Control Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pg_start_backup(label text [, fast boolean ])</code></td>
<td>text</td>
<td>Prepare for performing on-line backup</td>
</tr>
<tr>
<td><code>pg_stop_backup()</code></td>
<td>text</td>
<td>Finish performing on-line backup</td>
</tr>
<tr>
<td><code>pg_switch_xlog()</code></td>
<td>text</td>
<td>Force switch to a new transaction log file</td>
</tr>
<tr>
<td><code>pg_current_xlog_location()</code></td>
<td>text</td>
<td>Get current transaction log write location</td>
</tr>
<tr>
<td><code>pg_current_xlog_insert_location()</code></td>
<td>text</td>
<td>Get current transaction log insert location</td>
</tr>
<tr>
<td><code>pg_xlogfile_name_offset(location text)</code></td>
<td>text, integer</td>
<td>Convert transaction log location string to file name and decimal byte offset within file</td>
</tr>
<tr>
<td><code>pg_xlogfile_name(location text)</code></td>
<td>text</td>
<td>Convert transaction log location string to file name</td>
</tr>
</tbody>
</table>

`pg_start_backup` accepts an arbitrary user-defined label for the backup. (Typically this would be the name under which the backup dump file will be stored.) The function writes a backup label file (`backup_label`) into the database cluster’s data directory, performs a checkpoint, and then returns the backup’s starting transaction log location as text. The user can ignore this result value, but it is provided in case it is useful.

```sql
postgres=# select pg_start_backup('label_goes_here');
```

```
pg_start_backup
-----------------
0/D4445B8
(1 row)
```

There is an optional boolean second parameter. If `true`, it specifies executing `pg_start_backup` as quickly as possible. This forces an immediate checkpoint which will cause a spike in I/O operations, slowing any concurrently executing queries.

`pg_stop_backup` removes the label file created by `pg_start_backup`, and creates a backup history file in the transaction log archive area. The history file includes the label given to `pg_start_backup`, the starting and ending transaction log locations for the backup, and the starting and ending times of
Chapter 9. Functions and Operators

the backup. The return value is the backup’s ending transaction log location (which again can be ignored). After recording the ending location, the current transaction log insertion point is automatically advanced to the next transaction log file, so that the ending transaction log file can be archived immediately to complete the backup.

`pg_switch_xlog` moves to the next transaction log file, allowing the current file to be archived (assuming you are using continuous archiving). The return value is the ending transaction log location + 1 within the just-completed transaction log file. If there has been no transaction log activity since the last transaction log switch, `pg_switch_xlog` does nothing and returns the start location of the transaction log file currently in use.

`pg_current_xlog_location` displays the current transaction log write location in the same format used by the above functions. Similarly, `pg_current_xlog_insert_location` displays the current transaction log insertion point. The insertion point is the “logical” end of the transaction log at any instant, while the write location is the end of what has actually been written out from the server’s internal buffers. The write location is the end of what can be examined from outside the server, and is usually what you want if you are interested in archiving partially-complete transaction log files. The insertion point is made available primarily for server debugging purposes. These are both read-only operations and do not require superuser permissions.

You can use `pg_xlogfile_name_offset` to extract the corresponding transaction log file name and byte offset from the results of any of the above functions. For example:

```
postgres=# SELECT * FROM pg_xlogfile_name_offset(pg_stop_backup());
     file_name     |   file_offset
-----------------+----------------
00000001000000000000000D | 4039624
(1 row)
```

Similarly, `pg_xlogfile_name` extracts just the transaction log file name. When the given transaction log location is exactly at a transaction log file boundary, both these functions return the name of the preceding transaction log file. This is usually the desired behavior for managing transaction log archiving behavior, since the preceding file is the last one that currently needs to be archived.

For details about proper usage of these functions, see Section 24.3.

The functions shown in Table 9-57 calculate the disk space usage of database objects.

<table>
<thead>
<tr>
<th>Name</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pg_column_size(any)</code></td>
<td>int</td>
<td>Number of bytes used to store a particular value (possibly compressed)</td>
</tr>
<tr>
<td><code>pg_database_size(oid)</code></td>
<td>bigint</td>
<td>Disk space used by the database with the specified OID</td>
</tr>
<tr>
<td><code>pg_database_size(name)</code></td>
<td>bigint</td>
<td>Disk space used by the database with the specified name</td>
</tr>
<tr>
<td><code>pg_relation_size(relation regclass, fork text)</code></td>
<td>bigint</td>
<td>Disk space used by the specified fork (‘main’, ‘fsm’ or ‘vm’) of the table or index with the specified OID or name</td>
</tr>
</tbody>
</table>
Chapter 9. Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pg_relation_size(relation regclass)</td>
<td>bigint</td>
<td>Shorthand for pg_relation_size(..., 'main')</td>
</tr>
<tr>
<td>pg_size_pretty(bigint)</td>
<td>text</td>
<td>Converts a size in bytes into a human-readable format with size units</td>
</tr>
<tr>
<td>pg_tablespace_size(oid)</td>
<td>bigint</td>
<td>Disk space used by the tablespace with the specified OID</td>
</tr>
<tr>
<td>pg_tablespace_size(name)</td>
<td>bigint</td>
<td>Disk space used by the tablespace with the specified name</td>
</tr>
<tr>
<td>pg_total_relation_size(regclass)</td>
<td>bigint</td>
<td>Total disk space used by the table with the specified OID or name, including indexes and TOAST data</td>
</tr>
</tbody>
</table>

pg_column_size shows the space used to store any individual data value.

pg_database_size and pg_tablespace_size accept the OID or name of a database or tablespace, and return the total disk space used therein. To use pg_database_size, you must have CONNECT permission on the specified database (which is granted by default). To use pg_tablespace_size, you must have CREATE permission on the specified tablespace, unless it is the default tablespace for the current database.

pg_relation_size accepts the OID or name of a table, index or toast table, and returns the size in bytes. Specifying ‘main’ or leaving out the second argument returns the size of the main data fork of the relation. Specifying ‘fsm’ returns the size of the Free Space Map (see Section 53.3) associated with the relation. Specifying ‘vm’ returns the size of the Visibility Map (see Section 53.4) associated with the relation.

pg_size_pretty can be used to format the result of one of the other functions in a human-readable way, using kB, MB, GB or TB as appropriate.

pg_total_relation_size accepts the OID or name of a table or toast table, and returns the size in bytes of the data and all associated indexes and toast tables.

The functions shown in Table 9-58 provide native access to files on the machine hosting the server. Only files within the database cluster directory and the log_directory can be accessed. Use a relative path for files in the cluster directory, and a path matching the log_directory configuration setting for log files. Use of these functions is restricted to superusers.

Table 9-58. Generic File Access Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pg_ls_dir(dirname text)</td>
<td>setof text</td>
<td>List the contents of a directory</td>
</tr>
<tr>
<td>pg_read_file(filename text, offset bigint, length bigint)</td>
<td>text</td>
<td>Return the contents of a text file</td>
</tr>
<tr>
<td>pg_stat_file(filename text)</td>
<td>record</td>
<td>Return information about a file</td>
</tr>
</tbody>
</table>
pg_ls_dir returns all the names in the specified directory, except the special entries “.” and “..”.

pg_read_file returns part of a text file, starting at the given offset, returning at most length bytes (less if the end of file is reached first). If offset is negative, it is relative to the end of the file.

pg_stat_file returns a record containing the file size, last accessed time stamp, last modified time stamp, last file status change time stamp (Unix platforms only), file creation time stamp (Windows only), and a boolean indicating if it is a directory. Typical usages include:

```sql
SELECT * FROM pg_stat_file('filename');
SELECT (pg_stat_file('filename')).modification;
```

The functions shown in Table 9-59 manage advisory locks. For details about proper use of these functions, see Section 13.3.4.

**Table 9-59. Advisory Lock Functions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pg_advisory_lock(key bigint)</code></td>
<td>void</td>
<td>Obtain exclusive advisory lock</td>
</tr>
<tr>
<td><code>pg_advisory_lock(key1 int, key2 int)</code></td>
<td>void</td>
<td>Obtain exclusive advisory lock</td>
</tr>
<tr>
<td><code>pg_advisory_lock_shared(key bigint)</code></td>
<td>void</td>
<td>Obtain shared advisory lock</td>
</tr>
<tr>
<td><code>pg_advisory_lock_shared(key1 int, key2 int)</code></td>
<td>void</td>
<td>Obtain shared advisory lock</td>
</tr>
<tr>
<td><code>pg_try_advisory_lock(key bigint)</code></td>
<td>boolean</td>
<td>Obtain exclusive advisory lock if available</td>
</tr>
<tr>
<td><code>pg_try_advisory_lock(key1 int, key2 int)</code></td>
<td>boolean</td>
<td>Obtain exclusive advisory lock if available</td>
</tr>
<tr>
<td><code>pg_try_advisory_lock_shared(key bigint)</code></td>
<td>boolean</td>
<td>Obtain shared advisory lock if available</td>
</tr>
<tr>
<td><code>pg_try_advisory_lock_shared(key1 int, key2 int)</code></td>
<td>boolean</td>
<td>Obtain shared advisory lock if available</td>
</tr>
<tr>
<td><code>pg_advisory_unlock(key bigint)</code></td>
<td>boolean</td>
<td>Release an exclusive advisory lock</td>
</tr>
<tr>
<td><code>pg_advisory_unlock(key1 int, key2 int)</code></td>
<td>boolean</td>
<td>Release an exclusive advisory lock</td>
</tr>
<tr>
<td><code>pg_advisory_unlock_shared(key bigint)</code></td>
<td>boolean</td>
<td>Release a shared advisory lock</td>
</tr>
<tr>
<td><code>pg_advisory_unlock_shared(key1 int, key2 int)</code></td>
<td>boolean</td>
<td>Release a shared advisory lock</td>
</tr>
</tbody>
</table>
pg_advisory_lock locks an application-defined resource, which can be identified either by a single 64-bit key value or two 32-bit key values (note that these two key spaces do not overlap). The key type is specified in `pg_locks.objid`. If another session already holds a lock on the same resource, the function will wait until the resource becomes available. The lock is exclusive. Multiple lock requests stack, so that if the same resource is locked three times it must be also unlocked three times to be released for other sessions’ use.

pg_advisory_lock_shared works the same as `pg_advisory_lock`, except the lock can be shared with other sessions requesting shared locks. Only would-be exclusive lockers are locked out.

`pg_try_advisory_lock` is similar to `pg_advisory_lock`, except the function will not wait for the lock to become available. It will either obtain the lock immediately and return true, or return false if the lock cannot be acquired immediately.

`pg_try_advisory_lock_shared` works the same as `pg_try_advisory_lock`, except it attempts to acquire a shared rather than an exclusive lock.

`pg_advisory_unlock` will release a previously-acquired exclusive advisory lock. It returns true if the lock is successfully released. If the lock was not held, it will return false, and in addition, an SQL warning will be raised by the server.

`pg_advisory_unlock_shared` works the same as `pg_advisory_unlock`, except it releases a shared advisory lock.

`pg_advisory_unlock_all` will release all advisory locks held by the current session. (This function is implicitly invoked at session end, even if the client disconnects ungracefully.)

### 9.25. Trigger Functions

Currently PostgreSQL provides one built-in trigger function, `suppress_redundant_updates_trigger`, which will prevent any update that does not actually change the data in the row from taking place, in contrast to the normal behaviour which always performs the update regardless of whether or not the data has changed. (This normal behaviour makes updates run faster, since no checking is required, and is also useful in certain cases.)

Ideally, you should normally avoid running updates that don’t actually change the data in the record. Redundant updates can cost considerable unnecessary time, especially if there are lots of indexes to alter, and space in dead rows that will eventually have to be vacuumed. However, detecting such situations in client code is not always easy, or even possible, and writing expressions to detect them can be error-prone. An alternative is to use `suppress_redundant_updates_trigger`, which will skip updates that don’t change the data. You should use this with care, however. The trigger takes a small but non-trivial time for each record, so if most of the records affected by an update are actually changed, use of this trigger will actually make the update run slower.

The `suppress_redundant_updates_trigger` function can be added to a table like this:

```sql
CREATE TRIGGER z_min_update
    BEFORE UPDATE ON tablename
    FOR EACH ROW EXECUTE PROCEDURE suppress_redundant_updates_trigger();
```
In most cases, you would want to fire this trigger last for each row. Bearing in mind that triggers fire in name order, you would then choose a trigger name that comes after the name of any other trigger you might have on the table.

For more information about creating triggers, see CREATE TRIGGER.
Chapter 10. Type Conversion

SQL statements can, intentionally or not, require the mixing of different data types in the same expression. PostgreSQL has extensive facilities for evaluating mixed-type expressions.

In many cases a user does not need to understand the details of the type conversion mechanism. However, implicit conversions done by PostgreSQL can affect the results of a query. When necessary, these results can be tailored by using explicit type conversion.

This chapter introduces the PostgreSQL type conversion mechanisms and conventions. Refer to the relevant sections in Chapter 8 and Chapter 9 for more information on specific data types and allowed functions and operators.

10.1. Overview

SQL is a strongly typed language. That is, every data item has an associated data type which determines its behavior and allowed usage. PostgreSQL has an extensible type system that is more general and flexible than other SQL implementations. Hence, most type conversion behavior in PostgreSQL is governed by general rules rather than by ad hoc heuristics. This allows the use of mixed-type expressions even with user-defined types.

The PostgreSQL scanner/parser divides lexical elements into five fundamental categories: integers, non-integer numbers, strings, identifiers, and key words. Constants of most non-numeric types are first classified as strings. The SQL language definition allows specifying type names with strings, and this mechanism can be used in PostgreSQL to start the parser down the correct path. For example, the query:

```
SELECT text 'Origin' AS "label", point '(0,0)' AS "value";
```

<table>
<thead>
<tr>
<th>label</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Origin</td>
<td>(0,0)</td>
</tr>
</tbody>
</table>

has two literal constants, of type text and point. If a type is not specified for a string literal, then the placeholder type unknown is assigned initially, to be resolved in later stages as described below.

There are four fundamental SQL constructs requiring distinct type conversion rules in the PostgreSQL parser:

Function calls

Much of the PostgreSQL type system is built around a rich set of functions. Functions can have one or more arguments. Since PostgreSQL permits function overloading, the function name alone does not uniquely identify the function to be called; the parser must select the right function based on the data types of the supplied arguments.

Operators

PostgreSQL allows expressions with prefix and postfix unary (one-argument) operators, as well as binary (two-argument) operators. Like functions, operators can be overloaded, so the same problem of selecting the right operator exists.
Chapter 10. Type Conversion

Value Storage

SQL INSERT and UPDATE statements place the results of expressions into a table. The expressions in the statement must be matched up with, and perhaps converted to, the types of the target columns.

UNION, CASE, and related constructs

Since all query results from a unionized SELECT statement must appear in a single set of columns, the types of the results of each SELECT clause must be matched up and converted to a uniform set. Similarly, the result expressions of a CASE construct must be converted to a common type so that the CASE expression as a whole has a known output type. The same holds for ARRAY constructs, and for the GREATEST and LEAST functions.

The system catalogs store information about which conversions, or casts, exist between which data types, and how to perform those conversions. Additional casts can be added by the user with the CREATE CAST command. (This is usually done in conjunction with defining new data types. The set of casts between built-in types has been carefully crafted and is best not altered.)

An additional heuristic provided by the parser allows improved determination of the proper casting behavior among groups of types that have implicit casts. Data types are divided into several basic type categories, including boolean, numeric, string, bitstring, datetime, timespan, geometric, network, and user-defined. (For a list see Table 44-43; but note it is also possible to create custom type categories.) Within each category there can be one or more preferred types, which are preferred when there is a choice of possible types. With careful selection of preferred types and available implicit casts, it is possible to ensure that ambiguous expressions (those with multiple candidate parsing solutions) can be resolved in a useful way.

All type conversion rules are designed with several principles in mind:

- Implicit conversions should never have surprising or unpredictable outcomes.
- There should be no extra overhead in the parser or executor if a query does not need implicit type conversion. That is, if a query is well-formed and the types already match, then the query should execute without spending extra time in the parser and without introducing unnecessary implicit conversion calls in the query.

Additionally, if a query usually requires an implicit conversion for a function, and if then the user defines a new function with the correct argument types, the parser should use this new function and no longer do implicit conversion to use the old function.

10.2. Operators

The specific operator that is referenced by an operator expression is determined using the following procedure. Note that this procedure is indirectly affected by the precedence of the involved operators, since that will determine which sub-expressions are taken to be the inputs of which operators. See Section 4.1.6 for more information.

Operator Type Resolution

1. Select the operators to be considered from the pg_operator system catalog. If a non-schema-qualified operator name was used (the usual case), the operators considered are those with the
matching name and argument count that are visible in the current search path (see Section 5.7.3). If a qualified operator name was given, only operators in the specified schema are considered.

a. If the search path finds multiple operators with identical argument types, only the one appearing earliest in the path is considered. Operators with different argument types are considered on an equal footing regardless of search path position.

2. Check for an operator accepting exactly the input argument types. If one exists (there can be only one exact match in the set of operators considered), use it.

a. If one argument of a binary operator invocation is of the unknown type, then assume it is the same type as the other argument for this check. Invocations involving two unknown inputs, or a unary operator with an unknown input, will never find a match at this step.

3. Look for the best match.

a. Discard candidate operators for which the input types do not match and cannot be converted (using an implicit conversion) to match. unknown literals are assumed to be convertible to anything for this purpose. If only one candidate remains, use it; else continue to the next step.

b. Run through all candidates and keep those with the most exact matches on input types. (Domains are considered the same as their base type for this purpose.) Keep all candidates if none have exact matches. If only one candidate remains, use it; else continue to the next step.

c. Run through all candidates and keep those that accept preferred types (of the input data type’s type category) at the most positions where type conversion will be required. Keep all candidates if none accept preferred types. If only one candidate remains, use it; else continue to the next step.

d. If any input arguments are unknown, check the type categories accepted at those argument positions by the remaining candidates. At each position, select the string category if any candidate accepts that category. (This bias towards string is appropriate since an unknown-type literal looks like a string.) Otherwise, if all the remaining candidates accept the same type category, select that category; otherwise fail because the correct choice cannot be deduced without more clues. Now discard candidates that do not accept the selected type category. Furthermore, if any candidate accepts a preferred type in that category, discard candidates that accept non-preferred types for that argument.

e. If only one candidate remains, use it. If no candidate or more than one candidate remains, then fail.

Some examples follow.

**Example 10-1. Factorial Operator Type Resolution**

There is only one factorial operator (postfix !) defined in the standard catalog, and it takes an argument of type bigint. The scanner assigns an initial type of integer to the argument in this query expression:

```
SELECT 40 ! AS "40 factorial";
```

```
40 factorial

------------------------------
81591528324789773434561126959611589427200000000
```

255
Chapter 10. Type Conversion

So the parser does a type conversion on the operand and the query is equivalent to:

```sql
SELECT CAST(40 AS bigint) ! AS "40 factorial";
```

Example 10-2. String Concatenation Operator Type Resolution

A string-like syntax is used for working with string types and for working with complex extension types. Strings with unspecified type are matched with likely operator candidates.

An example with one unspecified argument:

```sql
SELECT text 'abc' || 'def' AS "text and unknown";
```

<table>
<thead>
<tr>
<th>text and unknown</th>
</tr>
</thead>
<tbody>
<tr>
<td>abcdef</td>
</tr>
</tbody>
</table>

(1 row)

In this case the parser looks to see if there is an operator taking `text` for both arguments. Since there is, it assumes that the second argument should be interpreted as type `text`.

Here is a concatenation on unspecified types:

```sql
SELECT 'abc' || 'def' AS "unspecified";
```

<table>
<thead>
<tr>
<th>unspecified</th>
</tr>
</thead>
<tbody>
<tr>
<td>abcdef</td>
</tr>
</tbody>
</table>

(1 row)

In this case there is no initial hint for which type to use, since no types are specified in the query. So, the parser looks for all candidate operators and finds that there are candidates accepting both string-category and bit-string-category inputs. Since string category is preferred when available, that category is selected, and then the preferred type for strings, `text`, is used as the specific type to resolve the unknown literals as.

Example 10-3. Absolute-Value and Negation Operator Type Resolution

The PostgreSQL operator catalog has several entries for the prefix operator `@`, all of which implement absolute-value operations for various numeric data types. One of these entries is for type `float8`, which is the preferred type in the numeric category. Therefore, PostgreSQL will use that entry when faced with an unknown input:

```sql
SELECT @ '-4.5' AS "abs";
```

<table>
<thead>
<tr>
<th>abs</th>
</tr>
</thead>
<tbody>
<tr>
<td>4.5</td>
</tr>
</tbody>
</table>

(1 row)

Here the system has implicitly resolved the unknown-type literal as type `float8` before applying the chosen operator. We can verify that `float8` and not some other type was used:

```sql
SELECT @ '-4.5e500' AS "abs";
```

ERROR: "-4.5e500" is out of range for type double precision
On the other hand, the prefix operator \( \sim \) (bitwise negation) is defined only for integer data types, not for float8. So, if we try a similar case with \( \sim \), we get:

```sql
SELECT \( \sim '20' \) AS "negation";
```

```
ERROR: operator is not unique: \( \sim 'unknown' \)
HINT: Could not choose a best candidate operator. You might need to add explicit type casts.
```

This happens because the system cannot decide which of the several possible \( \sim \) operators should be preferred. We can help it out with an explicit cast:

```sql
SELECT \( \sim \) CAST('20' AS int8) AS "negation";
```

```
negation
---------
   -21
(1 row)
```

### 10.3. Functions

The specific function that is referenced by a function call is determined using the following procedure.

**Function Type Resolution**

1. Select the functions to be considered from the `pg_proc` system catalog. If a non-schema-qualified function name was used, the functions considered are those with the matching name and argument count that are visible in the current search path (see Section 5.7.3). If a qualified function name was given, only functions in the specified schema are considered.

   a. If the search path finds multiple functions of identical argument types, only the one appearing earliest in the path is considered. Functions of different argument types are considered on an equal footing regardless of search path position.

   b. If a function is declared with a `VARIADIC` array parameter, and the call does not use the `VARIADIC` keyword, then the function is treated as if the array parameter were replaced by one or more occurrences of its element type, as needed to match the call. After such expansion the function might have effective argument types identical to some non-variadic function. In that case the function appearing earlier in the search path is used, or if the two functions are in the same schema, the non-variadic one is preferred.

   c. Functions that have default values for parameters are considered to match any call that omits zero or more of the defaultable parameter positions. If more than one such function matches a call, the one appearing earliest in the search path is used. If there are two or more such functions in the same schema with identical parameter types in the non-defaulted positions (which is possible if they have different sets of defaultable parameters), the system will not be able to determine which to prefer, and so an "ambiguous function call" error will result if no better match to the call can be found.

2. Check for a function accepting exactly the input argument types. If one exists (there can be only one exact match in the set of functions considered), use it. (Cases involving `unknown` will never find a match at this step.)

3. If no exact match is found, see if the function call appears to be a special type conversion request. This happens if the function call has just one argument and the function name is the same as
Chapter 10. Type Conversion

the (internal) name of some data type. Furthermore, the function argument must be either an unknown-type literal, or a type that is binary-coercible to the named data type, or a type that could be converted to the named data type by applying that type’s I/O functions (that is, the conversion is either to or from one of the standard string types). When these conditions are met, the function call is treated as a form of \texttt{CAST} specification.  

4. Look for the best match.

a. Discard candidate functions for which the input types do not match and cannot be converted (using an implicit conversion) to match. \texttt{unknown} literals are assumed to be convertible to anything for this purpose. If only one candidate remains, use it; else continue to the next step.

b. Run through all candidates and keep those with the most exact matches on input types. (Domains are considered the same as their base type for this purpose.) Keep all candidates if none have exact matches. If only one candidate remains, use it; else continue to the next step.

c. Run through all candidates and keep those that accept preferred types (of the input data type’s type category) at the most positions where type conversion will be required. Keep all candidates if none accept preferred types. If only one candidate remains, use it; else continue to the next step.

d. If any input arguments are \texttt{unknown}, check the type categories accepted at those argument positions by the remaining candidates. At each position, select the \texttt{string} category if any candidate accepts that category. (This bias towards string is appropriate since an unknown-type literal looks like a string.) Otherwise, if all the remaining candidates accept the same type category, select that category; otherwise fail because the correct choice cannot be deduced without more clues. Now discard candidates that do not accept the selected type category. Furthermore, if any candidate accepts a preferred type in that category, discard candidates that accept non-preferred types for that argument.

e. If only one candidate remains, use it. If no candidate or more than one candidate remains, then fail.

Note that the “best match” rules are identical for operator and function type resolution. Some examples follow.

Example 10-4. Rounding Function Argument Type Resolution

There is only one \texttt{round} function that takes two arguments; it takes a first argument of type \texttt{numeric} and a second argument of type \texttt{integer}. So the following query automatically converts the first argument of type \texttt{integer} to \texttt{numeric}:

\begin{verbatim}
SELECT round(4, 4);
\end{verbatim}

\begin{verbatim}
round
--------
4.0000
(1 row)
\end{verbatim}

That query is actually transformed by the parser to:

\begin{verbatim}
SELECT round(CAST (4 AS numeric), 4);
\end{verbatim}

1. The reason for this step is to support function-style cast specifications in cases where there is not an actual cast function. If there is a cast function, it is conventionally named after its output type, and so there is no need to have a special case. See \texttt{CREATE CAST} for additional commentary.
Chapter 10. Type Conversion

Since numeric constants with decimal points are initially assigned the type \texttt{numeric}, the following query will require no type conversion and therefore might be slightly more efficient:

\begin{verbatim}
SELECT round(4.0, 4);
\end{verbatim}

Example 10-5. Substring Function Type Resolution

There are several \texttt{substr} functions, one of which takes types \texttt{text} and \texttt{integer}. If called with a string constant of unspecified type, the system chooses the candidate function that accepts an argument of the preferred category \texttt{string} (namely of type \texttt{text}).

\begin{verbatim}
SELECT substr('1234', 3);
\end{verbatim}

\begin{verbatim}
substr
-------
  34
(1 row)
\end{verbatim}

If the string is declared to be of type \texttt{varchar}, as might be the case if it comes from a table, then the parser will try to convert it to become \texttt{text}:

\begin{verbatim}
SELECT substr(varchar '1234', 3);
\end{verbatim}

\begin{verbatim}
substr
-------
  34
(1 row)
\end{verbatim}

This is transformed by the parser to effectively become:

\begin{verbatim}
SELECT substr(CAST (varchar '1234' AS text), 3);
\end{verbatim}

\textbf{Note:} The parser learns from the \texttt{pg_cast} catalog that \texttt{text} and \texttt{varchar} are binary-compatible, meaning that one can be passed to a function that accepts the other without doing any physical conversion. Therefore, no type conversion call is really inserted in this case.

And, if the function is called with an argument of type \texttt{integer}, the parser will try to convert that to \texttt{text}:

\begin{verbatim}
SELECT substr(1234, 3);
\end{verbatim}

\texttt{ERROR: function substr(integer, integer) does not exist}

\texttt{HINT: No function matches the given name and argument types. You might need to add explicit type casts.}

This does not work because \texttt{integer} does not have an implicit cast to \texttt{text}. An explicit cast will work, however:

\begin{verbatim}
SELECT substr(CAST (1234 AS text), 3);
\end{verbatim}

\begin{verbatim}
substr
-------
  34
(1 row)
\end{verbatim}
10.4. Value Storage

Values to be inserted into a table are converted to the destination column’s data type according to the following steps.

Value Storage Type Conversion

1. Check for an exact match with the target.
2. Otherwise, try to convert the expression to the target type. This will succeed if there is a registered cast between the two types. If the expression is an unknown-type literal, the contents of the literal string will be fed to the input conversion routine for the target type.
3. Check to see if there is a sizing cast for the target type. A sizing cast is a cast from that type to itself. If one is found in the pg_cast catalog, apply it to the expression before storing into the destination column. The implementation function for such a cast always takes an extra parameter of type integer, which receives the destination column’s atttypmod value (typically its declared length, although the interpretation of atttypmod varies for different data types), and it may take a third boolean parameter that says whether the cast is explicit or implicit. The cast function is responsible for applying any length-dependent semantics such as size checking or truncation.

Example 10-6. character Storage Type Conversion

For a target column declared as character(20) the following statement shows that the stored value is sized correctly:

```sql
CREATE TABLE vv (v character(20));
INSERT INTO vv SELECT 'abc' || 'def';
SELECT v, octet_length(v) FROM vv;
```

<table>
<thead>
<tr>
<th>v</th>
<th>octet_length</th>
</tr>
</thead>
<tbody>
<tr>
<td>abcdef</td>
<td>20</td>
</tr>
</tbody>
</table>

(1 row)

What has really happened here is that the two unknown literals are resolved to text by default, allowing the || operator to be resolved as text concatenation. Then the text result of the operator is converted to bpchar (“blank-padded char”, the internal name of the character data type) to match the target column type. (Since the conversion from text to bpchar is binary-coercible, this conversion does not insert any real function call.) Finally, the sizing function bpchar(bpchar, integer, boolean) is found in the system catalog and applied to the operator’s result and the stored column length. This type-specific function performs the required length check and addition of padding spaces.

10.5. UNION, CASE, and Related Constructs

SQL UNION constructs must match up possibly dissimilar types to become a single result set. The resolution algorithm is applied separately to each output column of a union query. The INTERSECT and EXCEPT constructs resolve dissimilar types in the same way as UNION. The CASE, ARRAY, VALUES, GREATEST and LEAST constructs use the identical algorithm to match up their component expressions and select a result data type.
**Chapter 10. Type Conversion**

**Type Resolution for UNION, CASE, and Related Constructs**

1. If all inputs are of the same type, and it is not unknown, resolve as that type. Otherwise, replace any domain types in the list with their underlying base types.

2. If all inputs are of type unknown, resolve as type text (the preferred type of the string category). Otherwise, unknown inputs are ignored.

3. If the non-unknown inputs are not all of the same type category, fail.

4. Choose the first non-unknown input type which is a preferred type in that category, if there is one.

5. Otherwise, choose the last non-unknown input type that allows all the preceding non-unknown inputs to be implicitly converted to it. (There always is such a type, since at least the first type in the list must satisfy this condition.)

6. Convert all inputs to the selected type. Fail if there is not a conversion from a given input to the selected type.

Some examples follow.

**Example 10-7. Type Resolution with Underspecified Types in a Union**

```sql
SELECT text 'a' AS "text" UNION SELECT 'b';
```

<table>
<thead>
<tr>
<th>text</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
</tr>
<tr>
<td>b</td>
</tr>
</tbody>
</table>

(2 rows)

Here, the unknown-type literal 'b' will be resolved to type text.

**Example 10-8. Type Resolution in a Simple Union**

```sql
SELECT 1.2 AS "numeric" UNION SELECT 1;
```

<table>
<thead>
<tr>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>1.2</td>
</tr>
</tbody>
</table>

(2 rows)

The literal 1.2 is of type numeric, and the integer value 1 can be cast implicitly to numeric, so that type is used.

**Example 10-9. Type Resolution in a Transposed Union**

```sql
SELECT 1 AS "real" UNION SELECT CAST('2.2' AS REAL);
```

<table>
<thead>
<tr>
<th>real</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>2.2</td>
</tr>
</tbody>
</table>

(2 rows)
Here, since type real cannot be implicitly cast to integer, but integer can be implicitly cast to real, the union result type is resolved as real.
Chapter 11. Indexes

Indexes are a common way to enhance database performance. An index allows the database server to find and retrieve specific rows much faster than it could do without an index. But indexes also add overhead to the database system as a whole, so they should be used sensibly.

11.1. Introduction

Suppose we have a table similar to this:

```sql
CREATE TABLE test1 (
    id integer,
    content varchar
);
```

and the application issues many queries of the form:

```sql
SELECT content FROM test1 WHERE id = constant;
```

With no advance preparation, the system would have to scan the entire `test1` table, row by row, to find all matching entries. If there are many rows in `test1` and only a few rows (perhaps zero or one) that would be returned by such a query, this is clearly an inefficient method. But if the system has been instructed to maintain an index on the `id` column, it can use a more efficient method for locating matching rows. For instance, it might only have to walk a few levels deep into a search tree.

A similar approach is used in most non-fiction books: terms and concepts that are frequently looked up by readers are collected in an alphabetic index at the end of the book. The interested reader can scan the index relatively quickly and flip to the appropriate page(s), rather than having to read the entire book to find the material of interest. Just as it is the task of the author to anticipate the items that readers are likely to look up, it is the task of the database programmer to foresee which indexes will be useful.

The following command can be used to create an index on the `id` column, as discussed:

```sql
CREATE INDEX test1_id_index ON test1 (id);
```

The name `test1_id_index` can be chosen freely, but you should pick something that enables you to remember later what the index was for.

To remove an index, use the `DROP INDEX` command. Indexes can be added to and removed from tables at any time.

Once an index is created, no further intervention is required: the system will update the index when the table is modified, and it will use the index in queries when it thinks doing so would be more efficient than a sequential table scan. But you might have to run the `ANALYZE` command regularly to update statistics to allow the query planner to make educated decisions. See Chapter 14 for information about how to find out whether an index is used and when and why the planner might choose not to use an index.

Indexes can also benefit `UPDATE` and `DELETE` commands with search conditions. Indexes can moreover be used in join searches. Thus, an index defined on a column that is part of a join condition can also significantly speed up queries with joins.

Creating an index on a large table can take a long time. By default, PostgreSQL allows reads (selects) to occur on the table in parallel with index creation, but writes (INSERTs, UPDATEs, DELETEs) are
blocked until the index build is finished. In production environments this is often unacceptable. It is possible to allow writes to occur in parallel with index creation, but there are several caveats to be aware of — for more information see Building Indexes Concurrently.

After an index is created, the system has to keep it synchronized with the table. This adds overhead to data manipulation operations. Therefore indexes that are seldom or never used in queries should be removed.

11.2. Index Types

PostgreSQL provides several index types: B-tree, Hash, GiST and GIN. Each index type uses a different algorithm that is best suited to different types of queries. By default, the `CREATE INDEX` command creates B-tree indexes, which fit the most common situations.

B-trees can handle equality and range queries on data that can be sorted into some ordering. In particular, the PostgreSQL query planner will consider using a B-tree index whenever an indexed column is involved in a comparison using one of these operators:

```
<  
<=  
=  
>=  
>
```

Constructs equivalent to combinations of these operators, such as BETWEEN and IN, can also be implemented with a B-tree index search. Also, an IS NULL condition on an index column can be used with a B-tree index.

The optimizer can also use a B-tree index for queries involving the pattern matching operators LIKE and ~ if the pattern is a constant and is anchored to the beginning of the string — for example, `col LIKE 'foo%'` or `col ~ '^foo'`, but not `col LIKE '%bar'`. However, if your database does not use the C locale you will need to create the index with a special operator class to support indexing of pattern-matching queries; see Section 11.9 below. It is also possible to use B-tree indexes for ILIKE and ~*, but only if the pattern starts with non-alphabetic characters, i.e., characters that are not affected by upper/lower case conversion.

Hash indexes can only handle simple equality comparisons. The query planner will consider using a hash index whenever an indexed column is involved in a comparison using the = operator. (Hash indexes do not support IS NULL searches.) The following command is used to create a hash index:

```
CREATE INDEX name ON table USING hash (column);
```

**Note:** Hash index operations are not presently WAL-logged, so hash indexes might need to be rebuilt with REINDEX after a database crash. For this reason, hash index use is presently discouraged.

GiST indexes are not a single kind of index, but rather an infrastructure within which many different indexing strategies can be implemented. Accordingly, the particular operators with which a GiST index can be used vary depending on the indexing strategy (the operator class). As an example, the standard distribution of PostgreSQL includes GiST operator classes for several two-dimensional geometric data types, which support indexed queries using these operators:
Many other GiST operator classes are available in the contrib collection or as separate projects. For more information see Chapter 51.

GIN indexes are inverted indexes which can handle values that contain more than one key, arrays for example. Like GiST, GIN can support many different user-defined indexing strategies and the particular operators with which a GIN index can be used vary depending on the indexing strategy. As an example, the standard distribution of PostgreSQL includes GIN operator classes for one-dimensional arrays, which support indexed queries using these operators:

(See Section 9.17 for the meaning of these operators.) Many other GIN operator classes are available in the contrib collection or as separate projects. For more information see Chapter 52.

### 11.3. Multicolumn Indexes

An index can be defined on more than one column of a table. For example, if you have a table of this form:

```sql
CREATE TABLE test2 (  
major int,  
minor int,  
name varchar
);
```

(say, you keep your /dev directory in a database...) and you frequently issue queries like:

```sql
SELECT name FROM test2 WHERE major = constant AND minor = constant;
```

then it might be appropriate to define an index on the columns major and minor together, e.g.:

```sql
CREATE INDEX test2_mm_idx ON test2 (major, minor);
```

Currently, only the B-tree, GiST and GIN index types support multicolumn indexes. Up to 32 columns can be specified. (This limit can be altered when building PostgreSQL; see the file `pg_config_manual.h`.)
A multicolumn B-tree index can be used with query conditions that involve any subset of the index’s columns, but the index is most efficient when there are constraints on the leading (leftmost) columns. The exact rule is that equality constraints on leading columns, plus any inequality constraints on the first column that does not have an equality constraint, will be used to limit the portion of the index that is scanned. Constraints on columns to the right of these columns are checked in the index, so they save visits to the table proper, but they do not reduce the portion of the index that has to be scanned. For example, given an index on \((a, b, c)\) and a query condition `WHERE a = 5 AND b >= 42 AND c < 77`, the index would have to be scanned from the first entry with \(a = 5\) and \(b = 42\) up through the last entry with \(a = 5\). Index entries with \(c >= 77\) would be skipped, but they’d still have to be scanned through. This index could in principle be used for queries that have constraints on \(b\) and/or \(c\) with no constraint on \(a\) — but the entire index would have to be scanned, so in most cases the planner would prefer a sequential table scan over using the index.

A multicolumn GiST index can be used with query conditions that involve any subset of the index’s columns. Conditions on additional columns restrict the entries returned by the index, but the condition on the first column is the most important one for determining how much of the index needs to be scanned. A GiST index will be relatively ineffective if its first column has only a few distinct values, even if there are many distinct values in additional columns.

A multicolumn GIN index can be used with query conditions that involve any subset of the index’s columns. Unlike B-tree or GiST, index search effectiveness is the same regardless of which index column(s) the query conditions use.

Of course, each column must be used with operators appropriate to the index type; clauses that involve other operators will not be considered.

Multicolumn indexes should be used sparingly. In most situations, an index on a single column is sufficient and saves space and time. Indexes with more than three columns are unlikely to be helpful unless the usage of the table is extremely stylized. See also Section 11.5 for some discussion of the merits of different index configurations.

### 11.4. Indexes and `ORDER BY`

In addition to simply finding the rows to be returned by a query, an index may be able to deliver them in a specific sorted order. This allows a query’s `ORDER BY` specification to be honored without a separate sorting step. Of the index types currently supported by PostgreSQL, only B-tree can produce sorted output — the other index types return matching rows in an unspecified, implementation-dependent order.

The planner will consider satisfying an `ORDER BY` specification either by scanning an available index that matches the specification, or by scanning the table in physical order and doing an explicit sort. For a query that requires scanning a large fraction of the table, an explicit sort is likely to be faster than using an index because it requires less disk I/O due to following a sequential access pattern. Indexes are more useful when only a few rows need be fetched. An important special case is `ORDER BY` in combination with `LIMIT n`: an explicit sort will have to process all the data to identify the first \(n\) rows, but if there is an index matching the `ORDER BY`, the first \(n\) rows can be retrieved directly, without scanning the remainder at all.

By default, B-tree indexes store their entries in ascending order with nulls last. This means that a forward scan of an index on column \(x\) produces output satisfying `ORDER BY x` (or more verbosely, `ORDER BY x ASC NULLS LAST`). The index can also be scanned backward, producing output satisfying `ORDER BY x DESC` (or more verbosely, `ORDER BY x DESC NULLS FIRST`, since `NULLS FIRST` is the default for `ORDER BY DESC`).
You can adjust the ordering of a B-tree index by including the options ASC, DESC, NULLS FIRST, and/or NULLS LAST when creating the index; for example:

```
CREATE INDEX test2_info_nulls_low ON test2 (info NULLS FIRST);
CREATE INDEX test3_desc_index ON test3 (id DESC NULLS LAST);
```

An index stored in ascending order with nulls first can satisfy either ORDER BY x ASC NULLS FIRST or ORDER BY x DESC NULLS LAST depending on which direction it is scanned in.

You might wonder why bother providing all four options, when two options together with the possibility of backward scan would cover all the variants of ORDER BY. In single-column indexes the options are indeed redundant, but in multicolumn indexes they can be useful. Consider a two-column index on (x, y): this can satisfy ORDER BY x, y if we scan forward, or ORDER BY x DESC, y ASC if we scan backward. But it might be that the application frequently needs to use ORDER BY x ASC, y DESC. There is no way to get that ordering from a plain index, but it is possible if the index is defined as (x ASC, y DESC) or (x DESC, y ASC).

Obviously, indexes with non-default sort orderings are a fairly specialized feature, but sometimes they can produce tremendous speedups for certain queries. Whether it’s worth maintaining such an index depends on how often you use queries that require a special sort ordering.

### 11.5. Combining Multiple Indexes

A single index scan can only use query clauses that use the index’s columns with operators of its operator class and are joined with AND. For example, given an index on (a, b) a query condition like WHERE a = 5 AND b = 6 could use the index, but a query like WHERE a = 5 OR b = 6 could not directly use the index.

Fortunately, PostgreSQL has the ability to combine multiple indexes (including multiple uses of the same index) to handle cases that cannot be implemented by single index scans. The system can form AND and OR conditions across several index scans. For example, a query like WHERE x = 42 OR x = 47 OR x = 53 OR x = 99 could be broken down into four separate scans of an index on x, each scan using one of the query clauses. The results of these scans are then ORED together to produce the result. Another example is that if we have separate indexes on x and y, one possible implementation of a query like WHERE x = 5 AND y = 6 is to use each index with the appropriate query clause and then AND together the index results to identify the result rows.

To combine multiple indexes, the system scans each needed index and prepares a bitmap in memory giving the locations of table rows that are reported as matching that index’s conditions. The bitmaps are then ANDED and ORED together as needed by the query. Finally, the actual table rows are visited and returned. The table rows are visited in physical order, because that is how the bitmap is laid out; this means that any ordering of the original indexes is lost, and so a separate sort step will be needed if the query has an ORDER BY clause. For this reason, and because each additional index scan adds extra time, the planner will sometimes choose to use a simple index scan even though additional indexes are available that could have been used as well.

In all but the simplest applications, there are various combinations of indexes that might be useful, and the database developer must make trade-offs to decide which indexes to provide. Sometimes multicolumn indexes are best, but sometimes it’s better to create separate indexes and rely on the index-combination feature. For example, if your workload includes a mix of queries that sometimes involve only column x, sometimes only column y, and sometimes both columns, you might choose to create two separate indexes on x and y, relying on index combination to process the queries that use both columns. You could also create a multicolumn index on (x, y). This index would typically be more efficient than index combination for queries involving both columns, but as discussed in Section
11.3. it would be almost useless for queries involving only \( y \), so it should not be the only index. A combination of the multicolumn index and a separate index on \( y \) would serve reasonably well. For queries involving only \( x \), the multicolumn index could be used, though it would be larger and hence slower than an index on \( x \) alone. The last alternative is to create all three indexes, but this is probably only reasonable if the table is searched much more often than it is updated and all three types of query are common. If one of the types of query is much less common than the others, you’d probably settle for creating just the two indexes that best match the common types.

### 11.6. Unique Indexes

Indexes can also be used to enforce uniqueness of a column’s value, or the uniqueness of the combined values of more than one column.

```
CREATE UNIQUE INDEX name ON table (column [, ...]);
```

Currently, only B-tree indexes can be declared unique.

When an index is declared unique, multiple table rows with equal indexed values are not allowed. Null values are not considered equal. A multicolumn unique index will only reject cases where all indexed columns are equal in multiple rows.

PostgreSQL automatically creates a unique index when a unique constraint or primary key is defined for a table. The index covers the columns that make up the primary key or unique constraint (a multicolumn index, if appropriate), and is the mechanism that enforces the constraint.

**Note:** The preferred way to add a unique constraint to a table is `ALTER TABLE ... ADD CONSTRAINT`. The use of indexes to enforce unique constraints could be considered an implementation detail that should not be accessed directly. One should, however, be aware that there’s no need to manually create indexes on unique columns; doing so would just duplicate the automatically-created index.

### 11.7. Indexes on Expressions

An index column need not be just a column of the underlying table, but can be a function or scalar expression computed from one or more columns of the table. This feature is useful to obtain fast access to tables based on the results of computations.

For example, a common way to do case-insensitive comparisons is to use the `lower` function:

```
SELECT * FROM test1 WHERE lower(col1) = 'value';
```

This query can use an index if one has been defined on the result of the `lower(col1)` function:

```
CREATE INDEX test1_lower_col1_idx ON test1 (lower(col1));
```

If we were to declare this index **UNIQUE**, it would prevent creation of rows whose `col1` values differ only in case, as well as rows whose `col1` values are actually identical. Thus, indexes on expressions can be used to enforce constraints that are not definable as simple unique constraints.

As another example, if one often does queries like:
Chapter 11. Indexes

SELECT * FROM people WHERE (first_name || ' ' || last_name) = 'John Smith';

then it might be worth creating an index like this:

CREATE INDEX people_names ON people ((first_name || ' ' || last_name));

The syntax of the CREATE INDEX command normally requires writing parentheses around index expressions, as shown in the second example. The parentheses can be omitted when the expression is just a function call, as in the first example.

Index expressions are relatively expensive to maintain, because the derived expression(s) must be computed for each row upon insertion and whenever it is updated. However, the index expressions are not recomputed during an indexed search, since they are already stored in the index. In both examples above, the system sees the query as just WHERE indexedcolumn = 'constant’ and so the speed of the search is equivalent to any other simple index query. Thus, indexes on expressions are useful when retrieval speed is more important than insertion and update speed.

11.8. Partial Indexes

A partial index is an index built over a subset of a table; the subset is defined by a conditional expression (called the predicate of the partial index). The index contains entries only for those table rows that satisfy the predicate. Partial indexes are a specialized feature, but there are several situations in which they are useful.

One major reason for using a partial index is to avoid indexing common values. Since a query searching for a common value (one that accounts for more than a few percent of all the table rows) will not use the index anyway, there is no point in keeping those rows in the index at all. This reduces the size of the index, which will speed up those queries that do use the index. It will also speed up many table update operations because the index does not need to be updated in all cases. Example 11-1 shows a possible application of this idea.

Example 11-1. Setting up a Partial Index to Exclude Common Values

Suppose you are storing web server access logs in a database. Most accesses originate from the IP address range of your organization but some are from elsewhere (say, employees on dial-up connections). If your searches by IP are primarily for outside accesses, you probably do not need to index the IP range that corresponds to your organization’s subnet.

Assume a table like this:

```
CREATE TABLE access_log (  
    url varchar,  
    client_ip inet,  
    ...  
);
```

To create a partial index that suits our example, use a command such as this:

```
CREATE INDEX access_log_client_ip_ix ON access_log (client_ip)  
WHERE NOT (client_ip > inet '192.168.100.0' AND  
           client_ip < inet '192.168.100.255');
```

A typical query that can use this index would be:

```
SELECT *
```
FROM access_log
WHERE url = '/index.html' AND client_ip = inet '212.78.10.32';

A query that cannot use this index is:
SELECT *
FROM access_log
WHERE client_ip = inet '192.168.100.23';

Observe that this kind of partial index requires that the common values be predetermined, so such partial indexes are best used for data distributions that do not change. The indexes can be recreated occasionally to adjust for new data distributions, but this adds maintenance effort.

Another possible use for a partial index is to exclude values from the index that the typical query workload is not interested in; this is shown in Example 11-2. This results in the same advantages as listed above, but it prevents the “uninteresting” values from being accessed via that index, even if an index scan might be profitable in that case. Obviously, setting up partial indexes for this kind of scenario will require a lot of care and experimentation.

Example 11-2. Setting up a Partial Index to Exclude Uninteresting Values

If you have a table that contains both billed and unbilled orders, where the unbilled orders take up a small fraction of the total table and yet those are the most-accessed rows, you can improve performance by creating an index on just the unbilled rows. The command to create the index would look like this:

CREATE INDEX orders_unbilled_index ON orders (order_nr)
WHERE billed is not true;

A possible query to use this index would be:
SELECT * FROM orders WHERE billed is not true AND order_nr < 10000;

However, the index can also be used in queries that do not involve order_nr at all, e.g.:
SELECT * FROM orders WHERE billed is not true AND amount > 5000.00;

This is not as efficient as a partial index on the amount column would be, since the system has to scan the entire index. Yet, if there are relatively few unbilled orders, using this partial index just to find the unbilled orders could be a win.

Note that this query cannot use this index:
SELECT * FROM orders WHERE order_nr = 3501;

The order 3501 might be among the billed or unbilled orders.

Example 11-2 also illustrates that the indexed column and the column used in the predicate do not need to match. PostgreSQL supports partial indexes with arbitrary predicates, so long as only columns of the table being indexed are involved. However, keep in mind that the predicate must match the conditions used in the queries that are supposed to benefit from the index. To be precise, a partial index can be used in a query only if the system can recognize that the \texttt{WHERE} condition of the query mathematically implies the predicate of the index. PostgreSQL does not have a sophisticated theorem prover that can recognize mathematically equivalent expressions that are written in different forms. (Not only is such a general theorem prover extremely difficult to create, it would probably be too slow to be of any real use.) The system can recognize simple inequality implications, for example “\texttt{x < 1}” implies “\texttt{x < 2}”; otherwise the predicate condition must exactly match part of the query’s \texttt{WHERE} condition or the index will not be recognized as usable. Matching takes place at query planning time, not at run time. As a result, parameterized query clauses do not work with a partial index. For
example a prepared query with a parameter might specify “x < ?” which will never imply “x < 2” for all possible values of the parameter.

A third possible use for partial indexes does not require the index to be used in queries at all. The idea here is to create a unique index over a subset of a table, as in Example 11-3. This enforces uniqueness among the rows that satisfy the index predicate, without constraining those that do not.

**Example 11-3. Setting up a Partial Unique Index**

Suppose that we have a table describing test outcomes. We wish to ensure that there is only one “successful” entry for a given subject and target combination, but there might be any number of “unsuccessful” entries. Here is one way to do it:

```sql
CREATE TABLE tests (
    subject text,
    target text,
    success boolean,
    ...)
;

CREATE UNIQUE INDEX tests_success_constraint ON tests (subject, target) WHERE success;
```

This is a particularly efficient approach when there are few successful tests and many unsuccessful ones.

Finally, a partial index can also be used to override the system’s query plan choices. Also, data sets with peculiar distributions might cause the system to use an index when it really should not. In that case the index can be set up so that it is not available for the offending query. Normally, PostgreSQL makes reasonable choices about index usage (e.g., it avoids them when retrieving common values, so the earlier example really only saves index size, it is not required to avoid index usage), and grossly incorrect plan choices are cause for a bug report.

Keep in mind that setting up a partial index indicates that you know at least as much as the query planner knows, in particular you know when an index might be profitable. Forming this knowledge requires experience and understanding of how indexes in PostgreSQL work. In most cases, the advantage of a partial index over a regular index will be minimal.

More information about partial indexes can be found in *The case for partial indexes*, *Partial indexing in POSTGRES: research project*, and *Generalized Partial Indexes (cached version)*.

### 11.9. Operator Classes and Operator Families

An index definition can specify an **operator class** for each column of an index.

```sql
CREATE INDEX name ON table (column opclass [sort options] [, ...]);
```

The operator class identifies the operators to be used by the index for that column. For example, a B-tree index on the type `int4` would use the `int4_ops` class; this operator class includes comparison functions for values of type `int4`. In practice the default operator class for the column’s data type is usually sufficient. The main reason for having operator classes is that for some data types, there could be more than one meaningful index behavior. For example, we might want to sort a complex-number data type either by absolute value or by real part. We could do this by defining two operator classes for the data type and then selecting the proper class when making an index. The operator class determines
the basic sort ordering (which can then be modified by adding sort options ASC/DESC and/or NULLS FIRST/NULLS LAST).

There are also some built-in operator classes besides the default ones:

- The operator classes text_pattern_ops, varchar_pattern_ops, and bpchar_pattern_ops support B-tree indexes on the types text, varchar, and char respectively. The difference from the default operator classes is that the values are compared strictly character by character rather than according to the locale-specific collation rules. This makes these operator classes suitable for use by queries involving pattern matching expressions (LIKE or POSIX regular expressions) when the database does not use the standard “C” locale. As an example, you might index a varchar column like this:

```
CREATE INDEX test_index ON test_table (col varchar_pattern_ops);
```

Note that you should also create an index with the default operator class if you want queries involving ordinary <, <=, >, or >= comparisons to use an index. Such queries cannot use the xxx_pattern_ops operator classes. (Ordinary equality comparisons can use these operator classes, however.) It is possible to create multiple indexes on the same column with different operator classes. If you do use the C locale, you do not need the xxx_pattern_ops operator classes, because an index with the default operator class is usable for pattern-matching queries in the C locale.

The following query shows all defined operator classes:

```
SELECT am.amname AS index_method, opc.opcname AS opclass_name FROM pg_am am, pg_opclass opc WHERE opc.opcmethod = am.oid ORDER BY index_method, opclass_name;
```

An operator class is actually just a subset of a larger structure called an operator family. In cases where several data types have similar behaviors, it is frequently useful to define cross-data-type operators and allow these to work with indexes. To do this, the operator classes for each of the types must be grouped into the same operator family. The cross-type operators are members of the family, but are not associated with any single class within the family.

This query shows all defined operator families and all the operators included in each family:

```
SELECT am.amname AS index_method, opf.opfname AS opfamily_name, amop.amopopr::regoperator AS opfamily_operator FROM pg_am am, pg_opfamily opf, pg_amop amop WHERE opf.opfmethod = am.oid AND amop.amopfamily = opf.oid ORDER BY index_method, opfamily_name, opfamily_operator;
```

### 11.10. Examining Index Usage

Although indexes in PostgreSQL do not need maintenance or tuning, it is still important to check which indexes are actually used by the real-life query workload. Examining index usage for an in-
individual query is done with the \texttt{EXPLAIN} command; its application for this purpose is illustrated in Section 14.1. It is also possible to gather overall statistics about index usage in a running server, as described in Section 26.2.

It is difficult to formulate a general procedure for determining which indexes to create. There are a number of typical cases that have been shown in the examples throughout the previous sections. A good deal of experimentation is often necessary. The rest of this section gives some tips for that:

- Always run \texttt{ANALYZE} first. This command collects statistics about the distribution of the values in the table. This information is required to estimate the number of rows returned by a query, which is needed by the planner to assign realistic costs to each possible query plan. In absence of any real statistics, some default values are assumed, which are almost certain to be inaccurate. Examining an application’s index usage without having run \texttt{ANALYZE} is therefore a lost cause. See \textit{Updating Planner Statistics} and \textit{The Autovacuum Daemon} for more information.

- Use real data for experimentation. Using test data for setting up indexes will tell you what indexes you need for the test data, but that is all. It is especially fatal to use very small test data sets. While selecting 1000 out of 100000 rows could be a candidate for an index, selecting 1 out of 100 rows will hardly be, because the 100 rows probably fit within a single disk page, and there is no plan that can beat sequentially fetching 1 disk page.

- When indexes are not used, it can be useful for testing to force their use. There are run-time parameters that can turn off various plan types (see Section 18.6.1). For instance, turning off sequential scans (\texttt{enable_seqscan}) and nested-loop joins (\texttt{enable_nestloop}), which are the most basic plans, will force the system to use a different plan. If the system still chooses a sequential scan or nested-loop join then there is probably a more fundamental reason why the index is not being used; for example, the query condition does not match the index. (What kind of query can use what kind of index is explained in the previous sections.)

- If forcing index usage does use the index, then there are two possibilities: Either the system is right and using the index is indeed not appropriate, or the cost estimates of the query plans are not reflecting reality. So you should time your query with and without indexes. The \texttt{EXPLAIN ANALYZE} command can be useful here.

- If it turns out that the cost estimates are wrong, there are, again, two possibilities. The total cost is computed from the per-row costs of each plan node times the selectivity estimate of the plan node. The costs estimated for the plan nodes can be adjusted via run-time parameters (described in Section 18.6.2). An inaccurate selectivity estimate is due to insufficient statistics. It might be possible to improve this by tuning the statistics-gathering parameters (see \texttt{ALTER TABLE}).

If you do not succeed in adjusting the costs to be more appropriate, then you might have to resort to forcing index usage explicitly. You might also want to contact the PostgreSQL developers to examine the issue.
Chapter 12. Full Text Search

12.1. Introduction

Full Text Searching (or just text search) provides the capability to identify natural-language documents that satisfy a query, and optionally to sort them by relevance to the query. The most common type of search is to find all documents containing given query terms and return them in order of their similarity to the query. Notions of query and similarity are very flexible and depend on the specific application. The simplest search considers query as a set of words and similarity as the frequency of query words in the document.

Textual search operators have existed in databases for years. PostgreSQL has ~, ~*, LIKE, and ILIKE operators for textual data types, but they lack many essential properties required by modern information systems:

- There is no linguistic support, even for English. Regular expressions are not sufficient because they cannot easily handle derived words, e.g., satisfies and satisfy. You might miss documents that contain satisfies, although you probably would like to find them when searching for satisfy. It is possible to use OR to search for multiple derived forms, but this is tedious and error-prone (some words can have several thousand derivatives).
- They provide no ordering (ranking) of search results, which makes them ineffective when thousands of matching documents are found.
- They tend to be slow because there is no index support, so they must process all documents for every search.

Full text indexing allows documents to be preprocessed and an index saved for later rapid searching. Preprocessing includes:

Parsing documents into tokens. It is useful to identify various classes of tokens, e.g., numbers, words, complex words, email addresses, so that they can be processed differently. In principle token classes depend on the specific application, but for most purposes it is adequate to use a predefined set of classes. PostgreSQL uses a parser to perform this step. A standard parser is provided, and custom parsers can be created for specific needs.

Converting tokens into lexemes. A lexeme is a string, just like a token, but it has been normalized so that different forms of the same word are made alike. For example, normalization almost always includes folding upper-case letters to lower-case, and often involves removal of suffixes (such as s or es in English). This allows searches to find variant forms of the same word, without tediously entering all the possible variants. Also, this step typically eliminates stop words, which are words that are so common that they are useless for searching. (In short, then, tokens are raw fragments of the document text, while lexemes are words that are believed useful for indexing and searching.) PostgreSQL uses dictionaries to perform this step. Various standard dictionaries are provided, and custom ones can be created for specific needs.

Storing preprocessed documents optimized for searching. For example, each document can be represented as a sorted array of normalized lexemes. Along with the lexemes it is often desirable to store positional information to use for proximity ranking, so that a document that contains a more “dense” region of query words is assigned a higher rank than one with scattered query words.

Dictionaries allow fine-grained control over how tokens are normalized. With appropriate dictionaries, you can:
Define stop words that should not be indexed.
Map synonyms to a single word using Ispell.
Map phrases to a single word using a thesaurus.
Map different variations of a word to a canonical form using an Ispell dictionary.
Map different variations of a word to a canonical form using Snowball stemmer rules.

A data type tsvector is provided for storing preprocessed documents, along with a type tsquery for representing processed queries (Section 8.11). There are many functions and operators available for these data types (Section 9.13), the most important of which is the match operator @@, which we introduce in Section 12.1.2. Full text searches can be accelerated using indexes (Section 12.9).

12.1.1. What Is a Document?

A document is the unit of searching in a full text search system; for example, a magazine article or email message. The text search engine must be able to parse documents and store associations of lexemes (key words) with their parent document. Later, these associations are used to search for documents that contain query words.

For searches within PostgreSQL, a document is normally a textual field within a row of a database table, or possibly a combination (concatenation) of such fields, perhaps stored in several tables or obtained dynamically. In other words, a document can be constructed from different parts for indexing and it might not be stored anywhere as a whole. For example:

```sql
SELECT title || ' ' || author || ' ' || abstract || ' ' || body AS document
FROM messages
WHERE mid = 12;

SELECT m.title || ' ' || m.author || ' ' || m.abstract || ' ' || d.body AS document
FROM messages m, docs d
WHERE mid = did AND mid = 12;
```

Note: Actually, in these example queries, coalesce should be used to prevent a single NULL attribute from causing a NULL result for the whole document.

Another possibility is to store the documents as simple text files in the file system. In this case, the database can be used to store the full text index and to execute searches, and some unique identifier can be used to retrieve the document from the file system. However, retrieving files from outside the database requires superuser permissions or special function support, so this is usually less convenient than keeping all the data inside PostgreSQL. Also, keeping everything inside the database allows easy access to document metadata to assist in indexing and display.

For text search purposes, each document must be reduced to the preprocessed tsvector format. Searching and ranking are performed entirely on the tsvector representation of a document — the original text need only be retrieved when the document has been selected for display to a user. We therefore often speak of the tsvector as being the document, but of course it is only a compact representation of the full document.
12.1.2. Basic Text Matching

Full text searching in PostgreSQL is based on the match operator `@@`, which returns `true` if a `tsvector` (document) matches a `tsquery` (query). It doesn’t matter which data type is written first:

```sql
SELECT 'a fat cat sat on a mat and ate a fat rat':tsvector @@ 'cat & rat':tsquery;
?column?
--------------
t
```

```sql
SELECT 'fat & cow':tsquery @@ 'a fat cat sat on a mat and ate a fat rat':tsvector;
?column?
--------------
f
```

As the above example suggests, a `tsquery` is not just raw text, any more than a `tsvector` is. A `tsquery` contains search terms, which must be already-normalized lexemes, and may combine multiple terms using AND, OR, and NOT operators. (For details see Section 8.11.) There are functions `to_tsquery` and `plainto_tsquery` that are helpful in converting user-written text into a proper `tsquery`, for example by normalizing words appearing in the text. Similarly, `to_tsvector` is used to parse and normalize a document string. So in practice a text search match would look more like this:

```sql
SELECT to_tsvector('fat cats ate fat rats') @@ to_tsquery('fat & rat');
?column?
--------------
t
```

Observe that this match would not succeed if written as

```sql
SELECT 'fat cats ate fat rats':tsvector @@ to_tsquery('fat & rat');
?column?
--------------
f
```

since here no normalization of the word `rats` will occur. The elements of a `tsvector` are lexemes, which are assumed already normalized, so `rats` does not match `rat`.

The `@@` operator also supports text input, allowing explicit conversion of a text string to `tsvector` or `tsquery` to be skipped in simple cases. The variants available are:

```sql
tsvector @@ tsquery
tsquery @@ tsvector
text @@ tsquery
text @@ text
```

The first two of these we saw already. The form `text @@ tsquery` is equivalent to `to_tsvector(x) @@ y`. The form `text @@ text` is equivalent to `to_tsvector(x) @@ plainto_tsquery(y)`.
12.1.3. Configurations

The above are all simple text search examples. As mentioned before, full text search functionality includes the ability to do many more things: skip indexing certain words (stop words), process synonyms, and use sophisticated parsing, e.g., parse based on more than just white space. This functionality is controlled by text search configurations. PostgreSQL comes with predefined configurations for many languages, and you can easily create your own configurations. (psql's \dfs command shows all available configurations.)

During installation an appropriate configuration is selected and default_text_search_config is set accordingly in postgresql.conf. If you are using the same text search configuration for the entire cluster you can use the value in postgresql.conf. To use different configurations throughout the cluster but the same configuration within any one database, use ALTER DATABASE ... SET. Otherwise, you can set default_text_search_config in each session.

Each text search function that depends on a configuration has an optional regconfig argument, so that the configuration to use can be specified explicitly. default_text_search_config is used only when this argument is omitted.

To make it easier to build custom text search configurations, a configuration is built up from simpler database objects. PostgreSQL's text search facility provides four types of configuration-related database objects:

- **Text search parsers** break documents into tokens and classify each token (for example, as words or numbers).
- **Text search dictionaries** convert tokens to normalized form and reject stop words.
- **Text search templates** provide the functions underlying dictionaries. (A dictionary simply specifies a template and a set of parameters for the template.)
- **Text search configurations** select a parser and a set of dictionaries to use to normalize the tokens produced by the parser.

Text search parsers and templates are built from low-level C functions; therefore it requires C programming ability to develop new ones, and superuser privileges to install one into a database. (There are examples of add-on parsers and templates in the contrib/ area of the PostgreSQL distribution.) Since dictionaries and configurations just parameterize and connect together some underlying parsers and templates, no special privilege is needed to create a new dictionary or configuration. Examples of creating custom dictionaries and configurations appear later in this chapter.

12.2. Tables and Indexes

The examples in the previous section illustrated full text matching using simple constant strings. This section shows how to search table data, optionally using indexes.

12.2.1. Searching a Table

It is possible to do a full text search without an index. A simple query to print the title of each row that contains the word friend in its body field is:

```sql
SELECT title
FROM pgweb
WHERE to_tsvector('english', body) @@ to_tsquery('english', 'friend');
```
This will also find related words such as friends and friendly, since all these are reduced to the same normalized lexeme.

The query above specifies that the english configuration is to be used to parse and normalize the strings. Alternatively we could omit the configuration parameters:

```
SELECT title
FROM pgweb
WHERE to_tsvector(body) @@ to_tsquery('friend');
```

This query will use the configuration set by default_text_search_config.

A more complex example is to select the ten most recent documents that contain create and table in the title or body:

```
SELECT title
FROM pgweb
WHERE to_tsvector(title || ' ' || body) @@ to_tsquery('create & table')
ORDER BY last_mod_date DESC
LIMIT 10;
```

For clarity we omitted the coalesce function calls which would be needed to find rows that contain NULL in one of the two fields.

Although these queries will work without an index, most applications will find this approach too slow, except perhaps for occasional ad-hoc searches. Practical use of text searching usually requires creating an index.

### 12.2.2. Creating Indexes

We can create a GIN index (Section 12.9) to speed up text searches:

```
CREATE INDEX pgweb_idx ON pgweb USING gin(to_tsvector('english', body));
```

Notice that the 2-argument version of to_tsvector is used. Only text search functions that specify a configuration name can be used in expression indexes (Section 11.7). This is because the index contents must be unaffected by default_text_search_config. If they were affected, the index contents might be inconsistent because different entries could contain tsvector that were created with different text search configurations, and there would be no way to guess which was which. It would be impossible to dump and restore such an index correctly.

Because the two-argument version of to_tsvector was used in the index above, only a query reference that uses the 2-argument version of to_tsvector with the same configuration name will use that index. That is, WHERE to_tsvector('english', body) @@ 'a & b' can use the index, but WHERE to_tsvector(body) @@ 'a & b' cannot. This ensures that an index will be used only with the same configuration used to create the index entries.

It is possible to set up more complex expression indexes wherein the configuration name is specified by another column, e.g.:

```
CREATE INDEX pgweb_idx ON pgweb USING gin(to_tsvector(config_name, body));
```

where config_name is a column in the pgweb table. This allows mixed configurations in the same index while recording which configuration was used for each index entry. This would be useful, for example, if the document collection contained documents in different languages. Again, queries that are meant to use the index must be phrased to match, e.g., WHERE to_tsvector(config_name, body) @@ 'a & b'.
Indexes can even concatenate columns:

```
CREATE INDEX pgweb_idx ON pgweb USING gin(to_tsvector('english', title || ' ' || body));
```

Another approach is to create a separate `tsvector` column to hold the output of `to_tsvector`. This example is a concatenation of `title` and `body`, using `coalesce` to ensure that one field will still be indexed when the other is `NULL`:

```
ALTER TABLE pgweb ADD COLUMN textsearchable_index_col tsvector;
UPDATE pgweb SET textsearchable_index_col =
  to_tsvector('english', coalesce(title,"") || ' ' || coalesce(body,""));
```

Then we create a GIN index to speed up the search:

```
CREATE INDEX textsearch_idx ON pgweb USING gin(textsearchable_index_col);
```

Now we are ready to perform a fast full text search:

```
SELECT title
FROM pgweb
WHERE textsearchable_index_col @@ to_tsquery('create & table')
ORDER BY last_mod_date DESC
LIMIT 10;
```

When using a separate column to store the `tsvector` representation, it is necessary to create a trigger to keep the `tsvector` column current anytime `title` or `body` changes. Section 12.4.3 explains how to do that.

One advantage of the separate-column approach over an expression index is that it is not necessary to explicitly specify the text search configuration in queries in order to make use of the index. As shown in the example above, the query can depend on `default_text_search_config`. Another advantage is that searches will be faster, since it will not be necessary to redo the `to_tsvector` calls to verify index matches. (This is more important when using a GiST index than a GIN index; see Section 12.9.) The expression-index approach is simpler to set up, however, and it requires less disk space since the `tsvector` representation is not stored explicitly.

### 12.3. Controlling Text Search

To implement full text searching there must be a function to create a `tsvector` from a document and a `tsquery` from a user query. Also, we need to return results in a useful order, so we need a function that compares documents with respect to their relevance to the query. It’s also important to be able to display the results nicely. PostgreSQL provides support for all of these functions.

#### 12.3.1. Parsing Documents

PostgreSQL provides the function `to_tsvector` for converting a document to the `tsvector` data type.

```
to_tsvector([ config regconfig, ] document text) returns tsvector
```
to_tsvector parses a textual document into tokens, reduces the tokens to lexemes, and returns a tsvector which lists the lexemes together with their positions in the document. The document is processed according to the specified or default text search configuration. Here is a simple example:

```
SELECT to_tsvector('english', 'a fat cat sat on a mat - it ate a fat rats');
```

```
-----------------------------------------------------
'ate':9 'cat':3 'fat':2,11 'mat':7 'rat':12 'sat':4
```

In the example above we see that the resulting tsvector does not contain the words a, on, or it, the word rats became rat, and the punctuation sign – was ignored.

The to_tsvector function internally calls a parser which breaks the document text into tokens and assigns a type to each token. For each token, a list of dictionaries (Section 12.6) is consulted, where the list can vary depending on the token type. The first dictionary that recognizes the token emits one or more normalized lexemes to represent the token. For example, rats became rat because one of the dictionaries recognized that the word rats is a plural form of rat. Some words are recognized as stop words (Section 12.6.1), which causes them to be ignored since they occur too frequently to be useful in searching. In our example these are a, on, and it. If no dictionary in the list recognizes the token then it is also ignored. In this example that happened to the punctuation sign – because there are in fact no dictionaries assigned for its token type (Space symbols), meaning space tokens will never be indexed. The choices of parser, dictionaries and which types of tokens to index are determined by the selected text search configuration (Section 12.7). It is possible to have many different configurations in the same database, and predefined configurations are available for various languages. In our example we used the default configuration english for the English language.

The function setweight can be used to label the entries of a tsvector with a given weight, where a weight is one of the letters A, B, C, or D. This is typically used to mark entries coming from different parts of a document, such as title versus body. Later, this information can be used for ranking of search results.

Because to_tsvector(NULL) will return NULL, it is recommended to use coalesce whenever a field might be null. Here is the recommended method for creating a tsvector from a structured document:

```
UPDATE tt SET ti =
    setweight(to_tsvector(coalesce(title,")), 'A') ||
    setweight(to_tsvector(coalesce(keyword,")), 'B') ||
    setweight(to_tsvector(coalesce(abstract,")), 'C') ||
    setweight(to_tsvector(coalesce(body,")), 'D');
```

Here we have used setweight to label the source of each lexeme in the finished tsvector, and then merged the labeled tsvector values using the tsvector concatenation operator ||. (Section 12.4.1 gives details about these operations.)

### 12.3.2. Parsing Queries

PostgreSQL provides the functions to_tsquery and plainto_tsquery for converting a query to the tsquery data type. to_tsquery offers access to more features than plainto_tsquery, but is less forgiving about its input.

```
to_tsquery([ config regconfig, | querytext text]) returns tsquery
```
to_tsquery creates a tsquery value from querytext, which must consist of single tokens separated by the Boolean operators & (AND), | (OR) and ! (NOT). These operators can be grouped using parentheses. In other words, the input to to_tsquery must already follow the general rules for tsquery input, as described in Section 8.11. The difference is that while basic tsquery input takes the tokens at face value, to_tsquery normalizes each token to a lexeme using the specified or default configuration, and discards any tokens that are stop words according to the configuration. For example:

```sql
SELECT to_tsquery('english', 'The & Fat & Rats');
```

```
'fat' & 'rat'
```

As in basic tsquery input, weight(s) can be attached to each lexeme to restrict it to match only tsvector lexemes of those weight(s). For example:

```sql
SELECT to_tsquery('english', 'Fat | Rats:AB');
```

```
'fat' | 'rat':AB
```

Also, * can be attached to a lexeme to specify prefix matching:

```sql
SELECT to_tsquery('supern:*A & star:A*B');
```

```
'supern':*A & 'star':*AB
```

Such a lexeme will match any word in a tsvector that begins with the given string.

to_tsquery can also accept single-quoted phrases. This is primarily useful when the configuration includes a thesaurus dictionary that may trigger on such phrases. In the example below, a thesaurus contains the rule supernovae stars : sn:

```sql
SELECT to_tsquery('supernovae stars & !crab');
```

```
'sn' & !'crab'
```

Without quotes, to_tsquery will generate a syntax error for tokens that are not separated by an AND or OR operator.

```sql
plainto_tsquery(
    [ config regconfig, ]
    querytext text
) returns tsquery
```

plainto_tsquery transforms unformatted text querytext to tsquery. The text is parsed and normalized much as for to_tsvector, then the & (AND) Boolean operator is inserted between surviving words.

Example:

```sql
SELECT plainto_tsquery('english', 'The Fat Rats');
```

```
'fat' & 'rat'
```

Note that plainto_tsquery cannot recognize Boolean operators, weight labels, or prefix-match labels in its input:
Chapter 12. Full Text Search

SELECT plainto_tsquery('english', 'The Fat & Rats:C');
plainto_tsquery
---------------------
'fat' & 'rat' & 'c'

Here, all the input punctuation was discarded as being space symbols.

12.3.3. Ranking Search Results

Ranking attempts to measure how relevant documents are to a particular query, so that when there are many matches the most relevant ones can be shown first. PostgreSQL provides two predefined ranking functions, which take into account lexical, proximity, and structural information; that is, they consider how often the query terms appear in the document, how close together the terms are in the document, and how important is the part of the document where they occur. However, the concept of relevancy is vague and very application-specific. Different applications might require additional information for ranking, e.g., document modification time. The built-in ranking functions are only examples. You can write your own ranking functions and/or combine their results with additional factors to fit your specific needs.

The two ranking functions currently available are:

```sql
ts_rank([ weights float4[]], [vector tsvector, query tsquery [ , normalization integer ]]) returns float4
```

Standard ranking function.

```sql
ts_rank_cd([ weights float4[]], [vector tsvector, query tsquery [ , normalization integer ]]) returns float4
```

This function computes the cover density ranking for the given document vector and query, as described in Clarke, Cormack, and Tudhope’s "Relevance Ranking for One to Three Term Queries" in the journal "Information Processing and Management", 1999.

This function requires positional information in its input. Therefore it will not work on "stripped" tsvector values — it will always return zero.

For both these functions, the optional weights argument offers the ability to weigh word instances more or less heavily depending on how they are labeled. The weight arrays specify how heavily to weigh each category of word, in the order:

{D-weight, C-weight, B-weight, A-weight}

If no weights are provided, then these defaults are used:

{0.1, 0.2, 0.4, 1.0}

Typically weights are used to mark words from special areas of the document, like the title or an initial abstract, so they can be treated with more or less importance than words in the document body.

Since a longer document has a greater chance of containing a query term it is reasonable to take into account document size, e.g., a hundred-word document with five instances of a search word is probably more relevant than a thousand-word document with five instances. Both ranking functions take an integer normalization option that specifies whether and how a document’s length should
Chapter 12. Full Text Search

impact its rank. The integer option controls several behaviors, so it is a bit mask: you can specify one or more behaviors using | (for example, 2|4).

- 0 (the default) ignores the document length
- 1 divides the rank by 1 + the logarithm of the document length
- 2 divides the rank by the document length
- 4 divides the rank by the mean harmonic distance between extents (this is implemented only by ts_rank_cd)
- 8 divides the rank by the number of unique words in document
- 16 divides the rank by 1 + the logarithm of the number of unique words in document
- 32 divides the rank by itself + 1

If more than one flag bit is specified, the transformations are applied in the order listed.

It is important to note that the ranking functions do not use any global information, so it is impossible to produce a fair normalization to 1% or 100% as sometimes desired. Normalization option 32 \((\text{rank}/(\text{rank}+1))\) can be applied to scale all ranks into the range zero to one, but of course this is just a cosmetic change; it will not affect the ordering of the search results.

Here is an example that selects only the ten highest-ranked matches:

```sql
SELECT title, ts_rank_cd(textsearch, query) AS rank
FROM apod, to_tsquery('neutrino|(dark & matter)') query
WHERE query @@ textsearch
ORDER BY rank DESC
LIMIT 10;
```

<table>
<thead>
<tr>
<th>title</th>
<th>rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>Neutrinos in the Sun</td>
<td>3.1</td>
</tr>
<tr>
<td>The Sudbury Neutrino Detector</td>
<td>2.4</td>
</tr>
<tr>
<td>A MACHO View of Galactic Dark Matter</td>
<td>2.01317</td>
</tr>
<tr>
<td>Hot Gas and Dark Matter</td>
<td>1.91171</td>
</tr>
<tr>
<td>The Virgo Cluster: Hot Plasma and Dark Matter</td>
<td>1.90953</td>
</tr>
<tr>
<td>Rafting for Solar Neutrinos</td>
<td>1.85774</td>
</tr>
<tr>
<td>NGC 4650A: Strange Galaxy and Dark Matter</td>
<td>1.6123</td>
</tr>
<tr>
<td>Ice Fishing for Cosmic Neutrinos</td>
<td>1.6</td>
</tr>
<tr>
<td>Weak Lensing Distorts the Universe</td>
<td>0.818218</td>
</tr>
</tbody>
</table>

This is the same example using normalized ranking:

```sql
SELECT title, ts_rank_cd(textsearch, query, 32 /* rank/(rank+1) */) AS rank
FROM apod, to_tsquery('neutrino|(dark & matter)') query
WHERE query @@ textsearch
ORDER BY rank DESC
LIMIT 10;
```

<table>
<thead>
<tr>
<th>title</th>
<th>rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>Neutrinos in the Sun</td>
<td>0.756097569485493</td>
</tr>
<tr>
<td>The Sudbury Neutrino Detector</td>
<td>0.705882361190954</td>
</tr>
<tr>
<td>A MACHO View of Galactic Dark Matter</td>
<td>0.668123210574724</td>
</tr>
<tr>
<td>Hot Gas and Dark Matter</td>
<td>0.65655958650282</td>
</tr>
<tr>
<td>The Virgo Cluster: Hot Plasma and Dark Matter</td>
<td>0.656301290640973</td>
</tr>
<tr>
<td>Rafting for Solar Neutrinos</td>
<td>0.655172410958162</td>
</tr>
<tr>
<td>NGC 4650A: Strange Galaxy and Dark Matter</td>
<td>0.650072921219637</td>
</tr>
<tr>
<td>Hot Gas and Dark Matter</td>
<td>0.617195790024749</td>
</tr>
<tr>
<td>Ice Fishing for Cosmic Neutrinos</td>
<td>0.615384618911517</td>
</tr>
</tbody>
</table>
Ranking can be expensive since it requires consulting the tsvector of each matching document, which can be I/O bound and therefore slow. Unfortunately, it is almost impossible to avoid since practical queries often result in large numbers of matches.

### 12.3.4. Highlighting Results

To present search results it is ideal to show a part of each document and how it is related to the query. Usually, search engines show fragments of the document with marked search terms. PostgreSQL provides a function `ts_headline` that implements this functionality.

```sql
SELECT ts_headline('english', 'query string', options string);
```

The `ts_headline` function accepts a document along with a query, and returns an excerpt from the document in which terms from the query are highlighted. The configuration to be used to parse the document can be specified by `config`; if `config` is omitted, the `default_text_search_config` configuration is used.

If an `options` string is specified it must consist of a comma-separated list of one or more `option=value` pairs. The available options are:

- **StartSel, StopSel**: the strings with which to delimit query words appearing in the document, to distinguish them from other excerpted words. You must double-quote these strings if they contain spaces or commas.
- **MaxWords, MinWords**: these numbers determine the longest and shortest headlines to output.
- **ShortWord**: words of this length or less will be dropped at the start and end of a headline. The default value of three eliminates common English articles.
- **HighlightAll**: Boolean flag; if `true` the whole document will be used as the headline, ignoring the preceding three parameters.
- **MaxFragments**: maximum number of text excerpts or fragments to display. The default value of zero selects a non-fragment-oriented headline generation method. A value greater than zero selects fragment-based headline generation. This method finds text fragments with as many query words as possible and stretches those fragments around the query words. As a result query words are close to the middle of each fragment and have words on each side. Each fragment will be of at most `MaxWords` and words of length `ShortWord` or less are dropped at the start and end of each fragment. If not all query words are found in the document, then a single fragment of the first `MinWords` in the document will be displayed.
- **FragmentDelimiter**: When more than one fragment is displayed, the fragments will be separated by this string.

Any unspecified options receive these defaults:

- `StartSel=<b>, StopSel=</b>`
- `MaxWords=35, MinWords=15, ShortWord=3, HighlightAll=FALSE, MaxFragments=0, FragmentDelimiter=" ... "`

For example:

```sql
SELECT ts_headline('english', 'query string', 'option1=value1, option2=value2');
```
Chapter 12. Full Text Search

'\n
The most common type of search is to find all documents containing given query terms and return them in order of their similarity to the query.',

\texttt{to_tsquery('query & similarity')};
\texttt{ts_headline}

------------------------------------------------------------

containing given \texttt{query} terms and return them in order of their \texttt{similarity} to the \texttt{query}.

\texttt{SELECT ts_headline('english', 'The most common type of search is to find all documents containing given query terms and return them in order of their similarity to the query.', to_tsquery('query & similarity'), 'StartSel = <, StopSel = >');}
\texttt{ts_headline}

-------------------------------------------------------

containing given \texttt{query} terms and return them in order of their \texttt{similarity} to the \texttt{query}.

\texttt{ts_headline} uses the original document, not a tsvector summary, so it can be slow and should be used with care. A typical mistake is to call \texttt{ts_headline} for every matching document when only ten documents are to be shown. SQL subqueries can help; here is an example:

\texttt{SELECT id, ts_headline(body, q), rank}
\texttt{FROM (SELECT id, body, q, ts_rank_cd(ti, q) AS rank}
\texttt{FROM apod, to_tsquery('stars') q}
\texttt{WHERE ti @@ q}
\texttt{ORDER BY rank DESC}
\texttt{LIMIT 10) AS foo;}

12.4. Additional Features

This section describes additional functions and operators that are useful in connection with text search.

12.4.1. Manipulating Documents

Section 12.3.1 showed how raw textual documents can be converted into tsvector values. PostgreSQL also provides functions and operators that can be used to manipulate documents that are already in tsvector form.
The `tsvector` concatenation operator returns a vector which combines the lexemes and positional information of the two vectors given as arguments. Positions and weight labels are retained during the concatenation. Positions appearing in the right-hand vector are offset by the largest position mentioned in the left-hand vector, so that the result is nearly equivalent to the result of performing `to_tsvector` on the concatenation of the two original document strings. (The equivalence is not exact, because any stop-words removed from the end of the left-hand argument will not affect the result, whereas they would have affected the positions of the lexemes in the right-hand argument if textual concatenation were used.)

One advantage of using concatenation in the vector form, rather than concatenating text before applying `to_tsvector`, is that you can use different configurations to parse different sections of the document. Also, because the `setweight` function marks all lexemes of the given vector the same way, it is necessary to parse the text and do `setweight` before concatenating if you want to label different parts of the document with different weights.

```sql
setweight(vector tsvector, weight "char") returns tsvector
```

`setweight` returns a copy of the input vector in which every position has been labeled with the given `weight`, either A, B, C, or D. (D is the default for new vectors and as such is not displayed on output.) These labels are retained when vectors are concatenated, allowing words from different parts of a document to be weighted differently by ranking functions.

Note that weight labels apply to positions, not lexemes. If the input vector has been stripped of positions then `setweight` does nothing.

```sql
length(vector tsvector) returns integer
```

Returns the number of lexemes stored in the vector.

```sql
strip(vector tsvector) returns tsvector
```

Returns a vector which lists the same lexemes as the given vector, but which lacks any position or weight information. While the returned vector is much less useful than an unstripped vector for relevance ranking, it will usually be much smaller.

### 12.4.2. Manipulating Queries

Section 12.3.2 showed how raw textual queries can be converted into `tsquery` values. PostgreSQL also provides functions and operators that can be used to manipulate queries that are already in `tsquery` form.

```sql
tquery & tquery
```

Returns the AND-combination of the two given queries.

```sql
tquery || tquery
```

Returns the OR-combination of the two given queries.
Chapter 12. Full Text Search

!! tsquery

Returns the negation (NOT) of the given query.

numnode(query tsquery) returns integer

Returns the number of nodes (lexemes plus operators) in a tsquery. This function is useful to determine if the query is meaningful (returns > 0), or contains only stop words (returns 0).

Examples:
SELECT numnode(plainto_tsquery('the any'));
NOTICE: query contains only stopword(s) or doesn’t contain lexeme(s), ignored
numnode
--------
0
SELECT numnode('foo & bar':tsquery);
numnode
--------
3

querytree(query tsquery) returns text

Returns the portion of a tsquery that can be used for searching an index. This function is useful for detecting unindexable queries, for example those containing only stop words or only negated terms. For example:
SELECT querytree(to_tsquery('!defined'));
querytree
--------

12.4.2.1. Query Rewriting

The ts_rewrite family of functions search a given tsquery for occurrences of a target subquery, and replace each occurrence with a substitute subquery. In essence this operation is a tsquery-specific version of substring replacement. A target and substitute combination can be thought of as a query rewrite rule. A collection of such rewrite rules can be a powerful search aid. For example, you can expand the search using synonyms (e.g., new york, big apple, nyc, gotham) or narrow the search to direct the user to some hot topic. There is some overlap in functionality between this feature and thesaurus dictionaries (Section 12.6.4). However, you can modify a set of rewrite rules on-the-fly without reindexing, whereas updating a thesaurus requires reindexing to be effective.

ts_rewrite(query tsquery, target tsquery, substitute tsquery) returns tsquery

This form of ts_rewrite simply applies a single rewrite rule: target is replaced by substitute wherever it appears in query. For example:
SELECT ts_rewrite(‘a & b’:tsquery, ‘a’:tsquery, ‘c’:tsquery);
ts_rewrite
--------
‘b’ & ‘c’
ts_rewrite (query tsquery, select text) returns tsquery

This form of ts_rewrite accepts a starting query and a SQL select command, which is given as a text string. The select must yield two columns of tsquery type. For each row of the select result, occurrences of the first column value (the target) are replaced by the second column value (the substitute) within the current query value. For example:

```
CREATE TABLE aliases (t tsquery PRIMARY KEY, s tsquery);
INSERT INTO aliases VALUES('a', 'c');

SELECT ts_rewrite('a & b::tsquery, 'SELECT t,s FROM aliases');
```

```
ts_rewrite
------------
'b' & 'c'
```

Note that when multiple rewrite rules are applied in this way, the order of application can be important; so in practice you will want the source query to ORDER BY some ordering key.

Let's consider a real-life astronomical example. We'll expand query supernovae using table-driven rewriting rules:

```
CREATE TABLE aliases (t tsquery primary key, s tsquery);
INSERT INTO aliases VALUES(to_tsquery('supernovae'), to_tsquery('supernovae|sn'));

SELECT ts_rewrite(to_tsquery('supernovae & crab'), 'SELECT * FROM aliases');
```

```
ts_rewrite
---------------------------------
'crab' & ( 'supernova' | 'sn' )
```

We can change the rewriting rules just by updating the table:

```
UPDATE aliases
SET s = to_tsquery('supernovae|sn & !nebulae')
WHERE t = to_tsquery('supernovae');

SELECT ts_rewrite(to_tsquery('supernovae & crab'), 'SELECT * FROM aliases');
```

```
ts_rewrite
---------------------------------------------
'crab' & ( 'supernova' | 'sn' & !'nebula' )
```

Rewriting can be slow when there are many rewriting rules, since it checks every rule for a possible match. To filter out obvious non-candidate rules we can use the containment operators for the tsquery type. In the example below, we select only those rules which might match the original query:

```
SELECT ts_rewrite('a & b::tsquery,
    'SELECT t,s FROM aliases WHERE "a & b":tsquery @> t');
```

```
ts_rewrite
------------
'b' & 'c'
```
12.4.3. Triggers for Automatic Updates

When using a separate column to store the tsvector representation of your documents, it is necessary to create a trigger to update the tsvector column when the document content columns change. Two built-in trigger functions are available for this, or you can write your own.

\[
\begin{align*}
\text{tsvector_update_trigger} & (\text{tsvector_column_name}, \text{config_name}, \text{text_column_name}[, \ldots]) \\
\text{tsvector_update_trigger_column} & (\text{tsvector_column_name}, \text{config_column_name}, \text{text_column_name}[, \ldots])
\end{align*}
\]

These trigger functions automatically compute a tsvector column from one or more textual columns, under the control of parameters specified in the CREATE TRIGGER command. An example of their use is:

```
CREATE TABLE messages {
    title    text,
    body     text,
    tsv      tsvector
};

CREATE TRIGGER tsvectorupdate BEFORE INSERT OR UPDATE
ON messages FOR EACH ROW EXECUTE PROCEDURE
    tsvector_update_trigger(tsv, 'pg_catalog.english', title, body);

INSERT INTO messages VALUES('title here', 'the body text is here');
```

```
SELECT * FROM messages;
   title | body | tsv
-------+------|-----
  title here | the body text is here | 'bodi':4 'text':5 'titl':1
```

```
SELECT title, body FROM messages WHERE tsv @@ to_tsquery('title & body');
  title | body
-------+------
  title here | the body text is here
```

Having created this trigger, any change in title or body will automatically be reflected into tsv, without the application having to worry about it.

The first trigger argument must be the name of the tsvector column to be updated. The second argument specifies the text search configuration to be used to perform the conversion. For tsvector_update_trigger, the configuration name is simply given as the second trigger argument. It must be schema-qualified as shown above, so that the trigger behavior will not change with changes in search_path. For tsvector_update_trigger_column, the second trigger argument is the name of another table column, which must be of type regconfig. This allows a per-row selection of configuration to be made. The remaining argument(s) are the names of textual columns (of type text, varchar, or char). These will be included in the document in the order given. NULL values will be skipped (but the other columns will still be indexed).

A limitation of these built-in triggers is that they treat all the input columns alike. To process columns differently — for example, to weight title differently from body — it is necessary to write a custom trigger. Here is an example using PL/pgSQL as the trigger language:

```
CREATE FUNCTION messages_trigger() RETURNS trigger AS $$
begin
    new.tsv :=
        setweight(to_tsvector('pg_catalog.english', coalesce(new.title,"")), 'A') ||
```

Chapter 12. Full Text Search

```
setweight(to_tsvector('pg_catalog.english', coalesce(new.body,"")), 'D');
return new;
end
$$ LANGUAGE plpgsql;

CREATE TRIGGER tsvectorupdate BEFORE INSERT OR UPDATE
ON messages FOR EACH ROW EXECUTE PROCEDURE messages_trigger();
```

Keep in mind that it is important to specify the configuration name explicitly when creating tsvector values inside triggers, so that the column’s contents will not be affected by changes to default_text_search_config. Failure to do this is likely to lead to problems such as search results changing after a dump and reload.

### 12.4.4. Gathering Document Statistics

The function `ts_stat` is useful for checking your configuration and for finding stop-word candidates.

```
ts_stat(sqlquery text, [ weights text, ]
  OUT word text, OUT ndoc integer,
  OUT nentry integer) returns setof record
```

`sqlquery` is a text value containing an SQL query which must return a single tsvector column. `ts_stat` executes the query and returns statistics about each distinct lexeme (word) contained in the tsvector data. The columns returned are

- `word text` — the value of a lexeme
- `ndoc integer` — number of documents (tsvectors) the word occurred in
- `nentry integer` — total number of occurrences of the word

If `weights` is supplied, only occurrences having one of those weights are counted.

For example, to find the ten most frequent words in a document collection:

```
SELECT * FROM ts_stat('SELECT vector FROM apod')
ORDER BY nentry DESC, ndoc DESC, word
LIMIT 10;
```

The same, but counting only word occurrences with weight A or B:

```
SELECT * FROM ts_stat('SELECT vector FROM apod', 'ab')
ORDER BY nentry DESC, ndoc DESC, word
LIMIT 10;
```

### 12.5. Parsers

Text search parsers are responsible for splitting raw document text into tokens and identifying each token’s type, where the set of possible types is defined by the parser itself. Note that a parser does
not modify the text at all — it simply identifies plausible word boundaries. Because of this limited scope, there is less need for application-specific custom parsers than there is for custom dictionaries. At present PostgreSQL provides just one built-in parser, which has been found to be useful for a wide range of applications.

The built-in parser is named `pg_catalog.default`. It recognizes 23 token types:

Table 12-1. Default Parser’s Token Types

<table>
<thead>
<tr>
<th>Alias</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>asciiword</td>
<td>Word, all ASCII letters</td>
<td>elephant</td>
</tr>
<tr>
<td>word</td>
<td>Word, all letters</td>
<td>mañana</td>
</tr>
<tr>
<td>numword</td>

</tr>
<tr>
<td>protocol</td>
<td>Protocol head</td>
<td>http://</td>
</tr>
<tr>
<td>url</td>
<td>URL</td>
<td>example.com/stuff/index.html</td>
</tr>
<tr>
<td>host</td>
<td>Host</td>
<td>example.com</td>
</tr>
<tr>
<td>url_path</td>
<td>URL path</td>
<td>/stuff/index.html, in the</td>
</tr>
<tr>
<td></td>
<td></td>
<td>context of a URL</td>
</tr>
<tr>
<td>file</td>
<td>File or path name</td>
<td>/usr/local/foo.txt, if not</td>
</tr>
<tr>
<td></td>
<td></td>
<td>within a URL</td>
</tr>
<tr>
<td>sfloat</td>
<td>Scientific notation</td>
<td>-1.234e56</td>
</tr>
<tr>
<td>float</td>
<td>Decimal notation</td>
<td>-1.234</td>
</tr>
<tr>
<td>int</td>
<td>Signed integer</td>
<td>-1234</td>
</tr>
<tr>
<td>uint</td>
<td>Unsigned integer</td>
<td>1234</td>
</tr>
<tr>
<td>version</td>
<td>Version number</td>
<td>8.3.0</td>
</tr>
<tr>
<td>tag</td>
<td>XML tag</td>
<td>&lt;a href=&quot;dictionaries.html&quot;</td>
</tr>
<tr>
<td>entity</td>
<td>XML entity</td>
<td>&amp;</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td>(any whitespace or punctuation</td>
</tr>
<tr>
<td></td>
<td></td>
<td>not otherwise recognized)</td>
</tr>
</tbody>
</table>

**Note:** The parser’s notion of a “letter” is determined by the database’s locale setting, specifically `lc_ctype`. Words containing only the basic ASCII letters are reported as a separate token type, since it is sometimes useful to distinguish them. In most European languages, token types `word`
Chapter 12. Full Text Search

and asciiword should be treated alike.

It is possible for the parser to produce overlapping tokens from the same piece of text. As an example, a hyphenated word will be reported both as the entire word and as each component:

```
SELECT alias, description, token FROM ts_debug('foo-bar-beta1');
```

<table>
<thead>
<tr>
<th>alias</th>
<th>description</th>
<th>token</th>
</tr>
</thead>
<tbody>
<tr>
<td>numhword</td>
<td>Hyphenated word, letters and digits</td>
<td>foo-bar-beta1</td>
</tr>
<tr>
<td>hword_asciipart</td>
<td>Hyphenated word part, all ASCII</td>
<td>foo</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td>-</td>
</tr>
<tr>
<td>hword_asciipart</td>
<td>Hyphenated word part, all ASCII</td>
<td>bar</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td>-</td>
</tr>
<tr>
<td>hword_numpart</td>
<td>Hyphenated word part, letters and digits</td>
<td>beta1</td>
</tr>
</tbody>
</table>

This behavior is desirable since it allows searches to work for both the whole compound word and for components. Here is another instructive example:

```
SELECT alias, description, token FROM ts_debug('http://example.com/stuff/index.html');
```

<table>
<thead>
<tr>
<th>alias</th>
<th>description</th>
<th>token</th>
</tr>
</thead>
<tbody>
<tr>
<td>protocol</td>
<td>Protocol head</td>
<td>http://</td>
</tr>
<tr>
<td>url</td>
<td>URL</td>
<td>example.com/stuff/index.html</td>
</tr>
<tr>
<td>host</td>
<td>Host</td>
<td>example.com</td>
</tr>
<tr>
<td>url_path</td>
<td>URL path</td>
<td>/stuff/index.html</td>
</tr>
</tbody>
</table>

12.6. Dictionaries

Dictionaries are used to eliminate words that should not be considered in a search (stop words), and to normalize words so that different derived forms of the same word will match. A successfully normalized word is called a lexeme. Aside from improving search quality, normalization and removal of stop words reduce the size of the tsvector representation of a document, thereby improving performance. Normalization does not always have linguistic meaning and usually depends on application semantics.

Some examples of normalization:

- Linguistic - Ispell dictionaries try to reduce input words to a normalized form; stemmer dictionaries remove word endings
- URL locations can be canonicalized to make equivalent URLs match:
  - http://wwwpgsql.ru/db/mw/index.html
  - http://wwwpgsql.ru/db/mw/
  - http://wwwpgsql.ru/db/..//db/mw/index.html
- Color names can be replaced by their hexadecimal values, e.g., red, green, blue, magenta -> FF0000, 00FF00, 0000FF, FF00FF
- If indexing numbers, we can remove some fractional digits to reduce the range of possible numbers, so for example 3.14159265359, 3.1415926, 3.14 will be the same after normalization if only two digits are kept after the decimal point.
A dictionary is a program that accepts a token as input and returns:

- an array of lexemes if the input token is known to the dictionary (notice that one token can produce more than one lexeme)
- an empty array if the dictionary knows the token, but it is a stop word
- NULL if the dictionary does not recognize the input token

PostgreSQL provides predefined dictionaries for many languages. There are also several predefined templates that can be used to create new dictionaries with custom parameters. Each predefined dictionary template is described below. If no existing template is suitable, it is possible to create new ones; see the contrib/area of the PostgreSQL distribution for examples.

A text search configuration binds a parser together with a set of dictionaries to process the parser’s output tokens. For each token type that the parser can return, a separate list of dictionaries is specified by the configuration. When a token of that type is found by the parser, each dictionary in the list is consulted in turn, until some dictionary recognizes it as a known word. If it is identified as a stop word, or if no dictionary recognizes the token, it will be discarded and not indexed or searched for. The general rule for configuring a list of dictionaries is to place first the most narrow, most specific dictionary, then the more general dictionaries, finishing with a very general dictionary, like a Snowball stemmer or simple, which recognizes everything. For example, for an astronomy-specific search (astro_en configuration) one could bind token type asciiword (ASCII word) to a synonym dictionary of astronomical terms, a general English dictionary and a Snowball English stemmer:

```
ALTER TEXT SEARCH CONFIGURATION astro_en
    ADD MAPPING FOR asciiword WITH astrosyn, english_ispell, english_stem;
```

### 12.6.1. Stop Words

Stop words are words that are very common, appear in almost every document, and have no discrimination value. Therefore, they can be ignored in the context of full text searching. For example, every English text contains words like a and the, so it is useless to store them in an index. However, stop words do affect the positions in `tsvector`, which in turn affect ranking:

```sql
SELECT to_tsvector('english','in the list of stop words');
  to_tsvector
-------------------
 'list':3  'stop':5  'word':6
```

The missing positions 1,2,4 are because of stop words. Ranks calculated for documents with and without stop words are quite different:

```sql
SELECT ts_rank_cd (to_tsvector('english','in the list of stop words'), to_tsquery('list & stop'));
  ts_rank_cd
----------
  0.05

SELECT ts_rank_cd (to_tsvector('english','list stop words'), to_tsquery('list & stop'));
  ts_rank_cd
----------
  0.1
```
It is up to the specific dictionary how it treats stop words. For example, `ispell` dictionaries first normalize words and then look at the list of stop words, while `Snowball` stemmers first check the list of stop words. The reason for the different behavior is an attempt to decrease noise.

### 12.6.2. Simple Dictionary

The simple dictionary template operates by converting the input token to lower case and checking it against a file of stop words. If it is found in the file then an empty array is returned, causing the token to be discarded. If not, the lower-cased form of the word is returned as the normalized lexeme. Alternatively, the dictionary can be configured to report non-stop-words as unrecognized, allowing them to be passed on to the next dictionary in the list.

Here is an example of a dictionary definition using the simple template:

```sql
CREATE TEXT SEARCH DICTIONARY public.simple_dict (
    TEMPLATE = pg_catalog.simple,
    STOPWORDS = english
);
```

Here, `english` is the base name of a file of stop words. The file’s full name will be `$SHAREDIR/tsearch_data/english.stop`, where `$SHAREDIR` means the PostgreSQL installation’s shared-data directory, often `/usr/local/share/postgresql` (use `pg_config --sharedir` to determine it if you’re not sure). The file format is simply a list of words, one per line. Blank lines and trailing spaces are ignored, and upper case is folded to lower case, but no other processing is done on the file contents.

Now we can test our dictionary:

```sql
SELECT ts_lexize('public.simple_dict','YeS');
```

```
{yes}
```

```sql
SELECT ts_lexize('public.simple_dict','The');
```

```
{}
```

We can also choose to return `NULL`, instead of the lower-cased word, if it is not found in the stop words file. This behavior is selected by setting the dictionary’s `Accept` parameter to `false`. Continuing the example:

```sql
ALTER TEXT SEARCH DICTIONARY public.simple_dict ( Accept = false );
```

```sql
SELECT ts_lexize('public.simple_dict','YeS');
```

```
{yes}
```

```sql
SELECT ts_lexize('public.simple_dict','The');
```

```
{}
```
With the default setting of `Accept = true`, it is only useful to place a simple dictionary at the end of a list of dictionaries, since it will never pass on any token to a following dictionary. Conversely, `Accept = false` is only useful when there is at least one following dictionary.

**Caution**
Most types of dictionaries rely on configuration files, such as files of stop words. These files must be stored in UTF-8 encoding. They will be translated to the actual database encoding, if that is different, when they are read into the server.

**Caution**
Normally, a database session will read a dictionary configuration file only once, when it is first used within the session. If you modify a configuration file and want to force existing sessions to pick up the new contents, issue an `ALTER TEXT SEARCH DICTIONARY` command on the dictionary. This can be a “dummy” update that doesn’t actually change any parameter values.

### 12.6.3. Synonym Dictionary

This dictionary template is used to create dictionaries that replace a word with a synonym. Phrases are not supported (use the thesaurus template (Section 12.6.4) for that). A synonym dictionary can be used to overcome linguistic problems, for example, to prevent an English stemmer dictionary from reducing the word ‘Paris’ to ‘pari’. It is enough to have a `Paris paris` line in the synonym dictionary and put it before the `english_stem` dictionary. For example:

```sql
SELECT * FROM ts_debug('english', 'Paris');
```

<table>
<thead>
<tr>
<th>alias</th>
<th>description</th>
<th>token</th>
<th>dictionaries</th>
<th>dictionary</th>
<th>lexemes</th>
</tr>
</thead>
<tbody>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>Paris</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{pari}</td>
</tr>
</tbody>
</table>

CREATE TEXT SEARCH DICTIONARY my_synonym {
  TEMPLATE = synonym,
  SYNONYMS = my_synonyms
};

ALTER TEXT SEARCH CONFIGURATION english
ALTER MAPPING FOR asciiword
WITH my_synonym, english_stem;

SELECT * FROM ts_debug('english', 'Paris');
```

<table>
<thead>
<tr>
<th>alias</th>
<th>description</th>
<th>token</th>
<th>dictionaries</th>
<th>dictionary</th>
<th>lexemes</th>
</tr>
</thead>
<tbody>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>Paris</td>
<td>{my_synonym,english_stem}</td>
<td>my_synonym</td>
<td>{paris}</td>
</tr>
</tbody>
</table>

The only parameter required by the `synonym` template is `SYNONYMS`, which is the base name of its configuration file — `my_synonyms` in the above example. The file’s full name will be `$SHAREDIR/tsearch_data/my_synonyms.syn` (where `$SHAREDIR` means the PostgreSQL installation’s shared-data directory). The file format is just one line per word to be substituted, with
the word followed by its synonym, separated by white space. Blank lines and trailing spaces are ignored.

The synonym template also has an optional parameter CaseSensitive, which defaults to false. When CaseSensitive is false, words in the synonym file are folded to lower case, as are input tokens. When it is true, words and tokens are not folded to lower case, but are compared as-is.

### 12.6.4. Thesaurus Dictionary

A thesaurus dictionary (sometimes abbreviated as TZ) is a collection of words that includes information about the relationships of words and phrases, i.e., broader terms (BT), narrower terms (NT), preferred terms, non-preferred terms, related terms, etc.

Basically a thesaurus dictionary replaces all non-preferred terms by one preferred term and, optionally, preserves the original terms for indexing as well. PostgreSQL’s current implementation of the thesaurus dictionary is an extension of the synonym dictionary with added phrase support. A thesaurus dictionary requires a configuration file of the following format:

```
# this is a comment
sample word(s) : indexed word(s)
more sample word(s) : more indexed word(s)
...
```

where the colon (:) symbol acts as a delimiter between a a phrase and its replacement.

A thesaurus dictionary uses a subdictionary (which is specified in the dictionary’s configuration) to normalize the input text before checking for phrase matches. It is only possible to select one subdictionary. An error is reported if the subdictionary fails to recognize a word. In that case, you should remove the use of the word or teach the subdictionary about it. You can place an asterisk (*) at the beginning of an indexed word to skip applying the subdictionary to it, but all sample words must be known to the subdictionary.

The thesaurus dictionary chooses the longest match if there are multiple phrases matching the input, and ties are broken by using the last definition.

Specific stop words recognized by the subdictionary cannot be specified; instead use ? to mark the location where any stop word can appear. For example, assuming that a and the are stop words according to the subdictionary:

```
? one ? two : swsw
```

matches a one the two and the one a two; both would be replaced by swsw.

Since a thesaurus dictionary has the capability to recognize phrases it must remember its state and interact with the parser. A thesaurus dictionary uses these assignments to check if it should handle the next word or stop accumulation. The thesaurus dictionary must be configured carefully. For example, if the thesaurus dictionary is assigned to handle only the asciiword token, then a thesaurus dictionary definition like one 7 will not work since token type uint is not assigned to the thesaurus dictionary.

```
Caution
Thesauruses are used during indexing so any change in the thesaurus dictionary’s parameters requires reindexing. For most other dictionary types, small changes such as adding or removing stopwords does not force reindexing.
```

296
12.6.4.1. Thesaurus Configuration

To define a new thesaurus dictionary, use the *thesaurus* template. For example:

```sql
CREATE TEXT SEARCH DICTIONARY thesaurus_simple (
    TEMPLATE = thesaurus,
    DictFile = mythesaurus,
    Dictionary = pg_catalog.english_stem
);
```

Here:

- **thesaurus_simple** is the new dictionary’s name
- **mythesaurus** is the base name of the thesaurus configuration file. (Its full name will be `$SHAREDIR/tsearch_data/mythesaurus.ths`, where `$SHAREDIR` means the installation shared-data directory.)
- **pg_catalog.english_stem** is the subdictionary (here, a Snowball English stemmer) to use for thesaurus normalization. Notice that the subdictionary will have its own configuration (for example, stop words), which is not shown here.

Now it is possible to bind the thesaurus dictionary `thesaurus_simple` to the desired token types in a configuration, for example:

```sql
ALTER TEXT SEARCH CONFIGURATION russian
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart
    WITH thesaurus_simple;
```

12.6.4.2. Thesaurus Example

Consider a simple astronomical thesaurus `thesaurus_astro`, which contains some astronomical word combinations:

- supernovae stars : sn
- crab nebulae : crab

Below we create a dictionary and bind some token types to an astronomical thesaurus and English stemmer:

```sql
CREATE TEXT SEARCH DICTIONARY thesaurus_astro (
    TEMPLATE = thesaurus,
    DictFile = thesaurus_astro,
    Dictionary = english_stem
);
```

```sql
ALTER TEXT SEARCH CONFIGURATION russian
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart
    WITH thesaurus_astro, english_stem;
```

Now we can see how it works. *ts_lexize* is not very useful for testing a thesaurus, because it treats its input as a single token. Instead we can use *plainto_tsquery* and *to_tsvector* which will break their input strings into multiple tokens:

```sql
SELECT plainto_tsquery('supernova star');
```
planto_tsquery
-----------------
'sn'

SELECT to_tsvector('supernova star');
  to_tsvector
-----------------
'sn':1

In principle, one can use to_tsquery if you quote the argument:

SELECT to_tsquery('"supernova star"');
  to_tsquery
-----------------
'sn'

Notice that supernova star matches supernovae stars in thesaurus_astro because we specified the english_stem stemmer in the thesaurus definition. The stemmer removed the e and s.

To index the original phrase as well as the substitute, just include it in the right-hand part of the definition:

supernovae stars : sn supernovae stars

SELECT planto_tsquery('supernova star');
  planto_tsquery
-----------------
'sn' & 'supernova' & 'star'

12.6.5. Ispell Dictionary

The Ispell dictionary template supports morphological dictionaries, which can normalize many different linguistic forms of a word into the same lexeme. For example, an English Ispell dictionary can match all declensions and conjugations of the search term bank, e.g., banking, banked, banks, banks', and bank's.

The standard PostgreSQL distribution does not include any Ispell configuration files. Dictionaries for a large number of languages are available from Ispell\(^1\). Also, some more modern dictionary file formats are supported — MySpell\(^2\) (OO < 2.0.1) and Hunspell\(^3\) (OO >= 2.0.2). A large list of dictionaries is available on the OpenOffice Wiki\(^4\).

To create an Ispell dictionary, use the built-in ispell template and specify several parameters:

CREATE TEXT SEARCH DICTIONARY english_ispell {
    TEMPLATE = ispell,
    DictFile = english,
    AffFile = english,
    StopWords = english
};

Chapter 12. Full Text Search

Here, DictFile, AffFile, and StopWords specify the base names of the dictionary, affixes, and stop-words files. The stop-words file has the same format explained above for the simple dictionary type. The format of the other files is not specified here but is available from the above-mentioned web sites.

Ispell dictionaries usually recognize a limited set of words, so they should be followed by another broader dictionary; for example, a Snowball dictionary, which recognizes everything.

Ispell dictionaries support splitting compound words; a useful feature. Notice that the affix file should specify a special flag using the compoundwords controlled statement that marks dictionary words that can participate in compound formation:

```
compoundwords controlled z
```

Here are some examples for the Norwegian language:

```
SELECT ts_lexize('norwegian_ispell', 'overbuljongterningpakkmesterassistent');
{over,buljong,terning,pakk,mester,assistent}
SELECT ts_lexize('norwegian_ispell', 'sjokoladefabrikk');
{sjakoladefabrikk,sjakolade,fabrikk}
```

Note: MySpell does not support compound words. Hunspell has sophisticated support for compound words. At present, PostgreSQL implements only the basic compound word operations of Hunspell.

12.6.6. Snowball Dictionary

The Snowball dictionary template is based on a project by Martin Porter, inventor of the popular Porter’s stemming algorithm for the English language. Snowball now provides stemming algorithms for many languages (see the Snowball site\(^5\) for more information). Each algorithm understands how to reduce common variant forms of words to a base, or stem, spelling within its language. A Snowball dictionary requires a language parameter to identify which stemmer to use, and optionally can specify a stopword file name that gives a list of words to eliminate. (PostgreSQL’s standard stopword lists are also provided by the Snowball project.) For example, there is a built-in definition equivalent to

```
CREATE TEXT SEARCH DICTIONARY english_stem {
    TEMPLATE = snowball,
    Language = english,
    StopWords = english
};
```

The stopword file format is the same as already explained.

A Snowball dictionary recognizes everything, whether or not it is able to simplify the word, so it should be placed at the end of the dictionary list. It is useless to have it before any other dictionary because a token will never pass through it to the next dictionary.

\(^5\) http://snowball.tartarus.org
12.7. Configuration Example

A text search configuration specifies all options necessary to transform a document into a `tsvector`: the parser to use to break text into tokens, and the dictionaries to use to transform each token into a lexeme. Every call of `to_tsvector` or `to_tsquery` needs a text search configuration to perform its processing. The configuration parameter `default_text_search_config` specifies the name of the default configuration, which is the one used by text search functions if an explicit configuration parameter is omitted. It can be set in `postgresql.conf`, or set for an individual session using the `SET` command.

Several predefined text search configurations are available, and you can create custom configurations easily. To facilitate management of text search objects, a set of SQL commands is available, and there are several `psql` commands that display information about text search objects (Section 12.10).

As an example we will create a configuration `pg`, starting by duplicating the built-in `english` configuration:

```sql
CREATE TEXT SEARCH CONFIGURATION public.pg ( COPY = pg_catalog.english );
```

We will use a PostgreSQL-specific synonym list and store it in `$SHAREDIR/tsearch_data/pg_dict.syn`. The file contents look like:

```
postgres pg
pgsql pg
postgresql pg
```

We define the synonym dictionary like this:

```sql
CREATE TEXT SEARCH DICTIONARY pg_dict (
  TEMPLATE = synonym,
  SYNONYMS = pg_dict
);
```

Next we register the Ispell dictionary `english_ispell`, which has its own configuration files:

```sql
CREATE TEXT SEARCH DICTIONARY english_ispell (
  TEMPLATE = ispell,
  DictFile = english,
  AffFile = english,
  StopWords = english
);
```

Now we can set up the mappings for words in configuration `pg`:

```sql
ALTER TEXT SEARCH CONFIGURATION pg
  ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
                word, hword, hword_part
     WITH pg_dict, english_ispell, english_stem;
```

We choose not to index or search some token types that the built-in configuration does handle:

```sql
ALTER TEXT SEARCH CONFIGURATION pg
  DROP MAPPING FOR email, url, url_path, sfloat, float;
```

Now we can test our configuration:
SELECT * FROM ts_debug('public.pg', ' 
PostgreSQL, the highly scalable, SQL compliant, open source object-relational 
database management system, is now undergoing beta testing of the next 
version of our software.
');

The next step is to set the session to use the new configuration, which was created in the public 
schema:

=> \df
   List of text search configurations
   Schema | Name | Description
   --------+------+-----------------------------
   public | pg | 

SET default_text_search_config = 'public.pg';
SET

SHOW default_text_search_config;

default_text_search_config
------------------------------
public.pg

12.8. Testing and Debugging Text Search

The behavior of a custom text search configuration can easily become confusing. The functions de-
scribed in this section are useful for testing text search objects. You can test a complete configuration, 
or test parsers and dictionaries separately.

12.8.1. Configuration Testing

The function ts_debug allows easy testing of a text search configuration.

    ts_debug([ config regconfig, ] document text, 
    OUT alias text, 
    OUT description text, 
    OUT token text, 
    OUT dictionaries regdictionary[], 
    OUT dictionary regdictionary, 
    OUT lexemes text[]) 
    returns setof record

    ts_debug displays information about every token of document as produced by the parser 
and processed by the configured dictionaries. It uses the configuration specified by config, or 
default_text_search_config if that argument is omitted.

    ts_debug returns one row for each token identified in the text by the parser. The columns returned 
are

301
Chapter 12. Full Text Search

- **alias** text — short name of the token type
- **description** text — description of the token type
- **token** text — text of the token
- **dictionaries regdictionary[]** — the dictionaries selected by the configuration for this token type
- **dictionary regdictionary** — the dictionary that recognized the token, or NULL if none did
- **lexemes text[]** — the lexeme(s) produced by the dictionary that recognized the token, or NULL if none did; an empty array (()) means it was recognized as a stop word

Here is a simple example:

```
SELECT * FROM ts_debug('english','a fat cat sat on a mat - it ate a fat rats');
```

<table>
<thead>
<tr>
<th>alias</th>
<th>description</th>
<th>token</th>
<th>dictionaries</th>
<th>dictionary</th>
<th>lexemes</th>
</tr>
</thead>
<tbody>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>a</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{}</td>
</tr>
<tr>
<td>blank</td>
<td>Space symbols</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>asciiword</td>
<td>Word, all ASCII</td>
<td>fat</td>
<td>{english_stem}</td>
<td>english_stem</td>
<td>{fat}</td>

</tbody>
</table>

For a more extensive demonstration, we first create a `public.english` configuration and Ispell dictionary for the English language:

```
CREATE TEXT SEARCH CONFIGURATION public.english ( COPY = pg_catalog.english );
```

```
CREATE TEXT SEARCH DICTIONARY english_ispell {
    TEMPLATE = ispell,
    DictFile = english,
    AffFile = english,
    StopWords = english
};
```

```
ALTER TEXT SEARCH CONFIGURATION public.english
    ALTER MAPPING FOR asciiword WITH english_ispell, english_stem;
```
In this example, the word `Brightest` was recognized by the parser as an ASCII word (alias `asciiword`). For this token type the dictionary list is `english_ispell` and `english_stem`. The word was recognized by `english_ispell`, which reduced it to the noun `bright`. The word `supernovaes` is unknown to the `english_ispell` dictionary so it was passed to the next dictionary, and, fortunately, was recognized (in fact, `english_stem` is a Snowball dictionary which recognizes everything; that is why it was placed at the end of the dictionary list).

The word `The` was recognized by the `english_ispell` dictionary as a stop word (Section 12.6.1) and will not be indexed. The spaces are discarded too, since the configuration provides no dictionaries at all for them.

You can reduce the width of the output by explicitly specifying which columns you want to see:

```sql
SELECT alias, token, dictionary, lexemes
FROM ts_debug('public.english','The Brightest supernovaes');
```

```
alias | token | dictionary | lexemes
-----------+-------------+----------------+-------------
asciiword | The | english_ispell | {}
blank | | |
asciiword | Brightest | english_ispell | {bright}
blank | | |
asciiword | supernovaes | english_stem | {supernova}
```

### 12.8.2. Parser Testing

The following functions allow direct testing of a text search parser.

```sql
ts_parse(parser_name text, text text, OUT tokid integer, OUT token text) returns setof record
ts_parse(parser_oid oid, text text, OUT tokid integer, OUT token text) returns setof record
```

`ts_parse` parses the given `document` and returns a series of records, one for each token produced by parsing. Each record includes a `tokid` showing the assigned token type and a `token` which is the text of the token. For example:

```sql
SELECT * FROM ts_parse('default', '123 - a number');
tokid | token
-------+--------
22 | 123
12 | |
12 | -
1 | a
12 | |
```
ts_token_type(parser_name text, OUT tokid integer, 
OUT alias text, OUT description text) returns setof record

12.8.3. Dictionary Testing

The ts_lexize function facilitates dictionary testing.

    ts_lexize(dict regdictionary, token text) returns text[]

ts_lexize returns an array of lexemes if the input token is known to the dictionary, or an empty array if the token is known to the dictionary but it is a stop word, or NULL if it is an unknown word.

Examples:
SELECT ts_lexize('english_stem', 'stars');

```
t_s
-----------
{star}
```

SELECT ts_lexize('english_stem', 'a');

```
{}                                  
```

**Note:** The `ts_lexize` function expects a single *token*, not text. Here is a case where this can be confusing:

SELECT ts_lexize('thesaurus_astro','supernovae stars') is null;

```
?column?
-----------
t
```

The thesaurus dictionary `thesaurus_astro` does know the phrase `supernovae stars`, but `ts_lexize` fails since it does not parse the input text but treats it as a single token. Use `plainto_tsquery` or `to_tsvector` to test thesaurus dictionaries, for example:

SELECT plainto_tsquery('supernovae stars');

```
plainto_tsquery
-----------------
'sn'
```

## 12.9. GiST and GIN Index Types

There are two kinds of indexes that can be used to speed up full text searches. Note that indexes are not mandatory for full text searching, but in cases where a column is searched on a regular basis, an index is usually desirable.

```
CREATE INDEX name ON table USING gist(column);
```

Creates a GiST (Generalized Search Tree)-based index. The `column` can be of `tsvector` or `tsquery` type.

