</tr>
<tr>
<td>probin</td>
<td>text</td>
<td></td>
<td>Additional information about how to invoke the function. Again, the interpretation is language-specific.</td>
</tr>
<tr>
<td>proconfig</td>
<td>text[]</td>
<td></td>
<td>Function’s local settings for run-time configuration variables.</td>
</tr>
</tbody>
</table>
Chapter 48. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
</tbody>
</table>

For compiled functions, both built-in and dynamically loaded, prosrc contains the function’s C-language name (link symbol). For all other currently-known language types, prosrc contains the function’s source text. probin is unused except for dynamically-loaded C functions, for which it gives the name of the shared library file containing the function.

48.37. pg_range

The catalog pg_range stores information about range types. This is in addition to the types’ entries in pg_type.

Table 48-37. pg_range Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rngtypid</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>OID of the range type</td>
</tr>
<tr>
<td>rngsubtype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>OID of the element type (subtype) of this range type</td>
</tr>
<tr>
<td>rngcollation</td>
<td>oid</td>
<td>pg_collation.oid</td>
<td>OID of the collation used for range comparisons, or 0 if none</td>
</tr>
<tr>
<td>rngsubopc</td>
<td>oid</td>
<td>pg_opclass.oid</td>
<td>OID of the subtype’s operator class used for range comparisons</td>
</tr>
<tr>
<td>rngcanonical</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the function to convert a range value into canonical form, or 0 if none</td>
</tr>
<tr>
<td>rngsubdiff</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the function to return the difference between two element values as double precision, or 0 if none</td>
</tr>
</tbody>
</table>

rngsubopc (plus rngcollation, if the element type is collatable) determines the sort ordering used by the range type. rngcanonical is used when the element type is discrete. rngsubdiff is optional but should be supplied to improve performance of GiST indexes on the range type.

48.38. pg_rewrite

The catalog pg_rewrite stores rewrite rules for tables and views.
Table 48-38. pg_rewrite Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>

</tr>
<tr>
<td>ev_action</td>
<td>pg_node_tree</td>
<td></td>
<td>Query tree (in the form of a nodeToString() representation) for the rule’s action</td>
</tr>
</tbody>
</table>

**Note:** pg_class.relhasrules must be true if a table has any rules in this catalog.

48.39. pg_replication_slots

The pg_replication_slots view provides a listing of all replication slots that currently exist on the database cluster, along with their current state.

For more on replication slots, see Section 25.2.6 and Chapter 46.

Table 48-39. pg_replication_slots Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
</table>

1834

<td></td>
<td>The address (LSN) of oldest WAL which still might be required by the consumer of this slot and thus won’t be automatically removed during checkpoints.</td>
</tr>
</tbody>
</table>
48.40. pg_seclabel

The catalog pg_seclabel stores security labels on database objects. Security labels can be manipulated with the SECURITY LABEL command. For an easier way to view security labels, see Section 48.66.

See also pg_shseclabel, which performs a similar function for security labels of database objects that are shared across a database cluster.

Table 48-40. pg_seclabel Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>

<td>text</td>
<td></td>
<td>The label provider associated with this label.</td>
</tr>
<tr>
<td>label</td>
<td>text</td>
<td></td>
<td>The security label applied to this object.</td>
</tr>
</tbody>
</table>

48.41. pg_shdepend

The catalog pg_shdepend records the dependency relationships between database objects and shared objects, such as roles. This information allows PostgreSQL to ensure that those objects are unreferenced before attempting to delete them.

See also pg_depend, which performs a similar function for dependencies involving objects within a single database.

Unlike most system catalogs, pg_shdepend is shared across all databases of a cluster: there is only one copy of pg_shdepend per cluster, not one per database.

Table 48-41. pg_shdepend Columns

| Name    | Type | References | Description |
|---------|------|------------|-------------|-------------|
In all cases, a `pg_shdepend` entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

**SHARED_DEPENDENCY_OWNER (o)**

The referenced object (which must be a role) is the owner of the dependent object.

**SHARED_DEPENDENCY_ACL (a)**

The referenced object (which must be a role) is mentioned in the ACL (access control list, i.e., privileges list) of the dependent object. (A `SHARED_DEPENDENCY_ACL` entry is not made for the owner of the object, since the owner will have a `SHARED_DEPENDENCY_OWNER` entry anyway.)

**SHARED_DEPENDENCY_PIN (p)**

There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by `initdb`. The columns for the dependent object contain zeroes.

Other dependency flavors might be needed in future. Note in particular that the current definition only supports roles as referenced objects.
48.42. pg_shdescription

The catalog `pg_shdescription` stores optional descriptions (comments) for shared database objects. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`’s `	d` commands.

See also `pg_description`, which performs a similar function for descriptions involving objects within a single database.

Unlike most system catalogs, `pg_shdescription` is shared across all databases of a cluster: there is only one copy of `pg_shdescription` per cluster, not one per database.

**Table 48-42. pg_shdescription Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>description</td>
<td>text</td>
<td></td>
<td>Arbitrary text that serves as the description of this object</td>
</tr>
</tbody>
</table>

48.43. pg_shseclabel

The catalog `pg_shseclabel` stores security labels on shared database objects. Security labels can be manipulated with the `SECURITY LABEL` command. For an easier way to view security labels, see Section 48.66.

See also `pg_seclabel`, which performs a similar function for security labels involving objects within a single database.

Unlike most system catalogs, `pg_shseclabel` is shared across all databases of a cluster: there is only one copy of `pg_shseclabel` per cluster, not one per database.

**Table 48-43. pg_shseclabel Columns**

<table>
<thead>
<tr>

<td></td>
<td>The label provider associated with this label.</td>
</tr>
</tbody>
</table>
Chapter 48. System Catalogs

### Name | Type | References | Description
---|---|---|---
label | text | | The security label applied to this object.

#### 48.44. pg_statistic

The catalog `pg_statistic` stores statistical data about the contents of the database. Entries are created by `ANALYZE` and subsequently used by the query planner. Note that all the statistical data is inherently approximate, even assuming that it is up-to-date.

Normally there is one entry, with `stainherit = false`, for each table column that has been analyzed. If the table has inheritance children, a second entry with `stainherit = true` is also created. This row represents the column’s statistics over the inheritance tree, i.e., statistics for the data you’d see with `SELECT column FROM table*`, whereas the `stainherit = false` row represents the results of `SELECT column FROM ONLY table`.

`pg_statistic` also stores statistical data about the values of index expressions. These are described as if they were actual data columns; in particular, `starelid` references the index. No entry is made for an ordinary non-expression index column, however, since it would be redundant with the entry for the underlying table column. Currently, entries for index expressions always have `stainherit = false`.

Since different kinds of statistics might be appropriate for different kinds of data, `pg_statistic` is designed not to assume very much about what sort of statistics it stores. Only extremely general statistics (such as nullness) are given dedicated columns in `pg_statistic`. Everything else is stored in “slots”, which are groups of associated columns whose content is identified by a code number in one of the slot’s columns. For more information see `src/include/catalog/pg_statistic.h`.

`pg_statistic` should not be readable by the public, since even statistical information about a table’s contents might be considered sensitive. (Example: minimum and maximum values of a salary column might be quite interesting.) `pg_stats` is a publicly readable view on `pg_statistic` that only exposes information about those tables that are readable by the current user.

#### Table 48-44. pg_statistic Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>starelid</td>
<td>oid</td>
<td><code>pg_class.oid</code></td>
<td>The table or index that the described column belongs to</td>
</tr>
<tr>
<td>staattnum</td>
<td>int2</td>
<td><code>pg_attribute.attnum</code></td>
<td>The number of the described column</td>
</tr>
<tr>
<td>stainherit</td>
<td>bool</td>
<td></td>
<td>If true, the stats include inheritance child columns, not just the values in the specified relation</td>
</tr>
<tr>
<td>stanullfrac</td>
<td>float4</td>
<td></td>
<td>The fraction of the column’s entries that are null</td>
</tr>
</tbody>
</table>
### Name
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stawidth</td>
<td>int4</td>
<td>The average stored width, in bytes, of nonnull entries</td>
</tr>
<tr>
<td>stadistinct</td>
<td>float4</td>
<td>The number of distinct nonnull data values in the column. A value greater than zero is the actual number of distinct values. A value less than zero is the negative of a multiplier for the number of rows in the table; for example, a column in which about 80% of the values are nonnull and each nonnull value appears about twice on average could be represented by ( \text{stadistinct} = -0.4 ). A zero value means the number of distinct values is unknown.</td>
</tr>
<tr>
<td>stakindN</td>
<td>int2</td>
<td>A code number indicating the kind of statistics stored in the ( N )th “slot” of the ( pg\text{-}\text{statistic} ) row.</td>
</tr>
<tr>
<td>staopN</td>
<td>oid</td>
<td>An operator used to derive the statistics stored in the ( N )th “slot”. For example, a histogram slot would show the (&lt;) operator that defines the sort order of the data.</td>
</tr>
<tr>
<td>stanumbersN</td>
<td>float4[]</td>
<td>Numerical statistics of the appropriate kind for the ( N )th “slot”, or null if the slot kind does not involve numerical values</td>
</tr>
</tbody>
</table>
Chapter 48. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stavaluesN</td>
<td>anyarray</td>
<td></td>
<td>Column data values of the appropriate kind for the Nth “slot”, or null if the slot kind does not store any data values. Each array’s element values are actually of the specific column’s data type, or a related type such as an array’s element type, so there is no way to define these columns’ type more specifically than anyarray.</td>
</tr>
</tbody>
</table>

48.45. pg_tablespace

The catalog pg_tablespace stores information about the available tablespaces. Tables can be placed in particular tablespaces to aid administration of disk layout.

Unlike most system catalogs, pg_tablespace is shared across all databases of a cluster: there is only one copy of pg_tablespace per cluster, not one per database.

Table 48-45. pg_tablespace Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>spcname</td>
<td>name</td>
<td></td>
<td>Tablespace name</td>
</tr>
<tr>
<td>spcowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the tablespace, usually the user who created it</td>
</tr>
<tr>
<td>spc acl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
<tr>
<td>spc options</td>
<td>text[]</td>
<td></td>
<td>Tablespace-level options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

48.46. pg_trigger

The catalog pg_trigger stores triggers on tables and views. See CREATE TRIGGER for more information.
### Table 48-46. pg_trigger Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>tgrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table this trigger is on</td>
</tr>
<tr>
<td>tilename</td>
<td>name</td>
<td></td>
<td>Trigger name (must be unique among triggers of same table)</td>
</tr>
<tr>
<td>tgfoid</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>The function to be called</td>
</tr>
<tr>
<td>tgtype</td>
<td>int2</td>
<td></td>
<td>Bit mask identifying trigger firing conditions</td>
</tr>
<tr>
<td>tgenabled</td>
<td>char</td>
<td></td>
<td>Controls in which session_replication_role modes the trigger fires.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>$O = \text{trigger fires in &quot;origin&quot; and &quot;local&quot; modes}, \ D = \text{trigger is disabled}, \ R = \text{trigger fires in &quot;replica&quot; mode}, \ A = \text{trigger fires always.}$</td>
</tr>
<tr>
<td>tgisinternal</td>
<td>bool</td>
<td></td>
<td>True if trigger is internally generated (usually, to enforce the constraint identified by tgconstraint)</td>
</tr>
<tr>
<td>tgconstrrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table referenced by a referential integrity constraint</td>
</tr>
<tr>
<td>tgconstrindid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The index supporting a unique, primary key, referential integrity, or exclusion constraint</td>
</tr>
<tr>
<td>tgconstraint</td>
<td>oid</td>
<td>pg_constraint.oid</td>
<td>The pg_constraint entry associated with the trigger, if any</td>
</tr>
<tr>
<td>tgdeferrable</td>
<td>bool</td>
<td></td>
<td>True if constraint trigger is deferrable</td>
</tr>
<tr>
<td>tginitdeferred</td>
<td>bool</td>
<td></td>
<td>True if constraint trigger is initially deferred</td>
</tr>
<tr>
<td>tgnargs</td>
<td>int2</td>
<td></td>
<td>Number of argument strings passed to trigger function</td>
</tr>
</tbody>
</table>
Currently, column-specific triggering is supported only for **UPDATE** events, and so `tgattr` is relevant only for that event type. `tgtype` might contain bits for other event types as well, but those are presumed to be table-wide regardless of what is in `tgattr`.

**Note:** When `tgconstraint` is non-zero, `tgconstrrelid`, `tgconstrindid`, `tgdeferrable`, and `tginitdeferred` are largely redundant with the referenced `pg_constraint` entry. However, it is possible for a non-deferrable trigger to be associated with a deferrable constraint: foreign key constraints can have some deferrable and some non-deferrable triggers.

**Note:** `pg_class.relhastriggers` must be true if a relation has any triggers in this catalog.

### 48.47. `pg_ts_config`

The `pg_ts_config` catalog contains entries representing text search configurations. A configuration specifies a particular text search parser and a list of dictionaries to use for each of the parser’s output token types. The parser is shown in the `pg_ts_config` entry, but the token-to-dictionary mapping is defined by subsidiary entries in `pg_ts_config_map`.

PostgreSQL’s text search features are described at length in Chapter 12.

#### Table 48-47. `pg_ts_config` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>cfgname</td>
<td>name</td>
<td></td>
<td>Text search configuration name</td>
</tr>
</tbody>
</table>
Chapter 48. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cfgnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this configuration</td>
</tr>
<tr>
<td>cfgowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the configuration</td>
</tr>
<tr>
<td>cfgparser</td>
<td>oid</td>
<td>pg_ts_parser.oid</td>
<td>The OID of the text search parser for this configuration</td>
</tr>
</tbody>
</table>

### 48.48. pg_ts_config_map

The `pg_ts_config_map` catalog contains entries showing which text search dictionaries should be consulted, and in what order, for each output token type of each text search configuration’s parser.

PostgreSQL’s text search features are described at length in Chapter 12.

#### Table 48-48. pg_ts_config_map Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mapcfg</td>
<td>oid</td>
<td>pg_ts_config.oid</td>

<td>Order in which to consult this entry (lower mapseqnos first)</td>
</tr>
<tr>
<td>mapdict</td>
<td>oid</td>
<td>pg_ts_dict.oid</td>
<td>The OID of the text search dictionary to consult</td>
</tr>
</tbody>
</table>

### 48.49. pg_ts_dict

The `pg_ts_dict` catalog contains entries defining text search dictionaries. A dictionary depends on a text search template, which specifies all the implementation functions needed; the dictionary itself provides values for the user-settable parameters supported by the template. This division of labor allows dictionaries to be created by unprivileged users. The parameters are specified by a text string `d dictinitoption`, whose format and meaning vary depending on the template.

PostgreSQL’s text search features are described at length in Chapter 12.

#### Table 48-49. pg_ts_dict Columns
48.50. **pg_ts_parser**

The `pg_ts_parser` catalog contains entries defining text search parsers. A parser is responsible for splitting input text into lexemes and assigning a token type to each lexeme. Since a parser must be implemented by C-language-level functions, creation of new parsers is restricted to database superusers.

PostgreSQL’s text search features are described at length in Chapter 12.

</tr>
</tbody>
</table>
48.51. *pg_ts_template*

The *pg_ts_template* catalog contains entries defining text search templates. A template is the implementation skeleton for a class of text search dictionaries. Since a template must be implemented by C-language-level functions, creation of new templates is restricted to database superusers.

PostgreSQL’s text search features are described at length in Chapter 12.

Table 48-51. *pg_ts_template* Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>

<td>OID of the template’s initialization function</td>
</tr>
<tr>
<td>tmpllexize</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the template’s lexize function</td>
</tr>
</tbody>
</table>

48.52. *pg_type*

The catalog *pg_type* stores information about data types. Base types and enum types (scalar types) are created with CREATE TYPE, and domains with CREATE DOMAIN. A composite type is automatically created for each table in the database, to represent the row structure of the table. It is also possible to create composite types with CREATE TYPE AS.

Table 48-52. *pg_type* Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>typename</td>
<td>name</td>
<td></td>
<td>Data type name</td>
</tr>
<tr>
<td>typnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this type</td>
</tr>
<tr>

<td>-------------</td>
</tr>
</tbody>
</table>
| typalign | char |            | typalign is the alignment required when storing a value of this type. It applies to storage on disk as well as most representations of the value inside PostgreSQL. When multiple values are stored consecutively, such as in the representation of a complete row on disk, padding is inserted before a datum of this type so that it begins on the specified boundary. The alignment reference is the beginning of the first datum in the sequence. Possible values are:  
  • c = char alignment, i.e., no alignment needed. 
  • s = short alignment (2 bytes on most machines). 
  • i = int alignment (4 bytes on most machines). 
  • d = double alignment (8 bytes on many machines, but by no means all). |

**Note:** For types used in system tables, it is critical that the size and alignment defined in `pg_type` agree with the way that the compiler will lay out the column in a structure representing a table row.
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
</table>
| typstorage  | char      |            | typstorage tells for varlena types (those with \(\text{typlen} = -1\)) if the type is prepared for toasting and what the default strategy for attributes of this type should be. Possible values are: • \(p\): Value must always be stored plain.  
  • \(e\): Value can be stored in a "secondary" relation (if relation has one, see \(\text{pg\_class.reltoastrelid}\)).  
  • \(m\): Value can be stored compressed inline.  
  • \(x\): Value can be stored compressed inline or stored in "secondary" storage.  
  Note that \(m\) columns can also be moved out to secondary storage, but only as a last resort (\(e\) and \(x\) columns are moved first). |
<p>| typnotnull  | bool      |            | typnotnull represents a not-null constraint on a type. Used for domains only.                                                               |
| typbasetype | oid       | pg_type.oid| If this is a domain (see (\text{typtype})), then (\text{typbasetype}) identifies the type that this one is based on. Zero if this type is not a domain. |</p>
<table>
<thead>
<tr>
<th>Name</th>

<td>User mapping specific options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

48.54. **System Views**

In addition to the system catalogs, PostgreSQL provides a number of built-in views. Some system views provide convenient access to some commonly used queries on the system catalogs. Other views provide access to internal server state.

The information schema (Chapter 34) provides an alternative set of views which overlap the functionality of the system views. Since the information schema is SQL-standard whereas the views described here are PostgreSQL-specific, it's usually better to use the information schema if it provides all the information you need.

Table 48-55 lists the system views described here. More detailed documentation of each view follows below. There are some additional views that provide access to the results of the statistics collector; they are described in Table 27-1.

Except where noted, all the views described here are read-only.

**Table 48-55. System Views**

<table>
<thead>
<tr>
<th>View Name</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pg_available_extensions</code></td>
<td>available extensions</td>
</tr>
<tr>
<td><code>pg_available_extension_versions</code></td>
<td>available versions of extensions</td>
</tr>
<tr>
<td><code>pg_cursors</code></td>
<td>open cursors</td>
</tr>
<tr>
<td><code>pg_group</code></td>
<td>groups of database users</td>
</tr>
<tr>
<td><code>pg_indexes</code></td>
<td>indexes</td>
</tr>
<tr>
<td><code>pg_locks</code></td>
<td>currently held locks</td>
</tr>
<tr>
<td><code>pg_matviews</code></td>
<td>materialized views</td>
</tr>
</tbody>
</table>
### 48.55. pg_available_extensions

The `pg_available_extensions` view lists the extensions that are available for installation. See also the `pg_extension` catalog, which shows the extensions currently installed.

**Table 48-56. pg_available_extensions Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
<td>Extension name</td>
</tr>
<tr>
<td>default_version</td>
<td>text</td>
<td>Name of default version, or NULL if none is specified</td>
</tr>
<tr>
<td>installed_version</td>
<td>text</td>
<td>Currently installed version of the extension, or NULL if not installed</td>
</tr>
<tr>
<td>comment</td>
<td>text</td>
<td>Comment string from the extension’s control file</td>
</tr>
</tbody>
</table>

The `pg_available_extensions` view is read only.

### 48.56. pg_available_extension_versions

The `pg_available_extension_versions` view lists the specific extension versions that are available for installation. See also the `pg_extension` catalog, which shows the extensions currently installed.

**Table 48-57. pg_available_extension_versions Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
<td>Extension name</td>
</tr>
<tr>
<td>default_version</td>
<td>text</td>
<td>Name of default version, or NULL if none is specified</td>
</tr>
<tr>
<td>installed_version</td>
<td>text</td>
<td>Currently installed version of the extension, or NULL if not installed</td>
</tr>
<tr>
<td>comment</td>
<td>text</td>
<td>Comment string from the extension’s control file</td>
</tr>
</tbody>
</table>
The `pg_available_extension_versions` view is read only.

### 48.57. `pg_cursors`

The `pg_cursors` view lists the cursors that are currently available. Cursors can be defined in several ways:

- via the DECLARE statement in SQL
- via the Bind message in the frontend/backend protocol, as described in Section 49.2.3
- via the Server Programming Interface (SPI), as described in Section 44.1

The `pg_cursors` view displays cursors created by any of these means. Cursors only exist for the duration of the transaction that defines them, unless they have been declared WITH HOLD. Therefore non-holdable cursors are only present in the view until the end of their creating transaction.

**Note:** Cursors are used internally to implement some of the components of PostgreSQL, such as procedural languages. Therefore, the `pg_cursors` view might include cursors that have not been explicitly created by the user.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
<td>The name of the cursor</td>
</tr>
<tr>
<td>statement</td>
<td>text</td>
<td>The verbatim query string submitted to declare this cursor</td>
</tr>
</tbody>
</table>
### Chapter 48. System Catalogs

#### 48.58. pg_group

The view `pg_group` exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows the names and members of all roles that are marked as not `rolcanlogin`, which is an approximation to the set of roles that are being used as groups.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>groname</td>
<td>name</td>
<td><code>pg_authid.rolname</code></td>
<td>Name of the group</td>
</tr>
<tr>
<td>grosysid</td>
<td>oid</td>
<td><code>pg_authid.oid</code></td>
<td>ID of this group</td>
</tr>
<tr>
<td>grollst</td>
<td>oid[]</td>
<td><code>pg_authid.oid</code></td>
<td>An array containing the IDs of the roles in this group</td>
</tr>
</tbody>
</table>

#### 48.59. pg_indexes

The view `pg_indexes` provides access to useful information about each index in the database.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td><code>pg_namespace.nspname</code></td>
<td>Name of schema containing table and index</td>
</tr>
<tr>
<td>tablename</td>
<td>name</td>
<td><code>pg_class.relname</code></td>
<td>Name of table the index is for</td>
</tr>
<tr>
<td>indexname</td>
<td>name</td>
<td><code>pg_class.relname</code></td>
<td>Name of index</td>
</tr>
</tbody>
</table>
### 48.60. `pg_locks`

The view `pg_locks` provides access to information about the locks held by open transactions within the database server. See Chapter 13 for more discussion of locking.

`pg_locks` contains one row per active lockable object, requested lock mode, and relevant transaction. Thus, the same lockable object might appear many times, if multiple transactions are holding or waiting for locks on it. However, an object that currently has no locks on it will not appear at all.

There are several distinct types of lockable objects: whole relations (e.g., tables), individual pages of relations, individual tuples of relations, transaction IDs (both virtual and permanent IDs), and general database objects (identified by class OID and object OID, in the same way as in `pg_description` or `pg_depend`). Also, the right to extend a relation is represented as a separate lockable object. Also, "advisory" locks can be taken on numbers that have user-defined meanings.

#### Table 48-61. `pg_locks` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>locktype</td>

<td>OID of the lock target within its system catalog, or null if the target is not a general database object</td>
</tr>
<tr>
<td>objsubid</td>
<td>smallint</td>
<td></td>
<td>Column number targeted by the lock (the classid and objid refer to the table itself), or zero if the target is some other general database object, or null if the target is not a general database object</td>
</tr>
<tr>
<td>virtualtransaction</td>
<td>text</td>
<td></td>
<td>Virtual ID of the transaction that is holding or awaiting this lock</td>
</tr>
</tbody>
</table>
### pg_locks

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pid</td>
<td>integer</td>
<td></td>
<td>Process ID of the server process holding or awaiting this lock, or null if the lock is held by a prepared transaction</td>
</tr>
<tr>
<td>mode</td>
<td>text</td>
<td></td>
<td>Name of the lock mode held or desired by this process (see Section 13.3.1 and Section 13.2.3)</td>
</tr>
<tr>
<td>granted</td>
<td>boolean</td>
<td></td>
<td>True if lock is held, false if lock is awaited</td>
</tr>
<tr>
<td>fastpath</td>
<td>boolean</td>
<td></td>
<td>True if lock was taken via fast path, false if taken via main lock table</td>
</tr>
</tbody>
</table>

 granted is true in a row representing a lock held by the indicated transaction. False indicates that this transaction is currently waiting to acquire this lock, which implies that some other transaction is holding a conflicting lock mode on the same lockable object. The waiting transaction will sleep until the other lock is released (or a deadlock situation is detected). A single transaction can be waiting to acquire at most one lock at a time.

Every transaction holds an exclusive lock on its virtual transaction ID for its entire duration. If a permanent ID is assigned to the transaction (which normally happens only if the transaction changes the state of the database), it also holds an exclusive lock on its permanent transaction ID until it ends. When one transaction finds it necessary to wait specifically for another transaction, it does so by attempting to acquire share lock on the other transaction ID (either virtual or permanent ID depending on the situation). That will succeed only when the other transaction terminates and releases its locks.