```
CREATE INDEX name ON table USING gin(column);
```

Creates a GIN (Generalized Inverted Index)-based index. The `column` must be of `tsvector` type.

There are substantial performance differences between the two index types, so it is important to understand their characteristics.
A GiST index is *lossy*, meaning that the index may produce false matches, and it is necessary to check the actual table row to eliminate such false matches. (PostgreSQL does this automatically when needed.) GiST indexes are lossy because each document is represented in the index by a fixed-length signature. The signature is generated by hashing each word into a random bit in an n-bit string, with all these bits OR-ed together to produce an n-bit document signature. When two words hash to the same bit position there will be a false match. If all words in the query have matches (real or false) then the table row must be retrieved to see if the match is correct.

Lossiness causes performance degradation due to unnecessary fetches of table records that turn out to be false matches. Since random access to table records is slow, this limits the usefulness of GiST indexes. The likelihood of false matches depends on several factors, in particular the number of unique words, so using dictionaries to reduce this number is recommended.

GIN indexes are not lossy for standard queries, but their performance depends logarithmically on the number of unique words. (However, GIN indexes store only the words (lexemes) of `tsvector` values, and not their weight labels. Thus a table row recheck is needed when using a query that involves weights.)

In choosing which index type to use, GiST or GIN, consider these performance differences:

- GIN index lookups are about three times faster than GiST
- GIN indexes take about three times longer to build than GiST
- GIN indexes are moderately slower to update than GiST indexes, but about 10 times slower if fast-update support was disabled (see Section 52.3.1 for details)
- GIN indexes are two-to-three times larger than GiST indexes

As a rule of thumb, GIN indexes are best for static data because lookups are faster. For dynamic data, GiST indexes are faster to update. Specifically, GiST indexes are very good for dynamic data and fast if the number of unique words (lexemes) is under 100,000, while GIN indexes will handle 100,000+ lexemes better but are slower to update.

Note that GIN index build time can often be improved by increasing `maintenance_work_mem`, while GiST index build time is not sensitive to that parameter.

Partitioning of big collections and the proper use of GiST and GIN indexes allows the implementation of very fast searches with online update. Partitioning can be done at the database level using table inheritance, or by distributing documents over servers and collecting search results using the contrib/dblink extension module. The latter is possible because ranking functions use only local information.

### 12.10. psql Support

Information about text search configuration objects can be obtained in psql using a set of commands:

```bash
\dF{d,p,t} [+] [PATTERN]
```

An optional `+` produces more details.

The optional parameter `PATTERN` can be the name of a text search object, optionally schema-qualified. If `PATTERN` is omitted then information about all visible objects will be displayed. `PATTERN` can be a regular expression and can provide *separate* patterns for the schema and object names. The following examples illustrate this:

12.11. Limitations

The current limitations of PostgreSQL’s text search features are:

- The length of each lexeme must be less than 2K bytes
- The length of a tsvector (lexemes + positions) must be less than 1 megabyte
- The number of lexemes must be less than \(2^{31}\)
- Position values in tsvector must be greater than 0 and no more than 16,383
- No more than 256 positions per lexeme
- The number of nodes (lexemes + operators) in a tsquery must be less than 32,768

For comparison, the PostgreSQL 8.1 documentation contained 10,441 unique words, a total of 335,420 words, and the most frequent word “postgresql” was mentioned 6,127 times in 655 documents.

Another example — the PostgreSQL mailing list archives contained 910,989 unique words with 57,491,343 lexemes in 461,020 messages.

12.12. Migration from Pre-8.3 Text Search

Applications that used the contrib/tsearch2 add-on module for text searching will need some adjustments to work with the built-in features:

- Some functions have been renamed or had small adjustments in their argument lists, and all of them are now in the pg_catalog schema, whereas in a previous installation they would have been in public or another non-system schema. There is a new version of contrib/tsearch2 (see Section F.35) that provides a compatibility layer to solve most problems in this area.
- The old contrib/tsearch2 functions and other objects must be suppressed when loading pg_dump output from a pre-8.3 database. While many of them won’t load anyway, a few will and

309
then cause problems. One simple way to deal with this is to load the new contrib/tsearch2 module before restoring the dump; then it will block the old objects from being loaded.

- Text search configuration setup is completely different now. Instead of manually inserting rows into configuration tables, search is configured through the specialized SQL commands shown earlier in this chapter. There is no automated support for converting an existing custom configuration for 8.3; you’re on your own here.

- Most types of dictionaries rely on some outside-the-database configuration files. These are largely compatible with pre-8.3 usage, but note the following differences:
  - Configuration files now must be placed in a single specified directory ($SHAREDIR/tsearch_data), and must have a specific extension depending on the type of file, as noted previously in the descriptions of the various dictionary types. This restriction was added to forestall security problems.
  - Configuration files must be encoded in UTF-8 encoding, regardless of what database encoding is used.
  - In thesaurus configuration files, stop words must be marked with ?.
Chapter 13. Concurrency Control

This chapter describes the behavior of the PostgreSQL database system when two or more sessions try to access the same data at the same time. The goals in that situation are to allow efficient access for all sessions while maintaining strict data integrity. Every developer of database applications should be familiar with the topics covered in this chapter.

13.1. Introduction

PostgreSQL provides a rich set of tools for developers to manage concurrent access to data. Internally, data consistency is maintained by using a multiversion model (Multiversion Concurrency Control, MVCC). This means that while querying a database each transaction sees a snapshot of data (a database version) as it was some time ago, regardless of the current state of the underlying data. This protects the transaction from viewing inconsistent data that could be caused by (other) concurrent transaction updates on the same data rows, providing transaction isolation for each database session. MVCC, by eschewing explicit locking methodologies of traditional database systems, minimizes lock contention in order to allow for reasonable performance in multiuser environments.

The main advantage of using the MVCC model of concurrency control rather than locking is that in MVCC locks acquired for querying (reading) data do not conflict with locks acquired for writing data, and so reading never blocks writing and writing never blocks reading.

Table- and row-level locking facilities are also available in PostgreSQL for applications that cannot adapt easily to MVCC behavior. However, proper use of MVCC will generally provide better performance than locks. In addition, application-defined advisory locks provide a mechanism for acquiring locks that are not tied to a single transaction.

13.2. Transaction Isolation

The SQL standard defines four levels of transaction isolation in terms of three phenomena that must be prevented between concurrent transactions. These undesirable phenomena are:

- **dirty read**
  
  A transaction reads data written by a concurrent uncommitted transaction.

- **nonrepeatable read**
  
  A transaction re-reads data it has previously read and finds that data has been modified by another transaction (that committed since the initial read).

- **phantom read**
  
  A transaction re-executes a query returning a set of rows that satisfy a search condition and finds that the set of rows satisfying the condition has changed due to another recently-committed transaction.

The four transaction isolation levels and the corresponding behaviors are described in Table 13-1.

**Table 13-1. SQL Transaction Isolation Levels**
Chapter 13. Concurrency Control

<table>
<thead>
<tr>
<th>Isolation Level</th>
<th>Dirty Read</th>
<th>Nonrepeatable Read</th>
<th>Phantom Read</th>
</tr>
</thead>
<tbody>
<tr>
<td>Read uncommitted</td>
<td>Possible</td>
<td>Possible</td>
<td>Possible</td>
</tr>
<tr>
<td>Read committed</td>
<td>Not possible</td>
<td>Possible</td>
<td>Possible</td>
</tr>
<tr>
<td>Repeatable read</td>
<td>Not possible</td>
<td>Not possible</td>
<td>Possible</td>
</tr>
<tr>
<td>Serializable</td>
<td>Not possible</td>
<td>Not possible</td>
<td>Not possible</td>
</tr>
</tbody>
</table>

In PostgreSQL, you can request any of the four standard transaction isolation levels. But internally, there are only two distinct isolation levels, which correspond to the levels Read Committed and Serializable. When you select the level Read Uncommitted you really get Read Committed, and when you select Repeatable Read you really get Serializable, so the actual isolation level might be stricter than what you select. This is permitted by the SQL standard: the four isolation levels only define which phenomena must not happen, they do not define which phenomena must happen. The reason that PostgreSQL only provides two isolation levels is that this is the only sensible way to map the standard isolation levels to the multiversion concurrency control architecture. The behavior of the available isolation levels is detailed in the following subsections.

To set the transaction isolation level of a transaction, use the command `SET TRANSACTION`.

### 13.2.1. Read Committed Isolation Level

Read Committed is the default isolation level in PostgreSQL. When a transaction uses this isolation level, a `SELECT` query (without a `FOR UPDATE/SHARE` clause) sees only data committed before the query began; it never sees either uncommitted data or changes committed during query execution by concurrent transactions. In effect, a `SELECT` query sees a snapshot of the database as of the instant the query begins to run. However, `SELECT` does see the effects of previous updates executed within its own transaction, even though they are not yet committed. Also note that two successive `SELECT` commands can see different data, even though they are within a single transaction, if other transactions commit changes during execution of the first `SELECT`.

`UPDATE`, `DELETE`, `SELECT FOR UPDATE`, and `SELECT FOR SHARE` commands behave the same as `SELECT` in terms of searching for target rows: they will only find target rows that were committed as of the command start time. However, such a target row might have already been updated (or deleted or locked) by another concurrent transaction by the time it is found. In this case, the would-be updater will wait for the first updating transaction to commit or roll back (if it is still in progress). If the first updater rolls back, then its effects are negated and the second updater can proceed with updating the originally found row. If the first updater commits, the second updater will ignore the row if the first updater deleted it, otherwise it will attempt to apply its operation to the updated version of the row. The search condition of the command (the `WHERE` clause) is re-evaluated to see if the updated version of the row still matches the search condition. If so, the second updater proceeds with its operation using the updated version of the row. In the case of `SELECT FOR UPDATE` and `SELECT FOR SHARE`, this means it is the updated version of the row that is locked and returned to the client.

Because of the above rule, it is possible for an updating command to see an inconsistent snapshot: it can see the effects of concurrent updating commands on the same rows it is trying to update, but it does not see effects of those commands on other rows in the database. This behavior makes Read Committed mode unsuitable for commands that involve complex search conditions; however, it is just right for simpler cases. For example, consider updating bank balances with transactions like:

```
BEGIN;
UPDATE accounts SET balance = balance + 100.00 WHERE acctnum = 12345;
UPDATE accounts SET balance = balance - 100.00 WHERE acctnum = 7534;
COMMIT;
```
If two such transactions concurrently try to change the balance of account 12345, we clearly want the second transaction to start with the updated version of the account’s row. Because each command is affecting only a predetermined row, letting it see the updated version of the row does not create any troublesome inconsistency.

More complex usage can produce undesirable results in Read Committed mode. For example, consider a DELETE command operating on data that is being both added and removed from its restriction criteria by another command, e.g., assume website is a two-row table with website.hits equaling 9 and 10:

```sql
BEGIN;
UPDATE website SET hits = hits + 1;
-- run from another session: DELETE FROM website WHERE hits = 10;
COMMIT;
```

The DELETE will have no effect even though there is a website.hits = 10 row before and after the UPDATE. This occurs because the pre-update row value 9 is skipped, and when the UPDATE completes and DELETE obtains a lock, the new row value is no longer 10 but 11, which no longer matches the criteria.

Because Read Committed mode starts each command with a new snapshot that includes all transactions committed up to that instant, subsequent commands in the same transaction will see the effects of the committed concurrent transaction in any case. The point at issue above is whether or not a single command sees an absolutely consistent view of the database.

The partial transaction isolation provided by Read Committed mode is adequate for many applications, and this mode is fast and simple to use; however, it is not sufficient for all cases. Applications that do complex queries and updates might require a more rigorously consistent view of the database than Read Committed mode provides.

### 13.2.2. Serializable Isolation Level

The Serializable isolation level provides the strictest transaction isolation. This level emulates serial transaction execution, as if transactions had been executed one after another, serially, rather than concurrently. However, applications using this level must be prepared to retry transactions due to serialization failures.

When a transaction is using the serializable level, a SELECT query only sees data committed before the transaction began; it never sees either uncommitted data or changes committed during transaction execution by concurrent transactions. (However, the query does see the effects of previous updates executed within its own transaction, even though they are not yet committed.) This is different from Read Committed in that a query in a serializable transaction sees a snapshot as of the start of the transaction, not as of the start of the current query within the transaction. Thus, successive SELECT commands within a single transaction see the same data, i.e., they do not see changes made by other transactions that committed after their own transaction started. (This behavior can be ideal for reporting applications.)

UPDATE, DELETE, SELECT FOR UPDATE, and SELECT FOR SHARE commands behave the same as SELECT in terms of searching for target rows: they will only find target rows that were committed as of the transaction start time. However, such a target row might have already been updated (or deleted or locked) by another concurrent transaction by the time it is found. In this case, the serializable transaction will wait for the first updating transaction to commit or roll back (if it is still in progress). If the first updater rolls back, then its effects are negated and the serializable transaction can proceed with updating the originally found row. But if the first updater commits (and actually updated or deleted the row, not just locked it) then the serializable transaction will be rolled back with the message
because a serializable transaction cannot modify or lock rows changed by other transactions after the serializable transaction began.

When an application receives this error message, it should abort the current transaction and retry the whole transaction from the beginning. The second time through, the transaction will see the previously-committed change as part of its initial view of the database, so there is no logical conflict in using the new version of the row as the starting point for the new transaction’s update.

Note that only updating transactions might need to be retried; read-only transactions will never have serialization conflicts.

The Serializable mode provides a rigorous guarantee that each transaction sees a wholly consistent view of the database. However, the application has to be prepared to retry transactions when concurrent updates make it impossible to sustain the illusion of serial execution. Since the cost of redoing complex transactions can be significant, serializable mode is recommended only when updating transactions contain logic sufficiently complex that they might give wrong answers in Read Committed mode. Most commonly, Serializable mode is necessary when a transaction executes several successive commands that must see identical views of the database.

13.2.2.1. Serializable Isolation versus True Serializability

The intuitive meaning (and mathematical definition) of “serializable” execution is that any two successfully committed concurrent transactions will appear to have executed strictly serially, one after the other — although which one appeared to occur first might not be predictable in advance. It is important to realize that forbidding the undesirable behaviors listed in Table 13-1 is not sufficient to guarantee true serializability, and in fact PostgreSQL’s Serializable mode does not guarantee serializable execution in this sense. As an example, consider a table mytab, initially containing:

<table>
<thead>
<tr>
<th>class</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10</td>
</tr>
<tr>
<td>1</td>
<td>20</td>
</tr>
<tr>
<td>2</td>
<td>100</td>
</tr>
<tr>
<td>2</td>
<td>200</td>
</tr>
</tbody>
</table>

Suppose that serializable transaction A computes:

```sql
SELECT SUM(value) FROM mytab WHERE class = 1;
```

and then inserts the result (30) as the value in a new row with class = 2. Concurrently, serializable transaction B computes:

```sql
SELECT SUM(value) FROM mytab WHERE class = 2;
```

and obtains the result 300, which it inserts in a new row with class = 1. Then both transactions commit. None of the listed undesirable behaviors have occurred, yet we have a result that could not have occurred in either order serially. If A had executed before B, B would have computed the sum 330, not 300, and similarly the other order would have resulted in a different sum computed by A.

To guarantee true mathematical serializability, it is necessary for a database system to enforce predicate locking, which means that a transaction cannot insert or modify a row that would have matched the WHERE condition of a query in another concurrent transaction. For example, once transaction A has executed the query SELECT ... WHERE class = 1, a predicate-locking system would forbid
transaction B from inserting any new row with class 1 until A has committed. Such a locking system is complex to implement and extremely expensive in execution, since every session must be aware of the details of every query executed by every concurrent transaction. And this large expense is mostly wasted, since in practice most applications do not do the sorts of things that could result in problems. (Certainly the example above is rather contrived and unlikely to represent real software.) For these reasons, PostgreSQL does not implement predicate locking.

In cases where the possibility of non-serializable execution is a real hazard, problems can be prevented by appropriate use of explicit locking. Further discussion appears in the following sections.

13.3. Explicit Locking

PostgreSQL provides various lock modes to control concurrent access to data in tables. These modes can be used for application-controlled locking in situations where MVCC does not give the desired behavior. Also, most PostgreSQL commands automatically acquire locks of appropriate modes to ensure that referenced tables are not dropped or modified in incompatible ways while the command executes. (For example, ALTER TABLE cannot safely be executed concurrently with other operations on the same table, so it obtains an exclusive lock on the table to enforce that.)

To examine a list of the currently outstanding locks in a database server, use the pg_locks system view. For more information on monitoring the status of the lock manager subsystem, refer to Chapter 26.

13.3.1. Table-Level Locks

The list below shows the available lock modes and the contexts in which they are used automatically by PostgreSQL. You can also acquire any of these locks explicitly with the command LOCK. Remember that all of these lock modes are table-level locks, even if the name contains the word “row”; the names of the lock modes are historical. To some extent the names reflect the typical usage of each lock mode — but the semantics are all the same. The only real difference between one lock mode and another is the set of lock modes with which each conflicts (see Table 13-2). Two transactions cannot hold locks of conflicting modes on the same table at the same time. (However, a transaction never conflicts with itself. For example, it might acquire ACCESS EXCLUSIVE lock and later acquire ACCESS SHARE lock on the same table.) Non-conflicting lock modes can be held concurrently by many transactions. Notice in particular that some lock modes are self-conflicting (for example, an ACCESS EXCLUSIVE lock cannot be held by more than one transaction at a time) while others are not self-conflicting (for example, an ACCESS SHARE lock can be held by multiple transactions).

Table-level lock modes

ACCESS SHARE

Conflicts with the ACCESS EXCLUSIVE lock mode only.

The SELECT command acquires a lock of this mode on referenced tables. In general, any query that only reads a table and does not modify it will acquire this lock mode.

1. Essentially, a predicate-locking system prevents phantom reads by restricting what is written, whereas MVCC prevents them by restricting what is read.
Chapter 13. Concurrency Control

ROW SHARE

Conflicts with the EXCLUSIVE and ACCESS EXCLUSIVE lock modes.

The SELECT FOR UPDATE and SELECT FOR SHARE commands acquire a lock of this mode on the target table(s) (in addition to ACCESS SHARE locks on any other tables that are referenced but not selected FOR UPDATE/FOR SHARE).

ROW EXCLUSIVE

Conflicts with the SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, and ACCESS EXCLUSIVE lock modes.

The commands UPDATE, DELETE, and INSERT acquire this lock mode on the target table (in addition to ACCESS SHARE locks on any other referenced tables). In general, this lock mode will be acquired by any command that modifies data in a table.

SHARE UPDATE EXCLUSIVE

Conflicts with the SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, and ACCESS EXCLUSIVE lock modes. This mode protects a table against concurrent schema changes and VACUUM runs.

Acquired by VACUUM (without FULL), ANALYZE, and CREATE INDEX CONCURRENTLY.

SHARE

Conflicts with the ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, and ACCESS EXCLUSIVE lock modes. This mode protects a table against concurrent data changes.

Acquired by CREATE INDEX (without CONCURRENTLY).

SHARE ROW EXCLUSIVE

Conflicts with the ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, and ACCESS EXCLUSIVE lock modes.

This lock mode is not automatically acquired by any PostgreSQL command.

EXCLUSIVE

Conflicts with the ROW SHARE, ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, and ACCESS EXCLUSIVE lock modes. This mode allows only concurrent ACCESS SHARE locks, i.e., only reads from the table can proceed in parallel with a transaction holding this lock mode.

This lock mode is not automatically acquired on user tables by any PostgreSQL command. However it is acquired on certain system catalogs in some operations.

ACCESS EXCLUSIVE

Conflicts with locks of all modes (ACCESS SHARE, ROW SHARE, ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, and ACCESS EXCLUSIVE). This mode guarantees that the holder is the only transaction accessing the table in any way.

Acquired by the ALTER TABLE, DROP TABLE, TRUNCATE, REINDEX, CLUSTER, and VACUUM FULL commands. This is also the default lock mode for LOCK TABLE statements that do not specify a mode explicitly.

Tip: Only an ACCESS EXCLUSIVE lock blocks a SELECT (without FOR UPDATE/SHARE) statement.
Once acquired, a lock is normally held till end of transaction. But if a lock is acquired after establishing a savepoint, the lock is released immediately if the savepoint is rolled back to. This is consistent with the principle that `ROLLBACK` cancels all effects of the commands since the savepoint. The same holds for locks acquired within a PL/pgSQL exception block: an error escape from the block releases locks acquired within it.

### Table 13-2. Conflicting lock modes

<table>
<thead>

</tbody>
</table>

### 13.3.2. Row-Level Locks

In addition to table-level locks, there are row-level locks, which can be exclusive or shared locks. An exclusive row-level lock on a specific row is automatically acquired when the row is updated or deleted. The lock is held until the transaction commits or rolls back, just like table-level locks. Row-level locks do not affect data querying; they block only `writers to the same row`.  

---

317
To acquire an exclusive row-level lock on a row without actually modifying the row, select the row with `SELECT FOR UPDATE`. Note that once the row-level lock is acquired, the transaction can update the row multiple times without fear of conflicts.

To acquire a shared row-level lock on a row, select the row with `SELECT FOR SHARE`. A shared lock does not prevent other transactions from acquiring the same shared lock. However, no transaction is allowed to update, delete, or exclusively lock a row on which any other transaction holds a shared lock. Any attempt to do so will block until the shared lock(s) have been released.

PostgreSQL doesn’t remember any information about modified rows in memory, so there is no limit on the number of rows locked at one time. However, locking a row might cause a disk write, e.g., `SELECT FOR UPDATE` modifies selected rows to mark them locked, and so will result in disk writes.

In addition to table and row locks, page-level share/exclusive locks are used to control read/write access to table pages in the shared buffer pool. These locks are released immediately after a row is fetched or updated. Application developers normally need not be concerned with page-level locks, but they are mentioned here for completeness.

### 13.3.3. Deadlocks

The use of explicit locking can increase the likelihood of deadlocks, wherein two (or more) transactions each hold locks that the other wants. For example, if transaction 1 acquires an exclusive lock on table A and then tries to acquire an exclusive lock on table B, while transaction 2 has already exclusive-locked table B and now wants an exclusive lock on table A, then neither one can proceed. PostgreSQL automatically detects deadlock situations and resolves them by aborting one of the transactions involved, allowing the other(s) to complete. (Exactly which transaction will be aborted is difficult to predict and should not be relied upon.)

Note that deadlocks can also occur as the result of row-level locks (and thus, they can occur even if explicit locking is not used). Consider the case in which two concurrent transactions modify a table. The first transaction executes:

```sql
UPDATE accounts SET balance = balance + 100.00 WHERE acctnum = 11111;
```

This acquires a row-level lock on the row with the specified account number. Then, the second transaction executes:

```sql
UPDATE accounts SET balance = balance + 100.00 WHERE acctnum = 22222;
UPDATE accounts SET balance = balance - 100.00 WHERE acctnum = 11111;
```

The first `UPDATE` statement successfully acquires a row-level lock on the specified row, so it succeeds in updating that row. However, the second `UPDATE` statement finds that the row it is attempting to update has already been locked, so it waits for the transaction that acquired the lock to complete. Transaction two is now waiting on transaction one to complete before it continues execution. Now, transaction one executes:

```sql
UPDATE accounts SET balance = balance - 100.00 WHERE acctnum = 22222;
```

Transaction one attempts to acquire a row-level lock on the specified row, but it cannot: transaction two already holds such a lock. So it waits for transaction two to complete. Thus, transaction one is blocked on transaction two, and transaction two is blocked on transaction one: a deadlock condition. PostgreSQL will detect this situation and abort one of the transactions.

The best defense against deadlocks is generally to avoid them by being certain that all applications using a database acquire locks on multiple objects in a consistent order. In the example above, if both
transactions had updated the rows in the same order, no deadlock would have occurred. One should also ensure that the first lock acquired on an object in a transaction is the most restrictive mode that will be needed for that object. If it is not feasible to verify this in advance, then deadlocks can be handled on-the-fly by retrying transactions that abort due to deadlocks.

So long as no deadlock situation is detected, a transaction seeking either a table-level or row-level lock will wait indefinitely for conflicting locks to be released. This means it is a bad idea for applications to hold transactions open for long periods of time (e.g., while waiting for user input).

### 13.3.4. Advisory Locks

PostgreSQL provides a means for creating locks that have application-defined meanings. These are called *advisory locks*, because the system does not enforce their use — it is up to the application to use them correctly. Advisory locks can be useful for locking strategies that are an awkward fit for the MVCC model. Once acquired, an advisory lock is held until explicitly released or the session ends. Unlike standard locks, advisory locks do not honor transaction semantics: a lock acquired during a transaction that is later rolled back will still be held following the rollback, and likewise an unlock is effective even if the calling transaction fails later. The same lock can be acquired multiple times by its owning process: for each lock request there must be a corresponding unlock request before the lock is actually released. (If a session already holds a given lock, additional requests will always succeed, even if other sessions are awaiting the lock.) Like all locks in PostgreSQL, a complete list of advisory locks currently held by any session can be found in the `pg_locks` system view.

Advisory locks are allocated out of a shared memory pool whose size is defined by the configuration variables `max_locks_per_transaction` and `max_connections`. Care must be taken not to exhaust this memory or the server will be unable to grant any locks at all. This imposes an upper limit on the number of advisory locks grantable by the server, typically in the tens to hundreds of thousands depending on how the server is configured.

A common use of advisory locks is to emulate pessimistic locking strategies typical of so called “flat file” data management systems. While a flag stored in a table could be used for the same purpose, advisory locks are faster, avoid MVCC bloat, and are automatically cleaned up by the server at the end of the session. In certain cases using this advisory locking method, especially in queries involving explicit ordering and `LIMIT` clauses, care must be taken to control the locks acquired because of the order in which SQL expressions are evaluated. For example:

```sql
SELECT pg_advisory_lock(id) FROM foo WHERE id = 12345; -- ok
SELECT pg_advisory_lock(id) FROM foo WHERE id > 12345 LIMIT 100; -- danger!
SELECT pg_advisory_lock(q.id) FROM (SELECT id FROM foo WHERE id > 12345 LIMIT 100) q; -- ok
```

In the above queries, the second form is dangerous because the `LIMIT` is not guaranteed to be applied before the locking function is executed. This might cause some locks to be acquired that the application was not expecting, and hence would fail to release (until it ends the session). From the point of view of the application, such locks would be dangling, although still viewable in `pg_locks`.

The functions provided to manipulate advisory locks are described in Table 9-59.
13.4. Data Consistency Checks at the Application Level

Because readers in PostgreSQL do not lock data, regardless of transaction isolation level, data read by one transaction can be overwritten by another concurrent transaction. In other words, if a row is returned by `SELECT` it doesn’t mean that the row is still current at the instant it is returned (i.e., sometime after the current query began). The row might have been modified or deleted by an already-committed transaction that committed after the `SELECT` started. Even if the row is still valid “now”, it could be changed or deleted before the current transaction does a commit or rollback.

Another way to think about it is that each transaction sees a snapshot of the database contents, and concurrently executing transactions might very well see different snapshots. So the whole concept of “now” is somewhat ill-defined anyway. This is not normally a big problem if the client applications are isolated from each other, but if the clients can communicate via channels outside the database then serious confusion might ensue.

To ensure the current validity of a row and protect it against concurrent updates one must use `SELECT FOR UPDATE`, `SELECT FOR SHARE`, or an appropriate `LOCK TABLE` statement. (`SELECT FOR UPDATE` and `SELECT FOR SHARE` lock just the returned rows against concurrent updates, while `LOCK TABLE` locks the whole table.) This should be taken into account when porting applications to PostgreSQL from other environments.

Global validity checks require extra thought under MVCC. For example, a banking application might wish to check that the sum of all credits in one table equals the sum of debits in another table, when both tables are being actively updated. Comparing the results of two successive `SELECT sum(...)` commands will not work reliably in Read Committed mode, since the second query will likely include the results of transactions not counted by the first. Doing the two sums in a single serializable transaction will give an accurate picture of only the effects of transactions that committed before the serializable transaction started — but one might legitimately wonder whether the answer is still relevant by the time it is delivered. If the serializable transaction itself applied some changes before trying to make the consistency check, the usefulness of the check becomes even more debatable, since now it includes some but not all post-transaction-start changes. In such cases a careful person might wish to lock all tables needed for the check, in order to get an indisputable picture of current reality. A `SHARE` mode (or higher) lock guarantees that there are no uncommitted changes in the locked table, other than those of the current transaction.

Note also that if one is relying on explicit locking to prevent concurrent changes, one should either use Read Committed mode, or in Serializable mode be careful to obtain locks before performing queries. A lock obtained by a serializable transaction guarantees that no other transactions modifying the table are still running, but if the snapshot seen by the transaction predates obtaining the lock, it might predate some now-committed changes in the table. A serializable transaction’s snapshot is actually frozen at the start of its first query or data-modification command (`SELECT`, `INSERT`, `UPDATE`, or `DELETE`), so it is possible to obtain locks explicitly before the snapshot is frozen.

13.5. Locking and Indexes

Though PostgreSQL provides nonblocking read/write access to table data, nonblocking read/write access is not currently offered for every index access method implemented in PostgreSQL. The various index types are handled as follows:

B-tree and GiST indexes

Short-term share/exclusive page-level locks are used for read/write access. Locks are released immediately after each index row is fetched or inserted. These index types provide the highest
concurrency without deadlock conditions.

Hash indexes

Share/exclusive hash-bucket-level locks are used for read/write access. Locks are released after the whole bucket is processed. Bucket-level locks provide better concurrency than index-level ones, but deadlock is possible since the locks are held longer than one index operation.

GIN indexes

Short-term share/exclusive page-level locks are used for read/write access. Locks are released immediately after each index row is fetched or inserted. But note that insertion of a GIN-indexed value usually produces several index key insertions per row, so GIN might do substantial work for a single value’s insertion.

Currently, B-tree indexes offer the best performance for concurrent applications; since they also have more features than hash indexes, they are the recommended index type for concurrent applications that need to index scalar data. When dealing with non-scalar data, B-trees are not useful, and GiST or GIN indexes should be used instead.
Chapter 14. Performance Tips

Query performance can be affected by many things. Some of these can be controlled by the user, while others are fundamental to the underlying design of the system. This chapter provides some hints about understanding and tuning PostgreSQL performance.

14.1. Using EXPLAIN

PostgreSQL devises a query plan for each query it receives. Choosing the right plan to match the query structure and the properties of the data is absolutely critical for good performance, so the system includes a complex planner that tries to choose good plans. You can use the EXPLAIN command to see what query plan the planner creates for any query. Plan-reading is an art that deserves an extensive tutorial, which this is not; but here is some basic information.

The structure of a query plan is a tree of plan nodes. Nodes at the bottom level of the tree are table scan nodes: they return raw rows from a table. There are different types of scan nodes for different table access methods: sequential scans, index scans, and bitmap index scans. If the query requires joining, aggregation, sorting, or other operations on the raw rows, then there will be additional nodes above the scan nodes to perform these operations. Again, there is usually more than one possible way to do these operations, so different node types can appear here too. The output of EXPLAIN has one line for each node in the plan tree, showing the basic node type plus the cost estimates that the planner made for the execution of that plan node. The first line (topmost node) has the estimated total execution cost for the plan; it is this number that the planner seeks to minimize.

Here is a trivial example, just to show what the output looks like: ¹

```
EXPLAIN SELECT * FROM tenk1;
```

```
QUERY PLAN
-------------------------------------------------------------
Seq Scan on tenk1 (cost=0.00..458.00 rows=10000 width=244)
```

The numbers that are quoted by EXPLAIN are (left to right):

- Estimated start-up cost (time expended before the output scan can start, e.g., time to do the sorting in a sort node)
- Estimated total cost (if all rows are retrieved, though they might not be; e.g., a query with a LIMIT clause will stop short of paying the total cost of the Limit plan node’s input node)
- Estimated number of rows output by this plan node (again, only if executed to completion)
- Estimated average width (in bytes) of rows output by this plan node

The costs are measured in arbitrary units determined by the planner’s cost parameters (see Section 18.6.2). Traditional practice is to measure the costs in units of disk page fetches; that is, seq_page_cost is conventionally set to 1.0 and the other cost parameters are set relative to that. (The examples in this section are run with the default cost parameters.)

¹ Examples in this section are drawn from the regression test database after doing a VACUUM ANALYZE, using 8.2 development sources. You should be able to get similar results if you try the examples yourself, but your estimated costs and row counts might vary slightly because ANALYZE’s statistics are random samples rather than exact.
Chapter 14. Performance Tips

It’s important to note that the cost of an upper-level node includes the cost of all its child nodes. It’s also important to realize that the cost only reflects things that the planner cares about. In particular, the cost does not consider the time spent transmitting result rows to the client, which could be an important factor in the real elapsed time; but the planner ignores it because it cannot change it by altering the plan. (Every correct plan will output the same row set, we trust.)

The \texttt{rows} value is a little tricky because it is \textit{not} the number of rows processed or scanned by the plan node. It is usually less, reflecting the estimated selectivity of any \texttt{WHERE}-clause conditions that are being applied at the node. Ideally the top-level rows estimate will approximate the number of rows actually returned, updated, or deleted by the query.

Returning to our example:

\begin{verbatim}
EXPLAIN SELECT * FROM tenk1;

QUERY PLAN
-------------------------------------------------------------
Seq Scan on tenk1 (cost=0.00..458.00 rows=10000 width=244)

This is about as straightforward as it gets. If you do:

\begin{verbatim}
SELECT relpages, reltuples FROM pg_class WHERE relname = 'tenk1';
\end{verbatim}

you will find that \texttt{tenk1} has 358 disk pages and 10000 rows. The estimated cost is computed as (disk pages read $\times$ \texttt{seq_page_cost}) + (rows scanned $\times$ \texttt{cpu_tuple_cost}). By default, \texttt{seq_page_cost} is 1.0 and \texttt{cpu_tuple_cost} is 0.01, so the estimated cost is (358 $\times$ 1.0) + (10000 $\times$ 0.01) = 458.

Now let’s modify the original query to add a \texttt{WHERE} condition:

\begin{verbatim}
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 7000;

QUERY PLAN
------------------------------------------------------------
Seq Scan on tenk1 (cost=0.00..483.00 rows=7033 width=244)
Filter: (unique1 < 7000)

Notice that the \texttt{EXPLAIN} output shows the \texttt{WHERE} clause being applied as a “filter” condition; this means that the plan node checks the condition for each row it scans, and outputs only the ones that pass the condition. The estimate of output rows has been reduced because of the \texttt{WHERE} clause. However, the scan will still have to visit all 10000 rows, so the cost hasn’t decreased; in fact it has gone up a bit (by 10000 $\times$ \texttt{cpu_operator_cost}, to be exact) to reflect the extra CPU time spent checking the \texttt{WHERE} condition.

The actual number of rows this query would select is 7000, but the \texttt{rows} estimate is only approximate. If you try to duplicate this experiment, you will probably get a slightly different estimate; moreover, it will change after each \texttt{ANALYZE} command, because the statistics produced by \texttt{ANALYZE} are taken from a randomized sample of the table.

Now, let’s make the condition more restrictive:

\begin{verbatim}
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 100;

QUERY PLAN
------------------------------------------------------------------------------
Bitmap Heap Scan on tenk1 (cost=2.37..232.35 rows=106 width=244)
  Recheck Cond: (unique1 < 100)
  -> Bitmap Index Scan on tenk1_unique1 (cost=0.00..2.37 rows=106 width=0)
\end{verbatim}

323
Here the planner has decided to use a two-step plan: the bottom plan node visits an index to find the locations of rows matching the index condition, and then the upper plan node actually fetches those rows from the table itself. Fetching the rows separately is much more expensive than sequentially reading them, but because not all the pages of the table have to be visited, this is still cheaper than a sequential scan. (The reason for using two plan levels is that the upper plan node sorts the row locations identified by the index into physical order before reading them, to minimize the cost of separate fetches. The “bitmap” mentioned in the node names is the mechanism that does the sorting.)

If the WHERE condition is selective enough, the planner might switch to a “simple” index scan plan:

EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 3;

---

Index Scan using tenk1_unique1 on tenk1 (cost=0.00..10.00 rows=2 width=244)
Index Cond: (unique1 < 3)

In this case the table rows are fetched in index order, which makes them even more expensive to read, but there are so few that the extra cost of sorting the row locations is not worth it. You’ll most often see this plan type for queries that fetch just a single row, and for queries that have an ORDER BY condition that matches the index order.

Add another condition to the WHERE clause:

EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 3 AND stringu1 = ‘xxx’;

---

Index Scan using tenk1_unique1 on tenk1 (cost=0.00..10.01 rows=1 width=244)
Index Cond: (unique1 < 3)
Filter: (stringu1 = ‘xxx’::name)

The added condition stringu1 = ‘xxx’ reduces the output-rows estimate, but not the cost because we still have to visit the same set of rows. Notice that the stringu1 clause cannot be applied as an index condition (since this index is only on the unique1 column). Instead it is applied as a filter on the rows retrieved by the index. Thus the cost has actually gone up slightly to reflect this extra checking.

If there are indexes on several columns referenced in WHERE, the planner might choose to use an AND or OR combination of the indexes:

EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 100 AND unique2 > 9000;

---

Bitmap Heap Scan on tenk1 (cost=11.27..49.11 rows=11 width=244)
Recheck Cond: ((unique1 < 100) AND (unique2 > 9000))
  -> BitmapAnd (cost=11.27..11.27 rows=11 width=0)
    -> Bitmap Index Scan on tenk1_unique1 (cost=0.00..2.37 rows=106 width=0)
      Index Cond: (unique1 < 100)
    -> Bitmap Index Scan on tenk1_unique2 (cost=0.00..8.65 rows=1042 width=0)
      Index Cond: (unique2 > 9000)
But this requires visiting both indexes, so it’s not necessarily a win compared to using just one index and treating the other condition as a filter. If you vary the ranges involved you’ll see the plan change accordingly.

Let’s try joining two tables, using the columns we have been discussing:

```
EXPLAIN SELECT *
FROM tenk1 t1, tenk2 t2
WHERE t1.unique1 < 100 AND t1.unique2 = t2.unique2;
```

```
QUERY PLAN
--------------------------------------------------------------------------------------
Nested Loop (cost=2.37..553.11 rows=106 width=488)
 -> Bitmap Heap Scan on tenk1 t1 (cost=2.37..232.35 rows=106 width=244)
   Recheck Cond: (unique1 < 100)
   -> Bitmap Index Scan on tenk1_unique1 (cost=0.00..2.37 rows=106 width=0)
     Index Cond: (unique1 < 100)
 -> Index Scan using tenk2_unique2 on tenk2 t2 (cost=0.00..3.01 rows=1 width=244)
   Index Cond: (t2.unique2 = t1.unique2)
```

In this nested-loop join, the outer (upper) scan is the same bitmap index scan we saw earlier, and so its cost and row count are the same because we are applying the \texttt{WHERE} clause \texttt{unique1 < 100} at that node. The \texttt{t1.unique2 = t2.unique2} clause is not relevant yet, so it doesn’t affect the row count of the outer scan. For the inner (lower) scan, the \texttt{unique2} value of the current outer-scan row is plugged into the inner index scan to produce an index condition like \texttt{t2.unique2 = constant}. So we get the same inner-scan plan and costs that we’d get from, say, \texttt{EXPLAIN SELECT * FROM tenk2 WHERE unique2 = 42}. The costs of the loop node are then set on the basis of the cost of the outer scan, plus one repetition of the inner scan for each outer row (106 * 3.01, here), plus a little CPU time for join processing.

In this example the join’s output row count is the same as the product of the two scans’ row counts, but that’s not true in all cases because you can have \texttt{WHERE} clauses that mention both tables and so can only be applied at the join point, not to either input scan. For example, if we added \texttt{WHERE ... AND t1.hundred < t2.hundred}, that would decrease the output row count of the join node, but not change either input scan.

One way to look at variant plans is to force the planner to disregard whatever strategy it thought was the cheapest, using the enable/disable flags described in Section 18.6.1. (This is a crude tool, but useful. See also Section 14.3.)

```
SET enable_nestloop = off;
EXPLAIN SELECT *
FROM tenk1 t1, tenk2 t2
WHERE t1.unique1 < 100 AND t1.unique2 = t2.unique2;
```

```
QUERY PLAN
---------------------------------------------------------------------------------------------
Hash Join (cost=232.61..741.67 rows=106 width=488)
 Hash Cond: (t2.unique2 = t1.unique2)
 -> Seq Scan on tenk2 t2 (cost=0.00..458.00 rows=10000 width=244)
 -> Hash (cost=232.35..232.35 rows=106 width=244)
   -> Bitmap Heap Scan on tenk1 t1 (cost=2.37..232.35 rows=106 width=244)
     Recheck Cond: (unique1 < 100)
     -> Bitmap Index Scan on tenk1_unique1 (cost=0.00..2.37 rows=106 width=0)
       Index Cond: (unique1 < 100)
```

325
Chapter 14. Performance Tips

This plan proposes to extract the 100 interesting rows of \textit{tenk1} using that same old index scan, stash them into an in-memory hash table, and then do a sequential scan of \textit{tenk2}, probing into the hash table for possible matches of \textit{t1.unique2} = \textit{t2.unique2} for each \textit{tenk2} row. The cost to read \textit{tenk1} and set up the hash table is a start-up cost for the hash join, since there will be no output until we can start reading \textit{tenk2}. The total time estimate for the join also includes a hefty charge for the CPU time to probe the hash table 10000 times. Note, however, that we are \textit{not} charging 10000 times 232.35; the hash table setup is only done once in this plan type.

It is possible to check the accuracy of the planner’s estimated costs by using \texttt{EXPLAIN ANALYZE}. This command actually executes the query, and then displays the true run time accumulated within each plan node along with the same estimated costs that a plain \texttt{EXPLAIN} shows. For example, we might get a result like this:

\begin{verbatim}
EXPLAIN ANALYZE SELECT * 
FROM tenk1 t1, tenk2 t2 
WHERE t1.unique1 < 100 AND t1.unique2 = t2.unique2;
\end{verbatim}

\textbf{QUERY PLAN}

\begin{verbatim}
Nested Loop  (cost=2.37..553.11 rows=106 width=488) (actual time=1.392..12.700 rows=100)
  ->  Bitmap Heap Scan on tenk1 t1  (cost=2.37..232.35 rows=106 width=244) (actual time=0.878..2.367 rows=100 loops=1)
       Recheck Cond: (unique1 < 100) 
       ->  Bitmap Index Scan on tenk1_unique1  (cost=0.00..2.37 rows=106 width=0) (actual time=0.546..0.546 rows=100 loops=1)
             Index Cond: (unique1 < 100)
  ->  Index Scan using tenk2_unique2 on tenk2 t2  (cost=0.00..3.01 rows=1 width=244) (actual time=0.067..0.078 rows=1 loops=100)
       Index Cond: (t2.unique2 = t1.unique2)
Total runtime: 14.452 ms
\end{verbatim}

Note that the “actual time” values are in milliseconds of real time, whereas the \texttt{cost} estimates are expressed in arbitrary units; so they are unlikely to match up. The thing to pay attention to is whether the ratios of actual time and estimated costs are consistent.

In some query plans, it is possible for a subplan node to be executed more than once. For example, the inner index scan is executed once per outer row in the above nested-loop plan. In such cases, the \texttt{loops} value reports the total number of executions of the node, and the actual time and rows values shown are averages per-execution. This is done to make the numbers comparable with the way that the cost estimates are shown. Multiply by the \texttt{loops} value to get the total time actually spent in the node.

The \texttt{Total runtime} shown by \texttt{EXPLAIN ANALYZE} includes executor start-up and shut-down time, as well as time spent processing the result rows. It does not include parsing, rewriting, or planning time. For a \texttt{SELECT} query, the total run time will normally be just a little larger than the total time reported for the top-level plan node. For \texttt{INSERT}, \texttt{UPDATE}, and \texttt{DELETE} commands, the total run time might be considerably larger, because it includes the time spent processing the result rows. For these commands, the time for the top plan node is essentially the time spent locating the old rows and/or computing the new ones, but it doesn’t include the time spent applying the changes. Time spent firing triggers, if any, is also outside the top plan node, and is shown separately for each trigger.

It is worth noting that \texttt{EXPLAIN} results should not be extrapolated to situations other than the one you are actually testing; for example, results on a toy-sized table cannot be assumed to apply to large tables. The planner’s cost estimates are not linear and so it might choose a different plan for a larger or smaller table. An extreme example is that on a table that only occupies one disk page, you’ll nearly always get a sequential scan plan whether indexes are available or not. The planner realizes that it’s going to take one disk page read to process the table in any case, so there’s no value in expending additional page reads to look at an index.
14.2. Statistics Used by the Planner

As we saw in the previous section, the query planner needs to estimate the number of rows retrieved by a query in order to make good choices of query plans. This section provides a quick look at the statistics that the system uses for these estimates.

One component of the statistics is the total number of entries in each table and index, as well as the number of disk blocks occupied by each table and index. This information is kept in the table `pg_class`, in the columns `reltuples` and `retpages`. We can look at it with queries similar to this one:

```sql
SELECT relname, relkind, reltuples, retpages
FROM pg_class
WHERE relname LIKE 'tenk1%';
```

<table>
<thead>
<tr>
<th>relname</th>
<th>relkind</th>
<th>reltuples</th>
<th>retpages</th>
</tr>
</thead>
<tbody>
<tr>
<td>tenk1</td>
<td>r</td>
<td>10000</td>
<td>358</td>
</tr>
<tr>
<td>tenk1_hundred</td>
<td>i</td>
<td>10000</td>
<td>30</td>
</tr>
<tr>
<td>tenk1_thous_tenthous</td>
<td>i</td>
<td>10000</td>
<td>30</td>
</tr>
<tr>
<td>tenk1_unique1</td>
<td>i</td>
<td>10000</td>
<td>30</td>
</tr>
<tr>
<td>tenk1_unique2</td>
<td>i</td>
<td>10000</td>
<td>30</td>
</tr>
</tbody>
</table>

(5 rows)

Here we can see that `tenk1` contains 10000 rows, as do its indexes, but the indexes are (unsurprisingly) much smaller than the table.

For efficiency reasons, `reltuples` and `retpages` are not updated on-the-fly, and so they usually contain somewhat out-of-date values. They are updated by `VACUUM`, `ANALYZE`, and a few DDL commands such as `CREATE INDEX`. A stand-alone `ANALYZE`, that is one not part of `VACUUM`, generates an approximate `reltuples` value since it does not read every row of the table. The planner will scale the values it finds in `pg_class` to match the current physical table size, thus obtaining a closer approximation.

Most queries retrieve only a fraction of the rows in a table, due to `WHERE` clauses that restrict the rows to be examined. The planner thus needs to make an estimate of the selectivity of `WHERE` clauses, that is, the fraction of rows that match each condition in the `WHERE` clause. The information used for this task is stored in the `pg_statistic` system catalog. Entries in `pg_statistic` are updated by the `ANALYZE` and `VACUUM ANALYZE` commands, and are always approximate even when freshly updated.

Rather than look at `pg_statistic` directly, it’s better to look at its view `pg_stats` when examining the statistics manually. `pg_stats` is designed to be more easily readable. Furthermore, `pg_stats` is readable by all, whereas `pg_statistic` is only readable by a superuser. (This prevents unprivileged users from learning something about the contents of other people’s tables from the statistics. The `pg_stats` view is restricted to show only rows about tables that the current user can read.) For example, we might do:

```sql
SELECT attname, n_distinct, most_common_vals
FROM pg_stats
WHERE tablename = 'road';
```

<table>
<thead>
<tr>
<th>attname</th>
<th>n_distinct</th>
<th>most_common_vals</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>-0.467008</td>
<td>(&quot;I- 580 Ramp&quot;,&quot;I- 880 Ramp&quot;,&quot;Sp Railroad &quot;,&quot;I- 580 &quot;,&quot;I- 680 Ramp&quot;,&quot;I- 80 Ramp&quot;,&quot;14th St &quot;,&quot;5th St &quot;,&quot;Mission Blvd&quot;,&quot;I- 880 &quot;)</td>
</tr>
<tr>
<td>thepath</td>
<td>20</td>
<td>(&quot;([-122.089,37.71],[-122.0886,37.711])&quot;)</td>
</tr>
</tbody>
</table>

(2 rows)
Chapter 14. Performance Tips

The amount of information stored in `pg_statistic` by `ANALYZE`, in particular the maximum number of entries in the `most_common_vals` and `histogram_bounds` arrays for each column, can be set on a column-by-column basis using the `ALTER TABLE SET STATISTICS` command, or globally by setting the `default_statistics_target` configuration variable. The default limit is presently 100 entries. Raising the limit might allow more accurate planner estimates to be made, particularly for columns with irregular data distributions, at the price of consuming more space in `pg_statistic` and slightly more time to compute the estimates. Conversely, a lower limit might be sufficient for columns with simple data distributions.

Further details about the planner’s use of statistics can be found in Chapter 55.

14.3. Controlling the Planner with Explicit `JOIN` Clauses

It is possible to control the query planner to some extent by using the explicit `JOIN` syntax. To see why this matters, we first need some background.

In a simple join query, such as:

```sql
SELECT * FROM a, b, c WHERE a.id = b.id AND b.ref = c.id;
```

the planner is free to join the given tables in any order. For example, it could generate a query plan that joins A to B, using the `WHERE` condition `a.id = b.id`, and then joins C to this joined table, using the other `WHERE` condition. Or it could join B to C and then join A to that result. Or it could join A to C and then join them with B — but that would be inefficient, since the full Cartesian product of A and C would have to be formed, there being no applicable condition in the `WHERE` clause to allow optimization of the join. (All joins in the PostgreSQL executor happen between two input tables, so it’s necessary to build up the result in one or another of these fashions.) The important point is that these different join possibilities give semantically equivalent results but might have hugely different execution costs. Therefore, the planner will explore all of them to try to find the most efficient query plan.

When a query only involves two or three tables, there aren’t many join orders to worry about. But the number of possible join orders grows exponentially as the number of tables expands. Beyond ten or so input tables it’s no longer practical to do an exhaustive search of all the possibilities, and even for six or seven tables planning might take an annoyingly long time. When there are too many input tables, the PostgreSQL planner will switch from exhaustive search to a genetic probabilistic search through a limited number of possibilities. (The switch-over threshold is set by the `geqo_threshold` run-time parameter.) The genetic search takes less time, but it won’t necessarily find the best possible plan.

When the query involves outer joins, the planner has less freedom than it does for plain (inner) joins. For example, consider:

```sql
SELECT * FROM a LEFT JOIN (b JOIN c ON (b.ref = c.id)) ON (a.id = b.id);
```

Although this query’s restrictions are superficially similar to the previous example, the semantics are different because a row must be emitted for each row of A that has no matching row in the join of B and C. Therefore the planner has no choice of join order here: it must join B to C and then join A to that result. Accordingly, this query takes less time to plan than the previous query. In other cases, the planner might be able to determine that more than one join order is safe. For example, given:

```sql
SELECT * FROM a LEFT JOIN b ON (a.bid = b.id) LEFT JOIN c ON (a.cid = c.id);
```
it is valid to join A to either B or C first. Currently, only FULL JOIN completely constrains the join order. Most practical cases involving LEFT JOIN or RIGHT JOIN can be rearranged to some extent.

Explicit inner join syntax (INNER JOIN, CROSS JOIN, or unadorned JOIN) is semantically the same as listing the input relations in \texttt{FROM}, so it does not constrain the join order.

Even though most kinds of JOIN don’t completely constrain the join order, it is possible to instruct the PostgreSQL query planner to treat all JOIN clauses as constraining the join order anyway. For example, these three queries are logically equivalent:

\begin{verbatim}
SELECT * FROM a, b, c WHERE a.id = b.id AND b.ref = c.id;
SELECT * FROM a CROSS JOIN b CROSS JOIN c WHERE a.id = b.id AND b.ref = c.id;
SELECT * FROM a JOIN (b JOIN c ON (b.ref = c.id)) ON (a.id = b.id);
\end{verbatim}

But if we tell the planner to honor the JOIN order, the second and third take less time to plan than the first. This effect is not worth worrying about for only three tables, but it can be a lifesaver with many tables.

To force the planner to follow the join order laid out by explicit JOINs, set the join\_collapse\_limit run-time parameter to 1. (Other possible values are discussed below.)

You do not need to constrain the join order completely in order to cut search time, because it’s OK to use JOIN operators within items of a plain \texttt{FROM} list. For example, consider:

\begin{verbatim}
SELECT * FROM a CROSS JOIN b, c, d, e WHERE ...;
\end{verbatim}

With \texttt{join\_collapse\_limit} = 1, this forces the planner to join A to B before joining them to other tables, but doesn’t constrain its choices otherwise. In this example, the number of possible join orders is reduced by a factor of 5.

Constraining the planner’s search in this way is a useful technique both for reducing planning time and for directing the planner to a good query plan. If the planner chooses a bad join order by default, you can force it to choose a better order via JOIN syntax — assuming that you know of a better order, that is. Experimentation is recommended.

A closely related issue that affects planning time is collapsing of subqueries into their parent query. For example, consider:

\begin{verbatim}
SELECT * FROM x, y,
    (SELECT * FROM a, b, c WHERE something) AS ss
WHERE somethingelse;
\end{verbatim}

This situation might arise from use of a view that contains a join; the view’s SELECT rule will be inserted in place of the view reference, yielding a query much like the above. Normally, the planner will try to collapse the subquery into the parent, yielding:

\begin{verbatim}
SELECT * FROM x, y, a, b, c WHERE something AND somethingelse;
\end{verbatim}

This usually results in a better plan than planning the subquery separately. (For example, the outer \texttt{WHERE} conditions might be such that joining X to A first eliminates many rows of A, thus avoiding the need to form the full logical output of the subquery.) But at the same time, we have increased the planning time: here, we have a five-way join problem replacing two separate three-way join problems. Because of the exponential growth of the number of possibilities, this makes a big difference. The planner tries to avoid getting stuck in huge join search problems by not collapsing a subquery if more than \texttt{from\_collapse\_limit} \texttt{FROM} items would result in the parent query. You can trade off planning time against quality of plan by adjusting this run-time parameter up or down.
fromCollapseLimit and joinCollapseLimit are similarly named because they do almost the same thing: one controls when the planner will “flatten out” subqueries, and the other controls when it will flatten out explicit joins. Typically you would either set joinCollapseLimit equal to fromCollapseLimit (so that explicit joins and subqueries act similarly) or set joinCollapseLimit to 1 (if you want to control join order with explicit joins). But you might set them differently if you are trying to fine-tune the trade-off between planning time and run time.

14.4. Populating a Database

One might need to insert a large amount of data when first populating a database. This section contains some suggestions on how to make this process as efficient as possible.

14.4.1. Disable Autocommit

When using multiple INSERTs, turn off autocommit and just do one commit at the end. (In plain SQL, this means issuing BEGIN at the start and COMMIT at the end. Some client libraries might do this behind your back, in which case you need to make sure the library does it when you want it done.) If you allow each insertion to be committed separately, PostgreSQL is doing a lot of work for each row that is added. An additional benefit of doing all insertions in one transaction is that if the insertion of one row were to fail then the insertion of all rows inserted up to that point would be rolled back, so you won’t be stuck with partially loaded data.

14.4.2. Use COPY

Use COPY to load all the rows in one command, instead of using a series of INSERT commands. The COPY command is optimized for loading large numbers of rows; it is less flexible than INSERT, but incurs significantly less overhead for large data loads. Since COPY is a single command, there is no need to disable autocommit if you use this method to populate a table.

If you cannot use COPY, it might help to use PREPARE to create a prepared INSERT statement, and then use EXECUTE as many times as required. This avoids some of the overhead of repeatedly parsing and planning INSERT. Different interfaces provide this facility in different ways; look for “prepared statements” in the interface documentation.

Note that loading a large number of rows using COPY is almost always faster than using INSERT, even if PREPARE is used and multiple insertions are batched into a single transaction. COPY is fastest when used within the same transaction as an earlier CREATE TABLE or TRUNCATE command. In such cases no WAL needs to be written, because in case of an error, the files containing the newly loaded data will be removed anyway. However, this consideration does not apply when archive_mode is on, as all commands must write WAL in that case.

14.4.3. Remove Indexes

If you are loading a freshly created table, the fastest method is to create the table, bulk load the table’s data using COPY, then create any indexes needed for the table. Creating an index on pre-existing data is quicker than updating it incrementally as each row is loaded.

If you are adding large amounts of data to an existing table, it might be a win to drop the index, load the table, and then recreate the index. Of course, the database performance for other users might suffer
Chapter 14. Performance Tips

during the time the index is missing. One should also think twice before dropping unique indexes, since the error checking afforded by the unique constraint will be lost while the index is missing.

14.4.4. Remove Foreign Key Constraints

Just as with indexes, a foreign key constraint can be checked “in bulk” more efficiently than row-by-row. So it might be useful to drop foreign key constraints, load data, and re-create the constraints. Again, there is a trade-off between data load speed and loss of error checking while the constraint is missing.

14.4.5. Increase maintenance_work_mem

Temporarily increasing the maintenance_work_mem configuration variable when loading large amounts of data can lead to improved performance. This will help to speed up CREATE INDEX commands and ALTER TABLE ADD FOREIGN KEY commands. It won’t do much for COPY itself, so this advice is only useful when you are using one or both of the above techniques.

14.4.6. Increase checkpoint_segments

Temporarily increasing the checkpoint_segments configuration variable can also make large data loads faster. This is because loading a large amount of data into PostgreSQL will cause checkpoints to occur more often than the normal checkpoint frequency (specified by the checkpoint_timeout configuration variable). Whenever a checkpoint occurs, all dirty pages must be flushed to disk. By increasing checkpoint_segments temporarily during bulk data loads, the number of checkpoints that are required can be reduced.

14.4.7. Turn off archive_mode

When loading large amounts of data into an installation that uses WAL archiving, you might want to disable archiving (turn off the archive_mode configuration variable) while loading. It might be faster to take a new base backup after the load has completed than to process a large amount of incremental WAL data. But note that turning archive_mode on or off requires a server restart.

Aside from avoiding the time for the archiver to process the WAL data, doing this will actually make certain commands faster, because they are designed not to write WAL at all if archive_mode is off. (They can guarantee crash safety more cheaply by doing an fsync at the end than by writing WAL.) This applies to the following commands:

- CREATE TABLE AS SELECT
- CREATE INDEX (and variants such as ALTER TABLE ADD PRIMARY KEY)
- ALTER TABLE SET TABLESPACE
- CLUSTER
- COPY FROM, when the target table has been created or truncated earlier in the same transaction
14.4.8. Run `ANALYZE` Afterwards

Whenever you have significantly altered the distribution of data within a table, running `ANALYZE` is strongly recommended. This includes bulk loading large amounts of data into the table. Running `ANALYZE` (or `VACUUM ANALYZE`) ensures that the planner has up-to-date statistics about the table. With no statistics or obsolete statistics, the planner might make poor decisions during query planning, leading to poor performance on any tables with inaccurate or nonexistent statistics. Note that if the autovacuum daemon is enabled, it might run `ANALYZE` automatically; see *Updating Planner Statistics* and *The Autovacuum Daemon* for more information.

14.4.9. Some Notes About `pg_dump`

Dump scripts generated by `pg_dump` automatically apply several, but not all, of the above guidelines. To reload a `pg_dump` dump as quickly as possible, you need to do a few extra things manually. (Note that these points apply while *restoring* a dump, not while *creating* it. The same points apply when using `pg_restore` to load from a `pg_dump` archive file.)

By default, `pg_dump` uses `COPY`, and when it is generating a complete schema-and-data dump, it is careful to load data before creating indexes and foreign keys. So in this case several guidelines are handled automatically. What is left for you to do is to:

- Set appropriate (i.e., larger than normal) values for `maintenance_work_mem` and `checkpoint_segments`.
- If using WAL archiving, consider disabling it during the restore. To do that, turn off `archive_mode` before loading the dump script, and afterwards turn it back on and take a fresh base backup.
- Consider whether the whole dump should be restored as a single transaction. To do that, pass the `-1` or `--single-transaction` command-line option to `psql` or `pg_restore`. When using this mode, even the smallest of errors will rollback the entire restore, possibly discarding many hours of processing. Depending on how interrelated the data is, that might seem preferable to manual cleanup, or not. `COPY` commands will run fastest if you use a single transaction and have WAL archiving turned off.
- Run `ANALYZE` afterwards.

A data-only dump will still use `COPY`, but it does not drop or recreate indexes, and it does not normally touch foreign keys. ² So when loading a data-only dump, it is up to you to drop and recreate indexes and foreign keys if you wish to use those techniques. It’s still useful to increase `checkpoint_segments` while loading the data, but don’t bother increasing `maintenance_work_mem`; rather, you’d do that while manually recreating indexes and foreign keys afterwards. And don’t forget to `ANALYZE` when you’re done; see *Updating Planner Statistics* and *The Autovacuum Daemon* for more information.

---

² You can get the effect of disabling foreign keys by using the `--disable-triggers` option — but realize that that eliminates, rather than just postpones, foreign key validation, and so it is possible to insert bad data if you use it.
III. Server Administration

This part covers topics that are of interest to a PostgreSQL database administrator. This includes installation of the software, set up and configuration of the server, management of users and databases, and maintenance tasks. Anyone who runs a PostgreSQL server, even for personal use, but especially in production, should be familiar with the topics covered in this part.

The information in this part is arranged approximately in the order in which a new user should read it. But the chapters are self-contained and can be read individually as desired. The information in this part is presented in a narrative fashion in topical units. Readers looking for a complete description of a particular command should see Part VI.

The first few chapters are written so they can be understood without prerequisite knowledge, so new users who need to set up their own server can begin their exploration with this part. The rest of this part is about tuning and management; that material assumes that the reader is familiar with the general use of the PostgreSQL database system. Readers are encouraged to look at Part I and Part II for additional information.
Chapter 15. Installation from Source Code

This chapter describes the installation of PostgreSQL using the source code distribution. (If you are installing a pre-packaged distribution, such as an RPM or Debian package, ignore this chapter and read the packager’s instructions instead.)

15.1. Short Version

./configure
make
su
make install
adduser postgres
mkdir /usr/local/pgsql/data
chown postgres /usr/local/pgsql/data
su - postgres
/usr/local/pgsql/bin/initdb -D /usr/local/pgsql/data
/usr/local/pgsql/bin/postgres -D /usr/local/pgsql/data > logfile 2>&1 &
/usr/local/pgsql/bin/createdb test
/usr/local/pgsql/bin/psql test

The long version is the rest of this chapter.

15.2. Requirements

In general, a modern Unix-compatible platform should be able to run PostgreSQL. The platforms that had received specific testing at the time of release are listed in Section 15.7 below. In the doc subdirectory of the distribution there are several platform-specific FAQ documents you might wish to consult if you are having trouble.

The following software packages are required for building PostgreSQL:

- GNU make is required; other make programs will not work. GNU make is often installed under the name gmake; this document will always refer to it by that name. (On some systems GNU make is the default tool with the name make.) To test for GNU make enter:

  
gmake --version

  It is recommended to use version 3.76.1 or later.

- You need an ISO/ANSI C compiler (at least C89-compliant). Recent versions of GCC are recommendable, but PostgreSQL is known to build using a wide variety of compilers from different vendors.

- tar is required to unpack the source distribution, in addition to either gzip or bzip2. In addition, gzip is required to install the documentation.

- The GNU Readline library is used by default. It allows psql (the PostgreSQL command line SQL interpreter) to remember each command you type, and allows you to use arrow keys to recall and edit previous commands. This is very helpful and is strongly recommended. If you don’t want to use it then you must specify the --without-readline option to configure. As an alternative, you can often use the BSD-licensed libedit library, originally developed on NetBSD. The libedit library is GNU Readline-compatible and is used if libreadline is not found, or
if `--with-libedit-preferred` is used as an option to `configure`. If you are using a package-based Linux distribution, be aware that you need both the `readline` and `readline-devel` packages, if those are separate in your distribution.

- The zlib compression library will be used by default. If you don’t want to use it then you must specify the `--without-zlib` option to `configure`. Using this option disables support for compressed archives in `pg_dump` and `pg_restore`.

The following packages are optional. They are not required in the default configuration, but they are needed when certain build options are enabled, as explained below:

- To build the server programming language PL/Perl you need a full Perl installation, including the `libperl` library and the header files. Since PL/Perl will be a shared library, the `libperl` library must be a shared library also on most platforms. This appears to be the default in recent Perl versions, but it was not in earlier versions, and in any case it is the choice of whomever installed Perl at your site. If you intend to make more than incidental use of PL/Perl, you should ensure that the Perl installation was built with the `usemultiplicity` option enabled (`perl -V` will show whether this is the case).

If you don’t have the shared library but you need one, a message like this will appear during the PostgreSQL build to point out this fact:

```plaintext
*** Cannot build PL/Perl because libperl is not a shared library.
*** You might have to rebuild your Perl installation. Refer to
*** the documentation for details.
```

(If you don’t follow the on-screen output you will merely notice that the PL/Perl library object, `plperl.so` or similar, will not be installed.) If you see this, you will have to rebuild and install Perl manually to be able to build PL/Perl. During the configuration process for Perl, request a shared library.

- To build the PL/Python server programming language, you need a Python installation with the header files and the `distutils` module. The `distutils` module is included by default with Python 1.6 and later; users of earlier versions of Python will need to install it.

Since PL/Python will be a shared library, the `libpython` library must be a shared library also on most platforms. This is not the case in a default Python installation. If after building and installing PostgreSQL you have a file called `plpython.so` (possibly a different extension), then everything went well. Otherwise you should have seen a notice like this flying by:

```plaintext
*** Cannot build PL/Python because libpython is not a shared library.
*** You might have to rebuild your Python installation. Refer to
*** the documentation for details.
```

That means you have to rebuild (part of) your Python installation to create this shared library.

If you have problems, run Python 2.3 or later’s `configure` using the `--enable-shared` flag. On some operating systems you don’t have to build a shared library, but you will have to convince the PostgreSQL build system of this. Consult the `Makefile` in the `src/pl/plpython` directory for details.

- If you want to build the PL/Tcl procedural language, you of course need a Tcl installation. If you are using a pre-8.4 release of Tcl, ensure that it was built without multithreading support.

- To enable Native Language Support (NLS), that is, the ability to display a program’s messages in a language other than English, you need an implementation of the Gettext API. Some operating systems have this built-in (e.g., Linux, NetBSD, Solaris), for other systems you can download an add-on package from http://www.gnu.org/software/gettext/. If you are using the Gettext implemen-
If you are building from a Git tree instead of using a released source package, or if you want to do server development, you also need the following packages:

- GNU Flex and Bison are needed to build from a Git checkout, or if you changed the actual scanner and parser definition files. If you need them, be sure to get Flex 2.5.4 or later and Bison 1.875 or later. Other lex and yacc programs cannot be used.
- Perl 5.8 or later is needed to build from a Git checkout, or if you changed the input files for any of the build steps that use Perl scripts. If building on Windows you will need Perl in any case.

If you need to get a GNU package, you can find it at your local GNU mirror site (see http://www.gnu.org/order/ftp.html for a list) or at ftp://ftp.gnu.org/gnu/.

Also check that you have sufficient disk space. You will need about 100 MB for the source tree during compilation and about 20 MB for the installation directory. An empty database cluster takes about 35 MB; databases take about five times the amount of space that a flat text file with the same data would take. If you are going to run the regression tests you will temporarily need up to an extra 150 MB. Use the `df` command to check free disk space.

15.3. Getting The Source

The PostgreSQL 8.4.22 sources can be obtained by anonymous FTP from ftp://ftp.postgresql.org/pub/source/v8.4.22/postgresql-8.4.22.tar.gz. Other download options can be found on our website: http://www.postgresql.org/download/. After you have obtained the file, unpack it:

```
    gunzip postgresql-8.4.22.tar.gz
    tar xf postgresql-8.4.22.tar
```

This will create a directory `postgresql-8.4.22` under the current directory with the PostgreSQL sources. Change into that directory for the rest of the installation procedure.

You can also get the source directly from the version control repository, see Appendix H.

15.4. Upgrading

These instructions assume that your existing installation is under the `/usr/local/pgsql` directory, and that the data area is in `/usr/local/pgsql/data`. Substitute your paths appropriately.

The internal data storage format typically changes in every major release of PostgreSQL. Therefore, if you are upgrading an existing installation that does not have a version number of “8.4.x”, you must back up and restore your data. If you are upgrading from PostgreSQL “8.4.x”, the new version can use your current data files so you should skip the backup and restore steps below because they are unnecessary.
Chapter 15. Installation from Source Code

1. If making a backup, make sure that your database is not being updated. This does not affect
   the integrity of the backup, but the changed data would of course not be included. If necessary,
   edit the permissions in the file /usr/local/pgsql/data/pg_hba.conf (or equivalent) to
disallow access from everyone except you.

   To back up your database installation, type:

   `pg_dumpall > outputfile`

   If you need to preserve OIDs (such as when using them as foreign keys), then use the `-o`
   option when running pg_dumpall.

   To make the backup, you can use the pg_dumpall command from the version you are currently
   running. For best results, however, try to use the pg_dumpall command from PostgreSQL 8.4.22,
since this version contains bug fixes and improvements over older versions. While this advice
might seem idiosyncratic since you haven’t installed the new version yet, it is advisable to follow
it if you plan to install the new version in parallel with the old version. In that case you can com-
plete the installation normally and transfer the data later. This will also decrease the downtime.

2. Shut down the old server:

   `pg_ctl stop`

   On systems that have PostgreSQL started at boot time, there is probably a start-up file that will
   accomplish the same thing. For example, on a Red Hat Linux system one might find that this
   works:

   `/etc/rc.d/init.d/postgresql stop`

3. If restoring from backup, rename or delete the old installation directory. It is a good idea to
   rename the directory, rather than delete it, in case you have trouble and need to revert to it.
   Keep in mind the directory might consume significant disk space. To rename the directory, use a
   command like this:

   `mv /usr/local/pgsql /usr/local/pgsql.old`

4. Install the new version of PostgreSQL as outlined in Section 15.5.

5. Create a new database cluster if needed. Remember that you must execute these commands while
   logged in to the special database user account (which you already have if you are upgrading).

   `/usr/local/pgsql/bin/initdb -D /usr/local/pgsql/data`

6. Restore your previous `pg_hba.conf` and any `postgresql.conf` modifications.

7. Start the database server, again using the special database user account:

   `/usr/local/pgsql/bin/postgres -D /usr/local/pgsql/data`

8. Finally, restore your data from backup with:

   `/usr/local/pgsql/bin/psql -d postgres -f outputfile`

   using the new psql.

Further discussion appears in Section 24.5, including instructions on how the previous installation can
continue running while the new installation is installed.

15.5. Installation Procedure

1. Configuration
Chapter 15. Installation from Source Code

The first step of the installation procedure is to configure the source tree for your system and choose the options you would like. This is done by running the configure script. For a default installation simply enter:

```bash
./configure
```

This script will run a number of tests to determine values for various system dependent variables and detect any quirks of your operating system, and finally will create several files in the build tree to record what it found. (You can also run configure in a directory outside the source tree if you want to keep the build directory separate.)

The default configuration will build the server and utilities, as well as all client applications and interfaces that require only a C compiler. All files will be installed under /usr/local/pgsql by default.

You can customize the build and installation process by supplying one or more of the following command line options to configure:

```bash
--prefix=PREFIX
```

Install all files under the directory `PREFIX` instead of `/usr/local/pgsql`. The actual files will be installed into various subdirectories; no files will ever be installed directly into the `PREFIX` directory.

If you have special needs, you can also customize the individual subdirectories with the following options. However, if you leave these with their defaults, the installation will be relocatable, meaning you can move the directory after installation. (The `man` and `doc` locations are not affected by this.)

For relocatable installs, you might want to use configure’s `--disable-rpath` option. Also, you will need to tell the operating system how to find the shared libraries.

```bash
--exec-prefix=EXEC-PREFIX
```

You can install architecture-dependent files under a different prefix, `EXEC-PREFIX`, than what `PREFIX` was set to. This can be useful to share architecture-independent files between hosts. If you omit this, then `EXEC-PREFIX` is set equal to `PREFIX` and both architecture-dependent and independent files will be installed under the same tree, which is probably what you want.

```bash
--bindir=DIRECTORY
```

Specifies the directory for executable programs. The default is `EXEC-PREFIX/bin`, which normally means `/usr/local/pgsql/bin`.

```bash
--sysconfdir=DIRECTORY
```

Sets the directory for various configuration files, `PREFIX/etc` by default.

```bash
--libdir=DIRECTORY
```

Sets the location to install libraries and dynamically loadable modules. The default is `EXEC-PREFIX/lib`.

```bash
--includedir=DIRECTORY
```

Sets the directory for installing C and C++ header files. The default is `PREFIX/include`.

```bash
--datarootdir=DIRECTORY
```

Sets the root directory for various types of read-only data files. This only sets the default for some of the following options. The default is `PREFIX/share`. 

339
Chapter 15. Installation from Source Code

--datadir=DIRECTORY

Sets the directory for read-only data files used by the installed programs. The default is DATAROOTDIR. Note that this has nothing to do with where your database files will be placed.

--localedir=DIRECTORY

Sets the directory for installing locale data, in particular message translation catalog files. The default is DATAROOTDIR/locale.

--mandir=DIRECTORY

The man pages that come with PostgreSQL will be installed under this directory, in their respective man subdirectories. The default is DATAROOTDIR/man.

--docdir=DIRECTORY

Sets the root directory for installing documentation files, except “man” pages. This only sets the default for the following options. The default value for this option is DATAROOTDIR/doc/postgresql.

--htmldir=DIRECTORY

The HTML-formatted documentation for PostgreSQL will be installed under this directory. The default is DATAROOTDIR.

Note: Care has been taken to make it possible to install PostgreSQL into shared installation locations (such as /usr/local/include) without interfering with the namespace of the rest of the system. First, the string “/postgresql” is automatically appended to datadir, sysconfdir, and docdir, unless the fully expanded directory name already contains the string “postgresql” or “pgsql”. For example, if you choose /usr/local as prefix, the documentation will be installed in /usr/local/doc/postgresql, but if the prefix is /opt/postgres, then it will be in /opt/postgres/doc. The public C header files of the client interfaces are installed into includedir and are namespace-clean. The internal header files and the server header files are installed into private directories under includedir. See the documentation of each interface for information about how to access its header files. Finally, a private subdirectory will also be created, if appropriate, under libdir for dynamically loadable modules.

--with-includes=DIRECTORIES

DIRECTORIES is a colon-separated list of directories that will be added to the list the compiler searches for header files. If you have optional packages (such as GNU Readline) installed in a non-standard location, you have to use this option and probably also the corresponding --with-libraries option.

Example: --with-includes=/opt/gnu/include:/usr/sup/include.

--with-libraries=DIRECTORIES

DIRECTORIES is a colon-separated list of directories to search for libraries. You will probably have to use this option (and the corresponding --with-includes option) if you have packages installed in non-standard locations.

Example: --with-libraries=/opt/gnu/lib:/usr/sup/lib.

--enable-nls=[LANGUAGES]

Enables Native Language Support (NLS), that is, the ability to display a program’s messages in a language other than English. LANGUAGES is an optional space-separated list of codes.
of the languages that you want supported, for example --enable-nls='de fr'. (The
intersection between your list and the set of actually provided translations will be computed
automatically.) If you do not specify a list, then all available translations are installed.

To use this option, you will need an implementation of the Gettext API; see above.

--with-pgport=NUMBER

Set NUMBER as the default port number for server and clients. The default is 5432. The port
can always be changed later on, but if you specify it here then both server and clients will
have the same default compiled in, which can be very convenient. Usually the only good
reason to select a non-default value is if you intend to run multiple PostgreSQL servers on
the same machine.

--with-perl

Build the PL/Perl server-side language.

--with-python

Build the PL/Python server-side language.

--with-tcl

Build the PL/Tcl server-side language.

--with-tclconfig=DIRECTORY

Tcl installs the file tclConfig.sh, which contains configuration information needed to
build modules interfacing to Tcl. This file is normally found automatically at a well-known
location, but if you want to use a different version of Tcl you can specify the directory in
which to look for it.

--with-gssapi

Build with support for GSSAPI authentication. On many systems, the GSSAPI (usually
a part of the Kerberos installation) system is not installed in a location that is searched by
default (e.g., /usr/include, /usr/lib), so you must use the options --with-includes
and --with-libraries in addition to this option. configure will check for the required
header files and libraries to make sure that your GSSAPI installation is sufficient before
proceeding.

--with-krb5

Build with support for Kerberos 5 authentication. On many systems, the Kerberos system is
not installed in a location that is searched by default (e.g., /usr/include, /usr/lib), so
you must use the options --with-includes and --with-libraries in addition to this
option. configure will check for the required header files and libraries to make sure that
your Kerberos installation is sufficient before proceeding.

--with-krb-srvnam=NAME

The default name of the Kerberos service principal (also used by GSSAPI). postgres is the
default. There’s usually no reason to change this unless you have a Windows environment,
in which case it must be set to uppercase POSTGRES.

--with-openssl

Build with support for SSL (encrypted) connections. This requires the OpenSSL package to
be installed. configure will check for the required header files and libraries to make sure
that your OpenSSL installation is sufficient before proceeding.
--with-pam

Build with PAM (Pluggable Authentication Modules) support.

--with-ldap

Build with LDAP support for authentication and connection parameter lookup (see Section 30.16 and Section 19.3.7 for more information). On Unix, this requires the OpenLDAP package to be installed. On Windows, the default WinLDAP library is used. configure will check for the required header files and libraries to make sure that your OpenLDAP installation is sufficient before proceeding.

--without-readline

Prevents use of the Readline library (and libedit as well). This option disables command-line editing and history in psql, so it is not recommended.

--with-libedit-preferred

Favors the use of the BSD-licensed libedit library rather than GPL-licensed Readline. This option is significant only if you have both libraries installed; the default in that case is to use Readline.

--with-bonjour

Build with Bonjour support. This requires Bonjour support in your operating system. Recommended on Mac OS X.

--with-ossu-uuid

Use the OSSP UUID library when building contrib/uuid-ossu. The library provides functions to generate UUIDs.

--with-libxml

Build with libxml (enables SQL/XML support). Libxml version 2.6.23 or later is required for this feature.

Libxml installs a program xml2-config that can be used to detect the required compiler and linker options. PostgreSQL will use it automatically if found. To specify a libxml installation at an unusual location, you can either set the environment variable XML2_CONFIG to point to the xml2-config program belonging to the installation, or use the options --with-includes and --with-libraries.

--with-libxslt

Use libxslt when building contrib/xml2. contrib/xml2 relies on this library to perform XSL transformations of XML.

--disable-integer-datetimes

Disable support for 64-bit integer storage for timestamps and intervals, and store datetime values as floating-point numbers instead. Floating-point datetime storage was the default in PostgreSQL releases prior to 8.4, but it is now deprecated, because it does not support microsecond precision for the full range of timestamp values. However, integer-based datetime storage requires a 64-bit integer type. Therefore, this option can be used when no such type is available, or for compatibility with applications written for prior versions of PostgreSQL. See Section 8.5 for more information.

--disable-float4-byval

Disable passing float4 values “by value”, causing them to be passed “by reference” instead. This option costs performance, but may be needed for compatibility with old user-defined

functions that are written in C and use the “version 0” calling convention. A better long-term solution is to update any such functions to use the “version 1” calling convention.

`--disable-float8-byval`

Disable passing float8 values “by value”, causing them to be passed “by reference” instead. This option costs performance, but may be needed for compatibility with old user-defined functions that are written in C and use the “version 0” calling convention. A better long-term solution is to update any such functions to use the “version 1” calling convention. Note that this option affects not only float8, but also int8 and some related types such as timestamp. On 32-bit platforms, `--disable-float8-byval` is the default and it is not allowed to select `--enable-float8-byval`.

`--with-segsize=SEGSIZE`

Set the **segment size**, in gigabytes. Large tables are divided into multiple operating-system files, each of size equal to the segment size. This avoids problems with file size limits that exist on many platforms. The default segment size, 1 gigabyte, is safe on all supported platforms. If your operating system has “largefile” support (which most do, nowadays), you can use a larger segment size. This can be helpful to reduce the number of file descriptors consumed when working with very large tables. But be careful not to select a value larger than is supported by your platform and the filesystem(s) you intend to use. Other tools you might wish to use, such as tar, could also set limits on the usable file size. It is recommended, though not absolutely required, that this value be a power of 2. Note that changing this value requires an initdb.

`--with-blocksize=BLOCKSIZE`

Set the **block size**, in kilobytes. This is the unit of storage and I/O within tables. The default, 8 kilobytes, is suitable for most situations; but other values may be useful in special cases. The value must be a power of 2 between 1 and 32 (kilobytes). Note that changing this value requires an initdb.

`--with-wal-segsize=SEGSIZE`

Set the **WAL segment size**, in megabytes. This is the size of each individual file in the WAL log. It may be useful to adjust this size to control the granularity of WAL log shipping. The default size is 16 megabytes. The value must be a power of 2 between 1 and 64 (megabytes). Note that changing this value requires an initdb.

`--with-wal-blocksize=BLOCKSIZE`

Set the **WAL block size**, in kilobytes. This is the unit of storage and I/O within the WAL log. The default, 8 kilobytes, is suitable for most situations; but other values may be useful in special cases. The value must be a power of 2 between 1 and 64 (kilobytes). Note that changing this value requires an initdb.

`--disable-spinlocks`

Allow the build to succeed even if PostgreSQL has no CPU spinlock support for the platform. The lack of spinlock support will result in poor performance; therefore, this option should only be used if the build aborts and informs you that the platform lacks spinlock support. If this option is required to build PostgreSQL on your platform, please report the problem to the PostgreSQL developers.

`--enable-thread-safety`

Make the client libraries thread-safe. This allows concurrent threads in libpq and ECPG programs to safely control their private connection handles. This option requires adequate threading support in your operating system.
Chapter 15. Installation from Source Code

--with-system-tzdata=DIRECTORY

PostgreSQL includes its own time zone database, which it requires for date and time operations. This time zone database is in fact compatible with the “zoneinfo” time zone database provided by many operating systems such as FreeBSD, Linux, and Solaris, so it would be redundant to install it again. When this option is used, the system-supplied time zone database in DIRECTORY is used instead of the one included in the PostgreSQL source distribution. DIRECTORY must be specified as an absolute path. /usr/share/zoneinfo is a likely directory on some operating systems. Note that the installation routine will not detect mismatching or erroneous time zone data. If you use this option, you are advised to run the regression tests to verify that the time zone data you have pointed to works correctly with PostgreSQL.

This option is mainly aimed at binary package distributors who know their target operating system well. The main advantage of using this option is that the PostgreSQL package won’t need to be upgraded whenever any of the many local daylight-saving time rules change. Another advantage is that PostgreSQL can be cross-compiled more straightforwardly if the time zone database files do not need to be built during the installation.

--without-zlib

Prevents use of the Zlib library. This disables support for compressed archives in pg_dump and pg_restore. This option is only intended for those rare systems where this library is not available.

--enable-debug

Compiles all programs and libraries with debugging symbols. This means that you can run the programs in a debugger to analyze problems. This enlarges the size of the installed executables considerably, and on non-GCC compilers it usually also disables compiler optimization, causing slowdowns. However, having the symbols available is extremely helpful for dealing with any problems that might arise. Currently, this option is recommended for production installations only if you use GCC. But you should always have it on if you are doing development work or running a beta version.

--enable-coverage

If using GCC, all programs and libraries are compiled with code coverage testing instrumentation. When run, they generate files in the build directory with code coverage metrics. See Section 29.4 for more information. This option is for use only with GCC and when doing development work.

--enable-profiling

If using GCC, all programs and libraries are compiled so they can be profiled. On backend exit, a subdirectory will be created that contains the gmon.out file for use in profiling. This option is for use only with GCC and when doing development work.

--enable-cassert

Enables assertion checks in the server, which test for many “cannot happen” conditions. This is invaluable for code development purposes, but the tests can slow down the server significantly. Also, having the tests turned on won’t necessarily enhance the stability of your server! The assertion checks are not categorized for severity, and so what might be a relatively harmless bug will still lead to server restarts if it triggers an assertion failure. This option is not recommended for production use, but you should have it on for development work or when running a beta version.
Chapter 15. Installation from Source Code

--enable-depend

Enables automatic dependency tracking. With this option, the makefiles are set up so that all affected object files will be rebuilt when any header file is changed. This is useful if you are doing development work, but is just wasted overhead if you intend only to compile once and install. At present, this option only works with GCC.

--enable-dtrace

Compiles PostgreSQL with support for the dynamic tracing tool DTrace. See Section 26.4 for more information.

To point to the dtrace program, the environment variable DTRACE can be set. This will often be necessary because dtrace is typically installed under /usr/sbin, which might not be in the path.

Extra command-line options for the dtrace program can be specified in the environment variable DTRACEFLAGS. On Solaris, to include DTrace support in a 64-bit binary, you must specify DTRACEFLAGS="-64" to configure. For example, using the GCC compiler:

`.configure CC='gcc -m64' --enable-dtrace DTRACEFLAGS='-64' ...`

Using Sun’s compiler:

`.configure CC=’/opt/SUNWspro/bin/cc -xtarget=native64’ --enable-dtrace DTRACEFLAGS='-64' ...`

If you prefer a C compiler different from the one configure picks, you can set the environment variable CC to the program of your choice. By default, configure will pick gcc if available, else the platform’s default (usually cc). Similarly, you can override the default compiler flags if needed with the CFLAGS variable.

You can specify environment variables on the configure command line, for example:

`.configure CC=/opt/bin/gcc CFLAGS='-O2 -pipe’`

Here is a list of the significant variables that can be set in this manner:

BISON
  Bison program
CC
  C compiler
CFLAGS
  options to pass to the C compiler
CPP
  C preprocessor
CPPFLAGS
  options to pass to the C preprocessor
DTRACE
  location of the dtrace program
DTRACEFLAGS
  options to pass to the dtrace program
FLEX
  Flex program
Chapter 15. Installation from Source Code

**LDFLAGS**
- options to pass to the link editor

**LDFLAGS_SL**
- linker options for shared library linking

**MSGFMT**
- msgfmt program for native language support

**PERL**
- Full path to the Perl interpreter. This will be used to determine the dependencies for building PL/Perl.

**PYTHON**
- Full path to the Python interpreter. This will be used to determine the dependencies for building PL/Python.

**TCLSH**
- Full path to the Tcl interpreter. This will be used to determine the dependencies for building PL/Tcl, and it will be substituted into Tcl scripts.

**XML2_CONFIG**
- xml2-config program used to locate the libxml installation.

2. Build

To start the build, type:

```
gmake
```

(Remember to use GNU make.) The build will take a few minutes depending on your hardware. The last line displayed should be:

```
All of PostgreSQL is successfully made. Ready to install.
```

3. Regression Tests

If you want to test the newly built server before you install it, you can run the regression tests at this point. The regression tests are a test suite to verify that PostgreSQL runs on your machine in the way the developers expected it to. Type:

```
gmake check
```

(This won’t work as root; do it as an unprivileged user.) Chapter 29 contains detailed information about interpreting the test results. You can repeat this test at any later time by issuing the same command.

4. Installing the Files

**Note:** If you are upgrading an existing system and are going to install the new files over the old ones, be sure to back up your data and shut down the old server before proceeding, as explained in Section 15.4 above.

To install PostgreSQL enter:

```
gmake install
```
This will install files into the directories that were specified in step 1. Make sure that you have appropriate permissions to write into that area. Normally you need to do this step as root. Alternatively, you can create the target directories in advance and arrange for appropriate permissions to be granted.

You can use `gmake install-strip` instead of `gmake install` to strip the executable files and libraries as they are installed. This will save some space. If you built with debugging support, stripping will effectively remove the debugging support, so it should only be done if debugging is no longer needed. `install-strip` tries to do a reasonable job saving space, but it does not have perfect knowledge of how to strip every unneeded byte from an executable file, so if you want to save all the disk space you possibly can, you will have to do manual work.

The standard installation provides all the header files needed for client application development as well as for server-side program development, such as custom functions or data types written in C. (Prior to PostgreSQL 8.0, a separate `gmake install-all-headers` command was needed for the latter, but this step has been folded into the standard install.)

**Client-only installation:** If you want to install only the client applications and interface libraries, then you can use these commands:

- `gmake -C src/bin install`
- `gmake -C src/include install`
- `gmake -C src/interfaces install`
- `gmake -C doc install`

`src/bin` has a few binaries for server-only use, but they are small.

**Registering eventlog on Windows:** To register a Windows eventlog library with the operating system, issue this command after installation:

```
regsvr32 pgsql_library_directory/pgevent.dll
```

This creates registry entries used by the event viewer.

**Uninstallation:** To undo the installation use the command `gmake uninstall`. However, this will not remove any created directories.

**Cleaning:** After the installation you can free disk space by removing the built files from the source tree with the command `gmake clean`. This will preserve the files made by the `configure` program, so that you can rebuild everything with `gmake` later on. To reset the source tree to the state in which it was distributed, use `gmake distclean`. If you are going to build for several platforms within the same source tree you must do this and re-configure for each platform. (Alternatively, use a separate build tree for each platform, so that the source tree remains unmodified.)

If you perform a build and then discover that your `configure` options were wrong, or if you change anything that `configure` investigates (for example, software upgrades), then it’s a good idea to do `gmake distclean` before reconfiguring and rebuilding. Without this, your changes in configuration choices might not propagate everywhere they need to.

### 15.6. Post-Installation Setup

#### 15.6.1. Shared Libraries

On some systems with shared libraries you need to tell the system how to find the newly installed shared libraries. The systems on which this is *not* necessary include BSD/OS, FreeBSD, HP-UX,
IRIX, Linux, NetBSD, OpenBSD, Tru64 UNIX (formerly Digital UNIX), and Solaris.

The method to set the shared library search path varies between platforms, but the most widely-used method is to set the environment variable `LD_LIBRARY_PATH` like so: In Bourne shells (sh, ksh, bash, zsh):

```bash
LD_LIBRARY_PATH=/usr/local/pgsql/lib
export LD_LIBRARY_PATH
```
or in `csh` or `tcsh`:

```bash
setenv LD_LIBRARY_PATH /usr/local/pgsql/lib
```

Replace `/usr/local/pgsql/lib` with whatever you set `--libdir` to in step 1. You should put these commands into a shell start-up file such as `/etc/profile` or `~/.bash_profile`. Some good information about the caveats associated with this method can be found at http://www.visi.com/~barr/ldpath.html.

On some systems it might be preferable to set the environment variable `LD_RUN_PATH` before building.

On Cygwin, put the library directory in the `PATH` or move the `.dll` files into the `bin` directory.

If in doubt, refer to the manual pages of your system (perhaps `ld.so` or `rld`). If you later get a message like:

```
psql: error in loading shared libraries
libpq.so.2.1: cannot open shared object file: No such file or directory
```

then this step was necessary. Simply take care of it then.

If you are on BSD/OS, Linux, or SunOS 4 and you have root access you can run:

```
/sbin/ldconfig /usr/local/pgsql/lib
```

(or equivalent directory) after installation to enable the run-time linker to find the shared libraries faster. Refer to the manual page of `ldconfig` for more information. On FreeBSD, NetBSD, and OpenBSD the command is:

```
/sbin/ldconfig -m /usr/local/pgsql/lib
```

instead. Other systems are not known to have an equivalent command.

### 15.6.2. Environment Variables

If you installed into `/usr/local/pgsql` or some other location that is not searched for programs by default, you should add `/usr/local/pgsql/bin` (or whatever you set `--bindir` to in step 1) into your `PATH`. Strictly speaking, this is not necessary, but it will make the use of PostgreSQL much more convenient.

To do this, add the following to your shell start-up file, such as `.bash_profile` or `/etc/profile, if you want it to affect all users):

```bash
PATH=/usr/local/pgsql/bin:$PATH
export PATH
```

If you are using `csh` or `tcsh`, then use this command:
set path = ( /usr/local/pgsql/bin $path )

To enable your system to find the man documentation, you need to add lines like the following to a
shell start-up file unless you installed into a location that is searched by default:

MANPATH=/usr/local/pgsql/man:$MANPATH
export MANPATH

The environment variables PGHOST and PGPORT specify to client applications the host and port of
the database server, overriding the compiled-in defaults. If you are going to run client applications
remotely then it is convenient if every user that plans to use the database sets PGHOST. This is not
required, however; the settings can be communicated via command line options to most client pro-
grams.

15.7. Supported Platforms

A platform (that is, a CPU architecture and operating system combination) is considered supported
by the PostgreSQL development community if the code contains provisions to work on that platform
and it has recently been verified to build and pass its regression tests on that platform. Currently, most
testing of platform compatibility is done automatically by test machines in the PostgreSQL Build
Farm\(^2\). If you are interested in using PostgreSQL on a platform that is not represented in the build
farm, but on which the code works or can be made to work, you are strongly encouraged to set up a
build farm member machine so that continued compatibility can be assured.

In general, PostgreSQL can be expected to work on these CPU architectures: x86, x86_64, IA64,
PowerPC, PowerPC 64, S/390, S/390x, Sparc, Sparc 64, Alpha, ARM, MIPS, MIPSEL, M68K, and
PA-RISC. Code support exists for M32R, NS32K, and VAX, but these architectures are not known
to have been tested recently. It is often possible to build on an unsupported CPU type by configuring
with --disable-spinlocks, but performance will be poor.

PostgreSQL can be expected to work on these operating systems: Linux (all recent distributions),
Windows (Win2000 SP4 and later), FreeBSD, OpenBSD, NetBSD, Mac OS X, AIX, HP/UX, IRIX,
Solaris, Tru64 Unix, and UnixWare. Other Unix-like systems may also work but are not currently be-
ing tested. In most cases, all CPU architectures supported by a given operating system will work. Look
in the Section 15.8 below to see if there is information specific to your operating system, particularly
if using an older system.

If you have installation problems on a platform that is known to be supported according to recent build
farm results, please report it to <pgsql-bugs@postgresql.org>. If you are interested in porting
PostgreSQL to a new platform, <pgsql-hackers@postgresql.org> is the appropriate place to
discuss that.

15.8. Platform-Specific Notes

This section documents additional platform-specific issues regarding the installation and setup of
PostgreSQL. Be sure to read the installation instructions, and in particular Section 15.2 as well. Also,

\(^2\) http://buildfarm.postgresql.org/
check Chapter 29 regarding the interpretation of regression test results.

Platforms that are not covered here have no known platform-specific installation issues.

## 15.8.1. AIX

PostgreSQL works on AIX, but getting it installed properly can be challenging. AIX versions from 4.3.3 to 6.1 are considered supported. You can use GCC or the native IBM compiler xlc. In general, using recent versions of AIX and PostgreSQL helps. Check the build farm for up to date information about which versions of AIX are known to work.

Use the following `configure` flags in addition to your own if you have installed Readline or libz there:

```
--with-includes=/usr/local/include --with-libraries=/usr/local/lib
```

If you don’t have a PowerPC or use GCC you might see rounding differences in the geometry regression test. There will probably be warnings about 0.0/0.0 division and duplicate symbols which you can safely ignore.

Some of the AIX tools may be “a little different” from what you may be accustomed to on other platforms. If you are looking for a version of `ldd`, useful for determining what object code depends on what libraries, the following URLs may help you: [http://www.faqs.org/faqs/aix-faq/part4/section-22.html](http://www.faqs.org/faqs/aix-faq/part4/section-22.html), [http://www.han.de/~jum/aix/ldd.c](http://www.han.de/~jum/aix/ldd.c).

Table 15-1 shows the minimum recommended fix levels for various AIX versions. To check your current fix level, use `oslevel -r` in AIX 4.3.3 to AIX 5.2 ML 7, or `oslevel -s` in later versions.

### Table 15-1. Minimum recommended AIX fix levels

<table>
<thead>
<tr>
<th>AIX version</th>
<th>fix level</th>
</tr>
</thead>
<tbody>
<tr>
<td>AIX 4.3.3</td>
<td>Maintenance Level 11 + post ML11 bundle</td>
</tr>
<tr>
<td>AIX 5.1</td>
<td>Maintenance Level 9 + post ML9 bundle</td>
</tr>
<tr>
<td>AIX 5.2</td>
<td>Technology Level 10 Service Pack 3</td>
</tr>
<tr>
<td>AIX 5.3</td>
<td>Technology Level 7</td>
</tr>
<tr>
<td>AIX 6.1</td>
<td>Base Level</td>
</tr>
</tbody>
</table>

### 15.8.1.1. GCC issues

On AIX 5.3, there have been some problems getting PostgreSQL to compile and run using GCC.

You will want to use a version of GCC subsequent to 3.3.2, particularly if you use a prepackaged version. We had good success with 4.0.1. Problems with earlier versions seem to have more to do with the way IBM packaged GCC than with actual issues with GCC, so that if you compile GCC yourself, you might well have success with an earlier version of GCC.

### 15.8.1.2. Unix-domain sockets broken

AIX 5.3 has a problem where `sockaddr_storage` is not defined to be large enough. In version 5.3, IBM increased the size of `sockaddr_un`, the address structure for Unix-domain sockets, but did not correspondingly increase the size of `sockaddr_storage`. The result of this is that attempts to use Unix-domain sockets with PostgreSQL lead to `libpq` overflowing the data structure. TCP/IP connections work OK, but not Unix-domain sockets, which prevents the regression tests from working.

The problem was reported to IBM, and is recorded as bug report PMR29657. If you upgrade to maintenance level 5300-03 or later, that will include this fix. A quick workaround is to alter `_SS_MAXSIZE`
Chapter 15. Installation from Source Code

to 1025 in /usr/include/sys/socket.h. In either case, recompile PostgreSQL once you have the corrected header file.

15.8.1.3. Internet address issues

PostgreSQL relies on the system’s getaddrinfo function to parse IP addresses in listen_addresses, pg_hba.conf, etc. Older versions of AIX have assorted bugs in this function. If you have problems related to these settings, updating to the appropriate fix level shown in Table 15-1 should take care of it.

One user reports:

When implementing PostgreSQL version 8.1 on AIX 5.3, we periodically ran into problems where the statistics collector would “mysteriously” not come up successfully. This appears to be the result of unexpected behaviour in the IPv6 implementation. It looks like PostgreSQL and IPv6 do not play very well together at this time on AIX.

Any of the following actions “fix” the problem.

- Delete the IPv6 address for localhost:

  (as root)

  # ifconfig lo0 inet6 ::1/0 delete

- Remove IPv6 from net services. The file /etc/netsvc.conf on AIX is roughly equivalent to /etc/nsswitch.conf on Solaris/Linux. The default, on AIX, is thus:

  hosts=local,bind

  Replace this with:

  hosts=local4,bind4
to deactivate searching for IPv6 addresses.

15.8.1.4. Memory management

AIX can be somewhat peculiar with regards to the way it does memory management. You can have a server with many multiples of gigabytes of RAM free, but still get out of memory or address space errors when running applications. One example is createlang failing with unusual errors. For example, running as the owner of the PostgreSQL installation:

    -bash-3.00$ createlang plpgsql template1
    createlang: language installation failed: ERROR: could not load library "/opt/dbs/pgsql748/lib/plpgsql.so": A memory address is not in the address space for the process.

Running as a non-owner in the group possessing the PostgreSQL installation:

    -bash-3.00$ createlang plpgsql template1
    createlang: language installation failed: ERROR: could not load library "/opt/dbs/pgsql748/lib/plpgsql.so": Bad address

Another example is out of memory errors in the PostgreSQL server logs, with every memory allocation near or greater than 256 MB failing.

The overall cause of all these problems is the default bittedness and memory model used by the server process. By default, all binaries built on AIX are 32-bit. This does not depend upon hardware type or kernel in use. These 32-bit processes are limited to 4 GB of memory laid out in 256 MB segments using one of a few models. The default allows for less than 256 MB in the heap as it shares a single segment with the stack.
In the case of the `createlang` example above, check your umask and the permissions of the binaries in your PostgreSQL installation. The binaries involved in that example were 32-bit and installed as mode 750 instead of 755. Due to the permissions being set in this fashion, only the owner or a member of the possessing group can load the library. Since it isn’t world-readable, the loader places the object into the process’ heap instead of the shared library segments where it would otherwise be placed.

The “ideal” solution for this is to use a 64-bit build of PostgreSQL, but that is not always practical, because systems with 32-bit processors can build, but not run, 64-bit binaries.

If a 32-bit binary is desired, set `LDR_CNTRL` to `MAXDATA=0x{n}0000000`, where `1 <= n <= 8`, before starting the PostgreSQL server, and try different values and `postgresql.conf` settings to find a configuration that works satisfactorily. This use of `LDR_CNTRL` tells AIX that you want the server to have `MAXDATA` bytes set aside for the heap, allocated in 256 MB segments. When you find a workable configuration, `ldedit` can be used to modify the binaries so that they default to using the desired heap size. PostgreSQL can also be rebuilt, passing `configure LDFLAGS="-Wl,-bmaxdata:0x{n}0000000"` to achieve the same effect.

For a 64-bit build, set `OBJECT_MODE` to 64 and pass `CC="gcc -maix64"` and `LDFLAGS="-Wl,-bbigtoc"` to `configure`. (Options for `xlc` might differ.) If you omit the export of `OBJECT_MODE`, your build may fail with linker errors. When `OBJECT_MODE` is set, it tells AIX’s build utilities such as `ar`, `as`, and `ld` what type of objects to default to handling.

By default, overcommit of paging space can happen. While we have not seen this occur, AIX will kill processes when it runs out of memory and the overcommit is accessed. The closest to this that we have seen is fork failing because the system decided that there was not enough memory for another process. Like many other parts of AIX, the paging space allocation method and out-of-memory kill is configurable on a system- or process-wide basis if this becomes a problem.

Developing and Porting C and C++ Applications on AIX®, IBM Redbook.

15.8.2. Cygwin

PostgreSQL can be built using Cygwin, a Linux-like environment for Windows, but that method is inferior to the native Windows build (see Chapter 16) and is no longer recommended.

When building from source, proceed according to the normal installation procedure (i.e., ./configure; make; etc.), noting the following-Cygwin specific differences:

- Set your path to use the Cygwin bin directory before the Windows utilities. This will help prevent problems with compilation.
- The GNU make command is called "make" not "gmake".
- The adduser command is not supported; use the appropriate user management application on Windows NT, 2000, or XP. Otherwise, skip this step.
- The su command is not supported; use ssh to simulate su on Windows NT, 2000, or XP. Otherwise, skip this step.
- OpenSSL is not supported.
- Start cygserver for shared memory support. To do this, enter the command /usr/sbin/cygserver &. This program needs to be running anytime you start the PostgreSQL server or initialize a database cluster (initdb). The default cygserver configuration may need to be changed (e.g., increase SEMMNS) to prevent PostgreSQL from failing due to a lack of system resources.
- The parallel regression tests (make check) can generate spurious regression test failures due to overflowing the listen() backlog queue which causes connection refused errors or hangs. You can limit the number of connections using the make variable MAX_CONNECTIONS thus:

  make MAX_CONNECTIONS=5 check

(On some systems you can have up to about 10 simultaneous connections).

It is possible to install cygserver and the PostgreSQL server as Windows NT services. For information on how to do this, please refer to the README document included with the PostgreSQL binary package on Cygwin. It is installed in the directory /usr/share/doc/Cygwin.

15.8.3. HP-UX

PostgreSQL 7.3+ should work on Series 700/800 PA-RISC machines running HP-UX 10.X or 11.X, given appropriate system patch levels and build tools. At least one developer routinely tests on HP-UX 10.20, and we have reports of successful installations on HP-UX 11.00 and 11.11.

Aside from the PostgreSQL source distribution, you will need GNU make (HP’s make will not do), and either GCC or HP’s full ANSI C compiler. If you intend to build from Git sources rather than a distribution tarball, you will also need Flex (GNU lex) and Bison (GNU yacc). We also recommend making sure you are fairly up-to-date on HP patches. At a minimum, if you are building 64 bit binaries on HP-UX 11.11 you may need PHSS_30966 (11.11) or a successor patch otherwise initdb may hang:

PHSS_30966 s700_800 ld(1) and linker tools cumulative patch

On general principles you should be current on libc and ld/dld patches, as well as compiler patches if you are using HP’s C compiler. See HP’s support sites such as http://itrc.hp.com and ftp://us-ffs.external.hp.com/ for free copies of their latest patches.
Chapter 15. Installation from Source Code

If you are building on a PA-RISC 2.0 machine and want to have 64-bit binaries using GCC, you must use GCC 64-bit version. GCC binaries for HP-UX PA-RISC and Itanium are available from http://www.hp.com/go/gcc. Don't forget to get and install binutils at the same time.

If you are building on a PA-RISC 2.0 machine and want the compiled binaries to run on PA-RISC 1.1 machines you will need to specify +DAportable in CFLAGS.

If you are building on a HP-UX Itanium machine, you will need the latest HP ANSI C compiler with its dependent patch or successor patches:

PHSS_30848 s700_800 HP C Compiler (A.05.57)
PHSS_30849 s700_800 u2comp/be/plugin library Patch

If you have both HP's C compiler and GCC's, then you might want to explicitly select the compiler to use when you run configure:

./configure CC=cc

for HP's C compiler, or

./configure CC=gcc

for GCC. If you omit this setting, then configure will pick gcc if it has a choice.

The default install target location is /usr/local/pgsql, which you might want to change to something under /opt. If so, use the --prefix switch to configure.

In the regression tests, there might be some low-order-digit differences in the geometry tests, which vary depending on which compiler and math library versions you use. Any other error is cause for suspicion.

15.8.4. IRIX

PostgreSQL has been reported to run successfully on MIPS r8000, r10000 (both ip25 and ip27) and r12000(ip35) processors, running IRIX 6.5.5m, 6.5.12, 6.5.13, and 6.5.26 with MIPSPro compilers version 7.30, 7.3.1.2m, 7.3, and 7.4.4m.

You will need the MIPSPro full ANSI C compiler. There are problems trying to build with GCC. It is a known GCC bug (not fixed as of version 3.0) related to using functions that return certain kinds of structures. This bug affects functions like inet_ntoa, inet_lnaof, inet_netof, inet_makeaddr, and semctl. It is supposed to be fixed by forcing code to link those functions with libgcc, but this has not been tested yet.

It is known that version 7.4.1m of the MIPSPro compiler generates incorrect code. The symptom is “invalid primary checkpoint record” when trying to start the database.) Version 7.4.4m is OK; the status of intermediate versions is uncertain.

There may be a compilation problem like the following:

cc-1020 cc: ERROR File = pqcomm.c, Line = 427
The identifier "TCP_NODELAY" is undefined.

if (setsockopt(port->sock, IPPROTO_TCP, TCP_NODELAY, Some versions include TCP definitions in sys/xti.h, so it is necessary to add #include <sys/xti.h> in src/backend/libpq/pqcomm.c and in
src/interfaces/libpq/fe-connect.c. If you encounter this, please let us know so we can develop a proper fix.

In the regression tests, there might be some low-order-digit differences in the geometry tests, depending on which FPU are you using. Any other error is cause for suspicion.

15.8.5. MinGW/Native Windows

PostgreSQL for Windows can be built using MinGW, a Unix-like build environment for Microsoft operating systems, or using Microsoft’s Visual C++ compiler suite. The MinGW build variant uses the normal build system described in this chapter; the Visual C++ build works completely differently and is described in Chapter 16. It is a fully native build and uses no additional software like MinGW.

A ready-made installer is available on the main PostgreSQL web site.

The native Windows port requires a 32 or 64-bit version of Windows 2000 or later. Earlier operating systems do not have sufficient infrastructure (but Cygwin may be used on those). MinGW, the Unix-like build tools, and MSYS, a collection of Unix tools required to run shell scripts like configure, can be downloaded from http://www.mingw.org/. Neither is required to run the resulting binaries; they are needed only for creating the binaries.

After you have everything installed, it is suggested that you run psql under CMD.EXE, as the MSYS console has buffering issues.

15.8.6. SCO OpenServer and SCO UnixWare

PostgreSQL can be built on SCO UnixWare 7 and SCO OpenServer 5. On OpenServer, you can use either the OpenServer Development Kit or the Universal Development Kit. However, some tweaking may be needed, as described below.

15.8.6.1. Skunkware

You should locate your copy of the SCO Skunkware CD. The Skunkware CD is included with UnixWare 7 and current versions of OpenServer 5. Skunkware includes ready-to-install versions of many popular programs that are available on the Internet. For example, gzip, gunzip, GNU Make, Flex, and Bison are all included. For UnixWare 7.1, this CD is now labeled "Open License Software Supplement". If you do not have this CD, the software on it is available from http://www.sco.com/skunkware/.

Skunkware has different versions for UnixWare and OpenServer. Make sure you install the correct version for your operating system, except as noted below.

On UnixWare 7.1.3 and beyond, the GCC compiler is included on the UDK CD as is GNU Make.

15.8.6.2. GNU Make

You need to use the GNU Make program, which is on the Skunkware CD. By default, it installs as /usr/local/bin/make. To avoid confusion with the SCO make program, you may want to rename GNU make to gmake.

As of UnixWare 7.1.3 and above, the GNU Make program is is the OSTK portion of the UDK CD, and is in /usr/gnu/bin/gmake.
15.8.6.3. Readline

The Readline library is on the Skunkware CD. But it is not included on the UnixWare 7.1 Skunkware CD. If you have the UnixWare 7.0.0 or 7.0.1 Skunkware CDs, you can install it from there. Otherwise, try ftp://ftp.sco.com/skunkware.

By default, Readline installs into /usr/local/lib and /usr/local/include. However, the PostgreSQL configure program will not find it there without help. If you installed Readline, then use the following options to configure:

```
./configure --with-libraries=/usr/local/lib --with-includes=/usr/local/include
```

15.8.6.4. Using the UDK on OpenServer

If you are using the new Universal Development Kit (UDK) compiler on OpenServer, you need to specify the locations of the UDK libraries:

```
./configure --with-libraries=/udk/usr/lib --with-includes=/udk/usr/include
```

Putting these together with the Readline options from above:

```
./configure --with-libraries="/udk/usr/lib /usr/local/lib" --with-includes="/udk/usr/include /usr/local/include"
```

15.8.6.5. Reading the PostgreSQL man pages

By default, the PostgreSQL man pages are installed into /usr/local/pgsql/man. By default, UnixWare does not look there for man pages. To be able to read them you need to modify the MANPATH variable in /etc/default/man, for example:

```
```

On OpenServer, some extra research needs to be invested to make the man pages usable, because the man system is a bit different from other platforms. Currently, PostgreSQL will not install them at all.

15.8.6.6. C99 Issues with the 7.1.1b Feature Supplement

For compilers earlier than the one released with OpenUNIX 8.0.0 (UnixWare 7.1.2), including the 7.1.1b Feature Supplement, you may need to specify -Xb in CFLAGS or the CC environment variable. The indication of this is an error in compiling tuplesort.c referencing inline functions. Apparently there was a change in the 7.1.2(8.0.0) compiler and beyond.

15.8.6.7. --enable-thread-safety and UnixWare

If you use the configure option --enable-thread-safety, you must use -Kpthread on all libpq-using programs. libpq uses pthread_* calls, which are only available with the -Kpthread -Kthread flag.
15.8.7. Solaris

PostgreSQL is well-supported on Solaris. The more up to date your operating system, the fewer issues you will experience; details below.

Note that PostgreSQL is bundled with Solaris 10 (from update 2). Official packages are also available on http://pgfoundry.org/projects/solarispackages/. Packages for older Solaris versions (8, 9) you can be obtained from http://www.sunfreeware.com/ or http://www.blastwave.org/.

15.8.7.1. Required tools

You can build with either GCC or Sun’s compiler suite. For better code optimization, Sun’s compiler is strongly recommended on the SPARC architecture. We have heard reports of problems when using GCC 2.95.1; gcc 2.95.3 or later is recommended. If you are using Sun’s compiler, be careful not to select /usr/ucb/cc; use /opt/SUNWspro/bin/cc.

You can download Sun Studio from http://developers.sun.com/sunstudio/downloads/. Many of GNU tools are integrated into Solaris 10, or they are present on the Solaris companion CD. If you like packages for older version of Solaris, you can find these tools at http://www.sunfreeware.com or http://www.blastwave.org. If you prefer sources, look at http://www.gnu.org/order/ftp.html.

15.8.7.2. Problems with OpenSSL

When you build PostgreSQL with OpenSSL support you might get compilation errors in the following files:

- src/backend/libpq/crypt.c
- src/backend/libpq/password.c
- src/interfaces/libpq/fe-auth.c
- src/interfaces/libpq/fe-connect.c

This is because of a namespace conflict between the standard /usr/include/crypt.h header and the header files provided by OpenSSL.

Upgrading your OpenSSL installation to version 0.9.6a fixes this problem. Solaris 9 and above has a newer version of OpenSSL.

15.8.7.3. configure complains about a failed test program

If configure complains about a failed test program, this is probably a case of the run-time linker being unable to find some library, probably libz, libreadline or some other non-standard library such as libssl. To point it to the right location, set the LDFLAGS environment variable on the configure command line, e.g.,

configure ... LDFLAGS="-R /usr/sfw/lib:/opt/sfw/lib:/usr/local/lib"

See the ld man page for more information.

15.8.7.4. 64-bit build sometimes crashes

On Solaris 7 and older, the 64-bit version of libc has a buggy vsnprintf routine, which leads to erratic core dumps in PostgreSQL. The simplest known workaround is to force PostgreSQL to use its
own version of vsnprintf rather than the library copy. To do this, after you run configure edit a file produced by configure: In src/Makefile.global, change the line

```
LIBOBJJS =
```

to read

```
LIBOBJJS = snprintf.o
```

(There might be other files already listed in this variable. Order does not matter.) Then build as usual.

15.8.7.5. Compiling for optimal performance

On the SPARC architecture, Sun Studio is strongly recommended for compilation. Try using the `-xO5` optimization flag to generate significantly faster binaries. Do not use any flags that modify behavior of floating-point operations and `errno` processing (e.g., `-fast`). These flags could raise some nonstandard PostgreSQL behavior for example in the date/time computing.

If you do not have a reason to use 64-bit binaries on SPARC, prefer the 32-bit version. The 64-bit operations are slower and 64-bit binaries are slower than the 32-bit variants. And on other hand, 32-bit code on the AMD64 CPU family is not native, and that is why 32-bit code is significant slower on this CPU family.

Some tricks for tuning PostgreSQL and Solaris for performance can be found at http://www.sun.com/servers/coolthreads/tnb/applications_postgresql.jsp. This article is primarily focused on T2000 platform, but many of the recommendations are also useful on other hardware with Solaris.

15.8.7.6. Using DTrace for tracing PostgreSQL

Yes, using DTrace is possible. See Section 26.4 for further information. You can also find more information in this article: http://blogs.sun.com/robertlor/entry/user_level_dtrace_probes_in.

If you see the linking of the postgres executable abort with an error message like:

```
Undefined symbol first referenced in file
AbortTransaction in file utils/probes.o
CommitTransaction in file utils/probes.o
ld: fatal: Symbol referencing errors. No output written to postgres
collect2: ld returned 1 exit status
gmake: *** [postgres] Error 1
```

your DTrace installation is too old to handle probes in static functions. You need Solaris 10u4 or newer.
It is recommended that most users download the binary distribution for Windows, available as a Windows Installer package from the PostgreSQL website. Building from source is only intended for people developing PostgreSQL or extensions.

There are several different ways of building PostgreSQL on Windows. The complete system can be built using MinGW or Visual C++ 2005. It can also be built for older versions of Windows using Cygwin. Finally, the client access library (libpq) can be built using Visual C++ 7.1 or Borland C++ for compatibility with statically linked applications built using these tools.

Building using MinGW or Cygwin uses the normal build system, see Chapter 15 and the specific notes in Section 15.8.5 and Section 15.8.2. Cygwin is not recommended and should only be used for older versions of Windows where the native build does not work, such as Windows 98.

The tools for building using Visual C++ 2005, are in the src/tools/msvc directory. When building, make sure there are no tools from MinGW or Cygwin present in your system PATH. Also, make sure you have all the required Visual C++ tools available in the PATH, usually by starting a Visual Studio Command Prompt and running the commands from there. All commands should be run from the src/tools/msvc directory.

Before you build, edit the file config.pl to reflect the configuration options you want set, including the paths to libraries used. If you need to set any other environment variables, create a file called buildenv.pl and put the required commands there. For example, to add the path for bison when it’s not in the PATH, create a file containing:

```bash
$ENV{PATH}=$ENV{PATH} . ';c:\some\where\bison\bin';
```

16.1.1. Requirements

PostgreSQL will build using either the professional versions (any edition) or the free Express edition of Visual Studio 2005. The following additional products are required to build the complete package. Use the config.pl file to specify which directories the libraries are available in.

ActiveState Perl

ActiveState Perl is required to run the build generation scripts. MinGW or Cygwin Perl will not work. It must also be present in the PATH. Binaries can be downloaded from http://www.activestate.com (Note: version 5.8 or later is required, the free Standard Distribution is sufficient).

ActiveState TCL

Required for building PL/TCL (Note: version 8.4 is required, the free Standard Distribution is sufficient).
Bison and Flex

Bison and Flex are required to build from Git, but not required when building from a release file. Note that only Bison 1.875 or versions 2.2 and later will work. Bison and Flex can be downloaded from http://gnuwin32.sourceforge.net.

Diff

Diff is required to run the regression tests, and can be downloaded from http://gnuwin32.sourceforge.net.

Gettext

Gettext is required to build with NLS support, and can be downloaded from http://gnuwin32.sourceforge.net. Note that binaries, dependencies and developer files are all needed.

Microsoft Platform SDK

It is recommended that you upgrade to the latest available version of the Microsoft Platform SDK, available for download from http://www.microsoft.com/downloads/.

MIT Kerberos

libxml2 and libxslt

Required for XML support. Binaries can be downloaded from http://zlatkovic.com/pub/libxml or source from http://xmlsoft.org. Note that libxml2 requires iconv, which is available from the same download location.

openssl

ossp-uuid

Required for UUID-OSSP support (contrib only). Source can be downloaded from http://www.ossp.org/pkg/lib/uuid/.

Python

zlib

Required for compression support in pg_dump and pg_restore. Binaries can be downloaded from http://www.zlib.net.

16.1.2. Building

To build all of PostgreSQL in release configuration (the default), run the command:

```
build
```

To build all of PostgreSQL in debug configuration, run the command:
Chapter 16. Installation from Source Code on Windows

build DEBUG

To build just a single project, for example psql, run the commands:

build psql
build DEBUG psql

To change the default build configuration to debug, put the following in the buildenv.pl file:

$ENV{CONFIG}="Debug";

It is also possible to build from inside the Visual Studio GUI. In this case, you need to run:

perl mkvcbuild.pl

from the command prompt, and then open the generated psql.sln (in the root directory of the source tree) in Visual Studio.

16.1.3. Cleaning and installing

Most of the time, the automatic dependency tracking in Visual Studio will handle changed files. But if there have been large changes, you may need to clean the installation. To do this, simply run the clean.bat command, which will automatically clean out all generated files. You can also run it with the dist parameter, in which case it will behave like make distclean and remove the flex/bison output files as well.

By default, all files are written into a subdirectory of the debug or release directories. To install these files using the standard layout, and also generate the files required to initialize and use the database, run the command:

perl install.pl c:\destination\directory

16.1.4. Running the regression tests

To run the regression tests, make sure you have completed the build of all required parts first. Also, make sure that the DLLs required to load all parts of the system (such as the Perl and Python DLLs for the procedural languages) are present in the system path. If they are not, set it through the
Chapter 16. Installation from Source Code on Windows

buildenv.pl file. To run the tests, run one of the following commands from the src\tools\msvc
directory:

    vcregress check
    vcregress installcheck
    vcregress plcheck
    vcregress contribcheck

To change the schedule used (default is the parallel), append it to the command line like:

    vcregress check serial

For more information about the regression tests, see Chapter 29.

16.1.5. Building the documentation

Building the PostgreSQL documentation in HTML format requires several tools and files. Create a
root directory for all these files, and store them in the subdirectories in the list below.

OpenJade 1.3.1-2
    Download from http://sourceforge.net/project/downloading.php?groupname=openjade&filename=openjade-
1_3_1-2-bin.zip and uncompress in the subdirectory openjade-1.3.1.

DocBook DTD 4.2
    Download from http://www.oasis-open.org/docbook/sgml/4.2/docbook-4.2.zip and uncompress
in the subdirectory docbook.

DocBook DSSSL 1.79
    Download from http://sourceforge.net/project/downloading.php?groupname=docbook&filename=docbook-
dsssl-1.79.zip and uncompress in the subdirectory docbook-dsssl-1.79.

ISO character entities
    Download from http://www.oasis-open.org/cover/ISOEnts.zip and uncompress in the subdirectory
docbook.

Edit the buildenv.pl file, and add a variable for the location of the root directory, for example:

    $ENV{DOCROOT}='c:\docbook';

To build the documentation, run the command builddoc.bat. Note that this will actually run the
build twice, in order to generate the indexes. The generated HTML files will be in doc\src\sgml.
Chapter 16. Installation from Source Code on Windows

16.2. Building libpq with Visual C++ or Borland C++

Using Visual C++ 7.1-8.0 or Borland C++ to build libpq is only recommended if you need a version with different debug/release flags, or if you need a static library to link into an application. For normal use the MinGW or Visual Studio 2005 version is recommended.

To build the libpq client library using Visual Studio 7.1 or later, change into the src directory and type the command:

    nmake /f win32.mak

To build a 64-bit version of the libpq client library using Visual Studio 8.0 or later, change into the src directory and type in the command:

    nmake /f win32.mak CPU_AMD64

See the win32.mak file for further details about supported variables.

To build the libpq client library using Borland C++, change into the src directory and type the command:

    make -N -DCFG=Release /f bcc32.mak

16.2.1. Generated files

The following files will be built:

- interfaces\libpq\Release\libpq.dll
  - The dynamically linkable frontend library
- interfaces\libpq\Release\libpqdll.lib
  - Import library to link your programs to libpq.dll
- interfaces\libpq\Release\libpq.lib
  - Static version of the frontend library

Normally you do not need to install any of the client files. You should place the libpq.dll file in the same directory as your applications executable file. Do not install libpq.dll into your Windows, System or System32 directory unless absolutely necessary. If this file is installed using a setup program, it should be installed with version checking using the VERSIONINFO resource included in the file, to ensure that a newer version of the library is not overwritten.

If you are planning to do development using libpq on this machine, you will have to add the src\include and src\interfaces\libpq subdirectories of the source tree to the include path in your compiler’s settings.

To use the library, you must add the libpqdll.lib file to your project. (In Visual C++, just right-click on the project and choose to add it.)
Chapter 17. Server Setup and Operation

This chapter discusses how to set up and run the database server and its interactions with the operating system.

17.1. The PostgreSQL User Account

As with any other server daemon that is accessible to the outside world, it is advisable to run PostgreSQL under a separate user account. This user account should only own the data that is managed by the server, and should not be shared with other daemons. (For example, using the user nobody is a bad idea.) It is not advisable to install executables owned by this user because compromised systems could then modify their own binaries.

To add a Unix user account to your system, look for a command `useradd` or `adduser`. The user name postgres is often used, and is assumed throughout this book, but you can use another name if you like.

17.2. Creating a Database Cluster

Before you can do anything, you must initialize a database storage area on disk. We call this a database cluster. (SQL uses the term catalog cluster.) A database cluster is a collection of databases that is managed by a single instance of a running database server. After initialization, a database cluster will contain a database named `postgres`, which is meant as a default database for use by utilities, users and third party applications. The database server itself does not require the `postgres` database to exist, but many external utility programs assume it exists. Another database created within each cluster during initialization is called `template1`. As the name suggests, this will be used as a template for subsequently created databases; it should not be used for actual work. (See Chapter 21 for information about creating new databases within a cluster.)

In file system terms, a database cluster will be a single directory under which all data will be stored. We call this the data directory or data area. It is completely up to you where you choose to store your data. There is no default, although locations such as `/usr/local/pgsql/data` or `/var/lib/pgsql/data` are popular. To initialize a database cluster, use the command `initdb`, which is installed with PostgreSQL. The desired file system location of your database cluster is indicated by the `-D` option, for example:

```bash
$ initdb -D /usr/local/pgsql/data
```

Note that you must execute this command while logged into the PostgreSQL user account, which is described in the previous section.

**Tip:** As an alternative to the `-D` option, you can set the environment variable `PGDATA`.

`initdb` will attempt to create the directory you specify if it does not already exist. It is likely that it will not have the permission to do so (if you followed our advice and created an unprivileged account). In that case you should create the directory yourself (as root) and change the owner to be the PostgreSQL user. Here is how this might be done:

```
root# mkdir /usr/local/pgsql/data
```
Chapter 17. Server Setup and Operation

root# chown postgres /usr/local/pgsql/data
root# su postgres
postgres$ initdb -D /usr/local/pgsql/data

initdb will refuse to run if the data directory looks like it has already been initialized.

Because the data directory contains all the data stored in the database, it is essential that it be secured from unauthorized access. initdb therefore revokes access permissions from everyone but the PostgreSQL user.

However, while the directory contents are secure, the default client authentication setup allows any local user to connect to the database and even become the database superuser. If you do not trust other local users, we recommend you use one of initdb’s -W, --pwprompt or --pwfile options to assign a password to the database superuser. Also, specify -A md5 or -A password so that the default trust authentication mode is not used; or modify the generated pg_hba.conf file after running initdb, before you start the server for the first time. (Other reasonable approaches include using ident authentication or file system permissions to restrict connections. See Chapter 19 for more information.)

initdb also initializes the default locale for the database cluster. Normally, it will just take the locale settings in the environment and apply them to the initialized database. It is possible to specify a different locale for the database; more information about that can be found in Section 22.1. The default sort order used within the particular database cluster is set by initdb, and while you can create new databases using different sort order, the order used in the template databases that initdb creates cannot be changed without dropping and recreating them. There is also a performance impact for using locales other than C or POSIX. Therefore, it is important to make this choice correctly the first time.

initdb also sets the default character set encoding for the database cluster. Normally this should be chosen to match the locale setting. For details see Section 22.2.

17.2.1. Network File Systems

Many installations create database clusters on network file systems. Sometimes this is done directly via NFS, or by using a Network Attached Storage (NAS) device that uses NFS internally. PostgreSQL does nothing special for NFS file systems, meaning it assumes NFS behaves exactly like locally-connected drives (DAS, Direct Attached Storage). If client and server NFS implementations have non-standard semantics, this can cause reliability problems (see http://www.time-travellers.org/shane/papers/NFS_considered_harmful.html). Specifically, delayed (asynchronous) writes to the NFS server can cause reliability problems; if possible, mount NFS file systems synchronously (without caching) to avoid this. Also, soft-mounting NFS is not recommended. (Storage Area Networks (SAN) use a low-level communication protocol rather than NFS.)

17.3. Starting the Database Server

Before anyone can access the database, you must start the database server. The database server program is called postgres. The postgres program must know where to find the data it is supposed to use. This is done with the -D option. Thus, the simplest way to start the server is:

$ postgres -D /usr/local/pgsql/data
which will leave the server running in the foreground. This must be done while logged into the Post-
greSQL user account. Without -D, the server will try to use the data directory named by the environ-
ment variable PGDATA. If that variable is not provided either, it will fail.

Normally it is better to start postgres in the background. For this, use the usual shell syntax:

```
$ postgres -D /usr/local/pgsql/data > logfile 2>&1 &
```

It is important to store the server’s stdout and stderr output somewhere, as shown above. It will help
for auditing purposes and to diagnose problems. (See Section 23.3 for a more thorough discussion of
log file handling.)

The postgres program also takes a number of other command-line options. For more information,
see the postgres reference page and Chapter 18 below.

This shell syntax can get tedious quickly. Therefore the wrapper program pg_ctl is provided to sim-
plify some tasks. For example:

```
pg_ctl start -l logfile
```

will start the server in the background and put the output into the named log file. The -D option has
the same meaning here as for postgres. pg_ctl is also capable of stopping the server.

Normally, you will want to start the database server when the computer boots. Autostart
scripts are operating-system-specific. There are a few distributed with PostgreSQL in the
contrib/start-scripts directory. Installing one will require root privileges.

Different systems have different conventions for starting up daemons at boot time. Many systems have
a file /etc/rc.local or /etc/rc.d/rc.local. Others use rc.d directories. Whatever you do,
the server must be run by the PostgreSQL user account and not by root or any other user. Therefore
you probably should form your commands using su postgres -c ‘...’. For example:

```
su postgres -c 'pg_ctl start -D /usr/local/pgsql/data -l serverlog'
```

Here are a few more operating-system-specific suggestions. (In each case be sure to use the proper
installation directory and user name where we show generic values.)

- For FreeBSD, look at the file contrib/start-scripts/freebsd in the PostgreSQL source
distribution.
- On OpenBSD, add the following lines to the file /etc/rc.local:

  ```
  if [ -x /usr/local/pgsql/bin/pg_ctl -a -x /usr/local/pgsql/bin/postgres ]; then
    su -l postgres -c '/usr/local/pgsql/bin/pg_ctl start -s -l /var/postgresql/log -D /usr/local/pgsql/data'
    echo -n 'postgresql'
  fi
  ```
- On Linux systems either add

  `/usr/local/pgsql/bin/pg_ctl start -l logfile -D /usr/local/pgsql/data`
to /etc/rc.d/rc.local or look at the file contrib/start-scripts/linux in the Post-
greSQL source distribution.
- On NetBSD, use either the FreeBSD or Linux start scripts, depending on preference.
- On Solaris, create a file called /etc/init.d/postgresql that contains the following line:

  ```
  su - postgres -c "/usr/local/pgsql/bin/pg_ctl start -l logfile -D /usr/local/pgsql/data"
  ```

Then, create a symbolic link to it in /etc/rc3.d as S99postgresql.
While the server is running, its PID is stored in the file `postmaster.pid` in the data directory. This is used to prevent multiple server instances from running in the same data directory and can also be used for shutting down the server.

### 17.3.1. Server Start-up Failures

There are several common reasons the server might fail to start. Check the server’s log file, or start it by hand (without redirecting standard output or standard error) and see what error messages appear. Below we explain some of the most common error messages in more detail.

**LOG:** could not bind IPv4 socket: Address already in use  
**HINT:** Is another postmaster already running on port 5432? If not, wait a few seconds and try again.  
**FATAL:** could not create TCP/IP listen socket

This usually means just what it suggests: you tried to start another server on the same port where one is already running. However, if the kernel error message is not `Address already in use` or some variant of that, there might be a different problem. For example, trying to start a server on a reserved port number might draw something like:

```bash
$ postgres -p 666  
LOG: could not bind IPv4 socket: Permission denied  
HINT: Is another postmaster already running on port 666? If not, wait a few seconds and try again.  
FATAL: could not create TCP/IP listen socket
```

A message like:

**FATAL:** could not create shared memory segment: Invalid argument  
**DETAIL:** Failed system call was `shmget(key=5440001, size=4011376640, 03600)`.

probably means your kernel’s limit on the size of shared memory is smaller than the work area PostgreSQL is trying to create (4011376640 bytes in this example). Or it could mean that you do not have System-V-style shared memory support configured into your kernel at all. As a temporary workaround, you can try starting the server with a smaller-than-normal number of buffers (`shared_buffers`). You will eventually want to reconfigure your kernel to increase the allowed shared memory size. You might also see this message when trying to start multiple servers on the same machine, if their total space requested exceeds the kernel limit.

An error like:

**FATAL:** could not create semaphores: No space left on device  
**DETAIL:** Failed system call was `semget(5440126, 17, 03600)`.

does *not* mean you’ve run out of disk space. It means your kernel’s limit on the number of System V semaphores is smaller than the number PostgreSQL wants to create. As above, you might be able to work around the problem by starting the server with a reduced number of allowed connections (`max_connections`), but you’ll eventually want to increase the kernel limit.

If you get an “illegal system call” error, it is likely that shared memory or semaphores are not supported in your kernel at all. In that case your only option is to reconfigure the kernel to enable these features.

Details about configuring System V IPC facilities are given in Section 17.4.1.
17.3.2. Client Connection Problems

Although the error conditions possible on the client side are quite varied and application-dependent, a few of them might be directly related to how the server was started up. Conditions other than those shown below should be documented with the respective client application.

```
psql: could not connect to server: Connection refused
  Is the server running on host "server.joe.com" and accepting TCP/IP connections on port 5432?
```

This is the generic “I couldn’t find a server to talk to” failure. It looks like the above when TCP/IP communication is attempted. A common mistake is to forget to configure the server to allow TCP/IP connections.

Alternatively, you’ll get this when attempting Unix-domain socket communication to a local server:

```
psql: could not connect to server: No such file or directory
  Is the server running locally and accepting connections on Unix domain socket "/tmp/.s.PGSQL.5432"?
```

The last line is useful in verifying that the client is trying to connect to the right place. If there is in fact no server running there, the kernel error message will typically be either Connection refused or No such file or directory, as illustrated. (It is important to realize that Connection refused in this context does not mean that the server got your connection request and rejected it. That case will produce a different message, as shown in Section 19.4.) Other error messages such as Connection timed out might indicate more fundamental problems, like lack of network connectivity.

17.4. Managing Kernel Resources

A large PostgreSQL installation can quickly exhaust various operating system resource limits. (On some systems, the factory defaults are so low that you don’t even need a really “large” installation.) If you have encountered this kind of problem, keep reading.

17.4.1. Shared Memory and Semaphores

Shared memory and semaphores are collectively referred to as “System V IPC” (together with message queues, which are not relevant for PostgreSQL). Almost all modern operating systems provide these features, but not all of them have them turned on or sufficiently sized by default, especially systems with BSD heritage. (On Windows, PostgreSQL provides its own replacement implementation of these facilities, and so most of this section can be disregarded.)

The complete lack of these facilities is usually manifested by an Illegal system call error upon server start. In that case there’s nothing left to do but to reconfigure your kernel. PostgreSQL won’t work without them.

When PostgreSQL exceeds one of the various hard IPC limits, the server will refuse to start and should leave an instructive error message describing the problem encountered and what to do about it. (See also Section 17.3.1.) The relevant kernel parameters are named consistently across different systems; Table 17-1 gives an overview. The methods to set them, however, vary. Suggestions for some
platforms are given below. Be warned that it is often necessary to reboot your machine, and possibly even recompile the kernel, to change these settings.

Table 17-1. System V IPC parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Reasonable values</th>
</tr>
</thead>
<tbody>
<tr>
<td>SHMMAX</td>
<td>Maximum size of shared memory segment (bytes)</td>
<td>at least several megabytes (see text)</td>
</tr>
<tr>
<td>SHMMIN</td>
<td>Minimum size of shared memory segment (bytes)</td>
<td>1</td>
</tr>
<tr>
<td>SHMALL</td>
<td>Total amount of shared memory available (bytes or pages)</td>
<td>if bytes, same as SHMMAX; if pages, ceil(SHMMAX/PAGE_SIZE)</td>
</tr>
<tr>
<td>SHMSEG</td>
<td>Maximum number of shared memory segments per process</td>
<td>only 1 segment is needed, but the default is much higher</td>
</tr>
<tr>
<td>SHMMNI</td>
<td>Maximum number of shared memory segments system-wide</td>
<td>like SHMSEG plus room for other applications</td>
</tr>
<tr>
<td>SEMMNI</td>
<td>Maximum number of semaphore identifiers (i.e., sets)</td>
<td>at least ceil((max_connections + autovacuum_max_workers) / 16)</td>
</tr>
<tr>
<td>SEMMNS</td>
<td>Maximum number of semaphores system-wide</td>
<td>ceil((max_connections + autovacuum_max_workers) / 16) * 17 plus room for other applications</td>
</tr>
<tr>
<td>SEMMSL</td>
<td>Maximum number of semaphores per set</td>
<td>at least 17</td>
</tr>
<tr>
<td>SEMMAP</td>
<td>Number of entries in semaphore map</td>
<td>see text</td>
</tr>
<tr>
<td>SEMVMX</td>
<td>Maximum value of semaphore</td>
<td>at least 1000 (The default is often 32767, don’t change unless forced to)</td>
</tr>
</tbody>
</table>

The most important shared memory parameter is SHMMAX, the maximum size, in bytes, of a shared memory segment. If you get an error message from shmget like Invalid argument, it is likely that this limit has been exceeded. The size of the required shared memory segment varies depending on several PostgreSQL configuration parameters, as shown in Table 17-2. (Any error message you might get will include the exact size of the failed allocation request.) You can, as a temporary solution, lower some of those settings to avoid the failure. While it is possible to get PostgreSQL to run with SHMMAX as small as 2 MB, you need considerably more for acceptable performance. Desirable settings are in the tens to hundreds of megabytes.

Some systems also have a limit on the total amount of shared memory in the system (SHMALL). Make sure this is large enough for PostgreSQL plus any other applications that are using shared memory segments. (Caution: SHMALL is measured in pages rather than bytes on many systems.)

Less likely to cause problems is the minimum size for shared memory segments (SHMMIN), which should be at most approximately 500 kB for PostgreSQL (it is usually just 1). The maximum number of segments system-wide (SHMMNI) or per-process (SHMSEG) are unlikely to cause a problem unless your system has them set to zero.

PostgreSQL uses one semaphore per allowed connection (max_connections) and allowed autovac-
uum worker process (autovacuum_max_workers), in sets of 16. Each such set will also contain a 17th semaphore which contains a “magic number”, to detect collision with semaphore sets used by other applications. The maximum number of semaphores in the system is set by SEMMNS, which consequently must be at least as high as max_connections plus autovacuum_max_workers, plus one extra for each 16 allowed connections plus workers (see the formula in Table 17-1). The parameter SEMMNI determines the limit on the number of semaphore sets that can exist on the system at one time. Hence this parameter must be at least ceil((max_connections + autovacuum_max_workers) / 16). Lowering the number of allowed connections is a temporary workaround for failures, which are usually confusingly worded No space left on device, from the function semget.

In some cases it might also be necessary to increase SEMMAP to be at least on the order of SEMMNS. This parameter defines the size of the semaphore resource map, in which each contiguous block of available semaphores needs an entry. When a semaphore set is freed it is either added to an existing entry that is adjacent to the freed block or it is registered under a new map entry. If the map is full, the freed semaphores get lost (until reboot). Fragmentation of the semaphore space could over time lead to fewer available semaphores than there should be.

The SEMMSL parameter, which determines how many semaphores can be in a set, must be at least 17 for PostgreSQL.

Various other settings related to “semaphore undo”, such as SEMMNU and SEMUME, are not of concern for PostgreSQL.

AIX

At least as of version 5.1, it should not be necessary to do any special configuration for such parameters as SHMMAX, as it appears this is configured to allow all memory to be used as shared memory. That is the sort of configuration commonly used for other databases such as DB/2.

It might, however, be necessary to modify the global ulimit information in /etc/security/limits, as the default hard limits for file sizes (fsize) and numbers of files (nofiles) might be too low.

BSD/OS

Shared Memory. By default, only 4 MB of shared memory is supported. Keep in mind that shared memory is not pageable; it is locked in RAM. To increase the amount of shared memory supported by your system, add something like the following to your kernel configuration file:

```plaintext
options "SHMALL=8192"
options "SHMMAX=\$(SHMALL\*PAGE_SIZE)"
```

SHMALL is measured in 4 kB pages, so a value of 1024 represents 4 MB of shared memory. Therefore the above increases the maximum shared memory area to 32 MB. For those running 4.3 or later, you will probably also need to increase KERNEL_VIRTUAL_MB above the default 248. Once all changes have been made, recompile the kernel, and reboot.

For those running 4.0 and earlier releases, use bpatch to find the sysptsize value in the current kernel. This is computed dynamically at boot time.

```bash
$ bpatch -r sysptsize
0x9 = 9
```

Next, add SYSPTSIZE as a hard-coded value in the kernel configuration file. Increase the value you found using bpatch. Add 1 for every additional 4 MB of shared memory you desire.

```plaintext
options "SYSPTSIZE=16"
syptsize cannot be changed by sysctl.
```

Semaphores. You will probably want to increase the number of semaphores as well; the default system total of 60 will only allow about 50 PostgreSQL connections. Set the values you want in your kernel configuration file, e.g.:
FreeBSD

The default settings are only suitable for small installations (for example, default SHMMAX is 32 MB). Changes can be made via the sysctl or loader interfaces. The following parameters can be set using sysctl:

\[
\text{sysctl} -w \text{kern.ipc.shmall}=32768 \\
\text{sysctl} -w \text{kern.ipc.shmmax}=134217728 \\
\text{sysctl} -w \text{kern.ipc.semmap}=256
\]

To have these settings persist over reboots, modify `/etc/sysctl.conf`.

The remaining semaphore settings are read-only as far as sysctl is concerned, but can be changed before boot using the loader prompt:

\[
\text{(loader)} \text{ set } \text{kern.ipc.semmni}=256 \\
\text{(loader)} \text{ set } \text{kern.ipc.semmns}=512 \\
\text{(loader)} \text{ set } \text{kern.ipc.semmnu}=256
\]

Similarly these can be saved between reboots in `/boot/loader.conf`.

You might also want to configure your kernel to lock shared memory into RAM and prevent it from being paged out to swap. This can be accomplished using the `sysctl` setting `kern.ipc.shm_use_phys`.

If running in FreeBSD jails by enabling `sysctl`'s `security.jail.sysvipc_allowed`, postmasters running in different jails should be run by different operating system users. This improves security because it prevents non-root users from interfering with shared memory or semaphores in a different jail, and it allows the PostgreSQL IPC cleanup code to function properly. (In FreeBSD 6.0 and later the IPC cleanup code doesn’t properly detect processes in other jails, preventing the running of postmasters on the same port in different jails.)

FreeBSD versions before 4.0 work like OpenBSD (see below).

NetBSD

In NetBSD 5.0 and later, IPC parameters can be adjusted using `sysctl`, for example:

\[
\text{sysctl} -w \text{kern.ipc.shmmax}=16777216
\]

To have these settings persist over reboots, modify `/etc/sysctl.conf`.

You might also want to configure your kernel to lock shared memory into RAM and prevent it from being paged out to swap. This can be accomplished using the `sysctl` setting `kern.ipc.shm_use_phys`.

NetBSD versions before 5.0 work like OpenBSD (see below), except that parameters should be set with the keyword `options not option`.

OpenBSD

The options `SYSVSHM` and `SYSVSEM` need to be enabled when the kernel is compiled. (They are by default.) The maximum size of shared memory is determined by the option `SHMMAXPGS` (in pages). The following shows an example of how to set the various parameters:

```
option       SYSVSHM
option       SHMMAXPGS=4096
option       SHMSEG=256

option       SYSVSEM
option       SEMMNI=256
option       SEMMNS=512
option       SEMMNU=256
```

371
You might also want to configure your kernel to lock shared memory into RAM and prevent it from being paged out to swap. This can be accomplished using the `sysctl` setting `kern.ipc.shm_use_phys`.

**HP-UX**

The default settings tend to suffice for normal installations. On HP-UX 10, the factory default for `SEMMNS` is 128, which might be too low for larger database sites.

IPC parameters can be set in the System Administration Manager (SAM) under Kernel Configuration → Configurable Parameters. Hit Create A New Kernel when you’re done.

**Linux**

The default maximum segment size is 32 MB, which is only adequate for small PostgreSQL installations. However, the remaining defaults are quite generously sized, and usually do not require changes. The maximum shared memory segment size can be changed via the `sysctl` interface. For example, to allow 128 MB, and explicitly set the maximum total shared memory size to 2097152 pages (the default):

```bash
$ sysctl -w kernel.shmmax=134217728
$ sysctl -w kernel.shmall=2097152
```

In addition these settings can be saved between reboots in `/etc/sysctl.conf`.

Older distributions might not have the `sysctl` program, but equivalent changes can be made by manipulating the `/proc` file system:

```bash
$ echo 134217728 > /proc/sys/kernel/shmmax
$ echo 2097152 > /proc/sys/kernel/shmall
```

**MacOS X**

In OS X 10.2 and earlier, edit the file `/System/Library/StartupItems/SystemTuning/SystemTuning` and change the values in the following commands:

```bash
sysctl -w kern.sysv.shmmax
sysctl -w kern.sysv.shmmin
sysctl -w kern.sysv.shmmni
sysctl -w kern.sysv.shmseg
sysctl -w kern.sysv.shmall
```

In OS X 10.3 and later, these commands have been moved to `/etc/rc` and must be edited there. Note that `/etc/rc` is usually overwritten by OS X updates (such as 10.3.6 to 10.3.7) so you should expect to have to redo your editing after each update.

In OS X 10.3.9 and later, instead of editing `/etc/rc` you can create a file named `/etc/sysctl.conf`, containing variable assignments such as:

```plaintext
kern.sysv.shmmax=4194304
kern.sysv.shmmin=1
kern.sysv.shmmni=32
kern.sysv.shmseg=8
kern.sysv.shmall=1024
```

This method is better than editing `/etc/rc` because your changes will be preserved across system updates. Note that all five shared-memory parameters must be set in `/etc/sysctl.conf`, else the values will be ignored.

Beware that recent releases of OS X ignore attempts to set `SHMMAX` to a value that isn’t an exact multiple of 4096.

`SHMALL` is measured in 4 kB pages on this platform.
In all OS X versions, you’ll need to reboot to make changes in the shared memory parameters take effect.

**SCO OpenServer**

In the default configuration, only 512 kB of shared memory per segment is allowed. To increase the setting, first change to the directory `/etc/conf/cf.d`. To display the current value of `SHMMAX`, run:

```
./configure -y SHMMAX
```

To set a new value for `SHMMAX`, run:

```
./configure SHMMAX=value
```

where `value` is the new value you want to use (in bytes). After setting `SHMMAX`, rebuild the kernel:

```
./link_unix
```

and reboot.

**Solaris**

At least in version 2.6, the default maximum size of a shared memory segment is too low for PostgreSQL. The relevant settings can be changed in `/etc/system`, for example:

```
set shmsys:shminfo_shmmax=0x2000000
set shmsys:shminfo_shmmin=1
set shmsys:shminfo_shmmni=256
set shmsys:shminfo_shmseg=256

set semsys:seminfo_semmap=256
set semsys:seminfo_semmni=512
set semsys:seminfo_semmns=512
set semsys:seminfo_semmsl=32
```

You need to reboot for the changes to take effect.

See also [http://sunsite.uakom.sk/sunworldonline/swol-09-1997/swol-09-insidesolaris.html](http://sunsite.uakom.sk/sunworldonline/swol-09-1997/swol-09-insidesolaris.html) for information on shared memory under Solaris.

**UnixWare**

On UnixWare 7, the maximum size for shared memory segments is only 512 kB in the default configuration. To display the current value of `SHMMAX`, run:

```
/etc/conf/bin/idtune -g SHMMAX
```

which displays the current, default, minimum, and maximum values. To set a new value for `SHMMAX`, run:

```
/etc/conf/bin/idtune SHMMAX value
```

where `value` is the new value you want to use (in bytes). After setting `SHMMAX`, rebuild the kernel:

```
/etc/conf/bin/idbuild -B
```

and reboot.

### 17.4.2. Resource Limits

Unix-like operating systems enforce various kinds of resource limits that might interfere with the operation of your PostgreSQL server. Of particular importance are limits on the number of processes per user, the number of open files per process, and the amount of memory available to each process. Each of these have a “hard” and a “soft” limit. The soft limit is what actually counts but it can be changed by the user up to the hard limit. The hard limit can only be changed by the root user. The system call `setrlimit` is responsible for setting these parameters. The shell’s built-in command `ulimit` (Bourne shells) or `limit` (csh) is used to control the resource limits from the command line.

On BSD-derived systems the file `/etc/login.conf` controls the various resource limits set during login. See the operating system documentation for details. The relevant parameters are `maxproc`, `openfiles`, and `datasize`. For example:

```bash
default:\n  ...\n  :datasize-cur=256M:\n  :maxproc-cur=256:\n  :openfiles-cur=256:\n  ...\n```

(`-cur` is the soft limit. Append `-max` to set the hard limit.)

Kernels can also have system-wide limits on some resources.

- On Linux `/proc/sys/fs/file-max` determines the maximum number of open files that the kernel will support. It can be changed by writing a different number into the file or by adding an assignment in `/etc/sysctl.conf`. The maximum limit of files per process is fixed at the time the kernel is compiled; see `/usr/src/linux/Documentation/proc.txt` for more information.

The PostgreSQL server uses one process per connection so you should provide for at least as many processes as allowed connections, in addition to what you need for the rest of your system. This is usually not a problem but if you run several servers on one machine things might get tight.

The factory default limit on open files is often set to “socially friendly” values that allow many users to coexist on a machine without using an inappropriate fraction of the system resources. If you run many servers on a machine this is perhaps what you want, but on dedicated servers you might want to raise this limit.

On the other side of the coin, some systems allow individual processes to open large numbers of files; if more than a few processes do so then the system-wide limit can easily be exceeded. If you
find this happening, and you do not want to alter the system-wide limit, you can set PostgreSQL’s max_files_per_process configuration parameter to limit the consumption of open files.

### 17.4.3. Linux Memory Overcommit

In Linux 2.4 and later, the default virtual memory behavior is not optimal for PostgreSQL. Because of the way that the kernel implements memory overcommit, the kernel might terminate the PostgreSQL server (the master server process) if the memory demands of another process cause the system to run out of virtual memory.

If this happens, you will see a kernel message that looks like this (consult your system documentation and configuration on where to look for such a message):

```
Out of Memory: Killed process 12345 (postgres).
```

This indicates that the `postgres` process has been terminated due to memory pressure. Although existing database connections will continue to function normally, no new connections will be accepted. To recover, PostgreSQL will need to be restarted.

One way to avoid this problem is to run PostgreSQL on a machine where you can be sure that other processes will not run the machine out of memory. If memory is tight, increasing the swap space of the operating system can help avoiding the problem, because the out-of-memory (OOM) killer is invoked whenever physical memory and swap space are exhausted.

On Linux 2.6 and later, an additional measure is to modify the kernel’s behavior so that it will not “overcommit” memory. Although this setting will not prevent the OOM killer from being invoked altogether, it will lower the chances significantly and will therefore lead to more robust system behavior. This is done by selecting strict overcommit mode via `sysctl`:

```
sysctl -w vm.overcommit_memory=2
```

or placing an equivalent entry in `/etc/sysctl.conf`. You might also wish to modify the related setting `vm.overcommit_ratio`. For details see the kernel documentation file `Documentation/vm/overcommit-accounting`.

Some vendors’ Linux 2.4 kernels are reported to have early versions of the 2.6 overcommit `sysctl` parameter. However, setting `vm.overcommit_memory` to 2 on a kernel that does not have the relevant code will make things worse not better. It is recommended that you inspect the actual kernel source code (see the function `vm_enough_memory` in the file `mm/mmap.c`) to verify what is supported in your copy before you try this in a 2.4 installation. The presence of the `overcommit-accounting` documentation file should not be taken as evidence that the feature is there. If in any doubt, consult a kernel expert or your kernel vendor.

### 17.5. Shutting Down the Server

There are several ways to shut down the database server. You control the type of shutdown by sending different signals to the master `postgres` process.

**SIGTERM**

This is the *Smart Shutdown* mode. After receiving SIGTERM, the server disallows new connec-

---

1. [http://lwn.net/Articles/104179/](http://lwn.net/Articles/104179/)
tions, but lets existing sessions end their work normally. It shuts down only after all of the ses-
sions terminate. If the server is in online backup mode, it additionally waits until online backup
mode is no longer active. While backup mode is active, new connections will still be allowed,
but only to superusers (this exception allows a superuser to connect to terminate online backup
mode).

SIGINT
This is the Fast Shutdown mode. The server disallows new connections and sends all existing
server processes SIGTERM, which will cause them to abort their current transactions and exit
promptly. It then waits for the server processes to exit and finally shuts down. If the server is in
online backup mode, backup mode will be terminated, rendering the backup useless.

SIGQUIT
This is the Immediate Shutdown mode. The master postgres process will send a SIGQUIT
to all child processes and exit immediately, without properly shutting itself down. The child
processes likewise exit immediately upon receiving SIGQUIT. This will lead to recovery (by
replaying the WAL log) upon next start-up. This is recommended only in emergencies.

The pg_ctl program provides a convenient interface for sending these signals to shut down the server.
Alternatively, you can send the signal directly using kill on non-Windows systems. The PID of the
postgres process can be found using the ps program, or from the file postmaster.pid in the data
directory. For example, to do a fast shutdown:

```
$ kill -INT `head -1 /usr/local/pgsql/data/postmaster.pid`
```

Important: It is best not to use SIGKILL to shut down the server. Doing so will prevent the server
from releasing shared memory and semaphores, which might then have to be done manually be-
fore a new server can be started. Furthermore, SIGKILL kills the postgres process without letting
it relay the signal to its subprocesses, so it will be necessary to kill the individual subprocesses
by hand as well.

To terminate an individual session while allowing other sessions to continue, use
pg_terminate_backend() (see Table 9-55) or send a SIGTERM signal to the child process
associated with the session.

17.6. Preventing Server Spoofing

While the server is running, it is not possible for a malicious user to take the place of the normal
database server. However, when the server is down it is possible for a local user to spoof the normal
server by starting their own server. The spoof server could read passwords and queries sent by clients,
but could not return any data because the PGDATA directory would still be secure because of directory
permissions. Spoofing is possible because any user can start a database server; a client cannot identify
an invalid server unless it is specially configured.

The simplest way to prevent invalid servers for local connections is to use a Unix domain socket
directory (unix_socket_directory) that has write permission only for a trusted local user. This prevents
a malicious user from creating their own socket file in that directory. If you are concerned that some
applications might still reference /tmp for the socket file and hence be vulnerable to spoofing, during
operating system startup create symbolic link /tmp/.s.PGSQL.5432 that points to the relocated socket file. You also might need to modify your /tmp cleanup script to preserve the symbolic link.

For TCP connections the server must accept only hostssl connections (Section 19.1) and have SSL server.key (key) and server.crt (certificate) files (Section 17.8). The TCP client must connect using sslmode='verify-ca' or 'verify-full' and have the required certificate files present (Section 30.1).

17.7. Encryption Options

PostgreSQL offers encryption at several levels, and provides flexibility in protecting data from disclosure due to database server theft, unscrupulous administrators, and insecure networks. Encryption might also be required to secure sensitive data such as medical records or financial transactions.

Password Storage Encryption

By default, database user passwords are stored as MD5 hashes, so the administrator cannot determine the actual password assigned to the user. If MD5 encryption is used for client authentication, the unencrypted password is never even temporarily present on the server because the client MD5 encrypts it before being sent across the network.

Encryption For Specific Columns

The contrib function library pgcrypto allows certain fields to be stored encrypted. This is useful if only some of the data is sensitive. The client supplies the decryption key and the data is decrypted on the server and then sent to the client.

The decrypted data and the decryption key are present on the server for a brief time while it is being decrypted and communicated between the client and server. This presents a brief moment where the data and keys can be intercepted by someone with complete access to the database server, such as the system administrator.

Data Partition Encryption

On Linux, encryption can be layered on top of a file system mount using a “loopback device”. This allows an entire file system partition be encrypted on disk, and decrypted by the operating system. On FreeBSD, the equivalent facility is called GEOM Based Disk Encryption, or gbde.

This mechanism prevents unencrypted data from being read from the drives if the drives or the entire computer is stolen. This does not protect against attacks while the file system is mounted, because when mounted, the operating system provides an unencrypted view of the data. However, to mount the file system, you need some way for the encryption key to be passed to the operating system, and sometimes the key is stored somewhere on the host that mounts the disk.

Encrypting Passwords Across A Network

The MD5 authentication method double-encrypts the password on the client before sending it to the server. It first MD5 encrypts it based on the user name, and then encrypts it based on a random salt sent by the server when the database connection was made. It is this double-encrypted value that is sent over the network to the server. Double-encryption not only prevents the password from being discovered, it also prevents another connection from using the same encrypted password to connect to the database server at a later time.

Encrypting Data Across A Network

SSL connections encrypt all data sent across the network: the password, the queries, and the data returned. The pg_hba.conf file allows administrators to specify which hosts can use non-encrypted connections (host) and which require SSL-encrypted connections (hostssl). Also,
clients can specify that they connect to servers only via SSL. Stunnel or SSH can also be used to encrypt transmissions.

**SSL Host Authentication**

It is possible for both the client and server to provide SSL certificates to each other. It takes some extra configuration on each side, but this provides stronger verification of identity than the mere use of passwords. It prevents a computer from pretending to be the server just long enough to read the password sent by the client. It also helps prevent “man in the middle” attacks where a computer between the client and server pretends to be the server and reads and passes all data between the client and server.

**Client-Side Encryption**

If the system administrator cannot be trusted, it is necessary for the client to encrypt the data; this way, unencrypted data never appears on the database server. Data is encrypted on the client before being sent to the server, and database results have to be decrypted on the client before being used.

## 17.8. Secure TCP/IP Connections with SSL

PostgreSQL has native support for using SSL connections to encrypt client/server communications for increased security. This requires that OpenSSL is installed on both client and server systems and that support in PostgreSQL is enabled at build time (see Chapter 15).

With SSL support compiled in, the PostgreSQL server can be started with SSL enabled by setting the parameter `ssl` to `on` in `postgresql.conf`. The server will listen for both standard and SSL connections on the same TCP port, and will negotiate with any connecting client on whether to use SSL. By default, this is at the client’s option; see Section 19.1 about how to set up the server to require use of SSL for some or all connections.

PostgreSQL reads the system-wide OpenSSL configuration file. By default, this file is named `openssl.cnf` and is located in the directory reported by `openssl version -d`. This default can be overridden by setting environment variable `OPENSSL_CONF` to the name of the desired configuration file.

OpenSSL supports a wide range of ciphers and authentication algorithms, of varying strength. While a list of ciphers can be specified in the OpenSSL configuration file, you can specify ciphers specifically for use by the database server by modifying `ssl_ciphers` in `postgresql.conf`.

Note: It is possible to have authentication without encryption overhead by using NULL-SHA or NULL-MD5 ciphers. However, a man-in-the-middle could read and pass communications between client and server. Also, encryption overhead is minimal compared to the overhead of authentication. For these reasons NULL ciphers are not recommended.

To start in SSL mode, the files `server.crt` and `server.key` must exist in the server’s data directory. These files should contain the server certificate and private key, respectively. On Unix systems, the permissions on `server.key` must disallow any access to world or group; achieve this by the command `chmod 0600 server.key`. If the private key is protected with a passphrase, the server will prompt for the passphrase and will not start until it has been entered.
17.8.1. Using client certificates

To require the client to supply a trusted certificate, place certificates of the certificate authorities (CA) you trust in the file root.crt in the data directory, and set the clientcert parameter to 1 on the appropriate line(s) in pg_hba.conf. A certificate will then be requested from the client during SSL connection startup. (See Section 30.17 for a description of how to set up certificates on the client.) The server will verify that the client’s certificate is signed by one of the trusted certificate authorities. Certificate Revocation List (CRL) entries are also checked if the file root.crl exists. (See http://h71000.www7.hp.com/DOC/83final/BA554_90007/ch04s02.html for diagrams showing SSL certificate usage.)

The clientcert option in pg_hba.conf is available for all authentication methods, but only for rows specified as hostssl. Unless specified, the default is not to verify the client certificate.

You can use the authentication method cert to use the client certificate for authenticating users. See Section 19.3.8 for details.

17.8.2. SSL Server File Usage

The files server.key, server.crt, root.crt, and root.crl are only examined during server start; so you must restart the server for changes in them to take effect.

Table 17-3. SSL Server File Usage

<table>
<thead>
<tr>
<th>File</th>
<th>Contents</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>server.crt</td>
<td>server certificate</td>
<td>requested by client</td>

<td>server private key</td>
<td>proves server certificate sent by owner; does not indicate certificate owner is trustworthy</td>
</tr>
<tr>
<td>root.crt</td>
<td>trusted certificate authorities</td>
<td>checks that client certificate is signed by a trusted certificate authority</td>
</tr>
<tr>
<td>root.crl</td>
<td>certificates revoked by certificate authorities</td>
<td>client certificate must not be on this list</td>
</tr>
</tbody>
</table>

17.8.3. Creating a Self-Signed Certificate

To create a quick self-signed certificate for the server, use the following OpenSSL command:

```bash
openssl req -new -text -out server.req
```

Fill out the information that openssl asks for. Make sure you enter the local host name as “Common Name”; the challenge password can be left blank. The program will generate a key that is passphrase protected; it will not accept a passphrase that is less than four characters long. To remove the passphrase (as you must if you want automatic start-up of the server), run the commands:

```bash
openssl rsa -in privkey.pem -out server.key
rm privkey.pem
```

Enter the old passphrase to unlock the existing key. Now do:

```bash
openssl req -x509 -in server.req -text -key server.key -out server.crt
```
to turn the certificate into a self-signed certificate and to copy the key and certificate to where the server will look for them. Finally do:

\texttt{chmod og-rwx server.key}

because the server will reject the file if its permissions are more liberal than this. For more details on how to create your server private key and certificate, refer to the OpenSSL documentation. A self-signed certificate can be used for testing, but a certificate signed by a certificate authority (CA) (either one of the global CAs or a local one) should be used in production so the client can verify the server’s identity. If all the clients are local to the organization, using a local CA is recommended.

17.9. Secure TCP/IP Connections with SSH Tunnels

One can use SSH to encrypt the network connection between clients and a PostgreSQL server. Done properly, this provides an adequately secure network connection, even for non-SSL-capable clients.

First make sure that an SSH server is running properly on the same machine as the PostgreSQL server and that you can log in using \texttt{ssh} as some user. Then you can establish a secure tunnel with a command like this from the client machine:

\texttt{ssh -L 63333:localhost:5432 joe@foo.com}

The first number in the \texttt{-L} argument, 63333, is the port number of your end of the tunnel; it can be chosen freely. (IANA reserves ports 49152 through 65535 for private use.) The second number, 5432, is the remote end of the tunnel: the port number your server is using. The name or IP address between the port numbers is the host with the database server you are going to connect to, as seen from the host you are logging in to, which is \texttt{foo.com} in this example. In order to connect to the database server using this tunnel, you connect to port 63333 on the local machine:

\texttt{psql -h localhost -p 63333 postgres}

To the database server it will then look as though you are really user \texttt{joe} on host \texttt{foo.com} connecting to \texttt{localhost} in that context, and it will use whatever authentication procedure was configured for connections from this user and host. Note that the server will not think the connection is SSL-encrypted, since in fact it is not encrypted between the SSH server and the PostgreSQL server. This should not pose any extra security risk as long as they are on the same machine.

In order for the tunnel setup to succeed you must be allowed to connect via \texttt{ssh} as \texttt{joe@foo.com}, just as if you had attempted to use \texttt{ssh} to set up a terminal session.

You could also have set up the port forwarding as

\texttt{ssh -L 63333:foo.com:5432 joe@foo.com}

but then the database server will see the connection as coming in on its \texttt{foo.com} interface, which is not opened by the default setting \texttt{listen_addresses = ‘localhost’}. This is usually not what you want.

If you have to “hop” to the database server via some login host, one possible setup could look like this:

\texttt{ssh -L 63333:db.foo.com:5432 joe@shell.foo.com}
Note that this way the connection from `shell.foo.com` to `db.foo.com` will not be encrypted by the SSH tunnel. SSH offers quite a few configuration possibilities when the network is restricted in various ways. Please refer to the SSH documentation for details.

**Tip:** Several other applications exist that can provide secure tunnels using a procedure similar in concept to the one just described.
Chapter 18. Server Configuration

There are many configuration parameters that affect the behavior of the database system. In the first section of this chapter, we describe how to set configuration parameters. The subsequent sections discuss each parameter in detail.

18.1. Setting Parameters

All parameter names are case-insensitive. Every parameter takes a value of one of five types: Boolean, integer, floating point, string or enum. Boolean values can be written as ON, OFF, TRUE, FALSE, YES, NO, 1, 0 (all case-insensitive) or any unambiguous prefix of these.

Some settings specify a memory or time value. Each of these has an implicit unit, which is either kilobytes, blocks (typically eight kilobytes), milliseconds, seconds, or minutes. Default units can be found by referencing \texttt{pg\_settings\_unit}. For convenience, a different unit can also be specified explicitly. Valid memory units are \texttt{kb} (kilobytes), \texttt{MB} (megabytes), and \texttt{GB} (gigabytes); valid time units are \texttt{ms} (milliseconds), \texttt{s} (seconds), \texttt{min} (minutes), \texttt{h} (hours), and \texttt{d} (days). Note that the multiplier for memory units is 1024, not 1000.

Parameters of type “enum” are specified in the same way as string parameters, but are restricted to a limited set of values. The allowed values can be found from \texttt{pg\_settings\_enumvals}. Enum parameter values are case-insensitive.

One way to set these parameters is to edit the file \texttt{postgresql.conf}, which is normally kept in the data directory. (initdb installs a default copy there.) An example of what this file might look like is:

```
# This is a comment
log_connections = yes
log_destination = 'syslog'
search_path = "'$user', public"
shared_buffers = 128MB
```

One parameter is specified per line. The equal sign between name and value is optional. Whitespace is insignificant and blank lines are ignored. Hash marks (\#) introduce comments anywhere. Parameter values that are not simple identifiers or numbers must be single-quoted. To embed a single quote in a parameter value, write either two quotes (preferred) or backslash-quote.

In addition to parameter settings, the \texttt{postgresql.conf} file can contain include directives, which specify another file to read and process as if it were inserted into the configuration file at this point. Include directives simply look like:

```
include 'filename'
```

If the file name is not an absolute path, it is taken as relative to the directory containing the referencing configuration file. Inclusions can be nested.

The configuration file is reread whenever the main server process receives a SIGHUP signal (which is most easily sent by means of \texttt{pg\_ctl reload}). The main server process also propagates this signal to all currently running server processes so that existing sessions also get the new value. Alternatively, you can send the signal to a single server process directly. Some parameters can only be set at server start; any changes to their entries in the configuration file will be ignored until the server is restarted.

A second way to set these configuration parameters is to give them as a command-line option to the \texttt{postgres} command, such as:
postgres -c log_connections=yes -c log_destination='syslog'

Command-line options override any conflicting settings in `postgresql.conf`. Note that this means you won’t be able to change the value on-the-fly by editing `postgresql.conf`, so while the command-line method might be convenient, it can cost you flexibility later.

Occasionally it is useful to give a command line option to one particular session only. The environment variable `PGOPTIONS` can be used for this purpose on the client side:

```
env PGOPTIONS='--c geqo=off' psql
```

(This works for any libpq-based client application, not just `psql`.) Note that this won’t work for parameters that are fixed when the server is started or that must be specified in `postgresql.conf`.

Furthermore, it is possible to assign a set of parameter settings to a user or a database. Whenever a session is started, the default settings for the user and database involved are loaded. The commands `ALTER USER` and `ALTER DATABASE`, respectively, are used to configure these settings. Per-database settings override anything received from the `postgres` command-line or the configuration file, and in turn are overridden by per-user settings; both are overridden by per-session settings.

Some parameters can be changed in individual SQL sessions with the `SET` command, for example:

```
SET ENABLE_SEQSCAN TO OFF;
```

If `SET` is allowed, it overrides all other sources of values for the parameter. Some parameters cannot be changed via `SET`: for example, if they control behavior that cannot be changed without restarting the entire PostgreSQL server. Also, some parameters can be modified via `SET` or `ALTER` by superusers, but not by ordinary users.

The `SHOW` command allows inspection of the current values of all parameters.

The virtual table `pg_settings` (described in Section 44.53) also allows displaying and updating session run-time parameters. It is equivalent to `SHOW` and `SET`, but can be more convenient to use because it can be joined with other tables, or selected from using any desired selection condition. It also contains more information about what values are allowed for the parameters.

### 18.2. File Locations

In addition to the `postgresql.conf` file already mentioned, PostgreSQL uses two other manually-edited configuration files, which control client authentication (their use is discussed in Chapter 19). By default, all three configuration files are stored in the database cluster’s data directory. The parameters described in this section allow the configuration files to be placed elsewhere. (Doing so can ease administration. In particular it is often easier to ensure that the configuration files are properly backed-up when they are kept separate.)

`data_directory` (string)

Specifies the directory to use for data storage. This parameter can only be set at server start.

`config_file` (string)

Specifies the main server configuration file (customarily called `postgresql.conf`). This parameter can only be set on the `postgres` command line.

`hba_file` (string)

Specifies the configuration file for host-based authentication (customarily called `pg_hba.conf`). This parameter can only be set at server start.
ident_file (string)

Specifies the configuration file for Section 19.2 username mapping (customarily called pg_ident.conf). This parameter can only be set at server start.

external_pid_file (string)

Specifies the name of an additional process-id (PID) file that the server should create for use by server administration programs. This parameter can only be set at server start.

In a default installation, none of the above parameters are set explicitly. Instead, the data directory is specified by the -D command-line option or the PGDATA environment variable, and the configuration files are all found within the data directory.

If you wish to keep the configuration files elsewhere than the data directory, the postgres -D command-line option or PGDATA environment variable must point to the directory containing the configuration files, and the data_directory parameter must be set in postgresql.conf (or on the command line) to show where the data directory is actually located. Notice that data_directory overrides -D and PGDATA for the location of the data directory, but not for the location of the configuration files.

If you wish, you can specify the configuration file names and locations individually using the parameters config_file, hba_file and/or ident_file. config_file can only be specified on the postgres command line, but the others can be set within the main configuration file. If all three parameters plus data_directory are explicitly set, then it is not necessary to specify -D or PGDATA.

When setting any of these parameters, a relative path will be interpreted with respect to the directory in which postgres is started.

18.3. Connections and Authentication

18.3.1. Connection Settings

listen_addresses (string)

Specifies the TCP/IP address(es) on which the server is to listen for connections from client applications. The value takes the form of a comma-separated list of host names and/or numeric IP addresses. The special entry * corresponds to all available IP interfaces. If the list is empty, the server does not listen on any IP interface at all, in which case only Unix-domain sockets can be used to connect to it. The default value is localhost, which allows only local “loopback” connections to be made. This parameter can only be set at server start.

port (integer)

The TCP port the server listens on; 5432 by default. Note that the same port number is used for all IP addresses the server listens on. This parameter can only be set at server start.

max_connections (integer)

Determines the maximum number of concurrent connections to the database server. The default is typically 100 connections, but might be less if your kernel settings will not support it (as determined during initdb). This parameter can only be set at server start.

Increasing this parameter might cause PostgreSQL to request more System V shared memory or semaphores than your operating system’s default configuration allows. See Section 17.4.1 for information on how to adjust those parameters, if necessary.
superuser_reserved_connections (integer)

Determines the number of connection “slots” that are reserved for connections by PostgreSQL superusers. At most max_connections connections can ever be active simultaneously. Whenever the number of active concurrent connections is at least max_connections minus superuser_reserved_connections, new connections will be accepted only for superusers.

The default value is three connections. The value must be less than the value of max_connections. This parameter can only be set at server start.

unix_socket_directory (string)

Specifies the directory of the Unix-domain socket on which the server is to listen for connections from client applications. The default is normally /tmp, but can be changed at build time. This parameter can only be set at server start.

unix_socket_group (string)

Sets the owning group of the Unix-domain socket. (The owning user of the socket is always the user that starts the server.) In combination with the parameter unix_socket_permissions this can be used as an additional access control mechanism for Unix-domain connections. By default this is the empty string, which selects the default group for the current user. This parameter can only be set at server start.

unix_socket_permissions (integer)

Sets the access permissions of the Unix-domain socket. Unix-domain sockets use the usual Unix file system permission set. The parameter value is expected to be a numeric mode specification in the form accepted by the chmod and umask system calls. (To use the customary octal format the number must start with a 0 (zero).)

The default permissions are 0777, meaning anyone can connect. Reasonable alternatives are 0770 (only user and group, see also unix_socket_group) and 0700 (only user). (Note that for a Unix-domain socket, only write permission matters and so there is no point in setting or revoking read or execute permissions.)

This access control mechanism is independent of the one described in Chapter 19.

This parameter can only be set at server start.

This parameter is irrelevant on systems, notably Solaris as of Solaris 10, that ignore socket permissions entirely. There, one can achieve a similar effect by pointing unix_socket_directories to a directory having search permission limited to the desired audience. This parameter is also irrelevant on Windows, which does not have Unix-domain sockets.

bonjour_name (string)

Specifies the Bonjour broadcast name. The computer name is used if this parameter is set to the empty string “” (which is the default). This parameter is ignored if the server was not compiled with Bonjour support. This parameter can only be set at server start.

tcp_keepalives_idle (integer)

On systems that support the TCP_KEEPIDLE socket option, specifies the number of seconds between sending keepalives on an otherwise idle connection. A value of zero uses the system default. If TCP_KEEPIDLE is not supported, this parameter must be zero. This parameter is ignored for connections made via a Unix-domain socket.

tcp_keepalives_interval (integer)

On systems that support the TCP_KEEPINTVL socket option, specifies how long, in seconds, to wait for a response to a keepalive before retransmitting. A value of zero uses the system default.
Chapter 18. Server Configuration

If TCP_KEEPINTVL is not supported, this parameter must be zero. This parameter is ignored for connections made via a Unix-domain socket.

tcp_keepalives_count (integer)

On systems that support the TCP_KEEPCNT socket option, specifies how many keepalives can be lost before the connection is considered dead. A value of zero uses the system default. If TCP_KEEPCNT is not supported, this parameter must be zero. This parameter is ignored for connections made via a Unix-domain socket.

18.3.2. Security and Authentication

authentication_timeout (integer)

Maximum time to complete client authentication, in seconds. If a would-be client has not completed the authentication protocol in this much time, the server breaks the connection. This prevents hung clients from occupying a connection indefinitely. The default is one minute (1m). This parameter can only be set in the postgresql.conf file or on the server command line.

ssl (boolean)

Enables SSL connections. Please read Section 17.8 before using this. The default is off. This parameter can only be set at server start. SSL communication is only possible with TCP/IP connections.

ssl_renegotiation_limit (integer)

Specifies how much data can flow over an SSL encrypted connection before renegotiation of the session will take place. Renegotiation of the session decreases the chance of doing cryptanalysis when large amounts of data are sent, but it also carries a large performance penalty. The sum of sent and received traffic is used to check the limit. If the parameter is set to 0, renegotiation is disabled. The default is 512MB.

Note: SSL libraries from before November 2009 are insecure when using SSL renegotiation, due to a vulnerability in the SSL protocol. As a stop-gap fix for this vulnerability, some vendors also shipped SSL libraries incapable of doing renegotiation. If any of these libraries are in use on the client or server, SSL renegotiation should be disabled.

ssl_ciphers (string)

Specifies a list of SSL ciphers that are allowed to be used on secure connections. See the openssl manual page for a list of supported ciphers. This parameter is unavailable unless the server is compiled with support for SSL.

password_encryption (boolean)

When a password is specified in CREATE USER or ALTER USER without writing either ENCRYPTED or UNENCRYPTED, this parameter determines whether the password is to be encrypted. The default is on (encrypt the password).

krb_server_keyfile (string)

Sets the location of the Kerberos server key file. See Section 19.3.5 or Section 19.3.3 for details. This parameter can only be set in the postgresql.conf file or on the server command line.
Chapter 18. Server Configuration

krb_srvname (string)

Sets the Kerberos service name. See Section 19.3.5 for details. This parameter can only be set in the postgresql.conf file or on the server command line.

krb_caseins_users (boolean)

Sets whether Kerberos and GSSAPI user names should be treated case-insensitively. The default is off (case sensitive). This parameter can only be set in the postgresql.conf file or on the server command line.

db_user_namespace (boolean)

This parameter enables per-database user names. It is off by default. This parameter can only be set in the postgresql.conf file or on the server command line.

If this is on, you should create users as username@dbname. When username is passed by a connecting client, @ and the database name are appended to the user name and that database-specific user name is looked up by the server. Note that when you create users with names containing @ within the SQL environment, you will need to quote the user name.

With this parameter enabled, you can still create ordinary global users. Simply append @ when specifying the user name in the client. The @ will be stripped off before the user name is looked up by the server.

db_user_namespace causes the client’s and server’s user name representation to differ. Authentication checks are always done with the server’s user name so authentication methods must be configured for the server’s user name, not the client’s. Because md5 uses the user name as salt on both the client and server, md5 cannot be used with db_user_namespace.

Note: This feature is intended as a temporary measure until a complete solution is found. At that time, this option will be removed.

18.4. Resource Consumption

18.4.1. Memory

shared_buffers (integer)

Sets the amount of memory the database server uses for shared memory buffers. The default is typically 32 megabytes (32MB), but might be less if your kernel settings will not support it (as determined during initdb). This setting must be at least 128 kilobytes. (Non-default values of BLCKSZ change the minimum.) However, settings significantly higher than the minimum are usually needed for good performance. This parameter can only be set at server start.

If you have a dedicated database server with 1GB or more of RAM, a reasonable starting value for shared_buffers is 25% of the memory in your system. There are some workloads where even large settings for shared_buffers are effective, but because PostgreSQL also relies on the operating system cache, it is unlikely that an allocation of more than 40% of RAM to shared_buffers will work better than a smaller amount. Larger settings for shared_buffers
usually require a corresponding increase in `checkpoint_segments`, in order to spread out the process of writing large quantities of new or changed data over a longer period of time.

On systems with less than 1GB of RAM, a smaller percentage of RAM is appropriate, so as to leave adequate space for the operating system. Also, on Windows, large values for `shared_buffers` aren’t as effective. You may find better results keeping the setting relatively low and using the operating system cache more instead. The useful range for `shared_buffers` on Windows systems is generally from 64MB to 512MB.

Increasing this parameter might cause PostgreSQL to request more System V shared memory than your operating system’s default configuration allows. See Section 17.4.1 for information on how to adjust those parameters, if necessary.

### `temp_buffers` (integer)

Sets the maximum number of temporary buffers used by each database session. These are session-local buffers used only for access to temporary tables. The default is eight megabytes (8MB). The setting can be changed within individual sessions, but only up until the first use of temporary tables within a session; subsequent attempts to change the value will have no effect on that session.

A session will allocate temporary buffers as needed up to the limit given by `temp_buffers`. The cost of setting a large value in sessions that do not actually need a lot of temporary buffers is only a buffer descriptor, or about 64 bytes, per increment in `temp_buffers`. However if a buffer is actually used an additional 8192 bytes will be consumed for it (or in general, `BLCKSZ` bytes).

### `max_prepared_transactions` (integer)

Sets the maximum number of transactions that can be in the “prepared” state simultaneously (see `PREPARE TRANSACTION`). Setting this parameter to zero (which is the default) disables the prepared-transaction feature. This parameter can only be set at server start.

If you are not planning to use prepared transactions, this parameter should be set to zero to prevent accidental creation of prepared transactions. If you are using prepared transactions, you will probably want `max_prepared_transactions` to be at least as large as `max_connections`, so that every session can have a prepared transaction pending.

Increasing this parameter might cause PostgreSQL to request more System V shared memory than your operating system’s default configuration allows. See Section 17.4.1 for information on how to adjust those parameters, if necessary.

### `work_mem` (integer)

Specifies the amount of memory to be used by internal sort operations and hash tables before switching to temporary disk files. The value defaults to one megabyte (1MB). Note that for a complex query, several sort or hash operations might be running in parallel; each one will be allowed to use as much memory as this value specifies before it starts to put data into temporary files. Also, several running sessions could be doing such operations concurrently. So the total memory used could be many times the value of `work_mem`; it is necessary to keep this fact in mind when choosing the value. Sort operations are used for `ORDER BY`, `DISTINCT`, and merge joins. Hash tables are used in hash joins, hash-based aggregation, and hash-based processing of `IN` subqueries.

### `maintenance_work_mem` (integer)

Specifies the maximum amount of memory to be used in maintenance operations, such as `VACUUM`, `CREATE INDEX`, and `ALTER TABLE ADD FOREIGN KEY`. It defaults to 16 megabytes (16MB). Since only one of these operations can be executed at a time by a database session, and an installation normally doesn’t have many of them running concurrently, it’s safe to set this
value significantly larger than work_mem. Larger settings might improve performance for vacuuming and for restoring database dumps.

Note that when autovacuum runs, up to autovacuum_max_workers times this memory may be allocated, so be careful not to set the default value too high.

max_stack_depth (integer)

Specifies the maximum safe depth of the server’s execution stack. The ideal setting for this parameter is the actual stack size limit enforced by the kernel (as set by ulimit -s or local equivalent), less a safety margin of a megabyte or so. The safety margin is needed because the stack depth is not checked in every routine in the server, but only in key potentially-recursive routines such as expression evaluation. The default setting is two megabytes (2MB), which is conservatively small and unlikely to risk crashes. However, it might be too small to allow execution of complex functions. Only superusers can change this setting.

Setting max_stack_depth higher than the actual kernel limit will mean that a runaway recursive function can crash an individual backend process. On platforms where PostgreSQL can determine the kernel limit, it will not let you set this variable to an unsafe value. However, not all platforms provide the information, so caution is recommended in selecting a value.

18.4.2. Kernel Resource Usage

max_files_per_process (integer)

Sets the maximum number of simultaneously open files allowed to each server subprocess. The default is one thousand files. If the kernel is enforcing a safe per-process limit, you don’t need to worry about this setting. But on some platforms (notably, most BSD systems), the kernel will allow individual processes to open many more files than the system can really support when a large number of processes all try to open that many files. If you find yourself seeing “Too many open files” failures, try reducing this setting. This parameter can only be set at server start.

shared_preload_libraries (string)

This variable specifies one or more shared libraries that are to be preloaded at server start. If more than one library is to be loaded, separate their names with commas. For example, ‘$libdir/mylib’ would cause mylib.so (or on some platforms, mylib.sl) to be preloaded from the installation’s standard library directory. This parameter can only be set at server start.

PostgreSQL procedural language libraries can be preloaded in this way, typically by using the syntax ‘$libdir/plXXX’ where XXX is pgsql, perl, tcl, or python.

By preloading a shared library, the library startup time is avoided when the library is first used. However, the time to start each new server process might increase slightly, even if that process never uses the library. So this parameter is recommended only for libraries that will be used in most sessions.

Note: On Windows hosts, preloading a library at server start will not reduce the time required to start each new server process; each server process will re-load all preload libraries. However, shared_preload_libraries is still useful on Windows hosts because some shared libraries may need to perform certain operations that only take place at postmaster start (for example, a shared library may need to reserve lightweight locks or shared memory and you can’t do that after the postmaster has started).

If a specified library is not found, the server will fail to start.
Every PostgreSQL-supported library has a “magic block” that is checked to guarantee compatibility. For this reason, non-PostgreSQL libraries cannot be loaded in this way.

18.4.3. Cost-Based Vacuum Delay

During the execution of VACUUM and ANALYZE commands, the system maintains an internal counter that keeps track of the estimated cost of the various I/O operations that are performed. When the accumulated cost reaches a limit (specified by vacuum_cost_limit), the process performing the operation will sleep for a while (specified by vacuum_cost_delay). Then it will reset the counter and continue execution.

The intent of this feature is to allow administrators to reduce the I/O impact of these commands on concurrent database activity. There are many situations in which it is not very important that maintenance commands like VACUUM and ANALYZE finish quickly; however, it is usually very important that these commands do not significantly interfere with the ability of the system to perform other database operations. Cost-based vacuum delay provides a way for administrators to achieve this.

This feature is disabled by default for manually issued VACUUM commands. To enable it, set the vacuum_cost_delay variable to a nonzero value.

vacuum_cost_delay(integer)

The length of time, in milliseconds, that the process will sleep when the cost limit has been exceeded. The default value is zero, which disables the cost-based vacuum delay feature. Positive values enable cost-based vacuuming. Note that on many systems, the effective resolution of sleep delays is 10 milliseconds; setting vacuum_cost_delay to a value that is not a multiple of 10 might have the same results as setting it to the next higher multiple of 10.

When using cost-based vacuuming, appropriate values for vacuum_cost_delay are usually quite small, perhaps 10 or 20 milliseconds. Adjusting vacuum’s resource consumption is best done by changing the other vacuum cost parameters.

vacuum_cost_page_hit(integer)

The estimated cost for vacuuming a buffer found in the shared buffer cache. It represents the cost to lock the buffer pool, lookup the shared hash table and scan the content of the page. The default value is one.

vacuum_cost_page_miss(integer)

The estimated cost for vacuuming a buffer that has to be read from disk. This represents the effort to lock the buffer pool, lookup the shared hash table, read the desired block in from the disk and scan its content. The default value is 10.

vacuum_cost_page_dirty(integer)

The estimated cost charged when vacuum modifies a block that was previously clean. It represents the extra I/O required to flush the dirty block out to disk again. The default value is 20.

vacuum_cost_limit(integer)

The accumulated cost that will cause the vacuuming process to sleep. The default value is 200.

Note: There are certain operations that hold critical locks and should therefore complete as quickly as possible. Cost-based vacuum delays do not occur during such operations. Therefore it is possible that the cost accumulates far higher than the specified limit. To avoid uselessly long delays in such cases, the actual delay is calculated as \( \text{vacuum_cost_delay} \times \text{accumulated_balance} / \text{vacuum_cost_limit} \) with a maximum of \( \text{vacuum_cost_delay} \times 4 \).
Chapter 18. Server Configuration

18.4.4. Background Writer

There is a separate server process called the background writer, whose function is to issue writes of “dirty” shared buffers. The intent is that server processes handling user queries should seldom or never have to wait for a write to occur, because the background writer will do it. However there is a net overall increase in I/O load, because a repeatedly-dirtied page might otherwise be written only once per checkpoint interval, but the background writer might write it several times in the same interval. The parameters discussed in this subsection can be used to tune the behavior for local needs.

bgwriter_delay(integer)

Specifies the delay between activity rounds for the background writer. In each round the writer issues writes for some number of dirty buffers (controllable by the following parameters). It then sleeps for bgwriter_delay milliseconds, and repeats. The default value is 200 milliseconds (200ms). Note that on many systems, the effective resolution of sleep delays is 10 milliseconds; setting bgwriter_delay to a value that is not a multiple of 10 might have the same results as setting it to the next higher multiple of 10. This parameter can only be set in the postgresql.conf file or on the server command line.

bgwriter_lru_maxpages(integer)

In each round, no more than this many buffers will be written by the background writer. Setting this to zero disables background writing (except for checkpoint activity). The default value is 100 buffers. This parameter can only be set in the postgresql.conf file or on the server command line.

bgwriter_lru_multiplier(floating point)

The number of dirty buffers written in each round is based on the number of new buffers that have been needed by server processes during recent rounds. The average recent need is multiplied by bgwriter_lru_multiplier to arrive at an estimate of the number of buffers that will be needed during the next round. Dirty buffers are written until there are that many clean, reusable buffers available. (However, no more than bgwriter_lru_maxpages buffers will be written per round.) Thus, a setting of 1.0 represents a “just in time” policy of writing exactly the number of buffers predicted to be needed. Larger values provide some cushion against spikes in demand, while smaller values intentionally leave writes to be done by server processes. The default is 2.0. This parameter can only be set in the postgresql.conf file or on the server command line.

Smaller values of bgwriter_lru_maxpages and bgwriter_lru_multiplier reduce the extra I/O load caused by the background writer, but make it more likely that server processes will have to issue writes for themselves, delaying interactive queries.

18.4.5. Asynchronous Behavior

effective_io_concurrency(integer)

Sets the number of concurrent disk I/O operations that PostgreSQL expects can be executed simultaneously. Raising this value will increase the number of I/O operations that any individual PostgreSQL session attempts to initiate in parallel. The allowed range is 1 to 1000, or zero to disable issuance of asynchronous I/O requests.
A good starting point for this setting is the number of separate drives comprising a RAID 0 stripe or RAID 1 mirror being used for the database. (For RAID 5 the parity drive should not be counted.) However, if the database is often busy with multiple queries issued in concurrent sessions, lower values may be sufficient to keep the disk array busy. A value higher than needed to keep the disks busy will only result in extra CPU overhead.

For more exotic systems, such as memory-based storage or a RAID array that is limited by bus bandwidth, the correct value might be the number of I/O paths available. Some experimentation may be needed to find the best value.

Asynchronous I/O depends on an effective `posix_fadvise` function, which some operating systems lack. If the function is not present then setting this parameter to anything but zero will result in an error. On some operating systems (e.g., Solaris), the function is present but does not actually do anything.

### 18.5. Write Ahead Log

See also Section 28.4 for details on WAL and checkpoint tuning.

#### 18.5.1. Settings

**fsync (boolean)**

If this parameter is on, the PostgreSQL server will try to make sure that updates are physically written to disk, by issuing `fsync()` system calls or various equivalent methods (see `wal_sync_method`). This ensures that the database cluster can recover to a consistent state after an operating system or hardware crash.

However, using `fsync` results in a performance penalty: when a transaction is committed, PostgreSQL must wait for the operating system to flush the write-ahead log to disk. When `fsync` is disabled, the operating system is allowed to do its best in buffering, ordering, and delaying writes. This can result in significantly improved performance. However, if the system crashes, the results of the last few committed transactions might be lost in part or whole. In the worst case, unrecoverable data corruption might occur. (Crashes of the database software itself are not a risk factor here. Only an operating-system-level crash creates a risk of corruption.)

Due to the risks involved, there is no universally correct setting for `fsync`. Some administrators always disable `fsync`, while others only turn it off during initial bulk data loads, where there is a clear restart point if something goes wrong. Others always leave `fsync` enabled. The default is to enable `fsync`, for maximum reliability. If you trust your operating system, your hardware, and your utility company (or your battery backup), you can consider disabling `fsync`.

In many situations, turning off `synchronous_commit` for noncritical transactions can provide much of the potential performance benefit of turning off `fsync`, without the attendant risks of data corruption.

This parameter can only be set in the `postgresql.conf` file or on the server command line. If you turn this parameter off, also consider turning off `full_page_writes`.

**synchronous_commit (boolean)**

Specifies whether transaction commit will wait for WAL records to be written to disk before the command returns a “success” indication to the client. The default, and safe, setting is on. When `off`, there can be a delay between when success is reported to the client and when the
transaction is really guaranteed to be safe against a server crash. (The maximum delay is three
times wal_writer_delay.) Unlike fsync, setting this parameter to off does not create any risk
of database inconsistency: a crash might result in some recent allegedly-committed transactions
being lost, but the database state will be just the same as if those transactions had been aborted
cleanly. So, turning synchronous_commit off can be a useful alternative when performance is
more important than exact certainty about the durability of a transaction. For more discussion
see Section 28.3.

This parameter can be changed at any time; the behavior for any one transaction is determined
by the setting in effect when it commits. It is therefore possible, and useful, to have some trans-
actions commit synchronously and others asynchronously. For example, to make a single multi-
statement transaction commit asynchronously when the default is the opposite, issue SET LOCAL
synchronous_commit TO OFF within the transaction.

wal_sync_method (enum)
Method used for forcing WAL updates out to disk. If fsync is off then this setting is irrelevant,
since updates will not be forced out at all. Possible values are:

• open_datasync (write WAL files with open() option O_DSYNC)
• fdatasync (call fdatasync() at each commit)
• fsync (call fsync() at each commit)
• fsync_writethrough (call fsync() at each commit, forcing write-through of any disk
  write cache)
• open_sync (write WAL files with open() option O_SYNC)

The open_* options also use O_DIRECT if available. Not all of these choices are available on
all platforms. The default is the first method in the above list that is supported by the platform,
except that fdatasync is the default on Linux. The default is not necessarily ideal; it might be
necessary to change this setting or other aspects of your system configuration in order to create a
crash-safe configuration or achieve optimal performance. These aspects are discussed in Section
28.1. This parameter can only be set in the postgresql.conf file or on the server command
line.

full_page_writes (boolean)
When this parameter is on, the PostgreSQL server writes the entire content of each disk page
to WAL during the first modification of that page after a checkpoint. This is needed because a
page write that is in process during an operating system crash might be only partially completed,
leading to an on-disk page that contains a mix of old and new data. The row-level change data
normally stored in WAL will not be enough to completely restore such a page during post-crash
recovery. Storing the full page image guarantees that the page can be correctly restored, but at
a price in increasing the amount of data that must be written to WAL. (Because WAL replay
always starts from a checkpoint, it is sufficient to do this during the first change of each page
after a checkpoint. Therefore, one way to reduce the cost of full-page writes is to increase the
checkpoint interval parameters.)

Turning this parameter off speeds normal operation, but might lead to a corrupt database after
an operating system crash or power failure. The risks are similar to turning off fsync, though
smaller. It might be safe to turn off this parameter if you have hardware (such as a battery-
backed disk controller) or file-system software that reduces the risk of partial page writes to an
acceptably low level (e.g., ReiserFS 4).

Turning off this parameter does not affect use of WAL archiving for point-in-time recovery
(PITR) (see Section 24.3).
This parameter can only be set in the `postgresql.conf` file or on the server command line. The default is `on`.

**`wal_buffers` (integer)**

The amount of memory used in shared memory for WAL data. The default is 64 kilobytes (64kB). The setting need only be large enough to hold the amount of WAL data generated by one typical transaction, since the data is written out to disk at every transaction commit. This parameter can only be set at server start.

Increasing this parameter might cause PostgreSQL to request more System V shared memory than your operating system’s default configuration allows. See Section 17.4.1 for information on how to adjust those parameters, if necessary.

**`wal_writer_delay` (integer)**

Specifies the delay between activity rounds for the WAL writer. In each round the writer will flush WAL to disk. It then sleeps for `wal_writer_delay` milliseconds, and repeats. The default value is 200 milliseconds (200ms). Note that on many systems, the effective resolution of sleep delays is 10 milliseconds; setting `wal_writer_delay` to a value that is not a multiple of 10 might have the same results as setting it to the next higher multiple of 10. This parameter can only be set in the `postgresql.conf` file or on the server command line.

**`commit_delay` (integer)**

Time delay between writing a commit record to the WAL buffer and flushing the buffer out to disk, in microseconds. A nonzero delay can allow multiple transactions to be committed with only one `fsync()` system call, if system load is high enough that additional transactions become ready to commit within the given interval. But the delay is just wasted if no other transactions become ready to commit. Therefore, the delay is only performed if at least `commit_siblings` other transactions are active at the instant that a server process has written its commit record. The default is zero (no delay).

**`commit_siblings` (integer)**

Minimum number of concurrent open transactions to require before performing the `commit_delay` delay. A larger value makes it more probable that at least one other transaction will become ready to commit during the delay interval. The default is five transactions.

### 18.5.2. Checkpoints

**`checkpoint_segments` (integer)**

Maximum number of log file segments between automatic WAL checkpoints (each segment is normally 16 megabytes). The default is three segments. Increasing this parameter can increase the amount of time needed for crash recovery. This parameter can only be set in the `postgresql.conf` file or on the server command line.

**`checkpoint_timeout` (integer)**

Maximum time between automatic WAL checkpoints, in seconds. The default is five minutes (5min). Increasing this parameter can increase the amount of time needed for crash recovery. This parameter can only be set in the `postgresql.conf` file or on the server command line.

**`checkpoint_completion_target` (floating point)**

Specifies the target length of checkpoints, as a fraction of the checkpoint interval. The default is 0.5. This parameter can only be set in the `postgresql.conf` file or on the server command line.
checkpoint_warning (integer)

Write a message to the server log if checkpoints caused by the filling of checkpoint segment files happen closer together than this many seconds (which suggests that checkpoint_segments ought to be raised). The default is 30 seconds (30s). Zero disables the warning. This parameter can only be set in the postgresql.conf file or on the server command line.

18.5.3. Archiving

archive_mode (boolean)

When archive_mode is enabled, completed WAL segments can be sent to archive storage by setting archive_command. archive_mode and archive_command are separate variables so that archive_command can be changed without leaving archiving mode. This parameter can only be set at server start.

archive_command (string)

The shell command to execute to archive a completed segment of the WAL file series. Any %p in the string is replaced by the path name of the file to archive, and any %f is replaced by the file name only. (The path name is relative to the working directory of the server, i.e., the cluster’s data directory.) Use %% to embed an actual % character in the command. For more information see Section 24.3.1. This parameter can only be set in the postgresql.conf file or on the server command line. It is ignored unless archive_mode was enabled at server start. If archive_command is an empty string (the default) while archive_mode is enabled, then WAL archiving is temporarily disabled, but the server continues to accumulate WAL segment files in the expectation that a command will soon be provided.

It is important for the command to return a zero exit status if and only if it succeeds. Examples:

archive_command = 'cp "%p" /mnt/server/archivedir/%f''
archive_command = 'copy "%p" C:\server\archivedir\%f''  # Windows

archive_timeout (integer)

The archive_command is only invoked on completed WAL segments. Hence, if your server generates little WAL traffic (or has slack periods where it does so), there could be a long delay between the completion of a transaction and its safe recording in archive storage. To put a limit on how old unarchived data can be, you can set archive_timeout to force the server to switch to a new WAL segment file periodically. When this parameter is greater than zero, the server will switch to a new segment file whenever this many seconds have elapsed since the last segment file switch. Note that archived files that are closed early due to a forced switch are still the same length as completely full files. Therefore, it is unwise to use a very short archive_timeout — it will bloat your archive storage. archive_timeout settings of a minute or so are usually reasonable. This parameter can only be set in the postgresql.conf file or on the server command line.

18.6. Query Planning

18.6.1. Planner Method Configuration

These configuration parameters provide a crude method of influencing the query plans chosen by the
query optimizer. If the default plan chosen by the optimizer for a particular query is not optimal, a temporary solution can be found by using one of these configuration parameters to force the optimizer to choose a different plan. Turning one of these settings off permanently is seldom a good idea, however. Better ways to improve the quality of the plans chosen by the optimizer include adjusting the Planner Cost Constants, running ANALYZE more frequently, increasing the value of the default_statistics_target configuration parameter, and increasing the amount of statistics collected for specific columns using ALTER TABLE SET STATISTICS.

enable_bitmapscan(boolean)
   Enables or disables the query planner’s use of bitmap-scan plan types. The default is on.

enable_hashagg(boolean)
   Enables or disables the query planner’s use of hashed aggregation plan types. The default is on.

enable_hashjoin(boolean)
   Enables or disables the query planner’s use of hash-join plan types. The default is on.

enable_indexscan(boolean)
   Enables or disables the query planner’s use of index-scan plan types. The default is on.

enable_mergejoin(boolean)
   Enables or disables the query planner’s use of merge-join plan types. The default is on.

enable_nestloop(boolean)
   Enables or disables the query planner’s use of nested-loop join plans. It’s not possible to suppress nested-loop joins entirely, but turning this variable off discourages the planner from using one if there are other methods available. The default is on.

enable_seqscan(boolean)
   Enables or disables the query planner’s use of sequential scan plan types. It’s not possible to suppress sequential scans entirely, but turning this variable off discourages the planner from using one if there are other methods available. The default is on.

enable_sort(boolean)
   Enables or disables the query planner’s use of explicit sort steps. It’s not possible to suppress explicit sorts entirely, but turning this variable off discourages the planner from using one if there are other methods available. The default is on.

enable_tidscan(boolean)
   Enables or disables the query planner’s use of TID scan plan types. The default is on.

18.6.2. Planner Cost Constants

The cost variables described in this section are measured on an arbitrary scale. Only their relative values matter, hence scaling them all up or down by the same factor will result in no change in the planner’s choices. Traditionally, these variables have been referenced to sequential page fetches as the unit of cost; that is, seq_page_cost is conventionally set to 1.0 and the other cost variables are set with reference to that. But you can use a different scale if you prefer, such as actual execution times in milliseconds on a particular machine.
Chapter 18. Server Configuration

**Note:** Unfortunately, there is no well-defined method for determining ideal values for the cost variables. They are best treated as averages over the entire mix of queries that a particular installation will get. This means that changing them on the basis of just a few experiments is very risky.

seq_page_cost (floating point)
Sets the planner’s estimate of the cost of a disk page fetch that is part of a series of sequential fetches. The default is 1.0.

random_page_cost (floating point)
Sets the planner’s estimate of the cost of a non-sequentially-fetched disk page. The default is 4.0. Reducing this value relative to seq_page_cost will cause the system to prefer index scans; raising it will make index scans look relatively more expensive. You can raise or lower both values together to change the importance of disk I/O costs relative to CPU costs, which are described by the following parameters.

**Tip:** Although the system will let you set random_page_cost to less than seq_page_cost, it is not physically sensible to do so. However, setting them equal makes sense if the database is entirely cached in RAM, since in that case there is no penalty for touching pages out of sequence. Also, in a heavily-cached database you should lower both values relative to the CPU parameters, since the cost of fetching a page already in RAM is much smaller than it would normally be.

cpu_tuple_cost (floating point)
Sets the planner’s estimate of the cost of processing each row during a query. The default is 0.01.

cpu_index_tuple_cost (floating point)
Sets the planner’s estimate of the cost of processing each index entry during an index scan. The default is 0.005.

cpu_operator_cost (floating point)
Sets the planner’s estimate of the cost of processing each operator or function executed during a query. The default is 0.0025.

effective_cache_size (integer)
Sets the planner’s assumption about the effective size of the disk cache that is available to a single query. This is factored into estimates of the cost of using an index; a higher value makes it more likely index scans will be used, a lower value makes it more likely sequential scans will be used. When setting this parameter you should consider both PostgreSQL’s shared buffers and the portion of the kernel’s disk cache that will be used for PostgreSQL data files. Also, take into account the expected number of concurrent queries on different tables, since they will have to share the available space. This parameter has no effect on the size of shared memory allocated by PostgreSQL, nor does it reserve kernel disk cache; it is used only for estimation purposes. The default is 128 megabytes (128MB).

### 18.6.3. Genetic Query Optimizer

The genetic query optimizer (GEQO) is an algorithm that does query planning using heuristic searching. This reduces planning time for complex queries (those joining many relations), at the cost of
producing plans that are sometimes inferior to those found by the normal exhaustive-search algorithm. Also, GEQO’s searching is randomized and therefore its plans may vary nondeterministically. For more information see Chapter 49.

geqo (boolean)

Enables or disables genetic query optimization. This is on by default. It is usually best not to turn it off in production; the geqo_threshold variable provides a more granular way to control use of GEQO.

geqo_threshold (integer)

Use genetic query optimization to plan queries with at least this many FROM items involved. (Note that a FULL OUTER JOIN construct counts as only one FROM item.) The default is 12. For simpler queries it is usually best to use the deterministic, exhaustive planner, but for queries with many tables the deterministic planner takes too long.

geqo_effort (integer)

Controls the trade-off between planning time and query plan quality in GEQO. This variable must be an integer in the range from 1 to 10. The default value is five. Larger values increase the time spent doing query planning, but also increase the likelihood that an efficient query plan will be chosen.

geqo_effort doesn’t actually do anything directly; it is only used to compute the default values for the other variables that influence GEQO behavior (described below). If you prefer, you can set the other parameters by hand instead.

geqo_pool_size (integer)

Controls the pool size used by GEQO, that is the number of individuals in the genetic population. It must be at least two, and useful values are typically 100 to 1000. If it is set to zero (the default setting) then a suitable value is chosen based on geqo_effort and the number of tables in the query.

geqo_generations (integer)

Controls the number of generations used by GEQO, that is the number of iterations of the algorithm. It must be at least one, and useful values are in the same range as the pool size. If it is set to zero (the default setting) then a suitable value is chosen based on geqo_pool_size.

geqo_selection_bias (floating point)

Controls the selection bias used by GEQO. The selection bias is the selective pressure within the population. Values can be from 1.50 to 2.00; the latter is the default.

18.6.4. Other Planner Options

default_statistics_target (integer)

Sets the default statistics target for table columns that have not had a column-specific target set via ALTER TABLE SET STATISTICS. Larger values increase the time needed to do ANALYZE, but might improve the quality of the planner’s estimates. The default is 100. For more information on the use of statistics by the PostgreSQL query planner, refer to Section 14.2.

constraint_exclusion (enum)

Controls the query planner’s use of table constraints to optimize queries. The allowed values of constraint_exclusion are on (examine constraints for all tables), off (never examine
constraints), and partition (examine constraints only for inheritance child tables and UNION ALL subqueries), partition is the default setting.

When this parameter allows it for a particular table, the planner compares query conditions with the table’s CHECK constraints, and omits scanning tables for which the conditions contradict the constraints. For example:

```
CREATE TABLE parent(key integer, ...);
CREATE TABLE child1000(check (key between 1000 and 1999)) INHERITS(parent);
CREATE TABLE child2000(check (key between 2000 and 2999)) INHERITS(parent);
...
SELECT * FROM parent WHERE key = 2400;
```

With constraint exclusion enabled, this SELECT will not scan child1000 at all. This can improve performance when inheritance is used to build partitioned tables.

Currently, constraint exclusion is enabled by default only for cases that are often used to implement table partitioning. Turning it on for all tables imposes extra planning overhead that is quite noticeable on simple queries, and most often will yield no benefit for simple queries. If you have no partitioned tables you might prefer to turn it off entirely.

Refer to Section 5.9.4 for more information on using constraint exclusion and partitioning.

**cursor_tuple_fraction** (floating point)

Sets the planner’s estimate of the fraction of a cursor’s rows that will be retrieved. The default is 0.1. Smaller values of this setting bias the planner towards using “fast start” plans for cursors, which will retrieve the first few rows quickly while perhaps taking a long time to fetch all rows. Larger values put more emphasis on the total estimated time. At the maximum setting of 1.0, cursors are planned exactly like regular queries, considering only the total estimated time and not how soon the first rows might be delivered.

**fromCollapseLimit** (integer)

The planner will merge sub-queries into upper queries if the resulting FROM list would have no more than this many items. Smaller values reduce planning time but might yield inferior query plans. The default is eight. For more information see Section 14.3.

Setting this value to geqo_threshold or more may trigger use of the GEQO planner, resulting in nondeterministic plans. See Section 18.6.3.

**joinCollapseLimit** (integer)

The planner will rewrite explicit JOIN constructs (except FULL JOINs) into lists of FROM items whenever a list of no more than this many items would result. Smaller values reduce planning time but might yield inferior query plans.

By default, this variable is set the same as fromCollapseLimit, which is appropriate for most uses. Setting it to 1 prevents any reordering of explicit JOINs. Thus, the explicit join order specified in the query will be the actual order in which the relations are joined. The query planner does not always choose the optimal join order; advanced users can elect to temporarily set this variable to 1, and then specify the join order they desire explicitly. For more information see Section 14.3.

Setting this value to geqo_threshold or more may trigger use of the GEQO planner, resulting in nondeterministic plans. See Section 18.6.3.
18. Error Reporting and Logging

18.7. Where To Log

**log_destination (string)**

PostgreSQL supports several methods for logging server messages, including stderr, csvlog and syslog. On Windows, eventlog is also supported. Set this parameter to a list of desired log destinations separated by commas. The default is to log to stderr only. This parameter can only be set in the `postgresql.conf` file or on the server command line.

If csvlog is included in `log_destination`, log entries are output in “comma separated value” format, which is convenient for loading them into programs. See Section 18.7.4 for details. `logging_collector` must be enabled to generate CSV-format log output.

**logging_collector (boolean)**

This parameter allows messages sent to stderr, and CSV-format log output, to be captured and redirected into log files. This approach is often more useful than logging to syslog, since some types of messages might not appear in syslog output (a common example is dynamic-linker failure messages). This parameter can only be set at server start.

**log_directory (string)**

When `logging_collector` is enabled, this parameter determines the directory in which log files will be created. It can be specified as an absolute path, or relative to the cluster data directory. This parameter can only be set in the `postgresql.conf` file or on the server command line. The default is `pg_log`.

**log_filename (string)**

When `logging_collector` is enabled, this parameter sets the file names of the created log files. The value is treated as a strftime pattern, so %-escapes can be used to specify time-varying file names. (Note that if there are any time-zone-dependent %-escapes, the computation is done in the zone specified by `log_timezone`.) Note that the system’s strftime is not used directly, so platform-specific (nonstandard) extensions do not work. The default is `postgresql-%Y-%m-%d_%H%M%S.log`.

If you specify a file name without escapes, you should plan to use a log rotation utility to avoid eventually filling the entire disk. In releases prior to 8.4, if no % escapes were present, PostgreSQL would append the epoch of the new log file’s creation time, but this is no longer the case.

If CSV-format output is enabled in `log_destination`, .csv will be appended to the times-tamped log file name to create the file name for CSV-format output. (If `log_filename` ends in .log, the suffix is replaced instead.)
Chapter 18. Server Configuration

This parameter can only be set in the `postgresql.conf` file or on the server command line.

**log_rotation_age (integer)**

When `logging_collector` is enabled, this parameter determines the maximum lifetime of an individual log file. After this many minutes have elapsed, a new log file will be created. Set to zero to disable time-based creation of new log files. This parameter can only be set in the `postgresql.conf` file or on the server command line.

**log_rotation_size (integer)**

When `logging_collector` is enabled, this parameter determines the maximum size of an individual log file. After this many kilobytes have been emitted into a log file, a new log file will be created. Set to zero to disable size-based creation of new log files. This parameter can only be set in the `postgresql.conf` file or on the server command line.

**log_truncate_on_rotation (boolean)**

When `logging_collector` is enabled, this parameter will cause PostgreSQL to truncate (overwrite), rather than append to, any existing log file of the same name. However, truncation will occur only when a new file is being opened due to time-based rotation, not during server startup or size-based rotation. When off, pre-existing files will be appended to in all cases. For example, using this setting in combination with a log filename like `postgresql-%H.log` would result in generating twenty-four hourly log files and then cyclically overwriting them. This parameter can only be set in the `postgresql.conf` file or on the server command line.

Example: To keep 7 days of logs, one log file per day named `server_log.Mon`, `server_log.Tue`, etc, and automatically overwrite last week’s log with this week’s log, set `log_filename` to `server_log.%a`, `log_truncate_on_rotation` to `on`, and `log_rotation_age` to 1440.

Example: To keep 24 hours of logs, one log file per hour, but also rotate sooner if the log file size exceeds 1GB, set `log_filename` to `server_log.%H%M`, `log_truncate_on_rotation` to `on`, `log_rotation_age` to 60, and `log_rotation_size` to 1000000. Including `%M` in `log_filename` allows any size-driven rotations that might occur to select a file name different from the hour’s initial file name.

**syslog_facility (enum)**

When logging to syslog is enabled, this parameter determines the syslog “facility” to be used. You can choose from `LOCAL0`, `LOCAL1`, `LOCAL2`, `LOCAL3`, `LOCAL4`, `LOCAL5`, `LOCAL6`, `LOCAL7`; the default is `LOCAL0`. See also the documentation of your system’s syslog daemon. This parameter can only be set in the `postgresql.conf` file or on the server command line. This parameter is unavailable unless the server is compiled with support for syslog.

**syslog_ident (string)**

When logging to syslog is enabled, this parameter determines the program name used to identify PostgreSQL messages in syslog logs. The default is `postgres`. This parameter can only be set in the `postgresql.conf` file or on the server command line. This parameter is unavailable unless the server is compiled with support for syslog.

**silent_mode (boolean)**

Runs the server silently. If this parameter is set, the server will automatically run in background and disassociate from the controlling terminal. This parameter can only be set at server start.
Caution

When this parameter is set, the server’s standard output and standard error are redirected to the file `postmaster.log` within the data directory. There is no provision for rotating this file, so it will grow indefinitely unless server log output is redirected elsewhere by other settings. It is recommended that `log_destination` be set to `syslog` or that `logging_collector` be enabled when using this option. Even with those measures, errors reported early during startup may appear in `postmaster.log` rather than the normal log destination.

18.7.2. When To Log

`client_min_messages (enum)`

Controls which message levels are sent to the client. Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `LOG`, `NOTICE`, `WARNING`, `ERROR`, `FATAL`, and `PANIC`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The default is `NOTICE`. Note that `LOG` has a different rank here than in `log_min_messages`.

`log_min_messages (enum)`

Controls which message levels are written to the server log. Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `INFO`, `NOTICE`, `WARNING`, `ERROR`, `LOG`, `FATAL`, and `PANIC`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent to the log. The default is `WARNING`. Note that `LOG` has a different rank here than in `client_min_messages`. Only superusers can change this setting.

`log_error_verbosity (enum)`

Controls the amount of detail written in the server log for each message that is logged. Valid values are `TERSE`, `DEFAULT`, and `VERBOSE`, each adding more fields to displayed messages. Only superusers can change this setting.

`log_min_error_statement (enum)`

Controls whether or not the SQL statement that causes an error condition will be recorded in the server log. The current SQL statement is included in the log entry for any message of the specified severity or higher. Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `INFO`, `NOTICE`, `WARNING`, `ERROR`, `LOG`, `FATAL`, and `PANIC`. The default is `ERROR`, which means statements causing errors, log messages, fatal errors, or panics will be logged. To effectively turn off logging of failing statements, set this parameter to `PANIC`. Only superusers can change this setting.

`log_min_duration_statement (integer)`

Causes the duration of each completed statement to be logged if the statement ran for at least the specified number of milliseconds. Setting this to zero prints all statement durations. Minus-one (the default) disables logging statement durations. For example, if you set it to `250ms` then all SQL statements that run `250ms` or longer will be logged. Enabling this parameter can be helpful in tracking down unoptimized queries in your applications. Only superusers can change this setting.

For clients using extended query protocol, durations of the Parse, Bind, and Execute steps are logged independently.
Chapter 18. Server Configuration

**Note:** When using this option together with `log_statement`, the text of statements that are logged because of `log_statement` will not be repeated in the duration log message. If you are not using syslog, it is recommended that you log the PID or session ID using `log_line_prefix` so that you can link the statement message to the later duration message using the process ID or session ID.

Table 18-1 explains the message severity levels used by PostgreSQL. If logging output is sent to syslog or Windows’ eventlog, the severity levels are translated as shown in the table.

**Table 18-1. Message severity levels**

<table>
<thead>
<tr>
<th>Severity</th>
<th>Usage</th>
<th>syslog</th>
<th>eventlog</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEBUG1..DEBUG5</td>
<td>Provides successively-more-detailed information for use by developers.</td>
<td>DEBUG</td>
<td>INFORMATION</td>
</tr>
<tr>
<td>INFO</td>
<td>Provides information implicitly requested by the user, e.g., output from VACUUM VERBOSE.</td>
<td>INFO</td>
<td>INFORMATION</td>
</tr>
<tr>
<td>NOTICE</td>
<td>Provides information that might be helpful to users, e.g., notice of truncation of long identifiers.</td>
<td>NOTICE</td>
<td>INFORMATION</td>
</tr>
<tr>
<td>WARNING</td>
<td>Provides warnings of likely problems, e.g., COMMIT outside a transaction block.</td>
<td>NOTICE</td>
<td>WARNING</td>
</tr>
<tr>
<td>ERROR</td>
<td>Reports an error that caused the current command to abort.</td>
<td>WARNING</td>
<td>ERROR</td>
</tr>
<tr>
<td>LOG</td>
<td>Reports information of interest to administrators, e.g., checkpoint activity.</td>
<td>INFO</td>
<td>INFORMATION</td>
</tr>
<tr>
<td>FATAL</td>
<td>Reports an error that caused the current session to abort.</td>
<td>ERR</td>
<td>ERROR</td>
</tr>
<tr>
<td>PANIC</td>
<td>Reports an error that caused all database sessions to abort.</td>
<td>CRIT</td>
<td>ERROR</td>
</tr>
</tbody>
</table>
18.7.3. What To Log

debug_print_parse(boolean)
debug_print_rewritten(boolean)
debug_print_plan(boolean)

These parameters enable various debugging output to be emitted. When set, they print the resulting parse tree, the query rewriter output, or the execution plan for each executed query. These messages are emitted at LOG message level, so by default they will appear in the server log but will not be sent to the client. You can change that by adjusting client_min_messages and/or log_min_messages. These parameters are off by default.

debug_pretty_print(boolean)

When set, debug_pretty_print indents the messages produced by debug_print_parse, debug_print_rewritten, or debug_print_plan. This results in more readable but much longer output than the “compact” format used when it is off. It is on by default.

log_checkpoints(boolean)

Causes checkpoints to be logged in the server log. Some statistics about each checkpoint are included in the log messages, including the number of buffers written and the time spent writing them. This parameter can only be set in the postgresql.conf file or on the server command line. The default is off.

log_connections(boolean)

Causes each attempted connection to the server to be logged, as well as successful completion of client authentication. This parameter can only be set in the postgresql.conf file or on the server command line. The default is off.

Note: Some client programs, like psql, attempt to connect twice while determining if a password is required, so duplicate “connection received” messages do not necessarily indicate a problem.

log_disconnections(boolean)

This outputs a line in the server log similar to log_connections but at session termination, and includes the duration of the session. This is off by default. This parameter can only be set in the postgresql.conf file or on the server command line.

log_duration(boolean)

Causes the duration of every completed statement to be logged. The default is off. Only superusers can change this setting.

For clients using extended query protocol, durations of the Parse, Bind, and Execute steps are logged independently.

Note: The difference between setting this option and setting log_min_duration_statement to zero is that exceeding log_min_duration_statement forces the text of the query to be logged, but this option doesn’t. Thus, if log_duration is on and log_min_duration_statement has a positive value, all durations are logged but the query text is included only for statements exceeding the threshold. This behavior can be useful for gathering statistics in high-load installations.
log_hostname (boolean)

By default, connection log messages only show the IP address of the connecting host. Turning on this parameter causes logging of the host name as well. Note that depending on your host name resolution setup this might impose a non-negligible performance penalty. This parameter can only be set in the `postgresql.conf` file or on the server command line.

log_line_prefix (string)

This is a `printf`-style string that is output at the beginning of each log line. `%` characters begin “escape sequences” that are replaced with status information as outlined below. Unrecognized escapes are ignored. Other characters are copied straight to the log line. Some escapes are only recognized by session processes, and do not apply to background processes such as the main server process. This parameter can only be set in the `postgresql.conf` file or on the server command line. The default is an empty string.

<table>
<thead>
<tr>
<th>Escape</th>
<th>Effect</th>
<th>Session only</th>
</tr>
</thead>
<tbody>
<tr>
<td>%u</td>
<td>User name</td>
<td>yes</td>
</tr>
<tr>
<td>%d</td>
<td>Database name</td>
<td>yes</td>
</tr>
<tr>
<td>%r</td>
<td>Remote host name or IP address, and remote port</td>
<td>yes</td>
</tr>
<tr>
<td>%h</td>
<td>Remote host name or IP address</td>
<td>yes</td>
</tr>
<tr>
<td>%p</td>
<td>Process ID</td>
<td>no</td>
</tr>
<tr>
<td>%t</td>
<td>Time stamp without milliseconds</td>
<td>no</td>
</tr>
<tr>
<td>%m</td>
<td>Time stamp with milliseconds</td>
<td>no</td>
</tr>
<tr>
<td>%i</td>
<td>Command tag: type of session’s current command</td>
<td>yes</td>
</tr>
<tr>
<td>%c</td>
<td>Session ID: see below</td>
<td>no</td>
</tr>
<tr>
<td>%l</td>
<td>Number of the log line for each session or process, starting at 1</td>
<td>no</td>
</tr>
<tr>
<td>%s</td>
<td>Process start time stamp</td>
<td>no</td>
</tr>
<tr>
<td>%v</td>
<td>Virtual transaction ID (<code>backendID/localXID</code>)</td>
<td>no</td>
</tr>
<tr>
<td>%x</td>
<td>Transaction ID (0 if none is assigned)</td>
<td>no</td>
</tr>
<tr>
<td>%q</td>
<td>Produces no output, but tells non-session processes to stop at this point in the string; ignored by session processes</td>
<td>no</td>
</tr>
<tr>
<td>%</td>
<td>Literal %</td>
<td>no</td>
</tr>
</tbody>
</table>

The `%c` escape prints a quasi-unique session identifier, consisting of two 4-byte hexadecimal numbers (without leading zeros) separated by a dot. The numbers are the process start time and the process ID, so `%c` can also be used as a space saving way of printing those items. For example, to generate the session identifier from `pg_stat_activity`, use this query:

```
SELECT to_hex(EXTRACT(EPOCH FROM backend_start)::integer) || '.' ||
```
to_hex(procpid)
FROM pg_stat_activity;

**Tip:** If you set a nonempty value for `log_line_prefix`, you should usually make its last character be a space, to provide visual separation from the rest of the log line. A punctuation character could be used too.

**Tip:** Syslog produces its own time stamp and process ID information, so you probably do not want to use those escapes if you are logging to syslog.

```sql
log_lock_waits(boolean)
```

Controls whether a log message is produced when a session waits longer than `deadlock_timeout` to acquire a lock. This is useful in determining if lock waits are causing poor performance. The default is `off`.

```sql
log_statement(enum)
```

Controls which SQL statements are logged. Valid values are `none`, `ddl`, and `all`. DDL logs all data definition statements, such as `CREATE`, `ALTER`, and `DROP` statements. Mod logs all DDL statements, plus data-modifying statements such as `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, and `COPY FROM`, `PREPARE`, `EXECUTE`, and `EXPLAIN ANALYZE` statements are also logged if their contained command is of an appropriate type. For clients using extended query protocol, logging occurs when an Execute message is received, and values of the Bind parameters are included (with any embedded single-quote marks doubled).

The default is `none`. Only superusers can change this setting.

**Note:** Statements that contain simple syntax errors are not logged even by the `log_statement = all` setting, because the log message is emitted only after basic parsing has been done to determine the statement type. In the case of extended query protocol, this setting likewise does not log statements that fail before the Execute phase (i.e., during parse analysis or planning). Set `log_min_error_statement` to `ERROR` (or lower) to log such statements.

```sql
log_temp_files(integer)
```

Controls logging of use of temporary files. Temporary files can be created for sorts, hashes, and temporary query results. A log entry is made for each temporary file when it is deleted. A value of zero logs all temporary files, while positive values log only files whose size is greater than or equal to the specified number of kilobytes. The default setting is `-1`, which disables such logging. Only superusers can change this setting.

```sql
log_timezone(string)
```

Sets the time zone used for timestamps written in the log. Unlike `timezone`, this value is cluster-wide, so that all sessions will report timestamps consistently. The default is `unknown`, which means to use whatever the system environment specifies as the time zone. See Section 8.5.3 for more information. This parameter can only be set in the `postgresql.conf` file or on the server command line.
18.7.4. Using CSV-Format Log Output

Including `csvlog` in the `log_destination` list provides a convenient way to import log files into a database table. This option emits log lines in comma-separated-value format, with these columns:

- timestamp with milliseconds
- user name
- database name
- process ID
- host:port number
- session ID
- per-session or -process line number
- command tag
- session start time
- virtual transaction ID
- regular transaction id
- error severity
- SQL state code
- error message
- error message detail
- hint
- internal query that led to the error (if any)
- character count of the error position thereof
- error context
- user query that led to the error (if any and enabled by `log_min_error_statement`)
- character count of the error position thereof
- location of the error in the PostgreSQL source code (if `log_error_verbosity` is set to `verbose`).

Here is a sample table definition for storing CSV-format log output:

```sql
CREATE TABLE postgres_log
(
    log_time timestamp(3) with time zone,
    user_name text,
    database_name text,
    process_id integer,
    connection_from text,
    session_id text,
    session_line_num bigint,
    command_tag text,
    session_start_time timestamp with time zone,
    virtual_transaction_id text,
    transaction_id bigint,
    error_severity text,
    sql_state_code text,
    message text,
    detail text,
    hint text,
    internal_query text,
    internal_query_pos integer,
    context text,
    query text,
    query_pos integer,
    location text,
    PRIMARY KEY (session_id, session_line_num)
);
```

To import a log file into this table, use the `COPY FROM` command:

```sql
COPY postgres_log FROM '/full/path/to/logfile.csv' WITH csv;
```

There are a few things you need to do to simplify importing CSV log files easily and automatically:

1. Set `log_filename` and `log_rotation_age` to provide a consistent, predictable naming scheme for your log files. This lets you predict what the file name will be and know when an individual log file is complete and therefore ready to be imported.

2. Set `log_rotation_size` to 0 to disable size-based log rotation, as it makes the log file name difficult to predict.

3. Set `log_truncate_on_rotation` to `on` so that old log data isn’t mixed with the new in the same file.
4. The table definition above includes a primary key specification. This is useful to protect against accidentally importing the same information twice. The `COPY` command commits all of the data it imports at one time, so any error will cause the entire import to fail. If you import a partial log file and later import the file again when it is complete, the primary key violation will cause the import to fail. Wait until the log is complete and closed before importing. This procedure will also protect against accidentally importing a partial line that hasn’t been completely written, which would also cause `COPY` to fail.

### 18.8. Run-Time Statistics

#### 18.8.1. Query and Index Statistics Collector

These parameters control server-wide statistics collection features. When statistics collection is enabled, the data that is produced can be accessed via the `pg_stat` and `pg_statio` family of system views. Refer to Chapter 26 for more information.

**track_activities (boolean)**

Enables the collection of information on the currently executing command of each session, along with the time at which that command began execution. This parameter is on by default. Note that even when enabled, this information is not visible to all users, only to superusers and the user owning the session being reported on; so it should not represent a security risk. Only superusers can change this setting.

**track_activity_query_size (integer)**

Specifies the number of bytes reserved to track the currently executing command for each active session, for the `pg_stat_activity.current_query` field. The default value is 1024. This parameter can only be set at server start.

**track_counts (boolean)**

Enables collection of statistics on database activity. This parameter is on by default, because the autovacuum daemon needs the collected information. Only superusers can change this setting.

**track_functions (enum)**

Enables tracking of function call counts and time used. Specify `pl` to track only procedural-language functions, `all` to also track SQL and C language functions. The default is `none`, which disables function statistics tracking. Only superusers can change this setting.

**Note:** SQL-language functions that are simple enough to be “inlined” into the calling query will not be tracked, regardless of this setting.

**update_process_title (boolean)**

Enables updating of the process title every time a new SQL command is received by the server. The process title is typically viewed by the `ps` command, or in Windows by using the Process Explorer. Only superusers can change this setting.
stats_temp_directory (string)

Sets the directory to store temporary statistics data in. This can be a path relative to the data directory or an absolute path. The default is pg_stat_tmp. Pointing this at a RAM based filesystem will decrease physical I/O requirements and can lead to improved performance. This parameter can only be set in the postgresql.conf file or on the server command line.

18.8.2. Statistics Monitoring

log_statement_stats (boolean)
log_parser_stats (boolean)
log_planner_stats (boolean)
log_executor_stats (boolean)

For each query, write performance statistics of the respective module to the server log. This is a crude profiling instrument. log_statement_stats reports total statement statistics, while the others report per-module statistics. log_statement_stats cannot be enabled together with any of the per-module options. All of these options are disabled by default. Only superusers can change these settings.

18.9. Automatic Vacuuming

These settings control the behavior of the autovacuum feature. Refer to Section 23.1.5 for more information.

autovacuum (boolean)

Controls whether the server should run the autovacuum launcher daemon. This is on by default; however, track_counts must also be turned on for autovacuum to work. This parameter can only be set in the postgresql.conf file or on the server command line.

Note that even when this parameter is disabled, the system will launch autovacuum processes if necessary to prevent transaction ID wraparound. See Section 23.1.4 for more information.

log_autovacuum_min_duration (integer)

Causes each action executed by autovacuum to be logged if it ran for at least the specified number of milliseconds. Setting this to zero logs all autovacuum actions. Minus-one (the default) disables logging autovacuum actions. For example, if you set this to 250ms then all automatic vacuums and analyzes that run 250ms or longer will be logged. Enabling this parameter can be helpful in tracking autovacuum activity. This setting can only be set in the postgresql.conf file or on the server command line.

autovacuum_max_workers (integer)

Specifies the maximum number of autovacuum processes (other than the autovacuum launcher) which may be running at any one time. The default is three. This parameter can only be set in the postgresql.conf file or on the server command line.

autovacuum_naptime (integer)

Specifies the minimum delay between autovacuum runs on any given database. In each round the daemon examines the database and issues VACUUM and ANALYZE commands as needed for
Chapter 18. Server Configuration

tables in that database. The delay is measured in seconds, and the default is one minute (1m). This parameter can only be set in the postgresql.conf file or on the server command line.

**autovacuum_vacuum_threshold (integer)**

Specifies the minimum number of updated or deleted tuples needed to trigger a VACUUM in any one table. The default is 50 tuples. This parameter can only be set in the postgresql.conf file or on the server command line. This setting can be overridden for individual tables by changing storage parameters.

**autovacuum_analyze_threshold (integer)**

Specifies the minimum number of inserted, updated or deleted tuples needed to trigger an ANALYZE in any one table. The default is 50 tuples. This parameter can only be set in the postgresql.conf file or on the server command line. This setting can be overridden for individual tables by changing storage parameters.

**autovacuum_vacuum_scale_factor (floating point)**

Specifies a fraction of the table size to add to autovacuum_vacuum_threshold when deciding whether to trigger a VACUUM. The default is 0.2 (20% of table size). This parameter can only be set in the postgresql.conf file or on the server command line. This setting can be overridden for individual tables by changing storage parameters.

**autovacuum_analyze_scale_factor (floating point)**

Specifies a fraction of the table size to add to autovacuum_analyze_threshold when deciding whether to trigger an ANALYZE. The default is 0.1 (10% of table size). This parameter can only be set in the postgresql.conf file or on the server command line. This setting can be overridden for individual tables by changing storage parameters.

**autovacuum_freeze_max_age (integer)**

Specifies the maximum age (in transactions) that a table’s pg_class.relrofxidx field can attain before a VACUUM operation is forced to prevent transaction ID wraparound within the table. Note that the system will launch autovacuum processes to prevent wraparound even when autovacuum is otherwise disabled. The default is 200 million transactions. This parameter can only be set at server start, but the setting can be reduced for individual tables by changing storage parameters. For more information see Section 23.1.4.

**autovacuum_vacuum_cost_delay (integer)**

Specifies the cost delay value that will be used in automatic VACUUM operations. If -1 is specified, the regular vacuum_cost_delay value will be used. The default value is 20 milliseconds. This parameter can only be set in the postgresql.conf file or on the server command line. This setting can be overridden for individual tables by changing storage parameters.

**autovacuum_vacuum_cost_limit (integer)**

Specifies the cost limit value that will be used in automatic VACUUM operations. If -1 is specified (which is the default), the regular vacuum_cost_limit value will be used. Note that the value is distributed proportionally among the running autovacuum workers, if there is more than one, so that the sum of the limits of each worker never exceeds the limit on this variable. This parameter can only be set in the postgresql.conf file or on the server command line. This setting can be overridden for individual tables by changing storage parameters.
18.10. Client Connection Defaults

18.10.1. Statement Behavior

search_path(string)

This variable specifies the order in which schemas are searched when an object (table, data type, function, etc.) is referenced by a simple name with no schema component. When there are objects of identical names in different schemas, the one found first in the search path is used. An object that is not in any of the schemas in the search path can only be referenced by specifying its containing schema with a qualified (dotted) name.

The value for search_path has to be a comma-separated list of schema names. If one of the list items is the special value $user, then the schema having the name returned by SESSION_USER is substituted, if there is such a schema. (If not, $user is ignored.)

The system catalog schema, pg_catalog, is always searched, whether it is mentioned in the path or not. If it is mentioned in the path then it will be searched in the specified order. If pg_catalog is not in the path then it will be searched before searching any of the path items.

Likewise, the current session’s temporary-table schema, pg_temp_nnn, is always searched if it exists. It can be explicitly listed in the path by using the alias pg_temp. If it is not listed in the path then it is searched first (before even pg_catalog). However, the temporary schema is only searched for relation (table, view, sequence, etc) and data type names. It will never be searched for function or operator names.

When objects are created without specifying a particular target schema, they will be placed in the first schema listed in the search path. An error is reported if the search path is empty.

The default value for this parameter is ‘"$user", public’ (where the second part will be ignored if there is no schema named public). This supports shared use of a database (where no users have private schemas, and all share use of public), private per-user schemas, and combinations of these. Other effects can be obtained by altering the default search path setting, either globally or per-user.

The current effective value of the search path can be examined via the SQL function current_schemas(). This is not quite the same as examining the value of search_path, since current_schemas() shows how the requests appearing in search_path were resolved.

For more information on schema handling, see Section 5.7.

default_tablespace(string)

This variable specifies the default tablespace in which to create objects (tables and indexes) when a CREATE command does not explicitly specify a tablespace.

The value is either the name of a tablespace, or an empty string to specify using the default tablespace of the current database. If the value does not match the name of any existing tablespace, PostgreSQL will automatically use the default tablespace of the current database. If a nondefault tablespace is specified, the user must have CREATE privilege for it, or creation attempts will fail.

This variable is not used for temporary tables; for them, temp_tablespaces is consulted instead.

For more information on tablespaces, see Section 21.6.
temp_tablespaces (string)

This variable specifies tablespace(s) in which to create temporary objects (temp tables and
indexes on temp tables) when a CREATE command does not explicitly specify a tablespace. Temp-
orary files for purposes such as sorting large data sets are also created in these tablespace(s).

The value is a list of names of tablespaces. When there is more than one name in the list, Post-
greSQL chooses a random member of the list each time a temporary object is to be created;
except that within a transaction, successively created temporary objects are placed in successive
tablespaces from the list. If the selected element of the list is an empty string, PostgreSQL will
automatically use the default tablespace of the current database instead.

When temp_tablespaces is set interactively, specifying a nonexistent tablespace is an er-
ror, as is specifying a tablespace for which the user does not have CREATE privilege. However,
when using a previously set value, nonexistent tablespaces are ignored, as are tablespaces for
which the user lacks CREATE privilege. In particular, this rule applies when using a value set in
postgresql.conf.

The default value is an empty string, which results in all temporary objects being created in the
default tablespace of the current database.

See also default_tablespace.

check_function_bodies (boolean)

This parameter is normally on. When set to off, it disables validation of the function body string
during CREATE FUNCTION. Disabling validation avoids side effects of the validation process
and avoids false positives due to problems such as forward references. Set this parameter to off
before loading functions on behalf of other users; pg_dump does so automatically.

default_transaction_isolation (enum)

Each SQL transaction has an isolation level, which can be either “read uncommitted”, “read
committed”, “repeatable read”, or “serializable”. This parameter controls the default isolation
level of each new transaction. The default is “read committed”.

Consult Chapter 13 and SET TRANSACTION for more information.

default_transaction_read_only (boolean)

A read-only SQL transaction cannot alter non-temporary tables. This parameter controls the
default read-only status of each new transaction. The default is off (read/write).

Consult SET TRANSACTION for more information.

session_replication_role (enum)

Controls firing of replication-related triggers and rules for the current session. Setting this vari-
able requires superuser privilege and results in discarding any previously cached query plans.
Possible values are origin (the default), replica and local. See ALTER TABLE for more
information.

statement_timeout (integer)

Abort any statement that takes over the specified number of milliseconds, starting from the time
the command arrives at the server from the client. If log_min_error_statement is set to
ERROR or lower, the statement that timed out will also be logged. A value of zero (the default)
turns off the limitation.

Setting statement_timeout in postgresql.conf is not recommended because it affects all
sessions.
vacuum_freeze_table_age (integer)

VACUUM performs a whole-table scan if the table’s pg_class.relfrozenxid field has reached the age specified by this setting. The default is 150 million transactions. Although users can set this value anywhere from zero to one billion, VACUUM will silently limit the effective value to 95% of autovacuum_freeze_max_age, so that a periodical manual VACUUM has a chance to run before an anti-wraparound autovacuum is launched for the table. For more information see Section 23.1.4.

vacuum_freeze_min_age (integer)

Specifies the cutoff age (in transactions) that VACUUM should use to decide whether to replace transaction IDs with FrozenXID while scanning a table. The default is 50 million transactions. Although users can set this value anywhere from zero to one billion, VACUUM will silently limit the effective value to half the value of autovacuum_freeze_max_age, so that there is not an unreasonably short time between forced autovacuums. For more information see Section 23.1.4.

xmlbinary (enum)

Sets how binary values are to be encoded in XML. This applies for example when bytea values are converted to XML by the functions xmlelement or xmlforest. Possible values are base64 and hex, which are both defined in the XML Schema standard. The default is base64. For further information about XML-related functions, see Section 9.14.

The actual choice here is mostly a matter of taste, constrained only by possible restrictions in client applications. Both methods support all possible values, although the hex encoding will be somewhat larger than the base64 encoding.

xmloption (enum)

Sets whether DOCUMENT or CONTENT is implicit when converting between XML and character string values. See Section 8.13 for a description of this. Valid values are DOCUMENT and CONTENT. The default is CONTENT.

According to the SQL standard, the command to set this option is

```sql
SET XML OPTION { DOCUMENT | CONTENT };
```

This syntax is also available in PostgreSQL.

18.10.2. Locale and Formatting

DateStyle (string)

Sets the display format for date and time values, as well as the rules for interpreting ambiguous date input values. For historical reasons, this variable contains two independent components: the output format specification (ISO, Postgres, SQL, or German) and the input/output specification for year/month/day ordering (DMY, MDY, or YMD). These can be set separately or together. The keywords Euro and European are synonyms for DMY; the keywords US, NonEuro, and NonEuropean are synonyms for MDY. See Section 8.5 for more information. The built-in default is ISO, MDY, but initdb will initialize the configuration file with a setting that corresponds to the behavior of the chosen lc_time locale.

IntervalStyle (enum)

Sets the display format for interval values. The value sql_standard will produce output matching SQL standard interval literals. The value postgres (which is the default) will produce output matching PostgreSQL releases prior to 8.4 when the DateStyle parameter was set to ISO. The value postgres_verbose will produce output matching PostgreSQL releases prior to 8.4
when the DateStyle parameter was set to non-ISO output. The value iso_8601 will produce output matching the time interval “format with designators” defined in section 4.4.3.2 of ISO 8601.

The IntervalStyle parameter also affects the interpretation of ambiguous interval input. See Section 8.5.4 for more information.

timezone (string)
Sets the time zone for displaying and interpreting time stamps. The default is unknown, which means to use whatever the system environment specifies as the time zone. See Section 8.5.3 for more information.

timezone_abbreviations (string)
Sets the collection of time zone abbreviations that will be accepted by the server for datetime input. The default is ‘Default’, which is a collection that works in most of the world; there are also ‘Australia’ and ‘India’, and other collections can be defined for a particular installation. See Appendix B for more information.

extra_float_digits (integer)
This parameter adjusts the number of digits displayed for floating-point values, including float4, float8, and geometric data types. The parameter value is added to the standard number of digits (FLT_DIG or DBL_DIG as appropriate). The value can be set as high as 2, to include partially-significant digits; this is especially useful for dumping float data that needs to be restored exactly. Or it can be set negative to suppress unwanted digits. See also Section 8.1.3.

client_encoding (string)
Sets the client-side encoding (character set). The default is to use the database encoding.

lc_messages (string)
Sets the language in which messages are displayed. Acceptable values are system-dependent; see Section 22.1 for more information. If this variable is set to the empty string (which is the default) then the value is inherited from the execution environment of the server in a system-dependent way.

On some systems, this locale category does not exist. Setting this variable will still work, but there will be no effect. Also, there is a chance that no translated messages for the desired language exist. In that case you will continue to see the English messages.

Only superusers can change this setting, because it affects the messages sent to the server log as well as to the client.

lc_monetary (string)
Sets the locale to use for formatting monetary amounts, for example with the to_char family of functions. Acceptable values are system-dependent; see Section 22.1 for more information. If this variable is set to the empty string (which is the default) then the value is inherited from the execution environment of the server in a system-dependent way.

lc_numeric (string)
Sets the locale to use for formatting numbers, for example with the to_char family of functions. Acceptable values are system-dependent; see Section 22.1 for more information. If this variable is set to the empty string (which is the default) then the value is inherited from the execution environment of the server in a system-dependent way.
Chapter 18. Server Configuration

lc_time (string)

Sets the locale to use for formatting dates and times, for example with the to_char family of functions. Acceptable values are system-dependent; see Section 22.1 for more information. If this variable is set to the empty string (which is the default) then the value is inherited from the execution environment of the server in a system-dependent way.

default_text_search_config (string)

Selects the text search configuration that is used by those variants of the text search functions that do not have an explicit argument specifying the configuration. See Chapter 12 for further information. The built-in default is pg_catalog.simple, but initdb will initialize the configuration file with a setting that corresponds to the chosen lc_ctype locale, if a configuration matching that locale can be identified.

18.10.3. Other Defaults

dynamic_library_path (string)

If a dynamically loadable module needs to be opened and the file name specified in the CREATE FUNCTION or LOAD command does not have a directory component (i.e., the name does not contain a slash), the system will search this path for the required file.

The value for dynamic_library_path has to be a list of absolute directory paths separated by colons (or semi-colons on Windows). If a list element starts with the special string $libdir, the compiled-in PostgreSQL package library directory is substituted for $libdir. This is where the modules provided by the standard PostgreSQL distribution are installed. (Use pg_config --pkglibdir to find out the name of this directory.) For example:
dynamic_library_path = '/usr/local/lib/postgresql:/home/my_project/lib:$libdir'
or, in a Windows environment:
dynamic_library_path = 'C:\tools\postgresql;H:\my_project\lib;$libdir'
The default value for this parameter is '$libdir'. If the value is set to an empty string, the automatic path search is turned off.

This parameter can be changed at run time by superusers, but a setting done that way will only persist until the end of the client connection, so this method should be reserved for development purposes. The recommended way to set this parameter is in the postgresql.conf configuration file.

gin_fuzzy_search_limit (integer)

Soft upper limit of the size of the set returned by GIN index. For more information see Section 52.4.

local_preload_libraries (string)

This variable specifies one or more shared libraries that are to be preloaded at connection start. If more than one library is to be loaded, separate their names with commas. This parameter cannot be changed after the start of a particular session.

Because this is not a superuser-only option, the libraries that can be loaded are restricted to those appearing in the plugins subdirectory of the installation’s standard library directory. (It is the database administrator’s responsibility to ensure that only “safe” libraries are installed there.) Entries in local_preload_libraries can specify this directory explicitly, for example $libdir/plugins/mylib, or just specify the library name — mylib would have the same effect as $libdir/plugins/mylib.
There is no performance advantage to loading a library at session start rather than when it is first used. Rather, the intent of this feature is to allow debugging or performance-measurement libraries to be loaded into specific sessions without an explicit \texttt{LOAD} command being given. For example, debugging could be enabled for all sessions under a given user name by setting this parameter with \texttt{ALTER USER SET}.

If a specified library is not found, the connection attempt will fail.

Every PostgreSQL-supported library has a “magic block” that is checked to guarantee compatibility. For this reason, non-PostgreSQL libraries cannot be loaded in this way.

### 18.11. Lock Management

**deadlock_timeout (integer)**

This is the amount of time, in milliseconds, to wait on a lock before checking to see if there is a deadlock condition. The check for deadlock is relatively slow, so the server doesn’t run it every time it waits for a lock. We optimistically assume that deadlocks are not common in production applications and just wait on the lock for a while before starting the check for a deadlock. Increasing this value reduces the amount of time wasted in needless deadlock checks, but slows down reporting of real deadlock errors. The default is one second (\texttt{1s}), which is probably about the smallest value you would want in practice. On a heavily loaded server you might want to raise it. Ideally the setting should exceed your typical transaction time, so as to improve the odds that a lock will be released before the waiter decides to check for deadlock.

When \texttt{log_lock_waits} is set, this parameter also determines the length of time to wait before a log message is issued about the lock wait. If you are trying to investigate locking delays you might want to set a shorter than normal \texttt{deadlock_timeout}.

**max_locks_per_transaction (integer)**

The shared lock table is created to track locks on \texttt{max_locks_per_transaction} * (\texttt{max_connections} + \texttt{max_prepared_transactions}) objects (e.g., tables); hence, no more than this many distinct objects can be locked at any one time. This parameter controls the average number of object locks allocated for each transaction; individual transactions can lock more objects as long as the locks of all transactions fit in the lock table. This is not the number of rows that can be locked; that value is unlimited. The default, 64, has historically proven sufficient, but you might need to raise this value if you have clients that touch many different tables in a single transaction. This parameter can only be set at server start.

Increasing this parameter might cause PostgreSQL to request more System V shared memory than your operating system’s default configuration allows. See Section 17.4.1 for information on how to adjust those parameters, if necessary.
18.12. Version and Platform Compatibility

18.12.1. Previous PostgreSQL Versions

add_missing_from (boolean)

When on, tables that are referenced by a query will be automatically added to the FROM clause if not already present. This behavior does not comply with the SQL standard and many people dislike it because it can mask mistakes (such as referencing a table where you should have referenced its alias). The default is off. This variable can be enabled for compatibility with releases of PostgreSQL prior to 8.1, where this behavior was allowed by default.

Note that even when this variable is enabled, a warning message will be emitted for each implicit FROM entry referenced by a query. Users are encouraged to update their applications to not rely on this behavior, by adding all tables referenced by a query to the query’s FROM clause (or its USING clause in the case of DELETE).

array_nulls (boolean)

This controls whether the array input parser recognizes unquoted NULL as specifying a null array element. By default, this is on, allowing array values containing null values to be entered. However, PostgreSQL versions before 8.2 did not support null values in arrays, and therefore would treat NULL as specifying a normal array element with the string value “NULL”. For backwards compatibility with applications that require the old behavior, this variable can be turned off.

Note that it is possible to create array values containing null values even when this variable is off.

backslash_quote (enum)

This controls whether a quote mark can be represented by \’ in a string literal. The preferred, SQL-standard way to represent a quote mark is by doubling it (“”) but PostgreSQL has historically also accepted \’. However, use of \’ creates security risks because in some client character set encodings, there are multibyte characters in which the last byte is numerically equivalent to ASCII \. If client-side code does escaping incorrectly then a SQL-injection attack is possible. This risk can be prevented by making the server reject queries in which a quote mark appears to be escaped by a backslash. The allowed values of backslash_quote are on (allow \’ always), off (reject always), and safe_encoding (allow only if client encoding does not allow ASCII \ within a multibyte character). safe_encoding is the default setting.

Note that in a standard-conforming string literal, \ just means \ anyway. This parameter affects the handling of non-standard-conforming literals, including escape string syntax (E’...’).

default_with_oids (boolean)

This controls whether CREATE TABLE and CREATE TABLE AS include an OID column in newly-created tables, if neither WITH OIDS nor WITHOUT OIDS is specified. It also determines whether OIDs will be included in tables created by SELECT INTO. In PostgreSQL 8.1 default_with_oids is off by default; in prior versions of PostgreSQL, it was on by default.

The use of OIDs in user tables is considered deprecated, so most installations should leave this variable disabled. Applications that require OIDs for a particular table should specify WITH OIDS when creating the table. This variable can be enabled for compatibility with old applications that do not follow this behavior.
escape_string_warning (boolean)

When on, a warning is issued if a backslash (\) appears in an ordinary string literal ("...") syntax and standard_conforming_strings is off. The default is on.

Applications that wish to use backslash as escape should be modified to use escape string syntax (E'...' syntax), because the default behavior of ordinary strings will change in a future release for SQL compatibility. This variable can be enabled to help detect applications that will break.

regex_flavor (enum)

The regular expression “flavor” can be set to advanced, extended, or basic. The default is advanced. The extended setting might be useful for exact backwards compatibility with pre-7.4 releases of PostgreSQL. See Section 9.7.3.1 for details.

sql_inheritance (boolean)

This setting controls whether undecorated table references are considered to include inheritance child tables. The default is on, which means child tables are included (thus, a * suffix is assumed by default). If turned off, child tables are not included (thus, an ONLY prefix is assumed). The SQL standard requires child tables to be included, so the off setting is not spec-compliant, but it is provided for compatibility with PostgreSQL releases prior to 7.1. See Section 5.8 for more information.

Turning sql_inheritance off is deprecated, because that behavior has been found to be error-prone as well as contrary to SQL standard. Discussions of inheritance behavior elsewhere in this manual generally assume that it is on.

standard_conforming_strings (boolean)

This controls whether ordinary string literals ("...") treat backslashes literally, as specified in the SQL standard. The default is currently off, causing PostgreSQL to have its historical behavior of treating backslashes as escape characters. The default will change to on in a future release to improve compatibility with the standard. Applications can check this parameter to determine how string literals will be processed. The presence of this parameter can also be taken as an indication that the escape string syntax (E'...' syntax) is supported. Escape string syntax should be used if an application desires backslashes to be treated as escape characters.

synchronize_seqscans (boolean)

This allows sequential scans of large tables to synchronize with each other, so that concurrent scans read the same block at about the same time and hence share the I/O workload. When this is enabled, a scan might start in the middle of the table and then “wrap around” the end to cover all rows, so as to synchronize with the activity of scans already in progress. This can result in unpredictable changes in the row ordering returned by queries that have no ORDER BY clause. Setting this parameter to off ensures the pre-8.3 behavior in which a sequential scan always starts from the beginning of the table. The default is on.

18.12.2. Platform and Client Compatibility

transform_null_equals (boolean)

When on, expressions of the form expr = NULL (or NULL = expr) are treated as expr IS NULL, that is, they return true if expr evaluates to the null value, and false otherwise. The correct SQL-spec-compliant behavior of expr = NULL is to always return null (unknown). Therefore this parameter defaults to off.
However, filtered forms in Microsoft Access generate queries that appear to use \texttt{expr = NULL} to test for null values, so if you use that interface to access the database you might want to turn this option on. Since expressions of the form \texttt{expr = NULL} always return the null value (using the correct interpretation) they are not very useful and do not appear often in normal applications, so this option does little harm in practice. But new users are frequently confused about the semantics of expressions involving null values, so this option is not on by default.

Note that this option only affects the exact form \texttt{= NULL}, not other comparison operators or other expressions that are computationally equivalent to some expression involving the equals operator (such as \texttt{IN}). Thus, this option is not a general fix for bad programming.

Refer to Section 9.2 for related information.

### 18.13. Preset Options

The following “parameters” are read-only, and are determined when PostgreSQL is compiled or when it is installed. As such, they have been excluded from the sample \texttt{postgresql.conf} file. These options report various aspects of PostgreSQL behavior that might be of interest to certain applications, particularly administrative front-ends.

\texttt{block\_size (integer)}

Reports the size of a disk block. It is determined by the value of \texttt{BLCKSZ} when building the server. The default value is 8192 bytes. The meaning of some configuration variables (such as \texttt{shared\_buffers}) is influenced by \texttt{block\_size}. See Section 18.4 for information.

\texttt{integer\_datetimes (boolean)}

Reports whether PostgreSQL was built with support for 64-bit-integer dates and times. This can be disabled by configuring with \texttt{--disable-integer-datetime} when building PostgreSQL. The default value is \texttt{on}.

\texttt{lc\_collate (string)}

Reports the locale in which sorting of textual data is done. See Section 22.1 for more information. This value is determined when a database is created.

\texttt{lc\_ctype (string)}

Reports the locale that determines character classifications. See Section 22.1 for more information. This value is determined when a database is created. Ordinarily this will be the same as \texttt{lc\_collate}, but for special applications it might be set differently.

\texttt{max\_function\_args (integer)}

Reports the maximum number of function arguments. It is determined by the value of \texttt{FUNC\_MAX\_ARGS} when building the server. The default value is 100 arguments.

\texttt{max\_identifier\_length (integer)}

Reports the maximum identifier length. It is determined as one less than the value of \texttt{NAMEDATA\_LEN} when building the server. The default value of \texttt{NAMEDATA\_LEN} is 64; therefore the default \texttt{max\_identifier\_length} is 63 bytes.

\texttt{max\_index\_keys (integer)}

Reports the maximum number of index keys. It is determined by the value of \texttt{INDEX\_MAX\_KEYS} when building the server. The default value is 32 keys.
18.14. Customized Options

This feature was designed to allow parameters not normally known to PostgreSQL to be added by add-on modules (such as procedural languages). This allows add-on modules to be configured in the standard ways.

**custom_variable_classes (string)**

This variable specifies one or several class names to be used for custom variables, in the form of a comma-separated list. A custom variable is a variable not normally known to PostgreSQL proper but used by some add-on module. Such variables must have names consisting of a class name, a dot, and a variable name. `custom_variable_classes` specifies all the class names in use in a particular installation. This parameter can only be set in the `postgresql.conf` file or on the server command line.

The difficulty with setting custom variables in `postgresql.conf` is that the file must be read before add-on modules have been loaded, and so custom variables would ordinarily be rejected as unknown. When `custom_variable_classes` is set, the server will accept definitions of arbitrary variables within each specified class. These variables will be treated as placeholders and will have no function until the module that defines them is loaded. When a module for a specific class is loaded, it will add the proper variable definitions for its class name, convert any placeholder values according to those definitions, and issue warnings for any placeholders of its class that remain (which presumably would be misspelled configuration variables).

Here is an example of what `postgresql.conf` might contain when using custom variables:

```plaintext
custom_variable_classes = 'plr,plperl'
```
18.15. Developer Options

The following parameters are intended for work on the PostgreSQL source, and in some cases to assist with recovery of severely damaged databases. There should be no reason to use them in a production database setup. As such, they have been excluded from the sample `postgresql.conf` file. Note that many of these parameters require special source compilation flags to work at all.

`allow_system_table_mods (boolean)`

Allows modification of the structure of system tables. This is used by `initdb`. This parameter can only be set at server start.

`debug Assertions (boolean)`

Turns on various assertion checks. This is a debugging aid. If you are experiencing strange problems or crashes you might want to turn this on, as it might expose programming mistakes. To use this parameter, the macro `USE_ASSERT_CHECKING` must be defined when PostgreSQL is built (accomplished by the `configure` option `--enable-cassert`). Note that `debug Assertions` defaults to `on` if PostgreSQL has been built with assertions enabled.

`ignore_system_indexes (boolean)`

Ignore system indexes when reading system tables (but still update the indexes when modifying the tables). This is useful when recovering from damaged system indexes. This parameter cannot be changed after session start.

`post_auth Delay (integer)`

If nonzero, a delay of this many seconds occurs when a new server process is started, after it conducts the authentication procedure. This is intended to give an opportunity to attach to the server process with a debugger. This parameter cannot be changed after session start.

`pre_auth Delay (integer)`

If nonzero, a delay of this many seconds occurs just after a new server process is forked, before it conducts the authentication procedure. This is intended to give an opportunity to attach to the server process with a debugger to trace down misbehavior in authentication. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`trace_notify (boolean)`

Generates a great amount of debugging output for the `LISTEN` and `NOTIFY` commands. `client_min_messages` or `log_min_messages` must be `DEBUG1` or lower to send this output to the client or server log, respectively.

`trace_sort (boolean)`

If on, emit information about resource usage during sort operations. This parameter is only available if the `TRACE_SORT` macro was defined when PostgreSQL was compiled. (However, `TRACE_SORT` is currently defined by default.)
trace_locks (boolean)
If on, emit information about lock usage. Information dumped includes the type of lock operation, the type of lock and the unique identifier of the object being locked or unlocked. Also included are bitmasks for the lock types already granted on this object as well as for the lock types awaited on this object. For each lock type a count of the number of granted locks and waiting locks is also dumped as well as the totals. An example of the log file output is shown here:

LOG: LockAcquire: new: lock(0xb7acd844) id(24688,24696,0,0,0,1) grantMask(0)
req(0,0,0,0,0,0)=0 grant(0,0,0,0,0,0)=0 wait(0) type(AccessShareLock)
LOG: GrantLock: lock(0xb7acd844) id(24688,24696,0,0,0,1) grantMask(2) req(1,0,0,0,0,0)=1
grant(1,0,0,0,0,0)=1 wait(0) type(AccessShareLock)
LOG: UnGrantLock: updated: lock(0xb7acd844) id(24688,24696,0,0,0,1) grantMask(0)
req(0,0,0,0,0,0)=0 grant(0,0,0,0,0,0)=0 wait(0) type(AccessShareLock)
LOG: CleanUpLock: deleting: lock(0xb7acd844) id(24688,24696,0,0,0,1) grantMask(0)
req(0,0,0,0,0,0)=0 grant(0,0,0,0,0,0)=0 wait(0) type(INVALID)
Details of the structure being dumped may be found in src/include/storage/lock.h
This parameter is only available if the LOCK_DEBUG macro was defined when PostgreSQL was compiled.

trace_lwlocks (boolean)
If on, emit information about lightweight lock usage. Lightweight locks are intended primarily to provide mutual exclusion of access to shared-memory data structures.
This parameter is only available if the LOCK_DEBUG macro was defined when PostgreSQL was compiled.

trace_userlocks (boolean)
If on, emit information about user lock usage. Output is the same as for trace_locks, only for advisory locks.
This parameter is only available if the LOCK_DEBUG macro was defined when PostgreSQL was compiled.

trace_lock_oidmin (integer)
If set, do not trace locks for tables below this OID. (use to avoid output on system tables)
This parameter is only available if the LOCK_DEBUG macro was defined when PostgreSQL was compiled.

trace_lock_table (integer)
Unconditionally trace locks on this table (OID).
This parameter is only available if the LOCK_DEBUG macro was defined when PostgreSQL was compiled.

deadlocks (boolean)
If set, dumps information about all current locks when a DeadLockTimeout occurs.
This parameter is only available if the LOCK_DEBUG macro was defined when PostgreSQL was compiled.

log_btree_build_stats (boolean)
If set, logs system resource usage statistics (memory and CPU) on various btree operations.
This parameter is only available if the BTREE_BUILD_STATS macro was defined when PostgreSQL was compiled.

`wal_debug(boolean)`

If on, emit WAL-related debugging output. This parameter is only available if the WAL_DEBUG macro was defined when PostgreSQL was compiled.

`zero_damaged_pages(boolean)`

Detection of a damaged page header normally causes PostgreSQL to report an error, aborting the current command. Setting `zero_damaged_pages` to on causes the system to instead report a warning, zero out the damaged page, and continue processing. This behavior will destroy data, namely all the rows on the damaged page. But it allows you to get past the error and retrieve rows from any undamaged pages that might be present in the table. So it is useful for recovering data if corruption has occurred due to hardware or software error. You should generally not set this on until you have given up hope of recovering data from the damaged page(s) of a table. The default setting is off, and it can only be changed by a superuser.

### 18.16. Short Options

For convenience there are also single letter command-line option switches available for some parameters. They are described in Table 18-2. Some of these options exist for historical reasons, and their presence as a single-letter option does not necessarily indicate an endorsement to use the option heavily.

**Table 18-2. Short option key**

Chapter 19. Client Authentication

When a client application connects to the database server, it specifies which PostgreSQL database user name it wants to connect as, much the same way one logs into a Unix computer as a particular user. Within the SQL environment the active database user name determines access privileges to database objects — see Chapter 20 for more information. Therefore, it is essential to restrict which database users can connect.

Note: As explained in Chapter 20, PostgreSQL actually does privilege management in terms of “roles”. In this chapter, we consistently use database user to mean “role with the LOGIN privilege”.

Authentication is the process by which the database server establishes the identity of the client, and by extension determines whether the client application (or the user who runs the client application) is permitted to connect with the database user name that was requested.

PostgreSQL offers a number of different client authentication methods. The method used to authenticate a particular client connection can be selected on the basis of (client) host address, database, and user.

PostgreSQL database user names are logically separate from user names of the operating system in which the server runs. If all the users of a particular server also have accounts on the server’s machine, it makes sense to assign database user names that match their operating system user names. However, a server that accepts remote connections might have many database users who have no local operating system account, and in such cases there need be no connection between database user names and OS user names.

19.1. The pg_hba.conf file

Client authentication is controlled by a configuration file, which traditionally is named pg_hba.conf and is stored in the database cluster’s data directory. (HBA stands for host-based authentication.) A default pg_hba.conf file is installed when the data directory is initialized by initdb. It is possible to place the authentication configuration file elsewhere, however; see the hba_file configuration parameter.

The general format of the pg_hba.conf file is a set of records, one per line. Blank lines are ignored, as is any text after the # comment character. A record is made up of a number of fields which are separated by spaces and/or tabs. Fields can contain white space if the field value is quoted. Records cannot be continued across lines.

Each record specifies a connection type, a client IP address range (if relevant for the connection type), a database name, a user name, and the authentication method to be used for connections matching these parameters. The first record with a matching connection type, client address, requested database, and user name is used to perform authentication. There is no “fall-through” or “backup”: if one record is chosen and the authentication fails, subsequent records are not considered. If no record matches, access is denied.

A record can have one of the seven formats

```
local  database  user  auth-method  [auth-options]
host   database  user  CIDR-address auth-method  [auth-options]
hostssl database  user  CIDR-address auth-method  [auth-options]
hostnossl database user  CIDR-address auth-method  [auth-options]
```
Chapter 19. Client Authentication

The meaning of the fields is as follows:

**local**
This record matches connection attempts using Unix-domain sockets. Without a record of this type, Unix-domain socket connections are disallowed.

**host**
This record matches connection attempts made using TCP/IP. **host** records match either SSL or non-SSL connection attempts.

**Note:** Remote TCP/IP connections will not be possible unless the server is started with an appropriate value for the `listen_addresses` configuration parameter, since the default behavior is to listen for TCP/IP connections only on the local loopback address `localhost`.

**hostssl**
This record matches connection attempts made using TCP/IP, but only when the connection is made with SSL encryption.

To make use of this option the server must be built with SSL support. Furthermore, SSL must be enabled at server start time by setting the `ssl` configuration parameter (see Section 17.8 for more information).

**hostnossl**
This record type has the opposite logic to **hostssl**: it only matches connection attempts made over TCP/IP that do not use SSL.

**database**
Specifies which database name(s) this record matches. The value `all` specifies that it matches all databases. The value `sameuser` specifies that the record matches if the requested database has the same name as the requested user. The value `samerole` specifies that the requested user must be a member of the role with the same name as the requested database. (`samegroup` is an obsolete but still accepted spelling of `samerole`.) Otherwise, this is the name of a specific PostgreSQL database. Multiple database names can be supplied by separating them with commas. A separate file containing database names can be specified by preceding the file name with `@`.

**user**
Specifies which database user name(s) this record matches. The value `all` specifies that it matches all users. Otherwise, this is either the name of a specific database user, or a group name preceded by `+`. (Recall that there is no real distinction between users and groups in PostgreSQL; a + mark really means “match any of the roles that are directly or indirectly members of this role”, while a name without a + mark matches only that specific role.) Multiple user names can be supplied by separating them with commas. A separate file containing user names can be specified by preceding the file name with `@`.

**CIDR-address**
Specifies the client machine IP address range that this record matches. This field contains an IP address in standard dotted decimal notation and a CIDR mask length. (IP addresses can only be
Chapter 19. Client Authentication

specified numerically, not as domain or host names.) The mask length indicates the number of
high-order bits of the client IP address that must match. Bits to the right of this must be zero in
the given IP address. There must not be any white space between the IP address, the /, and the
CIDR mask length.

Typical examples of a CIDR-address are 172.20.143.89/32 for a single host, or
172.20.143.0/24 for a small network, or 10.6.0.0/16 for a larger one. To specify a single
host, use a CIDR mask of 32 for IPv4 or 128 for IPv6. In a network address, do not omit trailing
zeroes.