Although tuples are a lockable type of object, information about row-level locks is stored on disk, not in memory, and therefore row-level locks normally do not appear in this view. If a transaction is waiting for a row-level lock, it will usually appear in the view as waiting for the permanent transaction ID of the current holder of that row lock.

Advisory locks can be acquired on keys consisting of either a single bigint value or two integer values. A bigint key is displayed with its high-order half in the classid column, its low-order half in the objid column, and objsubid equal to 1. The original bigint value can be reassembled with the expression (classid::bigint << 32) | objid::bigint. Integer keys are displayed with the first key in the classid column, the second key in the objid column, and objsubid equal to 2. The actual meaning of the keys is up to the user. Advisory locks are local to each database, so the database column is meaningful for an advisory lock.

pg_locks provides a global view of all locks in the database cluster, not only those relevant to the current database. Although its relation column can be joined against pg_class.oid to identify locked relations, this will only work correctly for relations in the current database (those for which the database column is either the current database’s OID or zero).

The pid column can be joined to the pid column of the pg_stat_activity view to get more information on the session holding or waiting to hold each lock, for example:

```sql
SELECT * FROM pg_locks pl LEFT JOIN pg_stat_activity psa
```
ON pl.pid = psa.pid;

Also, if you are using prepared transactions, the virtualtransaction column can be joined to the transaction column of the pg_prepared_xacts view to get more information on prepared transactions that hold locks. (A prepared transaction can never be waiting for a lock, but it continues to hold the locks it acquired while running.) For example:

```
SELECT * FROM pg_locks pl LEFT JOIN pg_prepared_xacts ppx
ON pl.virtualtransaction = '-1/' || ppx.transaction;
```

The pg_locks view displays data from both the regular lock manager and the predicate lock manager, which are separate systems; in addition, the regular lock manager subdivides its locks into regular and fast-path locks. This data is not guaranteed to be entirely consistent. When the view is queried, data on fast-path locks (with fastpath = true) is gathered from each backend one at a time, without freezing the state of the entire lock manager, so it is possible for locks to be taken or released while information is gathered. Note, however, that these locks are known not to conflict with any other lock currently in place. After all backends have been queried for fast-path locks, the remainder of the regular lock manager is locked as a unit, and a consistent snapshot of all remaining locks is collected as an atomic action. After unlocking the regular lock manager, the predicate lock manager is similarly locked and all predicate locks are collected as an atomic action. Thus, with the exception of fast-path locks, each lock manager will deliver a consistent set of results, but as we do not lock both lock managers simultaneously, it is possible for locks to be taken or released after we interrogate the regular lock manager and before we interrogate the predicate lock manager.

Locking the regular and/or predicate lock manager could have some impact on database performance if this view is very frequently accessed. The locks are held only for the minimum amount of time necessary to obtain data from the lock managers, but this does not completely eliminate the possibility of a performance impact.

### 48.61. pg_matviews

The view pg_matviews provides access to useful information about each materialized view in the database.

#### Table 48-62. pg_matviews Columns

<td>boolean</td>
<td></td>
<td>True if materialized view has (or recently had) any indexes</td>
</tr>
<tr>
<td>ispopulated</td>
<td>boolean</td>
<td></td>
<td>True if materialized view is currently populated</td>
</tr>
<tr>
<td>definition</td>
<td>text</td>
<td></td>
<td>Materialized view definition (a reconstructed SELECT query)</td>
</tr>
</tbody>
</table>

#### 48.62. pg_prepared_statements

The `pg_prepared_statements` view displays all the prepared statements that are available in the current session. See PREPARE for more information about prepared statements.

`pg_prepared_statements` contains one row for each prepared statement. Rows are added to the view when a new prepared statement is created and removed when a prepared statement is released (for example, via the DEALLOCATE command).

#### Table 48-63. pg_prepared_statements Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
<td>The identifier of the prepared statement</td>
</tr>
<tr>
<td>statement</td>
<td>text</td>
<td>The query string submitted by the client to create this prepared statement. For prepared statements created via SQL, this is the PREPARE statement submitted by the client. For prepared statements created via the frontend/backend protocol, this is the text of the prepared statement itself.</td>
</tr>
<tr>
<td>prepare_time</td>
<td>timestamptz</td>
<td>The time at which the prepared statement was created</td>
</tr>
<tr>
<td>parameter_types</td>
<td>regtype[]</td>
<td>The expected parameter types for the prepared statement in the form of an array of regtype. The OID corresponding to an element of this array can be obtained by casting the regtype value to oid.</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>from_sql</td>
<td>boolean</td>
<td>true if the prepared statement was created via the PREPARE SQL statement; false if the statement was prepared via the frontend/backend protocol</td>
</tr>
</tbody>
</table>

The `pg_prepared_statements` view is read only.

### 48.63. `pg_prepared_xacts`

The view `pg_prepared_xacts` displays information about transactions that are currently prepared for two-phase commit (see PREPARE TRANSACTION for details).

`pg_prepared_xacts` contains one row per prepared transaction. An entry is removed when the transaction is committed or rolled back.

**Table 48-64. `pg_prepared_xacts` Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>transaction</td>
<td>xid</td>
<td></td>
<td>Numeric transaction identifier of the prepared transaction</td>
</tr>
<tr>
<td>gid</td>
<td>text</td>
<td></td>
<td>Global transaction identifier that was assigned to the transaction</td>
</tr>
<tr>
<td>prepared</td>
<td>timestamp with time zone</td>
<td></td>
<td>Time at which the transaction was prepared for commit</td>
</tr>
<tr>
<td>owner</td>
<td>name</td>
<td>pg_authid.rolname</td>
<td>Name of the user that executed the transaction</td>
</tr>
<tr>
<td>database</td>
<td>name</td>
<td>pg_database.datname</td>
<td>Name of the database in which the transaction was executed</td>
</tr>
</tbody>
</table>

When the `pg_prepared_xacts` view is accessed, the internal transaction manager data structures are momentarily locked, and a copy is made for the view to display. This ensures that the view produces a consistent set of results, while not blocking normal operations longer than necessary. Nonetheless there could be some impact on database performance if this view is frequently accessed.

### 48.64. `pg_roles`

The view `pg_roles` provides access to information about database roles. This is simply a publicly readable view of `pg_authid` that blanks out the password field.

This view explicitly exposes the OID column of the underlying table, since that is needed to do joins
to other catalogs.

Table 48-65. pg_roles Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rolname</td>
<td>name</td>
<td></td>
<td>Role name</td>
</tr>
<tr>
<td>rolsuper</td>
<td>bool</td>
<td></td>
<td>Role has superuser privileges</td>
</tr>
<tr>
<td>rolinherit</td>
<td>bool</td>
<td></td>
<td>Role automatically inherits privileges of roles it is a member of</td>
</tr>
<tr>
<td>rolcreaterole</td>
<td>bool</td>
<td></td>
<td>Role can create more roles</td>
</tr>
<tr>
<td>rolcreatedb</td>
<td>bool</td>
<td></td>
<td>Role can create databases</td>
</tr>
<tr>
<td>rolcatupdate</td>
<td>bool</td>
<td></td>
<td>Role can update system catalogs directly. (Even a superuser cannot do this unless this column is true)</td>
</tr>
<tr>
<td>rolcanlogin</td>
<td>bool</td>
<td></td>
<td>Role can log in. That is, this role can be given as the initial session authorization identifier</td>
</tr>
<tr>
<td>rolreplication</td>
<td>bool</td>
<td></td>
<td>Role is a replication role. That is, this role can initiate streaming replication (see Section 25.2.5) and set/unset the system backup mode using <code>pg_start_backup</code> and <code>pg_stop_backup</code></td>
</tr>
<tr>
<td>rolconnlimit</td>
<td>int4</td>
<td></td>
<td>For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit.</td>
</tr>
<tr>
<td>rolpassword</td>
<td>text</td>
<td></td>
<td>Not the password (always reads as ********)</td>
</tr>
</tbody>
</table>
### 48.65. pg_rules

The view `pg_rules` provides access to useful information about query rewrite rules.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td><code>pg_namespace.nspname</code></td>
<td>Name of schema containing table</td>
</tr>
<tr>
<td>tablename</td>
<td>name</td>
<td><code>pg_class.relname</code></td>
<td>Name of table the rule is for</td>
</tr>
<tr>
<td>rulename</td>
<td>name</td>
<td><code>pg_rewrite.rulename</code></td>
<td>Name of rule</td>
</tr>
<tr>
<td>definition</td>
<td>text</td>
<td></td>
<td>Rule definition (a reconstructed creation command)</td>
</tr>
</tbody>
</table>

The `pg_rules` view excludes the ON SELECT rules of views and materialized views; those can be seen in `pg_views` and `pg_matviews`.

### 48.66. pg_seclabels

The view `pg_seclabels` provides information about security labels. It as an easier-to-query version of the `pg_seclabel` catalog.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this security label pertains to</td>
</tr>
<tr>
<td>classoid</td>
<td>oid</td>
<td><code>pg_class.oid</code></td>
<td>The OID of the system catalog this object appears in</td>
</tr>
</tbody>
</table>
Chapter 48. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a security label on a table column, this is the column number (the objoid and classoid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>objtype</td>
<td>text</td>
<td></td>
<td>The type of object to which this label applies, as text.</td>
</tr>
<tr>
<td>objnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace for this object, if applicable; otherwise NULL.</td>
</tr>
<tr>
<td>objname</td>
<td>text</td>
<td></td>
<td>The name of the object to which this label applies, as text.</td>
</tr>
<tr>
<td>provider</td>
<td>text</td>
<td>pg_seclabel.provider</td>
<td>The label provider associated with this label.</td>
</tr>
<tr>
<td>label</td>
<td>text</td>
<td>pg_seclabel.label</td>
<td>The security label applied to this object.</td>
</tr>
</tbody>
</table>

48.67. pg_settings

The view pg_settings provides access to run-time parameters of the server. It is essentially an alternative interface to the SHOW and SET commands. It also provides access to some facts about each parameter that are not directly available from SHOW, such as minimum and maximum values.

Table 48-68. pg_settings Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
<td>Run-time configuration parameter name</td>
</tr>
<tr>
<td>setting</td>
<td>text</td>
<td>Current value of the parameter</td>
</tr>
<tr>
<td>unit</td>
<td>text</td>
<td>Implicit unit of the parameter</td>
</tr>
<tr>
<td>category</td>
<td>text</td>
<td>Logical group of the parameter</td>
</tr>
<tr>
<td>short_desc</td>
<td>text</td>
<td>A brief description of the parameter</td>
</tr>
<tr>
<td>extra_desc</td>
<td>text</td>
<td>Additional, more detailed description of the parameter</td>
</tr>
<tr>
<td>context</td>
<td>text</td>
<td>Context required to set the parameter’s value (see below)</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>vartype</td>
<td>text</td>
<td>Parameter type (bool, enum, integer, real, or string)</td>
</tr>
<tr>
<td>source</td>
<td>text</td>
<td>Source of the current parameter value</td>
</tr>
<tr>
<td>min_val</td>
<td>text</td>
<td>Minimum allowed value of the parameter (null for non-numeric values)</td>
</tr>
<tr>
<td>max_val</td>
<td>text</td>
<td>Maximum allowed value of the parameter (null for non-numeric values)</td>
</tr>
<tr>
<td>enumvals</td>
<td>text[]</td>
<td>Allowed values of an enum parameter (null for non-enum values)</td>
</tr>
<tr>
<td>boot_val</td>
<td>text</td>
<td>Parameter value assumed at server startup if the parameter is not otherwise set</td>
</tr>
<tr>
<td>reset_val</td>
<td>text</td>
<td>Value that reset would reset the parameter to in the current session</td>
</tr>
<tr>
<td>sourcefile</td>
<td>text</td>
<td>Configuration file the current value was set in (null for values set from sources other than configuration files, or when examined by a non-superuser); helpful when using include directives in configuration files</td>
</tr>
<tr>
<td>sourceline</td>
<td>integer</td>
<td>Line number within the configuration file the current value was set at (null for values set from sources other than configuration files, or when examined by a non-superuser)</td>
</tr>
</tbody>
</table>

There are several possible values of context. In order of decreasing difficulty of changing the setting, they are:

- **internal**

  These settings cannot be changed directly; they reflect internally determined values. Some of them may be adjustable by rebuilding the server with different configuration options, or by changing options supplied to initdb.

- **postmaster**

  These settings can only be applied when the server starts, so any change requires restarting the server. Values for these settings are typically stored in the `postgresql.conf` file, or passed on the command line when starting the server. Of course, settings with any of the lower context types can also be set at server start time.

- **sighup**

  Changes to these settings can be made in `postgresql.conf` without restarting the server. Send
a SIGHUP signal to the postmaster to cause it to re-read `postgresql.conf` and apply the changes. The postmaster will also forward the SIGHUP signal to its child processes so that they all pick up the new value.

**backend**

Changes to these settings can be made in `postgresql.conf` without restarting the server; they can also be set for a particular session in the connection request packet (for example, via libpq’s `PGOPTIONS` environment variable). However, these settings never change in a session after it is started. If you change them in `postgresql.conf`, send a SIGHUP signal to the postmaster to cause it to re-read `postgresql.conf`. The new values will only affect subsequently-launched sessions.

**superuser**

These settings can be set from `postgresql.conf`, or within a session via the `SET` command; but only superusers can change them via `SET`. Changes in `postgresql.conf` will affect existing sessions only if no session-local value has been established with `SET`.

**user**

These settings can be set from `postgresql.conf`, or within a session via the `SET` command. Any user is allowed to change his session-local value. Changes in `postgresql.conf` will affect existing sessions only if no session-local value has been established with `SET`.

See Section 18.1 for more information about the various ways to change these parameters.

The `pg_settings` view cannot be inserted into or deleted from, but it can be updated. An `UPDATE` applied to a row of `pg_settings` is equivalent to executing the `SET` command on that named parameter. The change only affects the value used by the current session. If an `UPDATE` is issued within a transaction that is later aborted, the effects of the `UPDATE` command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another `UPDATE` or `SET`.

### 48.68. pg_shadow

The view `pg_shadow` exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows properties of all roles that are marked as `rolcanlogin` in `pg_authid`.

The name stems from the fact that this table should not be readable by the public since it contains passwords. `pg_user` is a publicly readable view on `pg_shadow` that blanks out the password field.

**Table 48-69. pg_shadow Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>usename</td>
<td>name</td>
<td><code>pg_authid.rolname</code></td>
<td>User name</td>
</tr>
<tr>
<td>usesysid</td>
<td>oid</td>
<td><code>pg_authid.oid</code></td>
<td>ID of this user</td>
</tr>
<tr>
<td>usecreatedb</td>
<td>bool</td>
<td></td>
<td>User can create databases</td>
</tr>
<tr>
<td>usesuper</td>
<td>bool</td>
<td></td>
<td>User is a superuser</td>
</tr>
</tbody>
</table>
### 48.69. `pg_stats`

The view `pg_stats` provides access to the information stored in the `pg_statistic` catalog. This view allows access only to rows of `pg_statistic` that correspond to tables the user has permission to read, and therefore it is safe to allow public read access to this view.

`pg_stats` is also designed to present the information in a more readable format than the underlying catalog — at the cost that its schema must be extended whenever new slot types are defined for `pg_statistic`.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td><code>pg_namespace.nspname</code></td>
<td>Name of schema containing table</td>
</tr>
<tr>
<td>tablename</td>
<td>name</td>
<td><code>pg_class.relname</code></td>
<td>Name of table</td>
</tr>
<tr>
<td>attname</td>
<td>name</td>
<td><code>pg_attribute.attname</code></td>
<td>Name of the column described by this row</td>
</tr>
<tr>
<td>inherited</td>
<td>bool</td>
<td></td>
<td>If true, this row includes inheritance child columns, not just the values in the specified table</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>----------</td>
<td>------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>null_frac</td>
<td>real</td>
<td></td>
<td>Fraction of column entries that are null</td>
</tr>
<tr>
<td>avg_width</td>
<td>integer</td>
<td></td>
<td>Average width in bytes of column’s entries</td>
</tr>
<tr>
<td>n_distinct</td>
<td>real</td>
<td></td>
<td>If greater than zero, the estimated number of distinct values in the column. If less than zero, the negative of the number of distinct values divided by the number of rows. (The negated form is used when <code>ANALYZE</code> believes that the number of distinct values is likely to increase as the table grows; the positive form is used when the column seems to have a fixed number of possible values.) For example, -1 indicates a unique column in which the number of distinct values is the same as the number of rows.</td>
</tr>
<tr>
<td>most_common_vals</td>
<td>anyarray</td>
<td></td>
<td>A list of the most common values in the column. (Null if no values seem to be more common than any others.)</td>
</tr>
<tr>
<td>most_common_freqs</td>
<td>real[]</td>
<td></td>
<td>A list of the frequencies of the most common values, i.e., number of occurrences of each divided by total number of rows. (Null when <code>most_common_vals</code> is.)</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>histogram_bounds</td>
<td>anyarray</td>
<td></td>
<td>A list of values that divide the column’s values into groups of approximately equal population. The values in most_common_vals, if present, are omitted from this histogram calculation. (This column is null if the column data type does not have a &lt; operator or if the most_common_vals list accounts for the entire population.)</td>
</tr>
<tr>
<td>correlation</td>
<td>real</td>
<td></td>
<td>Statistical correlation between physical row ordering and logical ordering of the column values. This ranges from -1 to +1. When the value is near -1 or +1, an index scan on the column will be estimated to be cheaper than when it is near zero, due to reduction of random access to the disk. (This column is null if the column data type does not have a &lt; operator.)</td>
</tr>
<tr>
<td>most_common_elems</td>
<td>anyarray</td>
<td></td>
<td>A list of non-null element values most often appearing within values of the column. (Null for scalar types.)</td>
</tr>
</tbody>
</table>
48.70. pg_tables

The view pg_tables provides access to useful information about each table in the database.

Table 48-71. pg_tables Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td>pg_namespace.nspname</td>
<td>Name of schema containing table</td>
</tr>
<tr>
<td>tablename</td>
<td>name</td>
<td>pg_class.relname</td>
<td>Name of table</td>
</tr>
<tr>
<td>tableowner</td>
<td>name</td>
<td>pg_authid.rolname</td>
<td>Name of table’s owner</td>
</tr>
<tr>
<td>tablespace</td>
<td>name</td>
<td>pg_tablespace.spcname</td>
<td>Name of tablespace containing table (null if</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>default for database)</td>
</tr>
</tbody>
</table>
### 48.71. pg_timezone_abbrevs

The view `pg_timezone_abbrevs` provides a list of time zone abbreviations that are currently recognized by the datetime input routines. The contents of this view change when the timezone_abbreviations run-time parameter is modified.

Table 48-72. pg_timezone_abbrevs Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>abbrev</td>
<td>text</td>
<td>Time zone abbreviation</td>
</tr>
<tr>
<td>utc_offset</td>
<td>interval</td>
<td>Offset from UTC (positive means east of Greenwich)</td>
</tr>
<tr>
<td>is_dst</td>
<td>boolean</td>
<td>True if this is a daylight-savings abbreviation</td>
</tr>
</tbody>
</table>

While most timezone abbreviations represent fixed offsets from UTC, there are some that have historically varied in value (see Section B.4 for more information). In such cases this view presents their current meaning.

### 48.72. pg_timezone_names

The view `pg_timezone_names` provides a list of time zone names that are recognized by `SET TIMEZONE`, along with their associated abbreviations, UTC offsets, and daylight-savings status. (Technically, PostgreSQL uses UT1 rather than UTC because leap seconds are not handled.) Unlike the abbreviations shown in `pg_timezone_abbrevs`, many of these names imply a set of daylight-savings transition date rules. Therefore, the associated information changes across local DST boundaries. The displayed information is computed based on the current value of `CURRENT_TIMESTAMP`.

Table 48-73. pg_timezone_names Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
<td>Time zone name</td>
</tr>
<tr>
<td>abbrev</td>
<td>text</td>
<td>Time zone abbreviation</td>
</tr>
<tr>
<td>utc_offset</td>
<td>interval</td>
<td>Offset from UTC (positive means east of Greenwich)</td>
</tr>
<tr>
<td>is_dst</td>
<td>boolean</td>
<td>True if currently observing daylight savings</td>
</tr>
</tbody>
</table>
Chapter 48. System Catalogs

48.73. pg_user

The view pg_user provides access to information about database users. This is simply a publicly readable view of pg_shadow that blanks out the password field.

Table 48-74. pg_user Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>usename</td>
<td>name</td>
<td>User name</td>
</tr>
<tr>
<td>usesysid</td>
<td>oid</td>
<td>ID of this user</td>
</tr>
<tr>
<td>usecreatedb</td>
<td>bool</td>
<td>User can create databases</td>
</tr>
<tr>
<td>usesuper</td>
<td>bool</td>
<td>User is a superuser</td>
</tr>
<tr>
<td>usecatupd</td>
<td>bool</td>
<td>User can update system catalogs. (Even a superuser cannot do this unless this column is true.)</td>
</tr>
<tr>
<td>userepl</td>
<td>bool</td>
<td>User can initiate streaming replication and put the system in and out of backup mode.</td>
</tr>
<tr>
<td>passwd</td>
<td>text</td>
<td>Not the password (always reads as ********)</td>
</tr>
<tr>
<td>valuntil</td>
<td>abstime</td>
<td>Password expiry time (only used for password authentication)</td>
</tr>
<tr>
<td>useconfig</td>
<td>text[]</td>
<td>Session defaults for run-time configuration variables</td>
</tr>
</tbody>
</table>

48.74. pg_user_mappings

The view pg_user_mappings provides access to information about user mappings. This is essentially a publicly readable view of pg_user_mapping that leaves out the options field if the user has no rights to use it.

Table 48-75. pg_user_mappings Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>umid</td>
<td>oid</td>
<td>pg_user_mapping.oid</td>
<td>OID of the user mapping</td>
</tr>
<tr>
<td>srvid</td>
<td>oid</td>
<td>pg_foreign_server.oid</td>
<td>The OID of the foreign server that contains this mapping</td>
</tr>
<tr>
<td>srvname</td>
<td>name</td>
<td>pg_foreign_server.srvname</td>
<td>Name of the foreign server</td>
</tr>
<tr>
<td>umuser</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>OID of the local role being mapped, 0 if the user mapping is public</td>
</tr>
</tbody>
</table>
Chapter 48. System Catalogs

### Table 48-75. Name, Type, References, Description

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>usename</td>
<td>name</td>
<td></td>
<td>Name of the local user to be mapped</td>
</tr>
<tr>
<td>umoptions</td>
<td>text[]</td>
<td></td>
<td>User mapping specific options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

To protect password information stored as a user mapping option, the `umoptions` column will read as null unless one of the following applies:

- current user is the user being mapped, and owns the server or holds `USAGE` privilege on it
- current user is the server owner and mapping is for `PUBLIC`
- current user is a superuser

#### 48.75. `pg_views`

The view `pg_views` provides access to useful information about each view in the database.

**Table 48-76. `pg_views` Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td><code>pg_namespace.nspname</code></td>
<td>Name of schema containing view</td>
</tr>
<tr>
<td>viewname</td>
<td>name</td>
<td><code>pg_class.relname</code></td>
<td>Name of view</td>
</tr>
<tr>
<td>viewowner</td>
<td>name</td>
<td><code>pg_authid.rolname</code></td>
<td>Name of view’s owner</td>
</tr>
<tr>
<td>definition</td>
<td>text</td>
<td></td>
<td>View definition (a reconstructed <code>SELECT</code> query)</td>
</tr>
</tbody>
</table>
Chapter 49. Frontend/Backend Protocol

PostgreSQL uses a message-based protocol for communication between frontends and backends (clients and servers). The protocol is supported over TCP/IP and also over Unix-domain sockets. Port number 5432 has been registered with IANA as the customary TCP port number for servers supporting this protocol, but in practice any non-privileged port number can be used.

This document describes version 3.0 of the protocol, implemented in PostgreSQL 7.4 and later. For descriptions of the earlier protocol versions, see previous releases of the PostgreSQL documentation. A single server can support multiple protocol versions. The initial startup-request message tells the server which protocol version the client is attempting to use. If the major version requested by the client is not supported by the server, the connection will be rejected (for example, this would occur if the client requested protocol version 4.0, which does not exist as of this writing). If the minor version requested by the client is not supported by the server (e.g. the client requests version 3.1, but the server supports only 3.0), the server may either reject the connection or may respond with a NegotiateProtocolVersion message containing the highest minor protocol version which it supports. The client may then choose either to continue with the connection using the specified protocol version or to abort the connection.

In order to serve multiple clients efficiently, the server launches a new “backend” process for each client. In the current implementation, a new child process is created immediately after an incoming connection is detected. This is transparent to the protocol, however. For purposes of the protocol, the terms “backend” and “server” are interchangeable; likewise “frontend” and “client” are interchangeable.

49.1. Overview

The protocol has separate phases for startup and normal operation. In the startup phase, the frontend opens a connection to the server and authenticates itself to the satisfaction of the server. (This might involve a single message, or multiple messages depending on the authentication method being used.) If all goes well, the server then sends status information to the frontend, and finally enters normal operation. Except for the initial startup-request message, this part of the protocol is driven by the server.

During normal operation, the frontend sends queries and other commands to the backend, and the backend sends back query results and other responses. There are a few cases (such as NOTIFY) wherein the backend will send unsolicited messages, but for the most part this portion of a session is driven by frontend requests.

Termination of the session is normally by frontend choice, but can be forced by the backend in certain cases. In any case, when the backend closes the connection, it will roll back any open (incomplete) transaction before exiting.