An IP address given in IPv4 format will match IPv6 connections that have the corresponding
address, for example 127.0.0.1 will match the IPv6 address ::ffff:127.0.0.1. An entry
given in IPv6 format will match only IPv6 connections, even if the represented address is in the
IPv4-in-IPv6 range. Note that entries in IPv6 format will be rejected if the system’s C library
does not have support for IPv6 addresses.

This field only applies to host, hostssl, and hostnossl records.

IP-address
IP-mask

These fields can be used as an alternative to the CIDR-address notation. Instead of specifying
the mask length, the actual mask is specified in a separate column. For example, 255.0.0.0
represents an IPv4 CIDR mask length of 8, and 255.255.255.255 represents a CIDR mask
length of 32.

These fields only apply to host, hostssl, and hostnossl records.

auth-method

Specifies the authentication method to use when a connection matches this record. The possible
choices are summarized here; details are in Section 19.3.

trust

Allow the connection unconditionally. This method allows anyone that can connect to the
PostgreSQL database server to login as any PostgreSQL user they like, without the need for
a password. See Section 19.3.1 for details.

reject

Reject the connection unconditionally. This is useful for “filtering out” certain hosts from a
group.

md5

Require the client to supply an MD5-encrypted password for authentication. See Section
19.3.2 for details.

password

Require the client to supply an unencrypted password for authentication. Since the password
is sent in clear text over the network, this should not be used on untrusted networks. See
Section 19.3.2 for details.

gss

Use GSSAPI to authenticate the user. This is only available for TCP/IP connections. See
Section 19.3.3 for details.
Chapter 19. Client Authentication

**sspi**

Use SSPI to authenticate the user. This is only available on Windows. See Section 19.3.4 for details.

**krb5**

Use Kerberos V5 to authenticate the user. This is only available for TCP/IP connections. See Section 19.3.5 for details.

**ident**

Obtain the operating system user name of the client (for TCP/IP connections by contacting the ident server on the client, for local connections by getting it from the operating system) and check if it matches the requested database user name. See Section 19.3.6 for details.

**ldap**

Authenticate using an LDAP server. See Section 19.3.7 for details.

**cert**

Authenticate using SSL client certificates. See Section 19.3.8 for details.

**pam**

Authenticate using the Pluggable Authentication Modules (PAM) service provided by the operating system. See Section 19.3.9 for details.

**auth-options**

After the `auth-method` field, there can be field(s) of the form `name=value` that specify options for the authentication method. Details about which options are available for which authentication method appear below.

Files included by `@` constructs are read as lists of names, which can be separated by either whitespace or commas. Comments are introduced by `#`, just as in `pg_hba.conf`, and nested `@` constructs are allowed. Unless the file name following `@` is an absolute path, it is taken to be relative to the directory containing the referencing file.

Since the `pg_hba.conf` records are examined sequentially for each connection attempt, the order of the records is significant. Typically, earlier records will have tight connection match parameters and weaker authentication methods, while later records will have looser match parameters and stronger authentication methods. For example, one might wish to use `trust` authentication for local TCP/IP connections but require a password for remote TCP/IP connections. In this case a record specifying `trust` authentication for connections from 127.0.0.1 would appear before a record specifying password authentication for a wider range of allowed client IP addresses.

The `pg_hba.conf` file is read on start-up and when the main server process receives a SIGHUP signal. If you edit the file on an active system, you will need to signal the server (using `pg_ctl` `reload` or `kill -HUP`) to make it re-read the file.

**Tip:** To connect to a particular database, a user must not only pass the `pg_hba.conf` checks, but must have the `CONNECT` privilege for the database. If you wish to restrict which users can connect to which databases, it's usually easier to control this by granting/revoking `CONNECT` privilege than to put the rules into `pg_hba.conf` entries.
Some examples of `pg_hba.conf` entries are shown in Example 19-1. See the next section for details on the different authentication methods.

**Example 19-1. Example `pg_hba.conf` entries**

```plaintext
# Allow any user on the local system to connect to any database under any database user name using Unix-domain sockets (the default for local connections).
#
# TYPE DATABASE USER CIDR-ADDRESS METHOD
local all all trust

# The same using local loopback TCP/IP connections.
#
# TYPE DATABASE USER CIDR-ADDRESS METHOD
host all all 127.0.0.1/32 trust

# The same as the previous line, but using a separate netmask column
#
# TYPE DATABASE USER IP-ADDRESS IP-MASK METHOD
host all all 127.0.0.1 255.255.255.255 trust

# Allow any user from any host with IP address 192.168.93.x to connect to database "postgres" as the same user name that ident reports for the connection (typically the Unix user name).
#
# TYPE DATABASE USER CIDR-ADDRESS METHOD
host postgres all 192.168.93.0/24 ident

# Allow any user from host 192.168.12.10 to connect to database "postgres" if the user's password is correctly supplied.
#
# TYPE DATABASE USER CIDR-ADDRESS METHOD
host postgres all 192.168.12.10/32 md5

# In the absence of preceding "host" lines, these two lines will reject all connections from 192.168.54.1 (since that entry will be matched first), but allow Kerberos 5 connections from anywhere else on the Internet. The zero mask means that no bits of the host IP address are considered so it matches any host.
#
# TYPE DATABASE USER CIDR-ADDRESS METHOD
host all all 192.168.54.1/32 reject
host all all 0.0.0.0/0 krb5

# Allow users from 192.168.x.x hosts to connect to any database, if they pass the ident check. If, for example, ident says the user is "bryanh" and he requests to connect as PostgreSQL user "guest1", the connection is allowed if there is an entry in `pg_ident.conf` for map "omicron" that says "bryanh" is allowed to connect as "guest1".
#
# TYPE DATABASE USER CIDR-ADDRESS METHOD
host all all 192.168.0.0/16 ident map=omicron

# If these are the only three lines for local connections, they will allow local users to connect only to their own databases (databases with the same name as their database user name) except for administrators
```
and members of role "support", who can connect to all databases. The file
$PGDATA/admins contains a list of names of administrators. Passwords
are required in all cases.

<table>
<thead>
<tr>
<th>TYPE</th>
<th>DATABASE</th>
<th>USER</th>
<th>CIDR-ADDRESS</th>
<th>METHOD</th>
</tr>
</thead>
<tbody>
<tr>
<td>local</td>
<td>sameuser</td>
<td>all</td>
<td></td>
<td>md5</td>
</tr>
<tr>
<td>local</td>
<td>all</td>
<td>@admins</td>
<td></td>
<td>md5</td>
</tr>
<tr>
<td>local</td>
<td>all</td>
<td>+support</td>
<td></td>
<td>md5</td>
</tr>
</tbody>
</table>

# The last two lines above can be combined into a single line:
local all @admins,+support md5

# The database column can also use lists and file names:
local db1,db2,@demodbs all md5

19.2. Username maps

When using an external authentication system like Ident or GSSAPI, the name of the operating system
user that initiated the connection might not be the same as the database user he needs to connect as.
In this case, a user name map can be applied to map the operating system username to a database
user. To use username mapping, specify map=map-name in the options field in pg_hba.conf. This
option is supported for all authentication methods that receive external usernames. Since different
mappings might be needed for different connections, the name of the map to be used is specified in the
map-name parameter in pg_hba.conf to indicate which map to use for each individual connection.

Username maps are defined in the ident map file, which by default is named pg_ident.conf and is
stored in the cluster’s data directory. (It is possible to place the map file elsewhere, however; see the
ident_file configuration parameter.) The ident map file contains lines of the general form:

```
map-name system-username database-username
```

Comments and whitespace are handled in the same way as in pg_hba.conf. The map-name is an
arbitrary name that will be used to refer to this mapping in pg_hba.conf. The other two fields specify
an operating system user name and a matching database user name. The same map-name can be used
repeatedly to specify multiple user-mappings within a single map.

There is no restriction regarding how many database users a given operating system user can cor-
respond to, nor vice versa. Thus, entries in a map should be thought of as meaning “this operating
system user is allowed to connect as this database user”, rather than implying that they are equivalent.
The connection will be allowed if there is any map entry that matches the user name obtained from
the external authentication system to the database user name that the user has requested to connect as.

If the system-username field starts with a slash (/), the remainder of the field is treated as a regu-
lar expression. (See Section 9.7.3.1 for details of PostgreSQL’s regular expression syntax. Regular
expressions in username maps are always treated as being “advanced” flavor.) The regular expression
can include a single capture, or parenthesized subexpression, which can then be referenced in the
database-username field as \1 (backslash-one). This allows the mapping of multiple usernames
in a single line, which is particularly useful for simple syntax substitutions. For example, these entries

```
mymap /^(.*)@mydomain\..*com$/ \1
mymap /^(.*)@otherdomain\..*com$/ guest
```

will remove the domain part for users with system usernames that end with @mydomain.com, and
allow any user whose system name ends with @otherdomain.com to log in as guest.
Tip: Keep in mind that by default, a regular expression can match just part of a string. It's usually wise to use ^ and $, as shown in the above example, to force the match to be to the entire system username.

The pg_ident.conf file is read on start-up and when the main server process receives a SIGHUP signal. If you edit the file on an active system, you will need to signal the server (using pg_ctl reload or kill -HUP) to make it re-read the file.

A pg_ident.conf file that could be used in conjunction with the pg_hba.conf file in Example 19-1 is shown in Example 19-2. In this example setup, anyone logged in to a machine on the 192.168 network that does not have the Unix username bryanh, ann, or robert would not be granted access. Unix user robert would only be allowed access when he tries to connect as PostgreSQL user bob, not as robert or anyone else. ann would only be allowed to connect as ann. User bryanh would be allowed to connect as either bryanh himself or as guest1.

Example 19-2. An example pg_ident.conf file

```
# MAPNAME  SYSTEM-USERNAME  PG-USERNAME
omicron    bryanh             bryanh
omicron    ann                 ann
# bob has user name robert on these machines
omicron    robert              bob
# bryanh can also connect as guest1
omicron    bryanh              guest1
```

19.3. Authentication methods

The following subsections describe the authentication methods in more detail.

19.3.1. Trust authentication

When trust authentication is specified, PostgreSQL assumes that anyone who can connect to the server is authorized to access the database with whatever database user name they specify (even superuser names). Of course, restrictions made in the database and user columns still apply. This method should only be used when there is adequate operating-system-level protection on connections to the server.

trust authentication is appropriate and very convenient for local connections on a single-user workstation. It is usually not appropriate by itself on a multiuser machine. However, you might be able to use trust even on a multiuser machine, if you restrict access to the server’s Unix-domain socket file using file-system permissions. To do this, set the unix_socket_permissions (and possibly unix_socket_group) configuration parameters as described in Section 18.3. Or you could set the unix_socket_directory configuration parameter to place the socket file in a suitably restricted directory.

Setting file-system permissions only helps for Unix-socket connections. Local TCP/IP connections are not restricted by file-system permissions. Therefore, if you want to use file-system permissions for local security, remove the host ... 127.0.0.1 ... line from pg_hba.conf, or change it to a non-trust authentication method.
trust authentication is only suitable for TCP/IP connections if you trust every user on every machine that is allowed to connect to the server by the pg_hba.conf lines that specify trust. It is seldom reasonable to use trust for any TCP/IP connections other than those from localhost (127.0.0.1).

19.3.2. Password authentication

The password-based authentication methods are md5 and password. These methods operate similarly except for the way that the password is sent across the connection: respectively, MD5-hashed and clear-text.

If you are at all concerned about password “sniffing” attacks then md5 is preferred. Plain password should always be avoided if possible. However, md5 cannot be used with the db_user_namespace feature. If the connection is protected by SSL encryption then password can be used safely (though SSL certificate authentication might be a better choice if one is depending on using SSL).

PostgreSQL database passwords are separate from operating system user passwords. The password for each database user is stored in the pg_authid system catalog. Passwords can be managed with the SQL commands CREATE USER and ALTER USER, e.g., CREATE USER foo WITH PASSWORD 'secret';. By default, that is, if no password has been set up, the stored password is null and password authentication will always fail for that user.

19.3.3. GSSAPI authentication

GSSAPI is an industry-standard protocol for secure authentication defined in RFC 2743. PostgreSQL supports GSSAPI with Kerberos authentication according to RFC 1964. GSSAPI provides automatic authentication (single sign-on) for systems that support it. The authentication itself is secure, but the data sent over the database connection will be in clear unless SSL is used.

When GSSAPI uses Kerberos, it uses a standard principal in the format servicename/hostname@realm. For information about the parts of the principal, and how to set up the required keys, see Section 19.3.5. GSSAPI support has to be enabled when PostgreSQL is built; see Chapter 15 for more information.

The following configuration options are supported for GSSAPI:

map

Allows for mapping between system and database usernames. See Section 19.2 for details.

include_realm

If set to 1, the realm name from the authenticated user principal is included in the system user name that’s passed through username mapping (Section 19.2). This is useful for handling users from multiple realms.

krb_realm

Sets the realm to match user principal names against. If this parameter is set, only users of that realm will be accepted. If it is not set, users of any realm can connect, subject to whatever username mapping is done.
Chapter 19. Client Authentication

19.3.4. SSPI authentication

SSPI is a Windows technology for secure authentication with single sign-on. PostgreSQL will use SSPI in negotiate mode, which will use Kerberos when possible and automatically fall back to NTLM in other cases. SSPI authentication only works when both server and client are running Windows.

When using Kerberos authentication, SSPI works the same way GSSAPI does. See Section 19.3.3 for details.

The following configuration options are supported for SSPI:

map

Allows for mapping between system and database usernames. See Section 19.2 for details.

include_realm

If set to 1, the realm name from the authenticated user principal is included in the system user name that’s passed through username mapping (Section 19.2). This is useful for handling users from multiple realms.

krb_realm

Sets the realm to match user principal names against. If this parameter is set, only users of that realm will be accepted. If it is not set, users of any realm can connect, subject to whatever username mapping is done.

19.3.5. Kerberos authentication

Note: Native Kerberos authentication has been deprecated and should be used only for backward compatibility. New and upgraded installations are encouraged to use the industry-standard GSSAPI authentication (see Section 19.3.3) instead.

Kerberos is an industry-standard secure authentication system suitable for distributed computing over a public network. A description of the Kerberos system is far beyond the scope of this document; in full generality it can be quite complex (yet powerful). The Kerberos FAQ\(^1\) or MIT Kerberos page\(^2\) can be good starting points for exploration. Several sources for Kerberos distributions exist. Kerberos provides secure authentication but does not encrypt queries or data passed over the network; for that use SSL.

PostgreSQL supports Kerberos version 5. Kerberos support has to be enabled when PostgreSQL is built; see Chapter 15 for more information.

PostgreSQL operates like a normal Kerberos service. The name of the service principal is servicename/hostname@realm.

servicename can be set on the server side using the krb_srvname configuration parameter, and on the client side using the krbsrvname connection parameter. (See also Section 30.1.) The installation default can be changed from the default postgres at build time using `./configure --with-krb-srvname=whatever`. In most environments, this parameter never needs to be changed.

However, to support multiple PostgreSQL installations on the same host it is necessary. Some Kerberos implementations might also require a different service name, such as Microsoft Active Directory which requires the service name to be in uppercase (POSTGRES).

hostname is the fully qualified host name of the server machine. The service principal’s realm is the preferred realm of the server machine.

Client principals must have their PostgreSQL database user name as their first component, for example pgusername@realm. Alternatively, you can use a username mapping to map from the first component of the principal name to the database user name. By default, the realm of the client is not checked by PostgreSQL. If you have cross-realm authentication enabled and need to verify the realm, use the krb_real parameter, or enable include_realm and use username mapping to check the realm.

Make sure that your server keytab file is readable (and preferably only readable) by the PostgreSQL server account. (See also Section 17.1.) The location of the key file is specified by the krb_server_keyfile configuration parameter. The default is /usr/local/pgsql/etc/krb5.keytab (or whichever directory was specified as sysconfdir at build time).

The keytab file is generated by the Kerberos software; see the Kerberos documentation for details. The following example is for MIT-compatible Kerberos 5 implementations:

kadmin% ank -randkey postgres/server.my.domain.org
kadmin% ktadd -k krb5.keytab postgres/server.my.domain.org

When connecting to the database make sure you have a ticket for a principal matching the requested database user name. For example, for database user name fred, both principal fred@EXAMPLE.COM and fred/users.example.com@EXAMPLE.COM could be used to authenticate to the database server.

If you use mod_auth_kerb3 and mod_perl on your Apache web server, you can use AuthType KerberosV5SaveCredentials with a mod_perl script. This gives secure database access over the web, no extra passwords required.

The following configuration options are supported for Kerberos:

map

Allows for mapping between system and database usernames. See Section 19.2 for details.

include_realm

If set to 1, the realm name from the authenticated user principal is included in the system user name that’s passed through username mapping (Section 19.2). This is useful for handling users from multiple realms.

krb_realm

Sets the realm to match user principal names against. If this parameter is set, only users of that realm will be accepted. If it is not set, users of any realm can connect, subject to whatever username mapping is done.

krb_server_hostname

Sets the host name part of the service principal. This, combined with krb_srvname, is used to generate the complete service principal, that is

The ident authentication method works by obtaining the client’s operating system user name and using it as the allowed database user name (with an optional username mapping). The determination of the client’s user name is the security-critical point, and it works differently depending on the connection type.

The following configuration options are supported for ident:

map

Allows for mapping between system and database usernames. See Section 19.2 for details.

19.3.6.1. Ident Authentication over TCP/IP

The “Identification Protocol” is described in RFC 1413. Virtually every Unix-like operating system ships with an ident server that listens on TCP port 113 by default. The basic functionality of an ident server is to answer questions like “What user initiated the connection that goes out of your port $X$ and connects to my port $Y$?”. Since PostgreSQL knows both $X$ and $Y$ when a physical connection is established, it can interrogate the ident server on the host of the connecting client and could theoretically determine the operating system user for any given connection this way.

The drawback of this procedure is that it depends on the integrity of the client: if the client machine is untrusted or compromised an attacker could run just about any program on port 113 and return any user name he chooses. This authentication method is therefore only appropriate for closed networks where each client machine is under tight control and where the database and system administrators operate in close contact. In other words, you must trust the machine running the ident server. Heed the warning:

The Identification Protocol is not intended as an authorization or access control protocol.

—RFC 1413

Some ident servers have a nonstandard option that causes the returned user name to be encrypted, using a key that only the originating machine’s administrator knows. This option must not be used when using the ident server with PostgreSQL, since PostgreSQL does not have any way to decrypt the returned string to determine the actual user name.

19.3.6.2. Ident Authentication over Local Sockets

On systems supporting SO_PEERCRED requests for Unix-domain sockets (currently Linux, FreeBSD, NetBSD, OpenBSD, BSD/OS, and Solaris), ident authentication can also be applied to local connections. In this case, no security risk is added by using ident authentication; indeed it is a preferable choice for local connections on such systems.

On systems without SO_PEERCRED requests, ident authentication is only available for TCP/IP connections. As a work-around, it is possible to specify the localhost address 127.0.0.1 and make connections to this address. This method is trustworthy to the extent that you trust the local ident server.
### 19.3.7. LDAP authentication

This authentication method operates similarly to `password` except that it uses LDAP as the password verification method. LDAP is used only to validate the user name/password pairs. Therefore the user must already exist in the database before LDAP can be used for authentication.

The server will bind to the distinguished name constructed as `prefix username suffix`. Typically, the `prefix` parameter is used to specify `cn=`, or `DOMAIN\` in an Active Directory environment. `suffix` is used to specify the remaining part of the DN in a non-Active Directory environment.

The following configuration options are supported for LDAP:

- `ldapserver`
  Names or IP addresses of LDAP servers to connect to. Multiple servers may be specified, separated by spaces.

- `ldapprefix`
  String to prepend to the username when forming the DN to bind as.

- `ldapsuffix`
  String to append to the username when forming the DN to bind as.

- `ldapport`
  Port number on LDAP server to connect to. If no port is specified, the default port in the LDAP library will be used.

- `ldaptls`
  Set to 1 to make the connection between PostgreSQL and the LDAP server use TLS encryption. Note that this only encrypts the traffic to the LDAP server — the connection to the client will still be unencrypted unless SSL is used.

**Note:** Since LDAP often uses commas and spaces to separate the different parts of a DN, it is often necessary to use double-quoted parameter values when configuring LDAP options, for example:

```
ldapserver=ldap.example.net ldapprefix="cn=" ldapsuffix="", dc=example, dc=net"
```

### 19.3.8. Certificate authentication

This authentication method uses SSL client certificates to perform authentication. It is therefore only available for SSL connections. When using this authentication method, the server will require that the client provide a valid certificate. No password prompt will be sent to the client. The `cn` attribute of the certificate will be compared to the requested database username, and if they match the login will be allowed. Username mapping can be used to allow `cn` to be different from the database username.

The following configuration options are supported for SSL certificate authentication:

- `map`
  Allows for mapping between system and database usernames. See Section 19.2 for details.
Chapter 19. Client Authentication

19.3.9. PAM authentication

This authentication method operates similarly to password except that it uses PAM (Pluggable Authentication Modules) as the authentication mechanism. The default PAM service name is `postgresql`. PAM is used only to validate user name/password pairs. Therefore the user must already exist in the database before PAM can be used for authentication. For more information about PAM, please read the 'Linux-PAM Page' and the 'Solaris PAM Page'.

The following configuration options are supported for PAM:

```
pamservice
   PAM service name.
```

**Note:** If PAM is set up to read `/etc/shadow`, authentication will fail because the PostgreSQL server is started by a non-root user. However, this is not an issue when PAM is configured to use LDAP or other authentication methods.

19.4. Authentication problems

Authentication failures and related problems generally manifest themselves through error messages like the following:

**FATAL:** no pg_hba.conf entry for host "123.123.123.123", user "andym", database "testdb"

This is what you are most likely to get if you succeed in contacting the server, but it does not want to talk to you. As the message suggests, the server refused the connection request because it found no matching entry in its `pg_hba.conf` configuration file.

**FATAL:** Password authentication failed for user "andym"

Messages like this indicate that you contacted the server, and it is willing to talk to you, but not until you pass the authorization method specified in the `pg_hba.conf` file. Check the password you are providing, or check your Kerberos or ident software if the complaint mentions one of those authentication types.

**FATAL:** user "andym" does not exist

The indicated database user name was not found.

**FATAL:** database "testdb" does not exist

The database you are trying to connect to does not exist. Note that if you do not specify a database name, it defaults to the database user name, which might or might not be the right thing.

**Tip:** The server log might contain more information about an authentication failure than is reported to the client. If you are confused about the reason for a failure, check the log.

Chapter 20. Database Roles and Privileges

PostgreSQL manages database access permissions using the concept of roles. A role can be thought of as either a database user, or a group of database users, depending on how the role is set up. Roles can own database objects (for example, tables) and can assign privileges on those objects to other roles to control who has access to which objects. Furthermore, it is possible to grant membership in a role to another role, thus allowing the member role use of privileges assigned to the role it is a member of.

The concept of roles subsumes the concepts of “users” and “groups”. In PostgreSQL versions before 8.1, users and groups were distinct kinds of entities, but now there are only roles. Any role can act as a user, a group, or both.

This chapter describes how to create and manage roles and introduces the privilege system. More information about the various types of database objects and the effects of privileges can be found in Chapter 5.

20.1. Database Roles

Database roles are conceptually completely separate from operating system users. In practice it might be convenient to maintain a correspondence, but this is not required. Database roles are global across a database cluster installation (and not per individual database). To create a role use the `CREATE ROLE` SQL command:

```
CREATE ROLE name;
```

`name` follows the rules for SQL identifiers: either unadorned without special characters, or double-quoted. (In practice, you will usually want to add additional options, such as `LOGIN`, to the command. More details appear below.) To remove an existing role, use the analogous `DROP ROLE` command:

```
DROP ROLE name;
```

For convenience, the programs createuser and dropuser are provided as wrappers around these SQL commands that can be called from the shell command line:

```
createuser name
dropuser name
```

To determine the set of existing roles, examine the `pg_roles` system catalog, for example

```
SELECT rolname FROM pg_roles;
```

The psql program’s `\du` meta-command is also useful for listing the existing roles.

In order to bootstrap the database system, a freshly initialized system always contains one predefined role. This role is always a “superuser”, and by default (unless altered when running `initdb`) it will have the same name as the operating system user that initialized the database cluster. Customarily, this role will be named `postgres`. In order to create more roles you first have to connect as this initial role.

Every connection to the database server is made in the name of some particular role, and this role determines the initial access privileges for commands issued on that connection. The role name to use for a particular database connection is indicated by the client that is initiating the connection request.
in an application-specific fashion. For example, the `psql` program uses the `-U` command line option to indicate the role to connect as. Many applications assume the name of the current operating system user by default (including `createuser` and `psql`). Therefore it is often convenient to maintain a naming correspondence between roles and operating system users.

The set of database roles a given client connection can connect as is determined by the client authentication setup, as explained in Chapter 19. (Thus, a client is not necessarily limited to connect as the role with the same name as its operating system user, just as a person’s login name need not match her real name.) Since the role identity determines the set of privileges available to a connected client, it is important to carefully configure this when setting up a multiuser environment.

### 20.2. Role Attributes

A database role can have a number of attributes that define its privileges and interact with the client authentication system.

**login privilege**

Only roles that have the `LOGIN` attribute can be used as the initial role name for a database connection. A role with the `LOGIN` attribute can be considered the same thing as a "database user". To create a role with login privilege, use either:

```sql
CREATE ROLE name LOGIN;
CREATE USER name;
```

*(CREATE USER is equivalent to CREATE ROLE except that CREATE USER assumes LOGIN by default, while CREATE ROLE does not.)*

**superuser status**

A database superuser bypasses all permission checks. This is a dangerous privilege and should not be used carelessly; it is best to do most of your work as a role that is not a superuser. To create a new database superuser, use `CREATE ROLE name SUPERUSER`. You must do this as a role that is already a superuser.

**database creation**

A role must be explicitly given permission to create databases (except for superusers, since those bypass all permission checks). To create such a role, use `CREATE ROLE name CREATEDB`.

**role creation**

A role must be explicitly given permission to create more roles (except for superusers, since those bypass all permission checks). To create such a role, use `CREATE ROLE name CREATEROLE`. A role with `CREATEROLE` privilege can alter and drop other roles, too, as well as grant or revoke membership in them. However, to create, alter, drop, or change membership of a superuser role, superuser status is required; `CREATEROLE` is not sufficient for that.

**password**

A password is only significant if the client authentication method requires the user to supply a password when connecting to the database. The password and `md5` authentication methods make use of passwords. Database passwords are separate from operating system passwords.

Specify a password upon role creation with `CREATE ROLE name PASSWORD 'string'`.

A role’s attributes can be modified after creation with `ALTER ROLE`. See the reference pages for the `CREATE ROLE` and `ALTER ROLE` commands for details.
Tip: It is good practice to create a role that has the CREATEDB and CREATEROLE privileges, but is not a superuser, and then use this role for all routine management of databases and roles. This approach avoids the dangers of operating as a superuser for tasks that do not really require it.

A role can also have role-specific defaults for many of the run-time configuration settings described in Chapter 18. For example, if for some reason you want to disable index scans (hint: not a good idea) anytime you connect, you can use:

```
ALTER ROLE myname SET enable_indexscan TO off;
```

This will save the setting (but not set it immediately). In subsequent connections by this role it will appear as though `SET enable_indexscan TO off;` had been executed just before the session started. You can still alter this setting during the session; it will only be the default. To remove a role-specific default setting, use `ALTER ROLE rolename RESET varname;`. Note that role-specific defaults attached to roles without LOGIN privilege are fairly useless, since they will never be invoked.

### 20.3. Privileges

When an object is created, it is assigned an owner. The owner is normally the role that executed the creation statement. For most kinds of objects, the initial state is that only the owner (or a superuser) can do anything with the object. To allow other roles to use it, privileges must be granted. There are several different kinds of privilege: SELECT, INSERT, UPDATE, DELETE, TRUNCATE, REFERENCES, TRIGGER, CREATE, CONNECT, TEMPORARY, EXECUTE, and USAGE. For more information on the different types of privileges supported by PostgreSQL, see the GRANT reference page.

To assign privileges, the GRANT command is used. So, if `joe` is an existing role, and `accounts` is an existing table, the privilege to update the table can be granted with:

```
GRANT UPDATE ON accounts TO joe;
```

The special name `PUBLIC` can be used to grant a privilege to every role on the system. Writing `ALL` in place of a specific privilege specifies that all privileges that apply to the object will be granted.

To revoke a privilege, use the fittingly named REVOKE command:

```
REVOKE ALL ON accounts FROM PUBLIC;
```

The special privileges of an object’s owner (i.e., the right to modify or destroy the object) are always implicit in being the owner, and cannot be granted or revoked. But the owner can choose to revoke his own ordinary privileges, for example to make a table read-only for himself as well as others.

An object can be assigned to a new owner with an ALTER command of the appropriate kind for the object. Superusers can always do this; ordinary roles can only do it if they are both the current owner of the object (or a member of the owning role) and a member of the new owning role.

### 20.4. Role Membership

It is frequently convenient to group users together to ease management of privileges: that way, privileges can be granted to, or revoked from, a group as a whole. In PostgreSQL this is done by creating
a role that represents the group, and then granting *membership* in the group role to individual user roles.

To set up a group role, first create the role:

```
CREATE ROLE name;
```

Typically a role being used as a group would not have the `LOGIN` attribute, though you can set it if you wish.

Once the group role exists, you can add and remove members using the `GRANT` and `REVOKE` commands:

```
GRANT group_role TO role1, ... ;
REVOKE group_role FROM role1, ... ;
```

You can grant membership to other group roles, too (since there isn’t really any distinction between group roles and non-group roles). The database will not let you set up circular membership loops. Also, it is not permitted to grant membership in a role to `PUBLIC`.

The members of a role can use the privileges of the group role in two ways. First, every member of a group can explicitly do `SET ROLE` to temporarily “become” the group role. In this state, the database session has access to the privileges of the group role rather than the original login role, and any database objects created are considered owned by the group role not the login role. Second, member roles that have the `INHERIT` attribute automatically have use of privileges of roles they are members of. As an example, suppose we have done:

```
CREATE ROLE joe LOGIN INHERIT;
CREATE ROLE admin NOINHERIT;
CREATE ROLE wheel NOINHERIT;
GRANT admin TO joe;
GRANT wheel TO admin;
```

Immediately after connecting as role `joe`, a database session will have use of privileges granted directly to `joe` plus any privileges granted to `admin`, because `joe` “inherits” `admin`’s privileges. However, privileges granted to `wheel` are not available, because even though `joe` is indirectly a member of `wheel`, the membership is via `admin` which has the `NOINHERIT` attribute. After:

```
SET ROLE admin;
```

the session would have use of only those privileges granted to `admin`, and not those granted to `joe`. After:

```
SET ROLE wheel;
```

the session would have use of only those privileges granted to `wheel`, and not those granted to either `joe` or `admin`. The original privilege state can be restored with any of:

```
SET ROLE joe;
SET ROLE NONE;
RESET ROLE;
```

**Note:** The `SET ROLE` command always allows selecting any role that the original login role is directly or indirectly a member of. Thus, in the above example, it is not necessary to become `admin` before becoming `wheel`. 
Note: In the SQL standard, there is a clear distinction between users and roles, and users do not automatically inherit privileges while roles do. This behavior can be obtained in PostgreSQL by giving roles being used as SQL roles the `INHERIT` attribute, while giving roles being used as SQL users the `NOINHERIT` attribute. However, PostgreSQL defaults to giving all roles the `INHERIT` attribute, for backwards compatibility with pre-8.1 releases in which users always had use of permissions granted to groups they were members of.

The role attributes `LOGIN`, `SUPERUSER`, `CREATEDB`, and `CREATEROLE` can be thought of as special privileges, but they are not inherited as ordinary privileges on database objects are. You must actually `SET ROLE` to a specific role having one of these attributes in order to make use of the attribute. Continuing the above example, we might well choose to grant `CREATEDB` and `CREATEROLE` to the `admin` role. Then a session connecting as role `joe` would not have these privileges immediately, only after doing `SET ROLE admin`.

To destroy a group role, use `DROP ROLE`:

```
DROP ROLE name;
```

Any memberships in the group role are automatically revoked (but the member roles are not otherwise affected). Note however that any objects owned by the group role must first be dropped or reassigned to other owners; and any permissions granted to the group role must be revoked.

### 20.5. Functions and Triggers

Functions and triggers allow users to insert code into the backend server that other users might execute unintentionally. Hence, both mechanisms permit users to “Trojan horse” others with relative ease. The only real protection is tight control over who can define functions.

Functions run inside the backend server process with the operating system permissions of the database server daemon. If the programming language used for the function allows unchecked memory accesses, it is possible to change the server’s internal data structures. Hence, among many other things, such functions can circumvent any system access controls. Function languages that allow such access are considered “untrusted”, and PostgreSQL allows only superusers to create functions written in those languages.
Chapter 21. Managing Databases

Every instance of a running PostgreSQL server manages one or more databases. Databases are therefore the topmost hierarchical level for organizing SQL objects (“database objects”). This chapter describes the properties of databases, and how to create, manage, and destroy them.

21.1. Overview

A database is a named collection of SQL objects (“database objects”). Generally, every database object (tables, functions, etc.) belongs to one and only one database. (But there are a few system catalogs, for example pg_database, that belong to a whole cluster and are accessible from each database within the cluster.) More accurately, a database is a collection of schemas and the schemas contain the tables, functions, etc. So the full hierarchy is: server, database, schema, table (or some other kind of object, such as a function).

When connecting to the database server, a client must specify in its connection request the name of the database it wants to connect to. It is not possible to access more than one database per connection. (But an application is not restricted in the number of connections it opens to the same or other databases.) Databases are physically separated and access control is managed at the connection level. If one PostgreSQL server instance is to house projects or users that should be separate and for the most part unaware of each other, it is therefore recommendable to put them into separate databases. If the projects or users are interrelated and should be able to use each other’s resources they should be put in the same database, but possibly into separate schemas. Schemas are a purely logical structure and who can access what is managed by the privilege system. More information about managing schemas is in Section 5.7.

Databases are created with the CREATE DATABASE command (see Section 21.2) and destroyed with the DROP DATABASE command (see Section 21.5). To determine the set of existing databases, examine the pg_database system catalog, for example

SELECT datname FROM pg_database;

The psql program’s \l meta-command and -l command-line option are also useful for listing the existing databases.

Note: The SQL standard calls databases “catalogs”, but there is no difference in practice.

21.2. Creating a Database

In order to create a database, the PostgreSQL server must be up and running (see Section 17.3).

Databases are created with the SQL command CREATE DATABASE:

CREATE DATABASE name;

where name follows the usual rules for SQL identifiers. The current role automatically becomes the owner of the new database. It is the privilege of the owner of a database to remove it later on (which also removes all the objects in it, even if they have a different owner).

The creation of databases is a restricted operation. See Section 20.2 for how to grant permission.
Since you need to be connected to the database server in order to execute the `CREATE DATABASE` command, the question remains how the first database at any given site can be created. The first database is always created by the `initdb` command when the data storage area is initialized. (See Section 17.2.) This database is called `postgres`. So to create the first “ordinary” database you can connect to `postgres`.

A second database, `template1`, is also created by `initdb`. Whenever a new database is created within the cluster, `template1` is essentially cloned. This means that any changes you make in `template1` are propagated to all subsequently created databases. Therefore it is unwise to use `template1` for real work, but when used judiciously this feature can be convenient. More details appear in Section 21.3.

As a convenience, there is a program that you can execute from the shell to create new databases, `createdb`.

```
createdb dbname
```

`createdb` does no magic. It connects to the `postgres` database and issues the `CREATE DATABASE` command, exactly as described above. The `createdb` reference page contains the invocation details. Note that `createdb` without any arguments will create a database with the current user name, which might or might not be what you want.

**Note:** Chapter 19 contains information about how to restrict who can connect to a given database.

Sometimes you want to create a database for someone else. That role should become the owner of the new database, so he can configure and manage it himself. To achieve that, use one of the following commands:

```
CREATE DATABASE dbname OWNER rolename;
```

from the SQL environment, or:

```
createdb -O rolename dbname
```

from the shell. You must be a superuser to be allowed to create a database for someone else (that is, for a role you are not a member of).

### 21.3. Template Databases

`CREATE DATABASE` actually works by copying an existing database. By default, it copies the standard system database named `template1`. Thus that database is the “template” from which new databases are made. If you add objects to `template1`, these objects will be copied into subsequently created user databases. This behavior allows site-local modifications to the standard set of objects in databases. For example, if you install the procedural language PL/pgSQL in `template1`, it will automatically be available in user databases without any extra action being taken when those databases are made.

There is a second standard system database named `template0`. This database contains the same data as the initial contents of `template1`, that is, only the standard objects predefined by your version of PostgreSQL. `template0` should never be changed after `initdb`. By instructing `CREATE DATABASE` to copy `template0` instead of `template1`, you can create a “virgin” user database that contains none of the site-local additions in `template1`. This is particularly handy when restoring a `pg_dump`
dump: the dump script should be restored in a virgin database to ensure that one recreates the correct contents of the dumped database, without any conflicts with objects that might have been added to template1 later on.

Another common reason for copying template0 instead of template1 is that new encoding and locale settings can be specified when copying template0, whereas a copy of template1 must use the same settings it does. This is because template1 might contain encoding-specific or locale-specific data, while template0 is known not to.

To create a database by copying template0, use:

```
CREATE DATABASE dbname TEMPLATE template0;
```

from the SQL environment, or:

```
createdb -T template0 dbname
```

from the shell.

It is possible to create additional template databases, and indeed one can copy any database in a cluster by specifying its name as the template for CREATE DATABASE. It is important to understand, however, that this is not (yet) intended as a general-purpose "COPY DATABASE" facility. The principal limitation is that no other sessions can be connected to the source database while it is being copied. CREATE DATABASE will fail if any other connection exists when it starts; otherwise, new connections to the source database are locked out until CREATE DATABASE completes.

Two useful flags exist in pg_database for each database: the columns datistemplate and datallowconn. datistemplate can be set to indicate that a database is intended as a template for CREATE DATABASE. If this flag is set, the database can be cloned by any user with CREATEDB privileges; if it is not set, only superusers and the owner of the database can clone it. If datallowconn is false, then no new connections to that database will be allowed (but existing sessions are not killed simply by setting the flag false). The template0 database is normally marked datallowconn = false to prevent modification of it. Both template0 and template1 should always be marked with datistemplate = true.

Note: template1 and template0 do not have any special status beyond the fact that the name template1 is the default source database name for CREATE DATABASE. For example, one could drop template1 and recreate it from template0 without any ill effects. This course of action might be advisable if one has carelessly added a bunch of junk in template1. (To delete template1, it must have pg_database.datistemplate = false.)

The postgres database is also created when a database cluster is initialized. This database is meant as a default database for users and applications to connect to. It is simply a copy of template1 and can be dropped and recreated if required.

### 21.4. Database Configuration

Recall from Chapter 18 that the PostgreSQL server provides a large number of run-time configuration variables. You can set database-specific default values for many of these settings.

For example, if for some reason you want to disable the GEQO optimizer for a given database, you’d ordinarily have to either disable it for all databases or make sure that every connecting client is careful to issue SET geqo TO off; To make this setting the default within a particular database, you can execute the command:
ALTER DATABASE mydb SET geqo TO off;

This will save the setting (but not set it immediately). In subsequent connections to this database it will appear as though SET geqo TO off; had been executed just before the session started. Note that users can still alter this setting during their sessions; it will only be the default. To undo any such setting, use ALTER DATABASE dbname RESET varname;

21.5. Destroying a Database

Databases are destroyed with the command DROP DATABASE:

DROP DATABASE name;

Only the owner of the database, or a superuser, can drop a database. Dropping a database removes all objects that were contained within the database. The destruction of a database cannot be undone.

You cannot execute the DROP DATABASE command while connected to the victim database. You can, however, be connected to any other database, including the template1 database. template1 would be the only option for dropping the last user database of a given cluster.

For convenience, there is also a shell program to drop databases, dropdb:

dropdb dbname

(Unlike createdb, it is not the default action to drop the database with the current user name.)

21.6. Tablespaces

Tablespaces in PostgreSQL allow database administrators to define locations in the file system where the files representing database objects can be stored. Once created, a tablespace can be referred to by name when creating database objects.

By using tablespaces, an administrator can control the disk layout of a PostgreSQL installation. This is useful in at least two ways. First, if the partition or volume on which the cluster was initialized runs out of space and cannot be extended, a tablespace can be created on a different partition and used until the system can be reconfigured.

Second, tablespaces allow an administrator to use knowledge of the usage pattern of database objects to optimize performance. For example, an index which is very heavily used can be placed on a very fast, highly available disk, such as an expensive solid state device. At the same time a table storing archived data which is rarely used or not performance critical could be stored on a less expensive, slower disk system.

To define a tablespace, use the CREATE TABLESPACE command, for example:

CREATE TABLESPACE fastspace LOCATION '/mnt/sda1/postgresql/data';

The location must be an existing, empty directory that is owned by the PostgreSQL system user. All objects subsequently created within the tablespace will be stored in files underneath this directory.

Note: There is usually not much point in making more than one tablespace per logical file system, since you cannot control the location of individual files within a logical file system. However, PostgreSQL does not enforce any such limitation, and indeed it is not directly aware of the file system boundaries on your system. It just stores files in the directories you tell it to use.
Creation of the tablespace itself must be done as a database superuser, but after that you can allow ordinary database users to make use of it. To do that, grant them the **CREATE** privilege on it.

Tables, indexes, and entire databases can be assigned to particular tablespaces. To do so, a user with the **CREATE** privilege on a given tablespace must pass the tablespace name as a parameter to the relevant command. For example, the following creates a table in the tablespace `space1`:

```
CREATE TABLE foo(i int) TABLESPACE space1;
```

Alternatively, use the `default_tablespace` parameter:

```
SET default_tablespace = space1;
CREATE TABLE foo(i int);
```

When `default_tablespace` is set to anything but an empty string, it supplies an implicit **TABLESPACE** clause for **CREATE TABLE** and **CREATE INDEX** commands that do not have an explicit one.

There is also a `temp_tablespaces` parameter, which determines the placement of temporary tables and indexes, as well as temporary files that are used for purposes such as sorting large data sets. This can be a list of tablespace names, rather than only one, so that the load associated with temporary objects can be spread over multiple tablespaces. A random member of the list is picked each time a temporary object is to be created.

The tablespace associated with a database is used to store the system catalogs of that database. Furthermore, it is the default tablespace used for tables, indexes, and temporary files created within the database, if no **TABLESPACE** clause is given and no other selection is specified by `default_tablespace` or `temp_tablespaces` (as appropriate). If a database is created without specifying a tablespace for it, it uses the same tablespace as the template database it is copied from.

Two tablespaces are automatically created by `initdb`. The `pg_global` tablespace is used for shared system catalogs. The `pg_default` tablespace is the default tablespace of the `template1` and `template0` databases (and, therefore, will be the default tablespace for other databases as well, unless overridden by a **TABLESPACE** clause in **CREATE DATABASE**).

Once created, a tablespace can be used from any database, provided the requesting user has sufficient privilege. This means that a tablespace cannot be dropped until all objects in all databases using the tablespace have been removed.

To remove an empty tablespace, use the **DROP TABLESPACE** command.

To determine the set of existing tablespaces, examine the `pg_tablespace` system catalog, for example:

```
SELECT spcname FROM pg_tablespace;
```

The `psql` program’s `\db` meta-command is also useful for listing the existing tablespaces.

PostgreSQL makes use of symbolic links to simplify the implementation of tablespaces. This means that tablespaces can be used only on systems that support symbolic links.

The directory `$PGDATA/pg_tblspc` contains symbolic links that point to each of the non-built-in tablespaces defined in the cluster. Although not recommended, it is possible to adjust the tablespace layout by hand by redefining these links. Two warnings: do not do so while the server is running; and after you restart the server, update the `pg_tablespace` catalog to show the new locations. (If you do not, `pg_dump` will continue to show the old tablespace locations.)
Chapter 22. Localization

This chapter describes the available localization features from the point of view of the administrator. PostgreSQL supports localization with two approaches:

- Using the locale features of the operating system to provide locale-specific collation order, number formatting, translated messages, and other aspects.
- Providing a number of different character sets to support storing text in all kinds of languages, and providing character set translation between client and server.

22.1. Locale Support

Locale support refers to an application respecting cultural preferences regarding alphabets, sorting, number formatting, etc. PostgreSQL uses the standard ISO C and POSIX locale facilities provided by the server operating system. For additional information refer to the documentation of your system.

22.1.1. Overview

Locale support is automatically initialized when a database cluster is created using `initdb`. `initdb` will initialize the database cluster with the locale setting of its execution environment by default, so if your system is already set to use the locale that you want in your database cluster then there is nothing else you need to do. If you want to use a different locale (or you are not sure which locale your system is set to), you can instruct `initdb` exactly which locale to use by specifying the `--locale` option. For example:

```
initdb --locale=sv_SE
```

This example for Unix systems sets the locale to Swedish (`sv`) as spoken in Sweden (`SE`). Other possibilities might be `en_US` (U.S. English) and `fr_CA` (French Canadian). If more than one character set can be useful for a locale then the specifications look like this: `cs_CZ.ISO8859-2`. What locales are available under what names on your system depends on what was provided by the operating system vendor and what was installed. On most Unix systems, the command `locale -a` will provide a list of available locales. Windows uses more verbose locale names, such as `German_Germany` or `Swedish_Sweden.1252`, but the principles are the same.

Occasionally it is useful to mix rules from several locales, e.g., use English collation rules but Spanish messages. To support that, a set of locale subcategories exist that control only a certain aspect of the localization rules:

<table>
<thead>
<tr>
<th>LC_COLLATE</th>
<th>String sort order</th>
</tr>
</thead>
<tbody>
<tr>
<td>LC_CTYPE</td>
<td>Character classification (What is a letter? Its upper-case equivalent?)</td>
</tr>
<tr>
<td>LC_MESSAGES</td>
<td>Language of messages</td>
</tr>
<tr>
<td>LC_MONETARY</td>
<td>Formatting of currency amounts</td>
</tr>
<tr>
<td>LC_NUMERIC</td>
<td>Formatting of numbers</td>
</tr>
</tbody>
</table>
Chapter 22. Localization

The category names translate into names of `initdb` options to override the locale choice for a specific category. For instance, to set the locale to French Canadian, but use U.S. rules for formatting currency, use `initdb --locale=fr_CA --lc-monetary=en_US`.

If you want the system to behave as if it had no locale support, use the special locale `C` or `POSIX`.

The nature of some locale categories is that their value has to be fixed when the database is created. You can use different settings for different databases, but once a database is created, you cannot change them for that database anymore. `LC_COLLATE` and `LC_CTYPE` are these categories. They affect the sort order of indexes, so they must be kept fixed, or indexes on text columns will become corrupt. The default values for these categories are determined when `initdb` is run, and those values are used when new databases are created, unless specified otherwise in the `CREATE DATABASE` command.

The other locale categories can be changed whenever desired by setting the server configuration parameters that have the same name as the locale categories (see Section 18.10.2 for details). The values that are chosen by `initdb` are actually only written into the configuration file `postgresql.conf` to serve as defaults when the server is started. If you delete these assignments from `postgresql.conf` then the server will inherit the settings from its execution environment.

Note that the locale behavior of the server is determined by the environment variables seen by the server, not by the environment of any client. Therefore, be careful to configure the correct locale settings before starting the server. A consequence of this is that if client and server are set up in different locales, messages might appear in different languages depending on where they originated.

**Note:** When we speak of inheriting the locale from the execution environment, this means the following on most operating systems: For a given locale category, say the collation, the following environment variables are consulted in this order until one is found to be set: `LC_ALL`, `LC_COLLATE` (or the variable corresponding to the respective category), `LANG`. If none of these environment variables are set then the locale defaults to `C`.

Some message localization libraries also look at the environment variable `LANGUAGE` which overrides all other locale settings for the purpose of setting the language of messages. If in doubt, please refer to the documentation of your operating system, in particular the documentation about `gettext`, for more information.

To enable messages to be translated to the user’s preferred language, NLS must have been selected at build time (`configure --enable-nls`). All other locale support is built in automatically.

### 22.1.2. Behavior

The locale settings influence the following SQL features:

- Sort order in queries using `ORDER BY` or the standard comparison operators on textual data
- The ability to use indexes with `LIKE` clauses
- The ` upper, lower, and initcap` functions
- The `to_char` family of functions
Chapter 22. Localization

The drawback of using locales other than C or POSIX in PostgreSQL is its performance impact. It slows character handling and prevents ordinary indexes from being used by LIKE. For this reason use locales only if you actually need them.

As a workaround to allow PostgreSQL to use indexes with LIKE clauses under a non-C locale, several custom operator classes exist. These allow the creation of an index that performs a strict character-by-character comparison, ignoring locale comparison rules. Refer to Section 11.9 for more information.

22.1.3. Problems

If locale support doesn’t work according to the explanation above, check that the locale support in your operating system is correctly configured. To check what locales are installed on your system, you can use the command `locale -a` if your operating system provides it.

Check that PostgreSQL is actually using the locale that you think it is. The `LC_COLLATE` and `LC_CTYPE` settings are determined when a database is created, and cannot be changed except by creating a new database. Other locale settings including `LC_MESSAGES` and `LC_MONETARY` are initially determined by the environment the server is started in, but can be changed on-the-fly. You can check the active locale settings using the `SHOW` command.

The directory `src/test/locale` in the source distribution contains a test suite for PostgreSQL’s locale support.

Client applications that handle server-side errors by parsing the text of the error message will obviously have problems when the server’s messages are in a different language. Authors of such applications are advised to make use of the error code scheme instead.

Maintaining catalogs of message translations requires the on-going efforts of many volunteers that want to see PostgreSQL speak their preferred language well. If messages in your language are currently not available or not fully translated, your assistance would be appreciated. If you want to help, refer to Chapter 47 or write to the developers’ mailing list.

22.2. Character Set Support

The character set support in PostgreSQL allows you to store text in a variety of character sets (also called encodings), including single-byte character sets such as the ISO 8859 series and multiple-byte character sets such as EUC (Extended Unix Code), UTF-8, and Mule internal code. All supported character sets can be used transparently by clients, but a few are not supported for use within the server (that is, as a server-side encoding). The default character set is selected while initializing your PostgreSQL database cluster using `initdb`. It can be overridden when you create a database, so you can have multiple databases each with a different character set.

An important restriction, however, is that each database’s character set must be compatible with the database’s `LC_CTYPE` and `LC_COLLATE` locale settings. For C or POSIX locale, any character set is allowed, but for other locales there is only one character set that will work correctly. (On Windows, however, UTF-8 encoding can be used with any locale.)

22.2.1. Supported Character Sets

Table 22-1 shows the character sets available for use in PostgreSQL.

</table>

Not all APIs support all the listed character sets. For example, the PostgreSQL JDBC driver does not support MULE_INTERNAL, LATIN6, LATIN8, and LATIN10.

The SQL_ASCII setting behaves considerably differently from the other settings. When the server character set is SQL_ASCII, the server interprets byte values 0-127 according to the ASCII standard, while byte values 128-255 are taken as uninterpreted characters. No encoding conversion will be done when the setting is SQL_ASCII. Thus, this setting is not so much a declaration that a specific encoding is in use, as a declaration of ignorance about the encoding. In most cases, if you are working with any non-ASCII data, it is unwise to use the SQL_ASCII setting, because PostgreSQL will be unable to help you by converting or validating non-ASCII characters.

22.2.2. Setting the Character Set

initdb defines the default character set for a PostgreSQL cluster. For example,

```
initdb -E EUC_JP
```

sets the default character set (encoding) to EUC_JP (Extended Unix Code for Japanese). You can use --encoding instead of -E if you prefer to type longer option strings. If no -E or --encoding option is given, initdb attempts to determine the appropriate encoding to use based on the specified or default locale.

You can specify a non-default encoding at database creation time, provided that the encoding is compatible with the selected locale:

```
createdb -E EUC_KR -T template0 --lc-collate=ko_KR.euckr --lc-ctype=ko_KR.euckr korean
```

This will create a database named korean that uses the character set EUC_KR, and locale ko_KR.

Another way to accomplish this is to use this SQL command:

```
CREATE DATABASE korean WITH ENCODING 'EUC_KR' LC_COLLATE='ko_KR.euckr' LC_CTYPE='ko_KR.euckr' TEMPLATE=template0;
```

Notice that the above commands specify copying the template0 database. When copying any other database, the encoding and locale settings cannot be changed from those of the source database, because that might result in corrupt data. For more information see Section 21.3.

The encoding for a database is stored in the system catalog pg_database. You can see it by using the -l option or the \l command of psql.

```
$ psql -l
```

</tr>
</tbody>
</table>

454
Important: On most modern operating systems, PostgreSQL can determine which character set is implied by an LC_CTYPE setting, and it will enforce that only the matching database encoding is used. On older systems it is your responsibility to ensure that you use the encoding expected by the locale you have selected. A mistake in this area is likely to lead to strange misbehavior of locale-dependent operations such as sorting.

PostgreSQL will allow superusers to create databases with SQL_ASCII encoding even when LC_CTYPE is not C or POSIX. As noted above, SQL_ASCII does not enforce that the data stored in the database has any particular encoding, and so this choice poses risks of locale-dependent misbehavior. Using this combination of settings is deprecated and may someday be forbidden altogether.

22.2.3. Automatic Character Set Conversion Between Server and Client

PostgreSQL supports automatic character set conversion between server and client for certain character set combinations. The conversion information is stored in the pg_conversion system catalog. PostgreSQL comes with some predefined conversions, as shown in Table 22-2. You can create a new conversion using the SQL command CREATE CONVERSION.

Table 22-2. Client/Server Character Set Conversions

To enable automatic character set conversion, you have to tell PostgreSQL the character set (encoding) you would like to use in the client. There are several ways to accomplish this:

- **Using the `\encoding` command in psql.** `\encoding` allows you to change client encoding on the fly. For example, to change the encoding to SJIS, type:

  \encoding SJIS

- **libpq (Section 30.9) has functions to control the client encoding.**

- **Using `SET client_encoding TO`**. Setting the client encoding can be done with this SQL command:

  ```sql
  SET CLIENT_ENCODING TO 'value';
  ```

  Also you can use the standard SQL syntax `SET NAMES` for this purpose:

  ```sql
  SET NAMES 'value';
  ```

  To query the current client encoding:
SHOW client_encoding;

To return to the default encoding:

RESET client_encoding;

• Using PGCLIENTENCODING. If the environment variable PGCLIENTENCODING is defined in the client’s environment, that client encoding is automatically selected when a connection to the server is made. (This can subsequently be overridden using any of the other methods mentioned above.)

• Using the configuration variable client_encoding. If the client_encoding variable is set, that client encoding is automatically selected when a connection to the server is made. (This can subsequently be overridden using any of the other methods mentioned above.)

If the conversion of a particular character is not possible — suppose you chose EUC_JP for the server and LATIN1 for the client, then some Japanese characters do not have a representation in LATIN1 — then an error is reported.

If the client character set is defined as SQL_ASCII, encoding conversion is disabled, regardless of the server’s character set. Just as for the server, use of SQL_ASCII is unwise unless you are working with all-ASCII data.

Chapter 23. Routine Database Maintenance Tasks

PostgreSQL, like any database software, requires that certain tasks be performed regularly to achieve optimum performance. The tasks discussed here are required, but they are repetitive in nature and can easily be automated using standard tools such as cron scripts or Windows’ Task Scheduler. But it is the database administrator’s responsibility to set up appropriate scripts, and to check that they execute successfully.

One obvious maintenance task is creation of backup copies of the data on a regular schedule. Without a recent backup, you have no chance of recovery after a catastrophe (disk failure, fire, mistakenly dropping a critical table, etc.). The backup and recovery mechanisms available in PostgreSQL are discussed at length in Chapter 24.

The other main category of maintenance task is periodic “vacuuming” of the database. This activity is discussed in Section 23.1. Closely related to this is updating the statistics that will be used by the query planner, as discussed in Section 23.1.3.

Another task that might need periodic attention is log file management. This is discussed in Section 23.3.

check_postgres.pl\(^1\) is available for monitoring database health and reporting unusual conditions. check_postgres.pl integrates with Nagios and MRTG, but can be run standalone too.

PostgreSQL is low-maintenance compared to some other database management systems. Nonetheless, appropriate attention to these tasks will go far towards ensuring a pleasant and productive experience with the system.

23.1. Routine Vacuuming

PostgreSQL databases require periodic maintenance known as vacuuming. For many installations, it is sufficient to let vacuuming be performed by the autovacuum daemon, which is described in Section 23.1.5. You might need to adjust the autovacuuming parameters described there to obtain best results for your situation. Some database administrators will want to supplement or replace the daemon’s activities with manually-managed VACUUM commands, which typically are executed according to a schedule by cron or Task Scheduler scripts. To set up manually-managed vacuuming properly, it is essential to understand the issues discussed in the next few subsections. Administrators who rely on autovacuuming may still wish to skim this material to help them understand and adjust autovacuuming.

23.1.1. Vacuuming Basics

PostgreSQL’s VACUUM command has to process each table on a regular basis for several reasons:

1. To recover or reuse disk space occupied by updated or deleted rows.
2. To update data statistics used by the PostgreSQL query planner.
3. To protect against loss of very old data due to transaction ID wraparound.

\(^1\) http://bucardo.org/check_postgres/
Chapter 23. Routine Database Maintenance Tasks

Each of these reasons dictates performing \texttt{VACUUM} operations of varying frequency and scope, as explained in the following subsections.

There are two variants of \texttt{VACUUM}: standard \texttt{VACUUM} and \texttt{VACUUM FULL}. \texttt{VACUUM FULL} can reclaim more disk space but runs much more slowly. Also, the standard form of \texttt{VACUUM} can run in parallel with production database operations. (Commands such as \texttt{SELECT}, \texttt{INSERT}, \texttt{UPDATE}, and \texttt{DELETE} will continue to function as normal, though you will not be able to modify the definition of a table with commands such as \texttt{ALTER TABLE} while it is being vacuumed.) \texttt{VACUUM FULL} requires exclusive lock on the table it is working on, and therefore cannot be done in parallel with other use of the table. Another disadvantage of \texttt{VACUUM FULL} is that while it reduces table size, it does not reduce index size proportionally; in fact it can make indexes larger. Generally, therefore, administrators should strive to use standard \texttt{VACUUM} and avoid \texttt{VACUUM FULL}.

\texttt{VACUUM} creates a substantial amount of I/O traffic, which can cause poor performance for other active sessions. There are configuration parameters that can be adjusted to reduce the performance impact of background vacuuming — see Section 18.4.3.

23.1.2. Recovering Disk Space

In PostgreSQL, an \texttt{UPDATE} or \texttt{DELETE} of a row does not immediately remove the old version of the row. This approach is necessary to gain the benefits of multiversion concurrency control (see Chapter 13): the row version must not be deleted while it is still potentially visible to other transactions. But eventually, an outdated or deleted row version is no longer of interest to any transaction. The space it occupies must then be reclaimed for reuse by new rows, to avoid infinite growth of disk space requirements. This is done by running \texttt{VACUUM}.

The standard form of \texttt{VACUUM} removes dead row versions in tables and indexes and marks the space available for future reuse. However, it will not return the space to the operating system, except in the special case where one or more pages at the end of a table become entirely free and an exclusive table lock can be easily obtained. In contrast, \texttt{VACUUM FULL} actively compacts tables by moving row versions to earlier pages. It is thus able to force pages at the end of the table to become entirely free, whereupon it will return them to the operating system. However, if many rows must be moved, this can take a long time. Also, moving a row requires transiently making duplicate index entries for it (the entry pointing to its new location must be made before the old entry can be removed); so moving a lot of rows this way causes severe index bloat.

The usual goal of routine vacuuming is to do standard \texttt{VACUUM}s often enough to avoid needing \texttt{VACUUM FULL}. The autovacuum daemon attempts to work this way, and in fact will never issue \texttt{VACUUM FULL}. In this approach, the idea is not to keep tables at their minimum size, but to maintain steady-state usage of disk space: each table occupies space equivalent to its minimum size plus however much space gets used up between vacuumings. Although \texttt{VACUUM FULL} can be used to shrink a table back to its minimum size and return the disk space to the operating system, there is not much point in this if the table will just grow again in the future. Thus, moderately-frequent standard \texttt{VACUUM} runs are a better approach than infrequent \texttt{VACUUM FULL} runs for maintaining heavily-updated tables.

Some administrators prefer to schedule vacuuming themselves, for example doing all the work at night when load is low. The difficulty with doing vacuuming according to a fixed schedule is that if a table has an unexpected spike in update activity, it may get bloated to the point that \texttt{VACUUM FULL} is really necessary to reclaim space. Using the autovacuum daemon alleviates this problem, since the daemon schedules vacuuming dynamically in response to update activity. It is unwise to disable the daemon completely unless you have an extremely predictable workload. One possible compromise is to set the daemon’s parameters so that it will only react to unusually heavy update activity, thus keeping things from getting out of hand, while scheduled \texttt{VACUUM}s are expected to do the bulk of the work when the load is typical.
Chapter 23. Routine Database Maintenance Tasks

For those not using autovacuum, a typical approach is to schedule a database-wide \texttt{VACUUM} once a day during a low-usage period, supplemented by more frequent vacuuming of heavily-updated tables as necessary. (Some installations with extremely high update rates vacuum their busiest tables as often as once every few minutes.) If you have multiple databases in a cluster, don’t forget to \texttt{VACUUM} each one; the program \texttt{vacuumdb} might be helpful.

\textbf{Tip:} Neither form of \texttt{VACUUM} is entirely satisfactory when a table contains large numbers of dead row versions as a result of massive update or delete activity. If you have such a table and you need to reclaim the excess disk space it occupies, the best way is to use \texttt{CLUSTER} or one of the table-rewriting variants of \texttt{ALTER TABLE}. These commands rewrite an entire new copy of the table and build new indexes for it. Like \texttt{VACUUM FULL}, they require exclusive lock. Note that they also temporarily use extra disk space, since the old copies of the table and indexes can’t be released until the new ones are complete. In the worst case where your disk is nearly full, \texttt{VACUUM FULL} may be the only workable alternative.

\textbf{Tip:} If you have a table whose entire contents are deleted on a periodic basis, consider doing it with \texttt{TRUNCATE} rather than using \texttt{DELETE} followed by \texttt{VACUUM}. \texttt{TRUNCATE} removes the entire content of the table immediately, without requiring a subsequent \texttt{VACUUM} or \texttt{VACUUM FULL} to reclaim the now-unused disk space. The disadvantage is that strict MVCC semantics are violated.

23.1.3. Updating Planner Statistics

The PostgreSQL query planner relies on statistical information about the contents of tables in order to generate good plans for queries. These statistics are gathered by the \texttt{ANALYZE} command, which can be invoked by itself or as an optional step in \texttt{VACUUM}. It is important to have reasonably accurate statistics, otherwise poor choices of plans might degrade database performance.

The autovacuum daemon, if enabled, will automatically issue \texttt{ANALYZE} commands whenever the content of a table has changed sufficiently. However, administrators might prefer to rely on manually-scheduled \texttt{ANALYZE} operations, particularly if it is known that update activity on a table will not affect the statistics of “interesting” columns. The daemon schedules \texttt{ANALYZE} strictly as a function of the number of rows inserted or updated; it has no knowledge of whether that will lead to meaningful statistical changes.

As with vacuuming for space recovery, frequent updates of statistics are more useful for heavily-updated tables than for seldom-updated ones. But even for a heavily-updated table, there might be no need for statistics updates if the statistical distribution of the data is not changing much. A simple rule of thumb is to think about how much the minimum and maximum values of the columns in the table change. For example, a \texttt{timestamp} column that contains the time of row update will have a constantly-increasing maximum value as rows are added and updated; such a column will probably need more frequent statistics updates than, say, a column containing URLs for pages accessed on a website. The URL column might receive changes just as often, but the statistical distribution of its values probably changes relatively slowly.

It is possible to run \texttt{ANALYZE} on specific tables and even just specific columns of a table, so the flexibility exists to update some statistics more frequently than others if your application requires it. In practice, however, it is usually best to just analyze the entire database, because it is a fast operation. \texttt{ANALYZE} uses a statistical random sampling of the rows of a table rather than reading every single row.
Tip: Although per-column tweaking of `ANALYZE` frequency might not be very productive, you might well find it worthwhile to do per-column adjustment of the level of detail of the statistics collected by `ANALYZE`. Columns that are heavily used in `WHERE` clauses and have highly irregular data distributions might require a finer grain data histogram than other columns. See `ALTER TABLE SET STATISTICS`, or change the database-wide default using the `default_statistics_target` configuration parameter.

### 23.1.4. Preventing Transaction ID Wraparound Failures

PostgreSQL’s MVCC transaction semantics depend on being able to compare transaction ID (XID) numbers: a row version with an insertion XID greater than the current transaction’s XID is “in the future” and should not be visible to the current transaction. But since transaction IDs have limited size (32 bits at this writing) a cluster that runs for a long time (more than 4 billion transactions) would suffer transaction ID wraparound: the XID counter wraps around to zero, and all of a sudden transactions that were in the past appear to be in the future — which means their outputs become invisible. In short, catastrophic data loss. (Actually the data is still there, but that’s cold comfort if you cannot get at it.) To avoid this, it is necessary to vacuum every table in every database at least once every two billion transactions.

The reason that periodic vacuuming solves the problem is that PostgreSQL distinguishes a special XID `FrozenXID`. This XID is always considered older than every normal XID. Normal XIDs are compared using modulo-2³² arithmetic. This means that for every normal XID, there are two billion XIDs that are “older” and two billion that are “newer”; another way to say it is that the normal XID space is circular with no endpoint. Therefore, once a row version has been created with a particular normal XID, the row version will appear to be “in the past” for the next two billion transactions, no matter which normal XID we are talking about. If the row version still exists after more than two billion transactions, it will suddenly appear to be in the future. To prevent data loss, old row versions must be reassigned the XID `FrozenXID` sometime before they reach the two-billion-transactions-old mark. Once they are assigned this special XID, they will appear to be “in the past” to all normal transactions regardless of wraparound issues, and so such row versions will be good until deleted, no matter how long that is. This reassignment of old XIDs is handled by `VACUUM`.

`vacuum_freeze_min_age` controls how old an XID value has to be before it’s replaced with `FrozenXID`. Larger values of this setting preserve transactional information longer, while smaller values increase the number of transactions that can elapse before the table must be vacuumed again. `VACUUM` normally skips pages that don’t have any dead row versions, but those pages might still have row versions with old XID values. To ensure all old XIDs have been replaced by `FrozenXID`, a scan of the whole table is needed. `vacuum_freeze_table_age` controls when `VACUUM` does that: a whole table sweep is forced if the table hasn’t been fully scanned for `vacuum_freeze_table_age` minus `vacuum_freeze_min_age` transactions. Setting it to 0 forces `VACUUM` to always scan all pages, effectively ignoring the visibility map.

The maximum time that a table can go unvacuumed is two billion transactions minus the `vacuum_freeze_min_age` that was used when `VACUUM` last scanned the whole table. If it were to go unvacuumed for longer than that, data loss could result. To ensure that this does not happen, `autovacuum` is invoked on any table that might contain XIDs older than the age specified by the configuration parameter `autovacuum_freeze_max_age`. (This will happen even if `autovacuum` is otherwise disabled.)

This implies that if a table is not otherwise vacuumed, `autovacuum` will be invoked on it approximately once every `autovacuum_freeze_max_age` minus `vacuum_freeze_min_age` transactions.
For tables that are regularly vacuumed for space reclamation purposes, this is of little importance. However, for static tables (including tables that receive inserts, but no updates or deletes), there is no need for vacuuming for space reclamation, and so it can be useful to try to maximize the interval between forced autovacuums on very large static tables. Obviously one can do this either by increasing `autovacuum_freeze_max_age` or by decreasing `vacuum_freeze_min_age`.

The effective maximum for `vacuum_freeze_table_age` is 0.95 * `autovacuum_freeze_max_age`; a setting higher than that will be capped to the maximum. A value higher than `autovacuum_freeze_max_age` wouldn’t make sense because an anti-wraparound autovacuum would be triggered at that point anyway, and the 0.95 multiplier leaves some breathing room to run a manual VACUUM before that happens. As a rule of thumb, `vacuum_freeze_table_age` should be set to a value somewhat below `autovacuum_freeze_max_age`, leaving enough gap so that a regularly scheduled VACUUM or an autovacuum triggered by normal delete and update activity is run in that window. Setting it too close could lead to anti-wraparound autovacuums, even though the table was recently vacuumed to reclaim space, whereas lower values lead to more frequent whole-table scans.

The sole disadvantage of increasing `autovacuum_freeze_max_age` (and `vacuum_freeze_table_age` along with it) is that the `pg_clog` subdirectory of the database cluster will take more space, because it must store the commit status for all transactions back to the `autovacuum_freeze_max_age` horizon. The commit status uses two bits per transaction, so if `autovacuum_freeze_max_age` has its maximum allowed value of two billion, `pg_clog` can be expected to grow to about half a gigabyte. If this is trivial compared to your total database size, setting `autovacuum_freeze_max_age` to its maximum allowed value is recommended. Otherwise, set it depending on what you are willing to allow for `pg_clog` storage. (The default, 200 million transactions, translates to about 50MB of `pg_clog` storage.)

One disadvantage of decreasing `vacuum_freeze_min_age` is that it might cause VACUUM to do useless work: changing a table row’s XID to FrozenXID is a waste of time if the row is modified soon thereafter (causing it to acquire a new XID). So the setting should be large enough that rows are not frozen until they are unlikely to change any more. Another disadvantage of decreasing this setting is that details about exactly which transaction inserted or modified a row will be lost sooner. This information sometimes comes in handy, particularly when trying to analyze what went wrong after a database failure. For these two reasons, decreasing this setting is not recommended except for completely static tables.

To track the age of the oldest XIDs in a database, VACUUM stores XID statistics in the system tables `pg_class` and `pg_database`. In particular, the `relfrozenxid` column of a table’s `pg_class` row contains the freeze cutoff XID that was used by the last whole-table VACUUM for that table. All normal XIDs older than this cutoff XID are guaranteed to have been replaced by FrozenXID within the table. Similarly, the `datfrozenxid` column of a database’s `pg_database` row is a lower bound on the normal XIDs appearing in that database — it is just the minimum of the per-table `relfrozenxid` values within the database. A convenient way to examine this information is to execute queries such as:

```sql
SELECT c.oid::regclass as table_name,
       greatest(age(c.relfrozenxid),age(t.relfrozenxid)) as age
FROM pg_class c
LEFT JOIN pg_class t ON c.reltoastrelid = t.oid
WHERE c.relkind = 'r';
```

```sql
SELECT datname, age(datfrozenxid) FROM pg_database;
```

The `age` column measures the number of transactions from the cutoff XID to the current transaction’s XID.
Chapter 23. Routine Database Maintenance Tasks

VACUUM normally only scans pages that have been modified since the last vacuum, but relfrozenxid can only be advanced when the whole table is scanned. The whole table is scanned when relfrozenxid is more than vacuum_freeze_table_age transactions old, when the VACUUM FREEZE command is used, or when all pages happen to require vacuuming to remove dead row versions. When VACUUM scans the whole table, after it’s finished age(relfrozenxid) should be a little more than the vacuum_freeze_min_age setting that was used (more by the number of transactions started since the VACUUM started). If no whole-table-scanning VACUUM is issued on the table until autovacuum_freeze_max_age is reached, an autovacuum will soon be forced for the table.

If for some reason autovacuum fails to clear old XIDs from a table, the system will begin to emit warning messages like this when the database’s oldest XIDs reach ten million transactions from the wraparound point:

WARNING: database "mydb" must be vacuumed within 177009986 transactions
HINT: To avoid a database shutdown, execute a database-wide VACUUM in "mydb".

(A manual VACUUM should fix the problem, as suggested by the hint; but note that the VACUUM must be performed by a superuser, else it will fail to process system catalogs and thus not be able to advance the database’s datfrozenxid.) If these warnings are ignored, the system will shut down and refuse to execute any new transactions once there are fewer than 1 million transactions left until wraparound:

ERROR: database is not accepting commands to avoid wraparound data loss in database "mydb"
HINT: Stop the postmaster and use a standalone backend to VACUUM in "mydb".

The 1-million-transaction safety margin exists to let the administrator recover without data loss, by manually executing the required VACUUM commands. However, since the system will not execute commands once it has gone into the safety shutdown mode, the only way to do this is to stop the server and use a single-user backend to execute VACUUM. The shutdown mode is not enforced by a single-user backend. See the postgres reference page for details about using a single-user backend.

23.1.5. The Autovacuum Daemon

PostgreSQL has an optional but highly recommended feature called autovacuum, whose purpose is to automate the execution of VACUUM and ANALYZE commands. When enabled, autovacuum checks for tables that have had a large number of inserted, updated or deleted tuples. These checks use the statistics collection facility; therefore, autovacuum cannot be used unless track_counts is set to true.

In the default configuration, autovacuuming is enabled and the related configuration parameters are appropriately set.

The “autovacuum daemon” actually consists of multiple processes. There is a persistent daemon process, called the autovacuum launcher, which is in charge of starting autovacuum worker processes for all databases. The launcher will distribute the work across time, attempting to start one worker on each database every autovacuum_naptime seconds. One worker will be launched for each database, with a maximum of autovacuum_max_workers processes running at the same time. If there are more than autovacuum_max_workers databases to be processed, the next database will be processed as soon as the first worker finishes. Each worker process will check each table within its database and execute VACUUM and/or ANALYZE as needed.

The autovacuum_max_workers setting limits how many workers may be running at any time. If several large tables all become eligible for vacuuming in a short amount of time, all autovacuum workers may become occupied with vacuuming those tables for a long period. This would result in other tables and databases not being vacuumed until a worker became available. There is not a limit on how many workers might be in a single database, but workers do try to avoid repeating work that has already
been done by other workers. Note that the number of running workers does not count towards the max_connections nor the superuser_reserved_connections limits.

Tables whose relfrozenxid value is more than autovacuum_freeze_max_age transactions old are always vacuumed (this also applies to those tables whose freeze max age has been modified via storage parameters; see below). Otherwise, if the number of tuples obsoleted since the last VACUUM exceeds the “vacuum threshold”, the table is vacuumed. The vacuum threshold is defined as:

\[
\text{vacuum threshold} = \text{vacuum base threshold} + \text{vacuum scale factor} \times \text{number of tuples}
\]

where the vacuum base threshold is autovacuum_vacuum_threshold, the vacuum scale factor is autovacuum_vacuum_scale_factor, and the number of tuples is pg_class.reltuples. The number of obsolete tuples is obtained from the statistics collector; it is a semi-accurate count updated by each UPDATE and DELETE operation. (It is only semi-accurate because some information might be lost under heavy load.) If the relfrozenxid value of the table is more than vacuum_freeze_table_age transactions old, the whole table is scanned to freeze old tuples and advance relfrozenxid, otherwise only pages that have been modified since the last vacuum are scanned.

For analyze, a similar condition is used: the threshold, defined as:

\[
\text{analyze threshold} = \text{analyze base threshold} + \text{analyze scale factor} \times \text{number of tuples}
\]

is compared to the total number of tuples inserted or updated since the last ANALYZE.

The default thresholds and scale factors are taken from postgresql.conf, but it is possible to override them on a table-by-table basis; see Storage Parameters for more information. If a setting has been changed via storage parameters, that value is used; otherwise the global settings are used. See Section 18.9 for more details on the global settings.

Besides the base threshold values and scale factors, there are six more autovacuum parameters that can be set for each table via storage parameters. The first parameter, autovacuum_enabled, can be set to false to instruct the autovacuum daemon to skip that particular table entirely. In this case autovacuum will only touch the table if it must do so to prevent transaction ID wraparound. Another two parameters, autovacuum_vacuum_cost_delay and autovacuum_vacuum_cost_limit, are used to set table-specific values for the Cost-Based Vacuum Delay feature. autovacuum_freeze_min_age, autovacuum_freeze_max_age and autovacuum_freeze_table_age are used to set values for vacuum_freeze_min_age, autovacuum_freeze_max_age and vacuum_freeze_table_age respectively.

When multiple workers are running, the cost limit is “balanced” among all the running workers, so that the total impact on the system is the same, regardless of the number of workers actually running.

### 23.2. Routine Reindexing

In some situations it is worthwhile to rebuild indexes periodically with the REINDEX command.

In PostgreSQL releases before 7.4, periodic reindexing was frequently necessary to avoid “index bloat”, due to lack of internal space reclamation in B-tree indexes. Any situation in which the range of index keys changed over time — for example, an index on timestamps in a table where old entries are eventually deleted — would result in bloat, because index pages for no-longer-needed portions of the key range were not reclaimed for re-use. Over time, the index size could become indefinitely much larger than the amount of useful data in it.

In PostgreSQL 7.4 and later, index pages that have become completely empty are reclaimed for re-use. There is still a possibility for inefficient use of space: if all but a few index keys on a page have
been deleted, the page remains allocated. So a usage pattern in which all but a few keys in each range are eventually deleted will see poor use of space. For such usage patterns, periodic reindexing is recommended.

The potential for bloat in non-B-tree indexes has not been well characterized. It is a good idea to keep an eye on the index’s physical size when using any non-B-tree index type.

Also, for B-tree indexes a freshly-constructed index is somewhat faster to access than one that has been updated many times, because logically adjacent pages are usually also physically adjacent in a newly built index. (This consideration does not currently apply to non-B-tree indexes.) It might be worthwhile to reindex periodically just to improve access speed.

### 23.3. Log File Maintenance

It is a good idea to save the database server’s log output somewhere, rather than just routing it to `/dev/null`. The log output is invaluable when it comes time to diagnose problems. However, the log output tends to be voluminous (especially at higher debug levels) and you won’t want to save it indefinitely. You need to “rotate” the log files so that new log files are started and old ones removed after a reasonable period of time.

If you simply direct the stderr of `postgres` into a file, you will have log output, but the only way to truncate the log file is to stop and restart the server. This might be OK if you are using PostgreSQL in a development environment, but few production servers would find this behavior acceptable.

A better approach is to send the server’s stderr output to some type of log rotation program. There is a built-in log rotation program, which you can use by setting the configuration parameter `logging_collector` to `true` in `postgresql.conf`. The control parameters for this program are described in Section 18.7.1. You can also use this approach to capture the log data in machine readable CSV format.

Alternatively, you might prefer to use an external log rotation program, if you have one that you are already using with other server software. For example, the `rotatelogs` tool included in the Apache distribution can be used with PostgreSQL. To do this, just pipe the server’s stderr output to the desired program. If you start the server with `pg_ctl`, then stderr is already redirected to stdout, so you just need a pipe command, for example:

```
pg_ctl start | rotatelogs /var/log/pgsql_log 86400
```

Another production-grade approach to managing log output is to send it all to syslog and let syslog deal with file rotation. To do this, set the configuration parameter `log_destination` to `syslog` (to log to syslog only) in `postgresql.conf`. Then you can send a `SIGHUP` signal to the syslog daemon whenever you want to force it to start writing a new log file. If you want to automate log rotation, the logrotate program can be configured to work with log files from syslog.

On many systems, however, syslog is not very reliable, particularly with large log messages; it might truncate or drop messages just when you need them the most. Also, on Linux, syslog will sync each message to disk, yielding poor performance. (You can use a `−` at the start of the file name in the syslog configuration file to disable syncing.)

Note that all the solutions described above take care of starting new log files at configurable intervals, but they do not handle deletion of old, no-longer-interesting log files. You will probably want to set up a batch job to periodically delete old log files. Another possibility is to configure the rotation program so that old log files are overwritten cyclically.
Chapter 24. Backup and Restore

As with everything that contains valuable data, PostgreSQL databases should be backed up regularly. While the procedure is essentially simple, it is important to have a clear understanding of the underlying techniques and assumptions.

There are three fundamentally different approaches to backing up PostgreSQL data:

- SQL dump
- File system level backup
- Continuous archiving

Each has its own strengths and weaknesses. Each is discussed in turn below.

24.1. SQL Dump

The idea behind this dump method is to generate a text file with SQL commands that, when fed back to the server, will recreate the database in the same state as it was at the time of the dump. PostgreSQL provides the utility program pg_dump for this purpose. The basic usage of this command is:

```
pg_dump dbname > outfile
```

As you see, pg_dump writes its results to the standard output. We will see below how this can be useful.

pg_dump is a regular PostgreSQL client application (albeit a particularly clever one). This means that you can do this backup procedure from any remote host that has access to the database. But remember that pg_dump does not operate with special permissions. In particular, it must have read access to all tables that you want to back up, so in practice you almost always have to run it as a database superuser.

To specify which database server pg_dump should contact, use the command line options `-h host` and `-p port`. The default host is the local host or whatever your `PGHOST` environment variable specifies. Similarly, the default port is indicated by the `PGPORT` environment variable or, failing that, by the compiled-in default. (Conveniently, the server will normally have the same compiled-in default.)

Like any other PostgreSQL client application, pg_dump will by default connect with the database user name that is equal to the current operating system user name. To override this, either specify the `-U` option or set the environment variable `PGUSER`. Remember that pg_dump connections are subject to the normal client authentication mechanisms (which are described in Chapter 19).

Dumps created by pg_dump are internally consistent, that is, the dump represents a snapshot of the database as of the time pg_dump begins running. pg_dump does not block other operations on the database while it is working. (Exceptions are those operations that need to operate with an exclusive lock, such as most forms of `ALTER TABLE`.)

Important: If your database schema relies on OIDs (for instance as foreign keys) you must instruct pg_dump to dump the OIDs as well. To do this, use the `-o` command line option.
24.1.1. Restoring the dump

The text files created by pg_dump are intended to be read in by the psql program. The general command form to restore a dump is

```
psql dbname < infile
```

where `infile` is what you used as `outfile` for the pg_dump command. The database `dbname` will not be created by this command, so you must create it yourself from `template0` before executing `psql` (e.g., with `createdb -T template0 dbname`). `psql` supports options similar to pg_dump’s for specifying the database server to connect to and the user name to use. See the `psql` reference page for more information.

Before restoring a SQL dump, all the users who own objects or were granted permissions on objects in the dumped database must already exist. If they do not, then the restore will fail to recreate the objects with the original ownership and/or permissions. (Sometimes this is what you want, but usually it is not.)

By default, the `psql` script will continue to execute after an SQL error is encountered. You might wish to use the following command at the top of the script to alter that behaviour and have `psql` exit with an exit status of 3 if an SQL error occurs:

```
\set ON_ERROR_STOP
```

Either way, you will have an only partially restored database. Alternatively, you can specify that the whole dump should be restored as a single transaction, so the restore is either fully completed or fully rolled back. This mode can be specified by passing the `-1` or `--single-transaction` command-line options to `psql`. When using this mode, be aware that even the smallest of errors can rollback a restore that has already run for many hours. However, that might still be preferable to manually cleaning up a complex database after a partially restored dump.

The ability of pg_dump and psql to write to or read from pipes makes it possible to dump a database directly from one server to another, for example:

```
pg_dump -h host1 dbname | psql -h host2 dbname
```

Important: The dumps produced by pg_dump are relative to `template0`. This means that any languages, procedures, etc. added via `template1` will also be dumped by pg_dump. As a result, when restoring, if you are using a customized `template1`, you must create the empty database from `template0`, as in the example above.

After restoring a backup, it is wise to run `ANALYZE` on each database so the query optimizer has useful statistics; see `Updating Planner Statistics` and `The Autovacuum Daemon` for more information. For more advice on how to load large amounts of data into PostgreSQL efficiently, refer to Section 14.4.

24.1.2. Using pg_dumpall

pg_dump dumps only a single database at a time, and it does not dump information about roles or tablespaces (because those are cluster-wide rather than per-database). To support convenient dumping of the entire contents of a database cluster, the pg_dumpall program is provided. pg_dumpall backs
up each database in a given cluster, and also preserves cluster-wide data such as role and tablespace definitions. The basic usage of this command is:

```
pg_dumpall > outfile
```

The resulting dump can be restored with psql:

```
psql -f infile postgres
```

(Actually, you can specify any existing database name to start from, but if you are reloading into an empty cluster then `postgres` should usually be used.) It is always necessary to have database superuser access when restoring a pg_dumpall dump, as that is required to restore the role and tablespace information. If you use tablespaces, be careful that the tablespace paths in the dump are appropriate for the new installation.

pg_dumpall works by emitting commands to re-create roles, tablespaces, and empty databases, then invoking pg_dump for each database. This means that while each database will be internally consistent, the snapshots of different databases might not be exactly in-sync.

### 24.1.3. Handling large databases

Since PostgreSQL allows tables larger than the maximum file size on your system, it can be problematic to dump such a table to a file, since the resulting file will likely be larger than the maximum size allowed by your system. Since pg_dump can write to the standard output, you can use standard Unix tools to work around this possible problem. There are several ways to do it:

**Use compressed dumps.** You can use your favorite compression program, for example gzip:

```
pg_dump dbname | gzip > filename.gz
```

Reload with:

```
gunzip -c filename.gz | psql dbname
```

or:

```
cat filename.gz | gunzip | psql dbname
```

**Use split.** The split command allows you to split the output into pieces that are acceptable in size to the underlying file system. For example, to make chunks of 1 megabyte:

```
pg_dump dbname | split -b 1m - filename
```

Reload with:

```
cat filename* | psql dbname
```

**Use pg_dump’s custom dump format.** If PostgreSQL was built on a system with the zlib compression library installed, the custom dump format will compress data as it writes it to the output file. This will produce dump file sizes similar to using gzip, but it has the added advantage that tables can be restored selectively. The following command dumps a database using the custom dump format:

```
pg_dump -Fc dbname > filename
```

A custom-format dump is not a script for psql, but instead must be restored with pg_restore, for example:
Chapter 24. Backup and Restore

pg_restore -d dbname filename

See the pg_dump and pg_restore reference pages for details.
For very large databases, you might need to combine split with one of the other two approaches.

24.2. File System Level Backup

An alternative backup strategy is to directly copy the files that PostgreSQL uses to store the data in the database. In Section 17.2 it is explained where these files are located, but you have probably found them already if you are interested in this method. You can use whatever method you prefer for doing usual file system backups, for example:

tar -cf backup.tar /usr/local/pgsql/data

There are two restrictions, however, which make this method impractical, or at least inferior to the pg_dump method:

1. The database server must be shut down in order to get a usable backup. Half-way measures such as disallowing all connections will not work (in part because tar and similar tools do not take an atomic snapshot of the state of the file system, but also because of internal buffering within the server). Information about stopping the server can be found in Section 17.5. Needless to say that you also need to shut down the server before restoring the data.

2. If you have dug into the details of the file system layout of the database, you might be tempted to try to back up or restore only certain individual tables or databases from their respective files or directories. This will not work because the information contained in these files contains only half the truth. The other half is in the commit log files pg_clog/*, which contain the commit status of all transactions. A table file is only usable with this information. Of course it is also impossible to restore only a table and the associated pg_clog data because that would render all other tables in the database cluster useless. So file system backups only work for complete backup and restoration of an entire database cluster.

An alternative file-system backup approach is to make a “consistent snapshot” of the data directory, if the file system supports that functionality (and you are willing to trust that it is implemented correctly). The typical procedure is to make a “frozen snapshot” of the volume containing the database, then copy the whole data directory (not just parts, see above) from the snapshot to a backup device, then release the frozen snapshot. This will work even while the database server is running. However, a backup created in this way saves the database files in a state where the database server was not properly shut down; therefore, when you start the database server on the backed-up data, it will think the previous server instance had crashed and replay the WAL log. This is not a problem, just be aware of it (and be sure to include the WAL files in your backup).

If your database is spread across multiple file systems, there might not be any way to obtain exactly-simultaneous frozen snapshots of all the volumes. For example, if your data files and WAL log are on different disks, or if tablespaces are on different file systems, it might not be possible to use snapshot backup because the snapshots must be simultaneous. Read your file system documentation very carefully before trusting to the consistent-snapshot technique in such situations.
Chapter 24. Backup and Restore

If simultaneous snapshots are not possible, one option is to shut down the database server long enough to establish all the frozen snapshots. Another option is to perform a continuous archiving base backup (Section 24.3.2) because such backups are immune to file system changes during the backup. This requires enabling continuous archiving just during the backup process; restore is done using continuous archive recovery (Section 24.3.3).

Another option is to use rsync to perform a file system backup. This is done by first running rsync while the database server is running, then shutting down the database server just long enough to do a second rsync. The second rsync will be much quicker than the first, because it has relatively little data to transfer, and the end result will be consistent because the server was down. This method allows a file system backup to be performed with minimal downtime.

Note that a file system backup will not necessarily be smaller than an SQL dump. On the contrary, it will most likely be larger. (pg_dump does not need to dump the contents of indexes for example, just the commands to recreate them.) However, taking a file system backup might be faster.

24.3. Continuous Archiving and Point-In-Time Recovery (PITR)

At all times, PostgreSQL maintains a write ahead log (WAL) in the pg_xlog/ subdirectory of the cluster’s data directory. The log describes every change made to the database’s data files. This log exists primarily for crash-safety purposes: if the system crashes, the database can be restored to consistency by “replaying” the log entries made since the last checkpoint. However, the existence of the log makes it possible to use a third strategy for backing up databases: we can combine a file-system-level backup with backup of the WAL files. If recovery is needed, we restore the backup and then replay from the backed-up WAL files to bring the backup up to current time. This approach is more complex to administer than either of the previous approaches, but it has some significant benefits:

- We do not need a perfectly consistent backup as the starting point. Any internal inconsistency in the backup will be corrected by log replay (this is not significantly different from what happens during crash recovery). So we don’t need file system snapshot capability, just tar or a similar archiving tool.
- Since we can string together an indefinitely long sequence of WAL files for replay, continuous backup can be achieved simply by continuing to archive the WAL files. This is particularly valuable for large databases, where it might not be convenient to take a full backup frequently.
- There is nothing that says we have to replay the WAL entries all the way to the end. We could stop the replay at any point and have a consistent snapshot of the database as it was at that time. Thus, this technique supports point-in-time recovery: it is possible to restore the database to its state at any time since your base backup was taken.
- If we continuously feed the series of WAL files to another machine that has been loaded with the same base backup file, we have a warm standby system: at any point we can bring up the second machine and it will have a nearly-current copy of the database.

As with the plain file-system-backup technique, this method can only support restoration of an entire database cluster, not a subset. Also, it requires a lot of archival storage: the base backup might be bulky, and a busy system will generate many megabytes of WAL traffic that have to be archived. Still, it is the preferred backup technique in many situations where high reliability is needed.
To recover successfully using continuous archiving (also called “online backup” by many database vendors), you need a continuous sequence of archived WAL files that extends back at least as far as the start time of your backup. So to get started, you should set up and test your procedure for archiving WAL files before you take your first base backup. Accordingly, we first discuss the mechanics of archiving WAL files.

24.3.1. Setting up WAL archiving

In an abstract sense, a running PostgreSQL system produces an indefinitely long sequence of WAL records. The system physically divides this sequence into WAL segment files, which are normally 16MB apiece (although the segment size can be altered when building PostgreSQL). The segment files are given numeric names that reflect their position in the abstract WAL sequence. When not using WAL archiving, the system normally creates just a few segment files and then “recycles” them by renaming no-longer-needed segment files to higher segment numbers. It’s assumed that a segment file whose contents precede the checkpoint-before-last is no longer of interest and can be recycled. When archiving WAL data, we need to capture the contents of each segment file once it is filled, and save that data somewhere before the segment file is recycled for reuse. Depending on the application and the available hardware, there could be many different ways of “saving the data somewhere”: we could copy the segment files to an NFS-mounted directory on another machine, write them onto a tape drive (ensuring that you have a way of identifying the original name of each file), or batch them together and burn them onto CDs, or something else entirely. To provide the database administrator with as much flexibility as possible, PostgreSQL tries not to make any assumptions about how the archiving will be done. Instead, PostgreSQL lets the administrator specify a shell command to be executed to copy a completed segment file to wherever it needs to go. The command could be as simple as a `cp`, or it could invoke a complex shell script — it’s all up to you.

To enable WAL archiving, set the `archive_mode` configuration parameter to `on`, and specify the shell command to use in the `archive_command` configuration parameter. In practice these settings will always be placed in the `postgresql.conf` file. In `archive_command`, any `%p` is replaced by the path name of the file to archive, while any `%f` is replaced by the file name only. (The path name is relative to the current working directory, i.e., the cluster’s data directory.) Write `%%` if you need to embed an actual `%` character in the command. The simplest useful command is something like:

```
archive_command = 'test ! -f /mnt/server/archivedir/%f && cp %p /mnt/server/archivedir/%f'
archive_command = 'copy "%p" "C:\server\archivedir\%f"'  # Windows
```

which will copy archivable WAL segments to the directory `/mnt/server/archivedir`. (This is an example, not a recommendation, and might not work on all platforms.) After the `%p` and `%f` parameters have been replaced, the actual command executed might look like this:

```
test ! -f /mnt/server/archivedir/00000001000000A900000065 && cp pg_xlog/00000001000000A900000065 /mnt/server/archivedir/00000001000000A900000065
```

A similar command will be generated for each new file to be archived.

The archive command will be executed under the ownership of the same user that the PostgreSQL server is running as. Since the series of WAL files being archived contains effectively everything in your database, you will want to be sure that the archived data is protected from prying eyes; for example, archive into a directory that does not have group or world read access.

It is important that the archive command return zero exit status if and only if it succeeded. Upon getting a zero result, PostgreSQL will assume that the file has been successfully archived, and will remove or recycle it. However, a nonzero status tells PostgreSQL that the file was not archived; it will try again periodically until it succeeds.
Chapter 24. Backup and Restore

The archive command should generally be designed to refuse to overwrite any pre-existing archive file. This is an important safety feature to preserve the integrity of your archive in case of administrator error (such as sending the output of two different servers to the same archive directory).

It is advisable to test your proposed archive command to ensure that it indeed does not overwrite an existing file, and that it returns nonzero status in this case. The example command above for Unix ensures this by including a separate test step. On some Unix platforms, cp has switches such as -i that can be used to do the same thing less verbosely, but you should not rely on these without verifying that the right exit status is returned. (In particular, GNU cp will return status zero when -i is used and the target file already exists, which is not the desired behavior.)

While designing your archiving setup, consider what will happen if the archive command fails repeatedly because some aspect requires operator intervention or the archive runs out of space. For example, this could occur if you write to tape without an autochanger; when the tape fills, nothing further can be archived until the tape is swapped. You should ensure that any error condition or request to a human operator is reported appropriately so that the situation can be resolved reasonably quickly. The pg_xlog/ directory will continue to fill with WAL segment files until the situation is resolved. (If the filesystem containing pg_xlog/ fills up, PostgreSQL will do a PANIC shutdown. No prior transactions will be lost, but the database will be unavailable until you free some space.)

The speed of the archiving command is not important, so long as it can keep up with the average rate at which your server generates WAL data. Normal operation continues even if the archiving process falls a little behind. If archiving falls significantly behind, this will increase the amount of data that would be lost in the event of a disaster. It will also mean that the pg_xlog/ directory will contain large numbers of not-yet-archived segment files, which could eventually exceed available disk space. You are advised to monitor the archiving process to ensure that it is working as you intend.

In writing your archive command, you should assume that the file names to be archived can be up to 64 characters long and can contain any combination of ASCII letters, digits, and dots. It is not necessary to remember the original relative path (%p) but it is necessary to remember the file name (%f).

Note that although WAL archiving will allow you to restore any modifications made to the data in your PostgreSQL database, it will not restore changes made to configuration files (that is, postgresql.conf, pg_hba.conf and pg_ident.conf), since those are edited manually rather than through SQL operations. You might wish to keep the configuration files in a location that will be backed up by your regular file system backup procedures. See Section 18.2 for how to relocate the configuration files.

The archive command is only invoked on completed WAL segments. Hence, if your server generates only little WAL traffic (or has slack periods where it does so), there could be a long delay between the completion of a transaction and its safe recording in archive storage. To put a limit on how old unarchived data can be, you can set archive_timeout to force the server to switch to a new WAL segment file at least that often. Note that archived files that are ended early due to a forced switch are still the same length as completely full files. It is therefore unwise to set a very short archive_timeout — it will bloat your archive storage. archive_timeout settings of a minute or so are usually reasonable.

Also, you can force a segment switch manually with pg_switch_xlog, if you want to ensure that a just-finished transaction is archived as soon as possible. Other utility functions related to WAL management are listed in Table 9-56.

When archive_mode is off some SQL commands are optimized to avoid WAL logging, as described in Section 14.4.7. If archiving were turned on during execution of one of these statements, WAL would not contain enough information for archive recovery. (Crash recovery is unaffected.) For this reason, archive_mode can only be changed at server start. However, archive_command can be changed with a configuration file reload. If you wish to temporarily stop archiving, one way to do
it is to set `archive_command` to the empty string (`"`). This will cause WAL files to accumulate in `pg_xlog/` until a working `archive_command` is re-established.

### 24.3.2. Making a Base Backup

The procedure for making a base backup is relatively simple:

1. Ensure that WAL archiving is enabled and working.
2. Connect to the database as a superuser, and issue the command:
   ```sql
   SELECT pg_start_backup('label');
   
   where `label` is any string you want to use to uniquely identify this backup operation. (One good practice is to use the full path where you intend to put the backup dump file.) `pg_start_backup` creates a `backup label` file, called `backup_label`, in the cluster directory with information about your backup.

   It does not matter which database within the cluster you connect to to issue this command. You can ignore the result returned by the function; but if it reports an error, deal with that before proceeding.

   By default, `pg_start_backup` can take a long time to finish. This is because it performs a checkpoint, and the I/O required for the checkpoint will be spread out over a significant period of time, by default half your inter-checkpoint interval (see the configuration parameter `checkpoint_completion_target`). Usually this is what you want, because it minimizes the impact on query processing. If you just want to start the backup as soon as possible, use:
   ```sql
   SELECT pg_start_backup('label', true);
   ```

   This forces the checkpoint to be done as quickly as possible.

3. Perform the backup, using any convenient file-system-backup tool such as tar or cpio. It is neither necessary nor desirable to stop normal operation of the database while you do this.

4. Again connect to the database as a superuser, and issue the command:
   ```sql
   SELECT pg_stop_backup();
   ```

   This terminates the backup mode and performs an automatic switch to the next WAL segment. The reason for the switch is to arrange that the last WAL segment file written during the backup interval is immediately ready to archive.

5. Once the WAL segment files used during the backup are archived, you are done. The file identified by `pg_stop_backup`'s result is the last segment that is required to form a complete set of backup files. `pg_stop_backup` does not return until the last segment has been archived. Archiving of these files happens automatically since you have already configured `archive_command`. In most cases this happens quickly, but you are advised to monitor your archive system to ensure there are no delays. If the archive process has fallen behind because of failures of the archive command, it will keep retrying until the archive succeeds and the backup is complete. If you wish to place a time limit on the execution of `pg_stop_backup`, set an appropriate `statement_timeout` value.

Some backup tools that you might wish to use emit warnings or errors if the files they are trying to copy change while the copy proceeds. This situation is normal, and not an error, when taking a base backup of an active database; so you need to ensure that you can distinguish complaints of this sort from real errors. For example, some versions of rsync return a separate exit code for “vanished source files”, and you can write a driver script to accept this exit code as a non-error case. Also, some
versions of GNU tar return an error code indistinguishable from a fatal error if a file was truncated while tar was copying it. Fortunately, GNU tar versions 1.16 and later exit with 1 if a file was changed during the backup, and 2 for other errors.

It is not necessary to be very concerned about the amount of time elapsed between `pg_start_backup` and the start of the actual backup, nor between the end of the backup and `pg_stop_backup`; a few minutes’ delay won’t hurt anything. (However, if you normally run the server with `full_page_writes` disabled, you might notice a drop in performance between `pg_start_backup` and `pg_stop_backup`, since `full_page_writes` is effectively forced on during backup mode.) You must ensure that these steps are carried out in sequence without any possible overlap, or you will invalidate the backup.

Be certain that your backup dump includes all of the files underneath the database cluster directory (e.g., `/usr/local/pgsql/data`). If you are using tablespaces that do not reside underneath this directory, be careful to include them as well (and be sure that your backup dump archives symbolic links as links, otherwise the restore will mess up your tablespaces).

You can, however, omit from the backup dump the files within the `pg_xlog/` subdirectory of the cluster directory. This slight complication is worthwhile because it reduces the risk of mistakes when restoring. This is easy to arrange if `pg_xlog/` is a symbolic link pointing to someplace outside the cluster directory, which is a common setup anyway for performance reasons.

To make use of the backup, you will need to keep around all the WAL segment files generated during and after the file system backup. To aid you in doing this, the `pg_stop_backup` function creates a backup history file that is immediately stored into the WAL archive area. This file is named after the first WAL segment file that you need to have to make use of the backup. For example, if the starting WAL file is `0000000100001234000055CD` the backup history file will be named something like `0000000100001234000055CD.007C9330.backup`. (The second part of the file name stands for an exact position within the WAL file, and can ordinarily be ignored.) Once you have safely archived the file system backup and the WAL segment files used during the backup (as specified in the backup history file), all archived WAL segments with names numerically less are no longer needed to recover the file system backup and can be deleted. However, you should consider keeping several backup sets to be absolutely certain that you can recover your data.

The backup history file is just a small text file. It contains the label string you gave to `pg_start_backup`, as well as the starting and ending times and WAL segments of the backup. If you used the label to identify where the associated dump file is kept, then the archived history file is enough to tell you which dump file to restore, should you need to do so.

Since you have to keep around all the archived WAL files back to your last base backup, the interval between base backups should usually be chosen based on how much storage you want to expend on archived WAL files. You should also consider how long you are prepared to spend recovering, if recovery should be necessary — the system will have to replay all those WAL segments, and that could take awhile if it has been a long time since the last base backup.

It’s also worth noting that the `pg_start_backup` function makes a file named `backup_label` in the database cluster directory, which is then removed again by `pg_stop_backup`. This file will of course be archived as a part of your backup dump file. The backup label file includes the label string you gave to `pg_start_backup`, as well as the time at which `pg_start_backup` was run, and the name of the starting WAL file. In case of confusion it will therefore be possible to look inside a backup dump file and determine exactly which backup session the dump file came from.

It is also possible to make a backup dump while the server is stopped. In this case, you obviously cannot use `pg_start_backup` or `pg_stop_backup`, and you will therefore be left to your own devices to keep track of which backup dump is which and how far back the associated WAL files go. It is generally better to follow the continuous archiving procedure above.
Chapter 24. Backup and Restore

24.3.3. Recovering using a Continuous Archive Backup

Okay, the worst has happened and you need to recover from your backup. Here is the procedure:

1. Stop the server, if it’s running.

2. If you have the space to do so, copy the whole cluster data directory and any tablespaces to a temporary location in case you need them later. Note that this precaution will require that you have enough free space on your system to hold two copies of your existing database. If you do not have enough space, you need at the least to copy the contents of the pg_xlog subdirectory of the cluster data directory, as it might contain logs which were not archived before the system went down.

3. Clean out all existing files and subdirectories under the cluster data directory and under the root directories of any tablespaces you are using.

4. Restore the database files from your base backup. Be careful that they are restored with the right ownership (the database system user, not root!) and with the right permissions. If you are using tablespaces, you should verify that the symbolic links in pg_tblspc/ were correctly restored.

5. Remove any files present in pg_xlog/; these came from the backup dump and are therefore probably obsolete rather than current. If you didn’t archive pg_xlog/ at all, then recreate it, being careful to ensure that you re-establish it as a symbolic link if you had it set up that way before.

6. If you had unarchived WAL segment files that you saved in step 2, copy them into pg_xlog/.
   (It is best to copy them, not move them, so that you still have the unmodified files if a problem occurs and you have to start over.)

7. Create a recovery command file recovery.conf in the cluster data directory (see Recovery Settings). You might also want to temporarily modify pg_hba.conf to prevent ordinary users from connecting until you are sure the recovery has worked.

8. Start the server. The server will go into recovery mode and proceed to read through the archived WAL files it needs. Should the recovery be terminated because of an external error, the server can simply be restarted and it will continue recovery. Upon completion of the recovery process, the server will rename recovery.conf to recovery.done (to prevent accidentally re-entering recovery mode in case of a crash later) and then commence normal database operations.

9. Inspect the contents of the database to ensure you have recovered to where you want to be. If not, return to step 1. If all is well, let in your users by restoring pg_hba.conf to normal.

The key part of all this is to set up a recovery command file that describes how you want to recover and how far the recovery should run. You can use recovery.conf.sample (normally installed in the installation share/ directory) as a prototype. The one thing that you absolutely must specify in recovery.conf is the restore_command, which tells PostgreSQL how to get back archived WAL file segments. Like the archive_command, this is a shell command string. It can contain %f, which is replaced by the name of the desired log file, and %p, which is replaced by the path name to copy the log file to. (The path name is relative to the current working directory, i.e., the cluster’s data directory.) Write %% if you need to embed an actual % character in the command. The simplest useful command is something like:

   restore_command = ’cp /mnt/server/archivedir/%f %p’

which will copy previously archived WAL segments from the directory /mnt/server/archivedir.

You could of course use something much more complicated, perhaps even a shell script that requests
the operator to mount an appropriate tape.

It is important that the command return nonzero exit status on failure. The command will be asked for files that are not present in the archive; it must return nonzero when so asked. This is not an error condition. Not all of the requested files will be WAL segment files; you should also expect requests for files with a suffix of .backup or .history. Also be aware that the base name of the %p path will be different from %f; do not expect them to be interchangeable.

WAL segments that cannot be found in the archive will be sought in pg_xlog/; this allows use of recent un-archived segments. However segments that are available from the archive will be used in preference to files in pg_xlog/. The system will not overwrite the existing contents of pg_xlog/ when retrieving archived files.

Normally, recovery will proceed through all available WAL segments, thereby restoring the database to the current point in time (or as close as we can get given the available WAL segments). So a normal recovery will end with a “file not found” message, the exact text of the error message depending upon your choice of restore_command. You may also see an error message at the start of recovery for a file named something like 00000001.history. This is also normal and does not indicate a problem in simple recovery situations. See Section 24.3.4 for discussion.

If you want to recover to some previous point in time (say, right before the junior DBA dropped your main transaction table), just specify the required stopping point in recovery.conf. You can specify the stop point, known as the “recovery target”, either by date/time or by completion of a specific transaction ID. As of this writing only the date/time option is very usable, since there are no tools to help you identify with any accuracy which transaction ID to use.

Note: The stop point must be after the ending time of the base backup, i.e., the end time of pg_stop_backup. You cannot use a base backup to recover to a time when that backup was still going on. (To recover to such a time, you must go back to your previous base backup and roll forward from there.)

If recovery finds a corruption in the WAL data then recovery will complete at that point and the server will not start. In such a case the recovery process could be re-run from the beginning, specifying a “recovery target” before the point of corruption so that recovery can complete normally. If recovery fails for an external reason, such as a system crash or if the WAL archive has become inaccessible, then the recovery can simply be restarted and it will restart almost from where it failed. Recovery restart works much like checkpointing in normal operation: the server periodically forces all its state to disk, and then updates the pg_control file to indicate that the already-processed WAL data need not be scanned again.

24.3.3.1. Recovery Settings

These settings can only be made in the recovery.conf file, and apply only for the duration of the recovery. They must be reset for any subsequent recovery you wish to perform. They cannot be changed once recovery has begun.

restore_command(string)

The shell command to execute to retrieve an archived segment of the WAL file series. This parameter is required. Any %f in the string is replaced by the name of the file to retrieve from the archive, and any %p is replaced by the path name to copy it to on the server. (The path name is relative to the current working directory, i.e., the cluster’s data directory.) Any %r is replaced by the name of the file containing the last valid restart point. That is the earliest file that must be kept to allow a restore to be restartable, so this information can be used to truncate the archive to
just the minimum required to support restart from the current restore. $\%r$ would typically be used in a warm-standby configuration (see Section 24.4). Write $\%s$ to embed an actual $\%$ character in the command.

It is important for the command to return a zero exit status if and only if it succeeds. The command will be asked for file names that are not present in the archive; it must return nonzero when so asked. Examples:

```
restore_command = 'cp /mnt/server/archivedir/%f "$p"'
restore_command = 'copy "C:\server\archivedir\%f" "$p"'  # Windows
```

`recovery_end_command` *(string)*

This parameter specifies a shell command that will be executed once only at the end of recovery. This parameter is optional. The purpose of the `recovery_end_command` is to provide a mechanism for cleanup following replication or recovery. Any $\%r$ is replaced by the name of the file containing the last valid restart point. That is the earliest file that must be kept to allow a restore to be restartable, so this information can be used to truncate the archive to just the minimum required to support restart from the current restore. $\%r$ would typically be used in a warm-standby configuration (see Section 24.4). Write $\%s$ to embed an actual $\%$ character in the command.

If the command returns a non-zero exit status then a WARNING log message will be written and the database will proceed to start up anyway. An exception is that if the command was terminated by a signal, the database will not proceed with startup.

`recovery_target_time` *(timestamp)*

This parameter specifies the time stamp up to which recovery will proceed. At most one of `recovery_target_time` and `recovery_target_xid` can be specified. The default is to recover to the end of the WAL log. The precise stopping point is also influenced by `recovery_target_inclusive`.

`recovery_target_xid` *(string)*

This parameter specifies the transaction ID up to which recovery will proceed. Keep in mind that while transaction IDs are assigned sequentially at transaction start, transactions can complete in a different numeric order. The transactions that will be recovered are those that committed before (and optionally including) the specified one. At most one of `recovery_target_xid` and `recovery_target_time` can be specified. The default is to recover to the end of the WAL log. The precise stopping point is also influenced by `recovery_target_inclusive`.

`recovery_target_inclusive` *(boolean)*

Specifies whether we stop just after the specified recovery target (true), or just before the recovery target (false). Applies to both `recovery_target_time` and `recovery_target_xid`, whichever one is specified for this recovery. This indicates whether transactions having exactly the target commit time or ID, respectively, will be included in the recovery. Default is true.

`recovery_target_timeline` *(string)*

Specifies recovering into a particular timeline. The default is to recover along the same timeline that was current when the base backup was taken. You would only need to set this parameter in complex re-recovery situations, where you need to return to a state that itself was reached after a point-in-time recovery. See Section 24.3.4 for discussion.
24.3.4. Timelines

The ability to restore the database to a previous point in time creates some complexities that are akin to science-fiction stories about time travel and parallel universes. In the original history of the database, perhaps you dropped a critical table at 5:15PM on Tuesday evening, but didn’t realize your mistake until Wednesday noon. Unfazed, you get out your backup, restore to the point-in-time 5:14PM Tuesday evening, and are up and running. In this history of the database universe, you never dropped the table at all. But suppose you later realize this wasn’t such a great idea after all, and would like to return to sometime Wednesday morning in the original history. You won’t be able to if, while your database was up-and-running, it overwrote some of the sequence of WAL segment files that led up to the time you now wish you could get back to. So you really want to distinguish the series of WAL records generated after you’ve done a point-in-time recovery from those that were generated in the original database history.

To deal with these problems, PostgreSQL has a notion of timelines. Whenever an archive recovery is completed, a new timeline is created to identify the series of WAL records generated after that recovery. The timeline ID number is part of WAL segment file names, and so a new timeline does not overwrite the WAL data generated by previous timelines. It is in fact possible to archive many different timelines. While that might seem like a useless feature, it’s often a lifesaver. Consider the situation where you aren’t quite sure what point-in-time to recover to, and so have to do several point-in-time recoveries by trial and error until you find the best place to branch off from the old history. Without timelines this process would soon generate an unmanageable mess. With timelines, you can recover to any prior state, including states in timeline branches that you later abandoned.

Each time a new timeline is created, PostgreSQL creates a “timeline history” file that shows which timeline it branched off from and when. These history files are necessary to allow the system to pick the right WAL segment files when recovering from an archive that contains multiple timelines. Therefore, they are archived into the WAL archive area just like WAL segment files. The history files are just small text files, so it’s cheap and appropriate to keep them around indefinitely (unlike the segment files which are large). You can, if you like, add comments to a history file to make your own notes about how and why this particular timeline came to be. Such comments will be especially valuable when you have a thicket of different timelines as a result of experimentation.

The default behavior of recovery is to recover along the same timeline that was current when the base backup was taken. If you want to recover into some child timeline (that is, you want to return to some state that was itself generated after a recovery attempt), you need to specify the target timeline ID in recovery.conf. You cannot recover into timelines that branched off earlier than the base backup.

24.3.5. Tips and Examples

Some tips for configuring continuous archiving are given here.

24.3.5.1. Standalone hot backups

It is possible to use PostgreSQL’s backup facilities to produce standalone hot backups. These are backups that cannot be used for point-in-time recovery, yet are typically much faster to backup and restore than pg_dump dumps. (They are also much larger than pg_dump dumps, so in some cases the speed advantage could be negated.)

To prepare for standalone hot backups, set archive_mode to on, and set up an archive_command that performs archiving only when a “switch file” exists. For example:

```sql
archive_command = 'test ! -f /var/lib/pgsql/backup_in_progress || (test ! -f /var/lib/pgsql/archive/%f && cp %p /var/lib/pgsql/archive/%f)'
``
Chapter 24. Backup and Restore

This command will perform archiving when /var/lib/pgsql/backup_in_progress exists, and otherwise silently return zero exit status (allowing PostgreSQL to recycle the unwanted WAL file).

With this preparation, a backup can be taken using a script like the following:

```bash
touch /var/lib/pgsql/backup_in_progress
psql -c "select pg_start_backup('hot_backup');"
tar -cf /var/lib/pgsql/backup.tar /var/lib/pgsql/data/
psql -c "select pg_stop_backup();"
rm /var/lib/pgsql/backup_in_progress
tar -rf /var/lib/pgsql/backup.tar /var/lib/pgsql/archive/
```

The switch file /var/lib/pgsql/backup_in_progress is created first, enabling archiving of completed WAL files to occur. After the backup the switch file is removed. Archived WAL files are then added to the backup so that both base backup and all required WAL files are part of the same tar file. Please remember to add error handling to your backup scripts.

### 24.3.5.2. Compressed Archive Logs

If archive storage size is a concern, use pg_compresslog, http://pglesslog.projects.postgresql.org, to remove unnecessary full_page_writes and trailing space from the WAL files. You can then use gzip to further compress the output of pg_compresslog:

```bash
archive_command = 'pg_compresslog %p - | gzip > /var/lib/pgsql/archive/%f'
```

You will then need to use gunzip and pg_decompresslog during recovery:

```bash
restore_command = 'gunzip < /mnt/server/archivedir/%f | pg_decompresslog - %p'
```

### 24.3.5.3. archive_command scripts

Many people choose to use scripts to define their `archive_command`, so that their `postgresql.conf` entry looks very simple:

```bash
archive_command = 'local_backup_script.sh "%p" "%f"'
```

Using a separate script file is advisable any time you want to use more than a single command in the archiving process. This allows all complexity to be managed within the script, which can be written in a popular scripting language such as bash or perl.

Examples of requirements that might be solved within a script include:

- Copying data to secure off-site data storage
- Batching WAL files so that they are transferred every three hours, rather than one at a time
- Interfacing with other backup and recovery software
- Interfacing with monitoring software to report errors

**Tip:** When using an `archive_command` script, it’s desirable to enable logging_collector. Any messages written to stderr from the script will then appear in the database server log, allowing complex configurations to be diagnosed easily if they fail.
24.3.6. Caveats

At this writing, there are several limitations of the continuous archiving technique. These will probably be fixed in future releases:

- Operations on hash indexes are not presently WAL-logged, so replay will not update these indexes. The recommended workaround is to manually `REINDEX` each such index after completing a recovery operation.

- If a `CREATE DATABASE` command is executed while a base backup is being taken, and then the template database that the `CREATE DATABASE` copied is modified while the base backup is still in progress, it is possible that recovery will cause those modifications to be propagated into the created database as well. This is of course undesirable. To avoid this risk, it is best not to modify any template databases while taking a base backup.

- `CREATE TABLESPACE` commands are WAL-logged with the literal absolute path, and will therefore be replayed as tablespace creations with the same absolute path. This might be undesirable if the log is being replayed on a different machine. It can be dangerous even if the log is being replayed on the same machine, but into a new data directory: the replay will still overwrite the contents of the original tablespace. To avoid potential gotchas of this sort, the best practice is to take a new base backup after creating or dropping tablespaces.

It should also be noted that the default WAL format is fairly bulky since it includes many disk page snapshots. These page snapshots are designed to support crash recovery, since we might need to fix partially-written disk pages. Depending on your system hardware and software, the risk of partial writes might be small enough to ignore, in which case you can significantly reduce the total volume of archived logs by turning off page snapshots using the `full_page_writes` parameter. (Read the notes and warnings in Chapter 28 before you do so.) Turning off page snapshots does not prevent use of the logs for PITR operations. An area for future development is to compress archived WAL data by removing unnecessary page copies even when `full_page_writes` is on. In the meantime, administrators might wish to reduce the number of page snapshots included in WAL by increasing the checkpoint interval parameters as much as feasible.

24.4. Warm Standby Servers for High Availability

Continuous archiving can be used to create a high availability (HA) cluster configuration with one or more standby servers ready to take over operations if the primary server fails. This capability is widely referred to as warm standby or log shipping.

The primary and standby server work together to provide this capability, though the servers are only loosely coupled. The primary server operates in continuous archiving mode, while each standby server operates in continuous recovery mode, reading the WAL files from the primary. No changes to the database tables are required to enable this capability, so it offers low administration overhead in comparison with some other replication approaches. This configuration also has relatively low performance impact on the primary server.
Directly moving WAL records from one database server to another is typically described as log shipping. PostgreSQL implements file-based log shipping, which means that WAL records are transferred one file (WAL segment) at a time. WAL files (16MB) can be shipped easily and cheaply over any distance, whether it be to an adjacent system, another system on the same site or another system on the far side of the globe. The bandwidth required for this technique varies according to the transaction rate of the primary server. Record-based log shipping is also possible with custom-developed procedures, as discussed in Section 24.4.4.

It should be noted that the log shipping is asynchronous, i.e., the WAL records are shipped after transaction commit. As a result there is a window for data loss should the primary server suffer a catastrophic failure: transactions not yet shipped will be lost. The length of the window of data loss can be limited by use of the `archive_timeout` parameter, which can be set as low as a few seconds if required. However such low settings will substantially increase the bandwidth requirements for file shipping. If you need a window of less than a minute or so, it’s probably better to look into record-based log shipping.

The standby server is not available for access, since it is continually performing recovery processing. Recovery performance is sufficiently good that the standby will typically be only moments away from full availability once it has been activated. As a result, we refer to this capability as a warm standby configuration that offers high availability. Restoring a server from an archived base backup and rollforward will take considerably longer, so that technique only offers a solution for disaster recovery, not high availability.

### 24.4.1. Planning

It is usually wise to create the primary and standby servers so that they are as similar as possible, at least from the perspective of the database server. In particular, the path names associated with tablespaces will be passed across as-is, so both primary and standby servers must have the same mount paths for tablespaces if that feature is used. Keep in mind that if `CREATE TABLESPACE` is executed on the primary, any new mount point needed for it must be created on both the primary and all standby servers before the command is executed. Hardware need not be exactly the same, but experience shows that maintaining two identical systems is easier than maintaining two dissimilar ones over the lifetime of the application and system. In any case the hardware architecture must be the same — shipping from, say, a 32-bit to a 64-bit system will not work.

In general, log shipping between servers running different major PostgreSQL release levels will not be possible. It is the policy of the PostgreSQL Global Development Group not to make changes to disk formats during minor release upgrades, so it is likely that running different minor release levels on primary and standby servers will work successfully. However, no formal support for that is offered and you are advised to keep primary and standby servers at the same release level as much as possible. When updating to a new minor release, the safest policy is to update the standby servers first — a new minor release is more likely to be able to read WAL files from a previous minor release than vice versa.

There is no special mode required to enable a standby server. The operations that occur on both primary and standby servers are entirely normal continuous archiving and recovery tasks. The only point of contact between the two database servers is the archive of WAL files that both share: primary writing to the archive, standby reading from the archive. Care must be taken to ensure that WAL archives for separate primary servers do not become mixed together or confused. The archive need not be large, if it is only required for the standby operation.

The magic that makes the two loosely coupled servers work together is simply a `restore_command` used on the standby that, when asked for the next WAL file, waits for it to become available from the primary. The `restore_command` is specified in the `recovery.conf` file on the standby server.
Normal recovery processing would request a file from the WAL archive, reporting failure if the file was unavailable. For standby processing it is normal for the next WAL file to be unavailable, so we must be patient and wait for it to appear. For files ending in .backup or .history there is no need to wait, and a non-zero return code must be returned. A waiting restore_command can be written as a custom script that loops after polling for the existence of the next WAL file. There must also be some way to trigger failover, which should interrupt the restore_command, break the loop and return a file-not-found error to the standby server. This ends recovery and the standby will then come up as a normal server.

Pseudocode for a suitable restore_command is:

```c
triggered = false;
while (!NextWALFileReady() && !triggered)
{
    sleep(100000L); /* wait for ~0.1 sec */
    if (CheckForExternalTrigger())
        triggered = true;
}
if (!triggered)
    CopyWALFileForRecovery();
```

A working example of a waiting restore_command is provided as a contrib module named pg_standby. It should be used as a reference on how to correctly implement the logic described above. It can also be extended as needed to support specific configurations or environments.

PostgreSQL does not provide the system software required to identify a failure on the primary and notify the standby system and then the standby database server. Many such tools exist and are well integrated with other aspects required for successful failover, such as IP address migration.

The means for triggering failover is an important part of planning and design. The restore_command is executed in full once for each WAL file. The process running the restore_command is therefore created and dies for each file, so there is no daemon or server process and so we cannot use signals and a signal handler. A more permanent notification is required to trigger the failover. It is possible to use a simple timeout facility, especially if used in conjunction with a known archive_timeout setting on the primary. This is somewhat error prone since a network problem or busy primary server might be sufficient to initiate failover. A notification mechanism such as the explicit creation of a trigger file is less error prone, if this can be arranged.

The size of the WAL archive can be minimized by using the %r option of the restore_command. This option specifies the last archive file name that needs to be kept to allow the recovery to restart correctly. This can be used to truncate the archive once files are no longer required, if the archive is writable from the standby server.

### 24.4.2. Implementation

The short procedure for configuring a standby server is as follows. For full details of each step, refer to previous sections as noted.

1. Set up primary and standby systems as near identically as possible, including two identical copies of PostgreSQL at the same release level.
2. Set up continuous archiving from the primary to a WAL archive located in a directory on the standby server. Ensure that archive_mode, archive_command and archive_timeout are set appropriately on the primary (see Section 24.3.1).

3. Make a base backup of the primary server (see Section 24.3.2), and load this data onto the standby.

4. Begin recovery on the standby server from the local WAL archive, using a recovery.conf that specifies a restore_command that waits as described previously (see Section 24.3.3).

Recovery treats the WAL archive as read-only, so once a WAL file has been copied to the standby system it can be copied to tape at the same time as it is being read by the standby database server. Thus, running a standby server for high availability can be performed at the same time as files are stored for longer term disaster recovery purposes.

For testing purposes, it is possible to run both primary and standby servers on the same system. This does not provide any worthwhile improvement in server robustness, nor would it be described as HA.

### 24.4.3. Failover

If the primary server fails then the standby server should begin failover procedures.

If the standby server fails then no failover need take place. If the standby server can be restarted, even some time later, then the recovery process can also be immediately restarted, taking advantage of restartable recovery. If the standby server cannot be restarted, then a full new standby server instance should be created.

If the primary server fails and then immediately restarts, you must have a mechanism for informing it that it is no longer the primary. This is sometimes known as STONITH (Shoot the Other Node In The Head), which is necessary to avoid situations where both systems think they are the primary, which will lead to confusion and ultimately data loss.

Many failover systems use just two systems, the primary and the standby, connected by some kind of heartbeat mechanism to continually verify the connectivity between the two and the viability of the primary. It is also possible to use a third system (called a witness server) to prevent some cases of inappropriate failover, but the additional complexity might not be worthwhile unless it is set up with sufficient care and rigorous testing.

Once failover to the standby occurs, we have only a single server in operation. This is known as a degenerate state. The former standby is now the primary, but the former primary is down and might stay down. To return to normal operation we must fully recreate a standby server, either on the former primary system when it comes up, or on a third, possibly new, system. Once complete the primary and standby can be considered to have switched roles. Some people choose to use a third server to provide backup to the new primary until the new standby server is recreated, though clearly this complicates the system configuration and operational processes.

So, switching from primary to standby server can be fast but requires some time to re-prepare the failover cluster. Regular switching from primary to standby is useful, since it allows regular downtime on each system for maintenance. This also serves as a test of the failover mechanism to ensure that it will really work when you need it. Written administration procedures are advised.

### 24.4.4. Record-based Log Shipping

PostgreSQL directly supports file-based log shipping as described above. It is also possible to implement record-based log shipping, though this requires custom development.
An external program can call the `pg_xlogfile_name_offset()` function (see Section 9.24) to find out the file name and the exact byte offset within it of the current end of WAL. It can then access the WAL file directly and copy the data from the last known end of WAL through the current end over to the standby server(s). With this approach, the window for data loss is the polling cycle time of the copying program, which can be very small, but there is no wasted bandwidth from forcing partially-used segment files to be archived. Note that the standby servers’ `restore_command` scripts still deal in whole WAL files, so the incrementally copied data is not ordinarily made available to the standby servers. It is of use only when the primary dies — then the last partial WAL file is fed to the standby before allowing it to come up. So correct implementation of this process requires cooperation of the `restore_command` script with the data copying program.

### 24.5. Migration Between Releases

This section discusses how to migrate your database data from one PostgreSQL release to a newer one. The software installation procedure *per se* is not the subject of this section; those details are in Chapter 15.

As a general rule, the internal data storage format is subject to change between major releases of PostgreSQL (where the number after the first dot changes). This does not apply to different minor releases under the same major release (where the number after the second dot changes); these always have compatible storage formats. For example, releases 8.1.1, 8.2.3, and 8.3 are not compatible, whereas 8.2.3 and 8.2.4 are. When you update between compatible versions, you can simply replace the executables and reuse the data directory on disk. Otherwise you need to back up your data and restore it on the new server. This has to be done using `pg_dump`; file system level backup methods obviously won’t work. There are checks in place that prevent you from using a data directory with an incompatible version of PostgreSQL, so no great harm can be done by trying to start the wrong server version on a data directory.

It is recommended that you use the `pg_dump` and `pg_dumpall` programs from the newer version of PostgreSQL, to take advantage of any enhancements that might have been made in these programs. Current releases of the dump programs can read data from any server version back to 7.0.

The least downtime can be achieved by installing the new server in a different directory and running both the old and the new servers in parallel, on different ports. Then you can use something like:

```
gp_dumpall -p 5432 | psql -d postgres -p 5543
```

to transfer your data. Or use an intermediate file if you want. Then you can shut down the old server and start the new server at the port the old one was running at. You should make sure that the old database is not updated after you begin to run `pg_dumpall`, otherwise you will lose that data. See Chapter 19 for information on how to prohibit access.

It is also possible to use replication methods, such as Slony, to create a slave server with the updated version of PostgreSQL. The slave can be on the same computer or a different computer. Once it has synced up with the master server (running the older version of PostgreSQL), you can switch masters and make the slave the master and shut down the older database instance. Such a switch-over results in only several seconds of downtime for an upgrade.