Within normal operation, SQL commands can be executed through either of two sub-protocols. In the “simple query” protocol, the frontend just sends a textual query string, which is parsed and immediately executed by the backend. In the “extended query” protocol, processing of queries is separated into multiple steps: parsing, binding of parameter values, and execution. This offers flexibility and performance benefits, at the cost of extra complexity.

Normal operation has additional sub-protocols for special operations such as COPY.
49.1.1. Messaging Overview

All communication is through a stream of messages. The first byte of a message identifies the message type, and the next four bytes specify the length of the rest of the message (this length count includes itself, but not the message-type byte). The remaining contents of the message are determined by the message type. For historical reasons, the very first message sent by the client (the startup message) has no initial message-type byte.

To avoid losing synchronization with the message stream, both servers and clients typically read an entire message into a buffer (using the byte count) before attempting to process its contents. This allows easy recovery if an error is detected while processing the contents. In extreme situations (such as not having enough memory to buffer the message), the receiver can use the byte count to determine how much input to skip before it resumes reading messages.

Conversely, both servers and clients must take care never to send an incomplete message. This is commonly done by marshaling the entire message in a buffer before beginning to send it. If a communications failure occurs partway through sending or receiving a message, the only sensible response is to abandon the connection, since there is little hope of recovering message-boundary synchronization.

49.1.2. Extended Query Overview

In the extended-query protocol, execution of SQL commands is divided into multiple steps. The state retained between steps is represented by two types of objects: prepared statements and portals. A prepared statement represents the result of parsing and semantic analysis of a textual query string. A prepared statement is not in itself ready to execute, because it might lack specific values for parameters. A portal represents a ready-to-execute or already-partially-executed statement, with any missing parameter values filled in. (For SELECT statements, a portal is equivalent to an open cursor, but we choose to use a different term since cursors don’t handle non-SELECT statements.)

The overall execution cycle consists of a parse step, which creates a prepared statement from a textual query string; a bind step, which creates a portal given a prepared statement and values for any needed parameters; and an execute step that runs a portal’s query. In the case of a query that returns rows (SELECT, SHOW, etc), the execute step can be told to fetch only a limited number of rows, so that multiple execute steps might be needed to complete the operation.

The backend can keep track of multiple prepared statements and portals (but note that these exist only within a session, and are never shared across sessions). Existing prepared statements and portals are referenced by names assigned when they were created. In addition, an “unnamed” prepared statement and portal exist. Although these behave largely the same as named objects, operations on them are optimized for the case of executing a query only once and then discarding it, whereas operations on named objects are optimized on the expectation of multiple uses.

49.1.3. Formats and Format Codes

Data of a particular data type might be transmitted in any of several different formats. As of PostgreSQL 7.4 the only supported formats are “text” and “binary”, but the protocol makes provision for future extensions. The desired format for any value is specified by a format code. Clients can specify a format code for each transmitted parameter value and for each column of a query result. Text has format code zero, binary has format code one, and all other format codes are reserved for future definition.

The text representation of values is whatever strings are produced and accepted by the input/output conversion functions for the particular data type. In the transmitted representation, there is no trailing
null character; the frontend must add one to received values if it wants to process them as C strings.
(The text format does not allow embedded nulls, by the way.)
Binary representations for integers use network byte order (most significant byte first). For other data
types consult the documentation or source code to learn about the binary representation. Keep in
mind that binary representations for complex data types might change across server versions; the text
format is usually the more portable choice.

49.2. Message Flow

This section describes the message flow and the semantics of each message type. (Details of the exact
representation of each message appear in Section 49.5.) There are several different sub-protocols de-
pending on the state of the connection: start-up, query, function call, COPY, and termination. There are
also special provisions for asynchronous operations (including notification responses and command
cancellation), which can occur at any time after the start-up phase.

49.2.1. Start-up

To begin a session, a frontend opens a connection to the server and sends a startup message. This
message includes the names of the user and of the database the user wants to connect to; it also
identifies the particular protocol version to be used. (Optionally, the startup message can include
additional settings for run-time parameters.) The server then uses this information and the contents of
its configuration files (such as pg_hba.conf) to determine whether the connection is provisionally
acceptable, and what additional authentication is required (if any).

The server then sends an appropriate authentication request message, to which the frontend must
reply with an appropriate authentication response message (such as a password). For all authentication
methods except GSSAPI and SSPI, there is at most one request and one response. In some methods,
no response at all is needed from the frontend, and so no authentication request occurs. For GSSAPI
and SSPI, multiple exchanges of packets may be needed to complete the authentication.

The authentication cycle ends with the server either rejecting the connection attempt (ErrorResponse),
or sending AuthenticationOk.

The possible messages from the server in this phase are:

ErrorResponse

The connection attempt has been rejected. The server then immediately closes the connection.

AuthenticationOk

The authentication exchange is successfully completed.

AuthenticationKerberosV5

The frontend must now take part in a Kerberos V5 authentication dialog (not described here, part
of the Kerberos specification) with the server. If this is successful, the server responds with an
AuthenticationOk, otherwise it responds with an ErrorResponse. This is no longer supported.

AuthenticationCleartextPassword

The frontend must now send a PasswordMessage containing the password in clear-text form. If
this is the correct password, the server responds with an AuthenticationOk, otherwise it responds
with an ErrorResponse.
AuthenticationMD5Password

The frontend must now send a PasswordMessage containing the password (with username) encrypted via MD5, then encrypted again using the 4-byte random salt specified in the AuthenticationMD5Password message. If this is the correct password, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. The actual PasswordMessage can be computed in SQL as `concat('md5', md5(concat(md5(concat(password, username)), random-salt)))`. (Keep in mind the `md5()` function returns its result as a hex string.)

AuthenticationSCMCredential

This response is only possible for local Unix-domain connections on platforms that support SCM credential messages. The frontend must issue an SCM credential message and then send a single data byte. (The contents of the data byte are uninteresting; it’s only used to ensure that the server waits long enough to receive the credential message.) If the credential is acceptable, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. (This message type is only issued by pre-9.1 servers. It may eventually be removed from the protocol specification.)

AuthenticationGSS

The frontend must now initiate a GSSAPI negotiation. The frontend will send a PasswordMessage with the first part of the GSSAPI data stream in response to this. If further messages are needed, the server will respond with AuthenticationGSSContinue.

AuthenticationSSPI

The frontend must now initiate a SSPI negotiation. The frontend will send a PasswordMessage with the first part of the SSPI data stream in response to this. If further messages are needed, the server will respond with AuthenticationGSSContinue.

AuthenticationGSSContinue

This message contains the response data from the previous step of GSSAPI or SSPI negotiation (AuthenticationGSS, AuthenticationSSPI or a previous AuthenticationGSSContinue). If the GSSAPI or SSPI data in this message indicates more data is needed to complete the authentication, the frontend must send that data as another PasswordMessage. If GSSAPI or SSPI authentication is completed by this message, the server will next send AuthenticationOk to indicate successful authentication or ErrorResponse to indicate failure.

NegotiateProtocolVersion

The server does not support the minor protocol version requested by the client, but does support an earlier version of the protocol; this message indicates the highest supported minor version. This message will also be sent if the client requested unsupported protocol options (i.e. beginning with `_pq_`) in the startup packet. This message will be followed by an ErrorResponse or a message indicating the success or failure of authentication.

If the frontend does not support the authentication method requested by the server, then it should immediately close the connection.

After having received AuthenticationOk, the frontend must wait for further messages from the server. In this phase a backend process is being started, and the frontend is just an interested bystander. It is still possible for the startup attempt to fail (ErrorResponse) or the server to decline support for the requested minor protocol version (NegotiateProtocolVersion), but in the normal case the backend will send some ParameterStatus messages, BackendKeyData, and finally ReadyForQuery.
During this phase the backend will attempt to apply any additional run-time parameter settings that were given in the startup message. If successful, these values become session defaults. An error causes ErrorResponse and exit.

The possible messages from the backend in this phase are:

**BackendKeyData**

This message provides secret-key data that the frontend must save if it wants to be able to issue cancel requests later. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

**ParameterStatus**

This message informs the frontend about the current (initial) setting of backend parameters, such as client_encoding or DateStyle. The frontend can ignore this message, or record the settings for its future use; see Section 49.2.6 for more details. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

**ReadyForQuery**

Start-up is completed. The frontend can now issue commands.

**ErrorResponse**

Start-up failed. The connection is closed after sending this message.

**NoticeResponse**

A warning message has been issued. The frontend should display the message but continue listening for ReadyForQuery or ErrorResponse.

The ReadyForQuery message is the same one that the backend will issue after each command cycle. Depending on the coding needs of the frontend, it is reasonable to consider ReadyForQuery as starting a command cycle, or to consider ReadyForQuery as ending the start-up phase and each subsequent command cycle.

### 49.2.2. Simple Query

A simple query cycle is initiated by the frontend sending a Query message to the backend. The message includes an SQL command (or commands) expressed as a text string. The backend then sends one or more response messages depending on the contents of the query command string, and finally a ReadyForQuery response message. ReadyForQuery informs the frontend that it can safely send a new command. (It is not actually necessary for the frontend to wait for ReadyForQuery before issuing another command, but the frontend must then take responsibility for figuring out what happens if the earlier command fails and already-issued later commands succeed.)

The possible response messages from the backend are:

**CommandComplete**

An SQL command completed normally.

**CopyInResponse**

The backend is ready to copy data from the frontend to a table; see Section 49.2.5.

**CopyOutResponse**

The backend is ready to copy data from a table to the frontend; see Section 49.2.5.
Chapter 49. Frontend/Backend Protocol

RowDescription

Indicates that rows are about to be returned in response to a `SELECT`, `FETCH`, etc query. The contents of this message describe the column layout of the rows. This will be followed by a `DataRow` message for each row being returned to the frontend.

DataRow

One of the set of rows returned by a `SELECT`, `FETCH`, etc query.

EmptyQueryResponse

An empty query string was recognized.

ErrorResponse

An error has occurred.

ReadyForQuery

Processing of the query string is complete. A separate message is sent to indicate this because the query string might contain multiple SQL commands. (CommandComplete marks the end of processing one SQL command, not the whole string.) ReadyForQuery will always be sent, whether processing terminates successfully or with an error.

NoticeResponse

A warning message has been issued in relation to the query. Notices are in addition to other responses, i.e., the backend will continue processing the command.

The response to a `SELECT` query (or other queries that return row sets, such as `EXPLAIN` or `SHOW`) normally consists of RowDescription, zero or more `DataRow` messages, and then CommandComplete. `COPY` to or from the frontend invokes special protocol as described in Section 49.2.5. All other query types normally produce only a CommandComplete message.

Since a query string could contain several queries (separated by semicolons), there might be several such response sequences before the backend finishes processing the query string. ReadyForQuery is issued when the entire string has been processed and the backend is ready to accept a new query string.

If a completely empty (no contents other than whitespace) query string is received, the response is EmptyQueryResponse followed by ReadyForQuery.

In the event of an error, ErrorResponse is issued followed by ReadyForQuery. All further processing of the query string is aborted by ErrorResponse (even if more queries remained in it). Note that this might occur partway through the sequence of messages generated by an individual query.

In simple Query mode, the format of retrieved values is always text, except when the given command is a `FETCH` from a cursor declared with the `BINARY` option. In that case, the retrieved values are in binary format. The format codes given in the RowDescription message tell which format is being used.

A frontend must be prepared to accept ErrorResponse and NoticeResponse messages whenever it is expecting any other type of message. See also Section 49.2.6 concerning messages that the backend might generate due to outside events.

Recommended practice is to code frontends in a state-machine style that will accept any message type at any time that it could make sense, rather than wiring in assumptions about the exact sequence of messages.
49.2.3. Extended Query

The extended query protocol breaks down the above-described simple query protocol into multiple steps. The results of preparatory steps can be re-used multiple times for improved efficiency. Furthermore, additional features are available, such as the possibility of supplying data values as separate parameters instead of having to insert them directly into a query string.

In the extended protocol, the frontend first sends a Parse message, which contains a textual query string, optionally some information about data types of parameter placeholders, and the name of a destination prepared-statement object (an empty string selects the unnamed prepared statement). The response is either ParseComplete or ErrorResponse. Parameter data types can be specified by OID; if not given, the parser attempts to infer the data types in the same way as it would do for untyped literal string constants.

**Note:** A parameter data type can be left unspecified by setting it to zero, or by making the array of parameter type OIDs shorter than the number of parameter symbols \( n \) used in the query string. Another special case is that a parameter's type can be specified as void (that is, the OID of the void pseudotype). This is meant to allow parameter symbols to be used for function parameters that are actually OUT parameters. Ordinarily there is no context in which a void parameter could be used, but if such a parameter symbol appears in a function's parameter list, it is effectively ignored. For example, a function call such as \( \text{foo}(\$1,\$2,\$3,\$4) \) could match a function with two IN and two OUT arguments, if \$3 and \$4 are specified as having type void.

**Note:** The query string contained in a Parse message cannot include more than one SQL statement; else a syntax error is reported. This restriction does not exist in the simple-query protocol, but it does exist in the extended protocol, because allowing prepared statements or portals to contain multiple commands would complicate the protocol unduly.

If successfully created, a named prepared-statement object lasts till the end of the current session, unless explicitly destroyed. An unnamed prepared statement lasts only until the next Parse statement specifying the unnamed statement as destination is issued. (Note that a simple Query message also destroys the unnamed statement.) Named prepared statements must be explicitly closed before they can be redefined by another Parse message, but this is not required for the unnamed statement. Named prepared statements can also be created and accessed at the SQL command level, using PREPARE and EXECUTE.

Once a prepared statement exists, it can be readied for execution using a Bind message. The Bind message gives the name of the source prepared statement (empty string denotes the unnamed prepared statement), the name of the destination portal (empty string denotes the unnamed portal), and the values to use for any parameter placeholders present in the prepared statement. The supplied parameter set must match those needed by the prepared statement. (If you declared any void parameters in the Parse message, pass NULL values for them in the Bind message.) Bind also specifies the format to use for any data returned by the query; the format can be specified overall, or per-column. The response is either BindComplete or ErrorResponse.

**Note:** The choice between text and binary output is determined by the format codes given in Bind, regardless of the SQL command involved. The BINARY attribute in cursor declarations is irrelevant when using extended query protocol.
Query planning typically occurs when the Bind message is processed. If the prepared statement has no parameters, or is executed repeatedly, the server might save the created plan and re-use it during subsequent Bind messages for the same prepared statement. However, it will do so only if it finds that a generic plan can be created that is not much less efficient than a plan that depends on the specific parameter values supplied. This happens transparently so far as the protocol is concerned.

If successfully created, a named portal object lasts till the end of the current transaction, unless explicitly destroyed. An unnamed portal is destroyed at the end of the transaction, or as soon as the next Bind statement specifying the unnamed portal as destination is issued. (Note that a simple Query message also destroys the unnamed portal.) Named portals must be explicitly closed before they can be redefined by another Bind message, but this is not required for the unnamed portal. Named portals can also be created and accessed at the SQL command level, using \texttt{DECLARE CURSOR} and \texttt{FETCH}.

Once a portal exists, it can be executed using an Execute message. The Execute message specifies the portal name (empty string denotes the unnamed portal) and a maximum result-row count (zero meaning “fetch all rows”). The result-row count is only meaningful for portals containing commands that return row sets; in other cases the command is always executed to completion, and the row count is ignored. The possible responses to Execute are the same as those described above for queries issued via simple query protocol, except that Execute doesn’t cause ReadyForQuery or RowDescription to be issued.

If Execute terminates before completing the execution of a portal (due to reaching a nonzero result-row count), it will send a PortalSuspended message; the appearance of this message tells the frontend that another Execute should be issued against the same portal to complete the operation. The CommandComplete message indicating completion of the source SQL command is not sent until the portal’s execution is completed. Therefore, an Execute phase is always terminated by the appearance of exactly one of these messages: CommandComplete, EmptyQueryResponse (if the portal was created from an empty query string), ErrorResponse, or PortalSuspended.

At completion of each series of extended-query messages, the frontend should issue a Sync message. This parameterless message causes the backend to close the current transaction if it’s not inside a \texttt{BEGIN/COMMIT} transaction block (“close” meaning to commit if no error, or roll back if error). Then a ReadyForQuery response is issued. The purpose of Sync is to provide a resynchronization point for error recovery. When an error is detected while processing any extended-query message, the backend issues ErrorResponse, then reads and discards messages until a Sync is reached, then issues ReadyForQuery and returns to normal message processing. (But note that no skipping occurs if an error is detected \textit{while} processing Sync — this ensures that there is one and only one ReadyForQuery sent for each Sync.)

\textbf{Note:} Sync does not cause a transaction block opened with \texttt{BEGIN} to be closed. It is possible to detect this situation since the ReadyForQuery message includes transaction status information.

In addition to these fundamental, required operations, there are several optional operations that can be used with extended-query protocol.

The Describe message (portal variant) specifies the name of an existing portal (or an empty string for the unnamed portal). The response is a RowDescription message describing the rows that will be returned by executing the portal; or a NoData message if the portal does not contain a query that will return rows; or ErrorResponse if there is no such portal.

The Describe message (statement variant) specifies the name of an existing prepared statement (or an empty string for the unnamed prepared statement). The response is a ParameterDescription message describing the parameters needed by the statement, followed by a RowDescription message describing the rows that will be returned when the statement is eventually executed (or a NoData message if the
statement will not return rows). ErrorResponse is issued if there is no such prepared statement. Note that since Bind has not yet been issued, the formats to be used for returned columns are not yet known to the backend; the format code fields in the RowDescription message will be zeroes in this case.

Tip: In most scenarios the frontend should issue one or the other variant of Describe before issuing Execute, to ensure that it knows how to interpret the results it will get back.

The Close message closes an existing prepared statement or portal and releases resources. It is not an error to issue Close against a nonexistent statement or portal name. The response is normally CloseComplete, but could be ErrorResponse if some difficulty is encountered while releasing resources. Note that closing a prepared statement implicitly closes any open portals that were constructed from that statement.

The Flush message does not cause any specific output to be generated, but forces the backend to deliver any data pending in its output buffers. A Flush must be sent after any extended-query command except Sync, if the frontend wishes to examine the results of that command before issuing more commands. Without Flush, messages returned by the backend will be combined into the minimum possible number of packets to minimize network overhead.

Note: The simple Query message is approximately equivalent to the series Parse, Bind, portal Describe, Execute, Close, Sync, using the unnamed prepared statement and portal objects and no parameters. One difference is that it will accept multiple SQL statements in the query string, automatically performing the bind/describe/execute sequence for each one in succession. Another difference is that it will not return ParseComplete, BindComplete, CloseComplete, or NoData messages.

49.2.4. Function Call

The Function Call sub-protocol allows the client to request a direct call of any function that exists in the database's pg_proc system catalog. The client must have execute permission for the function.

Note: The Function Call sub-protocol is a legacy feature that is probably best avoided in new code. Similar results can be accomplished by setting up a prepared statement that does SELECT function($1, ...). The Function Call cycle can then be replaced with Bind/Execute.

A Function Call cycle is initiated by the frontend sending a FunctionCall message to the backend. The backend then sends one or more response messages depending on the results of the function call, and finally a ReadyForQuery response message. ReadyForQuery informs the frontend that it can safely send a new query or function call.

The possible response messages from the backend are:

ErrorResponse
An error has occurred.

FunctionCallResponse
The function call was completed and returned the result given in the message. (Note that the Function Call protocol can only handle a single scalar result, not a row type or set of results.)
ReadyForQuery

Processing of the function call is complete. ReadyForQuery will always be sent, whether processing terminates successfully or with an error.

NoticeResponse

A warning message has been issued in relation to the function call. Notices are in addition to other responses, i.e., the backend will continue processing the command.

49.2.5. COPY Operations

The `COPY` command allows high-speed bulk data transfer to or from the server. Copy-in and copy-out operations each switch the connection into a distinct sub-protocol, which lasts until the operation is completed.

Copy-in mode (data transfer to the server) is initiated when the backend executes a `COPY FROM STDIN` SQL statement. The backend sends a CopyInResponse message to the frontend. The frontend should then send zero or more CopyData messages, forming a stream of input data. (The message boundaries are not required to have anything to do with row boundaries, although that is often a reasonable choice.) The frontend can terminate the copy-in mode by sending either a CopyDone message (allowing successful termination) or a CopyFail message (which will cause the `COPY` SQL statement to fail with an error). The backend then reverts to the command-processing mode it was in before the `COPY` started, which will be either simple or extended query protocol. It will next send either CommandComplete (if successful) or ErrorResponse (if not).

In the event of a backend-detected error during copy-in mode (including receipt of a CopyFail message), the backend will issue an ErrorResponse message. If the `COPY` command was issued via an extended-query message, the backend will now discard frontend messages until a Sync message is received, then it will issue ReadyForQuery and return to normal processing. If the `COPY` command was issued in a simple Query message, the rest of that message is discarded and ReadyForQuery is issued. In either case, any subsequent CopyData, CopyDone, or CopyFail messages issued by the frontend will simply be dropped.

The backend will ignore Flush and Sync messages received during copy-in mode. Receipt of any other non-copy message type constitutes an error that will abort the copy-in state as described above. (The exception for Flush and Sync is for the convenience of client libraries that always send Flush or Sync after an Execute message, without checking whether the command to be executed is a `COPY FROM STDIN`.)

Copy-out mode (data transfer from the server) is initiated when the backend executes a `COPY TO STDOUT` SQL statement. The backend sends a CopyOutResponse message to the frontend, followed by zero or more CopyData messages (always one per row), followed by CopyDone. The backend then reverts to the command-processing mode it was in before the `COPY` started, and sends CommandComplete. The frontend cannot abort the transfer (except by closing the connection or issuing a Cancel request), but it can discard unwanted CopyData and CopyDone messages.

In the event of a backend-detected error during copy-out mode, the backend will issue an ErrorResponse message and revert to normal processing. The frontend should treat receipt of ErrorResponse as terminating the copy-out mode.

It is possible for NoticeResponse and ParameterStatus messages to be interspersed between CopyData messages; frontends must handle these cases, and should be prepared for other asynchronous message types as well (see Section 49.2.6). Otherwise, any message type other than CopyData or CopyDone may be treated as terminating copy-out mode.
There is another Copy-related mode called copy-both, which allows high-speed bulk data transfer to and from the server. Copy-both mode is initiated when a backend in walsender mode executes a \texttt{START_REPLICATION} statement. The backend sends a \texttt{CopyBothResponse} message to the frontend. Both the backend and the frontend may then send \texttt{CopyData} messages until either end sends a \texttt{CopyDone} message. After the client sends a \texttt{CopyDone} message, the connection goes from copy-both mode to copy-out mode, and the client may not send any more \texttt{CopyData} messages. Similarly, when the server sends a \texttt{CopyDone} message, the connection goes into copy-in mode, and the server may not send any more \texttt{CopyData} messages. After both sides have sent a \texttt{CopyDone} message, the copy mode is terminated, and the backend reverts to the command-processing mode. If a backend-detected error occurs during copy-both mode, the backend will issue an \texttt{ErrorResponse} message, discard frontend messages until a \texttt{Sync} message is received, and then issue \texttt{ReadyForQuery} and return to normal processing. The frontend should treat receipt of \texttt{ErrorResponse} as terminating the copy in both directions; no \texttt{CopyDone} should be sent in this case. See Section 49.3 for more information on the subprotocol transmitted over copy-both mode.

The \texttt{CopyInResponse}, \texttt{CopyOutResponse} and \texttt{CopyBothResponse} messages include fields that inform the frontend of the number of columns per row and the format codes being used for each column. (As of the present implementation, all columns in a given \texttt{COPY} operation will use the same format, but the message design does not assume this.)

### 49.2.6. Asynchronous Operations

There are several cases in which the backend will send messages that are not specifically prompted by the frontend’s command stream. Frontends must be prepared to deal with these messages at any time, even when not engaged in a query. At minimum, one should check for these cases before beginning to read a query response.

It is possible for \texttt{NoticeResponse} messages to be generated due to outside activity; for example, if the database administrator commands a “fast” database shutdown, the backend will send a \texttt{NoticeResponse} indicating this fact before closing the connection. Accordingly, frontends should always be prepared to accept and display \texttt{NoticeResponse} messages, even when the connection is nominally idle.

\texttt{ParameterStatus} messages will be generated whenever the active value changes for any of the parameters the backend believes the frontend should know about. Most commonly this occurs in response to a \texttt{SET SQL} command executed by the frontend, and this case is effectively synchronous — but it is also possible for parameter status changes to occur because the administrator changed a configuration file and then sent the \texttt{SIGHUP} signal to the server. Also, if a \texttt{SET} command is rolled back, an appropriate \texttt{ParameterStatus} message will be generated to report the current effective value.

At present there is a hard-wired set of parameters for which \texttt{ParameterStatus} will be generated: they are \texttt{server_version}, \texttt{server_encoding}, \texttt{client_encoding}, \texttt{application_name}, \texttt{is_superuser}, \texttt{session_authorization}, \texttt{DateStyle}, \texttt{IntervalStyle}, \texttt{TimeZone}, \texttt{integer_datetimes}, and \texttt{standard_conforming_strings}. (\texttt{server_encoding}, \texttt{TimeZone}, and \texttt{integer_datetimes} were not reported by releases before 8.0; \texttt{standard_conforming_strings} was not reported by releases before 8.1; \texttt{IntervalStyle} was not reported by releases before 8.4; \texttt{application_name} was not reported by releases before 9.0.) Note that \texttt{server_version}, \texttt{server_encoding} and \texttt{integer_datetimes} are pseudo-parameters that cannot change after startup. This set might change in the future, or even become configurable. Accordingly, a frontend should simply ignore \texttt{ParameterStatus} for parameters that it does not understand or care about.

If a frontend issues a \texttt{LISTEN} command, then the backend will send a \texttt{NotificationResponse} message (not to be confused with \texttt{NoticeResponse}!) whenever a \texttt{NOTIFY} command is executed for the same
channel name.

**Note:** At present, NotificationResponse can only be sent outside a transaction, and thus it will not occur in the middle of a command-response series, though it might occur just before ReadyForQuery. It is unwise to design frontend logic that assumes that, however. Good practice is to be able to accept NotificationResponse at any point in the protocol.

### 49.2.7. Canceling Requests in Progress

During the processing of a query, the frontend might request cancellation of the query. The cancel request is not sent directly on the open connection to the backend for reasons of implementation efficiency: we don’t want to have the backend constantly checking for new input from the frontend during query processing. Cancel requests should be relatively infrequent, so we make them slightly cumbersome in order to avoid a penalty in the normal case.

To issue a cancel request, the frontend opens a new connection to the server and sends a CancelRequest message, rather than the StartupMessage message that would ordinarily be sent across a new connection. The server will process this request and then close the connection. For security reasons, no direct reply is made to the cancel request message.

A CancelRequest message will be ignored unless it contains the same key data (PID and secret key) passed to the frontend during connection start-up. If the request matches the PID and secret key for a currently executing backend, the processing of the current query is aborted. (In the existing implementation, this is done by sending a special signal to the backend process that is processing the query.)

The cancellation signal might or might not have any effect — for example, if it arrives after the backend has finished processing the query, then it will have no effect. If the cancellation is effective, it results in the current command being terminated early with an error message.

The upshot of all this is that for reasons of both security and efficiency, the frontend has no direct way to tell whether a cancel request has succeeded. It must continue to wait for the backend to respond to the query. Issuing a cancel simply improves the odds that the current query will finish soon, and improves the odds that it will fail with an error message instead of succeeding.

Since the cancel request is sent across a new connection to the server and not across the regular frontend/backend communication link, it is possible for the cancel request to be issued by any process, not just the frontend whose query is to be canceled. This might provide additional flexibility when building multiple-process applications. It also introduces a security risk, in that unauthorized persons might try to cancel queries. The security risk is addressed by requiring a dynamically generated secret key to be supplied in cancel requests.

### 49.2.8. Termination

The normal, graceful termination procedure is that the frontend sends a Terminate message and immediately closes the connection. On receipt of this message, the backend closes the connection and terminates.

In rare cases (such as an administrator-commanded database shutdown) the backend might disconnect without any frontend request to do so. In such cases the backend will attempt to send an error or notice message giving the reason for the disconnection before it closes the connection.
Other termination scenarios arise from various failure cases, such as core dump at one end or the other, loss of the communications link, loss of message-boundary synchronization, etc. If either frontend or backend sees an unexpected closure of the connection, it should clean up and terminate. The frontend has the option of launching a new backend by recontacting the server if it doesn’t want to terminate itself. Closing the connection is also advisable if an unrecognizable message type is received, since this probably indicates loss of message-boundary sync.

For either normal or abnormal termination, any open transaction is rolled back, not committed. One should note however that if a frontend disconnects while a non-SELECT query is being processed, the backend will probably finish the query before noticing the disconnection. If the query is outside any transaction block (BEGIN ... COMMIT sequence) then its results might be committed before the disconnection is recognized.

### 49.2.9. SSL Session Encryption

If PostgreSQL was built with SSL support, frontend/backend communications can be encrypted using SSL. This provides communication security in environments where attackers might be able to capture the session traffic. For more information on encrypting PostgreSQL sessions with SSL, see Section 17.9.

To initiate an SSL-encrypted connection, the frontend initially sends an SSLRequest message rather than a StartupMessage. The server then responds with a single byte containing S or N, indicating that it is willing or unwilling to perform SSL, respectively. The frontend might close the connection at this point if it is dissatisfied with the response. To continue after S, perform an SSL startup handshake (not described here, part of the SSL specification) with the server. If this is successful, continue with sending the usual StartupMessage. In this case the StartupMessage and all subsequent data will be SSL-encrypted. To continue after N, send the usual StartupMessage and proceed without encryption.

The frontend should also be prepared to handle an ErrorMessage response to SSLRequest from the server. This would only occur if the server predates the addition of SSL support to PostgreSQL. (Such servers are now very ancient, and likely do not exist in the wild anymore.) In this case the connection must be closed, but the frontend might choose to open a fresh connection and proceed without requesting SSL.

An initial SSLRequest can also be used in a connection that is being opened to send a CancelRequest message.

While the protocol itself does not provide a way for the server to force SSL encryption, the administrator can configure the server to reject unencrypted sessions as a byproduct of authentication checking.

### 49.3. Streaming Replication Protocol

To initiate streaming replication, the frontend sends the replication parameter in the startup message. A Boolean value of true tells the backend to go into walsender mode, wherein a small set of replication commands can be issued instead of SQL statements. Only the simple query protocol can be used in walsender mode. Passing database as the value instructs walsender to connect to the database specified in the dbname parameter, which will allow the connection to be used for logical replication from that database.

For the purpose of testing replication commands, you can make a replication connection via psql or any other libpq-using tool with a connection string including the replication option, e.g.:
psql "dbname=postgres replication=database" -c "IDENTIFY_SYSTEM;"

However it is often more useful to use pg_receivexlog (for physical replication) or pg_recvlogical (for logical replication).

The commands accepted in walsender mode are:

**IDENTIFY_SYSTEM**
Requests the server to identify itself. Server replies with a result set of a single row, containing four fields:

- **systemid**
  The unique system identifier identifying the cluster. This can be used to check that the base backup used to initialize the standby came from the same cluster.

- **timeline**
  Current TimelineID. Also useful to check that the standby is consistent with the master.

- **xlogpos**
  Current xlog flush location. Useful to get a known location in the transaction log where streaming can start.

- **dbname**
  Database connected to or NULL.

**TIMELINE_HISTORY tli**
Requests the server to send over the timeline history file for timeline tli. Server replies with a result set of a single row, containing two fields:

- **filename**
  Filename of the timeline history file, e.g. 00000002.history.

- **content**
  Contents of the timeline history file.

**CREATE_REPLICATION_SLOT slot_name \{ PHYSICAL \| LOGICAL output_plugin \}**
Create a physical or logical replication slot. See Section 25.2.6 for more about replication slots.

- **slot_name**
  The name of the slot to create. Must be a valid replication slot name (see Section 25.2.6.1).

- **output_plugin**
  The name of the output plugin used for logical decoding (see Section 46.6).

**START_REPLICATION \[ SLOT slot_name \] \[ PHYSICAL \| XXX/XXX \[ TIMELINE tli \] \]**
Instructs server to start streaming WAL, starting at WAL position XXX/XXX. If TIMELINE option is specified, streaming starts on timeline tli; otherwise, the server’s current timeline is selected. The server can reply with an error, e.g. if the requested section of WAL has already been recycled. On success, server responds with a CopyBothResponse message, and then starts to stream WAL to the frontend.
Chapter 49. Frontend/Backend Protocol

If a slot's name is provided via `slot_name`, it will be updated as replication progresses so that the server knows which WAL segments, and if `hot_standby_feedback` is on which transactions, are still needed by the standby.

If the client requests a timeline that's not the latest, but is part of the history of the server, the server will stream all the WAL on that timeline starting from the requested startpoint, up to the point where the server switched to another timeline. If the client requests streaming at exactly the end of an old timeline, the server responds immediately with CommandComplete without entering COPY mode.

After streaming all the WAL on a timeline that is not the latest one, the server will end streaming by exiting the COPY mode. When the client acknowledges this by also exiting COPY mode, the server sends a result set with one row and two columns, indicating the next timeline in this server’s history. The first column is the next timeline’s ID, and the second column is the XLOG position where the switch happened. Usually, the switch position is the end of the WAL that was streamed, but there are corner cases where the server can send some WAL from the old timeline that it has not itself replayed before promoting. Finally, the server sends CommandComplete message, and is ready to accept a new command.

WAL data is sent as a series of CopyData messages. (This allows other information to be intermixed; in particular the server can send an ErrorResponse message if it encounters a failure after beginning to stream.) The payload of each CopyData message from server to the client contains a message of one of the following formats:

XLogData (B)

Byte1('w')

Identifies the message as WAL data.

Int64

The starting point of the WAL data in this message.

Int64

The current end of WAL on the server.

Int64

The server’s system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte:

A section of the WAL data stream.

A single WAL record is never split across two XLogData messages. When a WAL record crosses a WAL page boundary, and is therefore already split using continuation records, it can be split at the page boundary. In other words, the first main WAL record and its continuation records can be sent in different XLogData messages.

Primary keepalive message (B)

Byte1('k')

Identifies the message as a sender keepalive.
Chapter 49. Frontend/Backend Protocol

Int64
The current end of WAL on the server.

Int64
The server’s system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte1
1 means that the client should reply to this message as soon as possible, to avoid a timeout disconnect. 0 otherwise.

The receiving process can send replies back to the sender at any time, using one of the following message formats (also in the payload of a CopyData message):

Standby status update (F)

Byte1(‘r’)
Identifies the message as a receiver status update.

Int64
The location of the last WAL byte + 1 received and written to disk in the standby.

Int64
The location of the last WAL byte + 1 flushed to disk in the standby.

Int64
The location of the last WAL byte + 1 applied in the standby.

Int64
The client’s system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte1
If 1, the client requests the server to reply to this message immediately. This can be used to ping the server, to test if the connection is still healthy.

Hot Standby feedback message (F)

Byte1(‘h’)
Identifies the message as a Hot Standby feedback message.

Int64
The client’s system clock at the time of transmission, as microseconds since midnight on 2000-01-01.
Int32
The standby’s current xmin. This may be 0, if the standby is sending notification that Hot Standby feedback will no longer be sent on this connection. Later non-zero messages may reinitiate the feedback mechanism.

Int32
The standby’s current epoch.

START_REPLICATION SLOT slot_name LOGICAL XXX/XXX [ (option_name [option_value] [, ... ]) ]
Instructs server to start streaming WAL for logical replication, starting at WAL position XXX/XXX. The server can reply with an error, e.g. if the requested section of WAL has already been recycled. On success, server responds with a CopyBothResponse message, and then starts to stream WAL to the frontend.

The messages inside the CopyBothResponse messages are of the same format documented for START_REPLICATION ... PHYSICAL.

The output plugin associated with the selected slot is used to process the output for streaming.

SLOT slot_name
The name of the slot to stream changes from. This parameter is required, and must correspond to an existing logical replication slot created with CREATE_REPLICATION_SLOT in LOGICAL mode.

XXX/XXX
The WAL position to begin streaming at.

option_name
The name of an option passed to the slot’s logical decoding plugin.

option_value
Optional value, in the form of a string constant, associated with the specified option.

DROP_REPLICATION_SLOT slot_name
Drops a replication slot, freeing any reserved server-side resources. If the slot is currently in use by an active connection, this command fails.

slot_name
The name of the slot to drop.

BASE_BACKUP [LABEL ‘label’] [PROGRESS] [FAST] [WAL] [NOWAIT] [MAX_RATE rate]
Instructs the server to start streaming a base backup. The system will automatically be put in backup mode before the backup is started, and taken out of it when the backup is complete. The following options are accepted:

LABEL ‘label’
Sets the label of the backup. If none is specified, a backup label of base backup will be used. The quoting rules for the label are the same as a standard SQL string with standard_conforming_strings turned on.
Chapter 49. Frontend/Backend Protocol

PROGRESS
Request information required to generate a progress report. This will send back an approximate size in the header of each tablespace, which can be used to calculate how far along the stream is done. This is calculated by enumerating all the file sizes once before the transfer is even started, and may as such have a negative impact on the performance - in particular it may take longer before the first data is streamed. Since the database files can change during the backup, the size is only approximate and may both grow and shrink between the time of approximation and the sending of the actual files.

FAST
Request a fast checkpoint.

WAL
Include the necessary WAL segments in the backup. This will include all the files between start and stop backup in the `pg_xlog` directory of the base directory tar file.

NOWAIT
By default, the backup will wait until the last required xlog segment has been archived, or emit a warning if log archiving is not enabled. Specifying `NOWAIT` disables both the waiting and the warning, leaving the client responsible for ensuring the required log is available.

MAX_RATE rate
Limit (throttle) the maximum amount of data transferred from server to client per unit of time. The expected unit is kilobytes per second. If this option is specified, the value must either be equal to zero or it must fall within the range from 32 kB through 1 GB (inclusive). If zero is passed or the option is not specified, no restriction is imposed on the transfer.

When the backup is started, the server will first send two ordinary result sets, followed by one or more CopyResponse results.

The first ordinary result set contains the starting position of the backup, in a single row with two columns. The first column contains the start position given in XLogRecPtr format, and the second column contains the corresponding timeline ID.

The second ordinary result set has one row for each tablespace. The fields in this row are:

spcoid
The oid of the tablespace, or NULL if it's the base directory.

spclocation
The full path of the tablespace directory, or NULL if it's the base directory.

size
The approximate size of the tablespace, if progress report has been requested; otherwise it's NULL.

After the second regular result set, one or more CopyResponse results will be sent, one for `PGDATA` and one for each additional tablespace other than `pg_default` and `pg_global`. The data in the CopyResponse results will be a tar format (following the “ustar interchange format” specified in the POSIX 1003.1-2008 standard) dump of the tablespace contents, except that the two trailing blocks of zeroes specified in the standard are omitted. After the tar data is complete,
a final ordinary result set will be sent, containing the WAL end position of the backup, in the same format as the start position.

The tar archive for the data directory and each tablespace will contain all files in the directories, regardless of whether they are PostgreSQL files or other files added to the same directory. The only excluded files are:

- `postmaster.pid`
- `postmaster.opts`
- various temporary files created during the operation of the PostgreSQL server
- `pg_xlog`, including subdirectories. If the backup is run with WAL files included, a synthesized version of `pg_xlog` will be included, but it will only contain the files necessary for the backup to work, not the rest of the contents.
- `pg_replslot` is copied as an empty directory.
- Files other than regular files and directories, such as symbolic links and special device files, are skipped. (Symbolic links in `pg_tblspc` are maintained.)

Owner, group and file mode are set if the underlying file system on the server supports it.

Once all tablespaces have been sent, a final regular result set will be sent. This result set contains the end position of the backup, given in XLogRecPtr format as a single column in a single row.

### 49.4. Message Data Types

This section describes the base data types used in messages.

**Int\(_n\)(i)**

An \(n\)-bit integer in network byte order (most significant byte first). If \(i\) is specified it is the exact value that will appear, otherwise the value is variable. Eg. Int16, Int32(42).

**Int\(_n\)[k]**

An array of \(k\) \(n\)-bit integers, each in network byte order. The array length \(k\) is always determined by an earlier field in the message. Eg. Int16[M].

**String(s)**

A null-terminated string (C-style string). There is no specific length limitation on strings. If \(s\) is specified it is the exact value that will appear, otherwise the value is variable. Eg. String, String("user").

**Byte\(_n\)(c)**

Exactly \(n\) bytes. If the field width \(n\) is not a constant, it is always determinable from an earlier field in the message. If \(c\) is specified it is the exact value. Eg. Byte2, Byte1("\n").

**Note:** There is no predefined limit on the length of a string that can be returned by the backend. Good coding strategy for a frontend is to use an expandable buffer so that anything that fits in memory can be accepted. If that’s not feasible, read the full string and discard trailing characters that don’t fit into your fixed-size buffer.
49.5. Message Formats

This section describes the detailed format of each message. Each is marked to indicate that it can be sent by a frontend (F), a backend (B), or both (F & B). Notice that although each message includes a byte count at the beginning, the message format is defined so that the message end can be found without reference to the byte count. This aids validity checking. (The CopyData message is an exception, because it forms part of a data stream; the contents of any individual CopyData message cannot be interpretable on their own.)

AuthenticationOk (B)

Byte1(‘R’)
Identifies the message as an authentication request.

Int32(8)
Length of message contents in bytes, including self.

Int32(0)
Specifies that the authentication was successful.

AuthenticationKerberosV5 (B)

Byte1(‘R’)
Identifies the message as an authentication request.

Int32(8)
Length of message contents in bytes, including self.

Int32(2)
Specifies that Kerberos V5 authentication is required.

AuthenticationCleartextPassword (B)

Byte1(‘R’)
Identifies the message as an authentication request.

Int32(8)
Length of message contents in bytes, including self.

Int32(3)
Specifies that a clear-text password is required.

AuthenticationMD5Password (B)

Byte1(‘R’)
Identifies the message as an authentication request.

Int32(12)
Length of message contents in bytes, including self.
Chapter 49. Frontend/Backend Protocol

Int32(5)
Specifies that an MD5-encrypted password is required.

Byte4
The salt to use when encrypting the password.

AuthenticationSCMCredential (B)

Byte1 (‘R’)
Identifies the message as an authentication request.

Int32(8)
Length of message contents in bytes, including self.

Int32(6)
Specifies that an SCM credentials message is required.

AuthenticationGSS (B)

Byte1 (‘R’)
Identifies the message as an authentication request.

Int32(8)
Length of message contents in bytes, including self.

Int32(7)
Specifies that GSSAPI authentication is required.

AuthenticationSSPI (B)

Byte1 (‘R’)
Identifies the message as an authentication request.

Int32(8)
Length of message contents in bytes, including self.

Int32(9)
Specifies that SSPI authentication is required.

AuthenticationGSSContinue (B)

Byte1 (‘R’)
Identifies the message as an authentication request.

Int32
Length of message contents in bytes, including self.
Int32(8)
  Specifies that this message contains GSSAPI or SSPI data.

Byte
  GSSAPI or SSPI authentication data.

BackendKeyData (B)

Byte1('K')
  Identifies the message as cancellation key data. The frontend must save these values if it
  wishes to be able to issue CancelRequest messages later.

Int32(12)
  Length of message contents in bytes, including self.

Int32
  The process ID of this backend.

Int32
  The secret key of this backend.

Bind (F)

Byte1('B')
  Identifies the message as a Bind command.

Int32
  Length of message contents in bytes, including self.

String
  The name of the destination portal (an empty string selects the unnamed portal).

String
  The name of the source prepared statement (an empty string selects the unnamed prepared
  statement).

Int16
  The number of parameter format codes that follow (denoted $c$ below). This can be zero to
  indicate that there are no parameters or that the parameters all use the default format (text);
  or one, in which case the specified format code is applied to all parameters; or it can equal
  the actual number of parameters.

Int16[$c$]
  The parameter format codes. Each must presently be zero (text) or one (binary).

Int16
  The number of parameter values that follow (possibly zero). This must match the number
  of parameters needed by the query.

Next, the following pair of fields appear for each parameter:
Int32
The length of the parameter value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL parameter value. No value bytes follow in the NULL case.

Byte\text{n}
The value of the parameter, in the format indicated by the associated format code. \text{n} is the above length.

After the last parameter, the following fields appear:

Int16
The number of result-column format codes that follow (denoted \text{R} below). This can be zero to indicate that there are no result columns or that the result columns should all use the default format (text); or one, in which case the specified format code is applied to all result columns (if any); or it can equal the actual number of result columns of the query.

Int16[\text{R}]
The result-column format codes. Each must presently be zero (text) or one (binary).

BindComplete (B)

Byte1(‘2’)
Identifies the message as a Bind-complete indicator.

Int32(4)
Length of message contents in bytes, including self.

CancelRequest (F)

Int32(16)
Length of message contents in bytes, including self.

Int32(80877102)
The cancel request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5678 in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

Int32
The process ID of the target backend.

Int32
The secret key for the target backend.

Close (F)

Byte1(‘C’)
Identifies the message as a Close command.
Int32
Length of message contents in bytes, including self.

Byte1
's' to close a prepared statement; or 'p' to close a portal.

String
The name of the prepared statement or portal to close (an empty string selects the unnamed prepared statement or portal).

CloseComplete (B)

Byte1('3')
Identifies the message as a Close-complete indicator.

Int32(4)
Length of message contents in bytes, including self.

CommandComplete (B)

Byte1('C')
Identifies the message as a command-completed response.

Int32
Length of message contents in bytes, including self.

String
The command tag. This is usually a single word that identifies which SQL command was completed.

For an INSERT command, the tag is INSERT oid rows, where rows is the number of rows inserted. oid is the object ID of the inserted row if rows is 1 and the target table has OIDs; otherwise oid is 0.

For a DELETE command, the tag is DELETE rows where rows is the number of rows deleted.

For an UPDATE command, the tag is UPDATE rows where rows is the number of rows updated.

For a SELECT or CREATE TABLE AS command, the tag is SELECT rows where rows is the number of rows retrieved.

For a MOVE command, the tag is MOVE rows where rows is the number of rows the cursor’s position has been changed by.

For a FETCH command, the tag is FETCH rows where rows is the number of rows that have been retrieved from the cursor.

For a COPY command, the tag is COPY rows where rows is the number of rows copied.
(Note: the row count appears only in PostgreSQL 8.2 and later.)
CopyData (F & B)

Byte1('d')
Identifies the message as COPY data.

Int32
Length of message contents in bytes, including self.

Byte
Data that forms part of a COPY data stream. Messages sent from the backend will always correspond to single data rows, but messages sent by frontends might divide the data stream arbitrarily.

CopyDone (F & B)

Byte1('c')
Identifies the message as a COPY-complete indicator.

Int32(4)
Length of message contents in bytes, including self.

CopyFail (F)

Byte1('f')
Identifies the message as a COPY-failure indicator.

Int32
Length of message contents in bytes, including self.

CopyInResponse (B)

Byte1('G')
Identifies the message as a Start Copy In response. The frontend must now send copy-in data (if not prepared to do so, send a CopyFail message).

Int32
Length of message contents in bytes, including self.

Int8
0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16
The number of columns in the data to be copied (denoted N below).
Int16\[N\]
The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

CopyOutResponse (B)

Byte1(‘H’)
Identifies the message as a Start Copy Out response. This message will be followed by copy-out data.

Int32
Length of message contents in bytes, including self.

Int8
0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16
The number of columns in the data to be copied (denoted \(N\) below).

Int16[\(N\)]
The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

CopyBothResponse (B)

Byte1(‘W’)
Identifies the message as a Start Copy Both response. This message is used only for Streaming Replication.

Int32
Length of message contents in bytes, including self.

Int8
0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16
The number of columns in the data to be copied (denoted \(N\) below).

Int16[\(N\)]
The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.
DataRow (B)

Byte1('D')
   Identifies the message as a data row.
Int32
   Length of message contents in bytes, including self.
Int16
   The number of column values that follow (possibly zero).

Next, the following pair of fields appear for each column:

Int32
   The length of the column value, in bytes (this count does not include itself). Can be zero.
   As a special case, -1 indicates a NULL column value. No value bytes follow in the NULL case.

Byte n
   The value of the column, in the format indicated by the associated format code. n is the above length.

Describe (F)

Byte1('D')
   Identifies the message as a Describe command.
Int32
   Length of message contents in bytes, including self.
Byte1
   'S' to describe a prepared statement; or 'P' to describe a portal.
String
   The name of the prepared statement or portal to describe (an empty string selects the unnamed prepared statement or portal).

EmptyQueryResponse (B)

Byte1('I')
   Identifies the message as a response to an empty query string. (This substitutes for CommandComplete.)
Int32(4)
   Length of message contents in bytes, including self.
ErrorResponse (B)

Byte1(‘E’)
Identifies the message as an error.

Int32
Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:

Byte1
A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in Section 49.6. Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

String
The field value.

Execute (F)

Byte1(‘E’)
Identifies the message as an Execute command.

Int32
Length of message contents in bytes, including self.

String
The name of the portal to execute (an empty string selects the unnamed portal).

Int32
Maximum number of rows to return, if portal contains a query that returns rows (ignored otherwise). Zero denotes “no limit”.

Flush (F)

Byte1(‘H’)
Identifies the message as a Flush command.

Int32(4)
Length of message contents in bytes, including self.

FunctionCall (F)

Byte1(‘F’)
Identifies the message as a function call.

Int32
Length of message contents in bytes, including self.
Int32
Specifies the object ID of the function to call.

Int16
The number of argument format codes that follow (denoted C below). This can be zero to indicate that there are no arguments or that the arguments all use the default format (text); or one, in which case the specified format code is applied to all arguments; or it can equal the actual number of arguments.

Int16[C]
The argument format codes. Each must presently be zero (text) or one (binary).

Int16
Specifies the number of arguments being supplied to the function.

Next, the following pair of fields appear for each argument:

Int32
The length of the argument value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL argument value. No value bytes follow in the NULL case.

Byte
The value of the argument, in the format indicated by the associated format code. n is the above length.

After the last argument, the following field appears:

Int16
The format code for the function result. Must presently be zero (text) or one (binary).

FunctionCallResponse (B)

Byte1('V')
Identifies the message as a function call result.

Int32
Length of message contents in bytes, including self.

Int32
The length of the function result value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL function result. No value bytes follow in the NULL case.