If you cannot or do not want to run two servers in parallel, you can do the backup step before installing the new version, bring down the server, move the old version out of the way, install the new version, start the new server, and restore the data. For example:

```
gp_dumpall > backup
```
Chapter 24. Backup and Restore

pg_ctl stop
mv /usr/local/pgsql /usr/local/pgsql.old
cd ~/postgresql-8.4.22
gmake install
initdb -D /usr/local/pgsql/data
postgres -D /usr/local/pgsql/data
psql -f backup postgres

See Chapter 17 about ways to start and stop the server and other details. The installation instructions will advise you of strategic places to perform these steps.

Note: When you “move the old installation out of the way” it might no longer be perfectly usable. Some of the executable programs contain absolute paths to various installed programs and data files. This is usually not a big problem, but if you plan on using two installations in parallel for a while you should assign them different installation directories at build time. (This problem is rectified in PostgreSQL 8.0 and later, so long as you move all subdirectories containing installed files together; for example if /usr/local/postgres/bin/ goes to /usr/local/postgres.old/bin/, then /usr/local/postgres/share/ must go to /usr/local/postgres.old/share/. In pre-8.0 releases moving an installation like this will not work.)

In practice you probably want to test your client applications on the new version before switching over completely. This is another reason for setting up concurrent installations of old and new versions. When testing a PostgreSQL major upgrade, consider the following categories of possible changes:

Administration
The capabilities available for administrators to monitor and control the server often change and improve in each major release.

SQL
Typically this includes new SQL command capabilities and not changes in behavior, unless specifically mentioned in the release notes.

Library API
Typically libraries like libpq only add new functionality, again unless mentioned in the release notes.

System Catalogs
System catalog changes usually only affect database management tools.

Server C-language API
This involved changes in the backend function API, which is written in the C programming language. Such changes effect code that references backend functions deep inside the server.

485
Chapter 25. High Availability, Load Balancing, and Replication

Database servers can work together to allow a second server to take over quickly if the primary server fails (high availability), or to allow several computers to serve the same data (load balancing). Ideally, database servers could work together seamlessly. Web servers serving static web pages can be combined quite easily by merely load-balancing web requests to multiple machines. In fact, read-only database servers can be combined relatively easily too. Unfortunately, most database servers have a read/write mix of requests, and read/write servers are much harder to combine. This is because though read-only data needs to be placed on each server only once, a write to any server has to be propagated to all servers so that future read requests to those servers return consistent results.

This synchronization problem is the fundamental difficulty for servers working together. Because there is no single solution that eliminates the impact of the sync problem for all use cases, there are multiple solutions. Each solution addresses this problem in a different way, and minimizes its impact for a specific workload.

Some solutions deal with synchronization by allowing only one server to modify the data. Servers that can modify data are called read/write or "master" servers. Servers that can reply to read-only queries are called "slave" servers. Servers that cannot be accessed until they are changed to master servers are called "standby" servers.

Some solutions are synchronous, meaning that a data-modifying transaction is not considered committed until all servers have committed the transaction. This guarantees that a failover will not lose any data and that all load-balanced servers will return consistent results no matter which server is queried. In contrast, asynchronous solutions allow some delay between the time of a commit and its propagation to the other servers, opening the possibility that some transactions might be lost in the switch to a backup server, and that load balanced servers might return slightly stale results. Asynchronous communication is used when synchronous would be too slow.

Solutions can also be categorized by their granularity. Some solutions can deal only with an entire database server, while others allow control at the per-table or per-database level.

Performance must be considered in any choice. There is usually a trade-off between functionality and performance. For example, a full synchronous solution over a slow network might cut performance by more than half, while an asynchronous one might have a minimal performance impact.

The remainder of this section outlines various failover, replication, and load balancing solutions. A glossary is also available.

Shared Disk Failover

Shared disk failover avoids synchronization overhead by having only one copy of the database. It uses a single disk array that is shared by multiple servers. If the main database server fails, the standby server is able to mount and start the database as though it was recovering from a database crash. This allows rapid failover with no data loss.

Shared hardware functionality is common in network storage devices. Using a network file system is also possible, though care must be taken that the file system has full POSIX behavior (see Section 17.2.1). One significant limitation of this method is that if the shared disk array fails or becomes corrupt, the primary and standby servers are both nonfunctional. Another issue is that the standby server should never access the shared storage while the primary server is running.

1. http://www.postgres-r.org/documentation/terms
Chapter 25. High Availability, Load Balancing, and Replication

File System (Block-Device) Replication

A modified version of shared hardware functionality is file system replication, where all changes to a file system are mirrored to a file system residing on another computer. The only restriction is that the mirroring must be done in a way that ensures the standby server has a consistent copy of the file system — specifically, writes to the standby must be done in the same order as those on the master. DRBD is a popular file system replication solution for Linux.

Warm Standby Using Point-In-Time Recovery (PITR)

A warm standby server (see Section 24.4) can be kept current by reading a stream of write-ahead log (WAL) records. If the main server fails, the warm standby contains almost all of the data of the main server, and can be quickly made the new master database server. This is asynchronous and can only be done for the entire database server.

Master-Slave Replication

A master-slave replication setup sends all data modification queries to the master server. The master server asynchronously sends data changes to the slave server. The slave can answer read-only queries while the master server is running. The slave server is ideal for data warehouse queries. Slony-I is an example of this type of replication, with per-table granularity, and support for multiple slaves. Because it updates the slave server asynchronously (in batches), there is possible data loss during fail over.

Statement-Based Replication Middleware

With statement-based replication middleware, a program intercepts every SQL query and sends it to one or all servers. Each server operates independently. Read-write queries are sent to all servers, while read-only queries can be sent to just one server, allowing the read workload to be distributed. If queries are simply broadcast unmodified, functions like \texttt{random()}, \texttt{CURRENT\_TIMESTAMP}, and sequences would have different values on different servers. This is because each server operates independently, and because SQL queries are broadcast (and not actual modified rows). If this is unacceptable, either the middleware or the application must query such values from a single server and then use those values in write queries. Also, care must be taken that all transactions either commit or abort on all servers, perhaps using two-phase commit (\texttt{PREPARE TRANSACTION} and \texttt{COMMIT PREPARED}). Pgpool-II and Sequoia are examples of this type of replication.

Asynchronous Multimaster Replication

For servers that are not regularly connected, like laptops or remote servers, keeping data consistent among servers is a challenge. Using asynchronous multimaster replication, each server works independently, and periodically communicates with the other servers to identify conflicting transactions. The conflicts can be resolved by users or conflict resolution rules. Bucardo is an example of this type of replication.

Synchronous Multimaster Replication

In synchronous multimaster replication, each server can accept write requests, and modified data is transmitted from the original server to every other server before each transaction commits. Heavy write activity can cause excessive locking, leading to poor performance. In fact, write performance is often worse than that of a single server. Read requests can be sent to any server. Some implementations use shared disk to reduce the communication overhead. Synchronous multimaster replication is best for mostly read workloads, though its big advantage is that any server can accept write requests — there is no need to partition workloads between master and
slave servers, and because the data changes are sent from one server to another, there is no problem with non-deterministic functions like `random()`.

PostgreSQL does not offer this type of replication, though PostgreSQL two-phase commit (`PREPARE TRANSACTION` and `COMMIT PREPARED`) can be used to implement this in application code or middleware.

**Commercial Solutions**

Because PostgreSQL is open source and easily extended, a number of companies have taken PostgreSQL and created commercial closed-source solutions with unique failover, replication, and load balancing capabilities.

Table 25-1 summarizes the capabilities of the various solutions listed above.

There are a few solutions that do not fit into the above categories:

Data Partitioning

Data partitioning splits tables into data sets. Each set can be modified by only one server. For example, data can be partitioned by offices, e.g., London and Paris, with a server in each office. If queries combining London and Paris data are necessary, an application can query both servers, or master/slave replication can be used to keep a read-only copy of the other office’s data on each server.

Multiple-Server Parallel Query Execution

Many of the above solutions allow multiple servers to handle multiple queries, but none allow a single query to use multiple servers to complete faster. This solution allows multiple servers to work concurrently on a single query. It is usually accomplished by splitting the data among servers and having each server execute its part of the query and return results to a central server where they are combined and returned to the user. Pgpool-II has this capability. Also, this can be implemented using the PL/Proxy toolset.
Chapter 26. Monitoring Database Activity

A database administrator frequently wonders, “What is the system doing right now?” This chapter discusses how to find that out.

Several tools are available for monitoring database activity and analyzing performance. Most of this chapter is devoted to describing PostgreSQL’s statistics collector, but one should not neglect regular Unix monitoring programs such as `ps`, `top`, `iostat`, and `vmstat`. Also, once one has identified a poorly-performing query, further investigation might be needed using PostgreSQL’s `EXPLAIN` command. Section 14.1 discusses `EXPLAIN` and other methods for understanding the behavior of an individual query.

26.1. Standard Unix Tools

On most platforms, PostgreSQL modifies its command title as reported by `ps`, so that individual server processes can readily be identified. A sample display is

```
$ ps auxww | grep postgres
postgres   960 0.0 1.1  6104 1480 pts/1  SN 13:17  0:00 postgres -i
postgres   963 0.0 1.1  7084 1472 pts/1  SN 13:17  0:00 postgres: writer process
postgres   965 0.0 1.1  6152 1512 pts/1  SN 13:17  0:00 postgres: stats collector
postgres   998 0.0 2.3  6532 2992 pts/1  SN 13:18  0:00 postgres: tgl runbug 127.0.0.1 idle
postgres  1003 0.0 2.4  6532 3128 pts/1  SN 13:19  0:00 postgres: tgl regression waiting
postgres  1016 0.1 2.4  6532 3080 pts/1  SN 13:19  0:00 postgres: tgl regression idle in transaction
```

(The appropriate invocation of `ps` varies across different platforms, as do the details of what is shown. This example is from a recent Linux system.) The first process listed here is the master server process. The command arguments shown for it are the same ones given when it was launched. The next two processes are background worker processes automatically launched by the master process. (The “stats collector” process will not be present if you have set the system not to start the statistics collector.) Each of the remaining processes is a server process handling one client connection. Each such process sets its command line display in the form

```
postgres: user database host activity
```

The user, database, and connection source host items remain the same for the life of the client connection, but the activity indicator changes. The activity can be `idle` (i.e., waiting for a client command), `idle in transaction` (waiting for client inside a `BEGIN` block), or a command type name such as `SELECT`. Also, `waiting` is attached if the server process is presently waiting on a lock held by another server process. In the above example we can infer that process 1003 is waiting for process 1016 to complete its transaction and thereby release some lock or other.

If you have turned off `update_process_title` then the activity indicator is not updated; the process title is set only once when a new process is launched. On some platforms this saves a useful amount of per-command overhead, on others it’s insignificant.

**Tip:** Solaris requires special handling. You must use `/usr/ucb/ps`, rather than `/bin/ps`. You also must use two `-w` flags, not just one. In addition, your original invocation of the `postgres` command must have a shorter `ps` status display than that provided by each server process. If you fail to do all three things, the `ps` output for each server process will be the original `postgres` command line.
26.2. The Statistics Collector

PostgreSQL’s statistics collector is a subsystem that supports collection and reporting of information about server activity. Presently, the collector can count accesses to tables and indexes in both disk-block and individual-row terms. It also tracks total numbers of rows in each table, and the last vacuum and analyze times for each table. It can also count calls to user-defined functions and the total time spent in each one.

PostgreSQL also supports determining the exact command currently being executed by other server processes. This is an independent facility that does not depend on the collector process.

26.2.1. Statistics Collection Configuration

Since collection of statistics adds some overhead to query execution, the system can be configured to collect or not collect information. This is controlled by configuration parameters that are normally set in postgresql.conf. (See Chapter 18 for details about setting configuration parameters.) The parameter track_counts controls whether statistics are collected about table and index accesses. The parameter track_functions enables tracking of usage of user-defined functions. The parameter track_activities enables monitoring of the current command being executed by any server process.

Normally these parameters are set in postgresql.conf so that they apply to all server processes, but it is possible to turn them on or off in individual sessions using the SET command. (To prevent ordinary users from hiding their activity from the administrator, only superusers are allowed to change these parameters with SET.)

The statistics collector communicates with the backends needing information (including autovacuum) through temporary files. These files are stored in the pg_stat_tmp subdirectory. When the postmaster shuts down, a permanent copy of the statistics data is stored in the global subdirectory. For increased performance, the parameter stats_temp_directory can be pointed at a RAM based filesystem, decreasing physical I/O requirements.

26.2.2. Viewing Collected Statistics

Several predefined views, listed in Table 26-1, are available to show the results of statistics collection. Alternatively, one can build custom views using the underlying statistics functions.

When using the statistics to monitor current activity, it is important to realize that the information does not update instantaneously. Each individual server process transmits new statistical counts to the collector just before going idle; so a query or transaction still in progress does not affect the displayed totals. Also, the collector itself emits a new report at most once per PGSTAT_STAT_INTERVAL milliseconds (500 unless altered while building the server). So the displayed information lags behind actual activity. However, current-query information collected by track_activities is always up-to-date.

Another important point is that when a server process is asked to display any of these statistics, it first fetches the most recent report emitted by the collector process and then continues to use this snapshot for all statistical views and functions until the end of its current transaction. So the statistics will appear not to change as long as you continue the current transaction. Similarly, information about the current queries of all processes is collected when any such information is first requested within a transaction, and the same information will be displayed throughout the transaction. This is a feature, not a bug, because it allows you to perform several queries on the statistics and correlate the
results without worrying that the numbers are changing underneath you. But if you want to see new results with each query, be sure to do the queries outside any transaction block. Alternatively, you can invoke `pg_stat_clear_snapshot()`, which will discard the current transaction’s statistics snapshot (if any). The next use of statistical information will cause a new snapshot to be fetched.

Table 26-1. Standard Statistics Views

<table>
<thead>
<tr>
<th>View Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pg_stat_activity</code></td>
<td>One row per server process, showing database OID, database name, process ID, user OID, user name, current query, query’s waiting status, time at which the current transaction and current query began execution, time at which the process was started, and client’s address and port number. The columns that report data on the current query are available unless the parameter <code>track_activities</code> has been turned off. Furthermore, these columns are only visible if the user examining the view is a superuser or the same as the user owning the process being reported on.</td>
</tr>
<tr>
<td><code>pg_stat_bgwriter</code></td>
<td>One row only, showing cluster-wide statistics from the background writer: number of scheduled checkpoints, requested checkpoints, buffers written by checkpoints and cleaning scans, and the number of times the background writer stopped a cleaning scan because it had written too many buffers. Also includes statistics about the shared buffer pool, including buffers written by backends (that is, not by the background writer) and total buffers allocated.</td>
</tr>
<tr>
<td><code>pg_stat_database</code></td>
<td>One row per database, showing database OID, database name, number of active server processes connected to that database, number of transactions committed and rolled back in that database, total disk blocks read, total buffer hits (i.e., block read requests avoided by finding the block already in buffer cache), number of rows returned, fetched, inserted, updated and deleted.</td>
</tr>
<tr>
<td>View Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>pg_stat_all_tables</td>
<td>For each table in the current database (including TOAST tables), the table OID, schema and table name, number of sequential scans initiated, number of live rows fetched by sequential scans, number of index scans initiated (over all indexes belonging to the table), number of live rows fetched by index scans, numbers of row insertions, updates, and deletions, number of row updates that were HOT (i.e., no separate index update), numbers of live and dead rows, the last time the table was vacuumed manually, the last time it was vacuumed by the autovacuum daemon, the last time it was analyzed manually, and the last time it was analyzed by the autovacuum daemon.</td>
</tr>
<tr>
<td>pg_stat_sys_tables</td>
<td>Same as pg_stat_all_tables, except that only system tables are shown.</td>
</tr>
<tr>
<td>pg_stat_user_tables</td>
<td>Same as pg_stat_all_tables, except that only user tables are shown.</td>
</tr>
<tr>
<td>pg_stat_all_indexes</td>
<td>For each index in the current database, the table and index OID, schema, table and index name, number of index scans initiated on that index, number of index entries returned by index scans, and number of live table rows fetched by simple index scans using that index.</td>
</tr>
<tr>
<td>pg_stat_sys_indexes</td>
<td>Same as pg_stat_all_indexes, except that only indexes on system tables are shown.</td>
</tr>
<tr>
<td>pg_stat_user_indexes</td>
<td>Same as pg_stat_all_indexes, except that only indexes on user tables are shown.</td>
</tr>
<tr>
<td>pg_statio_all_tables</td>
<td>For each table in the current database (including TOAST tables), the table OID, schema and table name, number of disk blocks read from that table, number of buffer hits, numbers of disk blocks read and buffer hits in all indexes of that table, numbers of disk blocks read and buffer hits from that table’s auxiliary TOAST table (if any), and numbers of disk blocks read and buffer hits for the TOAST table’s index.</td>
</tr>
<tr>
<td>pg_statio_sys_tables</td>
<td>Same as pg_statio_all_tables, except that only system tables are shown.</td>
</tr>
<tr>
<td>pg_statio_user_tables</td>
<td>Same as pg_statio_all_tables, except that only user tables are shown.</td>
</tr>
<tr>
<td>pg_statio_all_indexes</td>
<td>For each index in the current database, the table and index OID, schema, table and index name, numbers of disk blocks read and buffer hits in that index.</td>
</tr>
<tr>
<td>pg_statio_sys_indexes</td>
<td>Same as pg_statio_all_indexes, except that only indexes on system tables are shown.</td>
</tr>
</tbody>
</table>
Chapter 26. Monitoring Database Activity

<table>
<thead>
<tr>
<th>View Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pg_statio_user_indexes</td>
<td>Same as pg_statio_all_indexes, except that only indexes on user tables are shown.</td>
</tr>
<tr>
<td>pg_statio_all_sequences</td>
<td>For each sequence object in the current database, the sequence OID, schema and sequence name, numbers of disk blocks read and buffer hits in that sequence.</td>
</tr>
<tr>
<td>pg_statio_sys_sequences</td>
<td>Same as pg_statio_all_sequences, except that only system sequences are shown. (Presently, no system sequences are defined, so this view is always empty.)</td>
</tr>
<tr>
<td>pg_statio_user_sequences</td>
<td>Same as pg_statio_all_sequences, except that only user sequences are shown.</td>
</tr>
<tr>
<td>pg_stat_user_functions</td>
<td>For all tracked functions, function OID, schema, name, number of calls, total time, and self time. Self time is the amount of time spent in the function itself, total time includes the time spent in functions it called. Time values are in milliseconds.</td>
</tr>
</tbody>
</table>

The per-index statistics are particularly useful to determine which indexes are being used and how effective they are.

Beginning in PostgreSQL 8.1, indexes can be used either directly or via "bitmap scans". In a bitmap scan the output of several indexes can be combined via AND or OR rules; so it is difficult to associate individual heap row fetches with specific indexes when a bitmap scan is used. Therefore, a bitmap scan increments the pg_stat_all_indexes.idx_tup_read count(s) for the index(es) it uses, and it increments the pg_stat_all_tables.idx_tup_fetch count for the table, but it does not affect pg_stat_all_indexes.idx_tup_fetch.

Note: Before PostgreSQL 8.1, the idx_tup_read and idx_tup_fetch counts were essentially always equal. Now they can be different even without considering bitmap scans, because idx_tup_read counts index entries retrieved from the index while idx_tup_fetch counts live rows fetched from the table; the latter will be less if any dead or not-yet-committed rows are fetched using the index.

The pg_statio_ views are primarily useful to determine the effectiveness of the buffer cache. When the number of actual disk reads is much smaller than the number of buffer hits, then the cache is satisfying most read requests without invoking a kernel call. However, these statistics do not give the entire story: due to the way in which PostgreSQL handles disk I/O, data that is not in the PostgreSQL buffer cache might still reside in the kernel’s I/O cache, and might therefore still be fetched without requiring a physical read. Users interested in obtaining more detailed information on PostgreSQL I/O behavior are advised to use the PostgreSQL statistics collector in combination with operating system utilities that allow insight into the kernel’s handling of I/O.

Other ways of looking at the statistics can be set up by writing queries that use the same underlying statistics access functions as these standard views do. These functions are listed in Table 26-2. The per-database access functions take a database OID as argument to identify which database to report on. The per-table and per-index functions take a table or index OID. The functions for function-call statistics take a function OID. (Note that only tables, indexes, and functions in the current database can
be seen with these functions.) The per-server-process access functions take a server process number, which ranges from one to the number of currently active server processes.

<tr>
<td><code>pg_stat_get_buf_written_backend()</code></td>
<td><code>bigint</code></td>
<td>The number of buffers written by backends because they needed to allocate a new buffer.</td>
</tr>
<tr>
<td><code>pg_stat_get_buf_alloc()</code></td>
<td><code>bigint</code></td>
<td>The total number of buffer allocations.</td>
</tr>
</tbody>
</table>
### 26.3. Viewing Locks

Another useful tool for monitoring database activity is the `pg_locks` system table. It allows the database administrator to view information about the outstanding locks in the lock manager. For example, this capability can be used to:

- View all the locks currently outstanding, all the locks on relations in a particular database, all the locks on a particular relation, or all the locks held by a particular PostgreSQL session.
- Determine the relation in the current database with the most ungranted locks (which might be a source of contention among database clients).
- Determine the effect of lock contention on overall database performance, as well as the extent to which contention varies with overall database traffic.

Details of the `pg_locks` view appear in Section 44.48. For more information on locking and managing concurrency with PostgreSQL, refer to Chapter 13.

### 26.4. Dynamic Tracing

PostgreSQL provides facilities to support dynamic tracing of the database server. This allows an external utility to be called at specific points in the code and thereby trace execution.
Chapter 26. Monitoring Database Activity

A number of probes or trace points are already inserted into the source code. These probes are intended to be used by database developers and administrators. By default the probes are not compiled into PostgreSQL; the user needs to explicitly tell the configure script to make the probes available.

Currently, only the DTrace\(^1\) utility is supported, which is available on OpenSolaris, Solaris 10, and Mac OS X Leopard. It is expected that DTrace will be available in the future on FreeBSD and possibly other operating systems. The SystemTap\(^2\) project for Linux also provides a DTrace equivalent. Supporting other dynamic tracing utilities is theoretically possible by changing the definitions for the macros in src/include/utils/probes.h.

26.4.1. Compiling for Dynamic Tracing

By default, probes are not available, so you will need to explicitly tell the configure script to make the probes available in PostgreSQL. To include DTrace support specify `--enable-dtrace` to configure. See Section 15.5 for further information.

26.4.2. Built-in Probes

A number of standard probes are provided in the source code, as shown in Table 26-3. More can certainly be added to enhance PostgreSQL’s observability.

<table>
<thead>
<tr>
<th>Name</th>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>transaction-start</td>
<td>(LocalTransactionId)</td>
<td>Probe that fires at the start of a new transaction. arg0 is the transaction id.</td>
</tr>
<tr>
<td>transaction-commit</td>
<td>(LocalTransactionId)</td>
<td>Probe that fires when a transaction completes successfully. arg0 is the transaction id.</td>
</tr>
<tr>
<td>transaction-abort</td>
<td>(LocalTransactionId)</td>
<td>Probe that fires when a transaction completes unsuccessfully. arg0 is the transaction id.</td>
</tr>
<tr>
<td>query-start</td>
<td>(const char *)</td>
<td>Probe that fires when the processing of a query is started. arg0 is the query string.</td>
</tr>
<tr>
<td>query-done</td>
<td>(const char *)</td>
<td>Probe that fires when the processing of a query is complete. arg0 is the query string.</td>
</tr>
<tr>
<td>query-parse-start</td>
<td>(const char *)</td>
<td>Probe that fires when the parsing of a query is started. arg0 is the query string.</td>
</tr>
</tbody>
</table>

### Chapter 26. Monitoring Database Activity

<table>
<thead>
<tr>
<th>Name</th>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query-parse-done</td>
<td>(const char *)</td>
<td>Probe that fires when the parsing of a query is complete. arg0 is the query string.</td>

### 26.4.3. Using Probes

The example below shows a DTrace script for analyzing transaction counts in the system, as an alternative to snapshotting `pg_stat_database` before and after a performance test:

```bash
#!/usr/sbin/dtrace -qs

postgresql$1:::transaction-start
{
    @start["Start"] = count();
    self->ts = timestamp;
}

postgresql$1:::transaction-abort
{
    @abort["Abort"] = count();
}

postgresql$1:::transaction-commit
/self->ts/
{
    @commit["Commit"] = count();
    @time["Total time (ns)"] = sum(timestamp - self->ts);
    self->ts=0;
}
```

When executed, the example D script gives output such as:

```
# ./txn_count.d 'pgrep -n postgres' or ./txn_count.d <PID>
^C
Start               71
Commit              70
Total time (ns)     2312105013
```

**Note:** SystemTap uses a different notation for trace scripts than DTrace does, even though the underlying trace points are compatible. One point worth noting is that at this writing, SystemTap scripts must reference probe names using double underlines in place of hyphens. This is expected to be fixed in future SystemTap releases.

You should remember that DTrace scripts need to be carefully written and debugged, otherwise the trace information collected might be meaningless. In most cases where problems are found it is the instrumentation that is at fault, not the underlying system. When discussing information found using dynamic tracing, be sure to enclose the script used to allow that too to be checked and discussed.
More example scripts can be found in the PgFoundry dtrace project³.

26.4.4. Defining New Probes

New probes can be defined within the code wherever the developer desires, though this will require a recompilation. Below are the steps for inserting new probes:

1. Decide on probe names and data to be made available through the probes
2. Add the probe definitions to src/backend/utils/probes.d
3. Include pg_trace.h if it is not already present in the module(s) containing the probe points, and insert TRACE_POSTGRESQL probe macros at the desired locations in the source code
4. Recompile and verify that the new probes are available

Example: Here is an example of how you would add a probe to trace all new transactions by transaction ID.

1. Decide that the probe will be named transaction-start and requires a parameter of type LocalTransactionId
2. Add the probe definition to src/backend/utils/probes.d:
   
   probe transaction__start(LocalTransactionId);

   Note the use of the double underline in the probe name. In a DTrace script using the probe, the double underline needs to be replaced with a hyphen, so transaction-start is the name to document for users.

3. At compile time, transaction__start is converted to a macro called TRACE_POSTGRESQL_TRANSACTION_START (notice the underscores are single here), which is available by including pg_trace.h. Add the macro call to the appropriate location in the source code. In this case, it looks like the following:

   TRACE_POSTGRESQL_TRANSACTION_START(vxid.localTransactionId);

4. After recompiling and running the new binary, check that your newly added probe is available by executing the following DTrace command. You should see similar output:

   # dtrace -ln transaction-start

   ID PROVIDER MODULE FUNCTION NAME
   18705 postgresql49878 postgres StartTransactionCommand transaction-start
   18755 postgresql49877 postgres StartTransactionCommand transaction-start
   18805 postgresql49876 postgres StartTransactionCommand transaction-start
   18855 postgresql49875 postgres StartTransactionCommand transaction-start
   18986 postgresql49873 postgres StartTransactionCommand transaction-start

There are a few things to be careful about when adding trace macros to the C code:

• You should take care that the data types specified for a probe’s parameters match the data types of the variables used in the macro. Otherwise, you will get compilation errors.

• On most platforms, if PostgreSQL is built with --enable-dtrace, the arguments to a trace macro will be evaluated whenever control passes through the macro, even if no tracing is being done. This is usually not worth worrying about if you are just reporting the values of a few local variables.

³ http://pgfoundry.org/projects/dtrace/
But beware of putting expensive function calls into the arguments. If you need to do that, consider protecting the macro with a check to see if the trace is actually enabled:

```c
if (TRACE_POSTGRESQL_TRANSACTION_START_ENABLED())
    TRACE_POSTGRESQL_TRANSACTION_START(some_function(...));
```

Each trace macro has a corresponding `ENABLED` macro.
Chapter 27. Monitoring Disk Usage

This chapter discusses how to monitor the disk usage of a PostgreSQL database system.

27.1. Determining Disk Usage

Each table has a primary heap disk file where most of the data is stored. If the table has any columns with potentially-wide values, there is also a TOAST file associated with the table, which is used to store values too wide to fit comfortably in the main table (see Section 53.2). There will be one index on the TOAST table, if present. There might also be indexes associated with the base table. Each table and index is stored in a separate disk file — possibly more than one file, if the file would exceed one gigabyte. Naming conventions for these files are described in Section 53.1.

You can monitor disk space from three ways: using SQL functions listed in Table 9-57, using VACUUM information, and from the command line using the tools in contrib/oid2name. The SQL functions are the easiest to use and report information about tables, tables with indexes and long value storage (TOAST), databases, and tablespaces.

Using psql on a recently vacuumed or analyzed database, you can issue queries to see the disk usage of any table:

```sql
SELECT relfilenode, relpages FROM pg_class WHERE relname = 'customer';
```

```
relfilenode relpages
-------------+----------
  16806       60
(1 row)
```

Each page is typically 8 kilobytes. (Remember, relpages is only updated by VACUUM, ANALYZE, and a few DDL commands such as CREATE INDEX.) The relfilenode value is of interest if you want to examine the table’s disk file directly.

To show the space used by TOAST tables, use a query like the following:

```sql
SELECT relname, relpages FROM pg_class,
       (SELECT reltoastrelid FROM pg_class
        WHERE relname = 'customer') ss
       WHERE oid = ss.reltoastrelid
       OR oid = (SELECT reltoastidxid FROM pg_class
                 WHERE oid = ss.reltoastrelid)
ORDER BY relname;
```

```
relname relpages
--------------+----------
 pg_toast_16806  0
 pg_toast_16806_index  1
```

You can easily display index sizes, too:

```sql
SELECT c2.relname, c2.relpages FROM pg_class c, pg_class c2, pg_index i
WHERE c.relname = 'customer'
  AND c.oid = i.indrelid
```

511
Chapter 27. Monitoring Disk Usage

AND c2.oid = i.indexrelid
ORDER BY c2.relname;

<table>
<thead>
<tr>
<th>relname</th>
<th>relpages</th>
</tr>
</thead>
<tbody>
<tr>
<td>customer_id_indexdex</td>
<td>26</td>
</tr>
</tbody>
</table>

It is easy to find your largest tables and indexes using this information:

```
SELECT relname, relpages FROM pg_class ORDER BY relpages DESC;
```

<table>
<thead>
<tr>
<th>relname</th>
<th>relpages</th>
</tr>
</thead>
<tbody>
<tr>
<td>bigtable</td>
<td>3290</td>
</tr>
<tr>
<td>customer</td>
<td>3144</td>
</tr>
</tbody>
</table>

You can also use `contrib/oid2name` to show disk usage. See `README.oid2name` in that directory for examples. It includes a script that shows disk usage for each database.

### 27.2. Disk Full Failure

The most important disk monitoring task of a database administrator is to make sure the disk doesn’t grow full. A filled data disk will not result in data corruption, but it might prevent useful activity from occurring. If the disk holding the WAL files grows full, database server panic and consequent shutdown might occur.

If you cannot free up additional space on the disk by deleting other things, you can move some of the database files to other file systems by making use of tablespaces. See Section 21.6 for more information about that.

**Tip:** Some file systems perform badly when they are almost full, so do not wait until the disk is completely full to take action.

If your system supports per-user disk quotas, then the database will naturally be subject to whatever quota is placed on the user the server runs as. Exceeding the quota will have the same bad effects as running out of space entirely.
Chapter 28. Reliability and the Write-Ahead Log

This chapter explains how the Write-Ahead Log is used to obtain efficient, reliable operation.

28.1. Reliability

Reliability is an important property of any serious database system, and PostgreSQL does everything possible to guarantee reliable operation. One aspect of reliable operation is that all data recorded by a committed transaction should be stored in a nonvolatile area that is safe from power loss, operating system failure, and hardware failure (except failure of the nonvolatile area itself, of course). Successfully writing the data to the computer’s permanent storage (disk drive or equivalent) ordinarily meets this requirement. In fact, even if a computer is fatally damaged, if the disk drives survive they can be moved to another computer with similar hardware and all committed transactions will remain intact.

While forcing data periodically to the disk platters might seem like a simple operation, it is not. Because disk drives are dramatically slower than main memory and CPUs, several layers of caching exist between the computer’s main memory and the disk platters. First, there is the operating system’s buffer cache, which caches frequently requested disk blocks and combines disk writes. Fortunately, all operating systems give applications a way to force writes from the buffer cache to disk, and PostgreSQL uses those features. (See the wal_sync_method parameter to adjust how this is done.)

Next, there might be a cache in the disk drive controller; this is particularly common on RAID controller cards. Some of these caches are write-through, meaning writes are passed along to the drive as soon as they arrive. Others are write-back, meaning data is passed on to the drive at some later time. Such caches can be a reliability hazard because the memory in the disk controller cache is volatile, and will lose its contents in a power failure. Better controller cards have battery-backed caches, meaning the card has a battery that maintains power to the cache in case of system power loss. After power is restored the data will be written to the disk drives.

And finally, most disk drives have caches. Some are write-through while some are write-back, and the same concerns about data loss exist for write-back drive caches as exist for disk controller caches. Consumer-grade IDE and SATA drives are particularly likely to have write-back caches that will not survive a power failure. To check write caching on Linux use hdparm -I; it is enabled if there is a * next to Write cache. hdparm -W to turn off write caching. On FreeBSD use atacontrol. (For SCSI disks use sdparm1 to turn off WCE.) On Solaris the disk write cache is controlled by format -e. (The Solaris ZFS file system is safe with disk write-cache enabled because it issues its own disk cache flush commands.) On Windows if wal_sync_method is open_dataasync (the default), write caching is disabled by unchecking My Computer\Open\{select disk drive\}Properties\Hardware\Properties\Policies\Enable write caching on the disk. Also on Windows, fsync and fsync_writethrough never do write caching. The fsync_writethrough option can also be used to disable write caching on MacOS X.

When the operating system sends a write request to the disk hardware, there is little it can do to make sure the data has arrived at a truly non-volatile storage area. Rather, it is the administrator’s responsibility to be sure that all storage components ensure data integrity. Avoid disk controllers that have non-battery-backed write caches. At the drive level, disable write-back caching if the drive cannot guarantee the data will be written before shutdown.

1. http://sg.torque.net/sd/sdparm.html
2. http://www.sun.com/bigadmin/content/submitted/format_utility.jsp
Another risk of data loss is posed by the disk platter write operations themselves. Disk platters are divided into sectors, commonly 512 bytes each. Every physical read or write operation processes a whole sector. When a write request arrives at the drive, it might be for 512 bytes, 1024 bytes, or 8192 bytes, and the process of writing could fail due to power loss at any time, meaning some of the 512-byte sectors were written, and others were not. To guard against such failures, PostgreSQL periodically writes full page images to permanent storage before modifying the actual page on disk. By doing this, during crash recovery PostgreSQL can restore partially-written pages. If you have a battery-backed disk controller or file-system software that prevents partial page writes (e.g., ReiserFS 4), you can turn off this page imaging by using the full_page_writes parameter.

### 28.2. Write-Ahead Logging (WAL)

**Write-Ahead Logging (WAL)** is a standard method for ensuring data integrity. A detailed description can be found in most (if not all) books about transaction processing. Briefly, WAL’s central concept is that changes to data files (where tables and indexes reside) must be written only after those changes have been logged, that is, after log records describing the changes have been flushed to permanent storage. If we follow this procedure, we do not need to flush data pages to disk on every transaction commit, because we know that in the event of a crash we will be able to recover the database using the log: any changes that have not been applied to the data pages can be redone from the log records. (This is roll-forward recovery, also known as REDO.)

**Tip:** Because WAL restores database file contents after a crash, journaled filesystems are not necessary for reliable storage of the data files or WAL files. In fact, journaling overhead can reduce performance, especially if journaling causes file system data to be flushed to disk. Fortunately, data flushing during journaling can often be disabled with a filesystem mount option, e.g. `data=writeback` on a Linux ext3 file system. Journaled file systems do improve boot speed after a crash.

Using WAL results in a significantly reduced number of disk writes, because only the log file needs to be flushed to disk to guarantee that a transaction is committed, rather than every data file changed by the transaction. The log file is written sequentially, and so the cost of syncing the log is much less than the cost of flushing the data pages. This is especially true for servers handling many small transactions touching different parts of the data store. Furthermore, when the server is processing many small concurrent transactions, one `fsync` of the log file may suffice to commit many transactions.

WAL also makes it possible to support on-line backup and point-in-time recovery, as described in Section 24.3. By archiving the WAL data we can support reverting to any time instant covered by the available WAL data; we simply install a prior physical backup of the database, and replay the WAL log just as far as the desired time. What’s more, the physical backup doesn’t have to be an instantaneous snapshot of the database state — if it is made over some period of time, then replaying the WAL log for that period will fix any internal inconsistencies.

### 28.3. Asynchronous Commit

**Asynchronous commit** is an option that allows transactions to complete more quickly, at the cost that the most recent transactions may be lost if the database should crash. In many applications this is an acceptable trade-off.
As described in the previous section, transaction commit is normally synchronous: the server waits for the transaction’s WAL records to be flushed to permanent storage before returning a success indication to the client. The client is therefore guaranteed that a transaction reported to be committed will be preserved, even in the event of a server crash immediately after. However, for short transactions this delay is a major component of the total transaction time. Selecting asynchronous commit mode means that the server returns success as soon as the transaction is logically completed, before the WAL records it generated have actually made their way to disk. This can provide a significant boost in throughput for small transactions.

Asynchronous commit introduces the risk of data loss. There is a short time window between the report of transaction completion to the client and the time that the transaction is truly committed (that is, it is guaranteed not to be lost if the server crashes). Thus asynchronous commit should not be used if the client will take external actions relying on the assumption that the transaction will be remembered. As an example, a bank would certainly not use asynchronous commit for a transaction recording an ATM’s dispensing of cash. But in many scenarios, such as event logging, there is no need for a strong guarantee of this kind.

The risk that is taken by using asynchronous commit is of data loss, not data corruption. If the database should crash, it will recover by replaying WAL up to the last record that was flushed. The database will therefore be restored to a self-consistent state, but any transactions that were not yet flushed to disk will not be reflected in that state. The net effect is therefore loss of the last few transactions. Because the transactions are replayed in commit order, no inconsistency can be introduced — for example, if transaction B made changes relying on the effects of a previous transaction A, it is not possible for A’s effects to be lost while B’s effects are preserved.

The user can select the commit mode of each transaction, so that it is possible to have both synchronous and asynchronous commit transactions running concurrently. This allows flexible trade-offs between performance and certainty of transaction durability. The commit mode is controlled by the user-settable parameter synchronous_commit, which can be changed in any of the ways that a configuration parameter can be set. The mode used for any one transaction depends on the value of synchronous_commit when transaction commit begins.

Certain utility commands, for instance DROP TABLE, are forced to commit synchronously regardless of the setting of synchronous_commit. This is to ensure consistency between the server’s file system and the logical state of the database. The commands supporting two-phase commit, such as PREPARE TRANSACTION, are also always synchronous.

If the database crashes during the risk window between an asynchronous commit and the writing of the transaction’s WAL records, then changes made during that transaction will be lost. The duration of the risk window is limited because a background process (the “WAL writer”) flushes unwritten WAL records to disk every wal_writer_delay milliseconds. The actual maximum duration of the risk window is three times wal_writer_delay because the WAL writer is designed to favor writing whole pages at a time during busy periods.

Caution
An immediate-mode shutdown is equivalent to a server crash, and will therefore cause loss of any unflushed asynchronous commits.

Asynchronous commit provides behavior different from setting fsync = off. fsync is a server-wide setting that will alter the behavior of all transactions. It disables all logic within PostgreSQL that attempts to synchronize writes to different portions of the database, and therefore a system crash (that is, a hardware or operating system crash, not a failure of PostgreSQL itself) could result in arbitrarily bad corruption of the database state. In many scenarios, asynchronous commit provides most of the...
performance improvement that could be obtained by turning off fsync, but without the risk of data corruption.

commit_delay also sounds very similar to asynchronous commit, but it is actually a synchronous commit method (in fact, commit_delay is ignored during an asynchronous commit). commit_delay causes a delay just before a synchronous commit attempts to flush WAL to disk, in the hope that a single flush executed by one such transaction can also serve other transactions committing at about the same time. Setting commit_delay can only help when there are many concurrently committing transactions, and it is difficult to tune it to a value that actually helps rather than hurting throughput.

28.4. WAL Configuration

There are several WAL-related configuration parameters that affect database performance. This section explains their use. Consult Chapter 18 for general information about setting server configuration parameters.

Checkpoints are points in the sequence of transactions at which it is guaranteed that the data files have been updated with all information written before the checkpoint. At checkpoint time, all dirty data pages are flushed to disk and a special checkpoint record is written to the log file. (The changes were previously flushed to the WAL files.) In the event of a crash, the crash recovery procedure looks at the latest checkpoint record to determine the point in the log (known as the redo record) from which it should start the REDO operation. Any changes made to data files before that point are guaranteed to be already on disk. Hence, after a checkpoint, log segments preceding the one containing the redo record are no longer needed and can be recycled or removed. (When WAL archiving is being done, the log segments must be archived before being recycled or removed.)

The checkpoint requirement of flushing all dirty data pages to disk can cause a significant I/O load. For this reason, checkpoint activity is throttled so I/O begins at checkpoint start and completes before the next checkpoint starts; this minimizes performance degradation during checkpoints.

The server’s background writer process will automatically perform a checkpoint every so often. A checkpoint is created every checkpoint_segments log segments, or every checkpoint_timeout seconds, whichever comes first. The default settings are 3 segments and 300 seconds respectively. It is also possible to force a checkpoint by using the SQL command CHECKPOINT.

Reducing checkpoint_segments and/or checkpoint_timeout causes checkpoints to be done more often. This allows faster after-crash recovery (since less work will need to be redone). However, one must balance this against the increased cost of flushing dirty data pages more often. If full_page_writes is set (as is the default), there is another factor to consider. To ensure data page consistency, the first modification of a data page after each checkpoint results in logging the entire page content. In that case, a smaller checkpoint interval increases the volume of output to the WAL log, partially negating the goal of using a smaller interval, and in any case causing more disk I/O.

Checkpoints are fairly expensive, first because they require writing out all currently dirty buffers, and second because they result in extra subsequent WAL traffic as discussed above. It is therefore wise to set the checkpointing parameters high enough that checkpoints don’t happen too often. As a simple sanity check on your checkpointing parameters, you can set the checkpoint_warning parameter. If checkpoints happen closer together than checkpoint_warning seconds, a message will be output to the server log recommending increasing checkpoint_segments. Occasional appearance of such a message is not cause for alarm, but if it appears often then the checkpoint control parameters should be increased. Bulk operations such as large COPY transfers might cause a number of such warnings to appear if you have not set checkpoint_segments high enough.
To avoid flooding the I/O system with a burst of page writes, writing dirty buffers during a checkpoint is spread over a period of time. That period is controlled by checkpoint_completion_target, which is given as a fraction of the checkpoint interval. The I/O rate is adjusted so that the checkpoint finishes when the given fraction of checkpoint_segments WAL segments have been consumed since checkpoint start, or the given fraction of checkpoint_timeout seconds have elapsed, whichever is sooner. With the default value of 0.5, PostgreSQL can be expected to complete each checkpoint in about half the time before the next checkpoint starts. On a system that’s very close to maximum I/O throughput during normal operation, you might want to increase checkpoint_completion_target to reduce the I/O load from checkpoints. The disadvantage of this is that prolonging checkpoints affects recovery time, because more WAL segments will need to be kept around for possible use in recovery. Although checkpoint_completion_target can be set as high as 1.0, it is best to keep it less than that (perhaps 0.9 at most) since checkpoints include some other activities besides writing dirty buffers. A setting of 1.0 is quite likely to result in checkpoints not being completed on time, which would result in performance loss due to unexpected variation in the number of WAL segments needed.

There will always be at least one WAL segment file, and will normally not be more than $(2 + \text{checkpoint_completion_target}) \times \text{checkpoint_segments} + 1$ files. Each segment file is normally 16 MB (though this size can be altered when building the server). You can use this to estimate space requirements for WAL. Ordinarily, when old log segment files are no longer needed, they are recycled (renamed to become the next segments in the numbered sequence). If, due to a short-term peak of log output rate, there are more than $3 \times \text{checkpoint_segments} + 1$ segment files, the unneeded segment files will be deleted instead of recycled until the system gets back under this limit.

There are two commonly used internal WAL functions: LogInsert and LogFlush. LogInsert is used to place a new record into the WAL buffers in shared memory. If there is no space for the new record, LogInsert will have to write (move to kernel cache) a few filled WAL buffers. This is undesirable because LogInsert is used on every database low level modification (for example, row insertion) at a time when an exclusive lock is held on affected data pages, so the operation needs to be as fast as possible. What is worse, writing WAL buffers might also force the creation of a new log segment, which takes even more time. Normally, WAL buffers should be written and flushed by a LogFlush request, which is made, for the most part, at transaction commit time to ensure that transaction records are flushed to permanent storage. On systems with high log output, LogFlush requests might not occur often enough to prevent LogInsert from having to do writes. On such systems one should increase the number of WAL buffers by modifying the configuration parameter wal_buffers. The default number of WAL buffers is 8. Increasing this value will correspondingly increase shared memory usage. When full_page_writes is set and the system is very busy, setting this value higher will help smooth response times during the period immediately following each checkpoint.

The commit_delay parameter defines for how many microseconds the server process will sleep after writing a commit record to the log with LogInsert but before performing a LogFlush. This delay allows other server processes to add their commit records to the log so as to have all of them flushed with a single log sync. No sleep will occur if fsync is not enabled, nor if fewer than commit_siblings other sessions are currently in active transactions; this avoids sleeping when it’s unlikely that any other session will commit soon. Note that on most platforms, the resolution of a sleep request is ten milliseconds, so that any nonzero commit_delay setting between 1 and 10000 microseconds would have the same effect. Good values for these parameters are not yet clear; experimentation is encouraged.

The wal_sync_method parameter determines how PostgreSQL will ask the kernel to force WAL updates out to disk. All the options should be the same in terms of reliability, with the exception of fsync_writethrough, which can sometimes force a flush of the disk cache even when other options do not do so. However, it’s quite platform-specific which one will be the fastest; you can test option speeds using the utility src/tools/fsync in the PostgreSQL source tree. Note that this pa-
Chapter 28. Reliability and the Write-Ahead Log

Parameter is irrelevant if fsync has been turned off.

Enabling the wal_debug configuration parameter (provided that PostgreSQL has been compiled with support for it) will result in each LogInsert and LogFlush WAL call being logged to the server log. This option might be replaced by a more general mechanism in the future.

28.5. WAL Internals

WAL is automatically enabled; no action is required from the administrator except ensuring that the disk-space requirements for the WAL logs are met, and that any necessary tuning is done (see Section 28.4).

WAL logs are stored in the directory pg_xlog under the data directory, as a set of segment files, normally each 16 MB in size (but the size can be changed by altering the --with-wal-segsiz e configure option when building the server). Each segment is divided into pages, normally 8 kB each (this size can be changed via the --with-wal-blocksize configure option). The log record headers are described in access/xlog.h; the record content is dependent on the type of event that is being logged. Segment files are given ever-increasing numbers as names, starting at 000000010000000000000000. The numbers do not wrap, at present, but it should take a very very long time to exhaust the available stock of numbers.

It is of advantage if the log is located on another disk than the main database files. This can be achieved by moving the directory pg_xlog to another location (while the server is shut down, of course) and creating a symbolic link from the original location in the main data directory to the new location.

The aim of WAL, to ensure that the log is written before database records are altered, can be subverted by disk drives that falsely report a successful write to the kernel, when in fact they have only cached the data and not yet stored it on the disk. A power failure in such a situation might still lead to irrecoverable data corruption. Administrators should try to ensure that disks holding PostgreSQL’s WAL log files do not make such false reports. (See Section 28.1.)

After a checkpoint has been made and the log flushed, the checkpoint’s position is saved in the file pg_control. Therefore, when recovery is to be done, the server first reads pg_control and then the checkpoint record; then it performs the REDO operation by scanning forward from the log position indicated in the checkpoint record. Because the entire content of data pages is saved in the log on the first page modification after a checkpoint (assuming full_page_writes is not disabled), all pages changed since the checkpoint will be restored to a consistent state.

To deal with the case where pg_control is corrupted, we should support the possibility of scanning existing log segments in reverse order — newest to oldest — in order to find the latest checkpoint. This has not been implemented yet. pg_control is small enough (less than one disk page) that it is not subject to partial-write problems, and as of this writing there have been no reports of database failures due solely to inability to read pg_control itself. So while it is theoretically a weak spot, pg_control does not seem to be a problem in practice.
Chapter 29. Regression Tests

The regression tests are a comprehensive set of tests for the SQL implementation in PostgreSQL. They test standard SQL operations as well as the extended capabilities of PostgreSQL.

29.1. Running the Tests

The regression tests can be run against an already installed and running server, or using a temporary installation within the build tree. Furthermore, there is a “parallel” and a “sequential” mode for running the tests. The sequential method runs each test script in turn, whereas the parallel method starts up multiple server processes to run groups of tests in parallel. Parallel testing gives confidence that interprocess communication and locking are working correctly. For historical reasons, the sequential test is usually run against an existing installation and the parallel method against a temporary installation, but there are no technical reasons for this.

To run the regression tests after building but before installation, type:

```
gmake check
```

in the top-level directory. (Or you can change to `src/test/regress` and run the command there.) This will first build several auxiliary files, such as some sample user-defined trigger functions, and then run the test driver script. At the end you should see something like:

```
=======================
All 115 tests passed.
=======================
```

or otherwise a note about which tests failed. See Section 29.2 below before assuming that a “failure” represents a serious problem.

```
Warning
On systems lacking Unix-domain sockets, notably Windows, this test method
starts a temporary server configured to accept any connection originating on
the local machine. Any local user can gain database superuser privileges when
connecting to this server, and could in principle exploit all privileges of the
operating-system user running the tests. Therefore, it is not recommended that
you use `gmake check` on an affected system shared with untrusted users. In-
stead, run the tests after completing the installation, as described in the next
section.
```

Because this test method runs a temporary server, it will not work if you did the build as the root user, since the server will not start as root. Recommended procedure is not to do the build as root, or else to perform testing after completing the installation.

If you have configured PostgreSQL to install into a location where an older PostgreSQL installation already exists, and you perform `gmake check` before installing the new version, you might find that the tests fail because the new programs try to use the already-installed shared libraries. (Typical symptoms are complaints about undefined symbols.) If you wish to run the tests before overwriting the old installation, you’ll need to build with `configure --disable-rpath`. It is not recommended that you use this option for the final installation, however.

The parallel regression test starts quite a few processes under your user ID. Presently, the maximum concurrency is twenty parallel test scripts, which means forty processes: there’s a server process
and a psql process for each test script. So if your system enforces a per-user limit on the number of processes, make sure this limit is at least fifty or so, else you might get random-seeming failures in the parallel test. If you are not in a position to raise the limit, you can cut down the degree of parallelism by setting the `MAX_CONNECTIONS` parameter. For example:

```bash
gmake MAX_CONNECTIONS=10 check
```

runs no more than ten tests concurrently.

To run the tests after installation (see Chapter 15), initialize a data area and start the server, as explained in Chapter 17, then type:

```bash
gmake installcheck
```

or for a parallel test:

```bash
gmake installcheck-parallel
```

The tests will expect to contact the server at the local host and the default port number, unless directed otherwise by `PGHOST` and `PGPORT` environment variables.

The source distribution also contains regression tests for the optional procedural languages and for some of the `contrib` modules. At present, these tests can be used only against an already-installed server. To run the tests for all procedural languages that have been built and installed, change to the `src/pl` directory of the build tree and type:

```bash
gmake installcheck
```

You can also do this in any of the subdirectories of `src/pl` to run tests for just one procedural language. To run the tests for all `contrib` modules that have them, change to the `contrib` directory of the build tree and type:

```bash
gmake installcheck
```

The `contrib` modules must have been built and installed first. You can also do this in a subdirectory of `contrib` to run the tests for just one module.

### 29.2. Test Evaluation

Some properly installed and fully functional PostgreSQL installations can “fail” some of these regression tests due to platform-specific artifacts such as varying floating-point representation and message wording. The tests are currently evaluated using a simple `diff` comparison against the outputs generated on a reference system, so the results are sensitive to small system differences. When a test is reported as “failed”, always examine the differences between expected and actual results; you might find that the differences are not significant. Nonetheless, we still strive to maintain accurate reference files across all supported platforms, so it can be expected that all tests pass.

The actual outputs of the regression tests are in files in the `src/test/regress/results` directory. The test script uses `diff` to compare each output file against the reference outputs stored in the `src/test/regress/expected` directory. Any differences are saved for your inspection in `src/test/regress/regression.diffs`. (Or you can run `diff` yourself, if you prefer.)

If for some reason a particular platform generates a “failure” for a given test, but inspection of the output convinces you that the result is valid, you can add a new comparison file to silence the failure report in future test runs. See Section 29.3 for details.
29.2.1. Error message differences

Some of the regression tests involve intentional invalid input values. Error messages can come from either the PostgreSQL code or from the host platform system routines. In the latter case, the messages can vary between platforms, but should reflect similar information. These differences in messages will result in a “failed” regression test that can be validated by inspection.

29.2.2. Locale differences

If you run the tests against a server that was initialized with a collation-order locale other than C, then there might be differences due to sort order and follow-up failures. The regression test suite is set up to handle this problem by providing alternative result files that together are known to handle a large number of locales.

To run the tests in a different locale when using the temporary-installation method, pass the appropriate locale-related environment variables on the make command line, for example:

```
gmake check LANG=de_DE.utf8
```

(The regression test driver unsets `LC_ALL`, so it does not work to choose the locale using that variable.) To use no locale, either unset all locale-related environment variables (or set them to C) or use the following special invocation:

```
gmake check NO_LOCALE=1
```

When running the tests against an existing installation, the locale setup is determined by the existing installation. To change it, initialize the database cluster with a different locale by passing the appropriate options to `initdb`.

In general, it is nevertheless advisable to try to run the regression tests in the locale setup that is wanted for production use, as this will exercise the locale- and encoding-related code portions that will actually be used in production. Depending on the operating system environment, you might get failures, but then you will at least know what locale-specific behaviors to expect when running real applications.

29.2.3. Date and time differences

Most of the date and time results are dependent on the time zone environment. The reference files are generated for time zone PST8PDT (Berkeley, California), and there will be apparent failures if the tests are not run with that time zone setting. The regression test driver sets environment variable `PGTZ` to `PST8PDT`, which normally ensures proper results.

29.2.4. Floating-point differences

Some of the tests involve computing 64-bit floating-point numbers (double precision) from table columns. Differences in results involving mathematical functions of double precision columns have been observed. The `float8` and `geometry` tests are particularly prone to small differences across platforms, or even with different compiler optimization options. Human eyeball comparison is needed to determine the real significance of these differences which are usually 10 places to the right of the decimal point.

Some systems display minus zero as `-0`, while others just show `0`.
Some systems signal errors from `pow()` and `exp()` differently from the mechanism expected by the current PostgreSQL code.

### 29.2.5. Row ordering differences

You might see differences in which the same rows are output in a different order than what appears in the expected file. In most cases this is not, strictly speaking, a bug. Most of the regression test scripts are not so pedantic as to use an `ORDER BY` for every single `SELECT`, and so their result row orderings are not well-defined according to the letter of the SQL specification. In practice, since we are looking at the same queries being executed on the same data by the same software, we usually get the same result ordering on all platforms, and so the lack of `ORDER BY` isn’t a problem. Some queries do exhibit cross-platform ordering differences, however. When testing against an already-installed server, ordering differences can also be caused by non-C locale settings or non-default parameter settings, such as custom values of `work_mem` or the planner cost parameters.

Therefore, if you see an ordering difference, it’s not something to worry about, unless the query does have an `ORDER BY` that your result is violating. But please report it anyway, so that we can add an `ORDER BY` to that particular query and thereby eliminate the bogus “failure” in future releases.

You might wonder why we don’t order all the regression test queries explicitly to get rid of this issue once and for all. The reason is that that would make the regression tests less useful, not more, since they’d tend to exercise query plan types that produce ordered results to the exclusion of those that don’t.

### 29.2.6. Insufficient stack depth

If the `errors` test results in a server crash at the `select infinite_recurse()` command, it means that the platform’s limit on process stack size is smaller than the `max_stack_depth` parameter indicates. This can be fixed by running the server under a higher stack size limit (4MB is recommended with the default value of `max_stack_depth`). If you are unable to do that, an alternative is to reduce the value of `max_stack_depth`.

### 29.2.7. The “random” test

The `random` test script is intended to produce random results. In rare cases, this causes the random regression test to fail. Typing:

```
diff results/random.out expected/random.out
```

should produce only one or a few lines of differences. You need not worry unless the random test fails repeatedly.

### 29.3. Variant Comparison Files

Since some of the tests inherently produce environment-dependent results, we have provided ways to specify alternative “expected” result files. Each regression test can have several comparison files showing possible results on different platforms. There are two independent mechanisms for determining which comparison file is used for each test.
The first mechanism allows comparison files to be selected for specific platforms. There is a mapping file, src/test/regress/resultmap, that defines which comparison file to use for each platform. To eliminate bogus test “failures” for a particular platform, you first choose or make a variant result file, and then add a line to the resultmap file.

Each line in the mapping file is of the form

```
testname:output:platformpattern=comparisonfilename
```

The test name is just the name of the particular regression test module. The output value indicates which output file to check. For the standard regression tests, this is always `out`. The value corresponds to the file extension of the output file. The platform pattern is a pattern in the style of the Unix tool `expr` (that is, a regular expression with an implicit `^` anchor at the start). It is matched against the platform name as printed by `config.guess`. The comparison file name is the base name of the substitute result comparison file.

For example: some systems interpret very small floating-point values as zero, rather than reporting an underflow error. This causes a few differences in the `float8` regression test. Therefore, we provide a variant comparison file, `float8-small-is-zero.out`, which includes the results to be expected on these systems. To silence the bogus “failure” message on OpenBSD platforms, resultmap includes:

```
float8:out:i.86-.*:openbsd=float8-small-is-zero.out
```

which will trigger on any machine for which the output of `config.guess` matches `i.86-.*:openbsd`. Other lines in resultmap select the variant comparison file for other platforms where it’s appropriate.

The second selection mechanism for variant comparison files is much more automatic: it simply uses the “best match” among several supplied comparison files. The regression test driver script considers both the standard comparison file for a test, `testname.out`, and variant files named `testname_digit.out` (where the `digit` is any single digit 0-9). If any such file is an exact match, the test is considered to pass; otherwise, the one that generates the shortest diff is used to create the failure report. (If resultmap includes an entry for the particular test, then the base `testname` is the substitute name given in resultmap.)

For example, for the `char` test, the comparison file `char.out` contains results that are expected in the `C` and `POSIX` locales, while the file `char_1.out` contains results sorted as they appear in many other locales.

The best-match mechanism was devised to cope with locale-dependent results, but it can be used in any situation where the test results cannot be predicted easily from the platform name alone. A limitation of this mechanism is that the test driver cannot tell which variant is actually “correct” for the current environment; it will just pick the variant that seems to work best. Therefore it is safest to use this mechanism only for variant results that you are willing to consider equally valid in all contexts.

### 29.4. Test Coverage Examination

The PostgreSQL source code can be compiled with coverage testing instrumentation, so that it becomes possible to examine which parts of the code are covered by the regression tests or any other test suite that is run with the code. This is currently supported when compiling with GCC and requires the `gcov` and `lcov` programs.

A typical workflow would look like this:
Chapter 29. Regression Tests

./configure --enable-coverage ... OTHER OPTIONS ...
gmake
gmake check # or other test suite
gmake coverage-html

Then point your HTML browser to coverage/index.html.

To reset the execution counts between test runs, run:

gmake coverage-clean
IV. Client Interfaces

This part describes the client programming interfaces distributed with PostgreSQL. Each of these chapters can be read independently. Note that there are many other programming interfaces for client programs that are distributed separately and contain their own documentation (Appendix G lists some of the more popular ones). Readers of this part should be familiar with using SQL commands to manipulate and query the database (see Part II) and of course with the programming language that the interface uses.
Chapter 30. libpq - C Library

libpq is the C application programmer’s interface to PostgreSQL. libpq is a set of library functions that allow client programs to pass queries to the PostgreSQL backend server and to receive the results of these queries.

libpq is also the underlying engine for several other PostgreSQL application interfaces, including those written for C++, Perl, Python, Tcl and ECPG. So some aspects of libpq’s behavior will be important to you if you use one of those packages. In particular, Section 30.13, Section 30.14 and Section 30.17 describe behavior that is visible to the user of any application that uses libpq.

Some short programs are included at the end of this chapter (Section 30.20) to show how to write programs that use libpq. There are also several complete examples of libpq applications in the directory src/test/examples in the source code distribution.

Client programs that use libpq must include the header file libpq-fe.h and must link with the libpq library.

30.1. Database Connection Control Functions

The following functions deal with making a connection to a PostgreSQL backend server. An application program can have several backend connections open at one time. (One reason to do that is to access more than one database.) Each connection is represented by a PGconn object, which is obtained from the function PQconnectdb or PQsetdbLogin. Note that these functions will always return a non-null object pointer, unless perhaps there is too little memory even to allocate the PGconn object. The PQstatus function should be called to check whether a connection was successfully made before queries are sent via the connection object.

Warning

On Unix, forking a process with open libpq connections can lead to unpredictable results because the parent and child processes share the same sockets and operating system resources. For this reason, such usage is not recommended, though doing an exec from the child process to load a new executable is safe.

Note: On Windows, there is a way to improve performance if a single database connection is repeatedly started and shutdown. Internally, libpq calls WSASStartup() and WSACleanup() for connection startup and shutdown, respectively. WSASStartup() increments an internal Windows library reference count which is decremented by WSACleanup(). When the reference count is just one, calling WSACleanup() frees all resources and all DLLs are unloaded. This is an expensive operation. To avoid this, an application can manually call WSASStartup() so resources will not be freed when the last database connection is closed.

PQconnectdb

Makes a new connection to the database server.

```c
PGconn *PQconnectdb(const char *conninfo);
```
This function opens a new database connection using the parameters taken from the string `conninfo`. Unlike `PQsetdbLogin` below, the parameter set can be extended without changing the function signature, so use of this function (or its nonblocking analogues `PQconnectStart` and `PQconnectPoll`) is preferred for new application programming.

The passed string can be empty to use all default parameters, or it can contain one or more parameter settings separated by whitespace. Each parameter setting is in the form `keyword = value`. Spaces around the equal sign are optional. To write an empty value or a value containing spaces, surround it with single quotes, e.g., `keyword = 'a value'`. Single quotes and backslashes within the value must be escaped with a backslash, i.e., `'` and `\`.

The currently recognized parameter key words are:

**host**
Name of host to connect to. If this begins with a slash, it specifies Unix-domain communication rather than TCP/IP communication; the value is the name of the directory in which the socket file is stored. The default behavior when `host` is not specified is to connect to a Unix-domain socket in `/tmp` (or whatever socket directory was specified when PostgreSQL was built). On machines without Unix-domain sockets, the default is to connect to `localhost`.

**hostaddr**
Numeric IP address of host to connect to. This should be in the standard IPv4 address format, e.g., `172.28.40.9`. If your machine supports IPv6, you can also use those addresses. TCP/IP communication is always used when a nonempty string is specified for this parameter.

Using `hostaddr` instead of `host` allows the application to avoid a host name look-up, which might be important in applications with time constraints. However, a host name is required for Kerberos, GSSAPI, or SSPI authentication, as well as for full SSL certificate verification. The following rules are used: If `host` is specified without `hostaddr`, a host name lookup occurs. If `hostaddr` is specified without `host`, the value for `hostaddr` gives the server address. The connection attempt will fail in any of the cases where a host name is required. If both `host` and `hostaddr` are specified, the value for `hostaddr` gives the server address. The value for `host` is ignored unless needed for authentication or verification purposes, in which case it will be used as the host name. Note that authentication is likely to fail if `host` is not the name of the machine at `hostaddr`. Also, note that `host` rather than `hostaddr` is used to identify the connection in `~/.pgpass` (see Section 30.14).

Without either a host name or host address, libpq will connect using a local Unix-domain socket; or on machines without Unix-domain sockets, it will attempt to connect to `localhost`.

**port**
Port number to connect to at the server host, or socket file name extension for Unix-domain connections.

**dbname**
The database name. Defaults to be the same as the user name.

**user**
PostgreSQL user name to connect as. Defaults to be the same as the operating system name of the user running the application.
password

Password to be used if the server demands password authentication.

connect_timeout

Maximum wait for connection, in seconds (write as a decimal integer string). Zero or not
specified means wait indefinitely. It is not recommended to use a timeout of less than 2
seconds.

options

Adds command-line options to send to the server at run-time. For example, setting this to `-c
ggeo=off` sets the session’s value of the `ggeo` parameter to `off`. For a detailed discussion
of the available options, consult Chapter 18.

tty

Ignored (formerly, this specified where to send server debug output).

sslmode

This option determines whether or with what priority a SSL TCP/IP connection will be
negotiated with the server. There are six modes:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>disable</td>
<td>only try a non-SSL connection</td>
</tr>
<tr>
<td>allow</td>
<td>first try a non-SSL connection; if that fails, try an SSL connection</td>
</tr>
<tr>
<td>prefer (default)</td>
<td>first try an SSL connection; if that fails, try a non-SSL connection</td>
</tr>
<tr>
<td>require</td>
<td>only try an SSL connection. If a root CA file is present, verify the certificate in the same way as if <code>verify-ca</code> was specified</td>
</tr>
<tr>
<td>verify-ca</td>
<td>only try an SSL connection, and verify that the server certificate is issued by a trusted CA.</td>
</tr>
<tr>
<td>verify-full</td>
<td>only try an SSL connection, verify that the server certificate is issued by a trusted CA and that the server hostname matches that in the certificate.</td>
</tr>
</tbody>
</table>

See Section 30.17 for a detailed description of how these options work.

`sslmode` is ignored for Unix domain socket communication. If PostgreSQL is compiled
without SSL support, using option `require` will cause an error, while options `allow` and
`prefer` will be accepted but `libpq` will not actually attempt an SSL connection.

requiressl

This option is deprecated in favor of the `sslmode` setting.

If set to 1, an SSL connection to the server is required (this is equivalent to `sslmode
require`). `libpq` will then refuse to connect if the server does not accept an SSL connec-
tion. If set to 0 (default), `libpq` will negotiate the connection type with the server (equivalent
to `sslmode prefer`). This option is only available if PostgreSQL is compiled with SSL
support.
sslcert
This parameter specifies the file name of the client SSL certificate.

sslkey
This parameter specifies the location for the secret key used for the client certificate. It can either specify a filename that will be used instead of the default 
"~/postgresql/postgresql.key", or can specify an external engine (engines are OpenSSL loadable modules). The external engine specification should consist of a colon-separated engine name and an engine-specific key identifier.

sslrootcert
This parameter specifies the file name of the root SSL certificate.

sslcrl
This parameter specifies the file name of the SSL certificate revocation list (CRL).

krbsrvname
Kerberos service name to use when authenticating with Kerberos 5 or GSSAPI. This must match the service name specified in the server configuration for Kerberos authentication to succeed. (See also Section 19.3.5 and Section 19.3.3.)

gsslib
GSS library to use for GSSAPI authentication. Only used on Windows. Set to gssapi to force libpq to use the GSSAPI library for authentication instead of the default SSPI.

service
Service name to use for additional parameters. It specifies a service name in pg_service.conf that holds additional connection parameters. This allows applications to specify only a service name so connection parameters can be centrally maintained. See Section 30.15.

If any parameter is unspecified, then the corresponding environment variable (see Section 30.13) is checked. If the environment variable is not set either, then the indicated built-in defaults are used.

PQsetdbLogin
Makes a new connection to the database server.

PGconn *PQsetdbLogin(const char *pghost,
const char *pgport,
const char *pgoptions,
const char *pgtty,
const char *dbName,
const char *login,
const char *pwd);

This is the predecessor of PQconnectdb with a fixed set of parameters. It has the same functionality except that the missing parameters will always take on default values. Write NULL or an empty string for any one of the fixed parameters that is to be defaulted.

If the dbName contains an = sign, it is taken as a conninfo string in exactly the same way as if it had been passed to PQconnectdb, and the remaining parameters are then applied as above.

PQsetdb
Makes a new connection to the database server.

PGconn *PQsetdb(char *pghost,
This is a macro that calls PQsetdbLogin with null pointers for the *login* and *pwd* parameters. It is provided for backward compatibility with very old programs.

**PQconnectStart**

Make a connection to the database server in a nonblocking manner.

```
PGconn *PQconnectStart(const char *conninfo);
```

**PQconnectPoll**

These two functions are used to open a connection to a database server such that your application’s thread of execution is not blocked on remote I/O whilst doing so. The point of this approach is that the waits for I/O to complete can occur in the application’s main loop, rather than down inside PQconnectdb, and so the application can manage this operation in parallel with other activities.

The database connection is made using the parameters taken from the string *conninfo*, passed to PQconnectStart. This string is in the same format as described above for PQconnectdb. Neither PQconnectStart nor PQconnectPoll will block, so long as a number of restrictions are met:

- The *hostaddr* and *host* parameters are used appropriately to ensure that name and reverse name queries are not made. See the documentation of these parameters under PQconnectdb above for details.
- If you call PQtrace, ensure that the stream object into which you trace will not block.
- You ensure that the socket is in the appropriate state before calling PQconnectPoll, as described below.

To begin a nonblocking connection request, call `conn = PQconnectStart("connection_info_string")`. If `conn` is null, then libpq has been unable to allocate a new PGconn structure. Otherwise, a valid PGconn pointer is returned (though not yet representing a valid connection to the database). On return from PQconnectStart, call `status = PQstatus(conn)`. If `status` equals CONNECTION_BAD, PQconnectStart has failed.

If PQconnectStart succeeds, the next stage is to poll libpq so that it can proceed with the connection sequence. Use PQsocket(conn) to obtain the descriptor of the socket underlying the database connection. Loop thus: If PQconnectPoll(conn) last returned PGRES_POLLING_READING, wait until the socket is ready to read (as indicated by select(), poll(), or similar system function). Then call PQconnectPoll(conn) again. Conversely, if PQconnectPoll(conn) last returned PGRES_POLLING_WRITING, wait until the socket is ready to write, then call PQconnectPoll(conn) again. If you have yet to call PQconnectPoll, i.e., just after the call to PQconnectStart, behave as if it last returned PGRES_POLLING_WRITING. Continue this loop until PQconnectPoll(conn) returns PGRES_POLLING_FAILED, indicating the connection procedure has failed, or PGRES POLLING_OK, indicating the connection has been successfully made.
At any time during connection, the status of the connection can be checked by calling PQstatus. If this gives CONNECTION_BAD, then the connection procedure has failed; if it gives CONNECTION_OK, then the connection is ready. Both of these states are equally detectable from the return value of PQconnectPoll, described above. Other states might also occur during (and only during) an asynchronous connection procedure. These indicate the current stage of the connection procedure and might be useful to provide feedback to the user for example. These statuses are:

CONNECTION_STARTED
   Waiting for connection to be made.
CONNECTION_MADE
   Connection OK; waiting to send.
CONNECTION_AWAITING_RESPONSE
   Waiting for a response from the server.
CONNECTION_AUTH_OK
   Received authentication; waiting for backend start-up to finish.
CONNECTION_SSL_STARTUP
   Negotiating SSL encryption.
CONNECTION_SETENV
   Negotiating environment-driven parameter settings.

Note that, although these constants will remain (in order to maintain compatibility), an application should never rely upon these occurring in a particular order, or at all, or on the status always being one of these documented values. An application might do something like this:

```c
switch(PQstatus(conn))
{
    case CONNECTION_STARTED:
        feedback = "Connecting...");
        break;
    case CONNECTION_MADE:
        feedback = "Connected to server...");
        break;
    .
    .
    default:
        feedback = "Connecting...");
}
```

The connect_timeout connection parameter is ignored when using PQconnectPoll; it is the application’s responsibility to decide whether an excessive amount of time has elapsed. Otherwise, PQconnectStart followed by a PQconnectPoll loop is equivalent to PQconnectdb.

Note that if PQconnectStart returns a non-null pointer, you must call PQfinish when you are finished with it, in order to dispose of the structure and any associated memory blocks. This must be done even if the connection attempt fails or is abandoned.
PQconndefaults

Returns the default connection options.

PQconninfoOption *PQconndefaults(void);

typedef struct {
    char *keyword;  /* The keyword of the option */
    char *envvar;  /* Fallback environment variable name */
    char *compiled;  /* Fallback compiled in default value */
    char *val;  /* Option’s current value, or NULL */
    char *label;  /* Label for field in connect dialog */
    char *dispchar;  /* Indicates how to display this field in a connect dialog. Values are:
                     
                      "" Display entered value as is
                      "*" Password field - hide value
                      "D" Debug option - don’t show by default */
    int dispsize;  /* Field size in characters for dialog */
} PQconninfoOption;

Returns a connection options array. This can be used to determine all possible PQconnectdb options and their current default values. The return value points to an array of PQconninfoOption structures, which ends with an entry having a null keyword pointer. The null pointer is returned if memory could not be allocated. Note that the current default values (val fields) will depend on environment variables and other context. Callers must treat the connection options data as read-only.

After processing the options array, free it by passing it to PQconninfoFree. If this is not done, a small amount of memory is leaked for each call to PQconndefaults.

PQconninfoParse

Returns parsed connection options from the provided connection string.

PQconninfoOption *PQconninfoParse(const char *conninfo, char **errmsg);

Parses a connection string and returns the resulting options as an array; or returns NULL if there is a problem with the connection string. This can be used to determine the PQconnectdb options in the provided connection string. The return value points to an array of PQconninfoOption structures, which ends with an entry having a null keyword pointer.

Note that only options explicitly specified in the string will have values set in the result array; no defaults are inserted.

If errmsg is not NULL, then *errmsg is set to NULL on success, else to a malloc’d error string explaining the problem. (It is also possible for *errmsg to be set to NULL even when NULL is returned; this indicates an out-of-memory situation.)

After processing the options array, free it by passing it to PQconninfoFree. If this is not done, some memory is leaked for each call to PQconninfoParse. Conversely, if an error occurs and errmsg is not NULL, be sure to free the error string using PQfreemem.

PQfinish

Closes the connection to the server. Also frees memory used by the PGconn object.

void PQfinish(PGconn *conn);

Note that even if the server connection attempt fails (as indicated by PQstatus), the application should call PQfinish to free the memory used by the PGconn object. The PGconn pointer must not be used again after PQfinish has been called.
Chapter 30. libpq - C Library

PQreset

Resets the communication channel to the server.

    void PQreset(PGconn *conn);

This function will close the connection to the server and attempt to reestablish a new connection
to the same server, using all the same parameters previously used. This might be useful for error
recovery if a working connection is lost.

PQresetStart

PQresetPoll

Reset the communication channel to the server, in a nonblocking manner.

    int PQresetStart(PGconn *conn);

    PostgresPollingStatusType PQresetPoll(PGconn *conn);

These functions will close the connection to the server and attempt to reestablish a new connection
to the same server, using all the same parameters previously used. This can be useful for error
recovery if a working connection is lost. They differ from PQreset (above) in that they act
in a nonblocking manner. These functions suffer from the same restrictions as PQconnectStart
and PQconnectPoll.

To initiate a connection reset, call PQresetStart. If it returns 0, the reset has failed. If it returns
1, poll the reset using PQresetPoll in exactly the same way as you would create the connection
using PQconnectPoll.

30.2. Connection Status Functions

These functions can be used to interrogate the status of an existing database connection object.

Tip: libpq application programmers should be careful to maintain the PGconn abstraction. Use
the accessor functions described below to get at the contents of PGconn. Reference to internal
PGconn fields using libpq-int.h is not recommended because they are subject to change in the
future.

The following functions return parameter values established at connection. These values are fixed for
the life of the PGconn object.

PQdb

Returns the database name of the connection.

    char *PQdb(const PGconn *conn);

PQuser

Returns the user name of the connection.

    char *PQuser(const PGconn *conn);
Chapter 30. libpq - C Library

PQpass
Returns the password of the connection.
char *PQpass(const PGconn *conn);

PQhost
Returns the server host name of the connection.
char *PQhost(const PGconn *conn);

PQport
Returns the port of the connection.
char *PQport(const PGconn *conn);

PQtty
Returns the debug TTY of the connection. (This is obsolete, since the server no longer pays attention to the TTY setting, but the function remains for backwards compatibility.)
char *PQtty(const PGconn *conn);

PQoptions
Returns the command-line options passed in the connection request.
char *PQoptions(const PGconn *conn);

The following functions return status data that can change as operations are executed on the PGconn object.

PQstatus
Returns the status of the connection.
ConnStatusType PQstatus(const PGconn *conn);

The status can be one of a number of values. However, only two of these are seen outside of an asynchronous connection procedure: CONNECTION_OK and CONNECTION_BAD. A good connection to the database has the status CONNECTION_OK. A failed connection attempt is signaled by status CONNECTION_BAD. Ordinarily, an OK status will remain so until PQfinish, but a communications failure might result in the status changing to CONNECTION_BAD prematurely. In that case the application could try to recover by calling PQreset.

See the entry for PQconnectStart and PQconnectPoll with regards to other status codes that might be seen.

PQtransactionStatus
Returns the current in-transaction status of the server.
PGTransactionStatusType PQtransactionStatus(const PGconn *conn);

The status can be PQTRANS_IDLE (currently idle), PQTRANS_ACTIVE (a command is in progress), PQTRANS_INTRANS (idle, in a valid transaction block), or PQTRANS_INERROR (idle, in a failed transaction block). PQTRANS_UNKNOWN is reported if the connection is bad.
PQTRANS_ACTIVE is reported only when a query has been sent to the server and not yet completed.

**Caution**
PQtransactionStatus will give incorrect results when using a PostgreSQL 7.3 server that has the parameter autocommit set to off. The server-side autocommit feature has been deprecated and does not exist in later server versions.

PQparameterStatus

Looks up a current parameter setting of the server.

```
const char *PQparameterStatus(const PGconn *conn, const char *paramName);
```

Certain parameter values are reported by the server automatically at connection startup or whenever their values change. PQparameterStatus can be used to interrogate these settings. It returns the current value of a parameter if known, or NULL if the parameter is not known.

Parameters reported as of the current release include server_version, server_encoding, client_encoding, is_superuser, session_authorization, DateStyle, IntervalStyle, TimeZone, integer_datetimes, and standard_conforming_strings. (server_encoding, TimeZone, and integer_datetimes were not reported by releases before 8.0; standard_conforming_strings was not reported by releases before 8.1; IntervalStyle was not reported by releases before 8.4.) Note that server_version, server_encoding, and integer_datetimes cannot change after startup.

Pre-3.0-protocol servers do not report parameter settings, but libpq includes logic to obtain values for server_version and client_encoding anyway. Applications are encouraged to use PQparameterStatus rather than ad hoc code to determine these values. (Beware however that on a pre-3.0 connection, changing client_encoding via SET after connection startup will not be reflected by PQparameterStatus.) For server_version, see also PQserverVersion, which returns the information in a numeric form that is much easier to compare against.

If no value for standard_conforming_strings is reported, applications can assume it is off, that is, backslashes are treated as escapes in string literals. Also, the presence of this parameter can be taken as an indication that the escape string syntax (E'...'') is accepted.

Although the returned pointer is declared const, it in fact points to mutable storage associated with the PGconn structure. It is unwise to assume the pointer will remain valid across queries.

PQprotocolVersion

Interrogates the frontend/backend protocol being used.

```
int PQprotocolVersion(const PGconn *conn);
```

Applications might wish to use this to determine whether certain features are supported. Currently, the possible values are 2 (2.0 protocol), 3 (3.0 protocol), or zero (connection bad). This will not change after connection startup is complete, but it could theoretically change during a connection reset. The 3.0 protocol will normally be used when communicating with PostgreSQL 7.4 or later servers; pre-7.4 servers support only protocol 2.0. (Protocol 1.0 is obsolete and not supported by libpq.)
Chapter 30. libpq - C Library

PQserverVersion

Returns an integer representing the backend version.

```c
int PQserverVersion(const PGconn *conn);
```

Applications might use this to determine the version of the database server they are connected to. The number is formed by converting the major, minor, and revision numbers into two-decimal-digit numbers and appending them together. For example, version 8.1.5 will be returned as 80105, and version 8.2 will be returned as 80200 (leading zeroes are not shown). Zero is returned if the connection is bad.

PQerrorMessage

Returns the error message most recently generated by an operation on the connection.

```c
char *PQerrorMessage(const PGconn *conn);
```

Nearly all libpq functions will set a message for PQerrorMessage if they fail. Note that by libpq convention, a nonempty PQerrorMessage result can be multiple lines, and will include a trailing newline. The caller should not free the result directly. It will be freed when the associated PGconn handle is passed to PQfinish. The result string should not be expected to remain the same across operations on the PGconn structure.

PQsocket

Obtains the file descriptor number of the connection socket to the server. A valid descriptor will be greater than or equal to 0; a result of -1 indicates that no server connection is currently open. (This will not change during normal operation, but could change during connection setup or reset.)

```c
int PQsocket(const PGconn *conn);
```

PQbackendPID

Returns the process ID (PID) of the backend server process handling this connection.

```c
int PQbackendPID(const PGconn *conn);
```

The backend PID is useful for debugging purposes and for comparison to NOTIFY messages (which include the PID of the notifying backend process). Note that the PID belongs to a process executing on the database server host, not the local host!

PQconnectionNeedsPassword

Returns true (1) if the connection authentication method required a password, but none was available. Returns false (0) if not.

```c
int PQconnectionNeedsPassword(const PGconn *conn);
```

This function can be applied after a failed connection attempt to decide whether to prompt the user for a password.

PQconnectionUsedPassword

Returns true (1) if the connection authentication method used a password. Returns false (0) if not.

```c
int PQconnectionUsedPassword(const PGconn *conn);
```
This function can be applied after either a failed or successful connection attempt to detect whether the server demanded a password.

**PQgetssl**

Returns the SSL structure used in the connection, or null if SSL is not in use.

```c
SSL *PQgetssl(const PGconn *conn);
```

This structure can be used to verify encryption levels, check server certificates, and more. Refer to the OpenSSL documentation for information about this structure.

You must define `USE_SSL` in order to get the correct prototype for this function. Doing this will also automatically include `ssl.h` from OpenSSL.

## 30.3. Command Execution Functions

Once a connection to a database server has been successfully established, the functions described here are used to perform SQL queries and commands.

### 30.3.1. Main Functions

**PQexec**

Submits a command to the server and waits for the result.

```c
PGresult *PQexec(PGconn *conn, const char *command);
```

Returns a `PGresult` pointer or possibly a null pointer. A non-null pointer will generally be returned except in out-of-memory conditions or serious errors such as inability to send the command to the server. If a null pointer is returned, it should be treated like a `PGRES_FATAL_ERROR` result. Use `PQerrorMessage` to get more information about such errors.

It is allowed to include multiple SQL commands (separated by semicolons) in the command string. Multiple queries sent in a single `PQexec` call are processed in a single transaction, unless there are explicit `BEGIN`/`COMMIT` commands included in the query string to divide it into multiple transactions. Note however that the returned `PGresult` structure describes only the result of the last command executed from the string. Should one of the commands fail, processing of the string stops with it and the returned `PGresult` describes the error condition.

**PQexecParams**

Submits a command to the server and waits for the result, with the ability to pass parameters separately from the SQL command text.

```c
PGresult *PQexecParams(PGconn *conn,
                        const char *command,
                        int nParams,
                        const Oid *paramTypes,
                        const char * const *paramValues,
                        const int *paramLengths,
                        const int *paramFormats,
                        int resultFormat);
```
PQexecParams is like PQexec, but offers additional functionality: parameter values can be specified separately from the command string proper, and query results can be requested in either text or binary format. PQexecParams is supported only in protocol 3.0 and later connections; it will fail when using protocol 2.0.

The function arguments are:

conn

The connection object to send the command through.

command

The SQL command string to be executed. If parameters are used, they are referred to in the command string as $1, $2, etc.

nParams

The number of parameters supplied; it is the length of the arrays paramTypes[], paramValues[], paramLengths[], and paramFormats[]. (The array pointers can be NULL when nParams is zero.)

paramTypes[]

Specifies, by OID, the data types to be assigned to the parameter symbols. If paramTypes is NULL, or any particular element in the array is zero, the server infers a data type for the parameter symbol in the same way it would do for an untyped literal string.

paramValues[]

Specifies the actual values of the parameters. A null pointer in this array means the corresponding parameter is null; otherwise the pointer points to a zero-terminated text string (for text format) or binary data in the format expected by the server (for binary format).

paramLengths[]

Specifies the actual data lengths of binary-format parameters. It is ignored for null parameters and text-format parameters. The array pointer can be null when there are no binary parameters.

paramFormats[]

Specifies whether parameters are text (put a zero in the array entry for the corresponding parameter) or binary (put a one in the array entry for the corresponding parameter). If the array pointer is null then all parameters are presumed to be text strings.

Values passed in binary format require knowledge of the internal representation expected by the backend. For example, integers must be passed in network byte order. Passing numeric values requires knowledge of the server storage format, as implemented in src/backend/utils/adt/numeric.c::numeric_send() and src/backend/utils/adt/numeric.c::numeric_recv().

resultFormat

Specify zero to obtain results in text format, or one to obtain results in binary format. (There is not currently a provision to obtain different result columns in different formats, although that is possible in the underlying protocol.)

The primary advantage of PQexecParams over PQexec is that parameter values can be separated from the command string, thus avoiding the need for tedious and error-prone quoting and escaping.
Unlike PQexec, PQexecParams allows at most one SQL command in the given string. (There can be semicolons in it, but not more than one nonempty command.) This is a limitation of the underlying protocol, but has some usefulness as an extra defense against SQL-injection attacks.

**Tip:** Specifying parameter types via OIDs is tedious, particularly if you prefer not to hard-wire particular OID values into your program. However, you can avoid doing so even in cases where the server by itself cannot determine the type of the parameter, or chooses a different type than you want. In the SQL command text, attach an explicit cast to the parameter symbol to show what data type you will send. For example:

```
SELECT * FROM mytable WHERE x = $1::bigint;
```

This forces parameter $1 to be treated as bigint, whereas by default it would be assigned the same type as x. Forcing the parameter type decision, either this way or by specifying a numeric type OID, is strongly recommended when sending parameter values in binary format, because binary format has less redundancy than text format and so there is less chance that the server will detect a type mismatch mistake for you.

PQprepare

Submits a request to create a prepared statement with the given parameters, and waits for completion.

```
PGresult *PQprepare(PGconn *conn,
    const char *stmtName,
    const char *query,
    int nParams,
    const Oid *paramTypes);
```

PQprepare creates a prepared statement for later execution with PQexecPrepared. This feature allows commands that will be used repeatedly to be parsed and planned just once, rather than each time they are executed. PQprepare is supported only in protocol 3.0 and later connections; it will fail when using protocol 2.0.

The function creates a prepared statement named stmtName from the query string, which must contain a single SQL command. stmtName can be "" to create an unnamed statement, in which case any pre-existing unnamed statement is automatically replaced; otherwise it is an error if the statement name is already defined in the current session. If any parameters are used, they are referred to in the query as $1, $2, etc. nParams is the number of parameters for which types are pre-specified in the array paramTypes[]. (The array pointer can be NULL when nParams is zero.) paramTypes[] specifies, by OID, the data types to be assigned to the parameter symbols. If paramTypes is NULL, or any particular element in the array is zero, the server assigns a data type to the parameter symbol in the same way it would do for an untyped literal string. Also, the query can use parameter symbols with numbers higher than nParams; data types will be inferred for these symbols as well. (See PQdescribePrepared for a means to find out what data types were inferred.)

As with PQexec, the result is normally a PGresult object whose contents indicate server-side success or failure. A null result indicates out-of-memory or inability to send the command at all. Use PQerrorMessage to get more information about such errors.

Prepared statements for use with PQexecPrepared can also be created by executing SQL PREPARE statements. Also, although there is no libpq function for deleting a prepared statement, the SQL DEALLOCATE statement can be used for that purpose.
PQexecPrepared

Sends a request to execute a prepared statement with given parameters, and waits for the result.

```c
PGresult *PQexecPrepared(PGconn *conn,
    const char *stmtName,
    int nParams,
    const char * const *paramValues,
    const int *paramLengths,
    const int *paramFormats,
    int resultFormat);
```

PQexecPrepared is like PQexecParams, but the command to be executed is specified by naming a previously-prepared statement, instead of giving a query string. This feature allows commands that will be used repeatedly to be parsed and planned just once, rather than each time they are executed. The statement must have been prepared previously in the current session. PQexecPrepared is supported only in protocol 3.0 and later connections; it will fail when using protocol 2.0.

The parameters are identical to PQexecParams, except that the name of a prepared statement is given instead of a query string, and the paramTypes[] parameter is not present (it is not needed since the prepared statement’s parameter types were determined when it was created).

PQdescribePrepared

Submits a request to obtain information about the specified prepared statement, and waits for completion.

```c
PGresult *PQdescribePrepared(PGconn *conn, const char *stmtName);
```

PQdescribePrepared allows an application to obtain information about a previously prepared statement. PQdescribePrepared is supported only in protocol 3.0 and later connections; it will fail when using protocol 2.0.

stmtName can be "" or NULL to reference the unnamed statement, otherwise it must be the name of an existing prepared statement. On success, a PGresult with status PGRES_COMMAND_OK is returned. The functions PQnparams and PQparamtype can be applied to this PGresult to obtain information about the parameters of the prepared statement, and the functions PQnfields, PQfname, PQftype, etc provide information about the result columns (if any) of the statement.

PQdescribePortal

Submits a request to obtain information about the specified portal, and waits for completion.

```c
PGresult *PQdescribePortal(PGconn *conn, const char *portalName);
```

PQdescribePortal allows an application to obtain information about a previously created portal. (libpq does not provide any direct access to portals, but you can use this function to inspect the properties of a cursor created with a DECLARE CURSOR SQL command.) PQdescribePortal is supported only in protocol 3.0 and later connections; it will fail when using protocol 2.0.

portalName can be "" or NULL to reference the unnamed portal, otherwise it must be the name of an existing portal. On success, a PGresult with status PGRES_COMMAND_OK is returned. The functions PQnfields, PQfname, PQftype, etc can be applied to the PGresult to obtain information about the result columns (if any) of the portal.

The PGresult structure encapsulates the result returned by the server. libpq application programmers should be careful to maintain the PGresult abstraction. Use the accessor functions below to get at
the contents of PGresult. Avoid directly referencing the fields of the PGresult structure because they are subject to change in the future.

**PQresultStatus**

Returns the result status of the command.

\[ \text{ExecStatusType PQresultStatus(const PGresult *res);} \]

PQresultStatus can return one of the following values:

- **PGRES_EMPTY_QUERY**: The string sent to the server was empty.
- **PGRES_COMMAND_OK**: Successful completion of a command returning no data.
- **PGRES_TUPLES_OK**: Successful completion of a command returning data (such as a SELECT or SHOW).
- **PGRES_COPY_OUT**: Copy Out (from server) data transfer started.
- **PGRES_COPY_IN**: Copy In (to server) data transfer started.
- **PGRES_BAD_RESPONSE**: The server’s response was not understood.
- **PGRES_NONFATAL_ERROR**: A nonfatal error (a notice or warning) occurred.
- **PGRES_FATAL_ERROR**: A fatal error occurred.

If the result status is **PGRES_TUPLES_OK**, then the functions described below can be used to retrieve the rows returned by the query. Note that a SELECT command that happens to retrieve zero rows still shows **PGRES_TUPLES_OK**. **PGRES_COMMAND_OK** is for commands that can never return rows (INSERT, UPDATE, etc.). A response of **PGRES_EMPTY_QUERY** might indicate a bug in the client software.

A result of status **PGRES_NONFATAL_ERROR** will never be returned directly by PQexec or other query execution functions; results of this kind are instead passed to the notice processor (see Section 30.11).

**PQresStatus**

Converts the enumerated type returned by PQresultStatus into a string constant describing the status code. The caller should not free the result.

\[ \text{char *PQresStatus(ExecStatusType status);} \]

**PQresultErrorMessage**

Returns the error message associated with the command, or an empty string if there was no error.

\[ \text{char *PQresultErrorMessage(const PGresult *res);} \]
If there was an error, the returned string will include a trailing newline. The caller should not free the result directly. It will be freed when the associated PGresult handle is passed to PQclear. Immediately following a PQexec or PQgetResult call, PQerrorMessage (on the connection) will return the same string as PQresultErrorMessage (on the result). However, a PGresult will retain its error message until destroyed, whereas the connection’s error message will change when subsequent operations are done. Use PQresultErrorMessage when you want to know the status associated with a particular PGresult; use PQerrorMessage when you want to know the status from the latest operation on the connection.

PQresultErrorField
Returns an individual field of an error report.

char *PQresultErrorField(const PGresult *res, int fieldcode);

fieldcode is an error field identifier; see the symbols listed below. NULL is returned if the PGresult is not an error or warning result, or does not include the specified field. Field values will normally not include a trailing newline. The caller should not free the result directly. It will be freed when the associated PGresult handle is passed to PQclear.

The following field codes are available:

PG_DIAG_SEVERITY
The severity; the field contents are ERROR, FATAL, or PANIC (in an error message), or WARNING, NOTICE, DEBUG, INFO, or LOG (in a notice message), or a localized translation of one of these. Always present.

PG_DIAG_SQLSTATE
The SQLSTATE code for the error. The SQLSTATE code identifies the type of error that has occurred; it can be used by front-end applications to perform specific operations (such as error handling) in response to a particular database error. For a list of the possible SQLSTATE codes, see Appendix A. This field is not localizable, and is always present.

PG_DIAG_MESSAGE_PRIMARY
The primary human-readable error message (typically one line). Always present.

PG_DIAG_MESSAGE_DETAIL
Detail: an optional secondary error message carrying more detail about the problem. Might run to multiple lines.

PG_DIAG_MESSAGE_HINT
Hint: an optional suggestion what to do about the problem. This is intended to differ from detail in that it offers advice (potentially inappropriate) rather than hard facts. Might run to multiple lines.

PG_DIAG_STATEMENT_POSITION
A string containing a decimal integer indicating an error cursor position as an index into the original statement string. The first character has index 1, and positions are measured in characters not bytes.

PG_DIAG_INTERNAL_POSITION
This is defined the same as the PG_DIAG_STATEMENT_POSITION field, but it is used when the cursor position refers to an internally generated command rather than the one submitted by the client. The PG_DIAG_INTERNAL_QUERY field will always appear when this field appears.
Chapter 30. libpq - C Library

30.3.2. Retrieving Query Result Information

These functions are used to extract information from a PGresult object that represents a successful query result (that is, one that has status PGRES_TUPLES_OK). They can also be used to extract information from a successful Describe operation: a Describe’s result has all the same column information that actual execution of the query would provide, but it has zero rows. For objects with other status values, these functions will act as though the result has zero rows and zero columns.
Chapter 30. libpq - C Library

PQntuples

Returns the number of rows (tuples) in the query result. Because it returns an integer result, large result sets might overflow the return value on 32-bit operating systems.

```c
int PQntuples(const PGresult *res);
```

PQnfields

Returns the number of columns (fields) in each row of the query result.

```c
int PQnfields(const PGresult *res);
```

PQfname

Returns the column name associated with the given column number. Column numbers start at 0. The caller should not free the result directly. It will be freed when the associated PGresult handle is passed to PQclear.

```c
char *PQfname(const PGresult *res,
               int column_number);
```

NULL is returned if the column number is out of range.

PQfnumber

Returns the column number associated with the given column name.

```c
int PQfnumber(const PGresult *res,
               const char *column_name);
```

-1 is returned if the given name does not match any column.

The given name is treated like an identifier in an SQL command, that is, it is downcased unless double-quoted. For example, given a query result generated from the SQL command:

```
SELECT 1 AS FOO, 2 AS "BAR";
```

we would have the results:

```c
PQfname(res, 0)  foo
PQfname(res, 1)  BAR
PQfnumber(res, "FOO")  0
PQfnumber(res, "foo")  0
PQfnumber(res, "BAR")  -1
PQfnumber(res, "\"BAR\"")  1
```

PQftable

Returns the OID of the table from which the given column was fetched. Column numbers start at 0.

```c
Oid PQftable(const PGresult *res,
              int column_number);
```

InvalidOid is returned if the column number is out of range, or if the specified column is not a simple reference to a table column, or when using pre-3.0 protocol. You can query the system table pg_class to determine exactly which table is referenced.

The type Oid and the constant InvalidOid will be defined when you include the libpq header file. They will both be some integer type.
PQftablecol

Returns the column number (within its table) of the column making up the specified query result column. Query-result column numbers start at 0, but table columns have nonzero numbers.

```c
int PQftablecol(const PGresult *res,
                 int column_number);
```

Zero is returned if the column number is out of range, or if the specified column is not a simple reference to a table column, or when using pre-3.0 protocol.

PQfformat

Returns the format code indicating the format of the given column. Column numbers start at 0.

```c
int PQfformat(const PGresult *res,
              int column_number);
```

Format code zero indicates textual data representation, while format code one indicates binary representation. (Other codes are reserved for future definition.)

PQftype

Returns the data type associated with the given column number. The integer returned is the internal OID number of the type. Column numbers start at 0.

```c
Oid PQftype(const PGresult *res,
            int column_number);
```

You can query the system table `pg_type` to obtain the names and properties of the various data types. The OIDs of the built-in data types are defined in the file `src/include/catalog/pg_type.h` in the source tree.

PQfmod

Returns the type modifier of the column associated with the given column number. Column numbers start at 0.

```c
int PQfmod(const PGresult *res,
           int column_number);
```

The interpretation of modifier values is type-specific; they typically indicate precision or size limits. The value -1 is used to indicate “no information available”. Most data types do not use modifiers, in which case the value is always -1.

PQfsize

Returns the size in bytes of the column associated with the given column number. Column numbers start at 0.

```c
int PQfsize(const PGresult *res,
            int column_number);
```

PQfsize returns the space allocated for this column in a database row, in other words the size of the server’s internal representation of the data type. (Accordingly, it is not really very useful to clients.) A negative value indicates the data type is variable-length.

PQbinaryTuples

Returns 1 if the PGresult contains binary data and 0 if it contains text data.

```c
int PQbinaryTuples(const PGresult *res);
```
This function is deprecated (except for its use in connection with `COPY`), because it is possible for a single `PGresult` to contain text data in some columns and binary data in others. `PQfformat` is preferred. `PQbinaryTuples` returns 1 only if all columns of the result are binary (format 1).

**PQgetvalue**

Returns a single field value of one row of a `PGresult`. Row and column numbers start at 0. The caller should not free the result directly. It will be freed when the associated `PGresult` handle is passed to `PQclear`.

```c
char *PQgetvalue(const PGresult *res,
                  int row_number,
                  int column_number);
```

For data in text format, the value returned by `PQgetvalue` is a null-terminated character string representation of the field value. For data in binary format, the value is in the binary representation determined by the data type’s `typpsend` and `typreceive` functions. (The value is actually followed by a zero byte in this case too, but that is not ordinarily useful, since the value is likely to contain embedded nulls.)

An empty string is returned if the field value is null. See `PQgetisnull` to distinguish null values from empty-string values.

The pointer returned by `PQgetvalue` points to storage that is part of the `PGresult` structure. One should not modify the data it points to, and one must explicitly copy the data into other storage if it is to be used past the lifetime of the `PGresult` structure itself.

**PQgetisnull**

Tests a field for a null value. Row and column numbers start at 0.

```c
int PQgetisnull(const PGresult *res,
                int row_number,
                int column_number);
```

This function returns 1 if the field is null and 0 if it contains a non-null value. (Note that `PQgetvalue` will return an empty string, not a null pointer, for a null field.)

**PQgetlength**

Returns the actual length of a field value in bytes. Row and column numbers start at 0.

```c
int PQgetlength(const PGresult *res,
                int row_number,
                int column_number);
```

This is the actual data length for the particular data value, that is, the size of the object pointed to by `PQgetvalue`. For text data format this is the same as `strlen()`. For binary format this is essential information. Note that one should not rely on `PQfsize` to obtain the actual data length.

**PQnparams**

Returns the number of parameters of a prepared statement.

```c
int PQnparams(const PGresult *res);
```

This function is only useful when inspecting the result of `PQdescribePrepared`. For other types of queries it will return zero.
PQparamtype

Returns the data type of the indicated statement parameter. Parameter numbers start at 0.

Oid PQparamtype(const PGresult *res, int param_number);

This function is only useful when inspecting the result of PQdescribePrepared. For other types of queries it will return zero.

PQprint

Prints out all the rows and, optionally, the column names to the specified output stream.

void PQprint(FILE *fout, /* output stream */
             const PGresult *res,
             const PQprintOpt *po);

typedef struct {
    pqbool header; /* print output field headings and row count */
    pqbool align; /* fill align the fields */
    pqbool standard; /* old brain dead format */
    pqbool html3; /* output HTML tables */
    pqbool expanded; /* expand tables */
    pqbool pager; /* use pager for output if needed */
    char *fieldSep; /* field separator */
    char *tableOpt; /* attributes for HTML table element */
    char *caption; /* HTML table caption */
    char **fieldName; /* null-terminated array of replacement field names */
} PQprintOpt;

This function was formerly used by psql to print query results, but this is no longer the case. Note that it assumes all the data is in text format.

30.3.3. Retrieving Result Information for Other Commands

These functions are used to extract information from PGresult objects that are not SELECT results.

PQcmdStatus

Returns the command status tag from the SQL command that generated the PGresult.

char *PQcmdStatus(PGresult *res);

Commonly this is just the name of the command, but it might include additional data such as the number of rows processed. The caller should not free the result directly. It will be freed when the associated PGresult handle is passed to PQclear.

PQcmdTuples

Returns the number of rows affected by the SQL command.

char *PQcmdTuples(PGresult *res);

This function returns a string containing the number of rows affected by the SQL statement that generated the PGresult. This function can only be used following the execution of an INSERT, UPDATE, DELETE, MOVE, FETCH, or COPY statement, or an EXECUTE of a prepared query that contains an INSERT, UPDATE, or DELETE statement. If the command that generated the PGresult was anything else, PQcmdTuples returns an empty string. The caller should not
free the return value directly. It will be freed when the associated PGresult handle is passed to PQclear.

PQoidValue

Returns the OID of the inserted row, if the SQL command was an INSERT that inserted exactly one row into a table that has OIDs, or a EXECUTE of a prepared query containing a suitable INSERT statement. Otherwise, this function returns InvalidOid. This function will also return InvalidOid if the table affected by the INSERT statement does not contain OIDs.

Oid PQoidValue(const PGresult *res);

PQoidStatus

Returns a string with the OID of the inserted row, if the SQL command was an INSERT that inserted exactly one row, or a EXECUTE of a prepared statement consisting of a suitable INSERT. (The string will be 0 if the INSERT did not insert exactly one row, or if the target table does not have OIDs.) If the command was not an INSERT, returns an empty string.

char *PQoidStatus(const PGresult *res);

This function is deprecated in favor of PQoidValue. It is not thread-safe.

30.3.4. Escaping Strings for Inclusion in SQL Commands

PQescapeStringConn escapes a string for use within an SQL command. This is useful when inserting data values as literal constants in SQL commands. Certain characters (such as quotes and backslashes) must be escaped to prevent them from being interpreted specially by the SQL parser. PQescapeStringConn performs this operation.

Tip: It is especially important to do proper escaping when handling strings that were received from an untrustworthy source. Otherwise there is a security risk: you are vulnerable to “SQL injection” attacks wherein unwanted SQL commands are fed to your database.

Note that it is not necessary nor correct to do escaping when a data value is passed as a separate parameter in PQexecParams or its sibling routines.

```c
size_t PQescapeStringConn (PGconn *conn, char *to, const char *from, size_t length, int *error);
```

PQescapeStringConn writes an escaped version of the from string to the to buffer, escaping special characters so that they cannot cause any harm, and adding a terminating zero byte. The single quotes that must surround PostgreSQL string literals are not included in the result string: they should be provided in the SQL command that the result is inserted into. The parameter from points to the first character of the string that is to be escaped, and the length parameter gives the number of bytes in this string. A terminating zero byte is not required, and should not be counted in length. (If a terminating zero byte is found before length bytes are processed, PQescapeStringConn stops at the zero; the behavior is thus rather like strncpy.) to shall point to a buffer that is able to hold at least one more byte than twice the value of length, otherwise the behavior is undefined. Behavior is likewise undefined if the to and from strings overlap.
If the `error` parameter is not NULL, then `*error` is set to zero on success, nonzero on error. Presently the only possible error conditions involve invalid multibyte encoding in the source string. The output string is still generated on error, but it can be expected that the server will reject it as malformed. On error, a suitable message is stored in the `conn` object, whether or not `error` is NULL.

`PQescapeStringConn` returns the number of bytes written to `to`, not including the terminating zero byte.

```c
size_t PQescapeString (char *to, const char *from, size_t length);
```

`PQescapeString` is an older, deprecated version of `PQescapeStringConn`; the difference is that it does not take `conn` or `error` parameters. Because of this, it cannot adjust its behavior depending on the connection properties (such as character encoding) and therefore it might give the wrong results. Also, it has no way to report error conditions.

`PQescapeString` can be used safely in single-threaded client programs that work with only one PostgreSQL connection at a time (in this case it can find out what it needs to know “behind the scenes”). In other contexts it is a security hazard and should be avoided in favor of `PQescapeStringConn`.

### 30.3.5. Escaping Binary Strings for Inclusion in SQL Commands

`PQescapeByteaConn`

Escapes binary data for use within an SQL command with the type `bytea`. As with `PQescapeStringConn`, this is only used when inserting data directly into an SQL command string.

```c
unsigned char *PQescapeByteaConn(PGconn *conn, const unsigned char *from, size_t from_length, size_t *to_length);
```

Certain byte values must be escaped (but all byte values can be escaped) when used as part of a `bytea` literal in an SQL statement. In general, to escape a byte, it is converted into the three digit octal number equal to the octet value, and preceded by usually two backslashes. The single quote (’’) and backslash (\) characters have special alternative escape sequences. See Section 8.4 for more information. `PQescapeByteaConn` performs this operation, escaping only the minimally required bytes.

The `from` parameter points to the first byte of the string that is to be escaped, and the `from_length` parameter gives the number of bytes in this binary string. (A terminating zero byte is neither necessary nor counted.) The `to_length` parameter points to a variable that will hold the resultant escaped string length. This result string length includes the terminating zero byte of the result.

`PQescapeByteaConn` returns an escaped version of the `from` parameter binary string in memory allocated with `malloc()`. This memory must be freed using `PQfreemem()` when the result is no longer needed. The return string has all special characters replaced so that they can be properly processed by the PostgreSQL string literal parser, and the `bytea` input function. A ter-
minating zero byte is also added. The single quotes that must surround PostgreSQL string literals are not part of the result string.

On error, a NULL pointer is returned, and a suitable error message is stored in the conn object. Currently, the only possible error is insufficient memory for the result string.

PQescapeBytea

PQescapeBytea is an older, deprecated version of PQescapeByteaConn.

```c
unsigned char *PQescapeBytea(const unsigned char *from,
size_t from_length,
size_t *to_length);
```

The only difference from PQescapeByteaConn is that PQescapeBytea does not take a
PGconn parameter. Because of this, it cannot adjust its behavior depending on the connection properties (in particular, whether standard-conforming strings are enabled) and therefore it might give the wrong results. Also, it has no way to return an error message on failure.

PQescapeBytea can be used safely in single-threaded client programs that work with only one PostgreSQL connection at a time (in this case it can find out what it needs to know “behind the scenes”). In other contexts it is a security hazard and should be avoided in favor of PQescapeByteaConn.

PQunescapeBytea

Converts a string representation of binary data into binary data — the reverse of
PQescapeBytea. This is needed when retrieving bytea data in text format, but not when retrieving it in binary format.

```c
unsigned char *PQunescapeBytea(const unsigned char *from, size_t *to_length);
```

The from parameter points to a string such as might be returned by PQgetValue when applied to a bytea column. PQunescapeBytea converts this string representation into its binary representation. It returns a pointer to a buffer allocated with malloc(), or null on error, and puts the size of the buffer in to_length. The result must be freed using PQfreemem when it is no longer needed.

This conversion is not exactly the inverse of PQescapeBytea, because the string is not expected to be “escaped” when received from PQgetValue. In particular this means there is no need for string quoting considerations, and so no need for a PGconn parameter.

### 30.4. Asynchronous Command Processing

The PQexec function is adequate for submitting commands in normal, synchronous applications. It has a couple of deficiencies, however, that can be of importance to some users:

- PQexec waits for the command to be completed. The application might have other work to do (such as maintaining a user interface), in which case it won’t want to block waiting for the response.
- Since the execution of the client application is suspended while it waits for the result, it is hard for the application to decide that it would like to try to cancel the ongoing command. (It can be done from a signal handler, but not otherwise.)
PQexec can return only one PGresult structure. If the submitted command string contains multiple SQL commands, all but the last PGresult are discarded by PQexec.

Applications that do not like these limitations can instead use the underlying functions that PQexec is built from: PQsendQuery and PQgetResult. There are also PQsendQueryParams, PQsendPrepare, PQsendQueryPrepared, PQsendDescribePrepared, and PQsendDescribePortal, which can be used with PQgetResult to duplicate the functionality of PQexecParams, PQprepare, PQexecPrepared, PQdescribePrepared, and PQdescribePortal respectively.

PQsendQuery

Submits a command to the server without waiting for the result(s). 1 is returned if the command was successfully dispatched and 0 if not (in which case, use PQerrorMessage to get more information about the failure).

```c
int PQsendQuery(PGconn *conn, const char *command);
```

After successfully calling PQsendQuery, call PQgetResult one or more times to obtain the results. PQsendQuery cannot be called again (on the same connection) until PQgetResult has returned a null pointer, indicating that the command is done.

PQsendQueryParams

Submits a command and separate parameters to the server without waiting for the result(s).

```c
int PQsendQueryParams(PGconn *conn, const char *command, const char *command);
```

This is equivalent to PQsendQuery except that query parameters can be specified separately from the query string. The function’s parameters are handled identically to PQexecParams. Like PQexecParams, it will not work on 2.0-protocol connections, and it allows only one command in the query string.

PQsendPrepare

Sends a request to create a prepared statement with the given parameters, without waiting for completion.

```c
int PQsendPrepare(PGconn *conn, const char *stmtName, const char *query, int nParams, const Oid *paramTypes);
```

This is an asynchronous version of PQprepare: it returns 1 if it was able to dispatch the request, and 0 if not. After a successful call, call PQgetResult to determine whether the server successfully created the prepared statement. The function’s parameters are handled identically to PQprepare. Like PQprepare, it will not work on 2.0-protocol connections.
Chapter 30. libpq - C Library

PQsendQueryPrepared

Sends a request to execute a prepared statement with given parameters, without waiting for the result(s).

```c
int PQsendQueryPrepared(PGconn *conn,
    const char *stmtName,
    int nParams,
    const char * const *paramValues,
    const int *paramLengths,
    const int *paramFormats,
    int resultFormat);
```

This is similar to PQsendQueryParams, but the command to be executed is specified by naming a previously-prepared statement, instead of giving a query string. The function’s parameters are handled identically to PQexecPrepared. Like PQexecPrepared, it will not work on 2.0-protocol connections.

PQsendDescribePrepared

Submits a request to obtain information about the specified prepared statement, without waiting for completion.

```c
int PQsendDescribePrepared(PGconn *conn, const char *stmtName);
```

This is an asynchronous version of PQdescribePrepared: it returns 1 if it was able to dispatch the request, and 0 if not. After a successful call, call PQgetResult to obtain the results. The function’s parameters are handled identically to PQdescribePrepared. Like PQdescribePrepared, it will not work on 2.0-protocol connections.

PQsendDescribePortal

Submits a request to obtain information about the specified portal, without waiting for completion.

```c
int PQsendDescribePortal(PGconn *conn, const char *portalName);
```

This is an asynchronous version of PQdescribePortal: it returns 1 if it was able to dispatch the request, and 0 if not. After a successful call, call PQgetResult to obtain the results. The function’s parameters are handled identically to PQdescribePortal. Like PQdescribePortal, it will not work on 2.0-protocol connections.

PQgetResult

Waits for the next result from a prior PQsendQuery, PQsendQueryParams, PQsendPrepare, or PQsendQueryPrepared call, and returns it. A null pointer is returned when the command is complete and there will be no more results.

```c
PGresult *PQgetResult(PGconn *conn);
```

PQgetResult must be called repeatedly until it returns a null pointer, indicating that the command is done. (If called when no command is active, PQgetResult will just return a null pointer at once.) Each non-null result from PQgetResult should be processed using the same PGresult accessor functions previously described. Don’t forget to free each result object with PQclear when done with it. Note that PQgetResult will block only if a command is active and the necessary response data has not yet been read by PQconsumeInput.

Using PQsendQuery and PQgetResult solves one of PQexec’s problems: If a command string contains multiple SQL commands, the results of those commands can be obtained individually. (This
allows a simple form of overlapped processing, by the way: the client can be handling the results of one command while the server is still working on later queries in the same command string.) However, calling PQgetResult will still cause the client to block until the server completes the next SQL command. This can be avoided by proper use of two more functions:

PQconsumeInput

If input is available from the server, consume it.

int PQconsumeInput(PGconn *conn);

PQconsumeInput normally returns 1 indicating “no error”, but returns 0 if there was some kind of trouble (in which case PQerrorMessage can be consulted). Note that the result does not say whether any input data was actually collected. After calling PQconsumeInput, the application can check PQisBusy and/or PQnotifies to see if their state has changed.

PQconsumeInput can be called even if the application is not prepared to deal with a result or notification just yet. The function will read available data and save it in a buffer, thereby causing a select() read-ready indication to go away. The application can thus use PQconsumeInput to clear the select() condition immediately, and then examine the results at leisure.

PQisBusy

Returns 1 if a command is busy, that is, PQgetResult would block waiting for input. A 0 return indicates that PQgetResult can be called with assurance of not blocking.

int PQisBusy(PGconn *conn);

PQisBusy will not itself attempt to read data from the server; therefore PQconsumeInput must be invoked first, or the busy state will never end.

A typical application using these functions will have a main loop that uses select() or poll() to wait for all the conditions that it must respond to. One of the conditions will be input available from the server, which in terms of select() means readable data on the file descriptor identified by PQsocket. When the main loop detects input ready, it should call PQconsumeInput to read the input. It can then call PQisBusy, followed by PQgetResult if PQisBusy returns false (0). It can also call PQnotifies to detect NOTIFY messages (see Section 30.7).

A client that uses PQsendQuery/PQgetResult can also attempt to cancel a command that is still being processed by the server; see Section 30.5. But regardless of the return value of PQcancel, the application must continue with the normal result-reading sequence using PQgetResult. A successful cancellation will simply cause the command to terminate sooner than it would have otherwise.

By using the functions described above, it is possible to avoid blocking while waiting for input from the database server. However, it is still possible that the application will block waiting to send output to the server. This is relatively uncommon but can happen if very long SQL commands or data values are sent. (It is much more probable if the application sends data via COPY IN, however.) To prevent this possibility and achieve completely nonblocking database operation, the following additional functions can be used.

PQsetnonblocking

Sets the nonblocking status of the connection.

int PQsetnonblocking(PGconn *conn, int arg);
Chapter 30. libpq - C Library

Sets the state of the connection to nonblocking if \( \text{arg} \) is 1, or blocking if \( \text{arg} \) is 0. Returns 0 if OK, -1 if error.

In the nonblocking state, calls to \( \text{PQsendQuery}, \text{PQputline}, \text{PQputnbytes}, \) and \( \text{PQendcopy} \) will not block but instead return an error if they need to be called again.

Note that \( \text{PQexec} \) does not honor nonblocking mode; if it is called, it will act in blocking fashion anyway.

**PQisnonblocking**

Returns the blocking status of the database connection.

\[
\text{int PQisnonblocking(const PGconn *conn);} 
\]

Returns 1 if the connection is set to nonblocking mode and 0 if blocking.

**PQflush**

Attempts to flush any queued output data to the server. Returns 0 if successful (or if the send queue is empty), -1 if it failed for some reason, or 1 if it was unable to send all the data in the send queue yet (this case can only occur if the connection is nonblocking).

\[
\text{int PQflush(PGconn *conn);} 
\]

After sending any command or data on a nonblocking connection, call \( \text{PQflush} \). If it returns 1, wait for the socket to be write-ready and call it again; repeat until it returns 0. Once \( \text{PQflush} \) returns 0, wait for the socket to be read-ready and then read the response as described above.

### 30.5. Cancelling Queries in Progress

A client application can request cancellation of a command that is still being processed by the server, using the functions described in this section.

**PQgetCancel**

Creates a data structure containing the information needed to cancel a command issued through a particular database connection.

\[
\text{PGcancel *PQgetCancel(PGconn *conn);} 
\]

\( \text{PQgetCancel} \) creates a \( \text{PGcancel} \) object given a \( \text{PGconn} \) connection object. It will return NULL if the given \( \text{conn} \) is NULL or an invalid connection. The \( \text{PGcancel} \) object is an opaque structure that is not meant to be accessed directly by the application; it can only be passed to \( \text{PQcancel} \) or \( \text{PQfreeCancel} \).

**PQfreeCancel**

Frees a data structure created by \( \text{PQgetCancel} \).

\[
\text{void PQfreeCancel(PGcancel *cancel);} 
\]

\( \text{PQfreeCancel} \) frees a data object previously created by \( \text{PQgetCancel} \).
Chapter 30. libpq - C Library

PQcancel

Requests that the server abandon processing of the current command.

```c
int PQcancel(PGcancel *cancel, char *errbuf, int errbufsize);
```

The return value is 1 if the cancel request was successfully dispatched and 0 if not. If not, errbuf is filled with an error message explaining why not. errbuf must be a char array of size errbufsize (the recommended size is 256 bytes).

Successful dispatch is no guarantee that the request will have any effect, however. If the cancellation is effective, the current command will terminate early and return an error result. If the cancellation fails (say, because the server was already done processing the command), then there will be no visible result at all.

PQcancel can safely be invoked from a signal handler, if the errbuf is a local variable in the signal handler. The PGcancel object is read-only as far as PQcancel is concerned, so it can also be invoked from a thread that is separate from the one manipulating the PGconn object.

PQrequestCancel

Requests that the server abandon processing of the current command.

```c
int PQrequestCancel(PGconn *conn);
```

PQrequestCancel is a deprecated variant of PQcancel. It operates directly on the PGconn object, and in case of failure stores the error message in the PGconn object (whence it can be retrieved by PQerrorMessage). Although the functionality is the same, this approach creates hazards for multiple-thread programs and signal handlers, since it is possible that overwriting the PGconn’s error message will mess up the operation currently in progress on the connection.

30.6. The Fast-Path Interface

PostgreSQL provides a fast-path interface to send simple function calls to the server.

**Tip:** This interface is somewhat obsolete, as one can achieve similar performance and greater functionality by setting up a prepared statement to define the function call. Then, executing the statement with binary transmission of parameters and results substitutes for a fast-path function call.

The function PQfn requests execution of a server function via the fast-path interface:

```c
PGresult *PQfn(PGconn *conn,
    int fnid,
    int *result_buf,
    int *result_len,
    int result_is_int,
    const PQArgBlock *args,
    int nargs);
```

typedef struct {
    int len;
    int isint;
```
The `fnid` argument is the OID of the function to be executed. `args` and `nargs` define the parameters to be passed to the function; they must match the declared function argument list. When the `isint` field of a parameter structure is true, the `u.integer` value is sent to the server as an integer of the indicated length (this must be 1, 2, or 4 bytes); proper byte-swapping occurs. When `isint` is false, the indicated number of bytes at `*u.ptr` are sent with no processing; the data must be in the format expected by the server for binary transmission of the function’s argument data type. `result_buf` is the buffer in which to place the return value. The caller must have allocated sufficient space to store the return value. (There is no check!) The actual result length will be returned in the integer pointed to by `result_len`. If a 1, 2, or 4-byte integer result is expected, set `result_is_int` to 1, otherwise set it to 0. Setting `result_is_int` to 1 causes `libpq` to byte-swap the value if necessary, so that it is delivered as a proper `int` value for the client machine. When `result_is_int` is 0, the binary-format byte string sent by the server is returned unmodified.

`PQfn` always returns a valid `PGresult` pointer. The result status should be checked before the result is used. The caller is responsible for freeing the `PGresult` with `PQclear` when it is no longer needed.

Note that it is not possible to handle null arguments, null results, nor set-valued results when using this interface.

### 30.7. Asynchronous Notification

PostgreSQL offers asynchronous notification via the `LISTEN` and `NOTIFY` commands. A client session registers its interest in a particular notification condition with the `LISTEN` command (and can stop listening with the `UNLISTEN` command). All sessions listening on a particular condition will be notified asynchronously when a `NOTIFY` command with that condition name is executed by any session. No additional information is passed from the notifier to the listener. Thus, typically, any actual data that needs to be communicated is transferred through a database table. Commonly, the condition name is the same as the associated table, but it is not necessary for there to be an associated table.

`libpq` applications submit `LISTEN` and `UNLISTEN` commands as ordinary SQL commands. The arrival of `NOTIFY` messages can subsequently be detected by calling `PQnotifies`.

The function `PQnotifies` returns the next notification from a list of unhandled notification messages received from the server. It returns a null pointer if there are no pending notifications. Once a notification is returned from `PQnotifies`, it is considered handled and will be removed from the list of notifications.

```c
PQnotifies *PQnotifies(PGconn *conn);
```

```c
typedef struct pgNotify {
    char *relname; /* notification condition name */
    int be_pid;    /* process ID of notifying server process */
    char *extra;   /* notification parameter */
} PGnotify;
```
After processing a PGnotify object returned by PQnotifies, be sure to free it with PQfreemem. It is sufficient to free the PGnotify pointer; the relname and extra fields do not represent separate allocations. (At present, the extra field is unused and will always point to an empty string.)

Example 30-2 gives a sample program that illustrates the use of asynchronous notification.

PQnotifies does not actually read data from the server; it just returns messages previously absorbed by another libpq function. In prior releases of libpq, the only way to ensure timely receipt of NOTIFY messages was to constantly submit commands, even empty ones, and then check PQnotifies after each PQexec. While this still works, it is deprecated as a waste of processing power.

A better way to check for NOTIFY messages when you have no useful commands to execute is to call PQconsumeInput, then check PQnotifies. You can use select() to wait for data to arrive from the server, thereby using no CPU power unless there is something to do. (See PQsocket to obtain the file descriptor number to use with select().) Note that this will work OK whether you submit commands with PQsendQuery/PQgetResult or simply use PQexec. You should, however, remember to check PQnotifies after each PQgetResult or PQexec, to see if any notifications came in during the processing of the command.

### 30.8. Functions Associated with the COPY Command

The COPY command in PostgreSQL has options to read from or write to the network connection used by libpq. The functions described in this section allow applications to take advantage of this capability by supplying or consuming copied data.

The overall process is that the application first issues the SQL COPY command via PQexec or one of the equivalent functions. The response to this (if there is no error in the command) will be a PGresult object bearing a status code of PGRES_COPY_OUT or PGRES_COPY_IN (depending on the specified copy direction). The application should then use the functions of this section to receive or transmit data rows. When the data transfer is complete, another PGresult object is returned to indicate success or failure of the transfer. Its status will be PGRES_COMMAND_OK for success or PGRES_FATAL_ERROR if some problem was encountered. At this point further SQL commands can be issued via PQexec. (It is not possible to execute other SQL commands using the same connection while the COPY operation is in progress.)

If a COPY command is issued via PQexec in a string that could contain additional commands, the application must continue fetching results via PQgetResult after completing the COPY sequence. Only when PQgetResult returns NULL is it certain that the PQexec command string is done and it is safe to issue more commands.

The functions of this section should be executed only after obtaining a result status of PGRES_COPY_OUT or PGRES_COPY_IN from PQexec or PQgetResult.

A PGresult object bearing one of these status values carries some additional data about the COPY operation that is starting. This additional data is available using functions that are also used in connection with query results:

**PQnfields**

Returns the number of columns (fields) to be copied.

**PQbinaryTuples**

0 indicates the overall copy format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary. See COPY for more information.
Chapter 30. libpq - C Library

PQfformat

Returns the format code (0 for text, 1 for binary) associated with each column of the copy operation. The per-column format codes will always be zero when the overall copy format is textual, but the binary format can support both text and binary columns. (However, as of the current implementation of COPY, only binary columns appear in a binary copy; so the per-column formats always match the overall format at present.)

Note: These additional data values are only available when using protocol 3.0. When using protocol 2.0, all these functions will return 0.

30.8.1. Functions for Sending COPY Data

These functions are used to send data during COPY FROM STDIN. They will fail if called when the connection is not in COPY_IN state.

PQputCopyData

Sends data to the server during COPY_IN state.

```c
int PQputCopyData(PGconn *conn,
                   const char *buffer,
                   int nbytes);
```

Transmits the COPY data in the specified buffer, of length nbytes, to the server. The result is 1 if the data was sent, zero if it was not sent because the attempt would block (this case is only possible if the connection is in nonblocking mode), or -1 if an error occurred. (Use PQerrorMessage to retrieve details if the return value is -1. If the value is zero, wait for write-ready and try again.)

The application can divide the COPY data stream into buffer loads of any convenient size. Buffer-load boundaries have no semantic significance when sending. The contents of the data stream must match the data format expected by the COPY command; see COPY for details.

PQputCopyEnd

Sends end-of-data indication to the server during COPY_IN state.

```c
int PQputCopyEnd(PGconn *conn,
                 const char *errmsg);
```

Ends the COPY_IN operation successfully if errmsg is NULL. If errmsg is not NULL then the COPY is forced to fail, with the string pointed to by errmsg used as the error message. (One should not assume that this exact error message will come back from the server, however, as the server might have already failed the COPY for its own reasons. Also note that the option to force failure does not work when using pre-3.0-protocol connections.)

The result is 1 if the termination data was sent, zero if it was not sent because the attempt would block (this case is only possible if the connection is in nonblocking mode), or -1 if an error occurred. (Use PQerrorMessage to retrieve details if the return value is -1. If the value is zero, wait for write-ready and try again.)
After successfully calling PQputCopyEnd, call PQgetResult to obtain the final result status of the COPY command. One can wait for this result to be available in the usual way. Then return to normal operation.

30.8.2. Functions for Receiving COPY Data

These functions are used to receive data during COPY TO STDOUT. They will fail if called when the connection is not in COPY_OUT state.

PQgetCopyData

Receives data from the server during COPY_OUT state.

```c
int PQgetCopyData(PGconn *conn,
                    char **buffer,
                    int async);
```

Attempts to obtain another row of data from the server during a COPY. Data is always returned one data row at a time; if only a partial row is available, it is not returned. Successful return of a data row involves allocating a chunk of memory to hold the data. The buffer parameter must be non-NULL. buffer is set to point to the allocated memory, or to NULL in cases where no buffer is returned. A non-NULL result buffer must be freed using PQfreemem when no longer needed.

When a row is successfully returned, the return value is the number of data bytes in the row (this will always be greater than zero). The returned string is always null-terminated, though this is probably only useful for textual COPY. A result of zero indicates that the COPY is still in progress, but no row is yet available (this is only possible when async is true). A result of -1 indicates that the COPY is done. A result of -2 indicates that an error occurred (consult PQerrorMessage for the reason).

When async is true (not zero), PQgetCopyData will not block waiting for input; it will return zero if the COPY is still in progress but no complete row is available. (In this case wait for read-ready and then call PQconsumeInput before calling PQgetCopyData again.) When async is false (zero), PQgetCopyData will block until data is available or the operation completes.

After PQgetCopyData returns -1, call PQgetResult to obtain the final result status of the COPY command. One can wait for this result to be available in the usual way. Then return to normal operation.

30.8.3. Obsolete Functions for COPY

These functions represent older methods of handling COPY. Although they still work, they are deprecated due to poor error handling, inconvenient methods of detecting end-of-data, and lack of support for binary or nonblocking transfers.

PQgetline

Reads a newline-terminated line of characters (transmitted by the server) into a buffer string of size length.