Byte
The value of the function result, in the format indicated by the associated format code. n is the above length.
NegotiateProtocolVersion (B)

Byte1(‘v’)
Identifies the message as a protocol version negotiation message.

Int32
Length of message contents in bytes, including self.

Int32
Newest minor protocol version supported by the server for the major protocol version requested by the client.

Int32
Number of protocol options not recognized by the server.

Then, for protocol option not recognized by the server, there is the following:

String
The option name.

NoData (B)

Byte1(‘n’)
Identifies the message as a no-data indicator.

Int32(4)
Length of message contents in bytes, including self.

NoticeResponse (B)

Byte1(‘N’)
Identifies the message as a notice.

Int32
Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:

Byte1
A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in Section 49.6. Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

String
The field value.
NotificationResponse (B)

Byte1(’A’)
Identifies the message as a notification response.

Int32
Length of message contents in bytes, including self.

Int32
The process ID of the notifying backend process.

String
The name of the channel that the notify has been raised on.

String
The “payload” string passed from the notifying process.

ParameterDescription (B)

Byte1(’t’)
Identifies the message as a parameter description.

Int32
Length of message contents in bytes, including self.

Int16
The number of parameters used by the statement (can be zero).

Then, for each parameter, there is the following:

Int32
Specifies the object ID of the parameter data type.

ParameterStatus (B)

Byte1(’S’)
Identifies the message as a run-time parameter status report.

Int32
Length of message contents in bytes, including self.

String
The name of the run-time parameter being reported.

String
The current value of the parameter.
Parse (F)

Byte1(‘P’)  
Identifies the message as a Parse command.

Int32  
Length of message contents in bytes, including self.

String  
The name of the destination prepared statement (an empty string selects the unnamed prepared statement).

String  
The query string to be parsed.

Int16  
The number of parameter data types specified (can be zero). Note that this is not an indication of the number of parameters that might appear in the query string, only the number that the frontend wants to prespecify types for.

Then, for each parameter, there is the following:

Int32  
Specifies the object ID of the parameter data type. Placing a zero here is equivalent to leaving the type unspecified.

ParseComplete (B)

Byte1(‘1’)  
Identifies the message as a Parse-complete indicator.

Int32(4)  
Length of message contents in bytes, including self.

PasswordMessage (F)

Byte1(‘p’)  
Identifies the message as a password response. Note that this is also used for GSSAPI and SSPI response messages (which is really a design error, since the contained data is not a null-terminated string in that case, but can be arbitrary binary data).

Int32  
Length of message contents in bytes, including self.

String  
The password (encrypted, if requested).
Chapter 49. Frontend/Backend Protocol

PortalSuspended (B)

Byte1('s')
Identifies the message as a portal-suspended indicator. Note this only appears if an Execute
message’s row-count limit was reached.

Int32(4)
Length of message contents in bytes, including self.

Query (F)

Byte1('Q')
Identifies the message as a simple query.

Int32
Length of message contents in bytes, including self.

String
The query string itself.

ReadyForQuery (B)

Byte1('Z')
Identifies the message type. ReadyForQuery is sent whenever the backend is ready for a
new query cycle.

Int32(5)
Length of message contents in bytes, including self.

Byte1
Current backend transaction status indicator. Possible values are 'I' if idle (not in a transac-
tion block); 'T' if in a transaction block; or 'E' if in a failed transaction block (queries will
be rejected until block is ended).

RowDescription (B)

Byte1('T')
Identifies the message as a row description.

Int32
Length of message contents in bytes, including self.

Int16
Specifies the number of fields in a row (can be zero).

Then, for each field, there is the following:

String
The field name.
Chapter 49. Frontend/Backend Protocol

Int32
If the field can be identified as a column of a specific table, the object ID of the table; otherwise zero.

Int16
If the field can be identified as a column of a specific table, the attribute number of the column; otherwise zero.

Int32
The object ID of the field’s data type.

Int16
The data type size (see `pg_type.typlen`). Note that negative values denote variable-width types.

Int32
The type modifier (see `pg_attribute.atttypmod`). The meaning of the modifier is type-specific.

Int16
The format code being used for the field. Currently will be zero (text) or one (binary). In a RowDescription returned from the statement variant of Describe, the format code is not yet known and will always be zero.

SSLRequest (F)

Int32(8)
Length of message contents in bytes, including self.

Int32(80877103)
The SSL request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5679 in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

StartupMessage (F)

Int32
Length of message contents in bytes, including self.

Int32(196608)
The protocol version number. The most significant 16 bits are the major version number (3 for the protocol described here). The least significant 16 bits are the minor version number (0 for the protocol described here).

The protocol version number is followed by one or more pairs of parameter name and value strings. A zero byte is required as a terminator after the last name/value pair. Parameters can appear in any order. `user` is required, others are optional. Each parameter is specified as:
Chapter 49. Frontend/Backend Protocol

String

The parameter name. Currently recognized names are:

user

The database user name to connect as. Required; there is no default.

database

The database to connect to. Defaults to the user name.

options

Command-line arguments for the backend. (This is deprecated in favor of setting individual run-time parameters.)

In addition to the above, other parameters may be listed. Parameter names beginning with _pq_ are reserved for use as protocol extensions, while others are treated as run-time parameters to be set at backend start time. Such settings will be applied during backend start (after parsing the command-line arguments if any) and will act as session defaults.

String

The parameter value.

Sync (F)

Byte1(‘S’)

Identifies the message as a Sync command.

Int32(4)

Length of message contents in bytes, including self.

Terminate (F)

Byte1(‘X’)

Identifies the message as a termination.

Int32(4)

Length of message contents in bytes, including self.

49.6. Error and Notice Message Fields

This section describes the fields that can appear in ErrorResponse and NoticeResponse messages. Each field type has a single-byte identification token. Note that any given field type should appear at most once per message.

S

Severity: the field contents are ERROR, FATAL, or PANIC (in an error message), or WARNING, NOTICE, DEBUG, INFO, or LOG (in a notice message), or a localized translation of one of these. Always present.
Code: the SQLSTATE code for the error (see Appendix A). Not localizable. Always present.

Message: the primary human-readable error message. This should be accurate but terse (typically one line). Always present.

Detail: an optional secondary error message carrying more detail about the problem. Might run to multiple lines.

Hint: an optional suggestion what to do about the problem. This is intended to differ from Detail in that it offers advice (potentially inappropriate) rather than hard facts. Might run to multiple lines.

Position: the field value is a decimal ASCII integer, indicating an error cursor position as an index into the original query string. The first character has index 1, and positions are measured in characters not bytes.

Internal position: this is defined the same as the Position field, but it is used when the cursor position refers to an internally generated command rather than the one submitted by the client. The Internal query field will always appear when this field appears.

Internal query: the text of a failed internally-generated command. This could be, for example, a SQL query issued by a PL/pgSQL function.

Where: an indication of the context in which the error occurred. Presently this includes a call stack traceback of active procedural language functions and internally-generated queries. The trace is one entry per line, most recent first.

Schema name: if the error was associated with a specific database object, the name of the schema containing that object, if any.

Table name: if the error was associated with a specific table, the name of the table. (Refer to the schema name field for the name of the table’s schema.)

Column name: if the error was associated with a specific table column, the name of the column. (Refer to the schema and table name fields to identify the table.)

Data type name: if the error was associated with a specific data type, the name of the data type. (Refer to the schema name field for the name of the data type’s schema.)
Constraint name: if the error was associated with a specific constraint, the name of the constraint. Refer to fields listed above for the associated table or domain. (For this purpose, indexes are treated as constraints, even if they weren’t created with constraint syntax.)

File: the file name of the source-code location where the error was reported.

Line: the line number of the source-code location where the error was reported.

Routine: the name of the source-code routine reporting the error.

Note: The fields for schema name, table name, column name, data type name, and constraint name are supplied only for a limited number of error types; see Appendix A. Frontends should not assume that the presence of any of these fields guarantees the presence of another field. Core error sources observe the interrelationships noted above, but user-defined functions may use these fields in other ways. In the same vein, clients should not assume that these fields denote contemporary objects in the current database.

The client is responsible for formatting displayed information to meet its needs; in particular it should break long lines as needed. Newline characters appearing in the error message fields should be treated as paragraph breaks, not line breaks.

49.7. Summary of Changes since Protocol 2.0

This section provides a quick checklist of changes, for the benefit of developers trying to update existing client libraries to protocol 3.0.

The initial startup packet uses a flexible list-of-strings format instead of a fixed format. Notice that session default values for run-time parameters can now be specified directly in the startup packet. (Actually, you could do that before using the options field, but given the limited width of options and the lack of any way to quote whitespace in the values, it wasn’t a very safe technique.)

All messages now have a length count immediately following the message type byte (except for startup packets, which have no type byte). Also note that PasswordMessage now has a type byte.

ErrorResponse and NoticeResponse (‘E’ and ‘N’) messages now contain multiple fields, from which the client code can assemble an error message of the desired level of verbosity. Note that individual fields will typically not end with a newline, whereas the single string sent in the older protocol always did.

The ReadyForQuery (‘Z’) message includes a transaction status indicator.

The distinction between BinaryRow and DataRow message types is gone; the single DataRow message type serves for returning data in all formats. Note that the layout of DataRow has changed to make it easier to parse. Also, the representation of binary values has changed: it is no longer directly tied to the server’s internal representation.

There is a new “extended query” sub-protocol, which adds the frontend message types Parse, Bind, Execute, Describe, Close, Flush, and Sync, and the backend message types ParseComplete, BindComplete, PortalSuspended, ParameterDescription, NoData, and CloseComplete. Existing clients do
not have to concern themselves with this sub-protocol, but making use of it might allow improvements in performance or functionality.

COPY data is now encapsulated into CopyData and CopyDone messages. There is a well-defined way to recover from errors during COPY. The special "\." last line is not needed anymore, and is not sent during COPY OUT. (It is still recognized as a terminator during COPY IN, but its use is deprecated and will eventually be removed.) Binary COPY is supported. The CopyInResponse and CopyOutResponse messages include fields indicating the number of columns and the format of each column.

The layout of FunctionCall and FunctionCallResponse messages has changed. FunctionCall can now support passing NULL arguments to functions. It also can handle passing parameters and retrieving results in either text or binary format. There is no longer any reason to consider FunctionCall a potential security hole, since it does not offer direct access to internal server data representations.

The backend sends ParameterStatus (‘S’) messages during connection startup for all parameters it considers interesting to the client library. Subsequently, a ParameterStatus message is sent whenever the active value changes for any of these parameters.

The RowDescription (‘T’) message carries new table OID and column number fields for each column of the described row. It also shows the format code for each column.

The CursorResponse (‘P’) message is no longer generated by the backend.

The NotificationResponse (‘A’) message has an additional string field, which can carry a “payload” string passed from the NOTIFY event sender.

The EmptyQueryResponse (‘I’) message used to include an empty string parameter; this has been removed.
Chapter 50. PostgreSQL Coding Conventions

50.1. Formatting

Source code formatting uses 4 column tab spacing, with tabs preserved (i.e., tabs are not expanded to spaces). Each logical indentation level is one additional tab stop.

Layout rules (brace positioning, etc) follow BSD conventions. In particular, curly braces for the controlled blocks of if, while, switch, etc go on their own lines.

Limit line lengths so that the code is readable in an 80-column window. (This doesn’t mean that you must never go past 80 columns. For instance, breaking a long error message string in arbitrary places just to keep the code within 80 columns is probably not a net gain in readability.)

Do not use C++ style comments ( // comments). Strict ANSI C compilers do not accept them. For the same reason, do not use C++ extensions such as declaring new variables mid-block.

The preferred style for multi-line comment blocks is

/*
 * comment text begins here
 * and continues here
 */

Note that comment blocks that begin in column 1 will be preserved as-is by pgindent, but it will re-flow indented comment blocks as though they were plain text. If you want to preserve the line breaks in an indented block, add dashes like this:

/*----------
 * comment text begins here
 * and continues here
 ----------*/

While submitted patches do not absolutely have to follow these formatting rules, it’s a good idea to do so. Your code will get run through pgindent before the next release, so there’s no point in making it look nice under some other set of formatting conventions. A good rule of thumb for patches is “make the new code look like the existing code around it”.

The src/tools directory contains sample settings files that can be used with the emacs, xemacs or vim editors to help ensure that they format code according to these conventions.

The text browsing tools more and less can be invoked as:

more -x4
less -x4

to make them show tabs appropriately.
50.2. Reporting Errors Within the Server

Error, warning, and log messages generated within the server code should be created using *ereport*, or its older cousin *elog*. The use of this function is complex enough to require some explanation.

There are two required elements for every message: a severity level (ranging from *DEBUG* to *PANIC*) and a primary message text. In addition there are optional elements, the most common of which is an error identifier code that follows the SQL spec’s SQLSTATE conventions. *ereport* itself is just a shell function, that exists mainly for the syntactic convenience of making message generation look like a function call in the C source code. The only parameter accepted directly by *ereport* is the severity level. The primary message text and any optional message elements are generated by calling auxiliary functions, such as *errmsg*, within the *ereport* call.

A typical call to *ereport* might look like this:

```
ereport(ERROR,
    (errcode(ERRCODE_DIVISION_BY_ZERO),
     errmsg("division by zero")));
```

This specifies error severity level *ERROR* (a run-of-the-mill error). The *errcode* call specifies the SQLSTATE error code using a macro defined in *src/include/utils/errcodes.h*. The *errmsg* call provides the primary message text. Notice the extra set of parentheses surrounding the auxiliary function calls — these are annoying but syntactically necessary.

Here is a more complex example:

```
ereport(ERROR,
    (errcode(ERRCODE_AMBIGUOUS_FUNCTION),
     errmsg("function $s is not unique",
           func_signature_string(funcname, nargs, 
                               NIL, actual_arg_types)),
     errhint("Unable to choose a best candidate function. 
             "You might need to add explicit typecasts.")));}
```

This illustrates the use of format codes to embed run-time values into a message text. Also, an optional “hint” message is provided.

If the severity level is *ERROR* or higher, *ereport* aborts the execution of the user-defined function and does not return to the caller. If the severity level is lower than *ERROR*, *ereport* returns normally.

The available auxiliary routines for *ereport* are:

- *errcode(sqlerrcode)* specifies the SQLSTATE error identifier code for the condition. If this routine is not called, the error identifier defaults to *ERRCODE_INTERNAL_ERROR* when the error severity level is *ERROR* or higher, *ERRCODE_WARNING* when the error level is *WARNING*, otherwise (for *NOTICE* and below) *ERRCODE_SUCCESSFUL_COMPLETION*. While these defaults are often convenient, always think whether they are appropriate before omitting the *errcode()* call.

- *errmsg(const char *msg, ...)* specifies the primary error message text, and possibly run-time values to insert into it. Insertions are specified by *sprintf*-style format codes. In addition to the standard format codes accepted by *sprintf*, the format code %m can be used to insert the error message returned by *strerror* for the current value of *errno*.1 %m does not require any corresponding entry in the parameter list for *errmsg*. Note that the message string will be run through *gettext* for possible localization before format codes are processed.

---

1. That is, the value that was current when the *ereport* call was reached; changes of *errno* within the auxiliary reporting routines will not affect it. That would not be true if you were to write *strerror(errno)* explicitly in *errmsg*’s parameter list; accordingly, do not do so.
• `errmsg_internal(const char *msg, ...)` is the same as `errmsg`, except that the message string will not be translated nor included in the internationalization message dictionary. This should be used for “cannot happen” cases that are probably not worth expending translation effort on.

• `errmsg_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)` is like `errmsg`, but with support for various plural forms of the message. `fmt_singular` is the English singular format, `fmt_plural` is the English plural format, `n` is the integer value that determines which plural form is needed, and the remaining arguments are formatted according to the selected format string. For more information see Section 51.2.2.

• `errdetail(const char *msg, ...)` supplies an optional “detail” message; this is to be used when there is additional information that seems inappropriate to put in the primary message. The message string is processed in just the same way as for `errmsg`.

• `errdetail_internal(const char *msg, ...)` is the same as `errdetail`, except that the message string will not be translated nor included in the internationalization message dictionary. This should be used for detail messages that are not worth expending translation effort on, for instance because they are too technical to be useful to most users.

• `errdetail_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)` is like `errdetail`, but with support for various plural forms of the message. For more information see Section 51.2.2.

• `errdetail_log(const char *msg, ...)` is the same as `errdetail` except that this string goes only to the server log, never to the client. If both `errdetail` (or one of its equivalents above) and `errdetail_log` are used then one string goes to the client and the other to the log. This is useful for error details that are too security-sensitive or too bulky to include in the report sent to the client.

• `errdetail_log_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)` is like `errdetail_log`, but with support for various plural forms of the message. For more information see Section 51.2.2.

• `errhint(const char *msg, ...)` supplies an optional “hint” message; this is to be used when offering suggestions about how to fix the problem, as opposed to factual details about what went wrong. The message string is processed in just the same way as for `errmsg`.

• `errcontext(const char *msg, ...)` is not normally called directly from an `ereport` message site; rather it is used in `error_context_stack` callback functions to provide information about the context in which an error occurred, such as the current location in a PL function. The message string is processed in just the same way as for `errmsg`. Unlike the other auxiliary functions, this can be called more than once per `ereport` call; the successive strings thus supplied are concatenated with separating newlines.

• `errposition(int cursorpos)` specifies the textual location of an error within a query string. Currently it is only useful for errors detected in the lexical and syntactic analysis phases of query processing.

• `errtable(Relation rel)` specifies a relation whose name and schema name should be included as auxiliary fields in the error report.

• `errtablecol(Relation rel, int attnum)` specifies a column whose name, table name, and schema name should be included as auxiliary fields in the error report.

• `errtableconstraint(Relation rel, const char *conname)` specifies a table constraint whose name, table name, and schema name should be included as auxiliary fields in the error report. Indexes should be considered to be constraints for this purpose, whether or not they have an associated `pg_constraint` entry. Be careful to pass the underlying heap relation, not the index itself, as `rel`. 

1917
Chapter 50. PostgreSQL Coding Conventions

- `errdatatype(Oid datatypeOid)` specifies a data type whose name and schema name should be included as auxiliary fields in the error report.
- `errdomainconstraint(Oid datatypeOid, const char *conname)` specifies a domain constraint whose name, domain name, and schema name should be included as auxiliary fields in the error report.
- `errcode_for_file_access()` is a convenience function that selects an appropriate SQLSTATE error identifier for a failure in a file-access-related system call. It uses the saved `errno` to determine which error code to generate. Usually this should be used in combination with `%m` in the primary error message text.
- `errcode_for_socket_access()` is a convenience function that selects an appropriate SQLSTATE error identifier for a failure in a socket-related system call.
- `errhidestmt(bool hide_stmt)` can be called to specify suppression of the `STATEMENT:portion of a message in the postmaster log. Generally this is appropriate if the message text includes the current statement already.

**Note:** At most one of the functions `errtable`, `errtablecol`, `errtableconstraint`, `errdatatype`, or `errdomainconstraint` should be used in an `ereport` call. These functions exist to allow applications to extract the name of a database object associated with the error condition without having to examine the potentially-localized error message text. These functions should be used in error reports for which it's likely that applications would wish to have automatic error handling. As of PostgreSQL 9.3, complete coverage exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

There is an older function `elog` that is still heavily used. An `elog` call:

```
elog(level, "format string", ...);
```

is exactly equivalent to:

```
ereport(level, (errmsg_internal("format string", ...)));
```

Notice that the SQLSTATE error code is always defaulted, and the message string is not subject to translation. Therefore, `elog` should be used only for internal errors and low-level debug logging. Any message that is likely to be of interest to ordinary users should go through `ereport`. Nonetheless, there are enough internal “cannot happen” error checks in the system that `elog` is still widely used; it is preferred for those messages for its notational simplicity.

Advice about writing good error messages can be found in Section 50.3.

### 50.3. Error Message Style Guide

This style guide is offered in the hope of maintaining a consistent, user-friendly style throughout all the messages generated by PostgreSQL.

#### 50.3.1. What Goes Where

The primary message should be short, factual, and avoid reference to implementation details such as specific function names. “Short” means “should fit on one line under normal conditions”. Use a detail
message if needed to keep the primary message short, or if you feel a need to mention implementation
details such as the particular system call that failed. Both primary and detail messages should be
factual. Use a hint message for suggestions about what to do to fix the problem, especially if the
suggestion might not always be applicable.

For example, instead of:

IpcMemoryCreate: shmget(key=%d, size=%u, 0%o) failed: %m

(plus a long addendum that is basically a hint)

write:

Primary: could not create shared memory segment: %m
Detail: Failed syscall was shmget(key=%d, size=%u, 0%o).
Hint: the addendum

Rationale: keeping the primary message short helps keep it to the point, and lets clients lay out screen
space on the assumption that one line is enough for error messages. Detail and hint messages can be
relegated to a verbose mode, or perhaps a pop-up error-details window. Also, details and hints would
normally be suppressed from the server log to save space. Reference to implementation details is best
avoided since users don’t know the details anyway.

50.3.2. Formatting

Don’t put any specific assumptions about formatting into the message texts. Expect clients and the
server log to wrap lines to fit their own needs. In long messages, newline characters (\n) can be used
to indicate suggested paragraph breaks. Don’t end a message with a newline. Don’t use tabs or other
formatting characters. (In error context displays, newlines are automatically added to separate levels
of context such as function calls.)

Rationale: Messages are not necessarily displayed on terminal-type displays. In GUI displays or
browsers these formatting instructions are at best ignored.

50.3.3. Quotation Marks

English text should use double quotes when quoting is appropriate. Text in other languages should
consistently use one kind of quotes that is consistent with publishing customs and computer output of
other programs.

Rationale: The choice of double quotes over single quotes is somewhat arbitrary, but tends to be the
preferred use. Some have suggested choosing the kind of quotes depending on the type of object
according to SQL conventions (namely, strings single quoted, identifiers double quoted). But this is
a language-internal technical issue that many users aren’t even familiar with, it won’t scale to other
kinds of quoted terms, it doesn’t translate to other languages, and it’s pretty pointless, too.

50.3.4. Use of Quotes

Use quotes always to delimit file names, user-supplied identifiers, and other variables that might
contain words. Do not use them to mark up variables that will not contain words (for example, operator
names).
There are functions in the backend that will double-quote their own output at need (for example, `format_type_be()`). Do not put additional quotes around the output of such functions.

Rationale: Objects can have names that create ambiguity when embedded in a message. Be consistent about denoting where a plugged-in name starts and ends. But don’t clutter messages with unnecessary or duplicate quote marks.

### 50.3.5. Grammar and Punctuation

The rules are different for primary error messages and for detail/hint messages:

Primary error messages: Do not capitalize the first letter. Do not end a message with a period. Do not even think about ending a message with an exclamation point.

Detail and hint messages: Use complete sentences, and end each with a period. Capitalize the first word of sentences. Put two spaces after the period if another sentence follows (for English text; might be inappropriate in other languages).

Error context strings: Do not capitalize the first letter and do not end the string with a period. Context strings should normally not be complete sentences.

Rationale: Avoiding punctuation makes it easier for client applications to embed the message into a variety of grammatical contexts. Often, primary messages are not grammatically complete sentences anyway. (And if they’re long enough to be more than one sentence, they should be split into primary and detail parts.) However, detail and hint messages are longer and might need to include multiple sentences. For consistency, they should follow complete-sentence style even when there’s only one sentence.

### 50.3.6. Upper Case vs. Lower Case

Use lower case for message wording, including the first letter of a primary error message. Use upper case for SQL commands and key words if they appear in the message.

Rationale: It’s easier to make everything look more consistent this way, since some messages are complete sentences and some not.

### 50.3.7. Avoid Passive Voice

Use the active voice. Use complete sentences when there is an acting subject (“A could not do B”). Use telegram style without subject if the subject would be the program itself; do not use “I” for the program.

Rationale: The program is not human. Don’t pretend otherwise.

### 50.3.8. Present vs. Past Tense

Use past tense if an attempt to do something failed, but could perhaps succeed next time (perhaps after fixing some problem). Use present tense if the failure is certainly permanent.

There is a nontrivial semantic difference between sentences of the form:

`could not open file "%s": %m`
and:

```c
cannot open file "%s"
```

The first one means that the attempt to open the file failed. The message should give a reason, such as “disk full” or “file doesn’t exist”. The past tense is appropriate because next time the disk might not be full anymore or the file in question might exist.

The second form indicates that the functionality of opening the named file does not exist at all in the program, or that it’s conceptually impossible. The present tense is appropriate because the condition will persist indefinitely.

Rationale: Granted, the average user will not be able to draw great conclusions merely from the tense of the message, but since the language provides us with a grammar we should use it correctly.

### 50.3.9. Type of the Object

When citing the name of an object, state what kind of object it is.

Rationale: Otherwise no one will know what “foo.bar.baz” refers to.

### 50.3.10. Brackets

Square brackets are only to be used (1) in command synopses to denote optional arguments, or (2) to denote an array subscript.

Rationale: Anything else does not correspond to widely-known customary usage and will confuse people.

### 50.3.11. Assembling Error Messages

When a message includes text that is generated elsewhere, embed it in this style:

```c
could not open file %s: %m
```

Rationale: It would be difficult to account for all possible error codes to paste this into a single smooth sentence, so some sort of punctuation is needed. Putting the embedded text in parentheses has also been suggested, but it’s unnatural if the embedded text is likely to be the most important part of the message, as is often the case.

### 50.3.12. Reasons for Errors

Messages should always state the reason why an error occurred. For example:

BAD:   `could not open file %s`
BETTER: `could not open file %s (I/O failure)`

If no reason is known you better fix the code.
50.3.13. Function Names

Don’t include the name of the reporting routine in the error text. We have other mechanisms for finding that out when needed, and for most users it’s not helpful information. If the error text doesn’t make as much sense without the function name, reword it.

BAD:   pg_atoi: error in "z": cannot parse "z"
BETTER: invalid input syntax for integer: "z"

Avoid mentioning called function names, either; instead say what the code was trying to do:

BAD:   open() failed: %m
BETTER: could not open file %s: %m

If it really seems necessary, mention the system call in the detail message. (In some cases, providing the actual values passed to the system call might be appropriate information for the detail message.)

Rationale: Users don’t know what all those functions do.

50.3.14. Tricky Words to Avoid

Unable. “Unable” is nearly the passive voice. Better use “cannot” or “could not”, as appropriate.

Bad. Error messages like “bad result” are really hard to interpret intelligently. It’s better to write why the result is “bad”, e.g., “invalid format”.

Illegal. “Illegal” stands for a violation of the law, the rest is “invalid”. Better yet, say why it’s invalid.

Unknown. Try to avoid “unknown”. Consider “error: unknown response”. If you don’t know what the response is, how do you know it’s erroneous? “Unrecognized” is often a better choice. Also, be sure to include the value being complained of.

BAD:   unknown node type
BETTER: unrecognized node type: 42

Find vs. Exists. If the program uses a nontrivial algorithm to locate a resource (e.g., a path search) and that algorithm fails, it is fair to say that the program couldn’t “find” the resource. If, on the other hand, the expected location of the resource is known but the program cannot access it there then say that the resource doesn’t “exist”. Using “find” in this case sounds weak and confuses the issue.

May vs. Can vs. Might. “May” suggests permission (e.g., “You may borrow my rake.”), and has little use in documentation or error messages. “Can” suggests ability (e.g., ”I can lift that log.”), and “might” suggests possibility (e.g., ”It might rain today.”). Using the proper word clarifies meaning and assists translation.

Contractions. Avoid contractions, like “can’t”; use “cannot” instead.

50.3.15. Proper Spelling

Spell out words in full. For instance, avoid:

- spec
- stats
Chapter 50. PostgreSQL Coding Conventions

- parens
- auth
- xact

Rationale: This will improve consistency.

### 50.3.16. Localization

Keep in mind that error message texts need to be translated into other languages. Follow the guidelines in Section 51.2.2 to avoid making life difficult for translators.
Chapter 51. Native Language Support

51.1. For the Translator

PostgreSQL programs (server and client) can issue their messages in your favorite language — if the messages have been translated. Creating and maintaining translated message sets needs the help of people who speak their own language well and want to contribute to the PostgreSQL effort. You do not have to be a programmer at all to do this. This section explains how to help.

51.1.1. Requirements

We won’t judge your language skills — this section is about software tools. Theoretically, you only need a text editor. But this is only in the unlikely event that you do not want to try out your translated messages. When you configure your source tree, be sure to use the `--enable-nls` option. This will also check for the libintl library and the `msgfmt` program, which all end users will need anyway. To try out your work, follow the applicable portions of the installation instructions.

If you want to start a new translation effort or want to do a message catalog merge (described later), you will need the programs `xgettext` and `msgmerge`, respectively, in a GNU-compatible implementation. Later, we will try to arrange it so that if you use a packaged source distribution, you won’t need `xgettext`. (If working from Git, you will still need it.) GNU Gettext 0.10.36 or later is currently recommended.

Your local gettext implementation should come with its own documentation. Some of that is probably duplicated in what follows, but for additional details you should look there.

51.1.2. Concepts

The pairs of original (English) messages and their (possibly) translated equivalents are kept in message catalogs, one for each program (although related programs can share a message catalog) and for each target language. There are two file formats for message catalogs: The first is the “PO” file (for Portable Object), which is a plain text file with special syntax that translators edit. The second is the “MO” file (for Machine Object), which is a binary file generated from the respective PO file and is used while the internationalized program is run. Translators do not deal with MO files; in fact hardly anyone does.

The extension of the message catalog file is to no surprise either `.po` or `.mo`. The base name is either the name of the program it accompanies, or the language the file is for, depending on the situation. This is a bit confusing. Examples are `psql.po` (PO file for `psql`) or `fr.mo` (MO file in French).

The file format of the PO files is illustrated here:

```
# comment
msgid "original string"
msgstr "translated string"
msgid "more original"
```
msgstr "another translated"
"string can be broken up like this"

...

The msgid’s are extracted from the program source. (They need not be, but this is the most common
way.) The msgstr lines are initially empty and are filled in with useful strings by the translator. The
strings can contain C-style escape characters and can be continued across lines as illustrated. (The
next line must start at the beginning of the line.)

The # character introduces a comment. If whitespace immediately follows the # character, then this
is a comment maintained by the translator. There can also be automatic comments, which have a
non-whitespace character immediately following the #. These are maintained by the various tools that
operate on the PO files and are intended to aid the translator.

#. automatic comment
#: filename.c:1023
#, flags, flags

The #. style comments are extracted from the source file where the message is used. Possibly the
programmer has inserted information for the translator, such as about expected alignment. The #:
comment indicates the exact location(s) where the message is used in the source. The translator need
not look at the program source, but he can if there is doubt about the correct translation. The #,
comments contain flags that describe the message in some way. There are currently two flags: fuzzy
is set if the message has possibly been outdated because of changes in the program source. The
translator can then verify this and possibly remove the fuzzy flag. Note that fuzzy messages are not
made available to the end user. The other flag is c-format, which indicates that the message is a
printf-style format template. This means that the translation should also be a format string with the
same number and type of placeholders. There are tools that can verify this, which key off the c-format
flag.

51.1.3. Creating and Maintaining Message Catalogs

OK, so how does one create a “blank” message catalog? First, go into the directory that contains the
program whose messages you want to translate. If there is a file nls.mk, then this program has been
prepared for translation.

If there are already some .po files, then someone has already done some translation work. The files are
named language.po, where language is the ISO 639-1 two-letter language code (in lower case)¹,
e.g., fr.po for French. If there is really a need for more than one translation effort per language
then the files can also be named language_region.po where region is the ISO 3166-1 two-letter
country code (in upper case)², e.g., pt_BR.po for Portuguese in Brazil. If you find the language you
wanted you can just start working on that file.

If you need to start a new translation effort, then first run the command:

```
make init-po
```

This will create a file progname.pot (.pot to distinguish it from PO files that are “in production”.
The T stands for “template”). Copy this file to language.po and edit it. To make it known that the
new language is available, also edit the file nls.mk and add the language (or language and country)
code to the line that looks like:

2. http://www.iso.org/iso/country_names_and_code_elements

1925
Chapter 51. Native Language Support

AVAIL_LANGUAGES := de fr

(Other languages can appear, of course.)

As the underlying program or library changes, messages might be changed or added by the programmers. In this case you do not need to start from scratch. Instead, run the command:

make update-po

which will create a new blank message catalog file (the pot file you started with) and will merge it with the existing PO files. If the merge algorithm is not sure about a particular message it marks it “fuzzy” as explained above. The new PO file is saved with a .po.new extension.

51.1.4. Editing the PO Files

The PO files can be edited with a regular text editor. The translator should only change the area between the quotes after the msgstr directive, add comments, and alter the fuzzy flag. There is (unsurprisingly) a PO mode for Emacs, which I find quite useful.

The PO files need not be completely filled in. The software will automatically fall back to the original string if no translation (or an empty translation) is available. It is no problem to submit incomplete translations for inclusions in the source tree; that gives room for other people to pick up your work. However, you are encouraged to give priority to removing fuzzy entries after doing a merge. Remember that fuzzy entries will not be installed; they only serve as reference for what might be the right translation.

Here are some things to keep in mind while editing the translations:

- Make sure that if the original ends with a newline, the translation does, too. Similarly for tabs, etc.
- If the original is a printf format string, the translation also needs to be. The translation also needs to have the same format specifiers in the same order. Sometimes the natural rules of the language make this impossible or at least awkward. In that case you can modify the format specifiers like this:

  msgstr "Die Datei %2$s hat %1$u Zeichen."

  Then the first placeholder will actually use the second argument from the list. The digits$ needs to follow the % immediately, before any other format manipulators. (This feature really exists in the printf family of functions. You might not have heard of it before because there is little use for it outside of message internationalization.)

- If the original string contains a linguistic mistake, report that (or fix it yourself in the program source) and translate normally. The corrected string can be merged in when the program sources have been updated. If the original string contains a factual mistake, report that (or fix it yourself) and do not translate it. Instead, you can mark the string with a comment in the PO file.
- Maintain the style and tone of the original string. Specifically, messages that are not sentences (cannot open file %s) should probably not start with a capital letter (if your language distinguishes letter case) or end with a period (if your language uses punctuation marks). It might help to read Section 50.3.
- If you don’t know what a message means, or if it is ambiguous, ask on the developers’ mailing list. Chances are that English speaking end users might also not understand it or find it ambiguous, so it’s best to improve the message.
51.2. For the Programmer

51.2.1. Mechanics

This section describes how to implement native language support in a program or library that is part of the PostgreSQL distribution. Currently, it only applies to C programs.

Adding NLS Support to a Program

1. Insert this code into the start-up sequence of the program:

```c
#ifdef ENABLE_NLS
#include <locale.h>
#endif
...

#ifdef ENABLE_NLS
setlocale(LC_ALL, "")
bindtextdomain("proname", LOCALEDIR)
textdomain("proname")
#endif
(The proname can actually be chosen freely.)
```

2. Wherever a message that is a candidate for translation is found, a call to `gettext()` needs to be inserted. E.g.:

```c
fprintf(stderr, "panic level %d\n", lvl);
```

would be changed to:

```c
fprintf(stderr, gettext("panic level %d\n"), lvl);
```

(`gettext` is defined as a no-op if NLS support is not configured.)

This tends to add a lot of clutter. One common shortcut is to use:

```c
#define _(x) gettext(x)
```

Another solution is feasible if the program does much of its communication through one or a few functions, such as `ereport()` in the backend. Then you make this function call `gettext` internally on all input strings.

3. Add a file `nls.mk` in the directory with the program sources. This file will be read as a makefile. The following variable assignments need to be made here:

- **CATALOG_NAME**
  - The program name, as provided in the `textdomain()` call.

- **AVAIL_LANGUAGES**
  - List of provided translations — initially empty.

- **GETTEXT_FILES**
  - List of files that contain translatable strings, i.e., those marked with `gettext` or an alternative solution. Eventually, this will include nearly all source files of the program. If this list gets too long you can make the first “file” be a `+` and the second word be a file that contains one file name per line.
Chapter 51. Native Language Support

GETTEXT_TRIGGERS

The tools that generate message catalogs for the translators to work on need to know what function calls contain translatable strings. By default, only gettext() calls are known. If you used _ or other identifiers you need to list them here. If the translatable string is not the first argument, the item needs to be of the form func:2 (for the second argument). If you have a function that supports pluralized messages, the item should look like func:1,2 (identifying the singular and plural message arguments).

The build system will automatically take care of building and installing the message catalogs.

51.2.2. Message-writing Guidelines

Here are some guidelines for writing messages that are easily translatable.

- Do not construct sentences at run-time, like:

  
  printf("Files were %s.\n", flag ? "copied" : "removed");
  
  The word order within the sentence might be different in other languages. Also, even if you remember to call gettext() on each fragment, the fragments might not translate well separately. It’s better to duplicate a little code so that each message to be translated is a coherent whole. Only numbers, file names, and such-like run-time variables should be inserted at run time into a message text.

- For similar reasons, this won’t work:

  
  printf("copied %d file%s", n, n!=1 ? "s" : ");
  
  because it assumes how the plural is formed. If you figured you could solve it like this:

  
  if (n==1)
      printf("copied 1 file");
  else
      printf("copied %d files", n);
  
  then be disappointed. Some languages have more than two forms, with some peculiar rules. It’s often best to design the message to avoid the issue altogether, for instance like this:

  
  printf("number of copied files: %d", n);
  
  If you really want to construct a properly pluralized message, there is support for this, but it’s a bit awkward. When generating a primary or detail error message in ereport(), you can write something like this:

  
  errmsg_plural("copied %d file",
                   "copied %d files",
                   n,
                   n)
  
  The first argument is the format string appropriate for English singular form, the second is the format string appropriate for English plural form, and the third is the integer control value that determines which plural form to use. Subsequent arguments are formatted per the format string as usual. (Normally, the pluralization control value will also be one of the values to be formatted, so it has to be written twice.) In English it only matters whether n is 1 or not 1, but in other languages there can be many different plural forms. The translator sees the two English forms as a group and has the opportunity to supply multiple substitute strings, with the appropriate one being selected based on the run-time value of n.
If you need to pluralize a message that isn’t going directly to an `errmsg` or `errdetail` report, you have to use the underlying function `ngettext`. See the gettext documentation.

- If you want to communicate something to the translator, such as about how a message is intended to line up with other output, precede the occurrence of the string with a comment that starts with `translator`, e.g.:
  
  /* translator: This message is not what it seems to be. */

  These comments are copied to the message catalog files so that the translators can see them.
Chapter 52. Writing A Procedural Language Handler

All calls to functions that are written in a language other than the current “version 1” interface for compiled languages (this includes functions in user-defined procedural languages, functions written in SQL, and functions using the version 0 compiled language interface) go through a call handler function for the specific language. It is the responsibility of the call handler to execute the function in a meaningful way, such as by interpreting the supplied source text. This chapter outlines how a new procedural language’s call handler can be written.

The call handler for a procedural language is a “normal” function that must be written in a compiled language such as C, using the version-1 interface, and registered with PostgreSQL as taking no arguments and returning the type `language_handler`. This special pseudotype identifies the function as a call handler and prevents it from being called directly in SQL commands. For more details on C language calling conventions and dynamic loading, see Section 35.9.

The call handler is called in the same way as any other function: It receives a pointer to a `FunctionCallInfoData` struct containing argument values and information about the called function, and it is expected to return a Datum result (and possibly set the `isnull` field of the `FunctionCallInfoData` structure, if it wishes to return an SQL null result). The difference between a call handler and an ordinary callee function is that the `flinfo->fn_oid` field of the `FunctionCallInfoData` structure will contain the OID of the actual function to be called, not of the call handler itself. The call handler must use this field to determine which function to execute. Also, the passed argument list has been set up according to the declaration of the target function, not of the call handler.

It’s up to the call handler to fetch the entry of the function from the `pg_proc` system catalog and to analyze the argument and return types of the called function. The `AS` clause from the `CREATE FUNCTION` command for the function will be found in the `prosrc` column of the `pg_proc` row. This is commonly source text in the procedural language, but in theory it could be something else, such as a path name to a file, or anything else that tells the call handler what to do in detail.

Often, the same function is called many times per SQL statement. A call handler can avoid repeated lookups of information about the called function by using the `flinfo->fn_extra` field. This will initially be `NULL`, but can be set by the call handler to point at information about the called function. On subsequent calls, if `flinfo->fn_extra` is already non-NULL then it can be used and the information lookup step skipped. The call handler must make sure that `flinfo->fn_extra` is made to point at memory that will live at least until the end of the current query, since an `FmgrInfo` data structure could be kept that long. One way to do this is to allocate the extra data in the memory context specified by `flinfo->fn_mcxt`; such data will normally have the same lifespan as the `FmgrInfo` itself. But the handler could also choose to use a longer-lived memory context so that it can cache function definition information across queries.

When a procedural-language function is invoked as a trigger, no arguments are passed in the usual way, but the `FunctionCallInfoData`’s `context` field points at a `TriggerData` structure, rather than being `NULL` as it is in a plain function call. A language handler should provide mechanisms for procedural-language functions to get at the trigger information.

This is a template for a procedural-language handler written in C:

```c
#include "postgres.h"
```
Chapter 52. Writing A Procedural Language Handler

#include "executor/spi.h"
#include "commands/trigger.h"
#include "fmgr.h"
#include "access/heapam.h"
#include "utils/syscache.h"
#include "catalog/pg_proc.h"
#include "catalog/pg_type.h"

#ifdef PG_MODULE_MAGIC
PG_MODULE_MAGIC;
#endif

PG_FUNCTION_INFO_V1(plsample_call_handler);

Datum plsample_call_handler(PG_FUNCTION_ARGS)
{
  Datum retval;

  if (CALLED_AS_TRIGGER(fcinfo))
  {
    /* Called as a trigger procedure */
    TriggerData *trigdata = (TriggerData *) fcinfo->context;
    retval = ...
  }
  else
  {
    /* Called as a function */
    retval = ...
  }

  return retval;
}

Only a few thousand lines of code have to be added instead of the dots to complete the call handler.

After having compiled the handler function into a loadable module (see Section 35.9.6), the following
commands then register the sample procedural language:

CREATE FUNCTION plsample_call_handler() RETURNS language_handler
  AS 'filename'
  LANGUAGE C;
CREATE LANGUAGE plsample
  HANDLER plsample_call_handler;

Although providing a call handler is sufficient to create a minimal procedural language, there are two
other functions that can optionally be provided to make the language more convenient to use. These
are a validator and an inline handler. A validator can be provided to allow language-specific checking
to be done during CREATE FUNCTION. An inline handler can be provided to allow the language to
support anonymous code blocks executed via the DO command.
Chapter 52. Writing A Procedural Language Handler

If a validator is provided by a procedural language, it must be declared as a function taking a single parameter of type \texttt{oid}. The validator’s result is ignored, so it is customarily declared to return \texttt{void}. The validator will be called at the end of a \texttt{CREATE FUNCTION} command that has created or updated a function written in the procedural language. The passed-in OID is the OID of the function’s \texttt{pg_proc} row. The validator must fetch this row in the usual way, and do whatever checking is appropriate. First, call \texttt{CheckFunctionValidatorAccess()} to diagnose explicit calls to the validator that the user could not achieve through \texttt{CREATE FUNCTION}. Typical checks then include verifying that the function’s argument and result types are supported by the language, and that the function’s body is syntactically correct in the language. If the validator finds the function to be okay, it should just return. If it finds an error, it should report that via the normal \texttt{ereport()} error reporting mechanism. Throwing an error will force a transaction rollback and thus prevent the incorrect function definition from being committed.

Validator functions should typically honor the \texttt{check_function_bodies} parameter: if it is turned off then any expensive or context-sensitive checking should be skipped. If the language provides for code execution at compilation time, the validator must suppress checks that would induce such execution. In particular, this parameter is turned off by \texttt{pg_dump} so that it can load procedural language functions without worrying about side effects or dependencies of the function bodies on other database objects. (Because of this requirement, the call handler should avoid assuming that the validator has fully checked the function. The point of having a validator is not to let the call handler omit checks, but to notify the user immediately if there are obvious errors in a \texttt{CREATE FUNCTION} command.) While the choice of exactly what to check is mostly left to the discretion of the validator function, note that the core \texttt{CREATE FUNCTION} code only executes \texttt{SET} clauses attached to a function when \texttt{check_function_bodies} is on. Therefore, checks whose results might be affected by GUC parameters definitely should be skipped when \texttt{check_function_bodies} is off, to avoid false failures when reloading a dump.

If an inline handler is provided by a procedural language, it must be declared as a function taking a single parameter of type \texttt{internal}. The inline handler’s result is ignored, so it is customarily declared to return \texttt{void}. The inline handler will be called when a \texttt{DO} statement is executed specifying the procedural language. The parameter actually passed is a pointer to an \texttt{InlineCodeBlock} struct, which contains information about the \texttt{DO} statement’s parameters, in particular the text of the anonymous code block to be executed. The inline handler should execute this code and return.

It’s recommended that you wrap all these function declarations, as well as the \texttt{CREATE LANGUAGE} command itself, into an \texttt{extension} so that a simple \texttt{CREATE EXTENSION} command is sufficient to install the language. See Section 35.15 for information about writing extensions.

The procedural languages included in the standard distribution are good references when trying to write your own language handler. Look into the \texttt{src/pl} subdirectory of the source tree. The \texttt{CREATE LANGUAGE} reference page also has some useful details.
Chapter 53. Writing A Foreign Data Wrapper

All operations on a foreign table are handled through its foreign data wrapper, which consists of a set of functions that the core server calls. The foreign data wrapper is responsible for fetching data from the remote data source and returning it to the PostgreSQL executor. If updating foreign tables is to be supported, the wrapper must handle that, too. This chapter outlines how to write a new foreign data wrapper.

The foreign data wrappers included in the standard distribution are good references when trying to write your own. Look into the contrib subdirectory of the source tree. The CREATE FOREIGN DATA WRAPPER reference page also has some useful details.

Note: The SQL standard specifies an interface for writing foreign data wrappers. However, PostgreSQL does not implement that API, because the effort to accommodate it into PostgreSQL would be large, and the standard API hasn’t gained wide adoption anyway.

53.1. Foreign Data Wrapper Functions

The FDW author needs to implement a handler function, and optionally a validator function. Both functions must be written in a compiled language such as C, using the version-1 interface. For details on C language calling conventions and dynamic loading, see Section 35.9.

The handler function simply returns a struct of function pointers to callback functions that will be called by the planner, executor, and various maintenance commands. Most of the effort in writing an FDW is in implementing these callback functions. The handler function must be registered with PostgreSQL as taking no arguments and returning the special pseudo-type fdw_handler. The callback functions are plain C functions and are not visible or callable at the SQL level. The callback functions are described in Section 53.2.

The validator function is responsible for validating options given in CREATE and ALTER commands for its foreign data wrapper, as well as foreign servers, user mappings, and foreign tables using the wrapper. The validator function must be registered as taking two arguments, a text array containing the options to be validated, and an OID representing the type of object the options are associated with (in the form of the OID of the system catalog the object would be stored in, either ForeignDataWrapperRelationId, ForeignServerRelationId, UserMappingRelationId, or ForeignTableRelationId). If no validator function is supplied, options are not checked at object creation time or object alteration time.

53.2. Foreign Data Wrapper Callback Routines

The FDW handler function returns a palloc’d FdwRoutine struct containing pointers to the callback functions described below. The scan-related functions are required, the rest are optional.

The FdwRoutine struct type is declared in src/include/foreign/fdwapi.h, which see for additional details.
### 53.2.1. FDW Routines For Scanning Foreign Tables

```c
void GetForeignRelSize (PlannerInfo *root,
    RelOptInfo *baserel,
    Oid foreigntableid);
```

Obtain relation size estimates for a foreign table. This is called at the beginning of planning for a query that scans a foreign table. `root` is the planner’s global information about the query; `baserel` is the planner’s information about this table; and `foreigntableid` is the `pg_class` OID of the foreign table. (`foreigntableid` could be obtained from the planner data structures, but it’s passed explicitly to save effort.)

This function should update `baserel->rows` to be the expected number of rows returned by the table scan, after accounting for the filtering done by the restriction quals. The initial value of `baserel->rows` is just a constant default estimate, which should be replaced if at all possible. The function may also choose to update `baserel->width` if it can compute a better estimate of the average result row width.

See Section 53.4 for additional information.

```c
void GetForeignPaths (PlannerInfo *root,
    RelOptInfo *baserel,
    Oid foreigntableid);
```

Create possible access paths for a scan on a foreign table. This is called during query planning. The parameters are the same as for `GetForeignRelSize`, which has already been called.

This function must generate at least one access path (`ForeignPath` node) for a scan on the foreign table and must call `add_path` to add each such path to `baserel->pathlist`. It’s recommended to use `create_foreignscan_path` to build the `ForeignPath` nodes. The function can generate multiple access paths, e.g., a path which has valid `pathkeys` to represent a pre-sorted result. Each access path must contain cost estimates, and can contain any FDW-private information that is needed to identify the specific scan method intended.

See Section 53.4 for additional information.

```c
ForeignScan * GetForeignPlan (PlannerInfo *root,
    RelOptInfo *baserel,
    Oid foreigntableid,
    ForeignPath *best_path,
    List *tlist,
    List *scan_clauses);
```

Create a `ForeignScan` plan node from the selected foreign access path. This is called at the end of query planning. The parameters are as for `GetForeignRelSize`, plus the selected `ForeignPath` (previously produced by `GetForeignPaths`), the target list to be emitted by the plan node, and the restriction clauses to be enforced by the plan node.

This function must create and return a `ForeignScan` plan node; it’s recommended to use `make_foreignscan` to build the `ForeignScan` node.

See Section 53.4 for additional information.
Chapter 53. Writing A Foreign Data Wrapper

BeginForeignScan (ForeignScanState *node, int eflags);

Begin executing a foreign scan. This is called during executor startup. It should perform any initialization needed before the scan can start, but not start executing the actual scan (that should be done upon the first call to IterateForeignScan). The ForeignScanState node has already been created, but its fdw_state field is still NULL. Information about the table to scan is accessible through the ForeignScanState node (in particular, from the underlying ForeignScan plan node, which contains any FDW-private information provided by GetForeignPlan). eflags contains flag bits describing the executor’s operating mode for this plan node.

Note that when (eflags & EXEC_FLAG_EXPLAIN_ONLY) is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for ExplainForeignScan and EndForeignScan.

TupleTableSlot * IterateForeignScan (ForeignScanState *node);

Fetch one row from the foreign source, returning it in a tuple table slot (the node’s ScanTupleSlot should be used for this purpose). Return NULL if no more rows are available. The tuple table slot infrastructure allows either a physical or virtual tuple to be returned; in most cases the latter choice is preferable from a performance standpoint. Note that this is called in a short-lived memory context that will be reset between invocations. Create a memory context in BeginForeignScan if you need longer-lived storage, or use the es_query_cxt of the node’s EState.