```c
int PQgetline(PGconn *conn,
              char *buffer,
              int length);
```
This function copies up to length-1 characters into the buffer and converts the terminating newline into a zero byte. PQgetline returns EOF at the end of input, 0 if the entire line has been read, and 1 if the buffer is full but the terminating newline has not yet been read.

Note that the application must check to see if a new line consists of the two characters \n, which indicates that the server has finished sending the results of the COPY command. If the application might receive lines that are more than length-1 characters long, care is needed to be sure it recognizes the \n line correctly (and does not, for example, mistake the end of a long data line for a terminator line).

PQgetlineAsync

Reads a row of COPY data (transmitted by the server) into a buffer without blocking.

```
int PQgetlineAsync(PGconn *conn, char *buffer, int bufsize);
```

This function is similar to PQgetline, but it can be used by applications that must read COPY data asynchronously, that is, without blocking. Having issued the COPY command and gotten a PGRES_COPY_OUT response, the application should call PQconsumeInput and PQgetlineAsync until the end-of-data signal is detected.

Unlike PQgetline, this function takes responsibility for detecting end-of-data.

On each call, PQgetlineAsync will return data if a complete data row is available in libpq’s input buffer. Otherwise, no data is returned until the rest of the row arrives. The function returns -1 if the end-of-copy-data marker has been recognized, or 0 if no data is available, or a positive number giving the number of bytes of data returned. If -1 is returned, the caller must next call PQendcopy, and then return to normal processing.

The data returned will not extend beyond a data-row boundary. If possible a whole row will be returned at one time. But if the buffer offered by the caller is too small to hold a row sent by the server, then a partial data row will be returned. With textual data this can be detected by testing whether the last returned byte is \n or not. (In a binary COPY, actual parsing of the COPY data format will be needed to make the equivalent determination.) The returned string is not null-terminated. (If you want to add a terminating null, be sure to pass a bufsize one smaller than the room actually available.)

PQputline

Sends a null-terminated string to the server. Returns 0 if OK and EOF if unable to send the string.

```
int PQputline(PGconn *conn, const char *string);
```

The COPY data stream sent by a series of calls to PQputline has the same format as that returned by PQgetlineAsync, except that applications are not obliged to send exactly one data row per PQputline call; it is okay to send a partial line or multiple lines per call.

**Note:** Before PostgreSQL protocol 3.0, it was necessary for the application to explicitly send the two characters \n, as a final line to indicate to the server that it had finished sending COPY data. While this still works, it is deprecated and the special meaning of \n can be expected to be removed in a future release. It is sufficient to call PQendcopy after having sent the actual data.
PQputnbytes

Sends a non-null-terminated string to the server. Returns 0 if OK and EOF if unable to send the string.

```c
int PQputnbytes(PGconn *conn, const char *buffer, int nbytes);
```

This is exactly like PQputline, except that the data buffer need not be null-terminated since the number of bytes to send is specified directly. Use this procedure when sending binary data.

PQendcopy

Synchronizes with the server.

```c
int PQendcopy(PGconn *conn);
```

This function waits until the server has finished the copying. It should either be issued when the last string has been sent to the server using PQputline or when the last string has been received from the server using PGgetline. It must be issued or the server will get “out of sync” with the client. Upon return from this function, the server is ready to receive the next SQL command. The return value is 0 on successful completion, nonzero otherwise. (Use PQerrorMessage to retrieve details if the return value is nonzero.)

When using PQgetResult, the application should respond to a PGRES_COPY_OUT result by executing PQgetline repeatedly, followed by PQendcopy after the terminator line is seen. It should then return to the PQgetResult loop until PQgetResult returns a null pointer. Similarly a PGRES_COPY_IN result is processed by a series of PQputline calls followed by PQendcopy, then return to the PQgetResult loop. This arrangement will ensure that a COPY command embedded in a series of SQL commands will be executed correctly.

Older applications are likely to submit a COPY via PQexec and assume that the transaction is done after PQendcopy. This will work correctly only if the COPY is the only SQL command in the command string.

### 30.9. Control Functions

These functions control miscellaneous details of libpq’s behavior.

**PQclientEncoding**

Returns the client encoding.

```c
int PQclientEncoding(const PGconn *conn);
```

Note that it returns the encoding ID, not a symbolic string such as EUC_JP. To convert an encoding ID to an encoding name, you can use:

```c
char *pg_encoding_to_char(int encoding_id);
```

**PQsetClientEncoding**

Sets the client encoding.

```c
int PQsetClientEncoding(PGconn *conn, const char *encoding);
```
**conn** is a connection to the server, and **encoding** is the encoding you want to use. If the function successfully sets the encoding, it returns 0, otherwise -1. The current encoding for this connection can be determined by using **PQclientEncoding**.

**PQsetErrorVerbosity**

Determines the verbosity of messages returned by **PQerrorMessage** and **PQresultErrorMessage**.

```c
typedef enum {
    PQERRORS_TERSE,
    PQERRORS_DEFAULT,
    PQERRORS_VERBOSE
} PGVerbosity;

PGVerbosity PQsetErrorVerbosity(PGconn *conn, PGVerbosity verbosity);
```

**PQsetErrorVerbosity** sets the verbosity mode, returning the connection’s previous setting. In **TERSE** mode, returned messages include severity, primary text, and position only; this will normally fit on a single line. The default mode produces messages that include the above plus any detail, hint, or context fields (these might span multiple lines). The **VERBOSE** mode includes all available fields. Changing the verbosity does not affect the messages available from already-existing **PGresult** objects, only subsequently-created ones.

**PQtrace**

Enables tracing of the client/server communication to a debugging file stream.

```c
void PQtrace(PGconn *conn, FILE *stream);
```

**Note:** On Windows, if the libpq library and an application are compiled with different flags, this function call will crash the application because the internal representation of the **FILE** pointers differ. Specifically, multithreaded/single-threaded, release/debug, and static/dynamic flags should be the same for the library and all applications using that library.

**PQuntrace**

Disables tracing started by **PQtrace**.

```c
void PQuntrace(PGconn *conn);
```

### 30.10. Miscellaneous Functions

As always, there are some functions that just don’t fit anywhere.

**PQfreemem**

Frees memory allocated by libpq.

```c
void PQfreemem(void *ptr);
```

Frees memory allocated by libpq, particularly **PQescapeByteaConn**, **PQescapeBytea**, **PQunescapeBytea**, and **PQnotifies**. It is particularly important that this function, rather than **free()**, be used on Microsoft Windows. This is because allocating memory in a DLL and
releasing it in the application works only if multithreaded/single-threaded, release/debug, and static/dynamic flags are the same for the DLL and the application. On non-Microsoft Windows platforms, this function is the same as the standard library function free().

**PQconninfoFree**

Frees the data structures allocated by PQconndefaults or PQconninfoParse.

```c
void PQconninfoFree(PQconninfoOption *connOptions);
```

A simple PQfreemem will not do for this, since the array contains references to subsidiary strings.

**PQencryptPassword**

Prepares the encrypted form of a PostgreSQL password.

```c
char * PQencryptPassword(const char *passwd, const char *user);
```

This function is intended to be used by client applications that wish to send commands like ALTER USER joe PASSWORD ‘pwd’. It is good practice not to send the original cleartext password in such a command, because it might be exposed in command logs, activity displays, and so on. Instead, use this function to convert the password to encrypted form before it is sent. The arguments are the cleartext password, and the SQL name of the user it is for. The return value is a string allocated by malloc, or NULL if out of memory. The caller can assume the string doesn’t contain any special characters that would require escaping. Use PQfreemem to free the result when done with it.

**PQmakeEmptyPGresult**

Constructs an empty PGresult object with the given status.

```c
PGresult *PQmakeEmptyPGresult(PGconn *conn, ExecStatusType status);
```

This is libpq’s internal function to allocate and initialize an empty PGresult object. This function returns NULL if memory could not be allocated. It is exported because some applications find it useful to generate result objects (particularly objects with error status) themselves. If conn is not null and status indicates an error, the current error message of the specified connection is copied into the PGresult. Also, if conn is not null, any event procedures registered in the connection are copied into the PGresult. (They do not get PGEVT_RESULTCREATE calls, but see PQfireResultCreateEvents.) Note that PQclear should eventually be called on the object, just as with a PGresult returned by libpq itself.

**PQfireResultCreateEvents**

Fires a PGEVT_RESULTCREATE event (see Section 30.12) for each event procedure registered in the PGresult object. Returns non-zero for success, zero if any event procedure fails.

```c
int PQfireResultCreateEvents(PGconn *conn, PGresult *res);
```

The conn argument is passed through to event procedures but not used directly. It can be NULL if the event procedures won’t use it.

Event procedures that have already received a PGEVT_RESULTCREATE or PGEVT_RESULTCOPY event for this object are not fired again.

The main reason that this function is separate from PQmakeEmptyPGresult is that it is often appropriate to create a PGresult and fill it with data before invoking the event procedures.
PQcopyResult

Makes a copy of a PGresult object. The copy is not linked to the source result in any way and PQclear must be called when the copy is no longer needed. If the function fails, NULL is returned.

```c
PGresult *PQcopyResult(const PGresult *src, int flags);
```

This is not intended to make an exact copy. The returned result is always put into PGRES_TUPLES_OK status, and does not copy any error message in the source. (It does copy the command status string, however.) The flags argument determines what else is copied. It is a bitwise OR of several flags. PG_COPYRES_ATTRS specifies copying the source result’s attributes (column definitions). PG_COPYRES_TUPLES specifies copying the source result’s tuples. (This implies copying the attributes, too.) PG_COPYRES_NOTICEHOOKS specifies copying the source result’s notify hooks. PG_COPYRES_EVENTS specifies copying the source result’s events. (But any instance data associated with the source is not copied.)

PQsetResultAttrs

Sets the attributes of a PGresult object.

```c
int PQsetResultAttrs(PGresult *res, int numAttributes, PGresAttDesc *attDescs);
```

The provided attDescs are copied into the result. If the attDescs pointer is NULL or numAttributes is less than one, the request is ignored and the function succeeds. If res already contains attributes, the function will fail. If the function fails, the return value is zero. If the function succeeds, the return value is non-zero.

PQsetvalue

Sets a tuple field value of a PGresult object.

```c
int PQsetvalue(PGresult *res, int tup_num, int field_num, char *value, int len);
```

The function will automatically grow the result’s internal tuples array as needed. However, the tup_num argument must be less than or equal to PQntuples, meaning this function can only grow the tuples array one tuple at a time. But any field of any existing tuple can be modified in any order. If a value at field_num already exists, it will be overwritten. If len is -1 or value is NULL, the field value will be set to an SQL NULL. The value is copied into the result’s private storage, thus is no longer needed after the function returns. If the function fails, the return value is zero. If the function succeeds, the return value is non-zero.

PQresultAlloc

Allocate subsidiary storage for a PGresult object.

```c
void *PQresultAlloc(PGresult *res, size_t nBytes);
```

Any memory allocated with this function will be freed when res is cleared. If the function fails, the return value is NULL. The result is guaranteed to be adequately aligned for any type of data, just as for malloc.

### 30.11. Notice Processing

Notice and warning messages generated by the server are not returned by the query execution functions, since they do not imply failure of the query. Instead they are passed to a notice handling func-
tion, and execution continues normally after the handler returns. The default notice handling function
prints the message on stderr, but the application can override this behavior by supplying its own
handling function.

For historical reasons, there are two levels of notice handling, called the notice receiver and notice
processor. The default behavior is for the notice receiver to format the notice and pass a string to the
notice processor for printing. However, an application that chooses to provide its own notice receiver
will typically ignore the notice processor layer and just do all the work in the notice receiver.

The function PQsetNoticeReceiver sets or examines the current notice receiver for a connection
object. Similarly, PQsetNoticeProcessor sets or examines the current notice processor.

```c
typedef void (*PQnoticeReceiver) (void *arg, const PGresult *res);
PQnoticeReceiver PQsetNoticeReceiver(PGconn *conn, 
PQnoticeReceiver proc, 
void *arg);

typedef void (*PQnoticeProcessor) (void *arg, const char *message);
PQnoticeProcessor PQsetNoticeProcessor(PGconn *conn, 
PQnoticeProcessor proc, 
void *arg);
```

Each of these functions returns the previous notice receiver or processor function pointer, and sets the
new value. If you supply a null function pointer, no action is taken, but the current pointer is returned.

When a notice or warning message is received from the server, or generated internally by libpq, the
notice receiver function is called. It is passed the message in the form of a PGRES_NONFATAL_ERROR
PGresult. (This allows the receiver to extract individual fields using PQresultErrorField, or the
complete preformatted message using PQresultErrorMessage.) The same void pointer passed to
PQsetNoticeReceiver is also passed. (This pointer can be used to access application-specific state
if needed.)

The default notice receiver simply extracts the message (using PQresultErrorMessage) and passes
it to the notice processor.

The notice processor is responsible for handling a notice or warning message given in text form. It is
passed the string text of the message (including a trailing newline), plus a void pointer that is the same
one passed to PQsetNoticeProcessor. (This pointer can be used to access application-specific state
if needed.)

The default notice processor is simply:

```c
static void
defaultNoticeProcessor(void *arg, const char *message)
{
    fprintf(stderr, "%s", message);
}
```

Once you have set a notice receiver or processor, you should expect that that function could be
called as long as either the PGconn object or PGresult objects made from it exist. At creation of a
PGresult, the PGconn’s current notice handling pointers are copied into the PGresult for possible
use by functions like PQgetvalue.
30.12. Event System

libpq’s event system is designed to notify registered event handlers about interesting libpq events, such as the creation or destruction of PGconn and PGresult objects. A principal use case is that this allows applications to associate their own data with a PGconn or PGresult and ensure that that data is freed at an appropriate time.

Each registered event handler is associated with two pieces of data, known to libpq only as opaque void * pointers. There is a passthrough pointer that is provided by the application when the event handler is registered with a PGconn. The passthrough pointer never changes for the life of the PGconn and all PGresult objects generated from it; so if used, it must point to long-lived data. In addition there is an instance data pointer, which starts out NULL in every PGconn and PGresult. This pointer can be manipulated using the PQinstanceData, PQsetInstanceData, PQresultInstanceData and PQsetResultInstanceData functions. Note that unlike the passthrough pointer, instance data of a PGconn is not automatically inherited by PGresult objects created from it. libpq does not know what passthrough and instance data pointers point to (if anything) and will never attempt to free them — that is the responsibility of the event handler.

30.12.1. Event Types

The enum PGEventId names the types of events handled by the event system. All its values have names beginning with PGEVT. For each event type, there is a corresponding event info structure that carries the parameters passed to the event handlers. The event types are:

PGEVT_REGISTER

The register event occurs when PQregisterEventProc is called. It is the ideal time to initialize any instanceData an event procedure may need. Only one register event will be fired per event handler per connection. If the event procedure fails, the registration is aborted.

typedef struct
{
    PGconn *conn;
} PGEventRegister;

When a PGEVT_REGISTER event is received, the evtInfo pointer should be cast to a PGEventRegister *. This structure contains a PGconn that should be in the CONNECTION_OK status; guaranteed if one calls PQregisterEventProc right after obtaining a good PGconn. When returning a failure code, all cleanup must be performed as no PGEVT_CONNDESTROY event will be sent.

PGEVT_CONNRESET

The connection reset event is fired on completion of PQreset or PQresetPoll. In both cases, the event is only fired if the reset was successful. If the event procedure fails, the entire connection reset will fail; the PGconn is put into CONNECTION_BAD status and PQresetPoll will return PGRES_POLLING_FAILED.

typedef struct
{
    PGconn *conn;
} PGEventConnReset;

When a PGEVT_CONNRESET event is received, the evtInfo pointer should be cast to a PGEventConnReset *. Although the contained PGconn was just reset, all event data remains unchanged. This event should be used to reset/reload/requery any associated instanceData.
Chapter 30. libpq - C Library

Note that even if the event procedure fails to process `PGEVT_CONNRESET`, it will still receive a `PGEVT_CONNDESTROY` event when the connection is closed.

**PGEVT_CONNDESTROY**

The connection destroy event is fired in response to `PQfinish`. It is the event procedure’s responsibility to properly clean up its event data as `libpq` has no ability to manage this memory. Failure to clean up will lead to memory leaks.

typedef struct
{  
    PGconn *conn;
} PGEvnetConnDestroy;

When a `PGEVT_CONNDESTROY` event is received, the `evtInfo` pointer should be cast to a `PGEvnetConnDestroy *`. This event is fired prior to `PQfinish` performing any other cleanup. The return value of the event procedure is ignored since there is no way of indicating a failure from `PQfinish`. Also, an event procedure failure should not abort the process of cleaning up unwanted memory.

**PGEVT_RESULTCREATE**

The result creation event is fired in response to any query execution function that generates a result, including `PQgetResult`. This event will only be fired after the result has been created successfully.

typedef struct
{  
    PGconn *conn;
    PGresult *result;
} PGEvnetResultCreate;

When a `PGEVT_RESULTCREATE` event is received, the `evtInfo` pointer should be cast to a `PGEvnetResultCreate *`. The `conn` is the connection used to generate the result. This is the ideal place to initialize any `instanceData` that needs to be associated with the result. If the event procedure fails, the result will be cleared and the failure will be propagated. The event procedure must not try to `PQclear` the result object for itself. When returning a failure code, all cleanup must be performed as no `PGEVT_RESULTDESTROY` event will be sent.

**PGEVT_RESULTCOPY**

The result copy event is fired in response to `PQcopyResult`. This event will only be fired after the copy is complete. Only event procedures that have successfully handled the `PGEVT_RESULTCREATE` or `PGEVT_RESULTCOPY` event for the source result will receive `PGEVT_RESULTCOPY` events.

typedef struct
{  
    const PGresult *src;
    PGresult *dest;
} PGEvnetResultCopy;

When a `PGEVT_RESULTCOPY` event is received, the `evtInfo` pointer should be cast to a `PGEvnetResultCopy *`. The `src` result is what was copied while the `dest` result is the copy destination. This event can be used to provide a deep copy of `instanceData`, since `PQcopyResult` cannot do that. If the event procedure fails, the entire copy operation will fail and the `dest` result will be cleared. When returning a failure code, all cleanup must be performed as no `PGEVT_RESULTDESTROY` event will be sent for the destination result.
The result destroy event is fired in response to a PQclear. It is the event procedure’s responsibility to properly clean up its event data as libpq has no ability to manage this memory. Failure to clean up will lead to memory leaks.

typedef struct
{
    PGresult *result;
} PGEventResultDestroy;

When a PGEVT_RESULTDESTROY event is received, the evtInfo pointer should be cast to a PGEventResultDestroy *. This event is fired prior to PQclear performing any other cleanup. The return value of the event procedure is ignored since there is no way of indicating a failure from PQclear. Also, an event procedure failure should not abort the process of cleaning up unwanted memory.

30.12.2. Event Callback Procedure

PGEvtProc

PGEvtProc is a typedef for a pointer to an event procedure, that is, the user callback function that receives events from libpq. The signature of an event procedure must be

int eventproc(PGEvtId evtId, void *evtInfo, void *passThrough)

The evtId parameter indicates which PGEVT event occurred. The evtInfo pointer must be cast to the appropriate structure type to obtain further information about the event. The passThrough parameter is the pointer provided to PQregisterEventProc when the event procedure was registered. The function should return a non-zero value if it succeeds and zero if it fails.

A particular event procedure can be registered only once in any PGconn. This is because the address of the procedure is used as a lookup key to identify the associated instance data.

Caution

On Windows, functions can have two different addresses: one visible from outside a DLL and another visible from inside the DLL. One should be careful that only one of these addresses is used with libpq’s event-procedure functions, else confusion will result. The simplest rule for writing code that will work is to ensure that event procedures are declared static. If the procedure’s address must be available outside its own source file, expose a separate function to return the address.

30.12.3. Event Support Functions

PQregisterEventProc

Registers an event callback procedure with libpq.

int PQregisterEventProc(PGconn *conn, PGEvtProc proc,
                        const char *name, void *passThrough);
Chapter 30. libpq - C Library

An event procedure must be registered once on each \texttt{PGconn} you want to receive events about. There is no limit, other than memory, on the number of event procedures that can be registered with a connection. The function returns a non-zero value if it succeeds and zero if it fails.

The \texttt{proc} argument will be called when a libpq event is fired. Its memory address is also used to lookup \texttt{instanceData}. The \texttt{name} argument is used to refer to the event procedure in error messages. This value cannot be NULL or a zero-length string. The name string is copied into the \texttt{PGconn}, so what is passed need not be long-lived. The \texttt{passThrough} pointer is passed to the \texttt{proc} whenever an event occurs. This argument can be NULL.

\begin{verbatim}
PQsetInstanceData

Sets the conn’s instanceData for proc to data. This returns non-zero for success and zero for failure. (Failure is only possible if the proc has not been properly registered in the conn.)

\begin{verbatim}
int PQsetInstanceData(PGconn *conn, PGEventProc proc, void *data);
\end{verbatim}
\end{verbatim}

\begin{verbatim}
PQinstanceData

Returns the conn’s instanceData associated with proc, or NULL if there is none.

\begin{verbatim}
void *PQinstanceData(const PGconn *conn, PGEventProc proc);
\end{verbatim}
\end{verbatim}

\begin{verbatim}
PQresultSetInstanceData

Sets the result’s instanceData for proc to data. This returns non-zero for success and zero for failure. (Failure is only possible if the proc has not been properly registered in the result.)

\begin{verbatim}
int PQresultSetInstanceData(PGresult *res, PGEventProc proc, void *data);
\end{verbatim}
\end{verbatim}

\begin{verbatim}
PQresultInstanceData

Returns the result’s instanceData associated with proc, or NULL if there is none.

\begin{verbatim}
void *PQresultInstanceData(const PGresult *res, PGEventProc proc);
\end{verbatim}
\end{verbatim}

\end{verbatim}

30.12.4. Event Example

Here is a skeleton example of managing private data associated with libpq connections and results.

```c
#include <libpq-events.h>

typedef struct
{
    int n;
    char *str;
} mydata;

static int myEventProc(PGEventId evtId, void *evtInfo, void *passThrough);

int main(void)
{

```
mydata *data;
PGresult *res;
PGconn *conn = PQconnectdb("dbname = postgres");

if (PQstatus(conn) != CONNECTION_OK)
{
    fprintf(stderr, "Connection to database failed: %s",
            PQerrorMessage(conn));
    PQfinish(conn);
    return 1;
}

/* called once on any connection that should receive events.
 * Sends a PGEVT_REGISTER to myEventProc.
 */
if (!PQregisterEventProc(conn, myEventProc, "mydata_proc", NULL))
{
    fprintf(stderr, "Cannot register PGEventProc
");    PQfinish(conn);
    return 1;
}

/* conn instanceData is available */
data = PQinstanceData(conn, myEventProc);

/* Sends a PGEVT_RESULTCREATE to myEventProc */
res = PQexec(conn, "SELECT 1 + 1");

/* result instanceData is available */
data = PQresultInstanceData(res, myEventProc);

/* If PG_COPYRES_EVENTS is used, sends a PGEVT_RESULTCOPY to myEventProc */
res_copy = PQcopyResult(res, PG_COPYRES_TUPLES | PG_COPYRES_EVENTS);

/* result instanceData is available if PG_COPYRES_EVENTS was
 * used during the PQcopyResult call. */
data = PQresultInstanceData(res_copy, myEventProc);

/* Both clears send a PGEVT_RESULTDESTROY to myEventProc */
PQclear(res);
PQclear(res_copy);

/* Sends a PGEVT_CONNDESTROY to myEventProc */
PQfinish(conn);

return 0;
}

static int
myEventProc(PGEvtId evtId, void *evtInfo, void *passThrough)
{
    switch (evtId)
    {
        case PGEVT_REGISTER:
        {
            PGEvtRegister *e = (PGEvtRegister *)evtInfo;
            break;
        }

        case PGEVT_RESULTCREATE:
        {
            PGEvtResultCreate *r = (PGEvtResultCreate *)evtInfo;
            break;
        }

        case PGEVT_RESULTCOPY:
        {
            PGEvtResultCopy *r = (PGEvtResultCopy *) evtInfo;
            break;
        }

        case PGEVT_RESULTDESTROY:
        {
            PGEvtResultDestroy *r = (PGEvtResultDestroy *)evtInfo;
            break;
        }

        case PGEVT_CONNDESTROY:
        {
            PGEvtConnDestroy *r = (PGEvtConnDestroy *)evtInfo;
            break;
        }
    }

    return 0;
}
mydata *data = get_mydata(e->conn);

/* associate app specific data with connection */
PQsetInstanceData(e->conn, myEventProc, data);
break;
}
case PGEVT_CONNRESET:
{
PGEventConnReset *e = (PGEventConnReset *)evtInfo;
mydata *data = PQinstanceData(e->conn, myEventProc);
if (data)
    memset(data, 0, sizeof(mydata));
break;
}
case PGEVT_CONNDESTROY:
{
PGEventConnDestroy *e = (PGEventConnDestroy *)evtInfo;
mydata *data = PQinstanceData(e->conn, myEventProc);
/* free instance data because the conn is being destroyed */
if (data)
    free_mydata(data);
break;
}
case PGEVT_RESULTCREATE:
{
PGEventResultCreate *e = (PGEventResultCreate *)evtInfo;
mydata *conn_data = PQinstanceData(e->conn, myEventProc);
mydata *res_data = dup_mydata(conn_data);
/* associate app specific data with result (copy it from conn) */
PQsetResultInstanceData(e->result, myEventProc, res_data);
break;
}
case PGEVT_RESULTCOPY:
{
PGEventResultCopy *e = (PGEventResultCopy *)evtInfo;
mydata *src_data = PQresultInstanceData(e->src, myEventProc);
mydata *dest_data = dup_mydata(src_data);
/* associate app specific data with result (copy it from a result) */
PQsetResultInstanceData(e->dest, myEventProc, dest_data);
break;
}
case PGEVT_RESULTDESTROY:
{
PGEventResultDestroy *e = (PGEventResultDestroy *)evtInfo;
mydata *data = PQresultInstanceData(e->result, myEventProc);
/* free instance data because the result is being destroyed */
if (data)
Chapter 30. libpq - C Library

free_mydata(data);
break;

/* unknown event id, just return TRUE. */
default:
  break;
}

return TRUE; /* event processing succeeded */

30.13. Environment Variables

The following environment variables can be used to select default connection parameter values, which will be used by PQconnectdb, PQsetdbLogin and PQsetdb if no value is directly specified by the calling code. These are useful to avoid hard-coding database connection information into simple client applications, for example.

- **PGHOST** behaves the same as host connection parameter.
- **PGHOSTADDR** behaves the same as hostaddr connection parameter. This can be set instead of or in addition to PGHOST to avoid DNS lookup overhead.
- **PGPORT** behaves the same as port connection parameter.
- **PGDATABASE** behaves the same as dbname connection parameter.
- **PGUSER** behaves the same as user connection parameter.
- **PGPASSWORD** behaves the same as password connection parameter. Use of this environment variable is not recommended for security reasons (some operating systems allow non-root users to see process environment variables via ps); instead consider using the ~/.pgpass file (see Section 30.14).
- **PGPASSFILE** specifies the name of the password file to use for lookups. If not set, it defaults to ~/.pgpass (see Section 30.14).
- **PGSERVICE** behaves the same as service connection parameter.
- **PGREALM** sets the Kerberos realm to use with PostgreSQL, if it is different from the local realm. If PGREALM is set, libpq applications will attempt authentication with servers for this realm and use separate ticket files to avoid conflicts with local ticket files. This environment variable is only used if Kerberos authentication is selected by the server.
- **PGOPTIONS** behaves the same as options connection parameter.
- **PGSSLMODE** behaves the same as sslmode connection parameter.
- **PGREQUIRESSL** behaves the same as requiressl connection parameter.
- **PGSSLCERT** behaves the same as sslcert connection parameter.
- **PGSSLKEY** behaves the same as sslkey connection parameter.
- **PGSSLROOTCERT** behaves the same as sslrootcert connection parameter.
- **PGSSLCRL** behaves the same as sslcrl connection parameter.
Chapter 30. libpq - C Library

- **PGKRBSRVNAME** behaves the same as krbsrvname connection parameter.
- **PGGSSSLIB** behaves the same as gsslib connection parameter.
- **PGCONNECT_TIMEOUT** behaves the same as connect_timeout connection parameter.

The following environment variables can be used to specify default behavior for each PostgreSQL session. (See also the **ALTER USER** and **ALTER DATABASE** commands for ways to set default behavior on a per-user or per-database basis.)

- **PGDATESTYLE** sets the default style of date/time representation. (Equivalent to `SET datestyle TO ...`)
- **PGTZ** sets the default time zone. (Equivalent to `SET timezone TO ...`)
- **PGCLIENTENCODING** sets the default client character set encoding. (Equivalent to `SET client_encoding TO ...`)
- **PGGEQO** sets the default mode for the genetic query optimizer. (Equivalent to `SET geqo TO ...`)

Refer to the SQL command `SET` for information on correct values for these environment variables.

The following environment variables determine internal behavior of libpq; they override compiled-in defaults.

- **PGSYSCONFDIR** sets the directory containing the `pg_service.conf` file.
- **PGLOCALEDIR** sets the directory containing the `locale` files for message internationalization.

### 30.14. The Password File

The file `.pgpass` in a user’s home directory or the file referenced by `PGPASSFILE` can contain passwords to be used if the connection requires a password (and no password has been specified otherwise). On Microsoft Windows the file is named `%APPDATA%\postgresql\pgpass.conf` (where `%APPDATA%` refers to the Application Data subdirectory in the user’s profile).

This file should contain lines of the following format:

```
hostname:port:database:username:password
```

Each of the first four fields can be a literal value, or *, which matches anything. The password field from the first line that matches the current connection parameters will be used. (Therefore, put more-specific entries first when you are using wildcards.) If an entry needs to contain :, or \, escape this character with \. A host name of `localhost` matches both TCP (host name `localhost`) and Unix domain socket (`pghost` empty or the default socket directory) connections coming from the local machine.

On Unix systems, the permissions on `.pgpass` must disallow any access to world or group; achieve this by the command `chmod 0600 ~/.pgpass`. If the permissions are less strict than this, the file will be ignored. On Microsoft Windows, it is assumed that the file is stored in a directory that is secure, so no special permissions check is made.
30.15. The Connection Service File

The connection service file allows libpq connection parameters to be associated with a single service name. That service name can then be specified by a libpq connection, and the associated settings will be used. This allows connection parameters to be modified without requiring a recompile of the libpq application. The service name can also be specified using the PGSERVICE environment variable.

To use this feature, copy `share/pg_service.conf.sample` to `etc/pg_service.conf` and edit the file to add service names and parameters. This file can be used for client-only installs too. The file’s location can also be specified by the PGSYSCONFDIR environment variable.

30.16. LDAP Lookup of Connection Parameters

If libpq has been compiled with LDAP support (option `--with-ldap` for `configure`) it is possible to retrieve connection options like `host` or `dbname` via LDAP from a central server. The advantage is that if the connection parameters for a database change, the connection information doesn’t have to be updated on all client machines.

LDAP connection parameter lookup uses the connection service file `pg_service.conf` (see Section 30.15). A line in a `pg_service.conf` stanza that starts with `ldap://` will be recognized as an LDAP URL and an LDAP query will be performed. The result must be a list of `keyword = value` pairs which will be used to set connection options. The URL must conform to RFC 1959 and be of the form

```
ldap://[hostname[:port]]/search_base?attribute?search_scope?filter
```

where `hostname` defaults to localhost and `port` defaults to 389.

Processing of `pg_service.conf` is terminated after a successful LDAP lookup, but is continued if the LDAP server cannot be contacted. This is to provide a fallback with further LDAP URL lines that point to different LDAP servers, classical `keyword = value` pairs, or default connection options. If you would rather get an error message in this case, add a syntactically incorrect line after the LDAP URL.

A sample LDAP entry that has been created with the LDIF file

```
version:1
dn:cn=mydatabase,dc=mycompany,dc=com
changetype:add
objectclass:top
objectclass:groupOfUniqueNames
cn=mydatabase
uniqueMember:host=dbserver.mycompany.com
uniqueMember:port=5439
uniqueMember:dbname=mydb
uniqueMember:user=mydb_user
uniqueMember:sslmode=require
```

might be queried with the following LDAP URL:

```
ldap://ldap.mycompany.com/dc=mycompany,dc=com?uniqueMember?one?(cn=mydatabase)
```
You can also mix regular service file entries with LDAP lookups. A complete example for a stanza in \texttt{pg\_service\.conf} would be:

\begin{verbatim}
# only host and port are stored in LDAP, specify dbname and user explicitly
[customerdb]
dbname=customer
user=appuser
ldap://ldap.acme.com/cn=dbserver,cn=hosts?pgconnectinfo?base?(objectclass=*)
\end{verbatim}

### 30.17. SSL Support

PostgreSQL has native support for using SSL connections to encrypt client/server communications for increased security. See Section 17.8 for details about the server-side SSL functionality.

\texttt{libpq} reads the system-wide OpenSSL configuration file. By default, this file is named \texttt{openssl.cnf} and is located in the directory reported by \texttt{openssl version -d}. This default can be overridden by setting environment variable \texttt{OPENSSL\_CONF} to the name of the desired configuration file.

#### 30.17.1. Certificate verification

By default, PostgreSQL will not perform any verification of the server certificate. This means that it is possible to spoof the server identity (for example by modifying a DNS record or by taking over the server IP address) without the client knowing. In order to prevent this, SSL certificate verification must be used.

If the parameter \texttt{sslmode} is set to \texttt{verify-ca} \texttt{libpq} will verify that the server is trustworthy by checking the certificate chain up to a trusted CA. If \texttt{sslmode} is set to \texttt{verify-full}, \texttt{libpq} will also verify that the server hostname matches that of the certificate. The SSL connection will fail if the server certificate cannot be verified. \texttt{verify-full} is recommended in most security sensitive environments.

In \texttt{verify-full} mode, the \texttt{cn} attribute of the certificate is matched against the hostname. If the \texttt{cn} attribute starts with an asterisk (*), it will be treated as a wildcard, and will match all characters except a dot (.). This means the certificate will not match subdomains. If the connection is made using an IP address instead of a hostname, the IP address will be matched (without doing any DNS lookups).

To allow verification, the certificate of a trusted CA must be placed in the file \texttt{~/.postgresql/root.crt} in the user’s home directory. (On Microsoft Windows the file is named \texttt{%APPDATA%\postgresql\root.crt}.)

Certificate Revocation List (CRL) entries are also checked if the file \texttt{~/.postgresql/root.crl} exists (\texttt{%APPDATA%\postgresql\root.crl} on Microsoft Windows).

The location of the root certificate store and the CRL can be overridden by the connection parameters \texttt{sslrootcert} and \texttt{sslcrl} or the environment variables \texttt{PGSSLROOTCERT} and \texttt{PGSSLCRL}.

\textbf{Note:} For backwards compatibility with earlier versions of PostgreSQL, if a root CA file exists, the behavior of \texttt{sslmode=require} will be the same as that of \texttt{verify-ca}, meaning the server certificate is validated against the CA. Relying on this behavior is discouraged, and applications that need certificate validation should always use \texttt{verify-ca} or \texttt{verify-full}.
30.17.2. Client certificates

If the server requests a trusted client certificate, libpq will send the certificate stored in file `~/.postgresql/postgresql.crt` in the user's home directory. The certificate must be signed by one of the certificate authorities (CA) trusted by the server. A matching private key file `~/.postgresql/postgresql.key` must also be present. The private key file must not allow any access to world or group; achieve this by the command `chmod 0600 ~/.postgresql/postgresql.key`. On Microsoft Windows these files are named `%APPDATA%\postgresql\postgresql.crt` and `%APPDATA%\postgresql\postgresql.key`, and there is no special permissions check since the directory is presumed secure. The location of the certificate and key files can be overridden by the connection parameters `sslcert` and `sslkey` or the environment variables `PGSSLCERT` and `PGSSLKEY`.

30.17.3. Protection provided in different modes

The different values for the `sslmode` parameter provide different levels of protection, in different environments. SSL itself provides protection against three different types of attacks:

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Eavesdropping</td>
<td>If a third party can listen to the network traffic between the client and the server, it can read both connection information (including the username and password) and the data that is passed. SSL uses encryption to prevent this.</td>
</tr>
<tr>
<td>Man in the middle (MITM)</td>
<td>If a third party can modify the data while passing between the client and server, it can pretend to be the server and therefore see and modify data even if it is encrypted. The third party can then forward the connection information and data to the original server, making it impossible to detect this attack. Common vectors to do this include DNS poisoning and address hijacking, whereby the client is directed to a different server than intended. There are also several other attack methods that can accomplish this. SSL uses certificate verification to prevent this, by authenticating the server to the client.</td>
</tr>
<tr>
<td>Impersonation</td>
<td>If a third party can pretend to be an authorized client, it can simply access data it should not have access to. Typically this can happen through insecure password management. SSL uses client certificates to prevent this, by making sure that only holders of valid certificates can access the server.</td>
</tr>
</tbody>
</table>

For a connection to be known secure, the two first of these have to be set up on both the client and the server before the connection is made. If it is only configured on the server, the client may end up sending sensitive information (e.g. passwords) before it knows that the server requires high security. In libpq, this is controlled by setting the `sslmode` parameter to `verify-full` or `verify-ca`, and
providing the system with a root certificate to verify against. This is analogous to using a https URL for encrypted web browsing.

Once the server has been authenticated, the client can pass sensitive data. This means that up until this point, the client does not need to know if certificates will be used for authentication, making it safe to specify this only in the server configuration.

All SSL options carry overhead in the form of encryption and key-exchange, and it is a tradeoff that has to be made between performance and security. The following table illustrates the risks the different sslmode values protect against, and what statement they make about security and overhead:

### Table 30-3. SSL mode descriptions

<table>
<thead>
<tr>
<th>sslmode</th>
<th>Eavesdropping protection</th>
<th>MITM protection</th>
<th>Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>disable</td>
<td>No</td>
<td>No</td>
<td>I don’t care about security, and I don’t want to pay the overhead of encryption.</td>
</tr>
<tr>
<td>allow</td>
<td>Maybe</td>
<td>No</td>
<td>I don’t care about security, but I will pay the overhead of encryption if the server insists on it.</td>
</tr>
<tr>
<td>prefer</td>
<td>Maybe</td>
<td>No</td>
<td>I don’t care about encryption, but I wish to pay the overhead of encryption if the server supports it.</td>
</tr>
<tr>
<td>require</td>
<td>Yes</td>
<td>No</td>
<td>I want my data to be encrypted, and I accept the overhead. I trust that the network will make sure I always connect to the server I want.</td>
</tr>
<tr>
<td>verify-ca</td>
<td>Yes</td>
<td>Depends on CA-policy</td>
<td>I want my data encrypted, and I accept the overhead. I want to be sure that I connect to a server that I trust.</td>
</tr>
<tr>
<td>verify-full</td>
<td>Yes</td>
<td>Yes</td>
<td>I want my data encrypted, and I accept the overhead. I want to be sure that I connect to a server I trust, and that it’s the one I specify.</td>
</tr>
</tbody>
</table>

The difference between verify-ca and verify-full depends on the policy of the root CA. If a public CA is used, verify-ca allows connections to a server that somebody else may have registered with the CA to succeed. In this case, verify-full should always be used. If a local CA is used, or
even a self-signed certificate, using `verify-ca` often provides enough protection.

The default value for `sslmode` is `prefer`. As is shown in the table, this makes no sense from a security point of view, and it only promises performance overhead if possible. It is only provided as the default for backwards compatibility, and not recommended in secure deployments.

### 30.17.4. SSL File Usage

#### Table 30-4. Libpq/Client SSL File Usage

<table>
<thead>
<tr>
<th>File</th>
<th>Contents</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>~/.postgresql/postgresql.crt</td>
<td>client certificate</td>
<td>requested by server</td>
</tr>
<tr>
<td>~/.postgresql/postgresql.key</td>
<td>client private key</td>
<td>proves client certificate sent by owner; does not indicate certificate owner is trustworthy</td>
</tr>
<tr>
<td>~/.postgresql/root.crt</td>
<td>trusted certificate authorities</td>
<td>checks server certificate is signed by a trusted certificate authority</td>
</tr>
<tr>
<td>~/.postgresql/root.crl</td>
<td>certificates revoked by certificate authorities</td>
<td>server certificate must not be on this list</td>
</tr>
</tbody>
</table>

### 30.17.5. SSL library initialization

If your application initializes `libssl` and/or `libcrypto` libraries and libpq is built with SSL support, you should call `PQinitOpenSSL` to tell libpq that the `libssl` and/or `libcrypto` libraries have been initialized by your application, so that libpq will not also initialize those libraries. See [http://h71000.www7.hp.com/doc/83final/BA554_90007/ch04.html](http://h71000.www7.hp.com/doc/83final/BA554_90007/ch04.html) for details on the SSL API.

#### `PQinitOpenSSL`

Allows applications to select which security libraries to initialize.

```c
void PQinitOpenSSL(int do_ssl, int do_crypto);
```

When `do_ssl` is non-zero, libpq will initialize the OpenSSL library before first opening a database connection. When `do_crypto` is non-zero, the `libcrypto` library will be initialized. By default (if `PQinitOpenSSL` is not called), both libraries are initialized. When SSL support is not compiled in, this function is present but does nothing.

If your application uses and initializes either OpenSSL or its underlying `libcrypto` library, you **must** call this function with zeroes for the appropriate parameter(s) before first opening a database connection. Also be sure that you have done that initialization before opening a database connection.

#### `PQinitSSL`

Allows applications to select which security libraries to initialize.

```c
void PQinitSSL(int do_ssl);
```
This function is equivalent to PQinitOpenSSL(do_ssl, do_ssl). It is sufficient for applications that initialize both or neither of OpenSSL and libcrypto.

PQinitSSL has been present since PostgreSQL 8.0, while PQinitOpenSSL was added in PostgreSQL 8.4, so PQinitSSL might be preferable for applications that need to work with older versions of libpq.

30.18. Behavior in Threaded Programs

libpq is reentrant and thread-safe if the configure command-line option --enable-thread-safety was used when the PostgreSQL distribution was built. In addition, you might need to use additional compiler command-line options when you compile your application code. Refer to your system’s documentation for information about how to build thread-enabled applications, or look in src/Makefile.global for PTHREAD_CFLAGS and PTHREAD_LIBS. This function allows the querying of libpq’s thread-safe status:

PQisthreadsafe

Returns the thread safety status of the libpq library.

int PQisthreadsafe();

Returns 1 if the libpq is thread-safe and 0 if it is not.

One thread restriction is that no two threads attempt to manipulate the same PGconn object at the same time. In particular, you cannot issue concurrent commands from different threads through the same connection object. (If you need to run concurrent commands, use multiple connections.)

PGresult objects are normally read-only after creation, and so can be passed around freely between threads. However, if you use any of the PGresult-modifying functions described in Section 30.10 or Section 30.12, it’s up to you to avoid concurrent operations on the same PGresult, too.

The deprecated functions PQrequestCancel and PQoidStatus are not thread-safe and should not be used in multithread programs. PQrequestCancel can be replaced by PQcancel. PQoidStatus can be replaced by PQoidValue.

If you are using Kerberos inside your application (in addition to inside libpq), you will need to do locking around Kerberos calls because Kerberos functions are not thread-safe. See function PQregisterThreadLock in the libpq source code for a way to do cooperative locking between libpq and your application.

If you experience problems with threaded applications, run the program in src/tools/thread to see if your platform has thread-unsafe functions. This program is run by configure, but for binary distributions your library might not match the library used to build the binaries.
30.19. Building libpq Programs

To build (i.e., compile and link) a program using libpq you need to do all of the following things:

• Include the libpq-fe.h header file:

```c
#include <libpq-fe.h>
```

If you failed to do that then you will normally get error messages from your compiler similar to:

```c
foo.c: In function 'main':
foo.c:34: 'PGconn' undeclared (first use in this function)
foo.c:35: 'PGresult' undeclared (first use in this function)
foo.c:54: 'CONNECTION_BAD' undeclared (first use in this function)
foo.c:68: 'PGRES_COMMAND_OK' undeclared (first use in this function)
foo.c:95: 'PGRES_TUPLES_OK' undeclared (first use in this function)
```

• Point your compiler to the directory where the PostgreSQL header files were installed, by supplying the -I directory option to your compiler. (In some cases the compiler will look into the directory in question by default, so you can omit this option.) For instance, your compile command line could look like:

```c
cc -c -I/usr/local/pgsql/include testprog.c
```

If you are using makefiles then add the option to the CPPFLAGS variable:

```c
CPPFLAGS += -I/usr/local/pgsql/include
```

If there is any chance that your program might be compiled by other users then you should not hardcode the directory location like that. Instead, you can run the utility `pg_config` to find out where the header files are on the local system:

```shell
$ pg_config --includedir
/usr/local/include
```

Failure to specify the correct option to the compiler will result in an error message such as:

```c
testlibpq.c:8:22: libpq-fe.h: No such file or directory
```

• When linking the final program, specify the option -lpq so that the libpq library gets pulled in, as well as the option -Ldirectory to point the compiler to the directory where the libpq library resides. (Again, the compiler will search some directories by default.) For maximum portability, put the -L option before the -lpq option. For example:

```c
cc -o testprog testprog1.o testprog2.o -L/usr/local/pgsql/lib -lpq
```

You can find out the library directory using `pg_config` as well:

```shell
$ pg_config --libdir
/usr/local/pgsql/lib
```

Error messages that point to problems in this area could look like the following:

```c
testlibpq.o: In function 'main':
testlibpq.o(.text+0x60): undefined reference to 'PQsetdbLogin'
testlibpq.o(.text+0x71): undefined reference to 'PQstatus'
testlibpq.o(.text+0xa4): undefined reference to 'PQerrorMessage'
This means you forgot -lpq.
/usr/bin/ld: cannot find -lpq
This means you forgot the -L option or did not specify the right directory.
```
30.20. Example Programs

These examples and others can be found in the directory `src/test/examples` in the source code distribution.

Example 30-1. libpq Example Program 1

```c
/*
 * testlibpq.c
 *
 * Test the C version of libpq, the PostgreSQL frontend library.
 */
#include <stdio.h>
#include <stdlib.h>
#include "libpq-fe.h"

static void
exit_nicely(PGconn *conn)
{
PQfinish(conn);
exit(1);
}

int
main(int argc, char **argv)
{
    const char *conninfo;
    PGconn    *conn;
    PGresult   *res;
    int        nFields;
    int        i,
                j;

    /*
     * If the user supplies a parameter on the command line, use it as the
     * conninfo string; otherwise default to setting dbname=postgres and using
     * environment variables or defaults for all other connection parameters.
     */
    if (argc > 1)
        conninfo = argv[1];
    else
        conninfo = "dbname = postgres";

    /* Make a connection to the database */
    conn = PQconnectdb(conninfo);

    /* Check to see that the backend connection was successfully made */
    if (PQstatus(conn) != CONNECTION_OK)
    {
        fprintf(stderr, "Connection to database failed: %s",
                PQerrorMessage(conn));
        exit_nicely(conn);
    }

    /* Our test case here involves using a cursor, for which we must be inside
     * a transaction block. We could do the whole thing with a single
    */
```
Chapter 30. libpq - C Library

PQexec() of "select * from pg_database", but that's too trivial to make
a good example.

/*
 * Start a transaction block */
res = PQexec(conn, "BEGIN");
if (PQresultStatus(res) != PGRES_COMMAND_OK)
{
    fprintf(stderr, "BEGIN command failed: %s", PQerrorMessage(conn));
PQclear(res);
    exit_nicely(conn);
}

/*
 * Should PQclear PGresult whenever it is no longer needed to avoid memory
 * leaks
 */
PQclear(res);

/*
 * Fetch rows from pg_database, the system catalog of databases
 */
res = PQexec(conn, "DECLARE myportal CURSOR FOR select * from pg_database");
if (PQresultStatus(res) != PGRES_COMMAND_OK)
{
    fprintf(stderr, "DECLARE CURSOR failed: %s", PQerrorMessage(conn));
PQclear(res);
    exit_nicely(conn);
}
PQclear(res);

res = PQexec(conn, "FETCH ALL in myportal");
if (PQresultStatus(res) != PGRES_TUPLES_OK)
{
    fprintf(stderr, "FETCH ALL failed: %s", PQerrorMessage(conn));
PQclear(res);
    exit_nicely(conn);
}

/* first, print out the attribute names */
nFields = PQnfields(res);
for (i = 0; i < nFields; i++)
    printf("%-15s", PQfname(res, i));
printf("\n\n");

/* next, print out the rows */
for (i = 0; i < PQntuples(res); i++)
{
    for (j = 0; j < nFields; j++)
        printf("%-15s", PQgetvalue(res, i, j));
    printf("\n");
}
PQclear(res);

/* close the portal ... we don't bother to check for errors ... */
res = PQexec(conn, "CLOSE myportal");
Chapter 30. libpq - C Library

PQclear(res);
/* end the transaction */
res = PQexec(conn, "END");
PQclear(res);

/* close the connection to the database and cleanup */
PQfinish(conn);
return 0;
}

Example 30-2. libpq Example Program 2

/*! testlibpq2.c
 * Test of the asynchronous notification interface
 * Start this program, then from psql in another window do
 * NOTIFY TBL2;
 * Repeat four times to get this program to exit.
 * Or, if you want to get fancy, try this:
 * populate a database with the following commands
 * (provided in src/test/examples/testlibpq2.sql):
 * CREATE TABLE TBL1 (i int4);
 * CREATE TABLE TBL2 (i int4);
 * CREATE RULE r1 AS ON INSERT TO TBL1 DO
 * (INSERT INTO TBL2 VALUES (new.i); NOTIFY TBL2);
 * and do this four times:
 * INSERT INTO TBL1 VALUES (10);
 */
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <errno.h>
#include <sys/time.h>
#include "libpq-fe.h"

static void
exit_nicely(PGconn *conn)
{
  PQfinish(conn);
  exit(1);
}

int
main(int argc, char **argv)
{
  const char *conninfo;
  PGconn *conn;
  PGRresult *res;

  

PGnotify *notify;
int nnotifies;

/*
 * If the user supplies a parameter on the command line, use it as the
 * conninfo string; otherwise default to setting dbname=postgres and using
 * environment variables or defaults for all other connection parameters.
 */
if (argc > 1)
    conninfo = argv[1];
else
    conninfo = "dbname = postgres";

/* Make a connection to the database */
conn = PQconnectdb(conninfo);

/* Check to see that the backend connection was successfully made */
if (PQstatus(conn) != CONNECTION_OK)
{
    fprintf(stderr, "Connection to database failed: %s",
                    PQerrorMessage(conn));
    exit_nicely(conn);
}

/*
 * Issue LISTEN command to enable notifications from the rule’s NOTIFY.
 */
res = PQexec(conn, "LISTEN TBL2");
if (PQresultStatus(res) != PGRES_COMMAND_OK)
{
    fprintf(stderr, "LISTEN command failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}

/*
 * should PQclear PGresult whenever it is no longer needed to avoid memory
 * leaks
 */
PQclear(res);

/* Quit after four notifies are received. */
nnotifies = 0;
while (nnotifies < 4)
{
    /*
     * Sleep until something happens on the connection. We use select(2)
     * to wait for input, but you could also use poll() or similar
     * facilities.
    */
    int sock;
    fd_set input_mask;

    sock = PQsocket(conn);

    if (sock < 0)
        break;  /* shouldn’t happen */
FD_ZERO(&input_mask);
FD_SET(sock, &input_mask);

if (select(sock + 1, &input_mask, NULL, NULL, NULL) < 0)
{
    fprintf(stderr, "select() failed: %s\n", strerror(errno));
    exit_nicely(conn);
}

/* Now check for input */
PQconsumeInput(conn);
while ((notify = PQnotifies(conn)) != NULL)
{
    fprintf(stderr,
            "ASYNC NOTIFY of '%s' received from backend pid %d\n",
            notify->relname, notify->be_pid);
    PQfreemem(notify);
    nnotifies++;
}

fprintf(stderr, "Done.\n");

/* close the connection to the database and cleanup */
PQfinish(conn);
return 0;
}

Example 30-3. libpq Example Program 3

/*
 * testlibpq3.c
 * Test out-of-line parameters and binary I/O.
 * Before running this, populate a database with the following commands
 * (provided in src/test/examples/testlibpq3.sql):
 * CREATE TABLE test1 (i int4, t text, b bytea);
 * INSERT INTO test1 values (1, 'joe"s place', '\000\001\002\003\004');
 * INSERT INTO test1 values (2, 'ho there', '\004\003\002\001\000');
 * The expected output is:
 * tuple 0: got
 * i = (4 bytes) 1
 * t = (11 bytes) 'joe’s place'
 * b = (5 bytes) \000\001\002\003\004
 * tuple 0: got
 * i = (4 bytes) 2
 * t = (8 bytes) ‘ho there’
 * b = (5 bytes) \004\003\002\001\000
 */
#include <stdio.h>
Chapter 30. libpq - C Library

```c
#include <stdlib.h>
#include <string.h>
#include <sys/types.h>
#include "libpq-fe.h"
/* for ntohl/htonl */
#include <netinet/in.h>
#include <arpa/inet.h>

static void
exit_nicely(PGconn *conn)
{
    PQfinish(conn);
    exit(1);
}

/*
 * This function prints a query result that is a binary-format fetch from
 * a table defined as in the comment above. We split it out because the
 * main() function uses it twice.
 */
static void
show_binary_results(PGresult *res)
{
    int i,
        j;
    int i_fnum,
        t_fnum,
        b_fnum;

    /* Use PQfnumber to avoid assumptions about field order in result */
    i_fnum = PQfnumber(res, "i");
    t_fnum = PQfnumber(res, "t");
    b_fnum = PQfnumber(res, "b");

    for (i = 0; i < PQntuples(res); i++)
    {
        char  *iptr;
        char  *tptr;
        char  *bptr;
        int    blen;
        int    ival;

        /* Get the field values (we ignore possibility they are null!) */
        iptr = PQgetvalue(res, i, i_fnum);
        tptr = PQgetvalue(res, i, t_fnum);
        bptr = PQgetvalue(res, i, b_fnum);

        /*
         * The binary representation of INT4 is in network byte order, which
         * we’d better coerce to the local byte order.
         */
        ival = ntohl(*((uint32_t *) iptr));

        /*
         * The binary representation of TEXT is, well, text, and since libpq
         */
    }
}
```
was nice enough to append a zero byte to it, it’ll work just fine
as a C string.

The binary representation of BYTEA is a bunch of bytes, which could
include embedded nulls so we have to pay attention to field length.

```c
blen = PQgetlength(res, i, b_fnum);

printf("tuple %d: got
", i);
printf(" i = (%d bytes) %d
", PQgetlength(res, i, i_fnum), ival);
printf(" t = (%d bytes) '%s'\n", PQgetlength(res, i, t_fnum), tptr);
printf(" b = (%d bytes) ", blen);
for (j = 0; j < blen; j++)
    printf("\%03o", bptr[j]);

```

```c
int
main(int argc, char **argv)
{
    const char *conninfo;
    PGconn *conn;
    PGresult *res;
    const char *paramValues[1];
    int paramLengths[1];
    int paramFormats[1];
    uint32_t binaryIntVal;

    /*
    * If the user supplies a parameter on the command line, use it as the
    * conninfo string; otherwise default to setting dbname=postgres and using
    * environment variables or defaults for all other connection parameters.
    */
    if (argc > 1)
        conninfo = argv[1];
    else
        conninfo = "dbname = postgres";

    /* Make a connection to the database */
    conn = PQconnectdb(conninfo);

    /* Check to see that the backend connection was successfully made */
    if (PQstatus(conn) != CONNECTION_OK)
    {
        fprintf(stderr, "Connection to database failed: $s",
                PQerrorMessage(conn));
        exit_nicely(conn);
    }

    /*
    * The point of this program is to illustrate use of PQexecParams() with
    * out-of-line parameters, as well as binary transmission of data.
    */
    * This first example transmits the parameters as text, but receives the
```
results in binary format. By using out-of-line parameters we can
* avoid a lot of tedious mucking about with quoting and escaping, even
* though the data is text. Notice how we don’t have to do anything
* special with the quote mark in the parameter value.
*
/* Here is our out-of-line parameter value */
paramValues[0] = "joe's place";

res = PQexecParams(conn,
    "SELECT * FROM test1 WHERE t = $1",
    1, /* one param */
    NULL, /* let the backend deduce param type */
    paramValues,
    NULL, /* don’t need param lengths since text */
    NULL, /* default to all text params */
    1); /* ask for binary results */

if (PQresultStatus(res) != PGRES_TUPLES_OK)
{
    fprintf(stderr, "SELECT failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}

show_binary_results(res);

PQclear(res);

/*
 * In this second example we transmit an integer parameter in binary
 * form, and again retrieve the results in binary form.
 *
 * Although we tell PQexecParams we are letting the backend deduce
 * parameter type, we really force the decision by casting the parameter
 * symbol in the query text. This is a good safety measure when sending
 * binary parameters.
 */

/* Convert integer value "2" to network byte order */
binaryIntVal = htonl((uint32_t) 2);

/* Set up parameter arrays for PQexecParams */
paramValues[0] = (char *) &binaryIntVal;
paramLengths[0] = sizeof(binaryIntVal);
paramFormats[0] = 1; /* binary */

res = PQexecParams(conn,
    "SELECT * FROM test1 WHERE i = $1::int4",
    1, /* one param */
    NULL, /* let the backend deduce param type */
    paramValues,
    paramLengths,
    paramFormats,
    1); /* ask for binary results */

if (PQresultStatus(res) != PGRES_TUPLES_OK)
{ 
    fprintf(stderr, "SELECT failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}

show_binary_results(res);

PQclear(res);

/* close the connection to the database and cleanup */
PQfinish(conn);

return 0;
}
Chapter 31. Large Objects

PostgreSQL has a large object facility, which provides stream-style access to user data that is stored in a special large-object structure. Streaming access is useful when working with data values that are too large to manipulate conveniently as a whole.

This chapter describes the implementation and the programming and query language interfaces to PostgreSQL large object data. We use the libpq C library for the examples in this chapter, but most programming interfaces native to PostgreSQL support equivalent functionality. Other interfaces might use the large object interface internally to provide generic support for large values. This is not described here.

31.1. Introduction

All large objects are placed in a single system table called `pg_largeobject`. PostgreSQL also supports a storage system called “TOAST” that automatically stores values larger than a single database page into a secondary storage area per table. This makes the large object facility partially obsolete. One remaining advantage of the large object facility is that it allows values up to 2 GB in size, whereas TOASTed fields can be at most 1 GB. Also, large objects can be randomly modified using a read/write API that is more efficient than performing such operations using TOAST.

31.2. Implementation Features

The large object implementation breaks large objects up into “chunks” and stores the chunks in rows in the database. A B-tree index guarantees fast searches for the correct chunk number when doing random access reads and writes.

31.3. Client Interfaces

This section describes the facilities that PostgreSQL client interface libraries provide for accessing large objects. All large object manipulation using these functions must take place within an SQL transaction block. The PostgreSQL large object interface is modeled after the Unix file-system interface, with analogues of `open`, `read`, `write`, `lseek`, etc.

Client applications which use the large object interface in libpq should include the header file `libpq/libpq-fs.h` and link with the libpq library.

31.3.1. Creating a Large Object

The function

```c
Oid lo_creat(PGconn *conn, int mode);
```

creates a new large object. The return value is the OID that was assigned to the new large object, or `InvalidOid` (zero) on failure. `mode` is unused and ignored as of PostgreSQL 8.1; however, for backwards compatibility with earlier releases it is best to set it to `INV_READ`, `INV_WRITE`, or `INV_READ | INV_WRITE`. (These symbolic constants are defined in the header file `libpq/libpq-fs.h`.)
Chapter 31. Large Objects

An example:

```c
inv_oid = lo_creat(conn, INV_READ|INV_WRITE);
```

The function

```c
Oid lo_create(PGconn *conn, Oid lobjId);
```

also creates a new large object. The OID to be assigned can be specified by `lobjId`; if so, failure occurs if that OID is already in use for some large object. If `lobjId` is `InvalidOid` (zero) then `lo_create` assigns an unused OID (this is the same behavior as `lo_creat`). The return value is the OID that was assigned to the new large object, or `InvalidOid` (zero) on failure.

`lo_create` is new as of PostgreSQL 8.1; if this function is run against an older server version, it will fail and return `InvalidOid`.

An example:

```c
inv_oid = lo_create(conn, desired_oid);
```

31.3.2. Importing a Large Object

To import an operating system file as a large object, call

```c
Oid lo_import(PGconn *conn, const char *filename);
```

`filename` specifies the operating system name of the file to be imported as a large object. The return value is the OID that was assigned to the new large object, or `InvalidOid` (zero) on failure. Note that the file is read by the client interface library, not by the server; so it must exist in the client file system and be readable by the client application.

The function

```c
Oid lo_import_with_oid(PGconn *conn, const char *filename, Oid lobjId);
```

also imports a new large object. The OID to be assigned can be specified by `lobjId`; if so, failure occurs if that OID is already in use for some large object. If `lobjId` is `InvalidOid` (zero) then `lo_import_with_oid` assigns an unused OID (this is the same behavior as `lo_import`). The return value is the OID that was assigned to the new large object, or `InvalidOid` (zero) on failure.

`lo_import_with_oid` is new as of PostgreSQL 8.4 and uses `lo_create` internally which is new in 8.1; if this function is run against 8.0 or before, it will fail and return `InvalidOid`.

31.3.3. Exporting a Large Object

To export a large object into an operating system file, call

```c
int lo_export(PGconn *conn, Oid lobjId, const char *filename);
```

The `lobjId` argument specifies the OID of the large object to export and the `filename` argument specifies the operating system name of the file. Note that the file is written by the client interface library, not by the server. Returns 1 on success, -1 on failure.
31.3.4. Opening an Existing Large Object

To open an existing large object for reading or writing, call

```c
int lo_open(PGconn *conn, Oid lobjId, int mode);
```

The `lobjId` argument specifies the OID of the large object to open. The `mode` bits control whether the object is opened for reading (INV_READ), writing (INV_WRITE), or both. (These symbolic constants are defined in the header file `libpq/libpq-fs.h`.) A large object cannot be opened before it is created. `lo_open` returns a (non-negative) large object descriptor for later use in `lo_read`, `lo_write`, `lo_lseek`, `lo_tell`, and `lo_close`. The descriptor is only valid for the duration of the current transaction. On failure, -1 is returned.

The server currently does not distinguish between modes INV_WRITE and INV_READ | INV_WRITE: you are allowed to read from the descriptor in either case. However there is a significant difference between these modes and INV_READ alone: with INV_READ you cannot write on the descriptor, and the data read from it will reflect the contents of the large object at the time of the transaction snapshot that was active when `lo_open` was executed, regardless of later writes by this or other transactions. Reading from a descriptor opened with INV_WRITE returns data that reflects all writes of other committed transactions as well as writes of the current transaction. This is similar to the behavior of SERIALIZABLE versus READ COMMITTED transaction modes for ordinary SQL SELECT commands.

An example:

```c
inv_fd = lo_open(conn, inv_oid, INV_READ|INV_WRITE);
```

31.3.5. Writing Data to a Large Object

The function

```c
int lo_write(PGconn *conn, int fd, const char *buf, size_t len);
```

writes `len` bytes from `buf` to large object descriptor `fd`. The `fd` argument must have been returned by a previous `lo_open`. The number of bytes actually written is returned. In the event of an error, the return value is negative.

31.3.6. Reading Data from a Large Object

The function

```c
int lo_read(PGconn *conn, int fd, char *buf, size_t len);
```

reads `len` bytes from large object descriptor `fd` into `buf`. The `fd` argument must have been returned by a previous `lo_open`. The number of bytes actually read is returned. In the event of an error, the return value is negative.

31.3.7. Seeking in a Large Object

To change the current read or write location associated with a large object descriptor, call

```c
int lo_lseek(PGconn *conn, int fd, int offset, int whence);
```
This function moves the current location pointer for the large object descriptor identified by \( fd \) to the new location specified by \( offset \). The valid values for \( whence \) are \texttt{SEEK_SET} (seek from object start), \texttt{SEEK_CUR} (seek from current position), and \texttt{SEEK_END} (seek from object end). The return value is the new location pointer, or -1 on error.

### 31.3.8. Obtaining the Seek Position of a Large Object

To obtain the current read or write location of a large object descriptor, call

\[
\text{int lo_tell(PGconn *conn, int fd);}
\]

If there is an error, the return value is negative.

### 31.3.9. Truncating a Large Object

To truncate a large object to a given length, call

\[
\text{int lo_truncate(PGconn *conn, int fd, size_t len);}
\]

truncates the large object descriptor \( fd \) to length \( len \). The \( fd \) argument must have been returned by a previous \texttt{lo_open}. If \( len \) is greater than the current large object length, the large object is extended with null bytes ("\0").

The file offset is not changed.

On success \texttt{lo_truncate} returns zero. On error, the return value is negative.

\texttt{lo_truncate} is new as of PostgreSQL 8.3; if this function is run against an older server version, it will fail and return a negative value.

### 31.3.10. Closing a Large Object Descriptor

A large object descriptor can be closed by calling

\[
\text{int lo_close(PGconn *conn, int fd);}
\]

where \( fd \) is a large object descriptor returned by \texttt{lo_open}. On success, \texttt{lo_close} returns zero. On error, the return value is negative.

Any large object descriptors that remain open at the end of a transaction will be closed automatically.

### 31.3.11. Removing a Large Object

To remove a large object from the database, call

\[
\text{int lo_unlink(PGconn *conn, Oid lobjId);} \]

The \( lobjId \) argument specifies the OID of the large object to remove. Returns 1 if successful, -1 on failure.
31.4. Server-Side Functions

There are server-side functions callable from SQL that correspond to each of the client-side functions described above; indeed, for the most part the client-side functions are simply interfaces to the equivalent server-side functions. The ones that are actually useful to call via SQL commands are `lo_creat`, `lo_create`, `lo_unlink`, `lo_import`, and `lo_export`. Here are examples of their use:

```sql
CREATE TABLE image (
    name text,
    raster oid
);

SELECT lo_creat(-1); -- returns OID of new, empty large object

SELECT lo_create(43213); -- attempts to create large object with OID 43213

SELECT lo_unlink(173454); -- deletes large object with OID 173454

INSERT INTO image (name, raster)
VALUES ('beautiful image', lo_import('/etc/motd'));

INSERT INTO image (name, raster) -- same as above, but specify OID to use
VALUES ('beautiful image', lo_import('/etc/motd', 68583));

SELECT lo_export(image.raster, '/tmp/motd') FROM image
WHERE name = 'beautiful image';
```

The server-side `lo_import` and `lo_export` functions behave considerably differently from their client-side analogs. These two functions read and write files in the server’s file system, using the permissions of the database’s owning user. Therefore, their use is restricted to superusers. In contrast, the client-side import and export functions read and write files in the client’s file system, using the permissions of the client program. The client-side functions can be used by any PostgreSQL user.

The functionality of `lo_read` and `lo_write` is also available via server-side calls, but the names of the server-side functions differ from the client side interfaces in that they do not contain underscores. You must call these functions as `loread` and `lowrite`.

31.5. Example Program

Example 31-1 is a sample program which shows how the large object interface in libpq can be used. Parts of the program are commented out but are left in the source for the reader’s benefit. This program can also be found in `src/test/examples/testlo.c` in the source distribution.

Example 31-1. Large Objects with libpq Example Program

```c
/*------------------------------------------------------------
* testlo.c--
* test using large objects with libpq
* Copyright (c) 1994, Regents of the University of California
*/
```
Chapter 31. Large Objects

#include <stdio.h>
#include "libpq-fe.h"
#include "libpq/libpq-fs.h"

#define BUFSIZE 1024

/*
 * importFile
 * import file "in_filename" into database as large object "lobjOid"
 *
 */

Oid importFile(PGconn *conn, char *filename)
{
    Oid lobjId;
    int lobj_fd;
    char buf[BUFSIZE];
    int nbytes,
        tmp;
    int fd;

    /*
    * open the file to be read in
    */
    fd = open(filename, O_RDONLY, 0666);
    if (fd < 0)
    { /* error */
        fprintf(stderr, "cannot open unix file %s\n", filename);
    }

    /*
    * create the large object
    */
    lobjId = lo_creat(conn, INV_READ | INV_WRITE);
    if (lobjId == 0)
        fprintf(stderr, "cannot create large object\n");

    lobj_fd = lo_open(conn, lobjId, INV_WRITE);

    /*
    * read in from the Unix file and write to the inversion file
    */
    while ((nbytes = read(fd, buf, BUFSIZE)) > 0)
    {
        tmp = lo_write(conn, lobj_fd, buf, nbytes);
        if (tmp < nbytes)
            fprintf(stderr, "error while reading large object\n");
    }

    (void) close(fd);
    (void) lo_close(conn, lobj_fd);

    return lobjId;
}

void
pickout(PGconn *conn, Oid lobjId, int start, int len)
{
    int lobj_fd;
    char *buf;
    int nbytes;
    int nread;

    lobj_fd = lo_open(conn, lobjId, INV_READ);
    if (lobj_fd < 0)
    {
        fprintf(stderr, "cannot open large object %d\n", lobjId);
    }

    lo_lseek(conn, lobj_fd, start, SEEK_SET);
    buf = malloc(len + 1);
    nread = 0;
    while (len - nread > 0)
    {
        nbytes = lo_read(conn, lobj_fd, buf, len - nread);
        buf[nbytes] = ' ';  /* to prevent being interrupted on EOF */
        fprintf(stderr, ">>> %s", buf);
        nread += nbytes;
    }
    free(buf);
    fprintf(stderr, "\n");
    lo_close(conn, lobj_fd);
}

overwrite(PGconn *conn, Oid lobjId, int start, int len)
{
    int lobj_fd;
    char *buf;
    int nbytes;
    int nwritten;
    int i;

    lobj_fd = lo_open(conn, lobjId, INV_WRITE);
    if (lobj_fd < 0)
    {
        fprintf(stderr, "cannot open large object %d\n", lobjId);
    }

    lo_lseek(conn, lobj_fd, start, SEEK_SET);
    buf = malloc(len + 1);
    nwritten = 0;
    while (len - nwritten > 0)
    {
        nbytes = lo_write(conn, lobj_fd, buf + nwritten, len - nwritten);
    }
}
Chapter 31. Large Objects

```c
nwritten += nbytes;
}
free(buf);
fprintf(stderr, "\n");
lo_close(conn, lobj_fd);
}

/*
 * exportFile
 * export large object "lobjOid" to file "out_filename"
 */
void exportFile(PGconn *conn, Oid lobjId, char *filename)
{
    int lobj_fd;
    char buf[BUFSIZE];
    int nbytes,
        tmp;
    int fd;

Chapter 32. ECPG - Embedded SQL in C

This chapter describes the embedded SQL package for PostgreSQL. It was written by Linus Tolke (<linus@epact.se>) and Michael Meskes (<meskes@postgresql.org>). Originally it was written to work with C. It also works with C++, but it does not recognize all C++ constructs yet.

This documentation is quite incomplete. But since this interface is standardized, additional information can be found in many resources about SQL.

32.1. The Concept

An embedded SQL program consists of code written in an ordinary programming language, in this case C, mixed with SQL commands in specially marked sections. To build the program, the source code is first passed through the embedded SQL preprocessor, which converts it to an ordinary C program, and afterwards it can be processed by a C compiler.

Embedded SQL has advantages over other methods for handling SQL commands from C code. First, it takes care of the tedious passing of information to and from variables in your C program. Second, the SQL code in the program is checked at build time for syntactical correctness. Third, embedded SQL in C is specified in the SQL standard and supported by many other SQL database systems. The PostgreSQL implementation is designed to match this standard as much as possible, and it is usually possible to port embedded SQL programs written for other SQL databases to PostgreSQL with relative ease.

As already stated, programs written for the embedded SQL interface are normal C programs with special code inserted to perform database-related actions. This special code always has the form:

```
EXEC SQL ...
```

These statements syntactically take the place of a C statement. Depending on the particular statement, they can appear at the global level or within a function. Embedded SQL statements follow the case-sensitivity rules of normal SQL code, and not those of C.

The following sections explain all the embedded SQL statements.

32.2. Connecting to the Database Server

One connects to a database using the following statement:

```
EXEC SQL CONNECT TO target [AS connection-name] [USER user-name];
```

The `target` can be specified in the following ways:

- `dbname[@hostname][:port]`
- `tcp:postgresql://hostname[:port]/dbname[?options]`
- `unix:postgresql://hostname[:port]/dbname[?options]`
- an SQL string literal containing one of the above forms
- a reference to a character variable containing one of the above forms (see examples)
- DEFAULT
If you specify the connection target literally (that is, not through a variable reference) and you don’t quote the value, then the case-insensitivity rules of normal SQL are applied. In that case you can also double-quote the individual parameters separately as needed. In practice, it is probably less error-prone to use a (single-quoted) string literal or a variable reference. The connection target `DEFAULT` initiates a connection to the default database under the default user name. No separate user name or connection name can be specified in that case.

There are also different ways to specify the user name:

- `username`
- `username/password`
- `username IDENTIFIED BY password`
- `username USING password`

As above, the parameters `username` and `password` can be an SQL identifier, an SQL string literal, or a reference to a character variable.

The connection-name is used to handle multiple connections in one program. It can be omitted if a program uses only one connection. The most recently opened connection becomes the current connection, which is used by default when an SQL statement is to be executed (see later in this chapter).

Here are some examples of `CONNECT` statements:

```sql
EXEC SQL CONNECT TO mydb@sql.mydomain.com;
EXEC SQL CONNECT TO unix:postgresql://sql.mydomain.com/mydb AS myconnection USER john;
EXEC SQL BEGIN DECLARE SECTION;
const char *target = "mydb@sql.mydomain.com";
const char *user = "john";
EXEC SQL END DECLARE SECTION;
EXEC SQL CONNECT TO :target USER :user;
```

The last form makes use of the variant referred to above as character variable reference. You will see in later sections how C variables can be used in SQL statements when you prefix them with a colon.

Be advised that the format of the connection target is not specified in the SQL standard. So if you want to develop portable applications, you might want to use something based on the last example above to encapsulate the connection target string somewhere.

### 32.3. Closing a Connection

To close a connection, use the following statement:

```sql
EXEC SQL DISCONNECT [connection];
```

The `connection` can be specified in the following ways:

- `connection-name`
- `DEFAULT`
If no connection name is specified, the current connection is closed.

It is good style that an application always explicitly disconnect from every connection it opened.

### 32.4. Running SQL Commands

Any SQL command can be run from within an embedded SQL application. Below are some examples of how to do that.

#### Creating a table:

EXEC SQL CREATE TABLE foo (number integer, ascii char(16));
EXEC SQL CREATE UNIQUE INDEX num1 ON foo(number);
EXEC SQL COMMIT;

#### Inserting rows:

EXEC SQL INSERT INTO foo (number, ascii) VALUES (9999, 'doodad');
EXEC SQL COMMIT;

#### Deleting rows:

EXEC SQL DELETE FROM foo WHERE number = 9999;
EXEC SQL COMMIT;

#### Single-row select:

EXEC SQL SELECT foo INTO :FooBar FROM table1 WHERE ascii = 'doodad';

#### Select using cursors:

EXEC SQL DECLARE foo_bar CURSOR FOR
    SELECT number, ascii FROM foo
    ORDER BY ascii;
EXEC SQL OPEN foo_bar;
EXEC SQL FETCH foo_bar INTO :FooBar, DooDad;
...
EXEC SQL CLOSE foo_bar;
EXEC SQL COMMIT;

#### Updates:

EXEC SQL UPDATE foo
    SET ascii = 'foobar'
    WHERE number = 9999;
EXEC SQL COMMIT;
Chapter 32. ECPG - Embedded SQL in C

32.5. Choosing a Connection

The SQL statements shown in the previous section are executed on the current connection, that is, the most recently opened one. If an application needs to manage multiple connections, then there are two ways to handle this.

The first option is to explicitly choose a connection for each SQL statement, for example:

EXEC SQL AT connection-name SELECT ...;

This option is particularly suitable if the application needs to use several connections in mixed order. If your application uses multiple threads of execution, they cannot share a connection concurrently. You must either explicitly control access to the connection (using mutexes) or use a connection for each thread. If each thread uses its own connection, you will need to use the AT clause to specify which connection the thread will use.

The second option is to execute a statement to switch the current connection. That statement is:

EXEC SQL SET CONNECTION connection-name;

This option is particularly convenient if many statements are to be executed on the same connection. It is not thread-aware.

32.6. Using Host Variables

In Section 32.4 you saw how you can execute SQL statements from an embedded SQL program. Some of those statements only used fixed values and did not provide a way to insert user-supplied values into statements or have the program process the values returned by the query. Those kinds of statements are not really useful in real applications. This section explains in detail how you can pass data between your C program and the embedded SQL statements using a simple mechanism called host variables. In an embedded SQL program we consider the SQL statements to be guests in the C program code which is the host language. Therefore the variables of the C program are called host variables.

32.6.1. Overview

Passing data between the C program and the SQL statements is particularly simple in embedded SQL. Instead of having the program paste the data into the statement, which entails various complications,
such as properly quoting the value, you can simply write the name of a C variable into the SQL statement, prefixed by a colon. For example:

```c
EXEC SQL INSERT INTO sometable VALUES (:v1, 'foo', :v2);
```

This statement refers to two C variables named `v1` and `v2` and also uses a regular SQL string literal, to illustrate that you are not restricted to use one kind of data or the other.

This style of inserting C variables in SQL statements works anywhere a value expression is expected in an SQL statement.

### 32.6.2. Declare Sections

To pass data from the program to the database, for example as parameters in a query, or to pass data from the database back to the program, the C variables that are intended to contain this data need to be declared in specially marked sections, so the embedded SQL preprocessor is made aware of them.

This section starts with:

```c
EXEC SQL BEGIN DECLARE SECTION;
```

and ends with:

```c
EXEC SQL END DECLARE SECTION;
```

Between those lines, there must be normal C variable declarations, such as:

```c
int x = 4;
char foo[16], bar[16];
```

As you can see, you can optionally assign an initial value to the variable. The variable’s scope is determined by the location of its declaring section within the program. You can also declare variables with the following syntax which implicitly creates a declare section:

```c
EXEC SQL int i = 4;
```

You can have as many declare sections in a program as you like.

The declarations are also echoed to the output file as normal C variables, so there’s no need to declare them again. Variables that are not intended to be used in SQL commands can be declared normally outside these special sections.

The definition of a structure or union also must be listed inside a `DECLARE` section. Otherwise the preprocessor cannot handle these types since it does not know the definition.

### 32.6.3. Different types of host variables

As a host variable you can also use arrays, typedefs, structs and pointers. Moreover there are special types of host variables that exist only in ECPG.

A few examples on host variables:
Arrays

One of the most common uses of an array declaration is probably the allocation of a char array as in:

EXEC SQL BEGIN DECLARE SECTION;
char str[50];
EXEC SQL END DECLARE SECTION;

Note that you have to take care of the length for yourself. If you use this host variable as the target variable of a query which returns a string with more than 49 characters, a buffer overflow occurs.

Typedefs

Use the typedef keyword to map new types to already existing types.

EXEC SQL BEGIN DECLARE SECTION;
typedef char mychartype[40];
typedef long serial_t;
EXEC SQL END DECLARE SECTION;

Note that you could also use:

EXEC SQL TYPE serial_t IS long;

This declaration does not need to be part of a declare section.

Pointers

You can declare pointers to the most common types. Note however that you cannot use pointers as target variables of queries without auto-allocation. See Section 32.10 for more information on auto-allocation.

EXEC SQL BEGIN DECLARE SECTION;
int *intp;
char **charp;
EXEC SQL END DECLARE SECTION;

Special types of variables

ECPG contains some special types that help you to interact easily with data from the SQL server. For example it has implemented support for the varchar, numeric, date, timestamp, and interval types. Section 32.8 contains basic functions to deal with those types, such that you do not need to send a query to the SQL server just for adding an interval to a timestamp for example.

The special type VARCHAR is converted into a named struct for every variable. A declaration like:

VARCHAR var[180];

is converted into:

struct varchar_var { int len; char arr[180]; } var;

This structure is suitable for interfacing with SQL datums of type varchar.

32.6.4. SELECT INTO and FETCH INTO

Now you should be able to pass data generated by your program into an SQL command. But how do you retrieve the results of a query? For that purpose, embedded SQL provides special variants of the usual commands SELECT and FETCH. These commands have a special INTO clause that specifies which host variables the retrieved values are to be stored in.
Here is an example:

```c
/*
 * assume this table:
 * CREATE TABLE test1 (a int, b varchar(50));
 */

EXEC SQL BEGIN DECLARE SECTION;
int v1;
VARCHAR v2;
EXEC SQL END DECLARE SECTION;
...
EXEC SQL SELECT a, b INTO :v1, :v2 FROM test;

So the INTO clause appears between the select list and the FROM clause. The number of elements in
the select list and the list after INTO (also called the target list) must be equal.

Here is an example using the command FETCH:

EXEC SQL BEGIN DECLARE SECTION;
int v1;
VARCHAR v2;
EXEC SQL END DECLARE SECTION;
...
EXEC SQL DECLARE foo CURSOR FOR SELECT a, b FROM test;
...
do {
    ...
    EXEC SQL FETCH NEXT FROM foo INTO :v1, :v2;
    ...
} while (...);

Here the INTO clause appears after all the normal clauses.

Both of these methods only allow retrieving one row at a time. If you need to process result sets that
potentially contain more than one row, you need to use a cursor, as shown in the second example.

32.6.5. Indicators

The examples above do not handle null values. In fact, the retrieval examples will raise an error if
they fetch a null value from the database. To be able to pass null values to the database or retrieve
null values from the database, you need to append a second host variable specification to each host
variable that contains data. This second host variable is called the indicator and contains a flag that
tells whether the datum is null, in which case the value of the real host variable is ignored. Here is an
example that handles the retrieval of null values correctly:

EXEC SQL BEGIN DECLARE SECTION;
VARCHAR val;
int val_ind;
EXEC SQL END DECLARE SECTION;
```
EXEC SQL SELECT b INTO :val :val_ind FROM test1;

The indicator variable val_ind will be zero if the value was not null, and it will be negative if the value was null.

The indicator has another function: if the indicator value is positive, it means that the value is not null, but it was truncated when it was stored in the host variable.

32.7. Dynamic SQL

In many cases, the particular SQL statements that an application has to execute are known at the time the application is written. In some cases, however, the SQL statements are composed at run time or provided by an external source. In these cases you cannot embed the SQL statements directly into the C source code, but there is a facility that allows you to call arbitrary SQL statements that you provide in a string variable.

The simplest way to execute an arbitrary SQL statement is to use the command EXECUTE IMMEDIATE. For example:

EXEC SQL BEGIN DECLARE SECTION;
const char *stmt = "CREATE TABLE test1 (...);");"
EXEC SQL END DECLARE SECTION;
EXEC SQL EXECUTE IMMEDIATE :stmt;

You cannot execute statements that retrieve data (e.g., SELECT) this way.

A more powerful way to execute arbitrary SQL statements is to prepare them once and execute the prepared statement as often as you like. It is also possible to prepare a generalized version of a statement and then execute specific versions of it by substituting parameters. When preparing the statement, write question marks where you want to substitute parameters later. For example:

EXEC SQL BEGIN DECLARE SECTION;
const char *stmt = "INSERT INTO test1 VALUES(?, ?);";
EXEC SQL END DECLARE SECTION;
EXEC SQL PREPARE mystmt FROM :stmt;
...
EXEC SQL EXECUTE mystmt USING 42, 'foobar';

If the statement you are executing returns values, then add an INTO clause:

EXEC SQL BEGIN DECLARE SECTION;
const char *stmt = "SELECT a, b, c FROM test1 WHERE a > ?";
int v1, v2;
VARCHAR v3;
EXEC SQL END DECLARE SECTION;
EXEC SQL PREPARE mystmt FROM :stmt;
...
EXEC SQL EXECUTE mystmt INTO v1, v2, v3 USING 37;
An `EXECUTE` command can have an `INTO` clause, a `USING` clause, both, or neither. When you don’t need the prepared statement anymore, you should deallocate it:

```sql
EXEC SQL DEALLOCATE PREPARE name;
```

### 32.8. pgtypes library

The `pgtypes` library maps PostgreSQL database types to C equivalents that can be used in C programs. It also offers functions to do basic calculations with those types within C, i.e., without the help of the PostgreSQL server. See the following example:

```sql
EXEC SQL BEGIN DECLARE SECTION;
    date date1;
    timestamp ts1, tsout;
    interval iv1;
    char *out;
EXEC SQL END DECLARE SECTION;

PGTYPESdate_today(&date1);
EXEC SQL SELECT started, duration INTO :ts1, :iv1 FROM datetbl WHERE d=:date1;
PGTYPEStimestamp_add_interval(&ts1, &iv1, &tsout);
out = PGTYPEStimestamp_to_asc(&tsout);
printf("Started + duration: %s\n", out);
free(out);
```

#### 32.8.1. The numeric type

The numeric type offers to do calculations with arbitrary precision. See Section 8.1 for the equivalent type in the PostgreSQL server. Because of the arbitrary precision this variable needs to be able to expand and shrink dynamically. That’s why you can only create variables on the heap by means of the `PGTYPESnumeric_new` and `PGTYPESnumeric_free` functions. The decimal type, which is similar but limited in the precision, can be created on the stack as well as on the heap.

The following functions can be used to work with the numeric type:

```c
PGTYPESnumeric_new
    Request a pointer to a newly allocated numeric variable.
    numeric *PGTYPESnumeric_new(void);

PGTYPESnumeric_free
    Free a numeric type, release all of its memory.
    void PGTYPESnumeric_free(numeric *var);

PGTYPESnumeric_from_asc
    Parse a numeric type from its string notation.
    numeric *PGTYPESnumeric_from_asc(char *str, char **endptr);
```
Valid formats are for example: -2.794, +3.44, 592.49E07 or -32.84e-4. If the value could be parsed successfully, a valid pointer is returned, else the NULL pointer. At the moment ecpg always parses the complete string and so it currently does not support to store the address of the first invalid character in *endptr. You can safely set endptr to NULL.

`PGTYPESnumeric_to_asc`

- Returns a pointer to a string allocated by malloc that contains the string representation of the numeric type num.
- char *PGTYPESnumeric_to_asc(numeric *num, int dscale);
- The numeric value will be printed with dscale decimal digits, with rounding applied if necessary.

`PGTYPESnumeric_add`

- Add two numeric variables into a third one.
- int PGTYPESnumeric_add(numeric *var1, numeric *var2, numeric *result);
- The function adds the variables var1 and var2 into the result variable result. The function returns 0 on success and -1 in case of error.

`PGTYPESnumeric_sub`

- Subtract two numeric variables and return the result in a third one.
- int PGTYPESnumeric_sub(numeric *var1, numeric *var2, numeric *result);
- The function subtracts the variable var2 from the variable var1. The result of the operation is stored in the variable result. The function returns 0 on success and -1 in case of error.

`PGTYPESnumeric_mul`

- Multiply two numeric variables and return the result in a third one.
- int PGTYPESnumeric_mul(numeric *var1, numeric *var2, numeric *result);
- The function multiplies the variables var1 and var2. The result of the operation is stored in the variable result. The function returns 0 on success and -1 in case of error.

`PGTYPESnumeric_div`

- Divide two numeric variables and return the result in a third one.
- int PGTYPESnumeric_div(numeric *var1, numeric *var2, numeric *result);
- The function divides the variables var1 by var2. The result of the operation is stored in the variable result. The function returns 0 on success and -1 in case of error.

`PGTYPESnumeric_cmp`

- Compare two numeric variables.
- int PGTYPESnumeric_cmp(numeric *var1, numeric *var2)
- This function compares two numeric variables. In case of error, INT_MAX is returned. On success, the function returns one of three possible results:
  - 1, if var1 is bigger than var2
  - -1, if var1 is smaller than var2
  - 0, if var1 and var2 are equal

`PGTYPESnumeric_from_int`

- Convert an int variable to a numeric variable.
- int PGTYPESnumeric_from_int(signed int int_val, numeric *var);
This function accepts a variable of type signed int and stores it in the numeric variable \texttt{var}. Upon success, 0 is returned and -1 in case of a failure.

\texttt{PGTYPESnumeric\_from\_long}

Convert a long int variable to a numeric variable.

\begin{verbatim}
int PGTYPESnumeric_from_long(signed long int long_val, numeric *var);
\end{verbatim}

This function accepts a variable of type signed long int and stores it in the numeric variable \texttt{var}. Upon success, 0 is returned and -1 in case of a failure.

\texttt{PGTYPESnumeric\_copy}

Copy over one numeric variable into another one.

\begin{verbatim}
int PGTYPESnumeric_copy(numeric *src, numeric *dst);
\end{verbatim}

This function copies over the value of the variable that \texttt{src} points to into the variable that \texttt{dst} points to. It returns 0 on success and -1 if an error occurs.

\texttt{PGTYPESnumeric\_from\_double}

Convert a variable of type double to a numeric.

\begin{verbatim}
int PGTYPESnumeric_from_double(double d, numeric *dst);
\end{verbatim}

This function accepts a variable of type double and stores the result in the variable that \texttt{dst} points to. It returns 0 on success and -1 if an error occurs.

\texttt{PGTYPESnumeric\_to\_double}

Convert a variable of type numeric to double.

\begin{verbatim}
int PGTYPESnumeric_to_double(numeric *nv, double *dp)
\end{verbatim}

The function converts the numeric value from the variable that \texttt{nv} points to into the double variable that \texttt{dp} points to. It returns 0 on success and -1 if an error occurs, including overflow. On overflow, the global variable \texttt{errno} will be set to \texttt{PGTYPES\_NUM\_OVERFLOW} additionally.

\texttt{PGTYPESnumeric\_to\_int}

Convert a variable of type numeric to int.

\begin{verbatim}
int PGTYPESnumeric_to_int(numeric *nv, int *ip);
\end{verbatim}

The function converts the numeric value from the variable that \texttt{nv} points to into the integer variable that \texttt{ip} points to. It returns 0 on success and -1 if an error occurs, including overflow. On overflow, the global variable \texttt{errno} will be set to \texttt{PGTYPES\_NUM\_OVERFLOW} additionally.

\texttt{PGTYPESnumeric\_to\_long}

Convert a variable of type numeric to long.

\begin{verbatim}
int PGTYPESnumeric_to_long(numeric *nv, long *ip);
\end{verbatim}

The function converts the numeric value from the variable that \texttt{nv} points to into the long integer variable that \texttt{ip} points to. It returns 0 on success and -1 if an error occurs, including overflow. On overflow, the global variable \texttt{errno} will be set to \texttt{PGTYPES\_NUM\_OVERFLOW} additionally.

\texttt{PGTYPESnumeric\_to\_decimal}

Convert a variable of type numeric to decimal.

\begin{verbatim}
int PGTYPESnumeric_to_decimal(numeric *src, decimal *dst);
\end{verbatim}

The function converts the numeric value from the variable that \texttt{src} points to into the decimal variable that \texttt{dst} points to. It returns 0 on success and -1 if an error occurs, including overflow. On overflow, the global variable \texttt{errno} will be set to \texttt{PGTYPES\_NUM\_OVERFLOW} additionally.
Chapter 32. ECPG - Embedded SQL in C

PGTYPESnumeric_from_decimal

Convert a variable of type decimal to numeric.

```c
int PGTYPESnumeric_from_decimal(decimal *src, numeric *dst);
```

The function converts the decimal value from the variable that `src` points to into the numeric variable that `dst` points to. It returns 0 on success and -1 if an error occurs. Since the decimal type is implemented as a limited version of the numeric type, overflow cannot occur with this conversion.

32.8.2. The date type

The date type in C enables your programs to deal with data of the SQL type date. See Section 8.5 for the equivalent type in the PostgreSQL server.

The following functions can be used to work with the date type:

PGTYPESdate_from_timestamp

Extract the date part from a timestamp.

```c
date PGTYPESdate_from_timestamp(timestamp dt);
```

The function receives a timestamp as its only argument and returns the extracted date part from this timestamp.

PGTYPESdate_from_asc

Parse a date from its textual representation.

```c
date PGTYPESdate_from_asc(char *str, char **endptr);
```

The function receives a C char* string `str` and a pointer to a C char* string `endptr`. At the moment ecpg always parses the complete string and so it currently does not support to store the address of the first invalid character in `*endptr`. You can safely set `endptr` to NULL.

Note that the function always assumes MDY-formatted dates and there is currently no variable to change that within ecpg.

Table 32-1 shows the allowed input formats.

</tr>
</tbody>
</table>

**PGTYPESdate_to_asc**

Return the textual representation of a date variable.

```c
char *PGTYPESdate_to_asc(date dDate);
```

The function receives the date `dDate` as its only parameter. It will output the date in the form `1999-01-18`, i.e., in the `YYYY-MM-DD` format.

**PGTYPESdate_julmdy**

Extract the values for the day, the month and the year from a variable of type date.

```c
void PGTYPESdate_julmdy(date d, int *mdy);
```

The function receives the date `d` and a pointer to an array of 3 integer values `mdy`. The variable name indicates the sequential order: `mdy[0]` will be set to contain the number of the month, `mdy[1]` will be set to the value of the day and `mdy[2]` will contain the year.

**PGTYPESdate_mdyjul**

Create a date value from an array of 3 integers that specify the day, the month and the year of the date.

```c
void PGTYPESdate_mdyjul(int *mdy, date *jdate);
```

The function receives the array of the 3 integers (`mdy`) as its first argument and as its second argument a pointer to a variable of type date that should hold the result of the operation.

**PGTYPESdate_dayofweek**

Return a number representing the day of the week for a date value.

```c
int PGTYPESdate_dayofweek(date d);
```

The function receives the date variable `d` as its only argument and returns an integer that indicates the day of the week for this date.

- 0 - Sunday
- 1 - Monday
- 2 - Tuesday
- 3 - Wednesday
- 4 - Thursday
- 5 - Friday
- 6 - Saturday

**PGTYPESdate_today**

Get the current date.

```c
void PGTYPESdate_today(date *d);
```

The function receives a pointer to a date variable (`d`) that it sets to the current date.

---

613
PGTYPESdate_fmt_asc

Convert a variable of type date to its textual representation using a format mask.

```c
int PGTYPESdate_fmt_asc(date dDate, char *fmtstring, char *outbuf);
```

The function receives the date to convert (dDate), the format mask (fmtstring) and the string that will hold the textual representation of the date (outbuf).

On success, 0 is returned and a negative value if an error occurred.

The following literals are the field specifiers you can use:

- **dd** - The number of the day of the month.
- **mm** - The number of the month of the year.
- **yy** - The number of the year as a two digit number.
- **yyyy** - The number of the year as a four digit number.
- **ddd** - The name of the day (abbreviated).
- **mmm** - The name of the month (abbreviated).

All other characters are copied 1:1 to the output string.

Table 32-2 indicates a few possible formats. This will give you an idea of how to use this function. All output lines are based on the same date: November 23, 1959.

### Table 32-2. Valid input formats for PGTYPESdate_fmt_asc

<td>Mon, Nov. 23, 1959</td>
</tr>
<tr>
<td>(ddd) mmm. dd, yyyy</td>
<td>(Mon) Nov. 23, 1959</td>
</tr>
</tbody>
</table>

PGTYPESdate_defmt_asc

Use a format mask to convert a C char* string to a value of type date.

```c
int PGTYPESdate_defmt_asc(date *d, char *fmt, char *str);
```

The function receives a pointer to the date value that should hold the result of the operation (d), the format mask to use for parsing the date (fmt) and the C char* string containing the textual representation of the date (str). The textual representation is expected to match the format mask. However you do not need to have a 1:1 mapping of the string to the format mask. The function only analyzes the sequential order and looks for the literals **yy** or **yyyy** that indicate the position of the year, **mm** to indicate the position of the month and **dd** to indicate the position of the day.

Table 32-3 indicates a few possible formats. This will give you an idea of how to use this function.

</table>

32.8.3. The timestamp type

The timestamp type in C enables your programs to deal with data of the SQL type timestamp. See Section 8.5 for the equivalent type in the PostgreSQL server.

The following functions can be used to work with the timestamp type:

**PGTYPEStimestamp_from_asc**

Parse a timestamp from its textual representation into a timestamp variable.

```c
timestamp PGTYPEStimestamp_from_asc(char *str, char **endptr);
```

The function receives the string to parse (`str`) and a pointer to a C char* (`endptr`). At the moment ecpg always parses the complete string and so it currently does not support to store the address of the first invalid character in `*endptr`. You can safely set `endptr` to NULL.

The function returns the parsed timestamp on success. On error, `PGTYPESInvalidTimestamp` is returned and `errno` is set to `PGTYPES_TS_BAD_TIMESTAMP`. See `PGTYPESInvalidTimestamp` for important notes on this value.

In general, the input string can contain any combination of an allowed date specification, a whitespace character and an allowed time specification. Note that timezones are not supported by ecpg. It can parse them but does not apply any calculation as the PostgreSQL server does for example. Timezone specifiers are silently discarded.

Table 32-4 contains a few examples for input strings.
Table 32-4. Valid input formats for `PGTYPEStimestamp_from_asc`

<table>
<thead>
<tr>
<th>Input</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>1999-01-08 04:05:06</td>
<td>1999-01-08 04:05:06</td>
</tr>
<tr>
<td>January 8 04:05:06 1999 PST</td>
<td>1999-01-08 04:05:06</td>
</tr>
<tr>
<td>1999-Jan-08 04:05:06.789-8</td>
<td>1999-01-08 04:05:06.789 (time zone specifier ignored)</td>
</tr>
<tr>
<td>J2451187 04:05-08:00</td>
<td>1999-01-08 04:05:00 (time zone specifier ignored)</td>
</tr>
</tbody>
</table>

`PGTYPEStimestamp_to_asc`

Converts a date to a C char* string.

```c
char *PGTYPEStimestamp_to_asc(timestamp tstamp);
```

The function receives the timestamp `tstamp` as its only argument and returns an allocated string that contains the textual representation of the timestamp.

`PGTYPEStimestamp_current`

Retrieve the current timestamp.

```c
void PGTYPEStimestamp_current(timestamp *ts);
```

The function retrieves the current timestamp and saves it into the timestamp variable that `ts` points to.

`PGTYPEStimestamp_fmt_asc`

Convert a timestamp variable to a C char* using a format mask.

```c
int PGTYPEStimestamp_fmt_asc(timestamp *ts, char *output, int str_len, char *fmtstr);
```

The function receives a pointer to the timestamp to convert as its first argument (`ts`), a pointer to the output buffer (`output`), the maximal length that has been allocated for the output buffer (`str_len`) and the format mask to use for the conversion (`fmtstr`).

Upon success, the function returns 0 and a negative value if an error occurred.

You can use the following format specifiers for the format mask. The format specifiers are the same ones that are used in the `strftime` function in libc. Any non-format specifier will be copied into the output buffer.

- `%A` - is replaced by national representation of the full weekday name.
- `%a` - is replaced by national representation of the abbreviated weekday name.
- `%B` - is replaced by national representation of the full month name.
- `%b` - is replaced by national representation of the abbreviated month name.
- `%C` - is replaced by (year / 100) as decimal number; single digits are preceded by a zero.
- `%c` - is replaced by national representation of time and date.
- `%d` - is equivalent to `%m/%d/%y`.
- `%d` - is replaced by the day of the month as a decimal number (01-31).
- `%E` - POSIX locale extensions. The sequences `%Ec` `%EC` `%Ex` `%EX` `%Ey` `%EY` `%Od` `%Oe` `%OH` `%OI` `%Om` `%OM` `%Os` `%Ou` `%OU` `%OV` `%Ow` `%OW` `%Oy` are supposed to provide alternative representations.

Additionally `%OB` implemented to represent alternative months names (used standalone, without day mentioned).
• %e - is replaced by the day of month as a decimal number (1-31); single digits are preceded by a blank.
• %F - is equivalent to %Y-%m-%d.
• %G - is replaced by a year as a decimal number with century. This year is the one that contains the greater part of the week (Monday as the first day of the week).
• %g - is replaced by the same year as in %G, but as a decimal number without century (00-99).
• %H - is replaced by the hour (24-hour clock) as a decimal number (00-23).
• %h - the same as %b.
• %I - is replaced by the hour (12-hour clock) as a decimal number (01-12).
• %j - is replaced by the day of the year as a decimal number (001-366).
• %k - is replaced by the hour (24-hour clock) as a decimal number (0-23); single digits are preceded by a blank.
• %l - is replaced by the hour (12-hour clock) as a decimal number (1-12); single digits are preceded by a blank.
• %m - is replaced by the month as a decimal number (01-12).
• %n - is replaced by a newline.
• %O* - the same as %E*.
• %p - is replaced by national representation of either "ante meridiem" or "post meridiem" as appropriate.
• %R - is equivalent to %H:%M.
• %r - is equivalent to %I:%M:%S %p.
• %S - is replaced by the second as a decimal number (00-60).
• %s - is replaced by the number of seconds since the Epoch, UTC.
• %T - is equivalent to %H:%M:%S
• %t - is replaced by a tab.
• %U - is replaced by the week number of the year (Sunday as the first day of the week) as a decimal number (00-53).
• %u - is replaced by the weekday (Monday as the first day of the week) as a decimal number (1-7).
• %V - is replaced by the week number of the year (Monday as the first day of the week) as a decimal number (01-53). If the week containing January 1 has four or more days in the new year, then it is week 1; otherwise it is the last week of the previous year, and the next week is week 1.
• %v - is equivalent to %e-%b-%Y.
• %W - is replaced by the week number of the year (Monday as the first day of the week) as a decimal number (00-53).
• %w - is replaced by the weekday (Sunday as the first day of the week) as a decimal number (0-6).
• %x - is replaced by national representation of the time.
• %x - is replaced by national representation of the date.
Chapter 32. ECPG - Embedded SQL in C

- `%Y` is replaced by the year with century as a decimal number.
- `%y` is replaced by the year without century as a decimal number (00-99).
- `%Z` is replaced by the time zone name.
- `%z` is replaced by the time zone offset from UTC; a leading plus sign stands for east of UTC, a minus sign for west of UTC, hours and minutes follow with two digits each and no delimiter between them (common form for RFC 822 date headers).
- `%+` is replaced by national representation of the date and time.
- `%-*` GNU libc extension. Do not do any padding when performing numerical outputs.
- `$_*` GNU libc extension. Explicitly specify space for padding.
- `%0*` GNU libc extension. Explicitly specify zero for padding.
- `%%` is replaced by `%`.

**PGTYPEStimestamp_sub**

Subtract one timestamp from another one and save the result in a variable of type interval.

```c
int PGTYPEStimestamp_sub(timestamp *ts1, timestamp *ts2, interval *iv);
```

The function will subtract the timestamp variable that `ts2` points to from the timestamp variable that `ts1` points to and will store the result in the interval variable that `iv` points to.

Upon success, the function returns 0 and a negative value if an error occurred.

**PGTYPEStimestamp_defmt_asc**

Parse a timestamp value from its textual representation using a formatting mask.

```c
int PGTYPEStimestamp_defmt_asc(char *str, char *fmt, timestamp *d);
```

The function receives the textual representation of a timestamp in the variable `str` as well as the formatting mask to use in the variable `fmt`. The result will be stored in the variable that `d` points to.

If the formatting mask `fmt` is NULL, the function will fall back to the default formatting mask which is `%Y-%m-%d %H:%M:%S`.

This is the reverse function to `PGTYPEStimestamp_fmt_asc`. See the documentation there in order to find out about the possible formatting mask entries.

**PGTYPEStimestamp_add_interval**

Add an interval variable to a timestamp variable.

```c
int PGTYPEStimestamp_add_interval(timestamp *tin, interval *span, timestamp *tout);
```

The function receives a pointer to a timestamp variable `tin` and a pointer to an interval variable `span`. It adds the interval to the timestamp and saves the resulting timestamp in the variable that `tout` points to.

Upon success, the function returns 0 and a negative value if an error occurred.

**PGTYPEStimestamp_sub_interval**

Subtract an interval variable from a timestamp variable.

```c
int PGTYPEStimestamp_sub_interval(timestamp *tin, interval *span, timestamp *tout);
```

The function subtracts the interval variable that `span` points to from the timestamp variable that `tin` points to and saves the result into the variable that `tout` points to.

Upon success, the function returns 0 and a negative value if an error occurred.
32.8.4. The interval type

The interval type in C enables your programs to deal with data of the SQL type interval. See Section 8.5 for the equivalent type in the PostgreSQL server.

The following functions can be used to work with the interval type:

**PGTYPESinterval_new**

Return a pointer to a newly allocated interval variable.

```
interval *PGTYPESinterval_new(void);
```

**PGTYPESinterval_free**

Release the memory of a previously allocated interval variable.

```
void PGTYPESinterval_new(interval *intvl);
```

**PGTYPESinterval_from_asc**

Parse an interval from its textual representation.

```
interval *PGTYPESinterval_from_asc(char *str, char **endptr);
```

The function parses the input string `str` and returns a pointer to an allocated interval variable. At the moment ecpg always parses the complete string and so it currently does not support to store the address of the first invalid character in `endptr`. You can safely set `endptr` to NULL.

**PGTYPESinterval_to_asc**

Convert a variable of type interval to its textual representation.

```
char *PGTYPESinterval_to_asc(interval *span);
```

The function converts the interval variable that `span` points to into a C char*. The output looks like this example: @ 1 day 12 hours 59 mins 10 secs.

**PGTYPESinterval_copy**

Copy a variable of type interval.

```
int PGTYPESinterval_copy(interval *intvlsrc, interval *intvldest);
```

The function copies the interval variable that `intvlsrc` points to into the variable that `intvldest` points to. Note that you need to allocate the memory for the destination variable before.

32.8.5. The decimal type

The decimal type is similar to the numeric type. However it is limited to a maximal precision of 30 significant digits. In contrast to the numeric type which can be created on the heap only, the decimal type can be created either on the stack or on the heap (by means of the functions `PTYPESdecimal_new()` and `PTYPESdecimal_free()`. There are a lot of other functions that deal with the decimal type in the Informix compatibility mode described in Section 32.9.

The following functions can be used to work with the decimal type and are not only contained in the libcompat library.

**PGTYPESdecimal_new**

Request a pointer to a newly allocated decimal variable.

```
decimal *PGTYPESdecimal_new(void);
```
32.8.6. errno values of pgtypeslib

PGTYPES_NUM_BAD_NUMERIC
An argument should contain a numeric variable (or point to a numeric variable) but in fact its
in-memory representation was invalid.

PGTYPES_NUM_OVERFLOW
An overflow occurred. Since the numeric type can deal with almost arbitrary precision, converting
a numeric variable into other types might cause overflow.

PGTYPES_NUM_OVERFLOW
An underflow occurred. Since the numeric type can deal with almost arbitrary precision, converting
a numeric variable into other types might cause underflow.

PGTYPES_NUM_DIVIDE_ZERO
A division by zero has been attempted.

32.8.7. Special constants of pgtypeslib

PGTYPESInvalidTimestamp
A value of type timestamp representing an invalid time stamp. This is returned by the function
PGTYPEStimestamp_from_asc on parse error. Note that due to the internal representation of
the timestamp datatype, PGTYPESInvalidTimestamp is also a valid timestamp at the same
time. It is set to 1899-12-31 23:59:59. In order to detect errors, make sure that your appli-
cation does not only test for PGTYPESInvalidTimestamp but also for errno != 0 after each
call to PGTYPEStimestamp_from_asc.
32.9. Informix compatibility mode

cepg can be run in a so-called Informix compatibility mode. If this mode is active, it tries to behave as if it were the Informix precompiler for Informix E/SQL. Generally spoken this will allow you to use the dollar sign instead of the EXEC SQL primitive to introduce embedded SQL commands:

\[
\begin{align*}
\$int j &= 3; \\
\$CONNECT TO :dbname; \\
\$CREATE TABLE test(i INT PRIMARY KEY, j INT); \\
\$INSERT INTO test(i, j) VALUES (7, :j); \\
\$COMMIT;
\end{align*}
\]

There are two compatibility modes: INFORMIX, INFORMIX_SE

When linking programs that use this compatibility mode, remember to link against libcompat that is shipped with ecpg.

Besides the previously explained syntactic sugar, the Informix compatibility mode ports some functions for input, output and transformation of data as well as embedded SQL statements known from E/SQL to ecpg.

Informix compatibility mode is closely connected to the pgtypeslib library of ecpg. pgtypeslib maps SQL data types to data types within the C host program and most of the additional functions of the Informix compatibility mode allow you to operate on those C host program types. Note however that the extent of the compatibility is limited. It does not try to copy Informix behaviour; it allows you to do more or less the same operations and gives you functions that have the same name and the same basic behavior but it is no drop-in replacement if you are using Informix at the moment. Moreover, some of the data types are different. For example, PostgreSQL’s datetime and interval types do not know about ranges like for example YEAR TO MINUTE so you won’t find support in ecpg for that either.

32.9.1. Additional embedded SQL statements

CLOSE DATABASE

This statement closes the current connection. In fact, this is a synonym for ecpg’s DISCONNECT CURRENT:

\[
\begin{align*}
\$CLOSE DATABASE; & \quad /* close the current connection */ \\
\text{EXEC SQL CLOSE DATABASE;}
\end{align*}
\]
32.9.2. Additional functions

decadd

Add two decimal type values.

```c
int decadd(decimal *arg1, decimal *arg2, decimal *sum);
```

The function receives a pointer to the first operand of type decimal (arg1), a pointer to the second operand of type decimal (arg2) and a pointer to a value of type decimal that will contain the sum (sum). On success, the function returns 0. ECPG_INFORMIX_NUM_OVERFLOW is returned in case of overflow and ECPG_INFORMIX_NUM_UNDERFLOW in case of underflow. -1 is returned for other failures and errno is set to the respective errno number of the pgtypeslib.

deccmp

Compare two variables of type decimal.

```c
int deccmp(decimal *arg1, decimal *arg2);
```

The function receives a pointer to the first decimal value (arg1), a pointer to the second decimal value (arg2) and returns an integer value that indicates which is the bigger value.

- 1, if the value that arg1 points to is bigger than the value that var2 points to
- -1, if the value that arg1 points to is smaller than the value that arg2 points to
- 0, if the value that arg1 points to and the value that arg2 points to are equal

deccopy

Copy a decimal value.

```c
void deccopy(decimal *src, decimal *target);
```

The function receives a pointer to the decimal value that should be copied as the first argument (src) and a pointer to the target structure of type decimal (target) as the second argument.

decvasc

Convert a value from its ASCII representation into a decimal type.

```c
int deccvasc(char *cp, int len, decimal *np);
```

The function receives a pointer to string that contains the string representation of the number to be converted (cp) as well as its length len. np is a pointer to the decimal value that saves the result of the operation.

Valid formats are for example: -2, .794, +3.44, 592.49E07 or -32.84e-4.

The function returns 0 on success. If overflow or underflow occurred, ECPG_INFORMIX_NUM_OVERFLOW or ECPG_INFORMIX_NUM_UNDERFLOW is returned. If the ASCII representation could not be parsed, ECPG_INFORMIX_BAD_NUMERIC is returned or ECPG_INFORMIX_BAD_EXPONENT if this problem occurred while parsing the exponent.

decvdbl

Convert a value of type double to a value of type decimal.

```c
int deccvdbl(double dbl, decimal *np);
```

The function receives the variable of type double that should be converted as its first argument (dbl). As the second argument (np), the function receives a pointer to the decimal variable that should hold the result of the operation.

The function returns 0 on success and a negative value if the conversion failed.
**Chapter 32. ECPG - Embedded SQL in C**

**deccvint**

Convert a value of type int to a value of type decimal.

```c
int deccvint(int in, decimal *np);
```

The function receives the variable of type int that should be converted as its first argument (`in`). As the second argument (`np`), the function receives a pointer to the decimal variable that should hold the result of the operation.

The function returns 0 on success and a negative value if the conversion failed.

**deccvlong**

Convert a value of type long to a value of type decimal.

```c
int deccvlong(long lng, decimal *np);
```

The function receives the variable of type long that should be converted as its first argument (`lng`). As the second argument (`np`), the function receives a pointer to the decimal variable that should hold the result of the operation.

The function returns 0 on success and a negative value if the conversion failed.

**decdiv**

Divide two variables of type decimal.

```c
int decdiv(decimal *n1, decimal *n2, decimal *result);
```

The function receives pointers to the variables that are the first (`n1`) and the second (`n2`) operands and calculates `n1/n2`. `result` is a pointer to the variable that should hold the result of the operation.

On success, 0 is returned and a negative value if the division fails. If overflow or underflow occurred, the function returns `ECPG_INFORMIX_NUM_OVERFLOW` or `ECPG_INFORMIX_NUM_UNDERFLOW` respectively. If an attempt to divide by zero is observed, the function returns `ECPG_INFORMIX_DIVIDE_ZERO`.

**decmul**

Multiply two decimal values.

```c
int decmul(decimal *n1, decimal *n2, decimal *result);
```

The function receives pointers to the variables that are the first (`n1`) and the second (`n2`) operands and calculates `n1*n2`. `result` is a pointer to the variable that should hold the result of the operation.

On success, 0 is returned and a negative value if the multiplication fails. If overflow or underflow occurred, the function returns `ECPG_INFORMIX_NUM_OVERFLOW` or `ECPG_INFORMIX_NUM_UNDERFLOW` respectively.

**decsup**

Subtract one decimal value from another.

```c
int decsup(decimal *n1, decimal *n2, decimal *result);
```

The function receives pointers to the variables that are the first (`n1`) and the second (`n2`) operands and calculates `n1-n2`. `result` is a pointer to the variable that should hold the result of the operation.

On success, 0 is returned and a negative value if the subtraction fails. If overflow or underflow occurred, the function returns `ECPG_INFORMIX_NUM_OVERFLOW` or `ECPG_INFORMIX_NUM_UNDERFLOW` respectively.
**dectoasc**

Convert a variable of type decimal to its ASCII representation in a C char* string.

```c
int dectoasc(decimal *np, char *cp, int len, int right)
```

The function receives a pointer to a variable of type decimal (`np`) that it converts to its textual representation. `cp` is the buffer that should hold the result of the operation. The parameter `right` specifies, how many digits right of the decimal point should be included in the output. The result will be rounded to this number of decimal digits. Setting `right` to -1 indicates that all available decimal digits should be included in the output. If the length of the output buffer, which is indicated by `len` is not sufficient to hold the textual representation including the trailing NUL character, only a single * character is stored in the result and -1 is returned.

The function returns either -1 if the buffer `cp` was too small or `ECPG_INFORMIX_OUT_OF_MEMORY` if memory was exhausted.

**dectodbl**

Convert a variable of type decimal to a double.

```c
int dectodbl(decimal *np, double *dblp);
```

The function receives a pointer to the decimal value to convert (`np`) and a pointer to the double variable that should hold the result of the operation (`dblp`).

On success, 0 is returned and a negative value if the conversion failed.

**dectoint**

Convert a variable to type decimal to an integer.

```c
int dectoint(decimal *np, int *ip);
```

The function receives a pointer to the decimal value to convert (`np`) and a pointer to the integer variable that should hold the result of the operation (`ip`).

On success, 0 is returned and a negative value if the conversion failed. If an overflow occurred, `ECPG_INFORMIX_NUM_OVERFLOW` is returned.

Note that the ecpg implementation differs from the Informix implementation. Informix limits an integer to the range from -32767 to 32767, while the limits in the ecpg implementation depend on the architecture (`-INT_MAX .. INT_MAX`).

**dectolong**

Convert a variable to type decimal to a long integer.

```c
int dectolong(decimal *np, long *lngp);
```

The function receives a pointer to the decimal value to convert (`np`) and a pointer to the long variable that should hold the result of the operation (`lngp`).

On success, 0 is returned and a negative value if the conversion failed. If an overflow occurred, `ECPG_INFORMIX_NUM_OVERFLOW` is returned.

Note that the ecpg implementation differs from the Informix implementation. Informix limits a long integer to the range from -2,147,483,647 to 2,147,483,647, while the limits in the ecpg implementation depend on the architecture (`-LONG_MAX .. LONG_MAX`).

**rdatestr**

Converts a date to a C char* string.

```c
int rdatestr(date d, char *str);
```

The function receives two arguments, the first one is the date to convert (`d`) and the second one is a pointer to the target string. The output format is always yyyy-mm-dd, so you need to allocate at least 11 bytes (including the NUL-terminator) for the string.
The function returns 0 on success and a negative value in case of error.

Note that ecpg’s implementation differs from the Informix implementation. In Informix the format can be influenced by setting environment variables. In ecpg however, you cannot change the output format.

rstrdate

Parse the textual representation of a date.

```c
int rstrdate(char *str, date *d);
```

The function receives the textual representation of the date to convert (str) and a pointer to a variable of type date (d). This function does not allow you to specify a format mask. It uses the default format mask of Informix which is `mm/dd/yyyy`. Internally, this function is implemented by means of `rdefmtdate`. Therefore, rstrdate is not faster and if you have the choice you should opt for rdefmtdate which allows you to specify the format mask explicitly.

The function returns the same values as `rdefmtdate`.

rtoday

Get the current date.

```c
void rtoday(date *d);
```

The function receives a pointer to a date variable (d) that it sets to the current date.

Internally this function uses the `PGTYPESdate_today` function.

rjulmdy

Extract the values for the day, the month and the year from a variable of type date.

```c
int rjulmdy(date d, short mdy[3]);
```

The function receives the date d and a pointer to an array of 3 short integer values mdy. The variable name indicates the sequential order: mdy[0] will be set to contain the number of the month, mdy[1] will be set to the value of the day and mdy[2] will contain the year.

The function always returns 0 at the moment.

Internally the function uses the `PGTYPESdate_julmdy` function.

rdefmtdate

Use a format mask to convert a character string to a value of type date.

```c
int rdefmtdate(date *d, char *fmt, char *str);
```

The function receives a pointer to the date value that should hold the result of the operation (d), the format mask to use for parsing the date (fmt) and the C char* string containing the textual representation of the date (str). The textual representation is expected to match the format mask. However you do not need to have a 1:1 mapping of the string to the format mask. The function only analyzes the sequential order and looks for the literals `yy` or `yyyy` that indicate the position of the year, `mm` to indicate the position of the month and `dd` to indicate the position of the day.

The function returns the following values:

- `0` - The function terminated successfully.
- `ECPG_INFORMIX_ENOSHORTDATE` - The date does not contain delimiters between day, month and year. In this case the input string must be exactly 6 or 8 bytes long but isn’t.
- `ECPG_INFORMIX_ENOTDMY` - The format string did not correctly indicate the sequential order of year, month and day.
- `ECPG_INFORMIX_BAD_DAY` - The input string does not contain a valid day.
- `ECPG_INFORMIX_BAD_MONTH` - The input string does not contain a valid month.
Chapter 32. ECPG - Embedded SQL in C

- **ECPG_INFORMIX_BAD_YEAR** - The input string does not contain a valid year.

Internally this function is implemented to use the `PGTYPESdate_defmt_asc` function. See the reference there for a table of example input.

**rfmtdate**

Convert a variable of type date to its textual representation using a format mask.

```c
int rfmtdate(date d, char *fmt, char *str);
```

The function receives the date to convert (`d`), the format mask (`fmt`) and the string that will hold the textual representation of the date (`str`).

On success, 0 is returned and a negative value if an error occurred.

Internally this function uses the `PGTYPESdate_fmt_asc` function, see the reference there for examples.

**rmdyjul**

Create a date value from an array of 3 short integers that specify the day, the month and the year of the date.

```c
int rmdyjul(short mdy[3], date *d);
```

The function receives the array of the 3 short integers (`mdy`) and a pointer to a variable of type `date` that should hold the result of the operation.

Currently the function returns always 0.

Internally the function is implemented to use the function `PGTYPESdate_mdyjul`.

**rdayofweek**

Return a number representing the day of the week for a date value.

```c
int rdayofweek(date d);
```

The function receives the date variable `d` as its only argument and returns an integer that indicates the day of the week for this date.

- 0 - Sunday
- 1 - Monday
- 2 - Tuesday
- 3 - Wednesday
- 4 - Thursday
- 5 - Friday
- 6 - Saturday

Internally the function is implemented to use the function `PGTYPESdate_dayofweek`.

**dtcurrent**

Retrieve the current timestamp.

```c
void dtcurrent(timestamp *ts);
```

The function retrieves the current timestamp and saves it into the timestamp variable that `ts` points to.
dtcvasc

Parses a timestamp from its textual representation in ANSI standard into a timestamp variable.

```c
int dtcvasc(char *str, timestamp *ts);
```

The function receives the string to parse (`str`) and a pointer to the timestamp variable that should hold the result of the operation (`ts`).

The function returns 0 on success and a negative value in case of error.

Internally this function uses the `PGTYPEStimestamp_from_asc` function. See the reference there for a table with example inputs.

dtcvfmtasc

Parses a timestamp from its textual representation in ANSI standard using a format mask into a timestamp variable.

```c
dtcvfmtasc(char *inbuf, char *fmtstr, timestamp *dtvalue)
```

The function receives the string to parse (`inbuf`), the format mask to use (`fmtstr`) and a pointer to the timestamp variable that should hold the result of the operation (`ts`).

This function is implemented by means of the `PGTYPEStimestamp_defmt_asc`. See the documentation there for a list of format specifiers that can be used.

The function returns 0 on success and a negative value in case of error.

dtsub

Subtract one timestamp from another and return a variable of type interval.

```c
int dtsub(timestamp *ts1, timestamp *ts2, interval *iv);
```

The function will subtract the timestamp variable that `ts2` points to from the timestamp variable that `ts1` points to and will store the result in the interval variable that `iv` points to.

Upon success, the function returns 0 and a negative value if an error occurred.

dttoasc

Convert a timestamp variable to a C char* string.

```c
int dttoasc(timestamp *ts, char *output);
```

The function receives a pointer to the timestamp variable to convert (`ts`) and the string that should hold the result of the operation (`output`). It converts `ts` to its textual representation in the ANSI SQL standard which is defined to be `YYYY-MM-DD HH:MM:SS`.

Upon success, the function returns 0 and a negative value if an error occurred.

dttofmtasc

Convert a timestamp variable to a C char* using a format mask.

```c
int dttofmtasc(timestamp *ts, char *output, int str_len, char *fmtstr);
```

The function receives a pointer to the timestamp to convert as its first argument (`ts`), a pointer to the output buffer (`output`), the maximal length that has been allocated for the output buffer (`str_len`) and the format mask to use for the conversion (`fmtstr`).

Upon success, the function returns 0 and a negative value if an error occurred.

Internally, this function uses the `PGTYPEStimestamp_fmt_asc` function. See the reference there for information on what format mask specifiers can be used.

intoasc

Convert an interval variable to a C char* string.

```c
int intoasc(interval *i, char *str);
```
The function receives a pointer to the interval variable to convert (i) and the string that should hold the result of the operation str). It converts i to its textual representation in the ANSI SQL standard which is defined to be YYYY-MM-DD HH:MM:SS.

Upon success, the function returns 0 and a negative value if an error occurred.

```
rfmtlong

Convert a long integer value to its textual representation using a format mask.

int rfmtlong(long lng_val, char *fmt, char *outbuf);
```

The function receives the long value lng_val, the format mask fmt and a pointer to the output buffer outbuf. It converts the long value according to the format mask to its textual representation.

The format mask can be composed of the following format specifying characters:

- * (asterisk) - if this position would be blank otherwise, fill it with an asterisk.
- & (ampersand) - if this position would be blank otherwise, fill it with a zero.
- # - turn leading zeroes into blanks.
- < - left-justify the number in the string.
- , (comma) - group numbers of four or more digits into groups of three digits separated by a comma.
- . (period) - this character separates the whole-number part of the number from the fractional part.
- - (minus) - the minus sign appears if the number is a negative value.
- + (plus) - the plus sign appears if the number is a positive value.
- ( - this replaces the minus sign in front of the negative number. The minus sign will not appear.
- ) - this character replaces the minus and is printed behind the negative value.
- $ - the currency symbol.

```
rupshift

Convert a string to upper case.

void rupshift(char *str);
```

The function receives a pointer to the string and transforms every lower case character to upper case.

```
byleng

Return the number of characters in a string without counting trailing blanks.

int byleng(char *str, int len);
```

The function expects a fixed-length string as its first argument (str) and its length as its second argument (len). It returns the number of significant characters, that is the length of the string without trailing blanks.

```
ldchar

Copy a fixed-length string into a null-terminated string.

void ldchar(char *src, int len, char *dest);
```

The function receives the fixed-length string to copy (src), its length (len) and a pointer to the destination memory (dest). Note that you need to reserve at least len+1 bytes for the string.
that dest points to. The function copies at most len bytes to the new location (less if the source string has trailing blanks) and adds the null-terminator.

rgetmsg
int rgetmsg(int msgnum, char *s, int maxsize);
This function exists but is not implemented at the moment!

rtypalign
int rtypalign(int offset, int type);
This function exists but is not implemented at the moment!

rtypmsize
int rtypmsize(int type, int len);
This function exists but is not implemented at the moment!

rtypwidth
int rtypwidth(int sqltype, int sqllen);
This function exists but is not implemented at the moment!

rsetnull
Set a variable to NULL.
int rsetnull(int t, char *ptr);
The function receives an integer that indicates the type of the variable and a pointer to the variable itself that is casted to a C char* pointer.

The following types exist:
• CCHARTYPE - For a variable of type char or char*
• CSHORTTYPE - For a variable of type short int
• CINTTYPE - For a variable of type int
• CBOOLTYPE - For a variable of type boolean
• CFLOATTYPE - For a variable of type float
• CLLONGTYPE - For a variable of type long
• CDATYPE - For a variable of type decimal
• CDATETIME - For a variable of type date
• CDTIMETYPE - For a variable of type timestamp

Here is an example of a call to this function:
$char c[] = "abc ";
$short s = 17;
<int i = -74874;
rsetnull (CCHARTYPE, (char *) c);
rsetnull (CSHORTTYPE, (char *) &s);
rsetnull (CINTTYPE, (char *) &i);
risnull
Test if a variable is NULL.

int risnull(int t, char *ptr);
The function receives the type of the variable to test (t) as well a pointer to this variable (ptr).
Note that the latter needs to be casted to a char*.

Here is an example of how to use this function:

$char c[] = "abc     ";
$short s = 17;
$int i = -74874;

testnull(CCHARTYPE, (char *) c);
risnull(CSHORTTYPE, (char *) &s);
risnull(CINTTYPE, (char *) &i);

32.9.3. Additional constants

Note that all constants here describe errors and all of them are defined to represent negative values.
In the descriptions of the different constants you can also find the value that the constants represent
in the current implementation. However you should not rely on this number. You can however rely on
the fact all of them are defined to represent negative values.

ECPG_INFORMIX_NUM_OVERFLOW
Functions return this value if an overflow occurred in a calculation. Internally it is defined to
-1200 (the Informix definition).

ECPG_INFORMIX_NUM_UNDERFLOW
Functions return this value if an underflow occurred in a calculation. Internally it is defined to
-1201 (the Informix definition).

ECPG_INFORMIX_DIVIDE_ZERO
Functions return this value if an attempt to divide by zero is observed. Internally it is defined to
-1202 (the Informix definition).

ECPG_INFORMIX_BAD_YEAR
Functions return this value if a bad value for a year was found while parsing a date. Internally it is
defined to -1204 (the Informix definition).

ECPG_INFORMIX_BAD_MONTH
Functions return this value if a bad value for a month was found while parsing a date. Internally it
is defined to -1205 (the Informix definition).

ECPG_INFORMIX_BAD_DAY
Functions return this value if a bad value for a day was found while parsing a date. Internally it is
defined to -1206 (the Informix definition).