The rows returned must match the column signature of the foreign table being scanned. If you choose to optimize away fetching columns that are not needed, you should insert nulls in those column positions.

Note that PostgreSQL’s executor doesn’t care whether the rows returned violate any NOT NULL constraints that were defined on the foreign table columns — but the planner does care, and may optimize queries incorrectly if NULL values are present in a column declared not to contain them. If a NULL value is encountered when the user has declared that none should be present, it may be appropriate to raise an error (just as you would need to do in the case of a data type mismatch).

void ReScanForeignScan (ForeignScanState *node);

Restart the scan from the beginning. Note that any parameters the scan depends on may have changed value, so the new scan does not necessarily return exactly the same rows.

void EndForeignScan (ForeignScanState *node);

End the scan and release resources. It is normally not important to release palloc’d memory, but for example open files and connections to remote servers should be cleaned up.

53.2.2. FDW Routines For Updating Foreign Tables

If an FDW supports writable foreign tables, it should provide some or all of the following callback functions depending on the needs and capabilities of the FDW:

void AddForeignUpdateTargets (Query *parsetree,
UPDATE and DELETE operations are performed against rows previously fetched by the table-scanning functions. The FDW may need extra information, such as a row ID or the values of primary-key columns, to ensure that it can identify the exact row to update or delete. To support that, this function can add extra hidden, or “junk”, target columns to the list of columns that are to be retrieved from the foreign table during an UPDATE or DELETE.

To do that, add TargetEntry items to parsetree->targetList, containing expressions for the extra values to be fetched. Each such entry must be marked resjunk = true, and must have a distinct resname that will identify it at execution time. Avoid using names matching ctidN, wholerow, or wholerowN, as the core system can generate junk columns of these names.

This function is called in the rewriter, not the planner, so the information available is a bit different from that available to the planning routines. parsetree is the parse tree for the UPDATE or DELETE command, while target_rte and target_relation describe the target foreign table.

If the AddForeignUpdateTargets pointer is set to NULL, no extra target expressions are added. (This will make it impossible to implement DELETE operations, though UPDATE may still be feasible if the FDW relies on an unchanging primary key to identify rows.)

Perform any additional planning actions needed for an insert, update, or delete on a foreign table. This function generates the FDW-private information that will be attached to the ModifyTable plan node that performs the update action. This private information must have the form of a List, and will be delivered to BeginForeignModify during the execution stage.

root is the planner’s global information about the query. plan is the ModifyTable plan node, which is complete except for the fdwPrivLists field. resultRelation identifies the target foreign table by its range table index. subplan_index identifies which target of the ModifyTable plan node this is, counting from zero; use this if you want to index into plan->plans or other substructure of the plan node.

See Section 53.4 for additional information.

If the PlanForeignModify pointer is set to NULL, no additional plan-time actions are taken, and the fdw_private list delivered to BeginForeignModify will be NIL.

Begin executing a foreign table modification operation. This routine is called during executor startup. It should perform any initialization needed prior to the actual table modifications. Subsequently, ExecForeignInsert, ExecForeignUpdate or ExecForeignDelete will be called for each tuple to be inserted, updated, or deleted.
mtstate is the overall state of the ModifyTable plan node being executed; global data about the plan and execution state is available via this structure. rinfo is the ResultRelInfo struct describing the target foreign table. (The ri_FdwState field of ResultRelInfo is available for the FDW to store any private state it needs for this operation.) fdw_private contains the private data generated by PlanForeignModify, if any. subplan_index identifies which target of the ModifyTable plan node this is. eflags contains flag bits describing the executor’s operating mode for this plan node.

Note that when (eflags & EXEC_FLAG_EXPLAIN_ONLY) is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for ExplainForeignModify and EndForeignModify.

If the BeginForeignModify pointer is set to NULL, no action is taken during executor startup.

TupleTableSlot *
ExecForeignInsert (EState *estate,
    ResultRelInfo *rinfo,
    TupleTableSlot *slot,
    TupleTableSlot *planSlot);

Insert one tuple into the foreign table. estate is global execution state for the query. rinfo is the ResultRelInfo struct describing the target foreign table. slot contains the tuple to be inserted; it will match the row-type definition of the foreign table. planSlot contains the tuple that was generated by the ModifyTable plan node’s subplan; it differs from slot in possibly containing additional “junk” columns. (The planSlot is typically of little interest for INSERT cases, but is provided for completeness.)

The return value is either a slot containing the data that was actually inserted (this might differ from the data supplied, for example as a result of trigger actions), or NULL if no row was actually inserted (again, typically as a result of triggers). The passed-in slot can be re-used for this purpose.

The data in the returned slot is used only if the INSERT query has a RETURNING clause or the foreign table has an AFTER ROW trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the RETURNING clause. Regardless, some slot must be returned to indicate success, or the query’s reported row count will be wrong.

If the ExecForeignInsert pointer is set to NULL, attempts to insert into the foreign table will fail with an error message.

TupleTableSlot *
ExecForeignUpdate (EState *estate,
    ResultRelInfo *rinfo,
    TupleTableSlot *slot,
    TupleTableSlot *planSlot);

Update one tuple in the foreign table. estate is global execution state for the query. rinfo is the ResultRelInfo struct describing the target foreign table. slot contains the new data for the tuple; it will match the row-type definition of the foreign table. planSlot contains the tuple that was generated by the ModifyTable plan node’s subplan; it differs from slot in possibly containing additional “junk” columns. In particular, any junk columns that were requested by AddForeignUpdateTargets will be available from this slot.

The return value is either a slot containing the row as it was actually updated (this might differ from the data supplied, for example as a result of trigger actions), or NULL if no row was actually updated (again, typically as a result of triggers). The passed-in slot can be re-used for this purpose.

The data in the returned slot is used only if the UPDATE query has a RETURNING clause or the foreign table has an AFTER ROW trigger. Triggers require all columns, but the FDW could choose to optimize
away returning some or all columns depending on the contents of the \texttt{RETURNING} clause. Regardless, some slot must be returned to indicate success, or the query’s reported row count will be wrong.

If the \texttt{ExecForeignUpdate} pointer is set to \texttt{NULL}, attempts to update the foreign table will fail with an error message.

\begin{verbatim}
TupleTableSlot *
ExecForeignDelete (EState *estate,
   ResultRelInfo *rinfo,
   TupleTableSlot *slot,
   TupleTableSlot *planSlot);
\end{verbatim}

Delete one tuple from the foreign table. \texttt{estate} is global execution state for the query. \texttt{rinfo} is the \texttt{ResultRelInfo} struct describing the target foreign table. \texttt{slot} contains nothing useful upon call, but can be used to hold the returned tuple. \texttt{planSlot} contains the tuple that was generated by the \texttt{ModifyTable} plan node’s subplan; in particular, it will carry any junk columns that were requested by \texttt{AddForeignUpdateTargets}. The junk column(s) must be used to identify the tuple to be deleted.

The return value is either a slot containing the row that was deleted, or \texttt{NULL} if no row was deleted (typically as a result of triggers). The passed-in \texttt{slot} can be used to hold the tuple to be returned.

The data in the returned slot is used only if the \texttt{DELETE} query has a \texttt{RETURNING} clause or the foreign table has an \texttt{AFTER ROW} trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the \texttt{RETURNING} clause. Regardless, some slot must be returned to indicate success, or the query’s reported row count will be wrong.

If the \texttt{ExecForeignDelete} pointer is set to \texttt{NULL}, attempts to delete from the foreign table will fail with an error message.

\begin{verbatim}
void
EndForeignModify (EState *estate,
   ResultRelInfo *rinfo);
\end{verbatim}

End the table update and release resources. It is normally not important to release \texttt{palloc’d} memory, but for example open files and connections to remote servers should be cleaned up.

If the \texttt{EndForeignModify} pointer is set to \texttt{NULL}, no action is taken during executor shutdown.

\begin{verbatim}
int
IsForeignRelUpdatable (Relation rel);
\end{verbatim}

Report which update operations the specified foreign table supports. The return value should be a bit mask of rule event numbers indicating which operations are supported by the foreign table, using the \texttt{CmdType} enumeration; that is, \texttt{(1 << CMD\_UPDATE)} = 4 for \texttt{UPDATE}, \texttt{(1 << CMD\_INSERT)} = 8 for \texttt{INSERT}, and \texttt{(1 << CMD\_DELETE)} = 16 for \texttt{DELETE}.

If the \texttt{IsForeignRelUpdatable} pointer is set to \texttt{NULL}, foreign tables are assumed to be insertable, updatable, or deletable if the FDW provides \texttt{ExecForeignInsert}, \texttt{ExecForeignUpdate}, or \texttt{ExecForeignDelete} respectively. This function is only needed if the FDW supports some tables that are updatable and some that are not. (Even then, it’s permissible to throw an error in the execution routine instead of checking in this function. However, this function is used to determine updatability for display in the \texttt{information\_schema} views.)
53.2.3. FDW Routines for EXPLAIN

```c
void ExplainForeignScan (ForeignScanState *node,
                        ExplainState *es);
```

Print additional EXPLAIN output for a foreign table scan. This function can call ExplainPropertyText and related functions to add fields to the EXPLAIN output. The flag fields in es can be used to determine what to print, and the state of the ForeignScanState node can be inspected to provide run-time statistics in the EXPLAIN ANALYZE case.

If the ExplainForeignScan pointer is set to NULL, no additional information is printed during EXPLAIN.

```c
void ExplainForeignModify (ModifyTableState *mtstate,
                        ResultRelInfo *rinfo,
                        List *fdw_private,
                        int subplan_index,
                        struct ExplainState *es);
```

Print additional EXPLAIN output for a foreign table update. This function can call ExplainPropertyText and related functions to add fields to the EXPLAIN output. The flag fields in es can be used to determine what to print, and the state of the ModifyTableState node can be inspected to provide run-time statistics in the EXPLAIN ANALYZE case. The first four arguments are the same as for BeginForeignModify.

If the ExplainForeignModify pointer is set to NULL, no additional information is printed during EXPLAIN.

53.2.4. FDW Routines for ANALYZE

```c
bool AnalyzeForeignTable (Relation relation,
                          AcquireSampleRowsFunc *func,
                          BlockNumber *totalpages);
```

This function is called when ANALYZE is executed on a foreign table. If the FDW can collect statistics for this foreign table, it should return true, and provide a pointer to a function that will collect sample rows from the table in func, plus the estimated size of the table in pages in totalpages. Otherwise, return false.

If the FDW does not support collecting statistics for any tables, the AnalyzeForeignTable pointer can be set to NULL.

If provided, the sample collection function must have the signature

```c
int AcquireSampleRowsFunc (Relation relation, int elevel,
                          HeapTuple *rows, int targrows,
                          double *totalrows,
                          double *totaldeadrows);
```

A random sample of up to targrows rows should be collected from the table and stored into the caller-provided rows array. The actual number of rows collected must be returned. In addition, store
estimates of the total numbers of live and dead rows in the table into the output parameters `totalrows` and `totaldeadrows`.

( Set `totaldeadrows` to zero if the FDW does not have any concept of dead rows.)

### 53.3. Foreign Data Wrapper Helper Functions

Several helper functions are exported from the core server so that authors of foreign data wrappers can get easy access to attributes of FDW-related objects, such as FDW options. To use any of these functions, you need to include the header file `foreign/foreign.h` in your source file. That header also defines the struct types that are returned by these functions.

```c
ForeignDataWrapper * GetForeignDataWrapper(Oid fdwid);
```

This function returns a `ForeignDataWrapper` object for the foreign-data wrapper with the given OID. A `ForeignDataWrapper` object contains properties of the FDW (see `foreign/foreign.h` for details).

```c
ForeignServer * GetForeignServer(Oid serverid);
```

This function returns a `ForeignServer` object for the foreign server with the given OID. A `ForeignServer` object contains properties of the server (see `foreign/foreign.h` for details).

```c
UserMapping * GetUserMapping(Oid userid, Oid serverid);
```

This function returns a `UserMapping` object for the user mapping of the given role on the given server. (If there is no mapping for the specific user, it will return the mapping for `PUBLIC`, or throw error if there is none.) A `UserMapping` object contains properties of the user mapping (see `foreign/foreign.h` for details).

```c
ForeignTable * GetForeignTable(Oid relid);
```

This function returns a `ForeignTable` object for the foreign table with the given OID. A `ForeignTable` object contains properties of the foreign table (see `foreign/foreign.h` for details).

```c
List * GetForeignColumnOptions(Oid relid, AttrNumber attnum);
```

This function returns the per-column FDW options for the column with the given foreign table OID and attribute number, in the form of a list of `DefElem`. NIL is returned if the column has no options. Some object types have name-based lookup functions in addition to the OID-based ones:

```c
ForeignDataWrapper * GetForeignDataWrapperByName(const char *name, bool missing_ok);
```

This function returns a `ForeignDataWrapper` object for the foreign-data wrapper with the given name. If the wrapper is not found, return NULL if `missing_ok` is true, otherwise raise an error.
ForeignServer *
GetForeignServerByName(const char *name, bool missing_ok);

This function returns a ForeignServer object for the foreign server with the given name. If the
server is not found, return NULL if missing_ok is true, otherwise raise an error.

53.4. Foreign Data Wrapper Query Planning

The FDW callback functions GetForeignRelSize, GetForeignPaths, GetForeignPlan, and
PlanForeignModify must fit into the workings of the PostgreSQL planner. Here are some notes
about what they must do.

The information in root and baserel can be used to reduce the amount of information that has to
be fetched from the foreign table (and therefore reduce the cost). baserel->baserestrictinfo
is particularly interesting, as it contains restriction quals (WHERE clauses) that should be used to filter
the rows to be fetched. (The FDW itself is not required to enforce these quals, as the core executor can
check them instead.) baserel->reltargetlist can be used to determine which columns need to
be fetched; but note that it only lists columns that have to be emitted by the ForeignScan plan node,
not columns that are used in qual evaluation but not output by the query.

Various private fields are available for the FDW planning functions to keep information in. Generally,
whatever you store in FDW private fields should be palloc’d, so that it will be reclaimed at the end
of planning.

baserel->fdw_private is a void pointer that is available for FDW planning functions to store
information relevant to the particular foreign table. The core planner does not touch it except to
initialize it to NULL when the baserel node is created. It is useful for passing information
forward from GetForeignRelSize to GetForeignPaths and/or GetForeignPaths to
GetForeignPlan, thereby avoiding recalculation.

GetForeignPaths can identify the meaning of different access paths by storing private information
in the fdw_private field of ForeignPath nodes. fdw_private is declared as a List pointer, but
could actually contain anything since the core planner does not touch it. However, best practice is to
use a representation that’s dumpable by nodeToString, for use with debugging support available in
the backend.

GetForeignPlan can examine the fdw_private field of the selected ForeignPath node, and can
generate fdw_exprs and fdw_private lists to be placed in the ForeignScan plan node, where they
will be available at execution time. Both of these lists must be represented in a form that copyObject
knows how to copy. The fdw_private list has no other restrictions and is not interpreted by the core
backend in any way. The fdw_exprs list, if not NIL, is expected to contain expression trees that are
intended to be executed at run time. These trees will undergo post-processing by the planner to make
them fully executable.

In GetForeignPlan, generally the passed-in target list can be copied into the plan node as-is. The
passed scan_clauses list contains the same clauses as baserel->baserestrictinfo, but may
be re-ordered for better execution efficiency. In simple cases the FDW can just strip RestrictInfo
nodes from the scan_clauses list (using extract_actual_clauses) and put all the clauses into
the plan node’s qual list, which means that all the clauses will be checked by the executor at run time.
More complex FDWs may be able to check some of the clauses internally, in which case those clauses
can be removed from the plan node’s qual list so that the executor doesn’t waste time rechecking them.

As an example, the FDW might identify some restriction clauses of the form foreign_variable
= sub_expression, which it determines can be executed on the remote server given the
locally-evaluated value of the sub_expression. The actual identification of such a clause should
happen during GetForeignPaths, since it would affect the cost estimate for the path. The path’s fdw_private field would probably include a pointer to the identified clause’s RestrictInfo node. Then GetForeignPlan would remove that clause from scan_clauses, but add the sub_expression to fdw_exprs to ensure that it gets massaged into executable form. It would probably also put control information into the plan node’s fdw_private field to tell the execution functions what to do at run time. The query transmitted to the remote server would involve something like WHERE foreign_variable = $1, with the parameter value obtained at run time from evaluation of the fdw_exprs expression tree.

The FDW should always construct at least one path that depends only on the table’s restriction clauses. In join queries, it might also choose to construct path(s) that depend on join clauses, for example foreign_variable = local_variable. Such clauses will not be found in baserel->baserestrictinfo but must be sought in the relation’s join lists. A path using such a clause is called a “parameterized path”. It must identify the other relations used in the selected join clause(s) with a suitable value of param_info; use get_baserel_parampathinfo to compute that value. In GetForeignPlan, the local_variable portion of the join clause would be added to fdw_exprs, and then at run time the case works the same as for an ordinary restriction clause.

When planning an UPDATE or DELETE, PlanForeignModify can look up the RelOptInfo struct for the foreign table and make use of the baserel->fdw_private data previously created by the scan-planning functions. However, in INSERT the target table is not scanned so there is no RelOptInfo for it. The List returned by PlanForeignModify has the same restrictions as the fdw_private list of a ForeignScan plan node, that is it must contain only structures that copyObject knows how to copy.

For an UPDATE or DELETE against an external data source that supports concurrent updates, it is recommended that the ForeignScan operation lock the rows that it fetches, perhaps via the equivalent of SELECT FOR UPDATE. The FDW may also choose to lock rows at fetch time when the foreign table is referenced in a SELECT FOR UPDATE/SHARE; if it does not, the FOR UPDATE or FOR SHARE option is essentially a no-op so far as the foreign table is concerned. This behavior may yield semantics slightly different from operations on local tables, where row locking is customarily delayed as long as possible: remote rows may get locked even though they subsequently fail locally-applied restriction or join conditions. However, matching the local semantics exactly would require an additional remote access for every row, and might be impossible anyway depending on what locking semantics the external data source provides.
Chapter 54. Genetic Query Optimizer

Author: Written by Martin Utesch (<utesch@aut.tu-freiberg.de>) for the Institute of Automatic Control at the University of Mining and Technology in Freiberg, Germany.

54.1. Query Handling as a Complex Optimization Problem

Among all relational operators the most difficult one to process and optimize is the join. The number of possible query plans grows exponentially with the number of joins in the query. Further optimization effort is caused by the support of a variety of join methods (e.g., nested loop, hash join, merge join in PostgreSQL) to process individual joins and a diversity of indexes (e.g., B-tree, hash, GiST and GIN in PostgreSQL) as access paths for relations.

The normal PostgreSQL query optimizer performs a near-exhaustive search over the space of alternative strategies. This algorithm, first introduced in IBM’s System R database, produces a near-optimal join order, but can take an enormous amount of time and memory space when the number of joins in the query grows large. This makes the ordinary PostgreSQL query optimizer inappropriate for queries that join a large number of tables.

The Institute of Automatic Control at the University of Mining and Technology, in Freiberg, Germany, encountered some problems when it wanted to use PostgreSQL as the backend for a decision support knowledge based system for the maintenance of an electrical power grid. The DBMS needed to handle large join queries for the inference machine of the knowledge based system. The number of joins in these queries made using the normal query optimizer infeasible.

In the following we describe the implementation of a genetic algorithm to solve the join ordering problem in a manner that is efficient for queries involving large numbers of joins.

54.2. Genetic Algorithms

The genetic algorithm (GA) is a heuristic optimization method which operates through randomized search. The set of possible solutions for the optimization problem is considered as a population of individuals. The degree of adaptation of an individual to its environment is specified by its fitness.

The coordinates of an individual in the search space are represented by chromosomes, in essence a set of character strings. A gene is a subsection of a chromosome which encodes the value of a single parameter being optimized. Typical encodings for a gene could be binary or integer.

Through simulation of the evolutionary operations recombination, mutation, and selection new generations of search points are found that show a higher average fitness than their ancestors.
Chapter 54. Genetic Query Optimizer

According to the comp.ai.genetic FAQ it cannot be stressed too strongly that a GA is not a pure random search for a solution to a problem. A GA uses stochastic processes, but the result is distinctly non-random (better than random).

Figure 54-1. Structured Diagram of a Genetic Algorithm

54.3. Genetic Query Optimization (GEQO) in PostgreSQL

The GEQO module approaches the query optimization problem as though it were the well-known traveling salesman problem (TSP). Possible query plans are encoded as integer strings. Each string represents the join order from one relation of the query to the next. For example, the join tree

```
  /
  /
  /
4 1
```

is encoded by the integer string '4-1-3-2', which means, first join relation '4' and '1', then '3', and then '2', where 1, 2, 3, 4 are relation IDs within the PostgreSQL optimizer.

Specific characteristics of the GEQO implementation in PostgreSQL are:

- Usage of a steady state GA (replacement of the least fit individuals in a population, not whole-generational replacement) allows fast convergence towards improved query plans. This is essential for query handling with reasonable time;
• Usage of *edge recombination crossover* which is especially suited to keep edge losses low for the solution of the TSP by means of a GA;
• Mutation as genetic operator is deprecated so that no repair mechanisms are needed to generate legal TSP tours.

Parts of the GEQO module are adapted from D. Whitley’s Genitor algorithm.

The GEQO module allows the PostgreSQL query optimizer to support large join queries effectively through non-exhaustive search.

### 54.3.1. Generating Possible Plans with GEQO

The GEQO planning process uses the standard planner code to generate plans for scans of individual relations. Then join plans are developed using the genetic approach. As shown above, each candidate join plan is represented by a sequence in which to join the base relations. In the initial stage, the GEQO code simply generates some possible join sequences at random. For each join sequence considered, the standard planner code is invoked to estimate the cost of performing the query using that join sequence. (For each step of the join sequence, all three possible join strategies are considered; and all the initially-determined relation scan plans are available. The estimated cost is the cheapest of these possibilities.) Join sequences with lower estimated cost are considered “more fit” than those with higher cost. The genetic algorithm discards the least fit candidates. Then new candidates are generated by combining genes of more-fit candidates — that is, by using randomly-chosen portions of known low-cost join sequences to create new sequences for consideration. This process is repeated until a preset number of join sequences have been considered; then the best one found at any time during the search is used to generate the finished plan.

This process is inherently nondeterministic, because of the randomized choices made during both the initial population selection and subsequent “mutation” of the best candidates. To avoid surprising changes of the selected plan, each run of the GEQO algorithm restarts its random number generator with the current geqo_seed parameter setting. As long as geqo_seed and the other GEQO parameters are kept fixed, the same plan will be generated for a given query (and other planner inputs such as statistics). To experiment with different search paths, try changing geqo_seed.

### 54.3.2. Future Implementation Tasks for PostgreSQL GEQO

Work is still needed to improve the genetic algorithm parameter settings. In file `src/backend/optimizer/geqo/geqo_main.c`, routines `gimme_pool_size` and `gimme_number_generations`, we have to find a compromise for the parameter settings to satisfy two competing demands:

• Optimality of the query plan
• Computing time

In the current implementation, the fitness of each candidate join sequence is estimated by running the standard planner’s join selection and cost estimation code from scratch. To the extent that different candidates use similar sub-sequences of joins, a great deal of work will be repeated. This could be made significantly faster by retaining cost estimates for sub-joins. The problem is to avoid expending unreasonable amounts of memory on retaining that state.
At a more basic level, it is not clear that solving query optimization with a GA algorithm designed for TSP is appropriate. In the TSP case, the cost associated with any substring (partial tour) is independent of the rest of the tour, but this is certainly not true for query optimization. Thus it is questionable whether edge recombination crossover is the most effective mutation procedure.

Chapter 55. Index Access Method Interface
Definition

This chapter defines the interface between the core PostgreSQL system and index access methods, which manage individual index types. The core system knows nothing about indexes beyond what is specified here, so it is possible to develop entirely new index types by writing add-on code.

All indexes in PostgreSQL are what are known technically as secondary indexes; that is, the index is physically separate from the table file that it describes. Each index is stored as its own physical relation and so is described by an entry in the pg_class catalog. The contents of an index are entirely under the control of its index access method. In practice, all index access methods divide indexes into standard-size pages so that they can use the regular storage manager and buffer manager to access the index contents. (All the existing index access methods furthermore use the standard page layout described in Section 59.6, and they all use the same format for index tuple headers; but these decisions are not forced on an access method.)

An index is effectively a mapping from some data key values to tuple identifiers, or TIDs, of row versions (tuples) in the index's parent table. A TID consists of a block number and an item number within that block (see Section 59.6). This is sufficient information to fetch a particular row version from the table. Indexes are not directly aware that under MVCC, there might be multiple extant versions of the same logical row; to an index, each tuple is an independent object that needs its own index entry. Thus, an update of a row always creates all-new index entries for the row, even if the key values did not change. (HOT tuples are an exception to this statement; but indexes do not deal with those, either.) Index entries for dead tuples are reclaimed (by vacuuming) when the dead tuples themselves are reclaimed.