ECPG_INFORMIX_ENOSHORTDATE
Functions return this value if a parsing routine needs a short date representation but did not get
the date string in the right length. Internally it is defined to -1209 (the Informix definition).
ECPG_INFORMIX_DATE_CONVERT

Functions return this value if an error occurred during date formatting. Internally it is defined to -1210 (the Informix definition).

ECPG_INFORMIX_OUT_OF_MEMORY

Functions return this value if memory was exhausted during their operation. Internally it is defined to -1211 (the Informix definition).

ECPG_INFORMIX_ENOTDMY

Functions return this value if a parsing routine was supposed to get a format mask (like mmddyy) but not all fields were listed correctly. Internally it is defined to -1212 (the Informix definition).

ECPG_INFORMIX_BAD_NUMERIC

Functions return this value either if a parsing routine cannot parse the textual representation for a numeric value because it contains errors or if a routine cannot complete a calculation involving numeric variables because at least one of the numeric variables is invalid. Internally it is defined to -1213 (the Informix definition).

ECPG_INFORMIX_BAD_EXPONENT

Functions return this value if Internally it is defined to -1216 (the Informix definition).

ECPG_INFORMIX_BAD_DATE

Functions return this value if Internally it is defined to -1218 (the Informix definition).

ECPG_INFORMIX_EXTRA_CHARS

Functions return this value if Internally it is defined to -1264 (the Informix definition).

32.10. Using SQL Descriptor Areas

An SQL descriptor area is a more sophisticated method for processing the result of a SELECT or FETCH statement. An SQL descriptor area groups the data of one row of data together with metadata items into one data structure. The metadata is particularly useful when executing dynamic SQL statements, where the nature of the result columns might not be known ahead of time.

An SQL descriptor area consists of a header, which contains information concerning the entire descriptor, and one or more item descriptor areas, which basically each describe one column in the result row.

Before you can use an SQL descriptor area, you need to allocate one:

EXEC SQL ALLOCATE DESCRIPTOR identifier;

The identifier serves as the “variable name” of the descriptor area. When you don’t need the descriptor anymore, you should deallocate it:

EXEC SQL DEALLOCATE DESCRIPTOR identifier;

To use a descriptor area, specify it as the storage target in an INTO clause, instead of listing host variables:
EXEC SQL FETCH NEXT FROM mycursor INTO DESCRIPTOR mydesc;

Now how do you get the data out of the descriptor area? You can think of the descriptor area as a structure with named fields. To retrieve the value of a field from the header and store it into a host variable, use the following command:

EXEC SQL GET DESCRIPTOR name : hostvar = field;

Currently, there is only one header field defined: COUNT, which tells how many item descriptor areas exist (that is, how many columns are contained in the result). The host variable needs to be of an integer type. To get a field from the item descriptor area, use the following command:

EXEC SQL GET DESCRIPTOR name VALUE num : hostvar = field;

num can be a literal integer or a host variable containing an integer. Possible fields are:

CARDINALITY (integer)
  number of rows in the result set
DATA
  actual data item (therefore, the data type of this field depends on the query)
DATETIME_INTERVAL_CODE (integer)
  ?
DATETIME_INTERVAL_PRECISION (integer)
  not implemented
INDICATOR (integer)
  the indicator (indicating a null value or a value truncation)
KEY_MEMBER (integer)
  not implemented
LENGTH (integer)
  length of the datum in characters
NAME (string)
  name of the column
NULLABLE (integer)
  not implemented
OCTET_LENGTH (integer)
  length of the character representation of the datum in bytes
PRECISION (integer)
  precision (for type numeric)
RETURNED_LENGTH (integer)
  length of the datum in characters
Chapter 32. ECPG - Embedded SQL in C

RETURNED_OCTET_LENGTH (integer)

length of the character representation of the datum in bytes

SCALE (integer)

scale (for type numeric)

TYPE (integer)

numeric code of the data type of the column

32.11. Error Handling

This section describes how you can handle exceptional conditions and warnings in an embedded SQL program. There are several nonexclusive facilities for this.

32.11.1. Setting Callbacks

One simple method to catch errors and warnings is to set a specific action to be executed whenever a particular condition occurs. In general:

EXEC SQL WHENEVER condition action;

condition can be one of the following:

SQLERROR

The specified action is called whenever an error occurs during the execution of an SQL statement.

SQLWARNING

The specified action is called whenever a warning occurs during the execution of an SQL statement.

NOT FOUND

The specified action is called whenever an SQL statement retrieves or affects zero rows. (This condition is not an error, but you might be interested in handling it specially.)

action can be one of the following:

CONTINUE

This effectively means that the condition is ignored. This is the default.

GOTO label

GO TO label

Jump to the specified label (using a C goto statement).

SQLPRINT

Print a message to standard error. This is useful for simple programs or during prototyping. The details of the message cannot be configured.
STOP

Call `exit(1)`, which will terminate the program.

DO BREAK

Execute the C statement `break`. This should only be used in loops or `switch` statements.

CALL name (args)
DO name (args)

Call the specified C functions with the specified arguments.

The SQL standard only provides for the actions `CONTINUE` and `GOTO` (and `GO TO`).

Here is an example that you might want to use in a simple program. It prints a simple message when a warning occurs and aborts the program when an error happens:

```c
EXEC SQL WHENEVER SQLWARNING SQLPRINT;
EXEC SQL WHENEVER SQLERROR STOP;
```

The statement `EXEC SQL WHENEVER` is a directive of the SQL preprocessor, not a C statement. The error or warning actions that it sets apply to all embedded SQL statements that appear below the point where the handler is set, unless a different action was set for the same condition between the first `EXEC SQL WHENEVER` and the SQL statement causing the condition, regardless of the flow of control in the C program. So neither of the two following C program excerpts will have the desired effect:

```c
/*
* WRONG
*/
int main(int argc, char *argv[])
{
    ...
    if (verbose) {
        EXEC SQL WHENEVER SQLWARNING SQLPRINT;
    }
    ...
    EXEC SQL SELECT ...;
    ...
}

/*
* WRONG
*/
int main(int argc, char *argv[])
{
    ...
    set_error_handler();
    ...
    EXEC SQL SELECT ...;
    ...
}

static void set_error_handler(void)
{
    EXEC SQL WHENEVER SQLERROR STOP;
}
```
32.11.2. sqlca

For more powerful error handling, the embedded SQL interface provides a global variable with the name sqlca that has the following structure:

```c
struct
{
    char sqlcaid[8];
    long sqlabc;
    long sqlcode;
    struct
    {
        int sqlerrml;
        char sqlerrmc[SQLERRMC_LEN];
    } sqlerrm;
    char sqlerrp[8];
    long sqlerrd[6];
    char sqlwarn[8];
    char sqlstate[5];
} sqlca;
```

(In a multithreaded program, every thread automatically gets its own copy of sqlca. This works similarly to the handling of the standard C global variable errno.)

sqlca covers both warnings and errors. If multiple warnings or errors occur during the execution of a statement, then sqlca will only contain information about the last one.

If no error occurred in the last SQL statement, sqlca.sqlcode will be 0 and sqlca.sqlstate will be "00000". If a warning or error occurred, then sqlca.sqlcode will be negative and sqlca.sqlstate will be different from "00000". A positive sqlca.sqlcode indicates a harmless condition, such as that the last query returned zero rows. sqlcode and sqlstate are two different error code schemes; details appear below.

If the last SQL statement was successful, then sqlca.sqlerrd[1] contains the OID of the processed row, if applicable, and sqlca.sqlerrd[2] contains the number of processed or returned rows, if applicable to the command.

In case of an error or warning, sqlca.sqlerrm.sqlerrmc will contain a string that describes the error. The field sqlca.sqlerrm.sqlerrml contains the length of the error message that is stored in sqlca.sqlerrm.sqlerrmc (the result of strlen()), not really interesting for a C programmer). Note that some messages are too long to fit in the fixed-size sqlerrmc array; they will be truncated.

In case of a warning, sqlca.sqlwarn[2] is set to W. (In all other cases, it is set to something different from W.) If sqlca.sqlwarn[1] is set to W, then a value was truncated when it was stored in a host variable. sqlca.sqlwarn[0] is set to W if any of the other elements are set to indicate a warning.

The fields sqlcaid, sqlcabc, sqlerrp, and the remaining elements of sqlerrd and sqlwarn currently contain no useful information.

The structure sqlca is not defined in the SQL standard, but is implemented in several other SQL database systems. The definitions are similar at the core, but if you want to write portable applications, then you should investigate the different implementations carefully.

32.11.3. SQLSTATE VS SQLCODE

The fields sqlca.sqlstate and sqlca.sqlcode are two different schemes that provide error codes. Both are derived from the SQL standard, but SQLCODE has been marked deprecated in the
SQL-92 edition of the standard and has been dropped in later editions. Therefore, new applications are strongly encouraged to use SQLSTATE.

SQLSTATE is a five-character array. The five characters contain digits or upper-case letters that represent codes of various error and warning conditions. SQLSTATE has a hierarchical scheme: the first two characters indicate the general class of the condition, the last three characters indicate a subclass of the general condition. A successful state is indicated by the code 00000. The SQLSTATE codes are for the most part defined in the SQL standard. The PostgreSQL server natively supports SQLSTATE error codes; therefore a high degree of consistency can be achieved by using this error code scheme throughout all applications. For further information see Appendix A.

SQLCODE, the deprecated error code scheme, is a simple integer. A value of 0 indicates success, a positive value indicates success with additional information, a negative value indicates an error. The SQL standard only defines the positive value +100, which indicates that the last command returned or affected zero rows, and no specific negative values. Therefore, this scheme can only achieve poor portability and does not have a hierarchical code assignment. Historically, the embedded SQL processor for PostgreSQL has assigned some specific SQLCODE values for its use, which are listed below with their numeric value and their symbolic name. Remember that these are not portable to other SQL implementations. To simplify the porting of applications to the SQLSTATE scheme, the corresponding SQLSTATE is also listed. There is, however, no one-to-one or one-to-many mapping between the two schemes (indeed it is many-to-many), so you should consult the global SQLSTATE listing in Appendix A in each case.

These are the assigned SQLCODE values:

-12 (ECPG_OUT_OF_MEMORY)
  Indicates that your virtual memory is exhausted. (SQLSTATE YE001)

-200 (ECPG_UNSUPPORTED)
  Indicates the preprocessor has generated something that the library does not know about. Perhaps you are running incompatible versions of the preprocessor and the library. (SQLSTATE YE002)

-201 (ECPG_TOO_MANY_ARGUMENTS)
  This means that the command specified more host variables than the command expected. (SQLSTATE 07001 or 07002)

-202 (ECPG_TOO_FEW_ARGUMENTS)
  This means that the command specified fewer host variables than the command expected. (SQLSTATE 07001 or 07002)

-203 (ECPG_TOO_MANY_MATCHES)
  This means a query has returned multiple rows but the statement was only prepared to store one result row (for example, because the specified variables are not arrays). (SQLSTATE 21000)

-204 (ECPG_INT_FORMAT)
  The host variable is of type int and the datum in the database is of a different type and contains a value that cannot be interpreted as an int. The library uses strtol() for this conversion. (SQLSTATE 42804)

-205 (ECPG_UINT_FORMAT)
  The host variable is of type unsigned int and the datum in the database is of a different type and contains a value that cannot be interpreted as an unsigned int. The library uses strtoul() for this conversion. (SQLSTATE 42804)
Chapter 32. ECPG - Embedded SQL in C

-206 (ECPG_FLOAT_FORMAT)

The host variable is of type float and the datum in the database is of another type and contains a value that cannot be interpreted as a float. The library uses `strtol()` for this conversion. (SQLSTATE 42804)

-211 (ECPG_CONVERT_BOOL)

This means the host variable is of type bool and the datum in the database is neither ‘t’ nor ‘f’. (SQLSTATE 42804)

-212 (ECPG_EMPTY)

The statement sent to the PostgreSQL server was empty. (This cannot normally happen in an embedded SQL program, so it might point to an internal error.) (SQLSTATE YE002)

-213 (ECPG_MISSING_INDICATOR)

A null value was returned and no null indicator variable was supplied. (SQLSTATE 22002)

-214 (ECPG_NO_ARRAY)

An ordinary variable was used in a place that requires an array. (SQLSTATE 42804)

-215 (ECPG_DATA_NOT_ARRAY)

The database returned an ordinary variable in a place that requires array value. (SQLSTATE 42804)

-220 (ECPG_NO_CONN)

The program tried to access a connection that does not exist. (SQLSTATE 08003)

-221 (ECPG_NOT_CONN)

The program tried to access a connection that does exist but is not open. (This is an internal error.) (SQLSTATE YE002)

-230 (ECPG_INVALID_STMT)

The statement you are trying to use has not been prepared. (SQLSTATE 26000)

-240 (ECPG_UNKNOWN_DESCRIPTOR)

The descriptor specified was not found. The statement you are trying to use has not been prepared. (SQLSTATE 33000)

-241 (ECPG_INVALID_DESCRIPTOR_INDEX)

The descriptor index specified was out of range. (SQLSTATE 07009)

-242 (ECPG_UNKNOWN_DESCRIPTOR_ITEM)

An invalid descriptor item was requested. (This is an internal error.) (SQLSTATE YE002)

-243 (ECPG_VAR_NOT_NUMERIC)

During the execution of a dynamic statement, the database returned a numeric value and the host variable was not numeric. (SQLSTATE 07006)

-244 (ECPG_VAR_NOT_CHAR)

During the execution of a dynamic statement, the database returned a non-numeric value and the host variable was numeric. (SQLSTATE 07006)

-400 (ECPG_PGSQl)

Some error caused by the PostgreSQL server. The message contains the error message from the PostgreSQL server.
Chapter 32. ECPG - Embedded SQL in C

-401 (ECPG_TRANS)
   The PostgreSQL server signaled that we cannot start, commit, or rollback the transaction. (SQL-STATE 08007)

-402 (ECPG_CONNECT)
   The connection attempt to the database did not succeed. (SQLSTATE 08001)

100 (ECPG_NOT_FOUND)
   This is a harmless condition indicating that the last command retrieved or processed zero rows, or that you are at the end of the cursor. (SQLSTATE 02000)

32.12. Preprocessor directives

32.12.1. Including files
   To include an external file into your embedded SQL program, use:

   EXEC SQL INCLUDE filename;

   The embedded SQL preprocessor will look for a file named filename.h, preprocess it, and include it in the resulting C output. Thus, embedded SQL statements in the included file are handled correctly.

   Note that this is not the same as:

   #include <filename.h>

   because this file would not be subject to SQL command preprocessing. Naturally, you can continue to use the C #include directive to include other header files.

   Note: The include file name is case-sensitive, even though the rest of the EXEC SQL INCLUDE command follows the normal SQL case-sensitivity rules.

32.12.2. The #define and #undef directives
   Similar to the directive #define that is known from C, embedded SQL has a similar concept:

   EXEC SQL DEFINE name;
   EXEC SQL DEFINE name value;

   So you can define a name:

   EXEC SQL DEFINE HAVE_FEATURE;

   And you can also define constants:

   EXEC SQL DEFINE MYNUMBER 12;
   EXEC SQL DEFINE MYSTRING 'abc';
Use `undef` to remove a previous definition:

```sql
EXEC SQL UNDEF MYNUMBER;
```

Of course you can continue to use the C versions `#define` and `#undef` in your embedded SQL program. The difference is where your defined values get evaluated. If you use `EXEC SQL DEFINE` then the ecpg preprocessor evaluates the defines and substitutes the values. For example if you write:

```sql
EXEC SQL DEFINE MYNUMBER 12;
...
EXEC SQL UPDATE Tbl SET col = MYNUMBER;
```

then ecpg will already do the substitution and your C compiler will never see any name or identifier `MYNUMBER`. Note that you cannot use `#define` for a constant that you are going to use in an embedded SQL query because in this case the embedded SQL precompiler is not able to see this declaration.

### 32.12.3. ifdef, ifndef, else, elif and endif directives

You can use the following directives to compile code sections conditionally:

```sql
EXEC SQL ifdef name;
    Checks a `name` and processes subsequent lines if `name` has been created with `EXEC SQL define name`.
EXEC SQL ifndef name;
    Checks a `name` and processes subsequent lines if `name` has not been created with `EXEC SQL define name`.
EXEC SQL else;
    Starts processing an alternative section to a section introduced by either `EXEC SQL ifdef name` or `EXEC SQL ifndef name`.
EXEC SQL elif name;
    Checks `name` and starts an alternative section if `name` has been created with `EXEC SQL define name`.
EXEC SQL endif;
    Ends an alternative section.
```

Example:

```sql
exec sql ifndef TZVAR;
exec sql SET TIMEZONE TO 'GMT';
exec sql elif TZONE;
exec sql SET TIMEZONE TO TZONE;
exec sql else;
exec sql SET TIMEZONE TO TZVAR;
exec sql endif;
```
32.13. Processing Embedded SQL Programs

Now that you have an idea how to form embedded SQL C programs, you probably want to know how to compile them. Before compiling you run the file through the embedded SQL C preprocessor, which converts the SQL statements you used to special function calls. After compiling, you must link with a special library that contains the needed functions. These functions fetch information from the arguments, perform the SQL command using the libpq interface, and put the result in the arguments specified for output.

The preprocessor program is called ecpg and is included in a normal PostgreSQL installation. Embedded SQL programs are typically named with an extension .pgc. If you have a program file called progl.pgc, you can preprocess it by simply calling:

```
ecpg progl.pgc
```

This will create a file called progl.c. If your input files do not follow the suggested naming pattern, you can specify the output file explicitly using the -o option.

The preprocessed file can be compiled normally, for example:

```
cc -c progl.c
```

The generated C source files include header files from the PostgreSQL installation, so if you installed PostgreSQL in a location that is not searched by default, you have to add an option such as -I/usr/local/pgsql/include to the compilation command line.

To link an embedded SQL program, you need to include the libecpg library, like so:

```
cc -o myprog progl.o prog2.o ... -lecpg
```

Again, you might have to add an option like -L/usr/local/pgsql/lib to that command line.

If you manage the build process of a larger project using make, it might be convenient to include the following implicit rule to your makefiles:

```
ECPG = ecpg
%.c: %.pgc
	$(ECPG) <
```

The complete syntax of the ecpg command is detailed in ecpg.

The ecpg library is thread-safe if it is built using the --enable-thread-safety command-line option to configure. (You might need to use other threading command-line options to compile your client code.)

32.14. Library Functions

The libecpg library primarily contains “hidden” functions that are used to implement the functionality expressed by the embedded SQL commands. But there are some functions that can usefully be called directly. Note that this makes your code unportable.

- `ECPGdebug(int on, FILE *stream)` turns on debug logging if called with the first argument non-zero. Debug logging is done on `stream`. The log contains all SQL statements with all the
input variables inserted, and the results from the PostgreSQL server. This can be very useful when searching for errors in your SQL statements.

**Note:** On Windows, if the ecpg libraries and an application are compiled with different flags, this function call will crash the application because the internal representation of the FILE pointers differ. Specifically, multithreaded/single-threaded, release/debug, and static/dynamic flags should be the same for the library and all applications using that library.

- **ECPGstatus(int lineno, const char* connection_name)** returns true if you are connected to a database and false if not. *connection_name* can be NULL if a single connection is being used.

### 32.15. Internals

This section explains how ECPG works internally. This information can occasionally be useful to help users understand how to use ECPG.

The first four lines written by ecpg to the output are fixed lines. Two are comments and two are include lines necessary to interface to the library. Then the preprocessor reads through the file and writes output. Normally it just echoes everything to the output.

When it sees an *EXEC SQL* statement, it intervenes and changes it. The command starts with *EXEC SQL* and ends with `;`. Everything in between is treated as an SQL statement and parsed for variable substitution.

Variable substitution occurs when a symbol starts with a colon (`:`). The variable with that name is looked up among the variables that were previously declared within a *EXEC SQL DECLARE* section.

The most important function in the library is **ECPGdo**, which takes care of executing most commands. It takes a variable number of arguments. This can easily add up to 50 or so arguments, and we hope this will not be a problem on any platform.

The arguments are:

A line number

This is the line number of the original line; used in error messages only.

A string

This is the SQL command that is to be issued. It is modified by the input variables, i.e., the variables that where not known at compile time but are to be entered in the command. Where the variables should go the string contains `?`.

Input variables

Every input variable causes ten arguments to be created. (See below.)

**ECPGt_EOIT**

An enum telling that there are no more input variables.

Output variables

Every output variable causes ten arguments to be created. (See below.) These variables are filled by the function.
ECPGt_EORT

An enum telling that there are no more variables.

For every variable that is part of the SQL command, the function gets ten arguments:

1. The type as a special symbol.
2. A pointer to the value or a pointer to the pointer.
3. The size of the variable if it is a char or varchar.
4. The number of elements in the array (for array fetches).
5. The offset to the next element in the array (for array fetches).
6. The type of the indicator variable as a special symbol.
7. A pointer to the indicator variable.
8. 0
9. The number of elements in the indicator array (for array fetches).
10. The offset to the next element in the indicator array (for array fetches).

Note that not all SQL commands are treated in this way. For instance, an open cursor statement like:

EXEC SQL OPEN cursor;

is not copied to the output. Instead, the cursor’s DECLARE command is used at the position of the OPEN command because it indeed opens the cursor.

Here is a complete example describing the output of the preprocessor of a file foo.pgc (details might change with each particular version of the preprocessor):

EXEC SQL BEGIN DECLARE SECTION;
int index;
int result;
EXEC SQL END DECLARE SECTION;
...
EXEC SQL SELECT res INTO :result FROM mytable WHERE index = :index;

is translated into:

/* Processed by ecpg (2.6.0) */
/* These two include files are added by the preprocessor */
#include <ecpgtype.h>;
#include <ecpglib.h>;

/* exec sql begin declare section */

#line 1 "foo.pgc"

int index;
int result;
/* exec sql end declare section */
...
ECPGDo(_LINE_, NULL, "SELECT res FROM mytable WHERE index = ? ",
    ECPGt_int,&(index),1L,1L,sizeof(int),

642
ECPGt_NO_INDICATOR, NULL, 0L, 0L, 0L, ECPGt_EEDIT,
ECPGt_int,&(result),1L,1L,sizeof(int),
ECPGt_NO_INDICATOR, NULL, 0L, 0L, 0L, ECPGt_EORT);
#line 147 "foo.pgc"

(The indentation here is added for readability and not something the preprocessor does.)
Chapter 33. The Information Schema

The information schema consists of a set of views that contain information about the objects defined in the current database. The information schema is defined in the SQL standard and can therefore be expected to be portable and remain stable — unlike the system catalogs, which are specific to PostgreSQL and are modelled after implementation concerns. The information schema views do not, however, contain information about PostgreSQL-specific features; to inquire about those you need to query the system catalogs or other PostgreSQL-specific views.

33.1. The Schema

The information schema itself is a schema named information_schema. This schema automatically exists in all databases. The owner of this schema is the initial database user in the cluster, and that user naturally has all the privileges on this schema, including the ability to drop it (but the space savings achieved by that are minuscule).

By default, the information schema is not in the schema search path, so you need to access all objects in it through qualified names. Since the names of some of the objects in the information schema are generic names that might occur in user applications, you should be careful if you want to put the information schema in the path.

33.2. Data Types

The columns of the information schema views use special data types that are defined in the information schema. These are defined as simple domains over ordinary built-in types. You should not use these types for work outside the information schema, but your applications must be prepared for them if they select from the information schema.

These types are:

- cardinal_number
  A nonnegative integer.
- character_data
  A character string (without specific maximum length).
- sql_identifier
  A character string. This type is used for SQL identifiers, the type character_data is used for any other kind of text data.
- time_stamp
  A domain over the type timestamp with time zone

Every column in the information schema has one of these four types.

Boolean (true/false) data is represented in the information schema by a column of type character_data that contains either YES or NO. (The information schema was invented before the type boolean was added to the SQL standard, so this convention is necessary to keep the information schema backward compatible.)
33.3. `information_schema_catalog_name`

`information_schema_catalog_name` is a table that always contains one row and one column containing the name of the current database (current catalog, in SQL terminology).

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>catalog_name</code></td>
<td><code>sql_identifier</code></td>
<td>Name of the database that contains this information schema</td>
</tr>
</tbody>
</table>

33.4. `administrable_role_authorizations`

The view `administrable_role_authorizations` identifies all roles that the current user has the admin option for.

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>grantee</code></td>
<td><code>sql_identifier</code></td>
<td>Name of the role to which this role membership was granted (can be the current user, or a different role in case of nested role memberships)</td>
</tr>
<tr>
<td><code>role_name</code></td>
<td><code>sql_identifier</code></td>
<td>Name of a role</td>
</tr>
<tr>
<td><code>is_grantable</code></td>
<td><code>character_data</code></td>
<td>Always YES</td>
</tr>
</tbody>
</table>

33.5. `applicable_roles`

The view `applicable_roles` identifies all roles whose privileges the current user can use. This means there is some chain of role grants from the current user to the role in question. The current user itself is also an applicable role. The set of applicable roles is generally used for permission checking.

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>grantee</code></td>
<td><code>sql_identifier</code></td>
<td>Name of the role to which this role membership was granted (can be the current user, or a different role in case of nested role memberships)</td>
</tr>
<tr>
<td><code>role_name</code></td>
<td><code>sql_identifier</code></td>
<td>Name of a role</td>
</tr>
</tbody>
</table>

645
33.6. attributes

The view `attributes` contains information about the attributes of composite data types defined in the database. (Note that the view does not give information about table columns, which are sometimes called attributes in PostgreSQL contexts.)

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>is_grantable</td>
<td>character_data</td>
<td>YES if the grantee has the admin option on the role, NO if not</td>
</tr>
</tbody>
</table>

Table 33-4. attributes Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>udt_catalog</td>
<td>sql_identifier</td>
<td>Name of the database containing the data type (always the current database)</td>
</tr>
<tr>
<td>udt_schema</td>
<td>sql_identifier</td>
<td>Name of the schema containing the data type</td>
</tr>
<tr>
<td>udt_name</td>
<td>sql_identifier</td>
<td>Name of the data type</td>
</tr>
<tr>
<td>attribute_name</td>
<td>sql_identifier</td>
<td>Name of the attribute</td>
</tr>
<tr>
<td>ordinal_position</td>
<td>cardinal_number</td>
<td>Ordinal position of the attribute within the data type (count starts at 1)</td>
</tr>
<tr>
<td>attribute_default</td>
<td>character_data</td>
<td>Default expression of the attribute</td>
</tr>
<tr>
<td>is_nullable</td>
<td>character_data</td>
<td>YES if the attribute is possibly nullable, NO if it is known not nullable.</td>
</tr>
<tr>
<td>data_type</td>
<td>character_data</td>
<td>Data type of the attribute, if it is a built-in type, or ARRAY if it is some array (in that case, see the view <code>element_types</code>), else USER-DEFINED (in that case, the type is identified in <code>attribute_udt_name</code> and associated columns).</td>
</tr>
<tr>
<td>character_maximum_length</td>
<td>cardinal_number</td>
<td>If <code>data_type</code> identifies a character or bit string type, the declared maximum length; null for all other data types or if no maximum length was declared.</td>
</tr>
<tr>
<td>Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>character_octet_length</td>
<td>cardinal_number</td>
<td>If <code>data_type</code> identifies a character type, the maximum possible length in octets (bytes) of a datum (this should not be of concern to PostgreSQL users); null for all other data types.</td>
</tr>
<tr>
<td>numeric_precision</td>
<td>cardinal_number</td>
<td>If <code>data_type</code> identifies a numeric type, this column contains the (declared or implicit) precision of the type for this attribute. The precision indicates the number of significant digits. It can be expressed in decimal (base 10) or binary (base 2) terms, as specified in the column <code>numeric_precision_radix</code>. For all other data types, this column is null.</td>
</tr>
<tr>
<td>numeric_precision_radix</td>
<td>cardinal_number</td>
<td>If <code>data_type</code> identifies a numeric type, this column indicates in which base the values in the columns <code>numeric_precision</code> and <code>numeric_scale</code> are expressed. The value is either 2 or 10. For all other data types, this column is null.</td>
</tr>
<tr>
<td>numeric_scale</td>
<td>cardinal_number</td>
<td>If <code>data_type</code> identifies an exact numeric type, this column contains the (declared or implicit) scale of the type for this attribute. The scale indicates the number of significant digits to the right of the decimal point. It can be expressed in decimal (base 10) or binary (base 2) terms, as specified in the column <code>numeric_precision_radix</code>. For all other data types, this column is null.</td>
</tr>
</tbody>
</table>
### Table: Column Descriptions

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>datetime_precision</td>
<td>cardinal_number</td>
<td>If <code>data_type</code> identifies a date, time, timestamp, or interval type, this column contains the (declared or implicit) fractional seconds precision of the type for this attribute, that is, the number of decimal digits maintained following the decimal point in the seconds value. For all other data types, this column is null.</td>
</tr>
<tr>
<td>interval_type</td>
<td>character_data</td>
<td>Not yet implemented</td>
</tr>
<tr>
<td>interval_precision</td>
<td>character_data</td>
<td>Not yet implemented</td>
</tr>
<tr>
<td>attribute_udt_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that the attribute data type is defined in (always the current database)</td>
</tr>
<tr>
<td>attribute_udt_schema</td>
<td>sql_identifier</td>
<td>Name of the schema that the attribute data type is defined in</td>
</tr>
<tr>
<td>attribute_udt_name</td>
<td>sql_identifier</td>
<td>Name of the attribute data type</td>
</tr>
<tr>
<td>scope_catalog</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>
<td>scope_schema</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>
<td>scope_name</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>
<td>maximum_cardinality</td>
<td>cardinal_number</td>
<td>Always null, because arrays always have unlimited maximum cardinality in PostgreSQL</td>
</tr>
<tr>
<td>dtd_identifier</td>
<td>sql_identifier</td>
<td>An identifier of the data type descriptor of the column, unique among the data type descriptors pertaining to the table. This is mainly useful for joining with other instances of such identifiers. (The specific format of the identifier is not defined and not guaranteed to remain the same in future versions.)</td>
</tr>
<tr>
<td>is_derived_reference_attribute</td>
<td>character_data</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
</tbody>
</table>

See also under Section 33.12, a similarly structured view, for further information on some of the columns.
33.7. **check_constraint_routine_usage**

The view `check_constraint_routine_usage` identifies routines (functions and procedures) that are used by a check constraint. Only those routines are shown that are owned by a currently enabled role.

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>constraint_catalog</td>
<td>sql_identifier</td>
<td>Name of the database containing the constraint (always the current database)</td>
</tr>
<tr>
<td>constraint_schema</td>
<td>sql_identifier</td>
<td>Name of the schema containing the constraint</td>
</tr>
<tr>
<td>constraint_name</td>
<td>sql_identifier</td>
<td>Name of the constraint</td>
</tr>
<tr>
<td>specific_catalog</td>
<td>sql_identifier</td>
<td>Name of the database containing the function (always the current database)</td>
</tr>
<tr>
<td>specific_schema</td>
<td>sql_identifier</td>
<td>Name of the schema containing the function</td>
</tr>
<tr>
<td>specific_name</td>
<td>sql_identifier</td>
<td>The “specific name” of the function. See Section 33.33 for more information.</td>
</tr>
</tbody>
</table>

33.8. **check_constraints**

The view `check_constraints` contains all check constraints, either defined on a table or on a domain, that are owned by a currently enabled role. (The owner of the table or domain is the owner of the constraint.)

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>constraint_catalog</td>
<td>sql_identifier</td>
<td>Name of the database containing the constraint (always the current database)</td>
</tr>
<tr>
<td>constraint_schema</td>
<td>sql_identifier</td>
<td>Name of the schema containing the constraint</td>
</tr>
<tr>
<td>constraint_name</td>
<td>sql_identifier</td>
<td>Name of the constraint</td>
</tr>
<tr>
<td>check_clause</td>
<td>character_data</td>
<td>The check expression of the check constraint</td>
</tr>
</tbody>
</table>

33.9. **column_domain_usage**

The view `column_domain_usage` identifies all columns (of a table or a view) that make use of some domain defined in the current database and owned by a currently enabled role.
Table 33-7. `column_domain_usage` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>domain_catalog</td>
<td><code>sql_identifier</code></td>
<td>Name of the database containing the domain (always the current database)</td>
</tr>
<tr>

<tr>
<td>table_name</td>
<td><code>sql_identifier</code></td>
<td>Name of the table</td>
</tr>
<tr>
<td>column_name</td>
<td><code>sql_identifier</code></td>
<td>Name of the column</td>
</tr>
</tbody>
</table>

33.10. `column_privileges`

The view `column_privileges` identifies all privileges granted on columns to a currently enabled role or by a currently enabled role. There is one row for each combination of column, grantor, and grantee.

If a privilege has been granted on an entire table, it will show up in this view as a grant for each column, but only for the privilege types where column granularity is possible: `SELECT`, `INSERT`, `UPDATE`, `REFERENCES`.

Table 33-8. `column_privileges` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grantor</td>
<td><code>sql_identifier</code></td>
<td>Name of the role that granted the privilege</td>
</tr>
<tr>
<td>grantee</td>
<td><code>sql_identifier</code></td>
<td>Name of the role that the privilege was granted to</td>
</tr>
<tr>
<td>table_catalog</td>

</tr>
<tr>
<td>column_name</td>
<td><code>sql_identifier</code></td>
<td>Name of the column</td>
</tr>
<tr>
<td>privilege_type</td>
<td><code>character_data</code></td>
<td>Type of the privilege: <code>SELECT</code>, <code>INSERT</code>, <code>UPDATE</code>, or <code>REFERENCES</code></td>
</tr>
</tbody>
</table>
### 33.11. `column_udt_usage`

The view `column_udt_usage` identifies all columns that use data types owned by a currently enabled role. Note that in PostgreSQL, built-in data types behave like user-defined types, so they are included here as well. See also Section 33.12 for details.

#### Table 33-9. `column_udt_usage` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>udt_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that the column data type (the underlying type of the domain, if applicable) is defined in (always the current database)</td>
</tr>
<tr>
<td>udt_schema</td>
<td>sql_identifier</td>
<td>Name of the schema that the column data type (the underlying type of the domain, if applicable) is defined in</td>
</tr>
<tr>
<td>udt_name</td>
<td>sql_identifier</td>
<td>Name of the column data type (the underlying type of the domain, if applicable)</td>
</tr>
<tr>
<td>table_catalog</td>
<td>sql_identifier</td>
<td>Name of the database containing the table (always the current database)</td>
</tr>
<tr>
<td>table_schema</td>
<td>sql_identifier</td>
<td>Name of the schema containing the table</td>
</tr>
<tr>
<td>table_name</td>
<td>sql_identifier</td>
<td>Name of the table</td>
</tr>
<tr>
<td>column_name</td>
<td>sql_identifier</td>
<td>Name of the column</td>
</tr>
</tbody>
</table>

### 33.12. `columns`

The view `columns` contains information about all table columns (or view columns) in the database. System columns (oid, etc.) are not included. Only those columns are shown that the current user has access to (by way of being the owner or having some privilege).

#### Table 33-10. `columns` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>
<td>maximum_cardinality</td>
<td>cardinal_number</td>
<td>Always null, because arrays always have unlimited maximum cardinality in PostgreSQL</td>
</tr>
</tbody>
</table>
Since data types can be defined in a variety of ways in SQL, and PostgreSQL contains additional ways to define data types, their representation in the information schema can be somewhat difficult. The column `data_type` is supposed to identify the underlying built-in type of the column. In PostgreSQL, this means that the type is defined in the system catalog schema `pg_catalog`. This column might be useful if the application can handle the well-known built-in types specially (for example, format the numeric types differently or use the data in the precision columns). The columns `udt_name`, `udt_schema`, and `udt_catalog` always identify the underlying data type of the column, even if the column is based on a domain. (Since PostgreSQL treats built-in types like user-defined types, built-in types appear here as well. This is an extension of the SQL standard.) These columns should be used if an application wants to process data differently according to the type, because in that case it wouldn’t matter if the column is really based on a domain. If the column is based on a domain, the identity

<table>

</tr>
</tbody>
</table>
of the domain is stored in the columns name, schema, and catalog. If you want to pair up columns with their associated data types and treat domains as separate types, you could write `coalesce(domain_name, udt_name)`, etc.

### 33.13. `constraint_column_usage`

The view `constraint_column_usage` identifies all columns in the current database that are used by some constraint. Only those columns are shown that are contained in a table owned by a currently enabled role. For a check constraint, this view identifies the columns that are used in the check expression. For a foreign key constraint, this view identifies the columns that the foreign key references. For a unique or primary key constraint, this view identifies the constrained columns.

#### Table 33-11. `constraint_column_usage` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that contains the table that contains the column that is used by some constraint (always the current database)</td>
</tr>
<tr>

</tr>
<tr>
<td>constraint_name</td>
<td>sql_identifier</td>
<td>Name of the constraint</td>
</tr>
</tbody>
</table>

### 33.14. `constraint_table_usage`

The view `constraint_table_usage` identifies all tables in the current database that are used by some constraint and are owned by a currently enabled role. (This is different from the view `table_constraints`, which identifies all table constraints along with the table they are defined on.) For a foreign key constraint, this view identifies the table that the foreign key references. For a unique or primary key constraint, this view simply identifies the table the constraint belongs to. Check constraints and not-null constraints are not included in this view.

#### Table 33-12. `constraint_table_usage` Columns

33.15. **data_type_privileges**

The view `data_type_privileges` identifies all data type descriptors that the current user has access to, by way of being the owner of the described object or having some privilege for it. A data type descriptor is generated whenever a data type is used in the definition of a table column, a domain, or a function (as parameter or return type) and stores some information about how the data type is used in that instance (for example, the declared maximum length, if applicable). Each data type descriptor is assigned an arbitrary identifier that is unique among the data type descriptor identifiers assigned for one object (table, domain, function). This view is probably not useful for applications, but it is used to define some other views in the information schema.

**Table 33-13. data_type_privileges Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that contains the described object (always the current database)</td>
</tr>
<tr>
<td>object_schema</td>
<td>sql_identifier</td>
<td>Name of the schema that contains the described object</td>
</tr>
<tr>
<td>object_name</td>
<td>sql_identifier</td>
<td>Name of the described object</td>
</tr>
<tr>
<td>object_type</td>
<td>character_data</td>
<td>The type of the described object: one of TABLE (the data type descriptor pertains to a column of that table), DOMAIN (the data type descriptors pertain to that domain), ROUTINE (the data type descriptor pertains to a parameter or the return data type of that function).</td>
</tr>
</tbody>
</table>
### 33.16. domain_constraints

The view `domain_constraints` contains all constraints belonging to domains defined in the current database.

**Table 33-14. domain_constraints Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>constraint_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that contains the constraint (always the current database)</td>

<tr>
<td>dtd_identifier</td>
<td>sql_identifier</td>
<td>An identifier of the data type descriptor of the domain, unique among the data type descriptors pertaining to the domain (which is trivial, because a domain only contains one data type descriptor). This is mainly useful for joining with other instances of such identifiers. (The specific format of the identifier is not defined and not guaranteed to remain the same in future versions.)</td>
</tr>
</tbody>
</table>
33.19. element_types

The view `element_types` contains the data type descriptors of the elements of arrays. When a table column, domain, function parameter, or function return value is defined to be of an array type, the respective information schema view only contains `ARRAY` in the column `data_type`. To obtain information on the element type of the array, you can join the respective view with this view. For example, to show the columns of a table with data types and array element types, if applicable, you could do:

```sql
SELECT c.column_name, c.data_type, e.data_type AS element_type
FROM information_schema.columns c LEFT JOIN information_schema.element_types e
  ON ((c.table_catalog, c.table_schema, c.table_name, 'TABLE', c.dtd_identifier)
      = (e.object_catalog, e.object_schema, e.object_name, e.object_type, e.collection_type_identifier))
WHERE c.table_schema = '...' AND c.table_name = '...'
ORDER BY c.ordinal_position;
```

This view only includes objects that the current user has access to, by way of being the owner or having some privilege.

**Table 33-17. element_types Columns**

</tbody>
</table>
### Chapter 33. The Information Schema

#### 33.20. enabled_roles

The view `enabled_roles` identifies the currently “enabled roles”. The enabled roles are recursively defined as the current user together with all roles that have been granted to the enabled roles with automatic inheritance. In other words, these are all roles that the current user has direct or indirect, automatically inheriting membership in.

For permission checking, the set of “applicable roles” is applied, which can be broader than the set of enabled roles. So generally, it is better to use the view `applicable_roles` instead of this one; see also there.

#### Table 33-18. enabled_roles Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>role_name</td>
<td>sql_identifier</td>
<td>Name of a role</td>
</tr>
</tbody>
</table>

---

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>interval_precision</td>
<td>character_data</td>
<td>Always null, since this information is not applied to array element data types in PostgreSQL</td>
</tr>
<tr>
<td>domain_default</td>
<td>character_data</td>
<td>Not yet implemented</td>
</tr>
<tr>
<td>udt_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that the data type of the elements is defined in (always the current database)</td>
</tr>
<tr>
<td>udt_schema</td>
<td>sql_identifier</td>
<td>Name of the schema that the data type of the elements is defined in</td>
</tr>
<tr>
<td>udt_name</td>
<td>sql_identifier</td>
<td>Name of the data type of the elements</td>
</tr>
<tr>
<td>scope_catalog</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>

<tr>
<td>maximum_cardinality</td>
<td>cardinal_number</td>
<td>Always null, because arrays always have unlimited maximum cardinality in PostgreSQL</td>
</tr>
<tr>
<td>dtd_identifier</td>
<td>sql_identifier</td>
<td>An identifier of the data type descriptor of the element. This is currently not useful.</td>
</tr>
</tbody>
</table>
### 33.21. foreign_data_wrapper_options

The view `foreign_data_wrapper_options` contains all the options defined for foreign-data wrappers in the current database. Only those foreign-data wrappers are shown that the current user has access to (by way of being the owner or having some privilege).

Table 33-19. foreign_data_wrapper_options Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreign_data_wrapper_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that the foreign-data wrapper is defined in (always the current database)</td>
</tr>
<tr>
<td>foreign_data_wrapper_name</td>
<td>sql_identifier</td>
<td>Name of the foreign-data wrapper</td>
</tr>
<tr>
<td>option_name</td>
<td>sql_identifier</td>
<td>Name of an option</td>
</tr>
<tr>
<td>option_value</td>
<td>character_data</td>
<td>Value of the option</td>
</tr>
</tbody>
</table>

### 33.22. foreign_data_wrappers

The view `foreign_data_wrappers` contains all foreign-data wrappers defined in the current database. Only those foreign-data wrappers are shown that the current user has access to (by way of being the owner or having some privilege).

Table 33-20. foreign_data_wrappers Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreign_data_wrapper_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that contains the foreign-data wrapper (always the current database)</td>
</tr>
<tr>
<td>foreign_data_wrapper_name</td>
<td>sql_identifier</td>
<td>Name of the foreign-data wrapper</td>
</tr>
<tr>
<td>authorization_identifier</td>
<td>sql_identifier</td>
<td>Name of the owner of the foreign server</td>
</tr>
<tr>
<td>library_name</td>
<td>character_data</td>
<td>File name of the library that implementing this foreign-data wrapper</td>
</tr>
<tr>
<td>foreign_data_wrapper_language</td>
<td>character_data</td>
<td>Language used to implement this foreign-data wrapper</td>
</tr>
</tbody>
</table>

### 33.23. foreign_server_options

The view `foreign_server_options` contains all the options defined for foreign servers in the current database. Only those foreign servers are shown that the current user has access to (by way of being the owner or having some privilege).
Table 33-21. foreign_server_options Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreign_server_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that the foreign server is defined in (always the current database)</td>
</tr>
<tr>
<td>foreign_server_name</td>
<td>sql_identifier</td>
<td>Name of the foreign server</td>
</tr>
<tr>
<td>option_name</td>
<td>sql_identifier</td>
<td>Name of an option</td>
</tr>
<tr>
<td>option_value</td>
<td>character_data</td>
<td>Value of the option</td>
</tr>
</tbody>
</table>

33.24. foreign_servers

The view foreign_servers contains all foreign servers defined in the current database. Only those foreign servers are shown that the current user has access to (by way of being the owner or having some privilege).

Table 33-22. foreign_servers Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreign_server_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that the foreign server is defined in (always the current database)</td>
</tr>
<tr>
<td>foreign_server_name</td>
<td>sql_identifier</td>
<td>Name of the foreign server</td>
</tr>
<tr>
<td>foreign_data_wrapper_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that contains the foreign-data wrapper used by the foreign server (always the current database)</td>
</tr>
<tr>
<td>foreign_data_wrapper_name</td>
<td>sql_identifier</td>
<td>Name of the foreign-data wrapper used by the foreign server</td>
</tr>
<tr>
<td>foreign_server_type</td>
<td>character_data</td>
<td>Foreign server type information, if specified upon creation</td>
</tr>
<tr>
<td>foreign_server_version</td>
<td>character_data</td>
<td>Foreign server version information, if specified upon creation</td>
</tr>
<tr>
<td>authorization_identifier</td>
<td>sql_identifier</td>
<td>Name of the owner of the foreign server</td>
</tr>
</tbody>
</table>

33.25. key_column_usage

The view key_column_usage identifies all columns in the current database that are restricted by some unique, primary key, or foreign key constraint. Check constraints are not included in this view. Only those columns are shown that the current user has access to, by way of being the owner or having some privilege.
Table 33-23. key_column_usage Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>constraint_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that contains the constraint (always the current database)</td>
</tr>
<tr>
<td>constraint_schema</td>
<td>sql_identifier</td>
<td>Name of the schema that contains the constraint</td>
</tr>
<tr>
<td>constraint_name</td>
<td>sql_identifier</td>
<td>Name of the constraint</td>
</tr>
<tr>
<td>table_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that contains the table that contains the column that is restricted by this constraint (always the current database)</td>
</tr>
<tr>
<td>table_schema</td>
<td>sql_identifier</td>
<td>Name of the schema that contains the table that contains the column that is restricted by this constraint</td>
</tr>
<tr>
<td>table_name</td>
<td>sql_identifier</td>
<td>Name of the table that contains the column that is restricted by this constraint</td>
</tr>
<tr>
<td>column_name</td>
<td>sql_identifier</td>
<td>Name of the column that is restricted by this constraint</td>
</tr>
<tr>
<td>ordinal_position</td>
<td>cardinal_number</td>
<td>Ordinal position of the column within the constraint key (count starts at 1)</td>
</tr>
<tr>
<td>position_in_unique_constraint</td>
<td>cardinal_number</td>
<td>For a foreign-key constraint, ordinal position of the referenced column within its unique constraint (count starts at 1); otherwise null</td>
</tr>
</tbody>
</table>

33.26. parameters

The view parameters contains information about the parameters (arguments) of all functions in the current database. Only those functions are shown that the current user has access to (by way of being the owner or having some privilege).

Table 33-24. parameters Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>specific_catalog</td>
<td>sql_identifier</td>
<td>Name of the database containing the function (always the current database)</td>
</tr>
<tr>
<td>specific_schema</td>
<td>sql_identifier</td>
<td>Name of the schema containing the function</td>
</tr>
<tr>
<td>Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>specific_name</td>
<td>sql_identifier</td>
<td>The “specific name” of the function. See Section 33.33 for more information.</td>
</tr>
<tr>
<td>ordinal_position</td>
<td>cardinal_number</td>
<td>Ordinal position of the parameter in the argument list of the function (count starts at 1)</td>
</tr>
<tr>
<td>parameter_mode</td>
<td>character_data</td>
<td>IN for input parameter, OUT for output parameter, and INOUT for input/output parameter.</td>
</tr>
<tr>
<td>is_result</td>
<td>character_data</td>
<td>Applies to a feature not available in PostgreSQL.</td>
</tr>
<tr>
<td>as_locator</td>
<td>character_data</td>
<td>Applies to a feature not available in PostgreSQL.</td>
</tr>
<tr>
<td>parameter_name</td>
<td>sql_identifier</td>
<td>Name of the parameter, or null if the parameter has no name.</td>
</tr>
<tr>
<td>data_type</td>
<td>character_data</td>
<td>Data type of the parameter, if it is a built-in type, or ARRAY if it is some array (in that case, see the view element_types), else USER-DEFINED (in that case, the type is identified in udt_name and associated columns).</td>
</tr>
<tr>
<td>character_maximum_length</td>
<td>cardinal_number</td>
<td>Always null, since this information is not applied to parameter data types in PostgreSQL.</td>
</tr>
<tr>
<td>character_octet_length</td>
<td>cardinal_number</td>
<td>Always null, since this information is not applied to parameter data types in PostgreSQL.</td>
</tr>
<tr>
<td>character_set_catalog</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL.</td>
</tr>
<tr>
<td>character_set_schema</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL.</td>

<tr>
<td>collation_catalog</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL.</td>
</tr>
<tr>
<td>collation_schema</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL.</td>
</tr>
<tr>
<td>collation_name</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL.</td>
</tr>
<tr>
<td>Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>numeric_precision</td>
<td>cardinal_number</td>
<td>Always null, since this information is not applied to parameter data types in PostgreSQL</td>
</tr>
<tr>
<td>numeric_precision_radix</td>
<td>cardinal_number</td>
<td>Always null, since this information is not applied to parameter data types in PostgreSQL</td>
</tr>
<tr>
<td>numeric_scale</td>
<td>cardinal_number</td>
<td>Always null, since this information is not applied to parameter data types in PostgreSQL</td>
</tr>
<tr>
<td>datetime_precision</td>
<td>cardinal_number</td>
<td>Always null, since this information is not applied to parameter data types in PostgreSQL</td>
</tr>
<tr>
<td>interval_type</td>
<td>character_data</td>
<td>Always null, since this information is not applied to parameter data types in PostgreSQL</td>
</tr>
<tr>
<td>interval_precision</td>
<td>character_data</td>
<td>Always null, since this information is not applied to parameter data types in PostgreSQL</td>
</tr>
<tr>
<td>udt_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that the data type of the parameter is defined in (always the current database)</td>
</tr>
<tr>
<td>udt_schema</td>
<td>sql_identifier</td>
<td>Name of the schema that the data type of the parameter is defined in</td>
</tr>
<tr>
<td>udt_name</td>
<td>sql_identifier</td>
<td>Name of the data type of the parameter</td>
</tr>
<tr>
<td>scope_catalog</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>
<td>scope_schema</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>
<td>scope_name</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>
<td>maximum_cardinality</td>
<td>cardinal_number</td>
<td>Always null, because arrays always have unlimited maximum cardinality in PostgreSQL</td>
</tr>
</tbody>
</table>
Chapter 33. The Information Schema

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dtd_identifier</td>
<td>sql_identifier</td>
<td>An identifier of the data type descriptor of the parameter, unique among the data type descriptors pertaining to the function. This is mainly useful for joining with other instances of such identifiers. (The specific format of the identifier is not defined and not guaranteed to remain the same in future versions.)</td>
</tr>
</tbody>
</table>

33.27. referential_constraints

The view referential_constraints contains all referential (foreign key) constraints in the current database. Only those constraints are shown for which the current user has write access to the referencing table (by way of being the owner or having some privilege other than SELECT).

Table 33-25. referential_constraints Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>constraint_catalog</td>
<td>sql_identifier</td>
<td>Name of the database containing the constraint (always the current database)</td>
</tr>
<tr>
<td>constraint_schema</td>
<td>sql_identifier</td>
<td>Name of the schema containing the constraint</td>
</tr>
<tr>
<td>constraint_name</td>
<td>sql_identifier</td>
<td>Name of the constraint</td>
</tr>
<tr>
<td>unique_constraint_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that contains the unique or primary key constraint that the foreign key constraint references (always the current database)</td>
</tr>
<tr>
<td>unique_constraint_schema</td>
<td>sql_identifier</td>
<td>Name of the schema that contains the unique or primary key constraint that the foreign key constraint references</td>
</tr>
<tr>
<td>unique_constraint_name</td>
<td>sql_identifier</td>
<td>Name of the unique or primary key constraint that the foreign key constraint references</td>
</tr>
<tr>
<td>match_option</td>
<td>character_data</td>
<td>Match option of the foreign key constraint: FULL, PARTIAL, or NONE.</td>
</tr>
<tr>
<td>update_rule</td>
<td>character_data</td>
<td>Update rule of the foreign key constraint: CASCADE, SET NULL, SET DEFAULT, RESTRICT, or NO ACTION.</td>
</tr>
</tbody>
</table>
33.28. role_column_grants

The view role_column_grants identifies all privileges granted on columns where the grantor or grantee is a currently enabled role. Further information can be found under column_privileges.

Table 33-26. role_column_grants Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grantor</td>
<td>sql_identifier</td>
<td>Name of the role that granted the privilege</td>
</tr>
<tr>
<td>grantee</td>
<td>sql_identifier</td>
<td>Name of the role that the privilege was granted to</td>
</tr>
<tr>
<td>table_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that contains the table that contains the column (always the current database)</td>
</tr>
<tr>
<td>table_schema</td>
<td>sql_identifier</td>
<td>Name of the schema that contains the table that contains the column</td>
</tr>
<tr>
<td>table_name</td>
<td>sql_identifier</td>
<td>Name of the table that contains the column</td>
</tr>
<tr>
<td>column_name</td>
<td>sql_identifier</td>
<td>Name of the column</td>
</tr>
<tr>
<td>privilege_type</td>
<td>character_data</td>
<td>Type of the privilege: SELECT, INSERT, UPDATE, or REFERENCES</td>
</tr>
<tr>
<td>is_grantable</td>
<td>character_data</td>
<td>YES if the privilege is grantable, NO if not</td>
</tr>
</tbody>
</table>

33.29. role_routine_grants

The view role_routine_grants identifies all privileges granted on functions where the grantor or grantee is a currently enabled role. Further information can be found under routine_privileges.

Table 33-27. role_routine_grants Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grantor</td>
<td>sql_identifier</td>
<td>Name of the role that granted the privilege</td>
</tr>
</tbody>
</table>
### Chapter 33. The Information Schema

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grantee</td>
<td>sql_identifier</td>
<td>Name of the role that the privilege was granted to</td>
</tr>
<tr>
<td>specific_catalog</td>
<td>sql_identifier</td>
<td>Name of the database containing the function (always the current database)</td>
</tr>
<tr>
<td>specific_schema</td>
<td>sql_identifier</td>
<td>Name of the schema containing the function</td>
</tr>
<tr>
<td>specific_name</td>
<td>sql_identifier</td>
<td>The “specific name” of the function. See Section 33.33 for more information.</td>
</tr>
<tr>
<td>routine_catalog</td>
<td>sql_identifier</td>
<td>Name of the database containing the function (always the current database)</td>
</tr>
<tr>
<td>routine_schema</td>
<td>sql_identifier</td>
<td>Name of the schema containing the function</td>
</tr>
<tr>
<td>routine_name</td>
<td>sql_identifier</td>
<td>Name of the function (might be duplicated in case of overloading)</td>
</tr>
<tr>
<td>privilege_type</td>
<td>character_data</td>
<td>Always EXECUTE (the only privilege type for functions)</td>
</tr>
<tr>
<td>is_grantable</td>
<td>character_data</td>
<td>YES if the privilege is grantable, NO if not</td>
</tr>
</tbody>
</table>

#### 33.30. role_table_grants

The view role_table_grants identifies all privileges granted on tables or views where the grantor or grantee is a currently enabled role. Further information can be found under table_privileges.

### Table 33-28. role_table_grants Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grantor</td>
<td>sql_identifier</td>
<td>Name of the role that granted the privilege</td>
</tr>
<tr>
<td>grantee</td>
<td>sql_identifier</td>
<td>Name of the role that the privilege was granted to</td>
</tr>
<tr>
<td>table_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that contains the table (always the current database)</td>
</tr>
<tr>
<td>table_schema</td>
<td>sql_identifier</td>
<td>Name of the schema that contains the table</td>
</tr>
<tr>
<td>table_name</td>
<td>sql_identifier</td>
<td>Name of the table</td>
</tr>
<tr>
<td>privilege_type</td>
<td>character_data</td>
<td>Type of the privilege: SELECT, INSERT, UPDATE, DELETE, TRUNCATE, REFERENCES, or TRIGGER</td>
</tr>
</tbody>
</table>
### 33.31. role_usage_grants

The view *role_usage_grants* identifies USAGE privileges granted on various kinds of objects where the grantor or grantee is a currently enabled role. Further information can be found under *usage_privileges*.

**Table 33-29. role_usage_grants Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grantor</td>
<td>sql_identifier</td>
<td>The name of the role that granted the privilege</td>
</tr>
<tr>
<td>grantee</td>
<td>sql_identifier</td>
<td>The name of the role that the privilege was granted to</td>
</tr>
<tr>
<td>object_catalog</td>
<td>sql_identifier</td>
<td>Name of the database containing the object (always the current database)</td>
</tr>
<tr>
<td>object_schema</td>
<td>sql_identifier</td>
<td>Name of the schema containing the object, if applicable, else an empty string</td>
</tr>
<tr>
<td>object_name</td>
<td>sql_identifier</td>
<td>Name of the object</td>
</tr>
<tr>
<td>object_type</td>
<td>character_data</td>
<td>DOMAIN or FOREIGN DATA WRAPPER or FOREIGN SERVER</td>
</tr>
<tr>
<td>privilege_type</td>
<td>character_data</td>
<td>Always USAGE</td>
</tr>
<tr>
<td>is_grantable</td>
<td>character_data</td>
<td>YES if the privilege is grantable, NO if not</td>
</tr>
</tbody>
</table>

### 33.32. routine_privileges

The view *routine_privileges* identifies all privileges granted on functions to a currently enabled role or by a currently enabled role. There is one row for each combination of function, grantor, and grantee.

**Table 33-30. routine_privileges Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grantor</td>
<td>sql_identifier</td>
<td>Name of the role that granted the privilege</td>
</tr>
</tbody>
</table>
### 33.33. routines

The view `routines` contains all functions in the current database. Only those functions are shown that the current user has access to (by way of being the owner or having some privilege).

#### Table 33-31. routines Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>specific_catalog</td>
<td>sql_identifier</td>
<td>Name of the database containing the function (always the current database)</td>
</tr>
<tr>
<td>specific_schema</td>
<td>sql_identifier</td>
<td>Name of the schema containing the function</td>
</tr>
<tr>
<td>specific_name</td>
<td>sql_identifier</td>
<td>The &quot;specific name&quot; of the function. See Section 33.33 for more information.</td>
</tr>
<tr>
<td>routine_catalog</td>
<td>sql_identifier</td>
<td>Name of the database containing the function (always the current database)</td>
</tr>
<tr>
<td>routine_schema</td>
<td>sql_identifier</td>
<td>Name of the schema containing the function</td>
</tr>
<tr>
<td>routine_name</td>
<td>sql_identifier</td>
<td>Name of the function (might be duplicated in case of overloading)</td>
</tr>
<tr>
<td>privilege_type</td>
<td>character_data</td>
<td>Always EXECUTE (the only privilege type for functions)</td>
</tr>
<tr>
<td>is_grantable</td>
<td>character_data</td>
<td>YES if the privilege is grantable, NO if not</td>

</table>
33.34. schemata

The view schemata contains all schemas in the current database that are owned by a currently enabled role.

Table 33-32. schemata Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>catalog_name</td>
<td>sql_identifier</td>
<td>Name of the database that the schema is contained in (always the current database)</td>
</tr>
<tr>
<td>schema_name</td>
<td>sql_identifier</td>
<td>Name of the schema</td>
</tr>
<tr>
<td>schema_owner</td>
<td>sql_identifier</td>
<td>Name of the owner of the schema</td>
</tr>
<tr>
<td>default_character_set_catalog</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>
<td>default_character_set_schema</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>

<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>
<td>sql_path</td>
<td>character_data</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
</tbody>
</table>

33.35. sequences

The view sequences contains all sequences defined in the current database. Only those sequences are shown that the current user has access to (by way of being the owner or having some privilege).

Table 33-33. sequences Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sequence_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that contains the sequence (always the current database)</td>
</tr>
<tr>
<td>sequence_schema</td>
<td>sql_identifier</td>
<td>Name of the schema that contains the sequence</td>
</tr>
<tr>
<td>sequence_name</td>
<td>sql_identifier</td>
<td>Name of the sequence</td>
</tr>
<tr>
<td>data_type</td>
<td>character_data</td>
<td>The data type of the sequence. In PostgreSQL, this is currently always bigint.</td>
</tr>
</tbody>
</table>
Chapter 33. The Information Schema

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric_precision</td>
<td>cardinal_number</td>
<td>This column contains the (declared or implicit) precision of the sequence data type (see above). The precision indicates the number of significant digits. It can be expressed in decimal (base 10) or binary (base 2) terms, as specified in the column numeric_precision_radix.</td>
</tr>
<tr>
<td>numeric_precision_radix</td>
<td>cardinal_number</td>
<td>This column indicates in which base the values in the columns numeric_precision and numeric_scale are expressed. The value is either 2 or 10.</td>
</tr>
<tr>
<td>numeric_scale</td>
<td>cardinal_number</td>
<td>This column contains the (declared or implicit) scale of the sequence data type (see above). The scale indicates the number of significant digits to the right of the decimal point. It can be expressed in decimal (base 10) or binary (base 2) terms, as specified in the column numeric_precision_radix.</td>
</tr>
<tr>
<td>maximum_value</td>
<td>cardinal_number</td>
<td>Not yet implemented</td>
</tr>
<tr>
<td>minimum_value</td>
<td>cardinal_number</td>
<td>Not yet implemented</td>
</tr>
<tr>
<td>increment</td>
<td>cardinal_number</td>
<td>Not yet implemented</td>
</tr>
<tr>
<td>cycle_option</td>
<td>character_data</td>
<td>Not yet implemented</td>
</tr>
</tbody>
</table>

33.36. sql_features

The table sql_features contains information about which formal features defined in the SQL standard are supported by PostgreSQL. This is the same information that is presented in Appendix D. There you can also find some additional background information.

Table 33-34. sql_features Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>feature_id</td>
<td>character_data</td>
<td>Identifier string of the feature</td>
</tr>
<tr>
<td>feature_name</td>
<td>character_data</td>
<td>Descriptive name of the feature</td>
</tr>
</tbody>
</table>
### 33.37. `sql_implementation_info`

The table `sql_implementation_info` contains information about various aspects that are left implementation-defined by the SQL standard. This information is primarily intended for use in the context of the ODBC interface; users of other interfaces will probably find this information to be of little use. For this reason, the individual implementation information items are not described here; you will find them in the description of the ODBC interface.

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>implementation_info_id</td>
<td>character_data</td>
<td>Identifier string of the implementation information item</td>
</tr>
<tr>
<td>implementation_info_name</td>
<td>character_data</td>
<td>Descriptive name of the implementation information item</td>
</tr>
<tr>
<td>integer_value</td>
<td>cardinal_number</td>
<td>Value of the implementation information item, or null if the value is contained in the character_value column</td>
</tr>
<tr>
<td>character_value</td>
<td>character_data</td>
<td>Value of the implementation information item, or null if the value is contained in the integer_value column</td>
</tr>
<tr>
<td>comments</td>
<td>character_data</td>
<td>Possibly a comment pertaining to the implementation information item</td>
</tr>
</tbody>
</table>
33.38. sql_languages

The table sql_languages contains one row for each SQL language binding that is supported by PostgreSQL. PostgreSQL supports direct SQL and embedded SQL in C; that is all you will learn from this table.

Table 33-36. sql_languages Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_language_source</td>
<td>character_data</td>
<td>The name of the source of the language definition; always ISO 9075, that is, the SQL standard</td>
</tr>
<tr>
<td>sql_language_year</td>
<td>character_data</td>
<td>The year the standard referenced in sql_language_source was approved; currently 2003</td>
</tr>
<tr>
<td>sql_language_conformance</td>
<td>character_data</td>
<td>The standard conformance level for the language binding. For ISO 9075:2003 this is always CORE.</td>
</tr>
<tr>
<td>sql_language_integrity</td>
<td>character_data</td>
<td>Always null (This value is relevant to an earlier version of the SQL standard.)</td>
</tr>
<tr>
<td>sql_language_implementation</td>
<td>character_data</td>
<td>Always null</td>
</tr>
<tr>
<td>sql_language_binding_style</td>
<td>character_data</td>
<td>The language binding style, either DIRECT or EMBEDDED</td>
</tr>
<tr>
<td>sql_language_programming_language</td>
<td>character_data</td>
<td>The programming language, if the binding style is EMBEDDED, else null. PostgreSQL only supports the language C.</td>
</tr>
</tbody>
</table>

33.39. sql_packages

The table sql_packages contains information about which feature packages defined in the SQL standard are supported by PostgreSQL. Refer to Appendix D for background information on feature packages.

Table 33-37. sql_packages Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>feature_id</td>
<td>character_data</td>
<td>Identifier string of the package</td>
</tr>
<tr>
<td>feature_name</td>
<td>character_data</td>
<td>Descriptive name of the package</td>
</tr>
<tr>
<td>is_supported</td>
<td>character_data</td>
<td>YES if the package is fully supported by the current version of PostgreSQL, NO if not</td>
</tr>
</tbody>
</table>
33.40. sql_parts

The table `sql_parts` contains information about which of the several parts of the SQL standard are supported by PostgreSQL.

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>feature_id</td>
<td>character_data</td>
<td>An identifier string containing the number of the part</td>
</tr>
<tr>
<td>feature_name</td>
<td>character_data</td>
<td>Descriptive name of the part</td>
</tr>
<tr>
<td>is_supported</td>
<td>character_data</td>
<td>YES if the part is fully supported by the current version of PostgreSQL, NO if not</td>
</tr>
<tr>
<td>is_verified_by</td>
<td>character_data</td>
<td>Always null, since the PostgreSQL development group does not perform formal testing of feature conformance</td>
</tr>
<tr>
<td>comments</td>
<td>character_data</td>
<td>Possibly a comment about the supported status of the package</td>
</tr>
</tbody>
</table>

33.41. sql_sizing

The table `sql_sizing` contains information about various size limits and maximum values in PostgreSQL. This information is primarily intended for use in the context of the ODBC interface; users of other interfaces will probably find this information to be of little use. For this reason, the individual sizing items are not described here; you will find them in the description of the ODBC interface.

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sizing_id</td>
<td>cardinal_number</td>
<td>Identifier of the sizing item</td>
</tr>
<tr>
<td>sizing_name</td>
<td>character_data</td>
<td>Descriptive name of the sizing item</td>
</tr>
</tbody>
</table>
### 33.42. `sql_sizing_profiles`

The table `sql_sizing_profiles` contains information about the `sql_sizing` values that are required by various profiles of the SQL standard. PostgreSQL does not track any SQL profiles, so this table is empty.

**Table 33-40. `sql_sizing_profiles` Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sizing_id</code></td>
<td>cardinal_number</td>
<td>Identifier of the sizing item</td>
</tr>
<tr>
<td><code>sizing_name</code></td>
<td>character_data</td>
<td>Descriptive name of the sizing item</td>
</tr>
<tr>
<td><code>profile_id</code></td>
<td>character_data</td>
<td>Identifier string of a profile</td>
</tr>
<tr>
<td><code>required_value</code></td>
<td>cardinal_number</td>
<td>The value required by the SQL profile for the sizing item, or 0 if the profile places no limit on the sizing item, or null if the profile does not require any of the features for which the sizing item is applicable</td>
</tr>
<tr>
<td><code>comments</code></td>
<td>character_data</td>
<td>Possibly a comment pertaining to the sizing item within the profile</td>
</tr>
</tbody>
</table>

### 33.43. `table_constraints`

The view `table_constraints` contains all constraints belonging to tables that the current user owns or has some non-SELECT privilege on.

**Table 33-41. `table_constraints` Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>constraint_catalog</code></td>
<td>sql_identifier</td>
<td>Name of the database that contains the constraint (always the current database)</td>
</tr>
</tbody>
</table>
### Chapter 33. The Information Schema

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>constraint_schema</td>
<td>sql_identifier</td>
<td>Name of the schema that contains the constraint</td>
</tr>
<tr>
<td>constraint_name</td>
<td>sql_identifier</td>
<td>Name of the constraint</td>
</tr>
<tr>
<td>table_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that contains the table (always the current database)</td>
</tr>
<tr>
<td>table_schema</td>
<td>sql_identifier</td>
<td>Name of the schema that contains the table</td>
</tr>
<tr>
<td>table_name</td>
<td>sql_identifier</td>
<td>Name of the table</td>
</tr>
<tr>
<td>constraint_type</td>
<td>character_data</td>
<td>Type of the constraint: CHECK, FOREIGN KEY, PRIMARY KEY, or UNIQUE</td>
</tr>
<tr>
<td>is_deferrable</td>
<td>character_data</td>
<td>YES if the constraint is deferrable, NO if not</td>
</tr>
<tr>
<td>initially_deferred</td>
<td>character_data</td>
<td>YES if the constraint is deferrable and initially deferred, NO if not</td>
</tr>
</tbody>
</table>

#### 33.44. table privileges

The view `table_privileges` identifies all privileges granted on tables or views to a currently enabled role or by a currently enabled role. There is one row for each combination of table, grantor, and grantee.

**Table 33-42. table_privileges Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grantor</td>
<td>sql_identifier</td>
<td>Name of the role that granted the privilege</td>
</tr>
<tr>
<td>grantee</td>
<td>sql_identifier</td>
<td>Name of the role that the privilege was granted to</td>
</tr>
<tr>
<td>table_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that contains the table (always the current database)</td>
</tr>
<tr>
<td>table_schema</td>
<td>sql_identifier</td>
<td>Name of the schema that contains the table</td>
</tr>
<tr>
<td>table_name</td>
<td>sql_identifier</td>
<td>Name of the table</td>
</tr>
<tr>
<td>privilege_type</td>
<td>character_data</td>
<td>Type of the privilege: SELECT, INSERT, UPDATE, DELETE, TRUNCATE, REFERENCES, or TRIGGER</td>
</tr>
<tr>
<td>is_grantable</td>
<td>character_data</td>
<td>YES if the privilege is grantable, NO if not</td>
</tr>
<tr>
<td>with_hierarchy</td>
<td>character_data</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
</tbody>
</table>
## 33.45. tables

The view `tables` contains all tables and views defined in the current database. Only those tables and views are shown that the current user has access to (by way of being the owner or having some privilege).

### Table 33-43. tables Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that contains the table (always the current database)</td>
</tr>
<tr>
<td>table_schema</td>
<td>sql_identifier</td>
<td>Name of the schema that contains the table</td>
</tr>
<tr>
<td>table_name</td>
<td>sql_identifier</td>
<td>Name of the table</td>
</tr>
<tr>
<td>table_type</td>
<td>character_data</td>
<td>Type of the table: <strong>BASE TABLE</strong> for a persistent base table (the normal table type), <strong>VIEW</strong> for a view, or <strong>LOCAL TEMPORARY</strong> for a temporary table</td>
</tr>
<tr>
<td>self_referencing_column_name</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>
<td>reference_generation</td>
<td>character_data</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>
<td>user_defined_type_catalog</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>
<td>user_defined_type_schema</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>
<td>user_defined_type_name</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>
<td>is_insertable_into</td>
<td>character_data</td>
<td>YES if the table is insertable into, NO if not (Base tables are always insertable into, views not necessarily.)</td>
</tr>
<tr>
<td>is_typed</td>
<td>character_data</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>
<td>commit_action</td>
<td>character_data</td>
<td>If the table is a temporary table, then <strong>PRESERVE</strong>, else null. (The SQL standard defines other commit actions for temporary tables, which are not supported by PostgreSQL.)</td>
</tr>
</tbody>
</table>

## 33.46. triggers

The view `triggers` contains all triggers defined in the current database on tables that the current user owns or has some non-SELECT privilege on.
Table 33-44. triggers Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>trigger_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that contains the trigger (always the current database)</td>
</tr>
<tr>
<td>trigger_schema</td>
<td>sql_identifier</td>
<td>Name of the schema that contains the trigger</td>
</tr>
<tr>
<td>trigger_name</td>
<td>sql_identifier</td>
<td>Name of the trigger</td>
</tr>
<tr>
<td>event_manipulation</td>
<td>character_data</td>
<td>Event that fires the trigger (INSERT, UPDATE, or DELETE)</td>
</tr>
<tr>
<td>event_object_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that contains the table that the trigger is defined on (always the current database)</td>
</tr>
<tr>
<td>event_object_schema</td>
<td>sql_identifier</td>
<td>Name of the schema that contains the table that the trigger is defined on</td>
</tr>
<tr>
<td>event_object_table</td>
<td>sql_identifier</td>
<td>Name of the table that the trigger is defined on</td>
</tr>
<tr>
<td>action_order</td>
<td>cardinal_number</td>
<td>Not yet implemented</td>
</tr>
<tr>
<td>action_condition</td>
<td>character_data</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>
<td>action_statement</td>
<td>character_data</td>
<td>Statement that is executed by the trigger (currently always EXECUTE PROCEDURE function(...))</td>
</tr>
<tr>
<td>action_orientation</td>
<td>character_data</td>
<td>Identifies whether the trigger fires once for each processed row or once for each statement (ROW or STATEMENT)</td>
</tr>
<tr>
<td>condition_timing</td>
<td>character_data</td>
<td>Time at which the trigger fires (BEFORE or AFTER)</td>
</tr>
<tr>
<td>condition_reference_old</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>
<td>condition_reference_new</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>
<td>condition_reference_old</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>
<td>condition_reference_new</td>
<td>sql_identifier</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
<tr>
<td>created</td>
<td>time_stamp</td>
<td>Applies to a feature not available in PostgreSQL</td>
</tr>
</tbody>
</table>

Triggers in PostgreSQL have two incompatibilities with the SQL standard that affect the representation in the information schema. First, trigger names are local to the table in PostgreSQL, rather than being independent schema objects. Therefore there can be duplicate trigger names defined in one schema, as long as they belong to different tables. (trigger_catalog and
trigger_schema are really the values pertaining to the table that the trigger is defined on.) Second, triggers can be defined to fire on multiple events in PostgreSQL (e.g., ON INSERT OR UPDATE), whereas the SQL standard only allows one. If a trigger is defined to fire on multiple events, it is represented as multiple rows in the information schema, one for each type of event. As a consequence of these two issues, the primary key of the view triggers is really (trigger_catalog, trigger_schema, trigger_name, event_object_table, event_manipulation) instead of (trigger_catalog, trigger_schema, trigger_name), which is what the SQL standard specifies. Nonetheless, if you define your triggers in a manner that conforms with the SQL standard (trigger names unique in the schema and only one event type per trigger), this will not affect you.

### 33.47. usage_privileges

The view usage_privileges identifies USAGE privileges granted on various kinds of objects to a currently enabled role or by a currently enabled role. In PostgreSQL, this currently applies to domains, foreign-data wrappers, and foreign servers. There is one row for each combination of object, grantor, and grantee.

Since domains do not have real privileges in PostgreSQL, this view shows implicit non-grantable USAGE privileges granted by the owner to PUBLIC for all domains. The other object types, however, show real privileges.

#### Table 33-45. usage_privileges Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grantor</td>
<td>sql_identifier</td>
<td>Name of the role that granted the privilege</td>
</tr>
<tr>
<td>grantee</td>
<td>sql_identifier</td>
<td>Name of the role that the privilege was granted to</td>
</tr>
<tr>
<td>object_catalog</td>
<td>sql_identifier</td>
<td>Name of the database containing the object (always the current database)</td>
</tr>
<tr>
<td>object_schema</td>
<td>sql_identifier</td>
<td>Name of the schema containing the object, if applicable, else an empty string</td>
</tr>
<tr>
<td>object_name</td>
<td>sql_identifier</td>
<td>Name of the object</td>
</tr>
<tr>
<td>object_type</td>
<td>character_data</td>
<td>DOMAIN or FOREIGN DATA WRAPPER or FOREIGN SERVER</td>
</tr>
<tr>
<td>privilege_type</td>
<td>character_data</td>
<td>Always USAGE</td>
</tr>
<tr>
<td>is_grantable</td>
<td>character_data</td>
<td>YES if the privilege is grantable, NO if not</td>
</tr>
</tbody>
</table>

### 33.48. user_mapping_options

The view user_mapping_options contains all the options defined for user mappings in the current database. Only those user mappings are shown where the current user has access to the corresponding foreign server (by way of being the owner or having some privilege).
### Table 33-46. *user_mapping_options* Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>authorization_identifier</td>
<td>sql_identifier</td>
<td>Name of the user being mapped, or PUBLIC if the mapping is public</td>
</tr>
<tr>
<td>foreign_server_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that the foreign server used by this mapping is defined in (always the current database)</td>
</tr>
<tr>
<td>foreign_server_name</td>
<td>sql_identifier</td>
<td>Name of the foreign server used by this mapping</td>
</tr>
<tr>
<td>option_name</td>
<td>sql_identifier</td>
<td>Name of an option</td>
</tr>
<tr>
<td>option_value</td>
<td>character_data</td>
<td>Value of the option. This column will show as null unless the current user is the user being mapped, or the mapping is for PUBLIC and the current user is the server owner, or the current user is a superuser. The intent is to protect password information stored as user mapping option.</td>
</tr>
</tbody>
</table>

### 33.49. *user_mappings*

The view *user_mappings* contains all user mappings defined in the current database. Only those user mappings are shown where the current user has access to the corresponding foreign server (by way of being the owner or having some privilege).

### Table 33-47. *user_mappings* Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>authorization_identifier</td>
<td>sql_identifier</td>
<td>Name of the user being mapped, or PUBLIC if the mapping is public</td>
</tr>
<tr>
<td>foreign_server_catalog</td>
<td>sql_identifier</td>
<td>Name of the database that the foreign server used by this mapping is defined in (always the current database)</td>
</tr>
<tr>
<td>foreign_server_name</td>
<td>sql_identifier</td>
<td>Name of the foreign server used by this mapping</td>
</tr>
</tbody>
</table>

### 33.50. *view_column_usage*

The view *view_column_usage* identifies all columns that are used in the query expression of a view

---

690
Ch. 33. The Information Schema

The \texttt{SELECT} statement that defines the view). A column is only included if the table that contains the column is owned by a currently enabled role.

\textbf{Note:} Columns of system tables are not included. This should be fixed sometime.

\textbf{Table 33-48. view_column_usage Columns}

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>

V. Server Programming

This part is about extending the server functionality with user-defined functions, data types, triggers, etc. These are advanced topics which should probably be approached only after all the other user documentation about PostgreSQL has been understood. Later chapters in this part describe the server-side programming languages available in the PostgreSQL distribution as well as general issues concerning server-side programming languages. It is essential to read at least the earlier sections of Chapter 34 (covering functions) before diving into the material about server-side programming languages.
Chapter 34. Extending SQL

In the sections that follow, we will discuss how you can extend the PostgreSQL SQL query language by adding:

- functions (starting in Section 34.3)
- aggregates (starting in Section 34.10)
- data types (starting in Section 34.11)
- operators (starting in Section 34.12)
- operator classes for indexes (starting in Section 34.14)

34.1. How Extensibility Works

PostgreSQL is extensible because its operation is catalog-driven. If you are familiar with standard relational database systems, you know that they store information about databases, tables, columns, etc., in what are commonly known as system catalogs. (Some systems call this the data dictionary.) The catalogs appear to the user as tables like any other, but the DBMS stores its internal bookkeeping in them. One key difference between PostgreSQL and standard relational database systems is that PostgreSQL stores much more information in its catalogs: not only information about tables and columns, but also information about data types, functions, access methods, and so on. These tables can be modified by the user, and since PostgreSQL bases its operation on these tables, this means that PostgreSQL can be extended by users. By comparison, conventional database systems can only be extended by changing hardcoded procedures in the source code or by loading modules specially written by the DBMS vendor.

The PostgreSQL server can moreover incorporate user-written code into itself through dynamic loading. That is, the user can specify an object code file (e.g., a shared library) that implements a new type or function, and PostgreSQL will load it as required. Code written in SQL is even more trivial to add to the server. This ability to modify its operation “on the fly” makes PostgreSQL uniquely suited for rapid prototyping of new applications and storage structures.

34.2. The PostgreSQL Type System

PostgreSQL data types are divided into base types, composite types, domains, and pseudo-types.

34.2.1. Base Types

Base types are those, like int4, that are implemented below the level of the SQL language (typically in a low-level language such as C). They generally correspond to what are often known as abstract data types. PostgreSQL can only operate on such types through functions provided by the user and only understands the behavior of such types to the extent that the user describes them. Base types are further subdivided into scalar and array types. For each scalar type, a corresponding array type is automatically created that can hold variable-size arrays of that scalar type.
34.2.2. Composite Types

Composite types, or row types, are created whenever the user creates a table. It is also possible to use `CREATE TYPE` to define a “stand-alone” composite type with no associated table. A composite type is simply a list of types with associated field names. A value of a composite type is a row or record of field values. The user can access the component fields from SQL queries. Refer to Section 8.15 for more information on composite types.

34.2.3. Domains

A domain is based on a particular base type and for many purposes is interchangeable with its base type. However, a domain can have constraints that restrict its valid values to a subset of what the underlying base type would allow.

Domains can be created using the SQL command `CREATE DOMAIN`. Their creation and use is not discussed in this chapter.

34.2.4. Pseudo-Types

There are a few “pseudo-types” for special purposes. Pseudo-types cannot appear as columns of tables or attributes of composite types, but they can be used to declare the argument and result types of functions. This provides a mechanism within the type system to identify special classes of functions. Table 8-23 lists the existing pseudo-types.

34.2.5. Polymorphic Types

Four pseudo-types of special interest are `anyelement`, `anynonarray`, `anyarray`, and `anyenum`, which are collectively called polymorphic types. Any function declared using these types is said to be a polymorphic function. A polymorphic function can operate on many different data types, with the specific data type(s) being determined by the data types actually passed to it in a particular call.

Polymorphic arguments and results are tied to each other and are resolved to a specific data type when a query calling a polymorphic function is parsed. Each position (either argument or return value) declared as `anyelement` is allowed to have any specific actual data type, but in any given call they must all be the same actual type. Each position declared as `anyarray` can have any array data type, but similarly they must all be the same type. If there are positions declared `anyarray` and others declared `anyelement`, the actual array type in the `anyarray` positions must be an array whose elements are the same type appearing in the `anyelement` positions. `anynonarray` is treated exactly the same as `anyelement`, but adds the additional constraint that the actual type must not be an array type. `anyenum` is treated exactly the same as `anyelement`, but adds the additional constraint that the actual type must be an enum type.

Thus, when more than one argument position is declared with a polymorphic type, the net effect is that only certain combinations of actual argument types are allowed. For example, a function declared as `equal(anyelement, anyelement)` will take any two input values, so long as they are of the same data type.

When the return value of a function is declared as a polymorphic type, there must be at least one argument position that is also polymorphic, and the actual data type supplied as the argument determines the actual result type for that call. For example, if there were not already an array subcripting mechanism, one could define a function that implements subscripting as `subscript(anyarray, integer) returns anyelement`. This declaration constrains the actual first argument to be an
array type, and allows the parser to infer the correct result type from the actual first argument’s type. Another example is that a function declared as \( f(\text{anyarray}) \) returns \( \text{anyenum} \) will only accept arrays of enum types.

Note that \( \text{anynonarray} \) and \( \text{anyenum} \) do not represent separate type variables; they are the same type as \( \text{anyelement} \), just with an additional constraint. For example, declaring a function as \( f(\text{anyelement}, \text{anyenum}) \) is equivalent to declaring it as \( f(\text{anyenum}, \text{anyenum}) \): both actual arguments have to be the same enum type.

A variadic function (one taking a variable number of arguments, as in Section 34.4.4) can be polymorphic: this is accomplished by declaring its last parameter as \( \text{VARIADIC anyarray} \). For purposes of argument matching and determining the actual result type, such a function behaves the same as if you had written the appropriate number of \( \text{anynonarray} \) parameters.

### 34.3. User-Defined Functions

PostgreSQL provides four kinds of functions:

- query language functions (functions written in SQL) (Section 34.4)
- procedural language functions (functions written in, for example, PL/pgSQL or PL/Tcl) (Section 34.7)
- internal functions (Section 34.8)
- C-language functions (Section 34.9)

Every kind of function can take base types, composite types, or combinations of these as arguments (parameters). In addition, every kind of function can return a base type or a composite type. Functions can also be defined to return sets of base or composite values.

Many kinds of functions can take or return certain pseudo-types (such as polymorphic types), but the available facilities vary. Consult the description of each kind of function for more details.

It’s easiest to define SQL functions, so we’ll start by discussing those. Most of the concepts presented for SQL functions will carry over to the other types of functions.

Throughout this chapter, it can be useful to look at the reference page of the \texttt{CREATE FUNCTION} command to understand the examples better. Some examples from this chapter can be found in \texttt{funcs.sql} and \texttt{funcs.c} in the \texttt{src/tutorial} directory in the PostgreSQL source distribution.

### 34.4. Query Language (SQL) Functions

SQL functions execute an arbitrary list of SQL statements, returning the result of the last query in the list. In the simple (non-set) case, the first row of the last query’s result will be returned. (Bear in mind that “the first row” of a multirow result is not well-defined unless you use \texttt{ORDER BY}.) If the last query happens to return no rows at all, the null value will be returned.

Alternatively, an SQL function can be declared to return a set, by specifying the function’s return type as \( \text{SETOF sometype} \), or equivalently by declaring it as \( \text{RETURNS TABLE(columns)} \). In this case all rows of the last query’s result are returned. Further details appear below.
Chapter 34. Extending SQL

The body of an SQL function must be a list of SQL statements separated by semicolons. A semicolon after the last statement is optional. Unless the function is declared to return `void`, the last statement must be a `SELECT`, or an `INSERT`, `UPDATE`, or `DELETE` that has a `RETURNING` clause.

Any collection of commands in the SQL language can be packaged together and defined as a function. Besides `SELECT` queries, the commands can include data modification queries (`INSERT`, `UPDATE`, and `DELETE`), as well as other SQL commands. (The only exception is that you cannot put `BEGIN`, `COMMIT`, `ROLLBACK`, or `SAVEPOINT` commands into a SQL function.) However, the final command must be a `SELECT` or have a `RETURNING` clause that returns whatever is specified as the function’s return type. Alternatively, if you want to define a SQL function that performs actions but has no useful value to return, you can define it as returning `void`. For example, this function removes rows with negative salaries from the `emp` table:

```sql
CREATE FUNCTION clean_emp() RETURNS void AS 'DELETE FROM emp WHERE salary < 0;' LANGUAGE SQL;
SELECT clean_emp();
clean_emp
----------
(1 row)
```

The syntax of the `CREATE FUNCTION` command requires the function body to be written as a string constant. It is usually most convenient to use dollar quoting (see Section 4.1.2.4) for the string constant. If you choose to use regular single-quoted string constant syntax, you must double single quote marks (’) and backslashes (\) (assuming escape string syntax) in the body of the function (see Section 4.1.2.1).

Arguments to the SQL function are referenced in the function body using the syntax `$n`: `$1` refers to the first argument, `$2` to the second, and so on. If an argument is of a composite type, then the dot notation, e.g., `$1.name`, can be used to access attributes of the argument. The arguments can only be used as data values, not as identifiers. Thus for example this is reasonable:

```sql
INSERT INTO mytable VALUES ($1);
```

but this will not work:

```sql
INSERT INTO $1 VALUES (42);
```

34.4.1. SQL Functions on Base Types

The simplest possible SQL function has no arguments and simply returns a base type, such as `integer`:

```sql
CREATE FUNCTION one() RETURNS integer AS $$
SELECT 1 AS result;
$$ LANGUAGE SQL;
```

-- Alternative syntax for string literal:
Chapter 34. Extending SQL

CREATE FUNCTION one() RETURNS integer AS 'SELECT 1 AS result;' LANGUAGE SQL;

SELECT one();

one
-----
  1

Notice that we defined a column alias within the function body for the result of the function (with the name result), but this column alias is not visible outside the function. Hence, the result is labeled one instead of result.

It is almost as easy to define SQL functions that take base types as arguments. In the example below, notice how we refer to the arguments within the function as $1 and $2.

CREATE FUNCTION add_em(integer, integer) RETURNS integer AS $$
SELECT $1 + $2;
$$ LANGUAGE SQL;

SELECT add_em(1, 2) AS answer;

answer
--------
    3

Here is a more useful function, which might be used to debit a bank account:

CREATE FUNCTION tf1(integer, numeric) RETURNS integer AS $$
UPDATE bank
    SET balance = balance - $2
    WHERE accountno = $1;
SELECT 1;
$$ LANGUAGE SQL;

A user could execute this function to debit account 17 by $100.00 as follows:

SELECT tf1(17, 100.0);

In practice one would probably like a more useful result from the function than a constant 1, so a more likely definition is:

CREATE FUNCTION tf1(integer, numeric) RETURNS numeric AS $$
UPDATE bank
    SET balance = balance - $2
    WHERE accountno = $1;
SELECT balance FROM bank WHERE accountno = $1;
$$ LANGUAGE SQL;

which adjusts the balance and returns the new balance. The same thing could be done in one command using RETURNING:
Chapter 34. Extending SQL

CREATE FUNCTION tf1 (integer, numeric) RETURNS numeric AS $$
UPDATE bank
    SET balance = balance - $2
WHERE accountno = $1
  RETURNING balance;
$$ LANGUAGE SQL;

34.4.2. SQL Functions on Composite Types

When writing functions with arguments of composite types, we must not only specify which argument
we want (as we did above with $1 and $2) but also the desired attribute (field) of that argument. For
example, suppose that emp is a table containing employee data, and therefore also the name of the
composite type of each row of the table. Here is a function double_salary that computes what
someone’s salary would be if it were doubled:

CREATE TABLE emp (  
    name   text,  
    salary numeric,  
    age    integer,  
    cubicle point
);  

CREATE FUNCTION double_salary(emp) RETURNS numeric AS $$
    SELECT $1.salary * 2 AS salary;
$$ LANGUAGE SQL;

SELECT name, double_salary(emp.*) AS dream  
FROM emp  
WHERE emp.cubicle ~= point '(2,1)';

<table>
<thead>
<tr>
<th>name</th>
<th>dream</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bill</td>
<td>8400</td>
</tr>
</tbody>
</table>

Notice the use of the syntax $1.salary to select one field of the argument row value. Also notice
how the calling SELECT command uses * to select the entire current row of a table as a composite
value. The table row can alternatively be referenced using just the table name, like this:

SELECT name, double_salary(emp) AS dream  
FROM emp  
WHERE emp.cubicle ~= point '(2,1)';

but this usage is deprecated since it’s easy to get confused.

Sometimes it is handy to construct a composite argument value on-the-fly. This can be done with the
ROW construct. For example, we could adjust the data being passed to the function:

SELECT name, double_salary(ROW(name, salary*1.1, age, cubicle)) AS dream  
FROM emp;
It is also possible to build a function that returns a composite type. This is an example of a function that returns a single `emp` row:

```sql
CREATE FUNCTION new_emp() RETURNS emp AS $$
    SELECT text 'None' AS name,
    1000.0 AS salary,
    25 AS age,
    point '(2,2)' AS cubicle;
$$ LANGUAGE SQL;
```

In this example we have specified each of the attributes with a constant value, but any computation could have been substituted for these constants.

Note two important things about defining the function:

- The select list order in the query must be exactly the same as that in which the columns appear in the table associated with the composite type. (Naming the columns, as we did above, is irrelevant to the system.)
- You must typecast the expressions to match the definition of the composite type, or you will get errors like this:

```
ERROR: function declared to return emp returns varchar instead of text at column 1
```

A different way to define the same function is:

```sql
CREATE FUNCTION new_emp() RETURNS emp AS $$
    SELECT ROW('None', 1000.0, 25, '(2,2)')::emp;
$$ LANGUAGE SQL;
```

Here we wrote a `SELECT` that returns just a single column of the correct composite type. This isn’t really better in this situation, but it is a handy alternative in some cases — for example, if we need to compute the result by calling another function that returns the desired composite value.

We could call this function directly in either of two ways:

```sql
SELECT new_emp();
```

```
new_emp
--------------------------
(None,1000.0,25,"(2,2)")
```

```sql
SELECT * FROM new_emp();
```

```
name | salary | age | cubicle
------+--------+-----+---------
None | 1000.0 | 25 | (2,2)
```

The second way is described more fully in Section 34.4.6.

When you use a function that returns a composite type, you might want only one field (attribute) from its result. You can do that with syntax like this:

```sql
SELECT (new_emp()).name;
```

```
name
------
None
```
The extra parentheses are needed to keep the parser from getting confused. If you try to do it without them, you get something like this:

```
SELECT new_emp().name;
ERROR: syntax error at or near "."
LINE 1: SELECT new_emp().name;
```

Another option is to use functional notation for extracting an attribute. The simple way to explain this is that we can use the notations `attribute(table)` and `table.attribute` interchangeably.

```
SELECT name(new_emp());
```

```
name
-----
None
```

```
-- This is the same as:
-- SELECT emp.name AS youngster FROM emp WHERE emp.age < 30;

SELECT name(emp) AS youngster FROM emp WHERE age(emp) < 30;
```

```
youngster
--------
Sam
Andy
```

**Tip:** The equivalence between functional notation and attribute notation makes it possible to use functions on composite types to emulate “computed fields”. For example, using the previous definition for `double_salary(emp)`, we can write

```
SELECT emp.name, emp.double_salary FROM emp;
```

An application using this wouldn’t need to be directly aware that `double_salary` isn’t a real column of the table. (You can also emulate computed fields with views.)

Another way to use a function returning a composite type is to pass the result to another function that accepts the correct row type as input:

```
CREATE FUNCTION getname(emp) RETURNS text AS $$
    SELECT $1.name;
$$ LANGUAGE SQL;
```

```
SELECT getname(new_emp());
```

```
getname
--------
None
```

(1 row)

Still another way to use a function that returns a composite type is to call it as a table function, as described in Section 34.4.6.
34.4.3. SQL Functions with Output Parameters

An alternative way of describing a function’s results is to define it with output parameters, as in this example:

```sql
CREATE FUNCTION add_em (IN x int, IN y int, OUT sum int)
AS 'SELECT $1 + $2'
LANGUAGE SQL;
```

```sql
SELECT add_em(3, 7);
```

```
add_em
--------
10
```

This is not essentially different from the version of `add_em` shown in Section 34.4.1. The real value of output parameters is that they provide a convenient way of defining functions that return several columns. For example,

```sql
CREATE FUNCTION sum_n_product (x int, y int, OUT sum int, OUT product int)
AS 'SELECT $1 + $2, $1 * $2'
LANGUAGE SQL;
```

```sql
SELECT * FROM sum_n_product(11, 42);
```

```
sum | product
-----+---------
53  | 462
```

What has essentially happened here is that we have created an anonymous composite type for the result of the function. The above example has the same end result as

```sql
CREATE TYPE sum_prod AS (sum int, product int);
CREATE FUNCTION sum_n_product (x int, y int) RETURNS sum_prod
AS 'SELECT $1 + $2, $1 * $2'
LANGUAGE SQL;
```

but not having to bother with the separate composite type definition is often handy.

Notice that output parameters are not included in the calling argument list when invoking such a function from SQL. This is because PostgreSQL considers only the input parameters to define the function’s calling signature. That means also that only the input parameters matter when referencing the function for purposes such as dropping it. We could drop the above function with either of

```sql
DROP FUNCTION sum_n_product (x int, y int, OUT sum int, OUT product int);
DROP FUNCTION sum_n_product (int, int);
```

Parameters can be marked as IN (the default), OUT, INOUT, or VARIADIC. An INOUT parameter serves as both an input parameter (part of the calling argument list) and an output parameter (part of the result record type). VARIADIC parameters are input parameters, but are treated specially as described next.
34.4.4. SQL Functions with Variable Numbers of Arguments

SQL functions can be declared to accept variable numbers of arguments, so long as all the “optional” arguments are of the same data type. The optional arguments will be passed to the function as an array. The function is declared by marking the last parameter as `VARIADIC`; this parameter must be declared as being of an array type. For example:

```
CREATE FUNCTION mleast(VARIADIC numeric[]) RETURNS numeric AS $$
  SELECT min($1[i]) FROM generate_subscripts($1, 1) g(i);
$$ LANGUAGE SQL;
```

```
SELECT mleast(10, -1, 5, 4.4);
```

```
mleast
--------
-1
(1 row)
```

Effectively, all the actual arguments at or beyond the `VARIADIC` position are gathered up into a one-dimensional array, as if you had written

```
SELECT mleast(ARRAY[10, -1, 5, 4.4]); -- doesn’t work
```

You can’t actually write that, though — or at least, it will not match this function definition. A parameter marked `VARIADIC` matches one or more occurrences of its element type, not of its own type.

Sometimes it is useful to be able to pass an already-constructed array to a variadic function; this is particularly handy when one variadic function wants to pass on its array parameter to another one. You can do that by specifying `VARIADIC` in the call:

```
SELECT mleast(VARIADIC ARRAY[10, -1, 5, 4.4]);
```

This prevents expansion of the function’s variadic parameter into its element type, thereby allowing the array argument value to match normally. `VARIADIC` can only be attached to the last actual argument of a function call.

34.4.5. SQL Functions with Default Values for Arguments

Functions can be declared with default values for some or all input arguments. The default values are inserted whenever the function is called with insufficiently many actual arguments. Since arguments can only be omitted from the end of the actual argument list, all parameters after a parameter with a default value have to have default values as well.

For example:

```
CREATE FUNCTION foo(a int, b int DEFAULT 2, c int DEFAULT 3)
RETURNS int
LANGUAGE SQL
AS $$
  SELECT $1 + $2 + $3;
$$;
```

```
SELECT foo(10, 20, 30);
```

```
foo
-----
60
```

705
SELECT foo(10, 20);
foo
-----
33
(1 row)

SELECT foo(10);
foo
-----
15
(1 row)

SELECT foo(); -- fails since there is no default for the first argument
ERROR: function foo() does not exist

The = sign can also be used in place of the key word DEFAULT.

### 34.4.6. SQL Functions as Table Sources

All SQL functions can be used in the FROM clause of a query, but it is particularly useful for functions returning composite types. If the function is defined to return a base type, the table function produces a one-column table. If the function is defined to return a composite type, the table function produces a column for each attribute of the composite type.

Here is an example:

```sql
CREATE TABLE foo (fooid int, foosubid int, fooname text);
INSERT INTO foo VALUES (1, 1, 'Joe');
INSERT INTO foo VALUES (1, 2, 'Ed');
INSERT INTO foo VALUES (2, 1, 'Mary');

CREATE FUNCTION getfoo(int) RETURNS foo AS $$
SELECT * FROM foo WHERE fooid = $1;
$$ LANGUAGE SQL;

SELECT *, upper(fooname) FROM getfoo(1) AS t1;

<table>
<thead>
<tr>
<th>fooid</th>
<th>foosubid</th>
<th>fooname</th>
<th>upper</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Joe</td>
<td>JOE</td>
</tr>
</tbody>
</table>
(1 row)
```

As the example shows, we can work with the columns of the function’s result just the same as if they were columns of a regular table.

Note that we only got one row out of the function. This is because we did not use SETOF. That is described in the next section.
34.4.7. SQL Functions Returning Sets

When an SQL function is declared as returning SETOF sometype, the function’s final query is executed to completion, and each row it outputs is returned as an element of the result set.

This feature is normally used when calling the function in the FROM clause. In this case each row returned by the function becomes a row of the table seen by the query. For example, assume that table foo has the same contents as above, and we say:

```sql
CREATE FUNCTION getfoo(int) RETURNS SETOF foo AS $$
    SELECT * FROM foo WHERE fooid = $1;
$$ LANGUAGE SQL;

SELECT * FROM getfoo(1) AS t1;
```

Then we would get:

<table>
<thead>
<tr>
<th>fooid</th>
<th>foosubid</th>
<th>fooname</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>Joe</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Ed</td>
</tr>
</tbody>
</table>

(2 rows)

It is also possible to return multiple rows with the columns defined by output parameters, like this:

```sql
CREATE FUNCTION sum_n_product_with_tab (x int, OUT sum int, OUT product int) RETURNS SETOF record AS $$
    SELECT $1 + tab.y, $1 * tab.y FROM tab;
$$ LANGUAGE SQL;

SELECT * FROM sum_n_product_with_tab(2, 3);
```

The key point here is that you must write RETURNS SETOF record to indicate that the function returns multiple rows instead of just one. If there is only one output parameter, write that parameter’s type instead of record.

Currently, functions returning sets can also be called in the select list of a query. For each row that the query generates by itself, the function returning set is invoked, and an output row is generated for each element of the function’s result set. Note, however, that this capability is deprecated and might be removed in future releases. The following is an example function returning a set from the select list:

```sql
CREATE FUNCTION listchildren(text) RETURNS SETOF text AS $$
    SELECT name FROM nodes WHERE parent = $1
$$ LANGUAGE SQL;

SELECT listchildren('Top');
```

listchildren
-----------
707
34.4.8. SQL Functions Returning TABLE

There is another way to declare a function as returning a set, which is to use the syntax "RETURNS TABLE (columns)." This is equivalent to using one or more "OUT" parameters plus marking the function as returning "SETOF record" (or "SETOF a single output parameter’s type", as appropriate). This notation is specified in recent versions of the SQL standard, and thus may be more portable than using "SETOF.

For example, the preceding sum-and-product example could also be done this way:

```
CREATE FUNCTION sum_n_product_with_tab (x int) RETURNS TABLE (sum int, product int) AS $$
SELECT $1 + tab.y, $1 * tab.y FROM tab;
$$ LANGUAGE SQL;
```

It is not allowed to use explicit "OUT" or "INOUT" parameters with the "RETURNS TABLE" notation — you must put all the output columns in the "TABLE list."

34.4.9. Polymorphic SQL Functions

SQL functions can be declared to accept and return the polymorphic types "anyelement," "anyarray," "anynonarray," and "anyenum." See Section 34.2.5 for a more detailed explanation of polymorphic functions. Here is a polymorphic function "make_array" that builds up an array from two arbitrary data type elements:

```
CREATE FUNCTION make_array (anyelement, anyelement) RETURNS anyarray AS $$
SELECT ARRAY[$1, $2];
$$ LANGUAGE SQL;
```
Chapter 34. Extending SQL

```sql
SELECT make_array(1, 2) AS intarray, make_array('a'::text, 'b') AS textarray;
```

<table>
<thead>
<tr>
<th>intarray</th>
<th>textarray</th>
</tr>
</thead>
<tbody>
<tr>
<td>{1,2}</td>
<td>{a,b}</td>
</tr>
</tbody>
</table>

(1 row)

Notice the use of the typecast `a'::text` to specify that the argument is of type `text`. This is required if the argument is just a string literal, since otherwise it would be treated as type `unknown`, and array of `unknown` is not a valid type. Without the typecast, you will get errors like this:

```
ERROR: could not determine polymorphic type because input has type "unknown"
```

It is permitted to have polymorphic arguments with a fixed return type, but the converse is not. For example:

```sql
CREATE FUNCTION is_greater(anyelement, anyelement) RETURNS boolean AS $$
SELECT $1 > $2;
$$ LANGUAGE SQL;
```

```sql
SELECT is_greater(1, 2);
```

<table>
<thead>
<tr>
<th>is_greater</th>
</tr>
</thead>
<tbody>
<tr>
<td>f</td>
</tr>
</tbody>
</table>

(1 row)

```
CREATE FUNCTION invalid_func() RETURNS anyelement AS $$
SELECT 1;
$$ LANGUAGE SQL;
```

```
ERROR: cannot determine result data type
DETAIL: A function returning a polymorphic type must have at least one polymorphic argument
```

Polymorphism can be used with functions that have output arguments. For example:

```sql
CREATE FUNCTION dup (f1 anyelement, OUT f2 anyelement, OUT f3 anyarray)
AS 'select $1, array[$1,$1]' LANGUAGE SQL;
```

```sql
SELECT * FROM dup(22);
```

<table>
<thead>
<tr>
<th>f2</th>
<th>f3</th>
</tr>
</thead>
<tbody>
<tr>
<td>22</td>
<td>{22,22}</td>
</tr>
</tbody>
</table>

(1 row)

Polymorphism can also be used with variadic functions. For example:

```sql
CREATE FUNCTION anyleast (VARIADIC anyarray) RETURNS anyelement AS $$
SELECT min($1[i]) FROM generate_subscripts($1, 1) g(i);
$$ LANGUAGE SQL;
```

```sql
SELECT anyleast(10, -1, 5, 4);
```

<table>
<thead>
<tr>
<th>anyleast</th>
</tr>
</thead>
<tbody>
<tr>
<td>709</td>
</tr>
</tbody>
</table>

(1 row)
34.5. Function Overloading

More than one function can be defined with the same SQL name, so long as the arguments they take are different. In other words, function names can be overloaded. When a query is executed, the server will determine which function to call from the data types and the number of the provided arguments. Overloading can also be used to simulate functions with a variable number of arguments, up to a finite maximum number.

When creating a family of overloaded functions, one should be careful not to create ambiguities. For instance, given the functions:

```sql
CREATE FUNCTION test(int, real) RETURNS ...
CREATE FUNCTION test(smallint, double precision) RETURNS ...
```

it is not immediately clear which function would be called with some trivial input like `test(1, 1.5)`. The currently implemented resolution rules are described in Chapter 10, but it is unwise to design a system that subtly relies on this behavior.

A function that takes a single argument of a composite type should generally not have the same name as any attribute (field) of that type. Recall that `attribute(table)` is considered equivalent to `table.attribute`. In the case that there is an ambiguity between a function on a composite type and an attribute of the composite type, the attribute will always be used. It is possible to override that choice by schema-qualifying the function name (that is, `schema.func(table)`) but it’s better to avoid the problem by not choosing conflicting names.

Another possible conflict is between variadic and non-variadic functions. For instance, it is possible to create both `foo(numeric)` and `foo(VARIADIC numeric[])`. In this case it is unclear which one should be matched to a call providing a single numeric argument, such as `foo(10.1)`. The rule is that the function appearing earlier in the search path is used, or if the two functions are in the same schema, the non-variadic one is preferred.

When overloading C-language functions, there is an additional constraint: The C name of each function in the family of overloaded functions must be different from the C names of all other functions,
either internal or dynamically loaded. If this rule is violated, the behavior is not portable. You might get a run-time linker error, or one of the functions will get called (usually the internal one). The alternative form of the AS clause for the SQL CREATE FUNCTION command decouples the SQL function name from the function name in the C source code. For instance:

```sql
CREATE FUNCTION test(int) RETURNS int
    AS 'filename', 'test_1arg'
    LANGUAGE C;
CREATE FUNCTION test(int, int) RETURNS int
    AS 'filename', 'test_2arg'
    LANGUAGE C;
```

The names of the C functions here reflect one of many possible conventions.

### 34.6. Function Volatility Categories

Every function has a volatility classification, with the possibilities being VOLATILE, STABLE, or IMMUTABLE. VOLATILE is the default if the CREATE FUNCTION command does not specify a category. The volatility category is a promise to the optimizer about the behavior of the function:

- A VOLATILE function can do anything, including modifying the database. It can return different results on successive calls with the same arguments. The optimizer makes no assumptions about the behavior of such functions. A query using a volatile function will re-evaluate the function at every row where its value is needed.

- A STABLE function cannot modify the database and is guaranteed to return the same results given the same arguments for all rows within a single statement. This category allows the optimizer to optimize multiple calls of the function to a single call. In particular, it is safe to use an expression containing such a function in an index scan condition. (Since an index scan will evaluate the comparison value only once, not once at each row, it is not valid to use a VOLATILE function in an index scan condition.)

- An IMMUTABLE function cannot modify the database and is guaranteed to return the same results given the same arguments forever. This category allows the optimizer to pre-evaluate the function when a query calls it with constant arguments. For example, a query like `SELECT ... WHERE x = 2 + 2` can be simplified on sight to `SELECT ... WHERE x = 4`, because the function underlying the integer addition operator is marked IMMUTABLE.

For best optimization results, you should label your functions with the strictest volatility category that is valid for them.

Any function with side-effects must be labeled VOLATILE, so that calls to it cannot be optimized away. Even a function with no side-effects needs to be labeled VOLATILE if its value can change within a single query; some examples are `random()`, `currval()`, `timeofday()`.

Another important example is that the `current_timestamp` family of functions qualify as STABLE, since their values do not change within a transaction.

There is relatively little difference between STABLE and IMMUTABLE categories when considering simple interactive queries that are planned and immediately executed: it doesn’t matter a lot whether a function is executed once during planning or once during query execution startup. But there is a big difference if the plan is saved and reused later. Labeling a function IMMUTABLE when it really isn’t
might allow it to be prematurely folded to a constant during planning, resulting in a stale value being re-used during subsequent uses of the plan. This is a hazard when using prepared statements or when using function languages that cache plans (such as PL/pgSQL).

For functions written in SQL or in any of the standard procedural languages, there is a second important property determined by the volatility category, namely the visibility of any data changes that have been made by the SQL command that is calling the function. A \texttt{VOLATILE} function will see such changes, a \texttt{STABLE} or \texttt{IMMUTABLE} function will not. This behavior is implemented using the snapshotting behavior of MVCC (see Chapter 13): \texttt{STABLE} and \texttt{IMMUTABLE} functions use a snapshot established as of the start of the calling query, whereas \texttt{VOLATILE} functions obtain a fresh snapshot at the start of each query they execute.

\textbf{Note:} Functions written in C can manage snapshots however they want, but it’s usually a good idea to make C functions work this way too.

Because of this snapshotting behavior, a function containing only \texttt{SELECT} commands can safely be marked \texttt{STABLE}, even if it selects from tables that might be undergoing modifications by concurrent queries. PostgreSQL will execute all commands of a \texttt{STABLE} function using the snapshot established for the calling query, and so it will see a fixed view of the database throughout that query.

The same snapshotting behavior is used for \texttt{SELECT} commands within \texttt{IMMUTABLE} functions. It is generally unwise to select from database tables within an \texttt{IMMUTABLE} function at all, since the immutability will be broken if the table contents ever change. However, PostgreSQL does not enforce that you do not do that.

A common error is to label a function \texttt{IMMUTABLE} when its results depend on a configuration parameter. For example, a function that manipulates timestamps might well have results that depend on the timezone setting. For safety, such functions should be labeled \texttt{STABLE} instead.

\textbf{Note:} Before PostgreSQL release 8.0, the requirement that \texttt{STABLE} and \texttt{IMMUTABLE} functions cannot modify the database was not enforced by the system. Releases 8.0 and later enforce it by requiring SQL functions and procedural language functions of these categories to contain no SQL commands other than \texttt{SELECT}. (This is not a completely bulletproof test, since such functions could still call \texttt{VOLATILE} functions that modify the database. If you do that, you will find that the \texttt{STABLE} or \texttt{IMMUTABLE} function does not notice the database changes applied by the called function, since they are hidden from its snapshot.)

\section*{34.7. Procedural Language Functions}

PostgreSQL allows user-defined functions to be written in other languages besides SQL and C. These other languages are generically called \textit{procedural languages} (PLs). Procedural languages aren’t built into the PostgreSQL server; they are offered by loadable modules. See Chapter 37 and following chapters for more information.

\section*{34.8. Internal Functions}

Internal functions are functions written in C that have been statically linked into the PostgreSQL server. The “body” of the function definition specifies the C-language name of the function, which
need not be the same as the name being declared for SQL use. (For reasons of backwards compatibility, an empty body is accepted as meaning that the C-language function name is the same as the SQL name.)

Normally, all internal functions present in the server are declared during the initialization of the database cluster (initdb), but a user could use CREATE FUNCTION to create additional alias names for an internal function. Internal functions are declared in CREATE FUNCTION with language name internal. For instance, to create an alias for the sqrt function:

```sql
CREATE FUNCTION square_root(double precision) RETURNS double precision
  AS 'dsqrt'
  LANGUAGE internal
  STRICT;
```

(Most internal functions expect to be declared “strict”.)

Note: Not all “predefined” functions are “internal” in the above sense. Some predefined functions are written in SQL.

### 34.9. C-Language Functions

User-defined functions can be written in C (or a language that can be made compatible with C, such as C++). Such functions are compiled into dynamically loadable objects (also called shared libraries) and are loaded by the server on demand. The dynamic loading feature is what distinguishes “C language” functions from “internal” functions — the actual coding conventions are essentially the same for both. (Hence, the standard internal function library is a rich source of coding examples for user-defined C functions.)

Two different calling conventions are currently used for C functions. The newer “version 1” calling convention is indicated by writing a `PG_FUNCTION_INFO_V1()` macro call for the function, as illustrated below. Lack of such a macro indicates an old-style (“version 0”) function. The language name specified in CREATE FUNCTION is C in either case. Old-style functions are now deprecated because of portability problems and lack of functionality, but they are still supported for compatibility reasons.

### 34.9.1. Dynamic Loading

The first time a user-defined function in a particular loadable object file is called in a session, the dynamic loader loads that object file into memory so that the function can be called. The CREATE FUNCTION for a user-defined C function must therefore specify two pieces of information for the function: the name of the loadable object file, and the C name (link symbol) of the specific function to call within that object file. If the C name is not explicitly specified then it is assumed to be the same as the SQL function name.

The following algorithm is used to locate the shared object file based on the name given in the CREATE FUNCTION command:

1. If the name is an absolute path, the given file is loaded.
2. If the name starts with the string `$libdir`, that part is replaced by the PostgreSQL package library directory name, which is determined at build time.
3. If the name does not contain a directory part, the file is searched for in the path specified by the configuration variable `dynamic_library_path`.

4. Otherwise (the file was not found in the path, or it contains a non-absolute directory part), the dynamic loader will try to take the name as given, which will most likely fail. (It is unreliable to depend on the current working directory.)

If this sequence does not work, the platform-specific shared library file name extension (often `.so`) is appended to the given name and this sequence is tried again. If that fails as well, the load will fail.

It is recommended to locate shared libraries either relative to `$libdir` or through the dynamic library path. This simplifies version upgrades if the new installation is at a different location. The actual directory that `$libdir` stands for can be found out with the command `pg_config --pkglibdir`.

The user ID the PostgreSQL server runs as must be able to traverse the path to the file you intend to load. Making the file or a higher-level directory not readable and/or not executable by the postgres user is a common mistake.

In any case, the file name that is given in the `CREATE FUNCTION` command is recorded literally in the system catalogs, so if the file needs to be loaded again the same procedure is applied.

**Note:** PostgreSQL will not compile a C function automatically. The object file must be compiled before it is referenced in a `CREATE FUNCTION` command. See Section 34.9.6 for additional information.

To ensure that a dynamically loaded object file is not loaded into an incompatible server, PostgreSQL checks that the file contains a “magic block” with the appropriate contents. This allows the server to detect obvious incompatibilities, such as code compiled for a different major version of PostgreSQL. A magic block is required as of PostgreSQL 8.2. To include a magic block, write this in one (and only one) of the module source files, after having included the header `fmgr.h`:

```c
#ifdef PG_MODULE_MAGIC
PG_MODULE_MAGIC;
#endif
```

The `#ifdef` test can be omitted if the code doesn’t need to compile against pre-8.2 PostgreSQL releases.

After it is used for the first time, a dynamically loaded object file is retained in memory. Future calls in the same session to the function(s) in that file will only incur the small overhead of a symbol table lookup. If you need to force a reload of an object file, for example after recompiling it, begin a fresh session.

Optionally, a dynamically loaded file can contain initialization and finalization functions. If the file includes a function named `_PG_init`, that function will be called immediately after loading the file. The function receives no parameters and should return void. If the file includes a function named `_PG_fini`, that function will be called immediately before unloading the file. Likewise, the function receives no parameters and should return void. Note that `_PG_fini` will only be called during an unload of the file, not during process termination. (Presently, unloads are disabled and will never occur, but this may change in the future.)

### 34.9.2. Base Types in C-Language Functions

To know how to write C-language functions, you need to know how PostgreSQL internally represents base data types and how they can be passed to and from functions. Internally, PostgreSQL regards a
base type as a “blob of memory”. The user-defined functions that you define over a type in turn define the way that PostgreSQL can operate on it. That is, PostgreSQL will only store and retrieve the data from disk and use your user-defined functions to input, process, and output the data.

Base types can have one of three internal formats:

- pass by value, fixed-length
- pass by reference, fixed-length
- pass by reference, variable-length

By-value types can only be 1, 2, or 4 bytes in length (also 8 bytes, if `sizeof(Datum)` is 8 on your machine). You should be careful to define your types such that they will be the same size (in bytes) on all architectures. For example, the `long` type is dangerous because it is 4 bytes on some machines and 8 bytes on others, whereas `int` type is 4 bytes on most Unix machines. A reasonable implementation of the `int4` type on Unix machines might be:

```c
/* 4-byte integer, passed by value */
typedef int int4;
```

On the other hand, fixed-length types of any size can be passed by-reference. For example, here is a sample implementation of a PostgreSQL type:

```c
/* 16-byte structure, passed by reference */
typedef struct
{
    double x, y;
} Point;
```

Only pointers to such types can be used when passing them in and out of PostgreSQL functions. To return a value of such a type, allocate the right amount of memory with `palloc`, fill in the allocated memory, and return a pointer to it. (Also, if you just want to return the same value as one of your input arguments that’s of the same data type, you can skip the extra `palloc` and just return the pointer to the input value.)

Finally, all variable-length types must also be passed by reference. All variable-length types must begin with a length field of exactly 4 bytes, and all data to be stored within that type must be located in the memory immediately following that length field. The length field contains the total length of the structure, that is, it includes the size of the length field itself.

**Warning**

Never modify the contents of a pass-by-reference input value. If you do so you are likely to corrupt on-disk data, since the pointer you are given might point directly into a disk buffer. The sole exception to this rule is explained in Section 34.10.

As an example, we can define the type `text` as follows:

```c
typedef struct {
    int4 length;
    char data[1];
} text;
```
Chapter 34. Extending SQL

Obviously, the data field declared here is not long enough to hold all possible strings. Since it’s impossible to declare a variable-size structure in C, we rely on the knowledge that the C compiler won’t range-check array subscripts. We just allocate the necessary amount of space and then access the array as if it were declared the right length. (This is a common trick, which you can read about in many textbooks about C.)

When manipulating variable-length types, we must be careful to allocate the correct amount of memory and set the length field correctly. For example, if we wanted to store 40 bytes in a text structure, we might use a code fragment like this:

```c
#include "postgres.h"
...
char buffer[40]; /* our source data */
...
text *destination = (text *) palloc(VARHDRSZ + 40);
destination->length = VARHDRSZ + 40;
memcpy(destination->data, buffer, 40);
...
```

VARHDRSZ is the same as `sizeof(int4)`, but it’s considered good style to use the macro VARHDRSZ to refer to the size of the overhead for a variable-length type.

Table 34-1 specifies which C type corresponds to which SQL type when writing a C-language function that uses a built-in type of PostgreSQL. The “Defined In” column gives the header file that needs to be included to get the type definition. (The actual definition might be in a different file that is included by the listed file. It is recommended that users stick to the defined interface.) Note that you should always include `postgres.h` first in any source file, because it declares a number of things that you will need anyway.

### Table 34-1. Equivalent C Types for Built-In SQL Types

<table>
<thead>
<tr>
<th>SQL Type</th>
<th>C Type</th>
<th>Defined In</th>

</tr>
</tbody>
</table>

Now that we’ve gone over all of the possible structures for base types, we can show some examples of real functions.

### 34.9.3. Version 0 Calling Conventions

We present the “old style” calling convention first — although this approach is now deprecated, it’s easier to get a handle on initially. In the version-0 method, the arguments and result of the C function are just declared in normal C style, but being careful to use the C representation of each SQL data type as shown above.

Here are some examples:

```c
#include "postgres.h"
#include <string.h>

/* by value */

int
add_one(int arg)
{
    return arg + 1;
}

/* by reference, fixed length */

float8 *
add_one_float8(float8 *arg)
{
    float8  *result = (float8 *) palloc(sizeof(float8));

    *result = *arg + 1.0;

    return result;
}
```
Chapter 34. Extending SQL

Point *
makepoint(Point *pointx, Point *pointy)
{
    Point *new_point = (Point *) palloc(sizeof(Point));
    new_point->x = pointx->x;
    new_point->y = pointy->y;
    return new_point;
}

/* by reference, variable length */
text *
copytext(text *t)
{
    /* 
     * VARSIZE is the total size of the struct in bytes.
     */
text *new_t = (text *) palloc(VARSIZE(t));
    SET_VARSIZE(new_t, VARSIZE(t));
    /*
     * VARDATA is a pointer to the data region of the struct.
     */
    memcpy((void *) VARDATA(new_t), /* destination */
            (void *) VARDATA(t), /* source */
            VARSIZE(t) - VARHDRSZ); /* how many bytes */
    return new_t;
}
text *
concat_text(text *arg1, text *arg2)
{
    int32 new_text_size = VARSIZE(arg1) + VARSIZE(arg2) - VARHDRSZ;
text *new_text = (text *) palloc(new_text_size);
    SET_VARSIZE(new_text, new_text_size);
    memcpy(VARDATA(new_text), VARDATA(arg1), VARSIZE(arg1) - VARHDRSZ);
    memcpy(VARDATA(new_text) + (VARSIZE(arg1) - VARHDRSZ),
            VARDATA(arg2), VARSIZE(arg2) - VARHDRSZ);
    return new_text;
}

Supposing that the above code has been prepared in file funcs.c and compiled into a shared object,
we could define the functions to PostgreSQL with commands like this:

CREATE FUNCTION add_one(integer) RETURNS integer
    AS 'DIRECTORY/funcs', 'add_one'
    LANGUAGE C STRICT;

-- note overloading of SQL function name "add_one"
CREATE FUNCTION add_one(double precision) RETURNS double precision
    AS 'DIRECTORY/funcs', 'add_one_float8'
    LANGUAGE C STRICT;

CREATE FUNCTION makepoint(point, point) RETURNS point
AS 'DIRECTORY/funcs', 'makepoint',
LANGUAGE C STRICT;

CREATE FUNCTION copytext(text) RETURNS text
AS 'DIRECTORY/funcs', 'copytext',
LANGUAGE C STRICT;

CREATE FUNCTION concat_text(text, text) RETURNS text
AS 'DIRECTORY/funcs', 'concat_text',
LANGUAGE C STRICT;

Here, DIRECTORY stands for the directory of the shared library file (for instance the PostgreSQL tutorial directory, which contains the code for the examples used in this section). (Better style would be to use just 'funcs' in the AS clause, after having added DIRECTORY to the search path. In any case, we can omit the system-specific extension for a shared library, commonly .so or .sl.)

Notice that we have specified the functions as “strict”, meaning that the system should automatically assume a null result if any input value is null. By doing this, we avoid having to check for null inputs in the function code. Without this, we’d have to check for null values explicitly, by checking for a null pointer for each pass-by-reference argument. (For pass-by-value arguments, we don’t even have a way to check!)

Although this calling convention is simple to use, it is not very portable; on some architectures there are problems with passing data types that are smaller than int this way. Also, there is no simple way to return a null result, nor to cope with null arguments in any way other than making the function strict. The version-1 convention, presented next, overcomes these objections.

34.9.4. Version 1 Calling Conventions

The version-1 calling convention relies on macros to suppress most of the complexity of passing arguments and results. The C declaration of a version-1 function is always:

Datum funcname(PG_FUNCTION_ARGS)

In addition, the macro call:

PG_FUNCTION_INFO_V1(funcname);

must appear in the same source file. (Conventionally, it’s written just before the function itself.) This macro call is not needed for internal-language functions, since PostgreSQL assumes that all internal functions use the version-1 convention. It is, however, required for dynamically-loaded functions.

In a version-1 function, each actual argument is fetched using a PG_GETARG_xxx() macro that corresponds to the argument’s data type, and the result is returned using a PG_RETURN_xxx() macro for the return type. PG_GETARG_xxx() takes as its argument the number of the function argument to fetch, where the count starts at 0. PG_RETURN_xxx() takes as its argument the actual value to return.

Here we show the same functions as above, coded in version-1 style:

#include "postgres.h"
#include <string.h>
#include "fmgr.h"

/* by value */
PG_FUNCTION_INFO_V1(add_one);

Datum
add_one(PG_FUNCTION_ARGS)
{
    int32 arg = PG_GETARG_INT32(0);
    PG_RETURN_INT32(arg + 1);
}

/* by reference, fixed length */
PG_FUNCTION_INFO_V1(add_one_float8);

Datum
add_one_float8(PG_FUNCTION_ARGS)
{
    /* The macros for FLOAT8 hide its pass-by-reference nature. */
    float8 arg = PG_GETARG_FLOAT8(0);
    PG_RETURN_FLOAT8(arg + 1.0);
}

PG_FUNCTION_INFO_V1(makepoint);

Datum
makepoint(PG_FUNCTION_ARGS)
{
    /* Here, the pass-by-reference nature of Point is not hidden. */
    Point *pointx = PG_GETARG_POINT_P(0);
    Point *pointy = PG_GETARG_POINT_P(1);
    Point *new_point = (Point *) palloc(sizeof(Point));

    new_point->x = pointx->x;
    new_point->y = pointy->y;

    PG_RETURN_POINT_P(new_point);
}

/* by reference, variable length */
PG_FUNCTION_INFO_V1(copytext);

Datum
copytext(PG_FUNCTION_ARGS)
{
    text *t = PG_GETARG_TEXT_P(0);
    /*
    * VARSIZE is the total size of the struct in bytes.
    * /
    text *new_t = (text *) palloc(VARSIZE(t));
    SET_VARSIZE(new_t, VARSIZE(t));
    /*
    * VARDATA is a pointer to the data region of the struct.
    * /
    memcpy((void *) VARDATA(new_t), /* destination */
            (void *) VARDATA(t), /* source */
            VARSIZE(t));
    PG_RETURN_TEXT_P(new_t);
}
Chapter 34. Extending SQL

VARSIZE(t) - VARHDRSZ); /* how many bytes */
PG_RETURN_TEXT_P(new_t);
}

PG_FUNCTION_INFO_V1(concat_text);

Datum
concat_text(PG_FUNCTION_ARGS)
{
  text  *arg1 = PG_GETARG_TEXT_P(0);
  text  *arg2 = PG_GETARG_TEXT_P(1);
  int32 new_text_size = VARSIZE(arg1) + VARSIZE(arg2) - VARHDRSZ;
  text *new_text = (text *) palloc(new_text_size);
  SET_VARSIZE(new_text, new_text_size);
  memcpy(VARDATA(new_text), VARDATA(arg1), VARSIZE(arg1) - VARHDRSZ);
  memcpy(VARDATA(new_text) + (VARSIZE(arg1) - VARHDRSZ),
          VARDATA(arg2), VARSIZE(arg2) - VARHDRSZ);
  PG_RETURN_TEXT_P(new_text);
}

The **CREATE FUNCTION** commands are the same as for the version-0 equivalents.

At first glance, the version-1 coding conventions might appear to be just pointless obscurantism. They do, however, offer a number of improvements, because the macros can hide unnecessary detail. An example is that in coding `add_one_float8`, we no longer need to be aware that `float8` is a pass-by-reference type. Another example is that the `GETARG` macros for variable-length types allow for more efficient fetching of “toasted” (compressed or out-of-line) values.

One big improvement in version-1 functions is better handling of null inputs and results. The macro `PG_ARGISNULL(n)` allows a function to test whether each input is null. (Of course, doing this is only necessary in functions not declared “strict”. ) As with the `PG_GETARG_xxx()` macros, the input arguments are counted beginning at zero. Note that one should refrain from executing `PG_GETARG_xxx()` until one has verified that the argument isn't null. To return a null result, execute `PG_RETURN_NULL();` this works in both strict and nonstrict functions.

Other options provided in the new-style interface are two variants of the `PG_GETARG_xxx()` macros. The first of these, `PG_GETARG_xxx_COPY()`, guarantees to return a copy of the specified argument that is safe for writing into. (The normal macros will sometimes return a pointer to a value that is physically stored in a table, which must not be written to. Using the `PG_GETARG_xxx_COPY()` macros guarantees a writable result.) The second variant consists of the `PG_GETARG_xxx_SLICE()` macros which take three arguments. The first is the number of the function argument (as above). The second and third are the offset and length of the segment to be returned. Offsets are counted from zero, and a negative length requests that the remainder of the value be returned. These macros provide more efficient access to parts of large values in the case where they have storage type “external”. (The storage type of a column can be specified using `ALTER TABLE tablename ALTER COLUMN colname SET STORAGE storagetype. storagetype is one of plain, external, extended, or main.)

Finally, the version-1 function call conventions make it possible to return set results (Section 34.9.10) and implement trigger functions (Chapter 35) and procedural-language call handlers (Chapter 48). Version-1 code is also more portable than version-0, because it does not break restrictions on function call protocol in the C standard. For more details see `src/backend/utils/fmgr/README` in the source distribution.

721
34.9.5. Writing Code

Before we turn to the more advanced topics, we should discuss some coding rules for PostgreSQL C-language functions. While it might be possible to load functions written in languages other than C into PostgreSQL, this is usually difficult (when it is possible at all) because other languages, such as C++, FORTRAN, or Pascal often do not follow the same calling convention as C. That is, other languages do not pass argument and return values between functions in the same way. For this reason, we will assume that your C-language functions are actually written in C.

The basic rules for writing and building C functions are as follows:

- Use `pg_config --includedir-server` to find out where the PostgreSQL server header files are installed on your system (or the system that your users will be running on).
- Compiling and linking your code so that it can be dynamically loaded into PostgreSQL always requires special flags. See Section 34.9.6 for a detailed explanation of how to do it for your particular operating system.
- Remember to define a “magic block” for your shared library, as described in Section 34.9.1.
- When allocating memory, use the PostgreSQL functions `palloc` and `pfree` instead of the corresponding C library functions `malloc` and `free`. The memory allocated by `palloc` will be freed automatically at the end of each transaction, preventing memory leaks.
- Always zero the bytes of your structures using `memset`. Without this, it’s difficult to support hash indexes or hash joins, as you must pick out only the significant bits of your data structure to compute a hash. Even if you initialize all fields of your structure, there might be alignment padding (holes in the structure) that contain garbage values.
- Most of the internal PostgreSQL types are declared in `postgres.h`, while the function manager interfaces (PG_FUNCTION_ARGS, etc.) are in `fmgr.h`, so you will need to include at least these two files. For portability reasons it’s best to include `postgres.h` first, before any other system or user header files. Including `postgres.h` will also include `elog.h` and `palloc.h` for you.
- Symbol names defined within object files must not conflict with each other or with symbols defined in the PostgreSQL server executable. You will have to rename your functions or variables if you get error messages to this effect.

34.9.6. Compiling and Linking Dynamically-Loaded Functions

Before you are able to use your PostgreSQL extension functions written in C, they must be compiled and linked in a special way to produce a file that can be dynamically loaded by the server. To be precise, a shared library needs to be created. For information beyond what is contained in this section you should read the documentation of your operating system, in particular the manual pages for the C compiler, `cc`, and the link editor, `ld`. In addition, the PostgreSQL source code contains several working examples in the `contrib` directory. If you rely on these examples you will make your modules dependent on the availability of the PostgreSQL source code, however.

Creating shared libraries is generally analogous to linking executables: first the source files are compiled into object files, then the object files are linked together. The object files need to be created as position-independent code (PIC), which conceptually means that they can be placed at an arbitrary location in memory when they are loaded by the executable. (Object files intended for executables
are usually not compiled that way.) The command to link a shared library contains special flags to
distinguish it from linking an executable (at least in theory — on some systems the practice is much
uglier).

In the following examples we assume that your source code is in a file foo.c and we will create a
shared library foo.so. The intermediate object file will be called foo.o unless otherwise noted. A
shared library can contain more than one object file, but we only use one here.

**BSD/OS**

The compiler flag to create PIC is -fpic. The linker flag to create shared libraries is -shared.

```
gcc -fpic -c foo.c
ld -shared -o foo.so foo.o
```

This is applicable as of version 4.0 of BSD/OS.

**FreeBSD**

The compiler flag to create PIC is -fpic. To create shared libraries the compiler flag is -shared.

```
gcc -fpic -c foo.c
gcc -shared -o foo.so foo.o
```

This is applicable as of version 3.0 of FreeBSD.

**HP-UX**

The compiler flag of the system compiler to create PIC is +z. When using GCC it’s -fpic. The
linker flag for shared libraries is -b. So:

```
cc +z -c foo.c
or:
gcc -fpic -c foo.c
and then:
ld -b -o foo.sl foo.o
```

HP-UX uses the extension .sl for shared libraries, unlike most other systems.

**IRIX**

PIC is the default, no special compiler options are necessary. The linker option to produce shared
libraries is -shared.

```
cc -c foo.c
ld -shared -o foo.so foo.o
```

**Linux**

The compiler flag to create PIC is -fpic. On some platforms in some situations -fPIC must be
used if -fpic does not work. Refer to the GCC manual for more information. The compiler flag
to create a shared library is -shared. A complete example looks like this:

```
cc -fpic -c foo.c
cc -shared -o foo.so foo.o
```

**MacOS X**

Here is an example. It assumes the developer tools are installed.

```
cc -c foo.c
cc -bundle -flat_namespace -undefined suppress -o foo.so foo.o
```
NetBSD

The compiler flag to create PIC is \texttt{-fpic}. For ELF systems, the compiler with the flag \texttt{-fshared} is used to link shared libraries. On the older non-ELF systems, \texttt{ld -Bshareable} is used.

\begin{verbatim}
gcc -fpic -c foo.c
gcc -shared -o foo.so foo.o
\end{verbatim}

OpenBSD

The compiler flag to create PIC is \texttt{-fpic}. \texttt{ld -Bshareable} is used to link shared libraries.

\begin{verbatim}
gcc -fpic -c foo.c
ld -Bshareable -o foo.so foo.o
\end{verbatim}

Solaris

The compiler flag to create PIC is \texttt{-KPIC} with the Sun compiler and \texttt{-fpic} with GCC. To link shared libraries, the compiler option is \texttt{-G} with either compiler or alternatively \texttt{-fshared} with GCC.

\begin{verbatim}
cc -KPIC -c foo.c
cc -G -o foo.so foo.o
\end{verbatim}

\textbf{or}

\begin{verbatim}
gcc -fpic -c foo.c
gcc -G -o foo.so foo.o
\end{verbatim}

Tru64 UNIX

PIC is the default, so the compilation command is the usual one. \texttt{ld} with special options is used to do the linking.

\begin{verbatim}
cc -c foo.c
ld -shared -expect_unresolved '*' -o foo.so foo.o
\end{verbatim}

The same procedure is used with GCC instead of the system compiler; no special options are required.

UnixWare

The compiler flag to create PIC is \texttt{-K PIC} with the SCO compiler and \texttt{-fpic} with GCC. To link shared libraries, the compiler option is \texttt{-G} with the SCO compiler and \texttt{-fshared} with GCC.

\begin{verbatim}
cc -K PIC -c foo.c
cc -G -o foo.so foo.o
\end{verbatim}

\textbf{or}

\begin{verbatim}
gcc -fpic -c foo.c
gcc -shared -o foo.so foo.o
\end{verbatim}

\textbf{Tip:} If this is too complicated for you, you should consider using GNU Libtool\footnote{\url{http://www.gnu.org/software/libtool/}}, which hides the platform differences behind a uniform interface.

The resulting shared library file can then be loaded into PostgreSQL. When specifying the file name to the \texttt{CREATE FUNCTION} command, one must give it the name of the shared library file, not the intermediate object file. Note that the system’s standard shared-library extension (usually \texttt{.so} or \texttt{.sl}) can be omitted from the \texttt{CREATE FUNCTION} command, and normally should be omitted for best portability.

Refer back to Section 34.9.1 about where the server expects to find the shared library files.
34.9.7. Extension Building Infrastructure

If you are thinking about distributing your PostgreSQL extension modules, setting up a portable build system for them can be fairly difficult. Therefore the PostgreSQL installation provides a build infrastructure for extensions, called PGXS, so that simple extension modules can be built simply against an already installed server. Note that this infrastructure is not intended to be a universal build system framework that can be used to build all software interfacing to PostgreSQL; it simply automates common build rules for simple server extension modules. For more complicated packages, you need to write your own build system.

To use the infrastructure for your extension, you must write a simple makefile. In that makefile, you need to set some variables and finally include the global PGXS makefile. Here is an example that builds an extension module named isbn_issn consisting of a shared library, an SQL script, and a documentation text file:

```
MODULES = isbn_issn
DATA_built = isbn_issn.sql
DOCS = README.isbn_issn

PG_CONFIG = pg_config
PGXS := $(shell $(PG_CONFIG) --pgxs)
include $(PGXS)
```

The last three lines should always be the same. Earlier in the file, you assign variables or add custom make rules.

The following variables can be set:

- **MODULES**: list of shared objects to be built from source file with same stem (do not include suffix in this list)
- **DATA**: random files to install into `/share/contrib`
- **DATA_built**: random files to install into `/share/contrib`, which need to be built first
- **DOCS**: random files to install under `/doc/contrib`
- **SCRIPTS**: script files (not binaries) to install into `/bin`
- **SCRIPTS_built**: script files (not binaries) to install into `/bin`, which need to be built first
- **REGRESS**: list of regression test cases (without suffix), see below or at most one of these two:
- **PROGRAM**: a binary program to build (list objects files in OBJJS)
MODULE_big
    a shared object to build (list object files in OBJS)

The following can also be set:

EXTRA_CLEAN
    extra files to remove in make clean

PG_CPPFLAGS
    will be added to CPPFLAGS

PG_LIBS
    will be added to PROGRAM link line

SHLIB_LINK
    will be added to MODULE_big link line

PG_CONFIG
    path to pg_config program for the PostgreSQL installation to build against (typically just pg_config to use the first one in your PATH)

Put this makefile as Makefile in the directory which holds your extension. Then you can do make to compile, and later make install to install your module. By default, the extension is compiled and installed for the PostgreSQL installation that corresponds to the first pg_config program found in your path. You can use a different installation by setting PG_CONFIG to point to its pg_config program, either within the makefile or on the make command line.

Caution

Changing PG_CONFIG only works when building against PostgreSQL 8.3 or later. With older releases it does not work to set it to anything except pg_config; you must alter your PATH to select the installation to build against.

The scripts listed in the REGRESS variable are used for regression testing of your module, just like make installcheck is used for the main PostgreSQL server. For this to work you need to have a subdirectory named sql/ in your extension’s directory, within which you put one file for each group of tests you want to run. The files should have extension .sql, which should not be included in the REGRESS list in the makefile. For each test there should be a file containing the expected result in a subdirectory named expected/, with extension .out. The tests are run by executing make installcheck, and the resulting output will be compared to the expected files. The differences will be written to the file regression.diffs in diff -c format. Note that trying to run a test which is missing the expected file will be reported as “trouble”, so make sure you have all expected files.

Tip: The easiest way of creating the expected files is creating empty files, then carefully inspecting the result files after a test run (to be found in the results/ directory), and copying them to expected/ if they match what you want from the test.
34.9.8. Composite-Type Arguments

Composite types do not have a fixed layout like C structures. Instances of a composite type can contain null fields. In addition, composite types that are part of an inheritance hierarchy can have different fields than other members of the same inheritance hierarchy. Therefore, PostgreSQL provides a function interface for accessing fields of composite types from C.

Suppose we want to write a function to answer the query:

```sql
SELECT name, c_overpaid(emp, 1500) AS overpaid
FROM emp
WHERE name = 'Bill' OR name = 'Sam';
```

Using call conventions version 0, we can define `c_overpaid` as:

```c
#include "postgres.h"
#include "executor/executor.h" /* for GetAttributeByName() */

bool
c_overpaid(HeapTupleHeader t, /* the current row of emp */
             int32 limit)
{
    bool isnull;
    int32 salary;

    salary = DatumGetInt32(GetAttributeByName(t, "salary", &isnull));
    if (isnull)
        return false;
    return salary > limit;
}
```

In version-1 coding, the above would look like this:

```c
#include "postgres.h"
#include "executor/executor.h" /* for GetAttributeByName() */

PG_FUNCTION_INFO_V1(c_overpaid);

Datum
c_overpaid(PG_FUNCTION_ARGS)
{
    HeapTupleHeader t = PG_GETARG.HEAPTUPLEHEADER(0);
    int32 limit = PG_GETARG.INT32(1);
    bool isnull;
    Datum salary;

    salary = GetAttributeByName(t, "salary", &isnull);
    if (isnull)
        PG_RETURN_BOOL(false);
    /* Alternatively, we might prefer to do PG_RETURN_NULL() for null salary. */
    PG_RETURN_BOOL(DatumGetInt32(salary) > limit);
}
```
GetAttributeByName is the PostgreSQL system function that returns attributes out of the specified row. It has three arguments: the argument of type HeapTupleHeader passed into the function, the name of the desired attribute, and a return parameter that tells whether the attribute is null. GetAttributeByName returns a Datum value that you can convert to the proper data type by using the appropriate DatumGetXXX() macro. Note that the return value is meaningless if the null flag is set; always check the null flag before trying to do anything with the result.

There is also GetAttributeByNum, which selects the target attribute by column number instead of name.

The following command declares the function c_overpaid in SQL:

```sql
CREATE FUNCTION c_overpaid(emp, integer) RETURNS boolean
   AS 'DIRECTORY/funcs', 'c_overpaid'
   LANGUAGE C STRICT;
```

Notice we have used STRICT so that we did not have to check whether the input arguments were NULL.

34.9.9. Returning Rows (Composite Types)

To return a row or composite-type value from a C-language function, you can use a special API that provides macros and functions to hide most of the complexity of building composite data types. To use this API, the source file must include:

```c
#include "funcapi.h"
```

There are two ways you can build a composite data value (henceforth a “tuple”): you can build it from an array of Datum values, or from an array of C strings that can be passed to the input conversion functions of the tuple’s column data types. In either case, you first need to obtain or construct a TupleDesc descriptor for the tuple structure. When working with Datums, you pass the TupleDesc to BlessTupleDesc, and then call heap_form_tuple for each row. When working with C strings, you pass the TupleDesc to TupleDescGetAttInMetadata, and then call BuildTupleFromCStrings for each row. In the case of a function returning a set of tuples, the setup steps can all be done once during the first call of the function.

Several helper functions are available for setting up the needed TupleDesc. The recommended way to do this in most functions returning composite values is to call:

```c
TypeFuncClass get_call_result_type(FunctionCallInfo fcinfo,
   Oid *resultTypeId,
   TupleDesc *resultTupleDesc)
```

passing the same fcinfo struct passed to the calling function itself. (This of course requires that you use the version-1 calling conventions.) resultTypeId can be specified as NULL or as the address of a local variable to receive the function’s result type OID. resultTupleDesc should be the address of a local TupleDesc variable. Check that the result is TYPEFUNC_COMPOSITE; if so, resultTupleDesc has been filled with the needed TupleDesc. (If it is not, you can report an error along the lines of “function returning record called in context that cannot accept type record”.)

**Tip:** get_call_result_type can resolve the actual type of a polymorphic function result; so it is useful in functions that return scalar polymorphic results, not only functions that return composites. The resultTypeId output is primarily useful for functions returning polymorphic scalars.
Note: `get_call_result_type` has a sibling `get_expr_result_type`, which can be used to resolve the expected output type for a function call represented by an expression tree. This can be used when trying to determine the result type from outside the function itself. There is also `get_func_result_type`, which can be used when only the function's OID is available. However, these functions are not able to deal with functions declared to return `record`, and `get_func_result_type` cannot resolve polymorphic types, so you should preferentially use `get_call_result_type`.

Older, now-deprecated functions for obtaining `TupleDescs` are:

```c
TupleDesc RelationNameGetTupleDesc(const char *relname)
```
to get a `TupleDesc` for the row type of a named relation, and:

```c
TupleDesc TypeGetTupleDesc(Oid typeoid, List *colaliases)
```
to get a `TupleDesc` based on a type OID. This can be used to get a `TupleDesc` for a base or composite type. It will not work for a function that returns `record`, however, and it cannot resolve polymorphic types.

Once you have a `TupleDesc`, call:

```c
TupleDesc BlessTupleDesc(TupleDesc tupdesc)
```
if you plan to work with Datums, or:

```c
AttInMetadata *TupleDescGetAttInMetadata(TupleDesc tupdesc)
```
if you plan to work with C strings. If you are writing a function returning set, you can save the results of these functions in the `FuncCallContext` structure — use the `tuple_desc` or `attinmeta` field respectively.

When working with Datums, use:

```c
HeapTuple heap_form_tuple(TupleDesc tupdesc, Datum *values, bool *isnull)
```
to build a `HeapTuple` given user data in Datum form.

When working with C strings, use:

```c
HeapTuple BuildTupleFromCStrings(AttInMetadata *attinmeta, char **values)
```
to build a `HeapTuple` given user data in C string form. `values` is an array of C strings, one for each attribute of the return row. Each C string should be in the form expected by the input function of the attribute data type. In order to return a null value for one of the attributes, the corresponding pointer in the `values` array should be set to `NULL`. This function will need to be called again for each row you return.

Once you have built a tuple to return from your function, it must be converted into a `Datum`. Use:

```c
HeapTupleGetDatum(HeapTuple tuple)
```
to convert a `HeapTuple` into a valid `Datum`. This `Datum` can be returned directly if you intend to return just a single row, or it can be used as the current return value in a set-returning function.

An example appears in the next section.
34.9.10. Returning Sets

There is also a special API that provides support for returning sets (multiple rows) from a C-language function. A set-returning function must follow the version-1 calling conventions. Also, source files must include funcapi.h, as above.

A set-returning function (SRF) is called once for each item it returns. The SRF must therefore save enough state to remember what it was doing and return the next item on each call. The structure FuncCallContext is provided to help control this process. Within a function, fcinfo->flinfo->fn_extra is used to hold a pointer to FuncCallContext across calls.

typedef struct
{  
  
    /*
     * Number of times we’ve been called before
     *
     * call_cntr is initialized to 0 for you by SRF_FIRSTCALL_INIT(), and
     * incremented for you every time SRF_RETURN_NEXT() is called.
     */
    uint32 call_cntr;

    /*
     * OPTIONAL maximum number of calls
     *
     * max_calls is here for convenience only and setting it is optional.
     * If not set, you must provide alternative means to know when the
     * function is done.
     */
    uint32 max_calls;

    /*
     * OPTIONAL pointer to result slot
     *
     * This is obsolete and only present for backwards compatibility, viz,
     * user-defined SRFs that use the deprecated TupleDescGetSlot().
     */
    TupleTableSlot *slot;

    /*
     * OPTIONAL pointer to miscellaneous user-provided context information
     *
     * user_fctx is for use as a pointer to your own data to retain
     * arbitrary context information between calls of your function.
     */
    void *user_fctx;

    /*
     * OPTIONAL pointer to struct containing attribute type input metadata
     *
     * attinmeta is for use when returning tuples (i.e., composite data types)
     * and is not used when returning base data types. It is only needed
     * if you intend to use BuildTupleFromCStrings() to create the return
     * tuple.
     */
    AttInMetadata *attinmeta;

    /*
     * memory context used for structures that must live for multiple calls
     */
}
Chapter 34. Extending SQL

* multi_call_memory_ctx is set by SRF_FIRSTCALL_INIT() for you, and used * by SRF_RETURN_DONE() for cleanup. It is the most appropriate memory * context for any memory that is to be reused across multiple calls * of the SRF.
* /
MemoryContext multi_call_memory_ctx;

/*
* OPTIONAL pointer to struct containing tuple description
* tuple_desc is for use when returning tuples (i.e., composite data types)
* and is only needed if you are going to build the tuples with
* heap_form_tuple() rather than with BuildTupleFromCStrings(). Note that
* the TupleDesc pointer stored here should usually have been run through
* BlessTupleDesc() first.
* /
TupleDesc tuple_desc;
} FuncCallContext;

An SRF uses several functions and macros that automatically manipulate the FuncCallContext structure (and expect to find it via fn_extra). Use:

SRF_IS_FIRSTCALL()

to determine if your function is being called for the first or a subsequent time. On the first call (only) use:

SRF_FIRSTCALL_INIT()

to initialize the FuncCallContext. On every function call, including the first, use:

SRF_PERCALL_SETUP()

to properly set up for using the FuncCallContext and clearing any previously returned data left over from the previous pass.

If your function has data to return, use:

SRF_RETURN_NEXT(funcctx, result)

to return it to the caller. (result must be of type Datum, either a single value or a tuple prepared as described above.) Finally, when your function is finished returning data, use:

SRF_RETURN_DONE(funcctx)

to clean up and end the SRF.

The memory context that is current when the SRF is called is a transient context that will be cleared between calls. This means that you do not need to call pfree on everything you allocated using palloc; it will go away anyway. However, if you want to allocate any data structures to live across calls, you need to put them somewhere else. The memory context referenced by multi_call_memory_ctx is a suitable location for any data that needs to survive until the SRF is finished running. In most cases, this means that you should switch into multi_call_memory_ctx while doing the first-call setup.

A complete pseudo-code example looks like the following:
Datum
my_set_returning_function(PG_FUNCTION_ARGS)
{
    FuncCallContext *funcctx;
    Datum result;
    MemoryContext oldcontext;
    further declarations as needed

    if (SRF_IS_FIRSTCALL())
    {
        funcctx = SRF_FIRSTCALL_INIT();
        oldcontext = MemoryContextSwitchTo(funcctx->multi_call_memory_ctx);
        /* One-time setup code appears here: */
        user code
        if returning composite
            build TupleDesc, and perhaps AttInMetadata
        endif returning composite
        user code
        MemoryContextSwitchTo(oldcontext);
    }

    /* Each-time setup code appears here: */
    user code
    funcctx = SRF_PERCALL_SETUP();
    user code

    /* this is just one way we might test whether we are done: */
    if (funcctx->call_cntr < funcctx->max_calls)
    {
        /* Here we want to return another item: */
        user code
        obtain result Datum
        SRF_RETURN_NEXT(funcctx, result);
    }
    else
    {
        /* Here we are done returning items and just need to clean up: */
        user code
        SRF_RETURN_DONE(funcctx);
    }
}

A complete example of a simple SRF returning a composite type looks like:

PG_FUNCTION_INFO_V1(retcomposite);

Datum
retcomposite(PG_FUNCTION_ARGS)
{
    FuncCallContext *funcctx;
    int call_cntr;
    int max_calls;
    TupleDesc tupdesc;
    AttInMetadata *attinmeta;

    /* stuff done only on the first call of the function */
if (SRF_IS_FIRSTCALL())
{
    MemoryContext oldcontext;

    /* create a function context for cross-call persistence */
    funcctx = SRF_FIRSTCALL_INIT();

    /* switch to memory context appropriate for multiple function calls */
    oldcontext = MemoryContextSwitchTo(funcctx->multi_call_memory_ctx);

    /* total number of tuples to be returned */
    funcctx->max_calls = PG_GETARG_UINT32(0);

    /* Build a tuple descriptor for our result type */
    if (get_call_result_type(fcinfo, NULL, &tupdesc) != TYPEFUNC_COMPOSITE)
        ereport(ERROR,
            {errcode(ERRCODE_FEATURE_NOT_SUPPORTED),
             errmsg("function returning record called in context "
                 "that cannot accept type record");

    /* generate attribute metadata needed later to produce tuples from raw
     * C strings */
    attinmeta = TupleDescGetAttInMetadata(tupdesc);
    funcctx->attinmeta = attinmeta;

    MemoryContextSwitchTo(oldcontext);
}

/* stuff done on every call of the function */
funcctx = SRF_PERCALL_SETUP();

call_cntr = funcctx->call_cntr;
max_calls = funcctx->max_calls;
attinmeta = funcctx->attinmeta;

if (call_cntr < max_calls) /* do when there is more left to send */
{
    char **values;
    HeapTuple tuple;
    Datum result;

    /* Prepare a values array for building the returned tuple.
    * This should be an array of C strings which will
    * be processed later by the type input functions. */
    values = (char **) palloc(3 * sizeof(char *));
    values[0] = (char *) palloc(16 * sizeof(char));
    values[1] = (char *) palloc(16 * sizeof(char));
    values[2] = (char *) palloc(16 * sizeof(char));

    snprintf(values[0], 16, "%d", 1 * PG_GETARG_INT32(1));
    snprintf(values[1], 16, "%d", 2 * PG_GETARG_INT32(1));
    snprintf(values[2], 16, "%d", 3 * PG_GETARG_INT32(1));
}
/* build a tuple */
tuple = BuildTupleFromCStrings(attinmeta, values);

/* make the tuple into a datum */
result = HeapTupleGetDatum(tuple);

/* clean up (this is not really necessary) */
pfree(values[0]);
pfree(values[1]);
pfree(values[2]);
pfree(values);

SRF_RETURN_NEXT(funcctx, result);
}
else /* do when there is no more left */
{
    SRF_RETURN_DONE(funcctx);
}
}

One way to declare this function in SQL is:

CREATE TYPE __retcomposite AS (f1 integer, f2 integer, f3 integer);

CREATE OR REPLACE FUNCTION retcomposite(integer, integer)
    RETURNS SETOF __retcomposite
    AS 'filename', 'retcomposite'
    LANGUAGE C IMMUTABLE STRICT;

A different way is to use OUT parameters:

CREATE OR REPLACE FUNCTION retcomposite(IN integer, IN integer,
    OUT f1 integer, OUT f2 integer, OUT f3 integer)
    RETURNS SETOF record
    AS 'filename', 'retcomposite'
    LANGUAGE C IMMUTABLE STRICT;

Notice that in this method the output type of the function is formally an anonymous record type.

The directory contrib/tablefunc in the source distribution contains more examples of set-returning functions.

34.9.11. Polymorphic Arguments and Return Types

C-language functions can be declared to accept and return the polymorphic types anyelement, anyarray, anynonarray, and anyenum. See Section 34.2.5 for a more detailed explanation of polymorphic functions. When function arguments or return types are defined as polymorphic types, the function author cannot know in advance what data type it will be called with, or need to return. There are two routines provided in fmgr.h to allow a version-1 C function to discover the actual data types of its arguments and the type it is expected to return. The routines are called get_fn_expr_rettype(FmgrInfo *flinfo) and get_fn_expr_argtype(FmgrInfo *flinfo, int argnum). They return the result or argument type OID, or InvalidOid if the information is not available. The structure flinfo is normally accessed as fcinfo->flinfo. The parameter argnum is zero based. get_call_result_type can also be used as an alternative to get_fn_expr_rettype.
For example, suppose we want to write a function to accept a single element of any type, and return a one-dimensional array of that type:

```c
PG_FUNCTION_INFO_V1(make_array);
Datum make_array(PG_FUNCTION_ARGS)
{
  ArrayType  *result;
  Oid       element_type = get_fn_expr_argtype(fcinfo->flinfo, 0);
  Datum     element;
  bool      isnull;
  int16     typlen;
  bool      typbyval;
  char      typalign;
  int       ndims;
  int       dims[MAXDIM];
  int       lbs[MAXDIM];

  if (!OidIsValid(element_type))
    elog(ERROR, "could not determine data type of input");

  /* get the provided element, being careful in case it’s NULL */
  isnull = PG_ARGISNULL(0);
  if (isnull)
    element = (Datum) 0;
  else
    element = PG_GETARG_DATUM(0);

  /* we have one dimension */
  ndims = 1;
  /* and one element */
  dims[0] = 1;
  /* and lower bound is 1 */
  lbs[0] = 1;

  /* get required info about the element type */
  get_typlenbyvalalign(element_type, &typlen, &typbyval, &typalign);

  /* now build the array */
  result = construct_md_array(&element, &isnull, ndims, dims, lbs,
                              element_type, typlen, typbyval, typalign);

  PG_RETURN_ARRAYTYPE_P(result);
}
```

The following command declares the function `make_array` in SQL:

```
CREATE FUNCTION make_array(anyelement) RETURNS anyarray
  AS 'DIRECTORY/funcs', 'make_array'
  LANGUAGE C IMMUTABLE;
```

There is a variant of polymorphism that is only available to C-language functions: they can be declared to take parameters of type "any". (Note that this type name must be double-quoted, since it’s also a SQL reserved word.) This works like anyelement except that it does not constrain different "any"
arguments to be the same type, nor do they help determine the function’s result type. A C-language function can also declare its final parameter to be VARIADIC "any". This will match one or more actual arguments of any type (not necessarily the same type). These arguments will not be gathered into an array as happens with normal variadic functions; they will just be passed to the function separately. The PG_NARGS() macro and the methods described above must be used to determine the number of actual arguments and their types when using this feature.

34.9.12. Shared Memory and LWLocks

Add-ins can reserve LWLocks and an allocation of shared memory on server startup. The add-in’s shared library must be preloaded by specifying it in shared_preload_libraries. Shared memory is reserved by calling:

```c
void RequestAddinShmemSpace(int size)
```

from your _PG_init function.

LWLocks are reserved by calling:

```c
void RequestAddinLWLocks(int n)
```

from _PG_init.

To avoid possible race-conditions, each backend should use the LWLock AddinShmemInitLock when connecting to and initializing its allocation of shared memory, as shown here:

```c
static mystruct *ptr = NULL;
if (!ptr)
{
  bool found;
  LWLockAcquire(AddinShmemInitLock, LW_EXCLUSIVE);
  ptr = ShmemInitStruct("my struct name", size, &found);
  if (!ptr)
    elog(ERROR, "out of shared memory");
  if (!found)
  {
    initialize contents of shmem area;
    acquire any requested LWLocks using:
    ptr->mylockid = LWLockAssign();
  }
  LWLockRelease(AddinShmemInitLock);
}
```

34.10. User-Defined Aggregates

Aggregate functions in PostgreSQL are expressed in terms of state values and state transition functions. That is, an aggregate operates using a state value that is updated as each successive input row is processed. To define a new aggregate function, one selects a data type for the state value, an initial value for the state, and a state transition function. The state transition function is just an ordinary
function that could also be used outside the context of the aggregate. A final function can also be specified, in case the desired result of the aggregate is different from the data that needs to be kept in the running state value.

Thus, in addition to the argument and result data types seen by a user of the aggregate, there is an internal state-value data type that might be different from both the argument and result types.

If we define an aggregate that does not use a final function, we have an aggregate that computes a running function of the column values from each row. \texttt{sum} is an example of this kind of aggregate. \texttt{sum} starts at zero and always adds the current row’s value to its running total. For example, if we want to make a \texttt{sum} aggregate to work on a data type for complex numbers, we only need the addition function for that data type. The aggregate definition would be:

\begin{verbatim}
CREATE AGGREGATE sum (complex)
(
  sfunc = complex_add,
  stype = complex,
  initcond = '(0,0)'
);

SELECT sum(a) FROM test_complex;

sum
-------
(34,53.9)
\end{verbatim}

(Notice that we are relying on function overloading: there is more than one aggregate named \texttt{sum}, but PostgreSQL can figure out which kind of \texttt{sum} applies to a column of type \texttt{complex}.)

The above definition of \texttt{sum} will return zero (the initial state condition) if there are no nonnull input values. Perhaps we want to return null in that case instead — the SQL standard expects \texttt{sum} to behave that way. We can do this simply by omitting the \texttt{initcond} phrase, so that the initial state condition is null. Ordinarily this would mean that the \texttt{sfunc} would need to check for a null state-condition input. But for \texttt{sum} and some other simple aggregates like \texttt{max} and \texttt{min}, it is sufficient to insert the first nonnull input value into the state variable and then start applying the transition function at the second nonnull input value. PostgreSQL will do that automatically if the initial condition is null and the transition function is marked “strict” (i.e., not to be called for null inputs).

Another bit of default behavior for a “strict” transition function is that the previous state value is retained unchanged whenever a null input value is encountered. Thus, null values are ignored. If you need some other behavior for null inputs, do not declare your transition function as strict; instead code it to test for null inputs and do whatever is needed.

\texttt{avg} (average) is a more complex example of an aggregate. It requires two pieces of running state: the sum of the inputs and the count of the number of inputs. The final result is obtained by dividing these quantities. Average is typically implemented by using an array as the state value. For example, the built-in implementation of \texttt{avg(float8)} looks like:

\begin{verbatim}
CREATE AGGREGATE avg (float8)
(
  sfunc = float8_accum,
  stype = float8[],
  finalfunc = float8_avg,
  initcond = '{0,0,0}';
);
\end{verbatim}
(float8_accum requires a three-element array, not just two elements, because it accumulates the sum of squares as well as the sum and count of the inputs. This is so that it can be used for some other aggregates besides avg.)

Aggregate functions can use polymorphic state transition functions or final functions, so that the same functions can be used to implement multiple aggregates. See Section 34.2.5 for an explanation of polymorphic functions. Going a step further, the aggregate function itself can be specified with polymorphic input type(s) and state type, allowing a single aggregate definition to serve for multiple input data types. Here is an example of a polymorphic aggregate:

```sql
CREATE AGGREGATE array_accum (anyelement)
(
    sfunc = array_append,
    stype = anyarray,
    initcond = '{}'
);
```

Here, the actual state type for any aggregate call is the array type having the actual input type as elements. The behavior of the aggregate is to concatenate all the inputs into an array of that type. (Note: the built-in aggregate array_agg provides similar functionality, with better performance than this definition would have.)

Here’s the output using two different actual data types as arguments:

```sql
SELECT attrelid::regclass, array_accum(attname)
    FROM pg_attribute
    WHERE attnum > 0 AND attrelid = 'pg_tablespace':regclass
    GROUP BY attrelid;
```

<table>
<thead>
<tr>
<th>attrelid</th>
<th>array_accum</th>
</tr>
</thead>
<tbody>
<tr>
<td>pg_tablespace</td>
<td>{spcname, spcowner, spclocation, spcacl}</td>
</tr>
</tbody>
</table>

A function written in C can detect that it is being called as an aggregate transition or final function by seeing if it was passed an AggState or WindowAggState node as the function call “context”, for example by:

```c
if (fcinfo->context &&
    (IsA(fcinfo->context, AggState) ||
     IsA(fcinfo->context, WindowAggState)))
```

One reason for checking this is that when it is true for a transition function, the first input must be a temporary transition value and can therefore safely be modified in-place rather than allocating a new copy. See int8inc() for an example. (This is the only case where it is safe for a function to modify a
pass-by-reference input. In particular, aggregate final functions should not modify their inputs in any case, because in some cases they will be re-executed on the same final transition value.)

For further details see the `CREATE AGGREGATE` command.

### 34.11. User-Defined Types

As described in Section 34.2, PostgreSQL can be extended to support new data types. This section describes how to define new base types, which are data types defined below the level of the SQL language. Creating a new base type requires implementing functions to operate on the type in a low-level language, usually C.

The examples in this section can be found in `complex.sql` and `complex.c` in the `src/tutorial` directory of the source distribution. See the `README` file in that directory for instructions about running the examples.

A user-defined type must always have input and output functions. These functions determine how the type appears in strings (for input by the user and output to the user) and how the type is organized in memory. The input function takes a null-terminated character string as its argument and returns the internal (in memory) representation of the type. The output function takes the internal representation of the type as argument and returns a null-terminated character string. If we want to do anything more with the type than merely store it, we must provide additional functions to implement whatever operations we’d like to have for the type.

Suppose we want to define a type `complex` that represents complex numbers. A natural way to represent a complex number in memory would be the following C structure:

```c
typedef struct Complex {
    double x;
    double y;
} Complex;
```

We will need to make this a pass-by-reference type, since it’s too large to fit into a single `Datum` value.

As the external string representation of the type, we choose a string of the form `(x,y)`.

The input and output functions are usually not hard to write, especially the output function. But when defining the external string representation of the type, remember that you must eventually write a complete and robust parser for that representation as your input function. For instance:

```c
PG_FUNCTION_INFO_V1(complex_in);

Datum complex_in(PG_FUNCTION_ARGS)
{
    char *str = PG_GETARG_CSTRING(0);
    double x, y;
    Complex *result;

    if (sscanf(str, " ( %lf , %lf )", &x, &y) != 2)
        ereport(ERROR,
                (errcode(ERRCODE_INVALID_TEXT_REPRESENTATION),
                errmsg("invalid input syntax for complex: "%s", str");

    result = (Complex *) palloc(sizeof(Complex));

    return result;
}
```

739
result->x = x;
result->y = y;
PG_RETURN_POINTER(result);
}

The output function can simply be:

PG_FUNCTION_INFO_V1(complex_out);

Datum
complex_out(PG_FUNCTION_ARGS)
{
  Complex *complex = (Complex *) PG_GETARG_POINTER(0);
  char *result;

  result = (char *) palloc(100);
  snprintf(result, 100, "(%g,%g)", complex->x, complex->y);
  PG_RETURN_CSTRING(result);
}

You should be careful to make the input and output functions inverses of each other. If you do not, you will have severe problems when you need to dump your data into a file and then read it back in. This is a particularly common problem when floating-point numbers are involved.

Optionally, a user-defined type can provide binary input and output routines. Binary I/O is normally faster but less portable than textual I/O. As with textual I/O, it is up to you to define exactly what the external binary representation is. Most of the built-in data types try to provide a machine-independent binary representation. For complex, we will piggy-back on the binary I/O converters for type float8:

PG_FUNCTION_INFO_V1(complex_recv);

Datum
complex_recv(PG_FUNCTION_ARGS)
{
  StringInfo buf = (StringInfo) PG_GETARG_POINTER(0);
  Complex *result;

  result = (Complex *) palloc(sizeof(Complex));
  result->x = pq_getmsgfloat8(buf);
  result->y = pq_getmsgfloat8(buf);
  PG_RETURN_POINTER(result);
}

PG_FUNCTION_INFO_V1(complex_send);

Datum
complex_send(PG_FUNCTION_ARGS)
{
  Complex *complex = (Complex *) PG_GETARG_POINTER(0);
  StringInfoData buf;

  pq_begintypsend(&buf);
  pq_sendfloat8(&buf, complex->x);
  pq_sendfloat8(&buf, complex->y);
  PG_RETURN_BYTEA_P(pq_endtypsend(&buf));
}
Once we have written the I/O functions and compiled them into a shared library, we can define the `complex` type in SQL. First we declare it as a shell type:

\[
\text{CREATE TYPE complex;}
\]

This serves as a placeholder that allows us to reference the type while defining its I/O functions. Now we can define the I/O functions:

\[
\begin{align*}
\text{CREATE FUNCTION complex_in(cstring) & \quad \text{RETURNS complex}} \\
& \quad \text{AS 'filename'} \\
& \quad \text{LANGUAGE C IMMUTABLE STRICT;}
\end{align*}
\]

\[
\begin{align*}
\text{CREATE FUNCTION complex_out(complex) & \quad \text{RETURNS cstring}} \\
& \quad \text{AS 'filename'} \\
& \quad \text{LANGUAGE C IMMUTABLE STRICT;}
\end{align*}
\]

\[
\begin{align*}
\text{CREATE FUNCTION complex_recv(internal) & \quad \text{RETURNS complex}} \\
& \quad \text{AS 'filename'} \\
& \quad \text{LANGUAGE C IMMUTABLE STRICT;}
\end{align*}
\]

\[
\begin{align*}
\text{CREATE FUNCTION complex_send(complex) & \quad \text{RETURNS bytea}} \\
& \quad \text{AS 'filename'} \\
& \quad \text{LANGUAGE C IMMUTABLE STRICT;}
\end{align*}
\]

Finally, we can provide the full definition of the data type:

\[
\text{CREATE TYPE complex (}
\quad \text{internallength = 16,} \\
\quad \text{input = complex_in,} \\
\quad \text{output = complex_out,} \\
\quad \text{receive = complex_recv,} \\
\quad \text{send = complex_send,} \\
\quad \text{alignment = double}
\quad \text{);} 
\]

When you define a new base type, PostgreSQL automatically provides support for arrays of that type. The array type typically has the same name as the base type with the underscore character (`_`) prepended.

Once the data type exists, we can declare additional functions to provide useful operations on the data type. Operators can then be defined atop the functions, and if needed, operator classes can be created to support indexing of the data type. These additional layers are discussed in following sections.

If the values of your data type vary in size (in internal form), you should make the data type TOAST-able (see Section 53.2). You should do this even if the data are always too small to be compressed or stored externally, because TOAST can save space on small data too, by reducing header overhead.
To do this, the internal representation must follow the standard layout for variable-length data: the first four bytes must be a char[4] field which is never accessed directly (customarily named vl_len_). You must use SET_VARSIZE() to store the size of the datum in this field and VARSIZE() to retrieve it. The C functions operating on the data type must always be careful to unpack any toasted values they are handed, by using PG_DETOAST_DATUM. (This detail is customarily hidden by defining typespecific GETARG_DATATYPE_P macros.) Then, when running the CREATE TYPE command, specify the internal length as variable and select the appropriate storage option.

If the alignment is unimportant (either just for a specific function or because the data type specifies byte alignment anyways) then it's possible to avoid some of the overhead of PG_DETOAST_DATUM. You can use PG_DETOAST_DATUM_PACKED instead (customarily hidden by defining a GETARG_DATATYPE_PP macro) and using the macros VARSIZE_ANY_EXHDR and VARDATA_ANY to access a potentially-packed datum. Again, the data returned by these macros is not aligned even if the data type definition specifies an alignment. If the alignment is important you must go through the regular PG_DETOAST_DATUM interface.

Note: Older code frequently declares vl_len_ as an int32 field instead of char[4]. This is OK as long as the struct definition has other fields that have at least int32 alignment. But it is dangerous to use such a struct definition when working with a potentially unaligned datum; the compiler may take it as license to assume the datum actually is aligned, leading to core dumps on architectures that are strict about alignment.

For further details see the description of the CREATE TYPE command.

34.12. User-Defined Operators

Every operator is “syntactic sugar” for a call to an underlying function that does the real work; so you must first create the underlying function before you can create the operator. However, an operator is not merely syntactic sugar, because it carries additional information that helps the query planner optimize queries that use the operator. The next section will be devoted to explaining that additional information.

PostgreSQL supports left unary, right unary, and binary operators. Operators can be overloaded; that is, the same operator name can be used for different operators that have different numbers and types of operands. When a query is executed, the system determines the operator to call from the number and types of the provided operands.

Here is an example of creating an operator for adding two complex numbers. We assume we’ve already created the definition of type complex (see Section 34.11). First we need a function that does the work, then we can define the operator:

```sql
CREATE FUNCTION complex_add(complex, complex) 
RETURNS complex 
AS 'filename', 'complex_add' 
LANGUAGE C IMMUTABLE STRICT;

CREATE OPERATOR + ( 
  leftarg = complex, 
  rightarg = complex, 
  procedure = complex_add, 
  commutator = + 
);```
Now we could execute a query like this:

```
SELECT (a + b) AS c FROM test_complex;
```

```
+--------+
<table>
<thead>
<tr>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>(5.2, 6.05)</td>
</tr>
<tr>
<td>(133.42, 144.95)</td>
</tr>
</tbody>
</table>
+--------+
```

We’ve shown how to create a binary operator here. To create unary operators, just omit one of `leftarg` (for left unary) or `rightarg` (for right unary). The `procedure` clause and the argument clauses are the only required items in `CREATE OPERATOR`. The `commutator` clause shown in the example is an optional hint to the query optimizer. Further details about `commutator` and other optimizer hints appear in the next section.

### 34.13. Operator Optimization Information

A PostgreSQL operator definition can include several optional clauses that tell the system useful things about how the operator behaves. These clauses should be provided whenever appropriate, because they can make for considerable speedups in execution of queries that use the operator. But if you provide them, you must be sure that they are right! Incorrect use of an optimization clause can result in slow queries, subtly wrong output, or other Bad Things. You can always leave out an optimization clause if you are not sure about it; the only consequence is that queries might run slower than they need to.

Additional optimization clauses might be added in future versions of PostgreSQL. The ones described here are all the ones that release 8.4.22 understands.

#### 34.13.1. Commutator

The `COMMUTATOR` clause, if provided, names an operator that is the commutator of the operator being defined. We say that operator A is the commutator of operator B if (x A y) equals (y B x) for all possible input values x, y. Notice that B is also the commutator of A. For example, operators `<` and `>` for a particular data type are usually each others’ commutators, and operator `+` is usually commutative with itself. But operator `-` is usually not commutative with anything.

The left operand type of a commutable operator is the same as the right operand type of its commutator, and vice versa. So the name of the commutator operator is all that PostgreSQL needs to be given to look up the commutator, and that’s all that needs to be provided in the `COMMUTATOR` clause.

It’s critical to provide commutator information for operators that will be used in indexes and join clauses, because this allows the query optimizer to “flip around” such a clause to the forms needed for different plan types. For example, consider a query with a `WHERE` clause like `tab1.x = tab2.y`, where `tab1.x` and `tab2.y` are of a user-defined type, and suppose that `tab2.y` is indexed. The optimizer cannot generate an index scan unless it can determine how to flip the clause around to `tab2.y = tab1.x`, because the index-scan machinery expects to see the indexed column on the left of the operator it is given. PostgreSQL will not simply assume that this is a valid transformation — the creator of the `=` operator must specify that it is valid, by marking the operator with commutator information.
When you are defining a self-commutative operator, you just do it. When you are defining a pair of commutative operators, things are a little trickier: how can the first one to be defined refer to the other one, which you haven’t defined yet? There are two solutions to this problem:

- One way is to omit the `COMMUTATOR` clause in the first operator that you define, and then provide one in the second operator’s definition. Since PostgreSQL knows that commutative operators come in pairs, when it sees the second definition it will automatically go back and fill in the missing `COMMUTATOR` clause in the first definition.

- The other, more straightforward way is just to include `COMMUTATOR` clauses in both definitions. When PostgreSQL processes the first definition and realizes that `COMMUTATOR` refers to a nonexistent operator, the system will make a dummy entry for that operator in the system catalog. This dummy’s entry will have valid data only for the operator name, left and right operand types, and result type, since that’s all that PostgreSQL can deduce at this point. The first operator’s catalog entry will link to this dummy entry. Later, when you define the second operator, the system updates the dummy entry with the additional information from the second definition. If you try to use the dummy operator before it’s been filled in, you’ll just get an error message.

### 34.13.2. NEGATOR

The `NEGATOR` clause, if provided, names an operator that is the negator of the operator being defined. We say that operator A is the negator of operator B if both return Boolean results and \((x \ A \ y)\) equals `NOT (x \ B \ y)` for all possible inputs \(x, y\). Notice that B is also the negator of A. For example, `<` and `>=` are a negator pair for most data types. An operator can never validly be its own negator.

Unlike commutators, a pair of unary operators could validly be marked as each others’ negators; that would mean \((A \ x)\) equals `NOT (B \ x)` for all \(x\), or the equivalent for right unary operators.

An operator’s negator must have the same left and/or right operand types as the operator to be defined, so just as with `COMMUTATOR`, only the operator name need be given in the `NEGATOR` clause.

Providing a negator is very helpful to the query optimizer since it allows expressions like `NOT (x = y)` to be simplified into \(x <> y\). This comes up more often than you might think, because `NOT` operations can be inserted as a consequence of other rearrangements.

Pairs of negator operators can be defined using the same methods explained above for commutator pairs.

### 34.13.3. RESTRICT

The `RESTRICT` clause, if provided, names a restriction selectivity estimation function for the operator. (Note that this is a function name, not an operator name.) `RESTRICT` clauses only make sense for binary operators that return `boolean`. The idea behind a restriction selectivity estimator is to guess what fraction of the rows in a table will satisfy a `WHERE`-clause condition of the form:

```
column OP constant
```

for the current operator and a particular constant value. This assists the optimizer by giving it some idea of how many rows will be eliminated by `WHERE` clauses that have this form. (What happens if the constant is on the left, you might be wondering? Well, that’s one of the things that `COMMUTATOR` is for...)
Writing new restriction selectivity estimation functions is far beyond the scope of this chapter, but fortunately you can usually just use one of the system's standard estimators for many of your own operators. These are the standard restriction estimators:

- `eqsel` for `=`
- `neqsel` for `<>`
- `scalarltselect` for `< or <=`
- `scalarmtselect` for `> or >=`

It might seem a little odd that these are the categories, but they make sense if you think about it. `=` will typically accept only a small fraction of the rows in a table; `<>` will typically reject only a small fraction. `<` will accept a fraction that depends on where the given constant falls in the range of values for that table column (which, it just so happens, is information collected by `ANALYZE` and made available to the selectivity estimator). `<=` will accept a slightly larger fraction than `<` for the same comparison constant, but they’re close enough to not be worth distinguishing, especially since we’re not likely to do better than a rough guess anyhow. Similar remarks apply to `>` and `>=`.

You can frequently get away with using either `eqsel` or `neqsel` for operators that have very high or very low selectivity, even if they aren’t really equality or inequality. For example, the approximate-equality geometric operators use `eqsel` on the assumption that they’ll usually only match a small fraction of the entries in a table.

You can use `scalarltselect` and `scalarmtselect` for comparisons on data types that have some sensible means of being converted into numeric scalars for range comparisons. If possible, add the data type to those understood by the function `convert_to_scalar()` in `src/backend/utils/adt/selfuncs.c`. (Eventually, this function should be replaced by per-data-type functions identified through a column of the `pg_type` system catalog; but that hasn’t happened yet.) If you do not do this, things will still work, but the optimizer’s estimates won’t be as good as they could be.

There are additional selectivity estimation functions designed for geometric operators in `src/backend/utils/adt/geo_selfuncs.c`: `areasel`, `positionsel`, and `contsel`. At this writing these are just stubs, but you might want to use them (or even better, improve them) anyway.

### 34.13.4. JOIN

The `JOIN` clause, if provided, names a join selectivity estimation function for the operator. (Note that this is a function name, not an operator name.) `JOIN` clauses only make sense for binary operators that return `boolean`. The idea behind a join selectivity estimator is to guess what fraction of the rows in a pair of tables will satisfy a `WHERE`-clause condition of the form:

```
table1.column1 OP table2.column2
```

for the current operator. As with the `RESTRICT` clause, this helps the optimizer very substantially by letting it figure out which of several possible join sequences is likely to take the least work.

As before, this chapter will make no attempt to explain how to write a join selectivity estimator function, but will just suggest that you use one of the standard estimators if one is applicable:

- `eqjoinsel` for `=`
- `neqjoinsel` for `<>`
- `scalarltjoinsel` for `< or <=`
- `scalarmtjoinsel` for `> or >=`
- `areajoinsel` for 2D area-based comparisons
- `positionjoinsel` for 2D position-based comparisons
34.13.5. HASHES

The HASHES clause, if present, tells the system that it is permissible to use the hash join method for a join based on this operator. HASHES only makes sense for a binary operator that returns boolean, and in practice the operator must represent equality for some data type or pair of data types.

The assumption underlying hash join is that the join operator can only return true for pairs of left and right values that hash to the same hash code. If two values get put in different hash buckets, the join will never compare them at all, implicitly assuming that the result of the join operator must be false. So it never makes sense to specify HASHES for operators that do not represent some form of equality.

In most cases it is only practical to support hashing for operators that take the same data type on both sides. However, sometimes it is possible to design compatible hash functions for two or more data types; that is, functions that will generate the same hash codes for “equal” values, even though the values have different representations. For example, it’s fairly simple to arrange this property when hashing integers of different widths.

To be marked HASHES, the join operator must appear in a hash index operator family. This is not enforced when you create the operator, since of course the referencing operator family couldn’t exist yet. But attempts to use the operator in hash joins will fail at run time if no such operator family exists. The system needs the operator family to find the data-type-specific hash function(s) for the operator’s input data type(s). Of course, you must also create suitable hash functions before you can create the operator family.

Care should be exercised when preparing a hash function, because there are machine-dependent ways in which it might fail to do the right thing. For example, if your data type is a structure in which there might be uninteresting pad bits, you cannot simply pass the whole structure to hash_any. (Unless you write your other operators and functions to ensure that the unused bits are always zero, which is the recommended strategy.) Another example is that on machines that meet the IEEE floating-point standard, negative zero and positive zero are different values (different bit patterns) but they are defined to compare equal. If a float value might contain negative zero then extra steps are needed to ensure it generates the same hash value as positive zero.

A hash-joinable operator must have a commutator (itself if the two operand data types are the same, or a related equality operator if they are different) that appears in the same operator family. If this is not the case, planner errors might occur when the operator is used. Also, it is a good idea (but not strictly required) for a hash operator family that supports multiple data types to provide equality operators for every combination of the data types; this allows better optimization.

Note: The function underlying a hash-joinable operator must be marked immutable or stable. If it is volatile, the system will never attempt to use the operator for a hash join.

Note: If a hash-joinable operator has an underlying function that is marked strict, the function must also be complete: that is, it should return true or false, never null, for any two nonnull inputs. If this rule is not followed, hash-optimization of IN operations might generate wrong results. (Specifically, IN might return false where the correct answer according to the standard would be null; or it might yield an error complaining that it wasn’t prepared for a null result.)
34.13.6. MERGES

The MERGES clause, if present, tells the system that it is permissible to use the merge-join method for a join based on this operator. MERGES only makes sense for a binary operator that returns boolean, and in practice the operator must represent equality for some data type or pair of data types. Merge join is based on the idea of sorting the left- and right-hand tables into order and then scanning them in parallel. So, both data types must be capable of being fully ordered, and the join operator must be one that can only succeed for pairs of values that fall at the “same place” in the sort order. In practice this means that the join operator must behave like equality. But it is possible to merge-join two distinct data types so long as they are logically compatible. For example, the smallint-versus-integer equality operator is merge-joinable. We only need sorting operators that will bring both data types into a logically compatible sequence.

To be marked MERGES, the join operator must appear as an equality member of a btree index operator family. This is not enforced when you create the operator, since of course the referencing operator family couldn’t exist yet. But the operator will not actually be used for merge joins unless a matching operator family can be found. The MERGES flag thus acts as a hint to the planner that it’s worth looking for a matching operator family.

A merge-joinable operator must have a commutator (itself if the two operand data types are the same, or a related equality operator if they are different) that appears in the same operator family. If this is not the case, planner errors might occur when the operator is used. Also, it is a good idea (but not strictly required) for a btree operator family that supports multiple data types to provide equality operators for every combination of the data types; this allows better optimization.

Note: The function underlying a merge-joinable operator must be marked immutable or stable. If it is volatile, the system will never attempt to use the operator for a merge join.

34.14. Interfacing Extensions To Indexes

The procedures described thus far let you define new types, new functions, and new operators. However, we cannot yet define an index on a column of a new data type. To do this, we must define an operator class for the new data type. Later in this section, we will illustrate this concept in an example: a new operator class for the B-tree index method that stores and sorts complex numbers in ascending absolute value order.

Operator classes can be grouped into operator families to show the relationships between semantically compatible classes. When only a single data type is involved, an operator class is sufficient, so we’ll focus on that case first and then return to operator families.

34.14.1. Index Methods and Operator Classes

The pg_am table contains one row for every index method (internally known as access method). Support for regular access to tables is built into PostgreSQL, but all index methods are described in pg_am. It is possible to add a new index method by defining the required interface routines and then creating a row in pg_am — but that is beyond the scope of this chapter (see Chapter 50).

The routines for an index method do not directly know anything about the data types that the index method will operate on. Instead, an operator class identifies the set of operations that the index method
Chapter 34. Extending SQL

Operator classes are so called because one thing they specify is the set of \texttt{WHERE}-clause operators that can be used with an index (i.e., can be converted into an index-scan qualification). An operator class can also specify some support procedures that are needed by the internal operations of the index method, but do not directly correspond to any \texttt{WHERE}-clause operator that can be used with the index.

It is possible to define multiple operator classes for the same data type and index method. By doing this, multiple sets of indexing semantics can be defined for a single data type. For example, a B-tree index requires a sort ordering to be defined for each data type it works on. It might be useful for a complex-number data type to have one B-tree operator class that sorts the data by complex absolute value, another that sorts by real part, and so on. Typically, one of the operator classes will be deemed most commonly useful and will be marked as the default operator class for that data type and index method.

The same operator class name can be used for several different index methods (for example, both B-tree and hash index methods have operator classes named \texttt{int4_ops}), but each such class is an independent entity and must be defined separately.

### 34.14.2. Index Method Strategies

The operators associated with an operator class are identified by “strategy numbers”, which serve to identify the semantics of each operator within the context of its operator class. For example, B-trees impose a strict ordering on keys, lesser to greater, and so operators like “less than” and “greater than or equal to” are interesting with respect to a B-tree. Because PostgreSQL allows the user to define operators, PostgreSQL cannot look at the name of an operator (e.g., < or \texttt{>=}) and tell what kind of comparison it is. Instead, the index method defines a set of “strategies”, which can be thought of as generalized operators. Each operator class specifies which actual operator corresponds to each strategy for a particular data type and interpretation of the index semantics.

The B-tree index method defines five strategies, shown in Table 34-2.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Strategy Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>less than</td>
<td>1</td>
</tr>
<tr>
<td>less than or equal</td>
<td>2</td>
</tr>
<tr>
<td>equal</td>
<td>3</td>
</tr>
<tr>
<td>greater than or equal</td>
<td>4</td>
</tr>
<tr>
<td>greater than</td>
<td>5</td>
</tr>
</tbody>
</table>

Hash indexes support only equality comparisons, and so they use only one strategy, shown in Table 34-3.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Strategy Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>equal</td>
<td>1</td>
</tr>
</tbody>
</table>

GiST indexes are more flexible: they do not have a fixed set of strategies at all. Instead, the “consistency” support routine of each particular GiST operator class interprets the strategy numbers however it likes. As an example, several of the built-in GiST index operator classes index two-dimensional geometric objects, providing the “R-tree” strategies shown in Table 34-4. Four of these are true two-
dimensional tests (overlaps, same, contains, contained by); four of them consider only the X direction; and the other four provide the same tests in the Y direction.

Table 34-4. GiST Two-Dimensional “R-tree” Strategies

<table>
<thead>
<tr>
<th>Operation</th>
<th>Strategy Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>strictly left of</td>
<td>1</td>
</tr>
<tr>
<td>does not extend to right of</td>
<td>2</td>
</tr>
<tr>
<td>overlaps</td>
<td>3</td>
</tr>
<tr>
<td>does not extend to left of</td>
<td>4</td>
</tr>
<tr>
<td>strictly right of</td>
<td>5</td>
</tr>
<tr>
<td>same</td>
<td>6</td>
</tr>
<tr>
<td>contains</td>
<td>7</td>
</tr>
<tr>
<td>contained by</td>
<td>8</td>
</tr>
<tr>
<td>does not extend above</td>
<td>9</td>
</tr>
<tr>
<td>strictly below</td>
<td>10</td>
</tr>
<tr>
<td>strictly above</td>
<td>11</td>
</tr>
<tr>
<td>does not extend below</td>
<td>12</td>
</tr>
</tbody>
</table>

GIN indexes are similar to GiST indexes in flexibility: they don’t have a fixed set of strategies. Instead the support routines of each operator class interpret the strategy numbers according to the operator class’s definition. As an example, the strategy numbers used by the built-in operator classes for arrays are shown in Table 34-5.

Table 34-5. GIN Array Strategies

<table>
<thead>
<tr>
<th>Operation</th>
<th>Strategy Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>overlap</td>
<td>1</td>
</tr>
<tr>
<td>contains</td>
<td>2</td>
</tr>
<tr>
<td>is contained by</td>
<td>3</td>
</tr>
<tr>
<td>equal</td>
<td>4</td>
</tr>
</tbody>
</table>

Notice that all strategy operators return Boolean values. In practice, all operators defined as index method strategies must return type `boolean`, since they must appear at the top level of a `WHERE` clause to be used with an index.

34.14.3. Index Method Support Routines

Strategies aren’t usually enough information for the system to figure out how to use an index. In practice, the index methods require additional support routines in order to work. For example, the B-tree index method must be able to compare two keys and determine whether one is greater than, equal to, or less than the other. Similarly, the hash index method must be able to compute hash codes for key values. These operations do not correspond to operators used in qualifications in SQL commands; they are administrative routines used by the index methods, internally.

Just as with strategies, the operator class identifies which specific functions should play each of these roles for a given data type and semantic interpretation. The index method defines the set of functions it needs, and the operator class identifies the correct functions to use by assigning them to the “support
Chapter 34. Extending SQL

function numbers” specified by the index method.

B-trees require a single support function, shown in Table 34-6.

Table 34-6. B-tree Support Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Support Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compare two keys and return an integer less than zero, zero, or greater</td>
<td>1</td>
</tr>
<tr>
<td>than zero, indicating whether the first key is less than, equal to, or</td>
<td></td>
</tr>
<tr>
<td>greater than the second</td>
<td></td>
</tr>
</tbody>
</table>

Hash indexes likewise require one support function, shown in Table 34-7.

Table 34-7. Hash Support Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Support Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compute the hash value for</td>
<td>1</td>
</tr>
<tr>
<td>a key</td>
<td></td>
</tr>
</tbody>
</table>

GiST indexes require seven support functions, shown in Table 34-8.

Table 34-8. GiST Support Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Support Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>consistent - determine whether key satisfies the query qualifier</td>
<td>1</td>
</tr>
<tr>
<td>union - compute union of a set of keys</td>
<td>2</td>
</tr>
<tr>
<td>compress - compute a compressed representation of a key or value to be</td>
<td>3</td>
</tr>
<tr>
<td>indexed</td>
<td></td>
</tr>
<tr>
<td>decompress - compute a decompressed representation of a compressed key</td>
<td>4</td>
</tr>
<tr>
<td>penalty - compute penalty for inserting new key into subtree with given</td>
<td>5</td>
</tr>
<tr>
<td>subtree’s key</td>
<td></td>
</tr>
<tr>
<td>picksplit - determine which entries of a page are to be moved to the new</td>
<td>6</td>
</tr>
<tr>
<td>page and compute the union keys for resulting pages</td>
<td></td>
</tr>
<tr>
<td>equal - compare two keys and return true if they are equal</td>
<td>7</td>
</tr>
</tbody>
</table>

GIN indexes require four support functions, shown in Table 34-9.

Table 34-9. GIN Support Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Support Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>compare - compare two keys and return an integer less than zero, zero,</td>
<td>1</td>
</tr>
<tr>
<td>or greater than zero, indicating whether the first key is less than,</td>
<td></td>
</tr>
<tr>
<td>equal to, or greater than the second</td>
<td></td>
</tr>
<tr>
<td>extractValue - extract keys from a value to be indexed</td>
<td>2</td>
</tr>
</tbody>
</table>
Unlike strategy operators, support functions return whichever data type the particular index method expects; for example in the case of the comparison function for B-trees, a signed integer. The number and types of the arguments to each support function are likewise dependent on the index method. For B-tree and hash the support functions take the same input data types as do the operators included in the operator class, but this is not the case for most GIN and GiST support functions.

### 34.14.4. An Example

Now that we have seen the ideas, here is the promised example of creating a new operator class. (You can find a working copy of this example in `src/tutorial/complex.c` and `src/tutorial/complex.sql` in the source distribution.) The operator class encapsulates operators that sort complex numbers in absolute value order, so we choose the name `complex_abs_ops`. First, we need a set of operators. The procedure for defining operators was discussed in Section 34.12. For an operator class on B-trees, the operators we require are:

- absolute-value less-than (strategy 1)
- absolute-value less-than-or-equal (strategy 2)
- absolute-value equal (strategy 3)
- absolute-value greater-than-or-equal (strategy 4)
- absolute-value greater-than (strategy 5)

The least error-prone way to define a related set of comparison operators is to write the B-tree comparison support function first, and then write the other functions as one-line wrappers around the support function. This reduces the odds of getting inconsistent results for corner cases. Following this approach, we first write:

```c
#define Mag(c) ((c)->x *(c)->x + (c)->y*(c)->y)

static int complex_abs_cmp_internal(Complex *a, Complex *b)
{
    double amag = Mag(a),
    bmag = Mag(b);
    if (amag < bmag)
        return -1;
    if (amag > bmag)
        return 1;
}
```

<table>
<thead>
<tr>
<th>Function</th>
<th>Support Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>extractQuery - extract keys from a query condition</td>
<td>3</td>
</tr>
<tr>
<td>consistent - determine whether value matches query condition</td>
<td>4</td>
</tr>
<tr>
<td>comparePartial - (optional method) compare partial key from query and key from index, and return an integer less than zero, zero, or greater than zero, indicating whether GIN should ignore this index entry, treat the entry as a match, or stop the index scan</td>
<td>5</td>
</tr>
</tbody>
</table>
Chapter 34. Extending SQL

```
return 0;
}

Now the less-than function looks like:

PG_FUNCTION_INFO_V1(complex_abs_lt);

Datum complex_abs_lt(PG_FUNCTION_ARGS)
{
Complex *a = (Complex *) PG_GETARG_POINTER(0);
Complex *b = (Complex *) PG_GETARG_POINTER(1);

PG_RETURN_BOOL(complex_abs_cmp_internal(a, b) < 0);
}

The other four functions differ only in how they compare the internal function’s result to zero.

Next we declare the functions and the operators based on the functions to SQL:

CREATE FUNCTION complex_abs_lt(complex, complex) RETURNS bool
AS 'filename', 'complex_abs_lt'
LANGUAGE C IMMUTABLE STRICT;

CREATE OPERATOR <
(leftarg = complex, rightarg = complex, procedure = complex_abs_lt,
commutator = >, negator = >=,
restrict = scalarltsel, join = scalarltjoinsel)
;

It is important to specify the correct commutator and negator operators, as well as suitable restriction and join selectivity functions, otherwise the optimizer will be unable to make effective use of the index. Note that the less-than, equal, and greater-than cases should use different selectivity functions.

Other things worth noting are happening here:

- There can only be one operator named, say, = and taking type complex for both operands. In this case we don’t have any other operator = for complex, but if we were building a practical data type we’d probably want = to be the ordinary equality operation for complex numbers (and not the equality of the absolute values). In that case, we’d need to use some other operator name for complex_abs_eq.

- Although PostgreSQL can cope with functions having the same SQL name as long as they have different argument data types, C can only cope with one global function having a given name. So we shouldn’t name the C function something simple like abs_eq. Usually it’s a good practice to include the data type name in the C function name, so as not to conflict with functions for other data types.

- We could have made the SQL name of the function abs_eq, relying on PostgreSQL to distinguish it by argument data types from any other SQL function of the same name. To keep the example simple, we make the function have the same names at the C level and SQL level.

The next step is the registration of the support routine required by B-trees. The example C code that implements this is in the same file that contains the operator functions. This is how we declare the function:

CREATE FUNCTION complex_abs_cmp(complex, complex)
Now that we have the required operators and support routine, we can finally create the operator class:

```sql
CREATE OPERATOR CLASS complex_abs_ops
DEFAULT FOR TYPE complex USING btree AS
   OPERATOR 1  < ,
   OPERATOR 2  <= ,
   OPERATOR 3  = ,
   OPERATOR 4  >= ,
   OPERATOR 5  > ,
   FUNCTION 1  complex_abs_cmp(complex, complex);
```

And we’re done! It should now be possible to create and use B-tree indexes on `complex` columns.

We could have written the operator entries more verbosely, as in:

```sql
OPERATOR 1  < (complex, complex) ,
```

but there is no need to do so when the operators take the same data type we are defining the operator class for.

The above example assumes that you want to make this new operator class the default B-tree operator class for the `complex` data type. If you don’t, just leave out the word `DEFAULT`.

### 34.14.5. Operator Classes and Operator Families

So far we have implicitly assumed that an operator class deals with only one data type. While there certainly can be only one data type in a particular index column, it is often useful to index operations that compare an indexed column to a value of a different data type. Also, if there is use for a cross-data-type operator in connection with an operator class, it is often the case that the other data type has a related operator class of its own. It is helpful to make the connections between related classes explicit, because this can aid the planner in optimizing SQL queries (particularly for B-tree operator classes, since the planner contains a great deal of knowledge about how to work with them).

To handle these needs, PostgreSQL uses the concept of an `operator family`. An operator family contains one or more operator classes, and can also contain indexable operators and corresponding support functions that belong to the family as a whole but not to any single class within the family. We say that such operators and functions are “loose” within the family, as opposed to being bound into a specific class. Typically each operator class contains single-data-type operators while cross-data-type operators are loose in the family.

All the operators and functions in an operator family must have compatible semantics, where the compatibility requirements are set by the index method. You might therefore wonder why bother to single out particular subsets of the family as operator classes; and indeed for many purposes the class divisions are irrelevant and the family is the only interesting grouping. The reason for defining operator classes is that they specify how much of the family is needed to support any particular index. If there is an index using an operator class, then that operator class cannot be dropped without dropping the index — but other parts of the operator family, namely other operator classes and loose operators, could be dropped. Thus, an operator class should be specified to contain the minimum set
of operators and functions that are reasonably needed to work with an index on a specific data type, and then related but non-essential operators can be added as loose members of the operator family.

As an example, PostgreSQL has a built-in B-tree operator family `integer_ops`, which includes operator classes `int8_ops`, `int4_ops`, and `int2_ops` for indexes on `bigint(int8)`, `integer(int4)`, and `smallint(int2)` columns respectively. The family also contains cross-data-type comparison operators allowing any two of these types to be compared, so that an index on one of these types can be searched using a comparison value of another type. The family could be duplicated by these definitions:

```sql
CREATE OPERATOR FAMILY integer_ops USING btree;

CREATE OPERATOR CLASS int8_ops
DEFAULT FOR TYPE int8 USING btree FAMILY integer_ops AS
  -- standard int8 comparisons
  OPERATOR 1 < ,
  OPERATOR 2 <= ,
  OPERATOR 3 = ,
  OPERATOR 4 >= ,
  OPERATOR 5 > ,
  FUNCTION 1 btint8cmp(int8, int8) ;

CREATE OPERATOR CLASS int4_ops
DEFAULT FOR TYPE int4 USING btree FAMILY integer_ops AS
  -- standard int4 comparisons
  OPERATOR 1 < ,
  OPERATOR 2 <= ,
  OPERATOR 3 = ,
  OPERATOR 4 >= ,
  OPERATOR 5 > ,
  FUNCTION 1 btint4cmp(int4, int4) ;

CREATE OPERATOR CLASS int2_ops
DEFAULT FOR TYPE int2 USING btree FAMILY integer_ops AS
  -- standard int2 comparisons

FUNCTION 1 `btint24cmp(int2, int4)` ;

Notice that this definition “overloads” the operator strategy and support function numbers: each number occurs multiple times within the family. This is allowed so long as each instance of a particular number has distinct input data types. The instances that have both input types equal to an operator class’s input type are the primary operators and support functions for that operator class, and in most cases should be declared as part of the operator class rather than as loose members of the family.

In a B-tree operator family, all the operators in the family must sort compatibly, meaning that the transitive laws hold across all the data types supported by the family: “if A = B and B = C, then A = C”, and “if A < B and B < C, then A < C”. For each operator in the family there must be a support function having the same two input data types as the operator. It is recommended that a family be complete, i.e., for each combination of data types, all operators are included. Each operator class should include just the non-cross-type operators and support function for its data type.

To build a multiple-data-type hash operator family, compatible hash support functions must be created for each data type supported by the family. Here compatibility means that the functions are guaranteed to return the same hash code for any two values that are considered equal by the family’s equality operators, even when the values are of different types. This is usually difficult to accomplish when the types have different physical representations, but it can be done in some cases. Notice that there is only one support function per data type, not one per equality operator. It is recommended that a family be complete, i.e., provide an equality operator for each combination of data types. Each operator class should include just the non-cross-type equality operator and the support function for its data type.
GIN and GiST indexes do not have any explicit notion of cross-data-type operations. The set of operators supported is just whatever the primary support functions for a given operator class can handle.

Note: Prior to PostgreSQL 8.3, there was no concept of operator families, and so any cross-data-type operators intended to be used with an index had to be bound directly into the index’s operator class. While this approach still works, it is deprecated because it makes an index’s dependencies too broad, and because the planner can handle cross-data-type comparisons more effectively when both data types have operators in the same operator family.

### 34.14.6. System Dependencies on Operator Classes

PostgreSQL uses operator classes to infer the properties of operators in more ways than just whether they can be used with indexes. Therefore, you might want to create operator classes even if you have no intention of indexing any columns of your data type.

In particular, there are SQL features such as `ORDER BY` and `DISTINCT` that require comparison and sorting of values. To implement these features on a user-defined data type, PostgreSQL looks for the default B-tree operator class for the data type. The “equals” member of this operator class defines the system’s notion of equality of values for `GROUP BY` and `DISTINCT`, and the sort ordering imposed by the operator class defines the default `ORDER BY` ordering.

Comparison of arrays of user-defined types also relies on the semantics defined by the default B-tree operator class.

If there is no default B-tree operator class for a data type, the system will look for a default hash operator class. But since that kind of operator class only provides equality, in practice it is only enough to support array equality.

When there is no default operator class for a data type, you will get errors like “could not identify an ordering operator” if you try to use these SQL features with the data type.

Note: In PostgreSQL versions before 7.4, sorting and grouping operations would implicitly use operators named `=`, `<`, and `>`. The new behavior of relying on default operator classes avoids having to make any assumption about the behavior of operators with particular names.

Another important point is that an operator that appears in a hash operator family is a candidate for hash joins, hash aggregation, and related optimizations. The hash operator family is essential here since it identifies the hash function(s) to use.

### 34.14.7. Special Features of Operator Classes

There are two special features of operator classes that we have not discussed yet, mainly because they are not useful with the most commonly used index methods.

Normally, declaring an operator as a member of an operator class (or family) means that the index method can retrieve exactly the set of rows that satisfy a `WHERE` condition using the operator. For example:

```
SELECT * FROM table WHERE integer_column < 4;
```
can be satisfied exactly by a B-tree index on the integer column. But there are cases where an index is useful as an inexact guide to the matching rows. For example, if a GiST index stores only bounding boxes for geometric objects, then it cannot exactly satisfy a \texttt{WHERE} condition that tests overlap between nonrectangular objects such as polygons. Yet we could use the index to find objects whose bounding box overlaps the bounding box of the target object, and then do the exact overlap test only on the objects found by the index. If this scenario applies, the index is said to be “lossy” for the operator. Lossy index searches are implemented by having the index method return a \texttt{recheck} flag when a row might or might not really satisfy the query condition. The core system will then test the original query condition on the retrieved row to see whether it should be returned as a valid match. This approach works if the index is guaranteed to return all the required rows, plus perhaps some additional rows, which can be eliminated by performing the original operator invocation. The index methods that support lossy searches (currently, GiST and GIN) allow the support functions of individual operator classes to set the recheck flag, and so this is essentially an operator-class feature.

Consider again the situation where we are storing in the index only the bounding box of a complex object such as a polygon. In this case there’s not much value in storing the whole polygon in the index entry — we might as well store just a simpler object of type \texttt{box}. This situation is expressed by the \texttt{STORAGE} option in \texttt{CREATE OPERATOR CLASS}: we’d write something like:

```sql
CREATE OPERATOR CLASS polygon_ops
  DEFAULT FOR TYPE polygon USING gist AS
  ...
  STORAGE box;
```

At present, only the GiST and GIN index methods support a \texttt{STORAGE} type that’s different from the column data type. The GiST \texttt{compress} and \texttt{decompress} support routines must deal with data-type conversion when \texttt{STORAGE} is used. In GIN, the \texttt{STORAGE} type identifies the type of the “key” values, which normally is different from the type of the indexed column — for example, an operator class for integer-array columns might have keys that are just integers. The GIN \texttt{extractValue} and \texttt{extractQuery} support routines are responsible for extracting keys from indexed values.
Chapter 35. Triggers

This chapter provides general information about writing trigger functions. Trigger functions can be written in most of the available procedural languages, including PL/pgSQL (Chapter 38), PL/Tcl (Chapter 39), PL/Perl (Chapter 40), and PL/Python (Chapter 41). After reading this chapter, you should consult the chapter for your favorite procedural language to find out the language-specific details of writing a trigger in it.

It is also possible to write a trigger function in C, although most people find it easier to use one of the procedural languages. It is not currently possible to write a trigger function in the plain SQL function language.

35.1. Overview of Trigger Behavior

A trigger is a specification that the database should automatically execute a particular function whenever a certain type of operation is performed. Triggers can be defined to execute either before or after any INSERT, UPDATE, or DELETE operation, either once per modified row, or once per SQL statement. Triggers can also fire for TRUNCATE statements. If a trigger event occurs, the trigger’s function is called at the appropriate time to handle the event.

The trigger function must be defined before the trigger itself can be created. The trigger function must be declared as a function taking no arguments and returning type trigger. (The trigger function receives its input through a specially-passed TriggerData structure, not in the form of ordinary function arguments.)

Once a suitable trigger function has been created, the trigger is established with CREATE TRIGGER. The same trigger function can be used for multiple triggers.

PostgreSQL offers both per-row triggers and per-statement triggers. With a per-row trigger, the trigger function is invoked once for each row that is affected by the statement that fired the trigger. In contrast, a per-statement trigger is invoked only once when an appropriate statement is executed, regardless of the number of rows affected by that statement. In particular, a statement that affects zero rows will still result in the execution of any applicable per-statement triggers. These two types of triggers are sometimes called row-level triggers and statement-level triggers, respectively. Triggers on TRUNCATE may only be defined at statement-level.

Triggers are also classified as before triggers and after triggers. Statement-level before triggers naturally fire before the statement starts to do anything, while statement-level after triggers fire at the very end of the statement. Row-level before triggers fire immediately before a particular row is operated on, while row-level after triggers fire at the end of the statement (but before any statement-level after triggers).

Trigger functions invoked by per-statement triggers should always return NULL. Trigger functions invoked by per-row triggers can return a table row (a value of type HeapTuple) to the calling executor, if they choose. A row-level trigger fired before an operation has the following choices:

- It can return NULL to skip the operation for the current row. This instructs the executor to not perform the row-level operation that invoked the trigger (the insertion or modification of a particular table row).
- For row-level INSERT and UPDATE triggers only, the returned row becomes the row that will be inserted or will replace the row being updated. This allows the trigger function to modify the row being inserted or updated.
A row-level before trigger that does not intend to cause either of these behaviors must be careful to return as its result the same row that was passed in (that is, the NEW row for INSERT and UPDATE triggers, the OLD row for DELETE triggers).

The return value is ignored for row-level triggers fired after an operation, and so they can return NULL. If more than one trigger is defined for the same event on the same relation, the triggers will be fired in alphabetical order by trigger name. In the case of before triggers, the possibly-modified row returned by each trigger becomes the input to the next trigger. If any before trigger returns NULL, the operation is abandoned for that row and subsequent triggers are not fired.

Typically, row before triggers are used for checking or modifying the data that will be inserted or updated. For example, a before trigger might be used to insert the current time into a timestamp column, or to check that two elements of the row are consistent. Row after triggers are most sensibly used to propagate the updates to other tables, or make consistency checks against other tables. The reason for this division of labor is that an after trigger can be certain it is seeing the final value of the row, while a before trigger cannot; there might be other before triggers firing after it. If you have no specific reason to make a trigger before or after, the before case is more efficient, since the information about the operation doesn’t have to be saved until end of statement.

If a trigger function executes SQL commands then these commands might fire triggers again. This is known as cascading triggers. There is no direct limitation on the number of cascade levels. It is possible for cascades to cause a recursive invocation of the same trigger; for example, an INSERT trigger might execute a command that inserts an additional row into the same table, causing the INSERT trigger to be fired again. It is the trigger programmer’s responsibility to avoid infinite recursion in such scenarios.

When a trigger is being defined, arguments can be specified for it. The purpose of including arguments in the trigger definition is to allow different triggers with similar requirements to call the same function. As an example, there could be a generalized trigger function that takes as its arguments two column names and puts the current user in one and the current time stamp in the other. Properly written, this trigger function would be independent of the specific table it is triggering on. So the same function could be used for INSERT events on any table with suitable columns, to automatically track creation of records in a transaction table for example. It could also be used to track last-update events if defined as an UPDATE trigger.

Each programming language that supports triggers has its own method for making the trigger input data available to the trigger function. This input data includes the type of trigger event (e.g., INSERT or UPDATE) as well as any arguments that were listed in CREATE TRIGGER. For a row-level trigger, the input data also includes the NEW row for INSERT and UPDATE triggers, and/or the OLD row for UPDATE and DELETE triggers. Statement-level triggers do not currently have any way to examine the individual row(s) modified by the statement.

### 35.2. Visibility of Data Changes

If you execute SQL commands in your trigger function, and these commands access the table that the trigger is for, then you need to be aware of the data visibility rules, because they determine whether these SQL commands will see the data change that the trigger is fired for. Briefly:

- Statement-level triggers follow simple visibility rules: none of the changes made by a statement are visible to statement-level triggers that are invoked before the statement, whereas all modifications are visible to statement-level after triggers.
• The data change (insertion, update, or deletion) causing the trigger to fire is naturally not visible to SQL commands executed in a row-level before trigger, because it hasn’t happened yet.

• However, SQL commands executed in a row-level before trigger will see the effects of data changes for rows previously processed in the same outer command. This requires caution, since the ordering of these change events is not in general predictable; a SQL command that affects multiple rows can visit the rows in any order.

• When a row-level after trigger is fired, all data changes made by the outer command are already complete, and are visible to the invoked trigger function.

If your trigger function is written in any of the standard procedural languages, then the above statements apply only if the function is declared VOLATILE. Functions that are declared STABLE or IMMUTABLE will not see changes made by the calling command in any case.

Further information about data visibility rules can be found in Section 42.4. The example in Section 35.4 contains a demonstration of these rules.

35.3. Writing Trigger Functions in C

This section describes the low-level details of the interface to a trigger function. This information is only needed when writing trigger functions in C. If you are using a higher-level language then these details are handled for you. In most cases you should consider using a procedural language before writing your triggers in C. The documentation of each procedural language explains how to write a trigger in that language.

Trigger functions must use the “version 1” function manager interface.

When a function is called by the trigger manager, it is not passed any normal arguments, but it is passed a “context” pointer pointing to a TriggerData structure. C functions can check whether they were called from the trigger manager or not by executing the macro:

CALLED_AS_TRIGGER(fcinfo)

which expands to:

{{fcinfo}-&gt;context != NULL &amp;&amp; IsA((fcinfo)-&gt;context, TriggerData)}

If this returns true, then it is safe to cast fcinfo-&gt;context to type TriggerData * and make use of the pointed-to TriggerData structure. The function must not alter the TriggerData structure or any of the data it points to.

struct TriggerData is defined in commands/trigger.h:

typedef struct TriggerData
{
    NodeTag       type;
    TriggerEvent  tg_event;
    Relation      tg_relation;
    HeapTuple     tg_trigtuple;
    HeapTuple     tg_newtuple;
    Trigger       *tg_trigger;
    Buffer        tg_trigtuplebuf;
    Buffer        tg_newtuplebuf;
} TriggerData;
where the members are defined as follows:

\begin{verbatim}
type
    Always T_TriggerData.

tg_event
    Describes the event for which the function is called. You can use the following macros to examine
    tg_event:

    TRIGGER_FIRED_BEFORE(tg_event)
    Returns true if the trigger fired before the operation.

    TRIGGER_FIRED_AFTER(tg_event)
    Returns true if the trigger fired after the operation.

    TRIGGER_FIRED_FOR_ROW(tg_event)
    Returns true if the trigger fired for a row-level event.

    TRIGGER_FIRED_FOR_STATEMENT(tg_event)
    Returns true if the trigger fired for a statement-level event.

    TRIGGER_FIRED_BY_INSERT(tg_event)
    Returns true if the trigger was fired by an INSERT command.

    TRIGGER_FIRED_BY_UPDATE(tg_event)
    Returns true if the trigger was fired by an UPDATE command.

    TRIGGER_FIRED_BY_DELETE(tg_event)
    Returns true if the trigger was fired by a DELETE command.

    TRIGGER_FIRED_BY_TRUNCATE(tg_event)
    Returns true if the trigger was fired by a TRUNCATE command.

tg_relation
    A pointer to a structure describing the relation that the trigger fired for. Look at utils/rel.h for
details about this structure. The most interesting things are tg_relation->rd_att (descriptor
of the relation tuples) and tg_relation->rd_rel->relname (relation name; the type is not
char* but NameData; use SPI_getrelname(tg_relation) to get a char* if you need a
copy of the name).

tg_trigtuple
    A pointer to the row for which the trigger was fired. This is the row being inserted, updated, or
deleted. If this trigger was fired for an INSERT or DELETE then this is what you should return
from the function if you don’t want to replace the row with a different one (in the case of INSERT)
or skip the operation.

tg_newtuple
    A pointer to the new version of the row, if the trigger was fired for an UPDATE, and NULL if it is
for an INSERT or a DELETE. This is what you have to return from the function if the event is an
UPDATE and you don’t want to replace this row by a different one or skip the operation.
\end{verbatim}
A pointer to a structure of type `Trigger`, defined in `utils/rel.h`:

```c
typedef struct Trigger {
    Oid tgoid;
    char *tgname;
    Oid tgfoid;
    int16 tgtype;
    char tgenabled;
    bool tgisconstraint;
    Oid tgconstrelid;
    Oid tgconstraint;
    bool tgdeferrable;
    bool tginitdeferred;
    int16 tgnargs;
    int16 tgnattr;
    int16 *tgattr;
    char **tgargs;
} Trigger;
```

where `tgname` is the trigger's name, `tgnargs` is number of arguments in `tgargs`, and `tgargs` is an array of pointers to the arguments specified in the `CREATE TRIGGER` statement. The other members are for internal use only.

The buffer containing `tg_trigtuplebuf`, or `InvalidBuffer` if there is no such tuple or it is not stored in a disk buffer.

The buffer containing `tg_newtuplebuf`, or `InvalidBuffer` if there is no such tuple or it is not stored in a disk buffer.

A trigger function must return either a `HeapTuple` pointer or a `NULL` pointer (*not* an SQL null value, that is, do not set `isNull` true). Be careful to return either `tg_trigtuplebuf` or `tg_newtuplebuf`, as appropriate, if you don’t want to modify the row being operated on.

### 35.4. A Complete Example

Here is a very simple example of a trigger function written in C. (Examples of triggers written in procedural languages can be found in the documentation of the procedural languages.)

The function `trigf` reports the number of rows in the table `ttest` and skips the actual operation if the command attempts to insert a null value into the column `x`. (So the trigger acts as a not-null constraint but doesn’t abort the transaction.)

First, the table definition:

```sql
CREATE TABLE ttest (  
    x integer
);
```

This is the source code of the trigger function:
#include "postgres.h"
#include "executor/spi.h" /* this is what you need to work with SPI */
#include "commands/trigger.h" /* ... and triggers */

extern Datum trigf(PG_FUNCTION_ARGS);

PG_FUNCTION_INFO_V1(trigf);

Datum
trigf(PG_FUNCTION_ARGS)
{
  TriggerData *trigdata = (TriggerData *) fcinfo->context;
  TupleDesc tupdesc;
  HeapTuple rettuple;
  char *when;
  bool checknull = false;
  bool isnull;
  int ret, i;

  /* make sure it’s called as a trigger at all */
  if (!CALLED_AS_TRIGGER(fcinfo))
    elog(ERROR, "trigf: not called by trigger manager");

  /* tuple to return to executor */
  if (TRIGGER_FIRED_BY_UPDATE(trigdata->tg_event))
    rettuple = trigdata->tg_newtuple;
  else
    rettuple = trigdata->tg_trigtuple;

  /* check for null values */
  if (!TRIGGER_FIRED_BY_DELETE(trigdata->tg_event)
      && TRIGGER_FIRED_BEFORE(trigdata->tg_event))
    checknull = true;

  if (TRIGGER_FIRED_BEFORE(trigdata->tg_event))
    when = "before";
  else
    when = "after ";
  tupdesc = trigdata->tg_relation->rd_att;

  /* connect to SPI manager */
  if ((ret = SPI_connect()) < 0)
    elog(ERROR, "trigf (fired %s): SPI_connect returned %d", when, ret);

  /* get number of rows in table */
  ret = SPI_exec("SELECT count(*) FROM ttest", 0);

  if (ret < 0)
    elog(ERROR, "trigf (fired %s): SPI_exec returned %d", when, ret);

  /* count(*) returns int8, so be careful to convert */
  i = DatumGetInt64(SPI_getbinval(SPI_tuptable->vals[0],
                                 SPI_tuptable->tupdesc,
                                 1,
                                 &isnull));

  /* ... */
}
eelog (INFO, "trigf (fired %s): there are %d rows in ttest", when, i);

SPI_finish();

if (checknull)
{
    SPI_getbinval(rettuple, tupdesc, 1, &isnull);
    if (isnull)
        rettuple = NULL;
}

return PointerGetDatum(rettuple);

After you have compiled the source code (see Section 34.9.6), declare the function and the triggers:

CREATE FUNCTION trigf() RETURNS trigger
    AS 'filename'
    LANGUAGE C;

CREATE TRIGGER tbefore BEFORE INSERT OR UPDATE OR DELETE ON ttest
    FOR EACH ROW EXECUTE PROCEDURE trigf();

CREATE TRIGGER tafter AFTER INSERT OR UPDATE OR DELETE ON ttest
    FOR EACH ROW EXECUTE PROCEDURE trigf();

Now you can test the operation of the trigger:

=> INSERT INTO ttest VALUES (NULL);
INFO: trigf (fired before): there are 0 rows in ttest
INSERT 0 0
-- Insertion skipped and AFTER trigger is not fired

=> SELECT * FROM ttest;
x
---
(0 rows)

=> INSERT INTO ttest VALUES (1);
INFO: trigf (fired before): there are 0 rows in ttest
INFO: trigf (fired after ): there are 1 rows in ttest

remember what we said about visibility.

INSERT 167793 1
vac=> SELECT * FROM ttest;
x
---
1
(1 row)

=> INSERT INTO ttest SELECT x * 2 FROM ttest;
INFO: trigf (fired before): there are 1 rows in ttest
INFO: trigf (fired after ): there are 2 rows in ttest

764
remember what we said about visibility.

INSERT 167794 1
=> SELECT * FROM ttest;
x
---
1
2
(2 rows)

=> UPDATE ttest SET x = NULL WHERE x = 2;
INFO: trigf (fired before): there are 2 rows in ttest
UPDATE 0
=> UPDATE ttest SET x = 4 WHERE x = 2;
INFO: trigf (fired before): there are 2 rows in ttest
INFO: trigf (fired after): there are 2 rows in ttest
UPDATE 1
vac=> SELECT * FROM ttest;
x
---
1
4
(2 rows)

=> DELETE FROM ttest;
INFO: trigf (fired before): there are 2 rows in ttest
INFO: trigf (fired before): there are 1 rows in ttest
INFO: trigf (fired after): there are 0 rows in ttest
INFO: trigf (fired after): there are 0 rows in ttest

remember what we said about visibility.

DELETE 2
=> SELECT * FROM ttest;
x
---
(0 rows)

There are more complex examples in src/test/regress/regress.c and in contrib/spi.
Chapter 36. The Rule System

This chapter discusses the rule system in PostgreSQL. Production rule systems are conceptually simple, but there are many subtle points involved in actually using them.

Some other database systems define active database rules, which are usually stored procedures and triggers. In PostgreSQL, these can be implemented using functions and triggers as well.

The rule system (more precisely speaking, the query rewrite rule system) is totally different from stored procedures and triggers. It modifies queries to take rules into consideration, and then passes the modified query to the query planner for planning and execution. It is very powerful, and can be used for many things such as query language procedures, views, and versions. The theoretical foundations and the power of this rule system are also discussed in On Rules, Procedures, Caching and Views in Database Systems and A Unified Framework for Version Modeling Using Production Rules in a Database System.

36.1. The Query Tree

To understand how the rule system works it is necessary to know when it is invoked and what its input and results are.

The rule system is located between the parser and the planner. It takes the output of the parser, one query tree, and the user-defined rewrite rules, which are also query trees with some extra information, and creates zero or more query trees as result. So its input and output are always things the parser itself could have produced and thus, anything it sees is basically representable as an SQL statement.

Now what is a query tree? It is an internal representation of an SQL statement where the single parts that it is built from are stored separately. These query trees can be shown in the server log if you set the configuration parameters debug_print_parse, debug_print_rewritten, or debug_print_plan. The rule actions are also stored as query trees, in the system catalog pg_rewrite. They are not formatted like the log output, but they contain exactly the same information.

Reading a raw query tree requires some experience. But since SQL representations of query trees are sufficient to understand the rule system, this chapter will not teach how to read them.

When reading the SQL representations of the query trees in this chapter it is necessary to be able to identify the parts the statement is broken into when it is in the query tree structure. The parts of a query tree are

the command type

This is a simple value telling which command (SELECT, INSERT, UPDATE, DELETE) produced the query tree.

the range table

The range table is a list of relations that are used in the query. In a SELECT statement these are the relations given after the FROM key word.

Every range table entry identifies a table or view and tells by which name it is called in the other parts of the query. In the query tree, the range table entries are referenced by number rather than by name, so here it doesn’t matter if there are duplicate names as it would in an SQL statement. This can happen after the range tables of rules have been merged in. The examples in this chapter will not have this situation.
the result relation

This is an index into the range table that identifies the relation where the results of the query go. SELECT queries normally don’t have a result relation. The special case of a SELECT INTO is mostly identical to a CREATE TABLE followed by an INSERT ... SELECT and is not discussed separately here.

For INSERT, UPDATE, and DELETE commands, the result relation is the table (or view!) where the changes are to take effect.

the target list

The target list is a list of expressions that define the result of the query. In the case of a SELECT, these expressions are the ones that build the final output of the query. They correspond to the expressions between the key words SELECT and FROM. (∗ is just an abbreviation for all the column names of a relation. It is expanded by the parser into the individual columns, so the rule system never sees it.)

DELETE commands don’t need a target list because they don’t produce any result. In fact, the planner will add a special CTID entry to the empty target list, but this is after the rule system and will be discussed later; for the rule system, the target list is empty.

For INSERT commands, the target list describes the new rows that should go into the result relation. It consists of the expressions in the VALUES clause or the ones from the SELECT clause in INSERT ... SELECT. The first step of the rewrite process adds target list entries for any columns that were not assigned to by the original command but have defaults. Any remaining columns (with neither a given value nor a default) will be filled in by the planner with a constant null expression.

For UPDATE commands, the target list describes the new rows that should replace the old ones. In the rule system, it contains just the expressions from the SET column = expression part of the command. The planner will handle missing columns by inserting expressions that copy the values from the old row into the new one. And it will add the special CTID entry just as for DELETE, too.

Every entry in the target list contains an expression that can be a constant value, a variable pointing to a column of one of the relations in the range table, a parameter, or an expression tree made of function calls, constants, variables, operators, etc.

the qualification

The query’s qualification is an expression much like one of those contained in the target list entries. The result value of this expression is a Boolean that tells whether the operation (INSERT, UPDATE, DELETE, or SELECT) for the final result row should be executed or not. It corresponds to the WHERE clause of an SQL statement.

the join tree

The query’s join tree shows the structure of the FROM clause. For a simple query like SELECT ... FROM a, b, c, the join tree is just a list of the FROM items, because we are allowed to join them in any order. But when JOIN expressions, particularly outer joins, are used, we have to join in the order shown by the joins. In that case, the join tree shows the structure of the JOIN expressions. The restrictions associated with particular JOIN clauses (from ON or USING expressions) are stored as qualification expressions attached to those join-tree nodes. It turns out to be convenient to store the top-level WHERE expression as a qualification attached to the top-level join-tree item, too. So really the join tree represents both the FROM and WHERE clauses of a SELECT.
the others

The other parts of the query tree like the ORDER BY clause aren’t of interest here. The rule system substitutes some entries there while applying rules, but that doesn’t have much to do with the fundamentals of the rule system.

36.2. Views and the Rule System

Views in PostgreSQL are implemented using the rule system. In fact, there is essentially no difference between:

```sql
CREATE VIEW myview AS SELECT * FROM mytab;
```

compared against the two commands:

```sql
CREATE TABLE myview (same column list as mytab);
CREATE RULE "_RETURN" AS ON SELECT TO myview DO INSTEAD
   SELECT * FROM mytab;
```

because this is exactly what the CREATE VIEW command does internally. This has some side effects. One of them is that the information about a view in the PostgreSQL system catalogs is exactly the same as it is for a table. So for the parser, there is absolutely no difference between a table and a view. They are the same thing: relations.

36.2.1. How SELECT Rules Work

Rules ON SELECT are applied to all queries as the last step, even if the command given is an INSERT, UPDATE or DELETE. And they have different semantics from rules on the other command types in that they modify the query tree in place instead of creating a new one. So SELECT rules are described first.

Currently, there can be only one action in an ON SELECT rule, and it must be an unconditional SELECT action that is INSTEAD. This restriction was required to make rules safe enough to open them for ordinary users, and it restricts ON SELECT rules to act like views.

The examples for this chapter are two join views that do some calculations and some more views using them in turn. One of the two first views is customized later by adding rules for INSERT, UPDATE, and DELETE operations so that the final result will be a view that behaves like a real table with some magic functionality. This is not such a simple example to start from and this makes things harder to get into. But it’s better to have one example that covers all the points discussed step by step rather than having many different ones that might mix up in mind.

For the example, we need a little min function that returns the lower of 2 integer values. We create that as:

```sql
CREATE FUNCTION min(integer, integer) RETURNS integer AS $$
   SELECT CASE WHEN $1 < $2 THEN $1 ELSE $2 END
$$ LANGUAGE SQL STRICT;
```

The real tables we need in the first two rule system descriptions are these:

```sql
CREATE TABLE shoe_data (shoename text, -- primary key
```
Chapter 36. The Rule System

CREATE TABLE shoelace_data {
    sl_name text, -- primary key
    sl_avail integer, -- available number of pairs
    sl_color text, -- shoelace color
    sl_len real, -- shoelace length
    sl_unit text -- length unit
};

CREATE TABLE unit {
    un_name text, -- primary key
    un_fact real -- factor to transform to cm
};

As you can see, they represent shoe-store data.

The views are created as:

CREATE VIEW shoe AS
SELECT sh.shoename,
    sh.sh_avail,
    sh.slcolor,
    sh.slminlen,
    sh.slminlen * un.un_fact AS slminlen_cm,
    sh.slmaxlen,
    sh.slmaxlen * un.un_fact AS slmaxlen_cm,
    sh.slunit
FROM shoe_data sh, unit un
WHERE sh.slunit = un.un_name;

CREATE VIEW shoelace AS
SELECT s.sl_name,
    s.sl_avail,
    s.sl_color,
    s.sl_len,
    s.sl_unit,
    s.sl_len * u.un_fact AS sl_len_cm
FROM shoelace_data s, unit u
WHERE s.sl_unit = u.un_name;

CREATE VIEW shoe_ready AS
SELECT rsh.shoename,
    rsh.sh_avail,
    rsl.sl_name,
    rsl.sl_avail,
    min(rsh.sh_avail, rsl.sl_avail) AS total_avail
FROM shoe rsh, shoelace rsl
WHERE rsl.sl_color = rsh.slcolor
    AND rsl.sl_len_cm >= rsh.slminlen_cm
    AND rsl.sl_len_cm <= rsh.slmaxlen_cm;
The `CREATE VIEW` command for the `shoelace` view (which is the simplest one we have) will create a relation `shoelace` and an entry in `pg_rewrite` that tells that there is a rewrite rule that must be applied whenever the relation `shoelace` is referenced in a query’s range table. The rule has no rule qualification (discussed later, with the non-`SELECT` rules, since `SELECT` rules currently cannot have them) and it is `INSTEAD`. Note that rule qualifications are not the same as query qualifications. The action of our rule has a query qualification. The action of the rule is one query tree that is a copy of the `SELECT` statement in the view creation command.

Note: The two extra range table entries for `NEW` and `OLD` (named `*NEW*` and `*OLD*` for historical reasons in the printed query tree) you can see in the `pg_rewrite` entry aren’t of interest for `SELECT` rules.

Now we populate `unit`, `shoe_data` and `shoelace_data` and run a simple query on a view:

```sql
INSERT INTO unit VALUES ('cm', 1.0);
INSERT INTO unit VALUES ('m', 100.0);
INSERT INTO unit VALUES ('inch', 2.54);

INSERT INTO shoe_data VALUES ('sh1', 2, 'black', 70.0, 90.0, 'cm');
INSERT INTO shoe_data VALUES ('sh2', 0, 'black', 30.0, 40.0, 'inch');
INSERT INTO shoe_data VALUES ('sh3', 4, 'brown', 50.0, 65.0, 'cm');
INSERT INTO shoe_data VALUES ('sh4', 3, 'brown', 40.0, 50.0, 'inch');

INSERT INTO shoelace_data VALUES ('sl1', 5, 'black', 80.0, 'cm');
INSERT INTO shoelace_data VALUES ('sl2', 6, 'black', 100.0, 'cm');
INSERT INTO shoelace_data VALUES ('sl3', 0, 'black', 35.0, 'inch');
INSERT INTO shoelace_data VALUES ('sl4', 8, 'black', 40.0, 'inch');
INSERT INTO shoelace_data VALUES ('sl5', 4, 'brown', 1.0, 'm');
INSERT INTO shoelace_data VALUES ('sl6', 0, 'brown', 0.9, 'm');
INSERT INTO shoelace_data VALUES ('sl7', 7, 'brown', 60, 'cm');
INSERT INTO shoelace_data VALUES ('sl8', 1, 'brown', 40, 'inch');

SELECT * FROM shoelace;
```

This is the simplest `SELECT` you can do on our views, so we take this opportunity to explain the basics of view rules. The `SELECT * FROM shoelace` was interpreted by the parser and produced the query tree:

```sql
SELECT shoelace.si_name, shoelace.si_avail, shoelace.si_color, shoelace.si_len, shoelace.si_unit, shoelace.si_len_cm
```

(8 rows)
FROM shoelace shoelace;

and this is given to the rule system. The rule system walks through the range table and checks if there
are rules for any relation. When processing the range table entry for shoelace (the only one up to
now) it finds the _RETURN rule with the query tree:

```
SELECT s.sl_name, s.sl_avail, 
   s.sl_color, s.sl_len, s.sl_unit,
   s.sl_len * u.un_fact AS sl_len_cm
FROM shoelace *OLD*, shoelace *NEW*,
   shoelace_data s, unit u
WHERE s.sl_unit = u.un_name;
```

To expand the view, the rewriter simply creates a subquery range-table entry containing the rule’s
action query tree, and substitutes this range table entry for the original one that referenced the view.
The resulting rewritten query tree is almost the same as if you had typed:

```
SELECT shoelace.sl_name, shoelace.sl_avail, 
   shoelace.sl_color, shoelace.sl_len, 
   shoelace.sl_unit, shoelace.sl_len_cm
FROM (SELECT s.sl_name, 
     s.sl_avail, 
     s.sl_color, 
     s.sl_len, 
     s.sl_unit, 
     s.sl_len * u.un_fact AS sl_len_cm
FROM shoelace_data s, unit u
WHERE s.sl_unit = u.un_name) shoelace;
```

There is one difference however: the subquery’s range table has two extra entries `shoelace *OLD*` and `shoelace *NEW*`. These entries don’t participate directly in the query, since they aren’t referenced by the subquery’s join tree or target list. The rewriter uses them to store the access privilege check information that was originally present in the range-table entry that referenced the view. In this way, the executor will still check that the user has proper privileges to access the view, even though there’s no direct use of the view in the rewritten query.

That was the first rule applied. The rule system will continue checking the remaining range-table entries in the top query (in this example there are no more), and it will recursively check the range-table entries in the added subquery to see if any of them reference views. (But it won’t expand `*OLD*` or `*NEW*` — otherwise we’d have infinite recursion!) In this example, there are no rewrite rules for `shoelace_data` or `unit`, so rewriting is complete and the above is the final result given to the planner.

Now we want to write a query that finds out for which shoes currently in the store we have the
matching shoelaces (color and length) and where the total number of exactly matching pairs is greater
or equal to two.

```
SELECT * FROM shoe_ready WHERE total_avail >= 2;
```

<table>
<thead>
<tr>
<th>shoename</th>
<th>sh_avail</th>
<th>sl_name</th>
<th>sl_avail</th>
<th>total_avail</th>
</tr>
</thead>
<tbody>
<tr>
<td>sh1</td>
<td>2</td>
<td>sl1</td>
<td>5</td>
<td>2</td>
</tr>
<tr>
<td>sh3</td>
<td>4</td>
<td>sl7</td>
<td>7</td>
<td>4</td>
</tr>
</tbody>
</table>

(2 rows)
The output of the parser this time is the query tree:

```
SELECT shoe_ready.shoename, shoe_ready.sh_avail,
       shoe_ready.sl_name, shoe_ready.sl_avail,
       shoe_ready.total_avail
FROM shoe_ready shoe_ready
WHERE shoe_ready.total_avail >= 2;
```

The first rule applied will be the one for the `shoe_ready` view and it results in the query tree:

```
SELECT shoe_ready.shoename, shoe_ready.sh_avail,
       shoe_ready.sl_name, shoe_ready.sl_avail,
       shoe_ready.total_avail
FROM (SELECT rsh.shoename,
           rsh.sh_avail,
           rsl.sl_name,
           rsl.sl_avail,
           min(rsh.sh_avail, rsl.sl_avail) AS total_avail
    FROM shoe rsh, shoelace rsl
    WHERE rsl.sl_color = rsh.slcolor
    AND rsl.sl_len_cm >= rsh.slminlen_cm
    AND rsl.sl_len_cm <= rsh.slmaxlen_cm) shoe_ready
WHERE shoe_ready.total_avail >= 2;
```

Similarly, the rules for `shoe` and `shoelace` are substituted into the range table of the subquery, leading to a three-level final query tree:

```
SELECT shoe_ready.shoename, shoe_ready.sh_avail,
       shoe_ready.sl_name, shoe_ready.sl_avail,
       shoe_ready.total_avail
FROM (SELECT rsh.shoename,
           rsh.sh_avail,
           rsl.sl_name,
           rsl.sl_avail,
           min(rsh.sh_avail, rsl.sl_avail) AS total_avail
    FROM (SELECT sh.shoename,
             sh.sh_avail,
             sh.slcolor,
             sh.slminlen,
             sh.slminlen * un.un_fact AS slminlen_cm,
             sh.slmaxlen,
             sh.slmaxlen * un.un_fact AS slmaxlen_cm,
             sh.slunit
         FROM shoe_data sh, unit un
         WHERE sh.slunit = un.un_name) rsh,
             (SELECT s.sl_name,
                  s.sl_avail,
                  s.sl_color,
                  s.sl_len,
                  s.sl_unit,
                  s.sl_len * u.un_fact AS sl_len_cm
         FROM shoelace_data s, unit u
         WHERE s.sl_unit = u.un_name) rsl
    WHERE rsl.sl_color = rsh.slcolor
    AND rsl.sl_len_cm >= rsh.slminlen_cm
    AND rsl.sl_len_cm <= rsh.slmaxlen_cm) shoe_ready
```

772
WHERE shoe_ready.total_avail > 2;

It turns out that the planner will collapse this tree into a two-level query tree: the bottommost SELECT commands will be “pulled up” into the middle SELECT since there’s no need to process them separately. But the middle SELECT will remain separate from the top, because it contains aggregate functions. If we pulled those up it would change the behavior of the topmost SELECT, which we don’t want. However, collapsing the query tree is an optimization that the rewrite system doesn’t have to concern itself with.

36.2.2. View Rules in Non-SELECT Statements

Two details of the query tree aren’t touched in the description of view rules above. These are the command type and the result relation. In fact, view rules don’t need this information.

There are only a few differences between a query tree for a SELECT and one for any other command. Obviously, they have a different command type and for a command other than a SELECT, the result relation points to the range-table entry where the result should go. Everything else is absolutely the same. So having two tables t1 and t2 with columns a and b, the query trees for the two statements:

SELECT t2.b FROM t1, t2 WHERE t1.a = t2.a;

UPDATE t1 SET b = t2.b FROM t2 WHERE t1.a = t2.a;

are nearly identical. In particular:

- The range tables contain entries for the tables t1 and t2.
- The target lists contain one variable that points to column b of the range table entry for table t2.
- The qualification expressions compare the columns a of both range-table entries for equality.
- The join trees show a simple join between t1 and t2.

The consequence is, that both query trees result in similar execution plans: They are both joins over the two tables. For the UPDATE the missing columns from t1 are added to the target list by the planner and the final query tree will read as:

UPDATE t1 SET a = t1.a, b = t2.b FROM t2 WHERE t1.a = t2.a;

and thus the executor run over the join will produce exactly the same result set as a:

SELECT t1.a, t2.b FROM t1, t2 WHERE t1.a = t2.a;

will do. But there is a little problem in UPDATE: The executor does not care what the results from the join it is doing are meant for. It just produces a result set of rows. The difference that one is a SELECT command and the other is an UPDATE is handled in the caller of the executor. The caller still knows (looking at the query tree) that this is an UPDATE, and it knows that this result should go into table t1. But which of the rows that are there has to be replaced by the new row?

To resolve this problem, another entry is added to the target list in UPDATE (and also in DELETE) statements: the current tuple ID (CTID). This is a system column containing the file block number.
and position in the block for the row. Knowing the table, the CTID can be used to retrieve the original row of `t1` to be updated. After adding the CTID to the target list, the query actually looks like:

```
SELECT t1.a, t2.b, t1.ctid FROM t1, t2 WHERE t1.a = t2.a;
```

Now another detail of PostgreSQL enters the stage. Old table rows aren’t overwritten, and this is why `ROLLBACK` is fast. In an `UPDATE`, the new result row is inserted into the table (after stripping the CTID) and in the row header of the old row, which the CTID pointed to, the `cmax` and `xmax` entries are set to the current command counter and current transaction ID. Thus the old row is hidden, and after the transaction commits the vacuum cleaner can really remove it.

Knowing all that, we can simply apply view rules in absolutely the same way to any command. There is no difference.

### 36.2.3. The Power of Views in PostgreSQL

The above demonstrates how the rule system incorporates view definitions into the original query tree. In the second example, a simple `SELECT` from one view created a final query tree that is a join of 4 tables (`unit` was used twice with different names).

The benefit of implementing views with the rule system is, that the planner has all the information about which tables have to be scanned plus the relationships between these tables plus the restrictive qualifications from the views plus the qualifications from the original query in one single query tree. And this is still the situation when the original query is already a join over views. The planner has to decide which is the best path to execute the query, and the more information the planner has, the better this decision can be. And the rule system as implemented in PostgreSQL ensures, that this is all information available about the query up to that point.

### 36.2.4. Updating a View

What happens if a view is named as the target relation for an `INSERT`, `UPDATE`, or `DELETE`? After doing the substitutions described above, we will have a query tree in which the result relation points at a subquery range-table entry. This will not work, so the rewriter throws an error if it sees it has produced such a thing.

To change this, we can define rules that modify the behavior of these kinds of commands. This is the topic of the next section.

### 36.3. Rules on `INSERT`, `UPDATE`, and `DELETE`

Rules that are defined on `INSERT`, `UPDATE`, and `DELETE` are significantly different from the view rules described in the previous section. First, their `CREATE RULE` command allows more:

- They are allowed to have no action.
- They can have multiple actions.
- They can be `INSTEAD` or `ALSO` (the default).
- The pseudorelations `NEW` and `OLD` become useful.
They can have rule qualifications.

Second, they don’t modify the query tree in place. Instead they create zero or more new query trees and can throw away the original one.

### 36.3.1. How Update Rules Work

Keep the syntax:

```sql
CREATE [ OR REPLACE ] RULE name AS ON event
to table [ WHERE condition ]
DO [ ALSO | INSTEAD ] { NOTHING | command | { command ; command ... } }
```

in mind. In the following, update rules means rules that are defined on INSERT, UPDATE, or DELETE.

Update rules get applied by the rule system when the result relation and the command type of a query tree are equal to the object and event given in the CREATE RULE command. For update rules, the rule system creates a list of query trees. Initially the query-tree list is empty. There can be zero (NOTHING key word), one, or multiple actions. To simplify, we will look at a rule with one action. This rule can have a qualification or not and it can be INSTEAD or ALSO (the default).

What is a rule qualification? It is a restriction that tells when the actions of the rule should be done and when not. This qualification can only reference the pseudorelations NEW and/or OLD, which basically represent the relation that was given as object (but with a special meaning).

So we have three cases that produce the following query trees for a one-action rule.

No qualification, with either ALSO or INSTEAD

- the query tree from the rule action with the original query tree’s qualification added

Qualification given and ALSO

- the query tree from the rule action with the rule qualification and the original query tree’s qualification added

Qualification given and INSTEAD

- the query tree from the rule action with the rule qualification and the original query tree’s qualification; and the original query tree with the negated rule qualification added

Finally, if the rule is ALSO, the unchanged original query tree is added to the list. Since only qualified INSTEAD rules already add the original query tree, we end up with either one or two output query trees for a rule with one action.

For ON INSERT rules, the original query (if not suppressed by INSTEAD) is done before any actions added by rules. This allows the actions to see the inserted row(s). But for ON UPDATE and ON DELETE rules, the original query is done after the actions added by rules. This ensures that the actions can see the to-be-updated or to-be-deleted rows; otherwise, the actions might do nothing because they find no rows matching their qualifications.

The query trees generated from rule actions are thrown into the rewrite system again, and maybe more rules get applied resulting in more or less query trees. So a rule’s actions must have either a different command type or a different result relation than the rule itself is on, otherwise this recursive process will end up in an infinite loop. (Recursive expansion of a rule will be detected and reported as an error.)

The query trees found in the actions of the pg_rewrite system catalog are only templates. Since they can reference the range-table entries for NEW and OLD, some substitutions have to be made before they can be used. For any reference to NEW, the target list of the original query is searched for a
corresponding entry. If found, that entry’s expression replaces the reference. Otherwise, NEW means the same as OLD (for an UPDATE) or is replaced by a null value (for an INSERT). Any reference to OLD is replaced by a reference to the range-table entry that is the result relation.

After the system is done applying update rules, it applies view rules to the produced query tree(s). Views cannot insert new update actions so there is no need to apply update rules to the output of view rewriting.

### 36.3.1.1. A First Rule Step by Step

Say we want to trace changes to the sl_avail column in the shoelace_data relation. So we set up a log table and a rule that conditionally writes a log entry when an UPDATE is performed on shoelace_data.

```sql
CREATE TABLE shoelace_log (  
    sl_name text, -- shoelace changed  
    sl_avail integer, -- new available value  
    log_who text, -- who did it  
    log_when timestamp -- when
);

CREATE RULE log_shoelace AS ON UPDATE TO shoelace_data  
    WHERE NEW.sl_avail <> OLD.sl_avail  
    DO INSERT INTO shoelace_log VALUES (  
        NEW.sl_name,  
        NEW.sl_avail,  
        current_user,  
        current_timestamp
    );
```

Now someone does:

```sql
UPDATE shoelace_data SET sl_avail = 6 WHERE sl_name = ‘sl7’;
```

and we look at the log table:

```sql
SELECT * FROM shoelace_log;
```

```
sl_name | sl_avail | log_who | log_when
---------+----------+---------+----------------------------------
   sl7 |     6 |   Al | Tue Oct 20 16:14:45 1998 MET DST
(1 row)
```

That’s what we expected. What happened in the background is the following. The parser created the query tree:

```sql
UPDATE shoelace_data SET sl_avail = 6  
FROM shoelace_data shoelace_data  
WHERE shoelace_data.sl_name = ‘sl7’;
```

There is a rule log_shoelace that is ON UPDATE with the rule qualification expression:

```sql
NEW.sl_avail <> OLD.sl_avail
```
and the action:

```sql
INSERT INTO shoelace_log VALUES (
    *NEW*.sl_name, *NEW*.sl_avail,
    current_user, current_timestamp )
FROM shoelace_data *NEW*, shoelace_data *OLD*;
```

(This looks a little strange since you cannot normally write `INSERT ... VALUES ... FROM`. The `FROM` clause here is just to indicate that there are range-table entries in the query tree for `*NEW*` and `*OLD*`. These are needed so that they can be referenced by variables in the `INSERT` command’s query tree.)

The rule is a qualified `ALSO` rule, so the rule system has to return two query trees: the modified rule action and the original query tree. In step 1, the range table of the original query is incorporated into the rule’s action query tree. This results in:

```sql
INSERT INTO shoelace_log VALUES (
    *NEW*.sl_name, *NEW*.sl_avail,
    current_user, current_timestamp )
FROM shoelace_data *NEW*, shoelace_data *OLD*,
    shoelace_data shoelace_data
```

In step 2, the rule qualification is added to it, so the result set is restricted to rows where `sl_avail` changes:

```sql
INSERT INTO shoelace_log VALUES (
    *NEW*.sl_name, *NEW*.sl_avail,
    current_user, current_timestamp )
FROM shoelace_data *NEW*, shoelace_data *OLD*,
    shoelace_data shoelace_data
WHERE *NEW*.sl_avail <> *OLD*.sl_avail;
```

(This looks even stranger, since `INSERT ... VALUES` doesn’t have a `WHERE` clause either, but the planner and executor will have no difficulty with it. They need to support this same functionality anyway for `INSERT ... SELECT`.)

In step 3, the original query tree’s qualification is added, restricting the result set further to only the rows that would have been touched by the original query:

```sql
INSERT INTO shoelace_log VALUES (
    *NEW*.sl_name, *NEW*.sl_avail,
    current_user, current_timestamp )
FROM shoelace_data *NEW*, shoelace_data *OLD*,
    shoelace_data shoelace_data
WHERE *NEW*.sl_avail <> *OLD*.sl_avail
    AND shoelace_data.sl_name = 'sl7';
```

Step 4 replaces references to `NEW` by the target list entries from the original query tree or by the matching variable references from the result relation:

```sql
INSERT INTO shoelace_log VALUES ( 
    shoelace_data.sl_name, 6,
    current_user, current_timestamp )
FROM shoelace_data *NEW*, shoelace_data *OLD*,
    shoelace_data shoelace_data
WHERE 6 <> *OLD*.sl_avail
```
Step 5 changes OLD references into result relation references:

```
INSERT INTO shoelace_log VALUES ( 
    shoelace_data.sl_name, 6, 
    current_user, current_timestamp ) 
FROM shoelace_data *NEW*, shoelace_data *OLD*, 
shoelace_data shoelace_data 
WHERE 6 != shoelace_data.sl_avail 
AND shoelace_data.sl_name = 'sl7';
```

That’s it. Since the rule is ALSO, we also output the original query tree. In short, the output from the rule system is a list of two query trees that correspond to these statements:

```
INSERT INTO shoelace_log VALUES ( 
    shoelace_data.sl_name, 6, 
    current_user, current_timestamp ) 
FROM shoelace_data 
WHERE 6 != shoelace_data.sl_avail 
AND shoelace_data.sl_name = 'sl7';
```

```
UPDATE shoelace_data SET sl_avail = 6 
WHERE sl_name = 'sl7';
```

These are executed in this order, and that is exactly what the rule was meant to do.

The substitutions and the added qualifications ensure that, if the original query would be, say:

```
UPDATE shoelace_data SET sl_color = 'green' 
WHERE sl_name = 'sl7';
```

no log entry would get written. In that case, the original query tree does not contain a target list entry for sl_avail, so NEW.sl_avail will get replaced by shoelace_data.sl_avail. Thus, the extra command generated by the rule is:

```
INSERT INTO shoelace_log VALUES ( 
    shoelace_data.sl_name, shoelace_data.sl_avail, 
    current_user, current_timestamp ) 
FROM shoelace_data 
WHERE shoelace_data.sl_avail != shoelace_data.sl_avail 
AND shoelace_data.sl_name = 'sl7';
```

and that qualification will never be true.

It will also work if the original query modifies multiple rows. So if someone issued the command:

```
UPDATE shoelace_data SET sl_avail = 0 
WHERE sl_color = 'black';
```

four rows in fact get updated (sl1, sl2, sl3, and sl4). But sl3 already has sl_avail = 0. In this case, the original query trees qualification is different and that results in the extra query tree:

```
INSERT INTO shoelace_log 
SELECT shoelace_data.sl_name, 0, 
    current_user, current_timestamp
```
FROM shoelace_data
WHERE 0 <> shoelace_data.sl_avail
    AND shoelace_data.sl_color = 'black';

being generated by the rule. This query tree will surely insert three new log entries. And that’s abso-
lutely correct.

Here we can see why it is important that the original query tree is executed last. If the UPDATE had
been executed first, all the rows would have already been set to zero, so the logging INSERT would
not find any row where 0 <> shoelace_data.sl_avail.

36.3.2. Cooperation with Views

A simple way to protect view relations from the mentioned possibility that someone can try to run
INSERT, UPDATE, or DELETE on them is to let those query trees get thrown away. So we could create
the rules:

CREATE RULE shoe_ins_protect AS ON INSERT TO shoe
    DO INSTEAD NOTHING;
CREATE RULE shoe_upd_protect AS ON UPDATE TO shoe
    DO INSTEAD NOTHING;
CREATE RULE shoe_del_protect AS ON DELETE TO shoe
    DO INSTEAD NOTHING;

If someone now tries to do any of these operations on the view relation shoe, the rule system will
apply these rules. Since the rules have no actions and are INSTEAD, the resulting list of query trees
will be empty and the whole query will become nothing because there is nothing left to be optimized
or executed after the rule system is done with it.

A more sophisticated way to use the rule system is to create rules that rewrite the query tree into
one that does the right operation on the real tables. To do that on the shoeace view, we create the
following rules:

CREATE RULE shoelace_ins AS ON INSERT TO shoelace
    DO INSTEAD
    INSERT INTO shoelace_data VALUES ( NEW.sl_name,
        NEW.sl_avail,
        NEW.sl_color,
        NEW.sl_len,
        NEW.sl_unit
    )
;
CREATE RULE shoelace_upd AS ON UPDATE TO shoelace
    DO INSTEAD
    UPDATE shoelace_data
        SET sl_name = NEW.sl_name,
            sl_avail = NEW.sl_avail,
            sl_color = NEW.sl_color,
            sl_len = NEW.sl_len,
            sl_unit = NEW.sl_unit
        WHERE sl_name = OLD.sl_name;
CREATE RULE shoelace_del AS ON DELETE TO shoelace
    DO INSTEAD
If you want to support RETURNING queries on the view, you need to make the rules include RETURNING clauses that compute the view rows. This is usually pretty trivial for views on a single table, but it’s a bit tedious for join views such as shoelace. An example for the insert case is:

```sql
CREATE RULE shoelace_ins AS ON INSERT TO shoelace
DO INSTEAD
    INSERT INTO shoelace_data VALUES (
        NEW.sl_name,
        NEW.sl_avail,
        NEW.sl_color,
        NEW.sl_len,
        NEW.sl_unit
    )
RETURNING
    shoelace_data.*,
    (SELECT shoelace_data.sl_len * u.un_fact
    FROM unit u WHERE shoelace_data.sl_unit = u.un_name);
```

Note that this one rule supports both INSERT and INSERT RETURNING queries on the view — the RETURNING clause is simply ignored for INSERT.

Now assume that once in a while, a pack of shoelaces arrives at the shop and a big parts list along with it. But you don’t want to manually update the shoelace view every time. Instead we setup two little tables: one where you can insert the items from the part list, and one with a special trick. The creation commands for these are:

```sql
CREATE TABLE shoelace_arrive {
    arr_name    text,
    arr_quant   integer
};

CREATE TABLE shoelace_ok {
    ok_name    text,
    ok_quant   integer
};

CREATE RULE shoelace_ok_ins AS ON INSERT TO shoelace_ok
DO INSTEAD
    UPDATE shoelace
    SET sl_avail = sl_avail + NEW.ok_quant
    WHERE sl_name = NEW.ok_name;
```

Now you can fill the table shoelace_arrive with the data from the parts list:

```sql
SELECT * FROM shoelace_arrive;
```

```
<table>
<thead>
<tr>
<th>arr_name</th>
<th>arr_quant</th>
</tr>
</thead>
<tbody>
<tr>
<td>sl3</td>
<td>10</td>
</tr>
<tr>
<td>sl6</td>
<td>20</td>
</tr>
<tr>
<td>sl8</td>
<td>20</td>
</tr>
</tbody>
</table>
```

(3 rows)
Take a quick look at the current data:

```
SELECT * FROM shoelace;
```

<table>
<thead>
<tr>
<th>sl_name</th>
<th>sl_avail</th>
<th>sl_color</th>
<th>sl_len</th>
<th>sl_unit</th>
<th>sl_len_cm</th>
</tr>
</thead>
<tbody>
<tr>
<td>sl1</td>
<td>5</td>
<td>black</td>
<td>80</td>
<td>cm</td>
<td>80</td>
</tr>
<tr>
<td>sl2</td>
<td>6</td>
<td>black</td>
<td>100</td>
<td>cm</td>
<td>100</td>
</tr>
<tr>
<td>sl7</td>
<td>6</td>
<td>brown</td>
<td>60</td>
<td>cm</td>
<td>60</td>
</tr>
<tr>
<td>sl3</td>
<td>0</td>
<td>black</td>
<td>35</td>
<td>inch</td>
<td>88.9</td>
</tr>
<tr>
<td>sl4</td>
<td>8</td>
<td>black</td>
<td>40</td>
<td>inch</td>
<td>101.6</td>
</tr>
<tr>
<td>sl8</td>
<td>1</td>
<td>brown</td>
<td>40</td>
<td>inch</td>
<td>101.6</td>
</tr>
<tr>
<td>sl5</td>
<td>4</td>
<td>brown</td>
<td>1</td>
<td>m</td>
<td>100</td>
</tr>
<tr>
<td>sl6</td>
<td>0</td>
<td>brown</td>
<td>0.9</td>
<td>m</td>
<td>90</td>
</tr>
</tbody>
</table>

(8 rows)

Now move the arrived shoelaces in:

```
INSERT INTO shoelace_ok SELECT * FROM shoelace_arrive;
```

and check the results:

```
SELECT * FROM shoelace ORDER BY sl_name;
```

<table>
<thead>
<tr>
<th>sl_name</th>
<th>sl_avail</th>
<th>sl_color</th>
<th>sl_len</th>
<th>sl_unit</th>
<th>sl_len_cm</th>
</tr>
</thead>
<tbody>
<tr>
<td>sl1</td>
<td>5</td>
<td>black</td>
<td>80</td>
<td>cm</td>
<td>80</td>
</tr>
<tr>
<td>sl2</td>
<td>6</td>
<td>black</td>
<td>100</td>
<td>cm</td>
<td>100</td>
</tr>
<tr>
<td>sl7</td>
<td>6</td>
<td>brown</td>
<td>60</td>
<td>cm</td>
<td>60</td>
</tr>
<tr>
<td>sl4</td>
<td>8</td>
<td>black</td>
<td>40</td>
<td>inch</td>
<td>101.6</td>
</tr>
<tr>
<td>sl3</td>
<td>10</td>
<td>black</td>
<td>35</td>
<td>inch</td>
<td>88.9</td>
</tr>
<tr>
<td>sl8</td>
<td>21</td>
<td>brown</td>
<td>40</td>
<td>inch</td>
<td>101.6</td>
</tr>
<tr>
<td>sl5</td>
<td>4</td>
<td>brown</td>
<td>1</td>
<td>m</td>
<td>100</td>
</tr>
<tr>
<td>sl6</td>
<td>20</td>
<td>brown</td>
<td>0.9</td>
<td>m</td>
<td>90</td>
</tr>
</tbody>
</table>

(8 rows)

```
SELECT * FROM shoelace_log;
```

<table>
<thead>
<tr>
<th>sl_name</th>
<th>sl_avail</th>
<th>log_who</th>
<th>log_when</th>
</tr>
</thead>
<tbody>
<tr>
<td>sl7</td>
<td>6</td>
<td>Al</td>
<td>Tue Oct 20 19:14:45 1998 MET DST</td>
</tr>
<tr>
<td>sl3</td>
<td>10</td>
<td>Al</td>
<td>Tue Oct 20 19:25:16 1998 MET DST</td>
</tr>
<tr>
<td>sl6</td>
<td>20</td>
<td>Al</td>
<td>Tue Oct 20 19:25:16 1998 MET DST</td>
</tr>
<tr>