55.1. Catalog Entries for Indexes

Each index access method is described by a row in the pg_am system catalog (see Section 48.3). The principal contents of a pg_am row are references to pg_proc entries that identify the index access functions supplied by the access method. The APIs for these functions are defined later in this chapter. In addition, the pg_am row specifies a few fixed properties of the access method, such as whether it can support multicolumn indexes. There is not currently any special support for creating or deleting pg_am entries; anyone able to write a new access method is expected to be competent to insert an appropriate row for themselves.

To be useful, an index access method must also have one or more operator families and operator classes defined in pg_opfamily, pg_opclass, pg_amop, and pg_amproc. These entries allow the planner to determine what kinds of query qualifications can be used with indexes of this access method. Operator families and classes are described in Section 35.14, which is prerequisite material for reading this chapter.

An individual index is defined by a pg_class entry that describes it as a physical relation, plus a pg_index entry that shows the logical content of the index — that is, the set of index columns it has and the semantics of those columns, as captured by the associated operator classes. The index columns (key values) can be either simple columns of the underlying table or expressions over the table rows. The index access method normally has no interest in where the index key values come from (it is always handed precomputed key values) but it will be very interested in the operator class
information in pg_index. Both of these catalog entries can be accessed as part of the Relation data structure that is passed to all operations on the index.

Some of the flag columns of pg_am have nonobvious implications. The requirements of amcanunique are discussed in Section 55.5. The amcanmulticol flag asserts that the access method supports multicolored indexes, while amoptionalkey asserts that it allows scans where no indexable restriction clause is given for the first index column. When amcanmulticol is false, amoptionalkey essentially says whether the access method supports full-index scans without any restriction clause. Access methods that support multiple index columns must support scans that omit restrictions on any or all of the columns after the first; however they are permitted to require some restriction to appear for the first index column, and this is signaled by setting amoptionalkey false. One reason that an index AM might set amoptionalkey false is if it doesn’t index null values. Since most indexable operators are strict and hence cannot return true for null inputs, it is at first sight attractive to not store index entries for null values: they could never be returned by an index scan anyway. However, this argument fails when an index scan has no restriction clause for a given index column. In practice this means that indexes that have amoptionalkey true must index nulls, since the planner might decide to use such an index with no scan keys at all. A related restriction is that an index access method that supports multiple index columns must support indexing null values in columns after the first, because the planner will assume the index can be used for queries that do not restrict these columns. For example, consider an index on (a,b) and a query with WHERE a = 4. The system will assume the index can be used to scan for rows with a = 4, which is wrong if the index omits rows where b is null. It is, however, OK to omit rows where the first indexed column is null. An index access method that does index nulls may also set amsearchnulls, indicating that it supports IS NULL and IS NOT NULL clauses as search conditions.

55.2. Index Access Method Functions

The index construction and maintenance functions that an index access method must provide are:

```c
IndexBuildResult *
ambuild (Relation heapRelation,
        Relation indexRelation,
        IndexInfo *indexInfo);
```

Build a new index. The index relation has been physically created, but is empty. It must be filled in with whatever fixed data the access method requires, plus entries for all tuples already existing in the table. Ordinarily the ambuild function will call IndexBuildHeapScan() to scan the table for existing tuples and compute the keys that need to be inserted into the index. The function must return a palloc’d struct containing statistics about the new index.

```c
void
ambuildempty (Relation indexRelation);
```

Build an empty index, and write it to the initialization fork (INIT_FORKNUM) of the given relation. This method is called only for unlogged tables; the empty index written to the initialization fork will be copied over the main relation fork on each server restart.

```c
bool
aminsert (Relation indexRelation,
           Datum *values,
           bool *isnull,
           ItemPointer heap_tid,
```
Chapter 55. Index Access Method Interface Definition

Relation heapRelation,
IndexUniqueCheck checkUnique);

Insert a new tuple into an existing index. The values and isnull arrays give the key values to be indexed, and heap_tid is the TID to be indexed. If the access method supports unique indexes (its pg_am.amcanunique flag is true) then checkUnique indicates the type of uniqueness check to perform. This varies depending on whether the unique constraint is deferrable; see Section 55.5 for details. Normally the access method only needs the heapRelation parameter when performing uniqueness checking (since then it will have to look into the heap to verify tuple liveness).

The function’s Boolean result value is significant only when checkUnique is UNIQUE_CHECK_PARTIAL. In this case a TRUE result means the new entry is known unique, whereas FALSE means it might be non-unique (and a deferred uniqueness check must be scheduled). For other cases a constant FALSE result is recommended.

Some indexes might not index all tuples. If the tuple is not to be indexed, aminsert should just return without doing anything.

IndexBulkDeleteResult *
ambulkdelete (IndexVacuumInfo *info,
IndexBulkDeleteResult *stats,
IndexBulkDeleteCallback callback,
void *callback_state);

Delete tuple(s) from the index. This is a “bulk delete” operation that is intended to be implemented by scanning the whole index and checking each entry to see if it should be deleted. The passed-in callback function must be called, in the style callback(TID, callback_state) returns bool, to determine whether any particular index entry, as identified by its referenced TID, is to be deleted. Must return either NULL or a palloc’d struct containing statistics about the effects of the deletion operation. It is OK to return NULL if no information needs to be passed on to amvacuumcleanup.

Because of limited maintenance_work_mem, ambulkdelete might need to be called more than once when many tuples are to be deleted. The stats argument is the result of the previous call for this index (it is NULL for the first call within a VACUUM operation). This allows the AM to accumulate statistics across the whole operation. Typically, ambulkdelete will modify and return the same struct if the passed stats is not null.

IndexBulkDeleteResult *
amvacuumcleanup (IndexVacuumInfo *info,
IndexBulkDeleteResult *stats);

Clean up after a VACUUM operation (zero or more ambulkdelete calls). This does not have to do anything beyond returning index statistics, but it might perform bulk cleanup such as reclaiming empty index pages. stats is whatever the last ambulkdelete call returned, or NULL if ambulkdelete was not called because no tuples needed to be deleted. If the result is not NULL it must be a palloc’d struct. The statistics it contains will be used to update pg_class, and will be reported by VACUUM if VERBOSE is given. It is OK to return NULL if the index was not changed at all during the VACUUM operation, but otherwise correct stats should be returned.

As of PostgreSQL 8.4, amvacuumcleanup will also be called at completion of an ANALYZE operation. In this case stats is always NULL and any return value will be ignored. This case can be distinguished by checking info->analyze_only. It is recommended that the access method do nothing except post-insert cleanup in such a call, and that only in an autovacuum worker process.
bool amcanreturn (Relation indexRelation);

Check whether the index can support index-only scans by returning the indexed column values for an index entry in the form of an IndexTuple. Return TRUE if so, else FALSE. If the index AM can never support index-only scans (an example is hash, which stores only the hash values not the original data), it is sufficient to set its amcanreturn field to zero in pg_am.

void amcostestimate (PlannerInfo *root, IndexPath *path, double loop_count, Cost *indexStartupCost, Cost *indexTotalCost, Selectivity *indexSelectivity, double *indexCorrelation);

Estimate the costs of an index scan. This function is described fully in Section 55.6, below.

bytea * amoptions (ArrayType *reloptions, bool validate);

Parse and validate the reloptions array for an index. This is called only when a non-null reloptions array exists for the index. reloptions is a text array containing entries of the form name=value. The function should construct a bytea value, which will be copied into the rd_options field of the index’s relcache entry. The data contents of the bytea value are open for the access method to define; most of the standard access methods use struct StdRdOptions. When validate is true, the function should report a suitable error message if any of the options are unrecognized or have invalid values; when validate is false, invalid entries should be silently ignored. (validate is false when loading options already stored in pg_catalog; an invalid entry could only be found if the access method has changed its rules for options, and in that case ignoring obsolete entries is appropriate.) It is OK to return NULL if default behavior is wanted.

The purpose of an index, of course, is to support scans for tuples matching an indexable WHERE condition, often called a qualifier or scan key. The semantics of index scanning are described more fully in Section 55.3, below. An index access method can support “plain” index scans, “bitmap” index scans, or both. The scan-related functions that an index access method must or may provide are:

IndexScanDesc
ambeginscan (Relation indexRelation, int nkeys, int norderbys);

Prepare for an index scan. The nkeys and norderbys parameters indicate the number of quals and ordering operators that will be used in the scan; these may be useful for space allocation purposes. Note that the actual values of the scan keys aren’t provided yet. The result must be a palloc’d struct. For implementation reasons the index access method must create this struct by calling RelationGetIndexScan(). In most cases ambeginscan does little beyond making that call and perhaps acquiring locks; the interesting parts of index-scan startup are in amrescan.

void amrescan (IndexScanDesc scan, ScanKey keys,
Start or restart an index scan, possibly with new scan keys. (To restart using previously-passed keys, NULL is passed for keys and/or orderbys.) Note that it is not allowed for the number of keys or order-by operators to be larger than what was passed to ambeginscan. In practice the restart feature is used when a new outer tuple is selected by a nested-loop join and so a new key comparison value is needed, but the scan key structure remains the same.

boolean
amgettuple (IndexScanDesc scan,
    ScanDirection direction);

Fetch the next tuple in the given scan, moving in the given direction (forward or backward in the index). Returns TRUE if a tuple was obtained, FALSE if no matching tuples remain. In the TRUE case the tuple TID is stored into the scan structure. Note that “success” means only that the index contains an entry that matches the scan keys, not that the tuple necessarily still exists in the heap or will pass the caller’s snapshot test. On success, amgettuple must also set scan->xs_recheck to TRUE or FALSE. FALSE means it is certain that the index entry matches the scan keys. TRUE means this is not certain, and the conditions represented by the scan keys must be rechecked against the heap tuple after fetching it. This provision supports “lossy” index operators. Note that rechecking will extend only to the scan conditions; a partial index predicate (if any) is never rechecked by amgettuple callers.

If the index supports index-only scans (i.e., amcanreturn returns TRUE for it), then on success the AM must also check scan->xs_want_itup, and if that is true it must return the original indexed data for the index entry, in the form of an IndexTuple pointer stored at scan->xs_itup, with tuple descriptor scan->xs_itupdesc. (Management of the data referenced by the pointer is the access method’s responsibility. The data must remain good at least until the next amgettuple, amrescan, or amendscan call for the scan.)

The amgettuple function need only be provided if the access method supports “plain” index scans. If it doesn’t, the amgettuple field in its pg_am row must be set to zero.

int64
amgetbitmap (IndexScanDesc scan,
    TIDBitmap *tbm);

Fetch all tuples in the given scan and add them to the caller-supplied TIDBitmap (that is, OR the set of tuple IDs into whatever set is already in the bitmap). The number of tuples fetched is returned (this might be just an approximate count, for instance some AMs do not detect duplicates). While inserting tuple IDs into the bitmap, amgetbitmap can indicate that rechecking of the scan conditions is required for specific tuple IDs. This is analogous to the xs_recheck output parameter of amgettuple. Note: in the current implementation, support for this feature is conflated with support for lossy storage of the bitmap itself, and therefore callers recheck both the scan conditions and the partial index predicate (if any) for recheckable tuples. That might not always be true, however. amgetbitmap and amgettuple cannot be used in the same index scan; there are other restrictions too when using amgetbitmap, as explained in Section 55.3.

The amgetbitmap function need only be provided if the access method supports “bitmap” index scans. If it doesn’t, the amgetbitmap field in its pg_am row must be set to zero.
End a scan and release resources. The scan struct itself should not be freed, but any locks or pins taken internally by the access method must be released, as well as any other memory allocated by ambeginscan and other scan-related functions.

```c
void ammarkpos (IndexScanDesc scan);
```

Mark current scan position. The access method need only support one remembered scan position per scan.

```c
void amrestrpos (IndexScanDesc scan);
```

Restore the scan to the most recently marked position.

By convention, the `pg_proc` entry for an index access method function should show the correct number of arguments, but declare them all as type `internal` (since most of the arguments have types that are not known to SQL, and we don’t want users calling the functions directly anyway). The return type is declared as `void`, `internal`, or `boolean` as appropriate. The only exception is `amoptions`, which should be correctly declared as taking `text[]` and `bool` and returning `bytea`. This provision allows client code to execute `amoptions` to test validity of options settings.

### 55.3. Index Scanning

In an index scan, the index access method is responsible for regurgitating the TIDs of all the tuples it has been told about that match the scan keys. The access method is not involved in actually fetching those tuples from the index’s parent table, nor in determining whether they pass the scan’s time qualification test or other conditions.

A scan key is the internal representation of a `WHERE` clause of the form `index_key operator constant`, where the index key is one of the columns of the index and the operator is one of the members of the operator family associated with that index column. An index scan has zero or more scan keys, which are implicitly ANDed — the returned tuples are expected to satisfy all the indicated conditions.

The access method can report that the index is *lossy*, or requires rechecks, for a particular query. This implies that the index scan will return all the entries that pass the scan key, plus possibly additional entries that do not. The core system’s index-scan machinery will then apply the index conditions again to the heap tuple to verify whether or not it really should be selected. If the recheck option is not specified, the index scan must return exactly the set of matching entries.

Note that it is entirely up to the access method to ensure that it correctly finds all and only the entries passing all the given scan keys. Also, the core system will simply hand off all the `WHERE` clauses that match the index keys and operator families, without any semantic analysis to determine whether they are redundant or contradictory. As an example, given `WHERE x > 4 AND x > 14` where `x` is a b-tree indexed column, it is left to the b-tree `amrescan` function to realize that the first scan key is redundant and can be discarded. The extent of preprocessing needed during `amrescan` will depend on the extent to which the index access method needs to reduce the scan keys to a “normalized” form.

Some access methods return index entries in a well-defined order, others do not. There are actually two different ways that an access method can support sorted output:
• Access methods that always return entries in the natural ordering of their data (such as btree) should set `pg_am.amcanorder` to true. Currently, such access methods must use btree-compatible strategy numbers for their equality and ordering operators.

• Access methods that support ordering operators should set `pg_am.amcanorderbyop` to true. This indicates that the index is capable of returning entries in an order satisfying `ORDER BY index_key` operator constant. Scan modifiers of that form can be passed to `amrescan` as described previously.

The `amgettuple` function has a direction argument, which can be either `ForwardScanDirection` (the normal case) or `BackwardScanDirection`. If the first call after `amrescan` specifies `BackwardScanDirection`, then the set of matching index entries is to be scanned back-to-front rather than in the normal front-to-back direction, so `amgettuple` must return the last matching tuple in the index, rather than the first one as it normally would. (This will only occur for access methods that set `amcanorder` to true.) After the first call, `amgettuple` must be prepared to advance the scan in either direction from the most recently returned entry. (But if `pg_am.amcanbackward` is false, all subsequent calls will have the same direction as the first one.)

Access methods that support ordered scans must support “marking” a position in a scan and later returning to the marked position. The same position might be restored multiple times. However, only one position need be remembered per scan; a new `ammarkpos` call overrides the previously marked position. An access method that does not support ordered scans should still provide mark and restore functions in `pg_am`, but it is sufficient to have them throw errors if called.

Both the scan position and the mark position (if any) must be maintained consistently in the face of concurrent insertions or deletions in the index. It is OK if a freshly-inserted entry is not returned by a scan that would have found the entry if it had existed when the scan started, or for the scan to return such an entry upon rescanning or backing up even though it had not been returned the first time through. Similarly, a concurrent delete might or might not be reflected in the results of a scan. What is important is that insertions or deletions not cause the scan to miss or multiply return entries that were not themselves being inserted or deleted.

If the index stores the original indexed data values (and not some lossy representation of them), it is useful to support index-only scans, in which the index returns the actual data not just the TID of the heap tuple. This will only work if the visibility map shows that the TID is on an all-visible page; else the heap tuple must be visited anyway to check MVCC visibility. But that is no concern of the access method’s.

Instead of using `amgettuple`, an index scan can be done with `amgetbitmap` to fetch all tuples in one call. This can be noticeably more efficient than `amgettuple` because it allows avoiding lock/unlock cycles within the access method. In principle `amgetbitmap` should have the same effects as repeated `amgettuple` calls, but we impose several restrictions to simplify matters. First of all, `amgetbitmap` returns all tuples at once and marking or restoring scan positions isn’t supported. Secondly, the tuples are returned in a bitmap which doesn’t have any specific ordering, which is why `amgetbitmap` doesn’t take a direction argument. (Ordering operators will never be supplied for such a scan, either.) Also, there is no provision for index-only scans with `amgetbitmap`, since there is no way to return the contents of index tuples. Finally, `amgetbitmap` does not guarantee any locking of the returned tuples, with implications spelled out in Section 55.4.

Note that it is permitted for an access method to implement only `amgetbitmap` and not `amgettuple`, or vice versa, if its internal implementation is unsuited to one API or the other.
55.4. Index Locking Considerations

Index access methods must handle concurrent updates of the index by multiple processes. The core PostgreSQL system obtains AccessShareLock on the index during an index scan, and RowExclusiveLock when updating the index (including plain VACUUM). Since these lock types do not conflict, the access method is responsible for handling any fine-grained locking it might need. An exclusive lock on the index as a whole will be taken only during index creation, destruction, or REINDEX.

Building an index type that supports concurrent updates usually requires extensive and subtle analysis of the required behavior. For the b-tree and hash index types, you can read about the design decisions involved in src/backend/access/nbtree/README and src/backend/access/hash/README.

Aside from the index’s own internal consistency requirements, concurrent updates create issues about consistency between the parent table (the heap) and the index. Because PostgreSQL separates accesses and updates of the heap from those of the index, there are windows in which the index might be inconsistent with the heap. We handle this problem with the following rules:

- A new heap entry is made before making its index entries. (Therefore a concurrent index scan is likely to fail to see the heap entry. This is okay because the index reader would be uninterested in an uncommitted row anyway. But see Section 55.5.)
- When a heap entry is to be deleted (by VACUUM), all its index entries must be removed first.
- An index scan must maintain a pin on the index page holding the item last returned by amgettuple, and ambulkdelete cannot delete entries from pages that are pinned by other backends. The need for this rule is explained below.

Without the third rule, it is possible for an index reader to see an index entry just before it is removed by VACUUM, and then to arrive at the corresponding heap entry after that was removed by VACUUM. This creates no serious problems if that item number is still unused when the reader reaches it, since an empty item slot will be ignored by heap_fetch(). But what if a third backend has already reused the item slot for something else? When using an MVCC-compliant snapshot, there is no problem because the new occupant of the slot is certain to be too new to pass the snapshot test. However, with a non-MVCC-compliant snapshot (such as SnapshotAny), it would be possible to accept and return a row that does not in fact match the scan keys. We could defend against this scenario by requiring the scan keys to be rechecked against the heap row in all cases, but that is too expensive. Instead, we use a pin on an index page as a proxy to indicate that the reader might still be “in flight” from the index entry to the matching heap entry. Making ambulkdelete block on such a pin ensures that VACUUM cannot delete the heap entry before the reader is done with it. This solution costs little in run time, and adds blocking overhead only in the rare cases where there actually is a conflict.

This solution requires that index scans be “synchronous”: we have to fetch each heap tuple immediately after scanning the corresponding index entry. This is expensive for a number of reasons. An “asynchronous” scan in which we collect many TIDs from the index, and only visit the heap tuples sometime later, requires much less index locking overhead and can allow a more efficient heap access pattern. Per the above analysis, we must use the synchronous approach for non-MVCC-compliant snapshots, but an asynchronous scan is workable for a query using an MVCC snapshot.

In an amgetbitmap index scan, the access method does not keep an index pin on any of the returned tuples. Therefore it is only safe to use such scans with MVCC-compliant snapshots.

When the ampredlocks flag is not set, any scan using that index access method within a serializable transaction will acquire a nonblocking predicate lock on the full index. This will generate a read-write conflict with the insert of any tuple into that index by a concurrent serializable transaction. If certain patterns of read-write conflicts are detected among a set of concurrent serializable transactions, one
of those transactions may be canceled to protect data integrity. When the flag is set, it indicates that the index access method implements finer-grained predicate locking, which will tend to reduce the frequency of such transaction cancellations.

55.5. Index Uniqueness Checks

PostgreSQL enforces SQL uniqueness constraints using unique indexes, which are indexes that disallow multiple entries with identical keys. An access method that supports this feature sets pg_am.amcanunique true. (At present, only b-tree supports it.)

Because of MVCC, it is always necessary to allow duplicate entries to exist physically in an index: the entries might refer to successive versions of a single logical row. The behavior we actually want to enforce is that no MVCC snapshot could include two rows with equal index keys. This breaks down into the following cases that must be checked when inserting a new row into a unique index:

- If a conflicting valid row has been deleted by the current transaction, it’s okay. (In particular, since an UPDATE always deletes the old row version before inserting the new version, this will allow an UPDATE on a row without changing the key.)
- If a conflicting row has been inserted by an as-yet-uncommitted transaction, the would-be inserter must wait to see if that transaction commits. If it rolls back then there is no conflict. If it commits without deleting the conflicting row again, there is a uniqueness violation. (In practice we just wait for the other transaction to end and then redo the visibility check in toto.)
- Similarly, if a conflicting valid row has been deleted by an as-yet-uncommitted transaction, the would-be inserter must wait for that transaction to commit or abort, and then repeat the test.

Furthermore, immediately before reporting a uniqueness violation according to the above rules, the access method must recheck the liveness of the row being inserted. If it is committed dead then no violation should be reported. (This case cannot occur during the ordinary scenario of inserting a row that’s just been created by the current transaction. It can happen during CREATE UNIQUE INDEX CONCURRENTLY, however.)

We require the index access method to apply these tests itself, which means that it must reach into the heap to check the commit status of any row that is shown to have a duplicate key according to the index contents. This is without a doubt ugly and non-modular, but it saves redundant work: if we did a separate probe then the index lookup for a conflicting row would be essentially repeated while finding the place to insert the new row’s index entry. What’s more, there is no obvious way to avoid race conditions unless the conflict check is an integral part of insertion of the new index entry.

If the unique constraint is deferrable, there is additional complexity: we need to be able to insert an index entry for a new row, but defer any uniqueness-violation error until end of statement or even later. To avoid unnecessary repeat searches of the index, the index access method should do a preliminary uniqueness check during the initial insertion. If this shows that there is definitely no conflicting live tuple, we are done. Otherwise, we schedule a recheck to occur when it is time to enforce the constraint. If, at the time of the recheck, both the inserted tuple and some other tuple with the same key are live, then the error must be reported. (Note that for this purpose, “live” actually means “any tuple in the index entry’s HOT chain is live”.) To implement this, the aminsert function is passed a checkUnique parameter having one of the following values:

- UNIQUE_CHECK_NO indicates that no uniqueness checking should be done (this is not a unique index).
• `UNIQUE_CHECK_YES` indicates that this is a non-deferrable unique index, and the uniqueness check must be done immediately, as described above.

• `UNIQUE_CHECK_PARTIAL` indicates that the unique constraint is deferrable. PostgreSQL will use this mode to insert each row’s index entry. The access method must allow duplicate entries into the index, and report any potential duplicates by returning FALSE from `aminsert`. For each row for which FALSE is returned, a deferred recheck will be scheduled.

The access method must identify any rows which might violate the unique constraint, but it is not an error for it to report false positives. This allows the check to be done without waiting for other transactions to finish; conflicts reported here are not treated as errors and will be rechecked later, by which time they may no longer be conflicts.

• `UNIQUE_CHECK_EXISTING` indicates that this is a deferred recheck of a row that was reported as a potential uniqueness violation. Although this is implemented by calling `aminsert`, the access method must not insert a new index entry in this case. The index entry is already present. Rather, the access method must check to see if there is another live index entry. If so, and if the target row is also still live, report error.

It is recommended that in a `UNIQUE_CHECK_EXISTING` call, the access method further verify that the target row actually does have an existing entry in the index, and report error if not. This is a good idea because the index tuple values passed to `aminsert` will have been recomputed. If the index definition involves functions that are not really immutable, we might be checking the wrong area of the index. Checking that the target row is found in the recheck verifies that we are scanning for the same tuple values as were used in the original insertion.

55.6. Index Cost Estimation Functions

The `amcostestimate` function is given information describing a possible index scan, including lists of WHERE and ORDER BY clauses that have been determined to be usable with the index. It must return estimates of the cost of accessing the index and the selectivity of the WHERE clauses (that is, the fraction of parent-table rows that will be retrieved during the index scan). For simple cases, nearly all the work of the cost estimator can be done by calling standard routines in the optimizer; the point of having an `amcostestimate` function is to allow index access methods to provide index-type-specific knowledge, in case it is possible to improve on the standard estimates.

Each `amcostestimate` function must have the signature:

```c
void amcostestimate (PlannerInfo *root,
    IndexPath *path,
    double loop_count,
    Cost *indexStartupCost,
    Cost *indexTotalCost,
    Selectivity *indexSelectivity,
    double *indexCorrelation);
```

The first three parameters are inputs:

```c
root
```

The planner’s information about the query being processed.
path

The index access path being considered. All fields except cost and selectivity values are valid.

loop_count

The number of repetitions of the index scan that should be factored into the cost estimates. This will typically be greater than one when considering a parameterized scan for use in the inside of a nestloop join. Note that the cost estimates should still be for just one scan; a larger loop_count means that it may be appropriate to allow for some caching effects across multiple scans.

The last four parameters are pass-by-reference outputs:

*indexStartupCost
  Set to cost of index start-up processing

*indexTotalCost
  Set to total cost of index processing

*indexSelectivity
  Set to index selectivity

*indexCorrelation
  Set to correlation coefficient between index scan order and underlying table’s order

Note that cost estimate functions must be written in C, not in SQL or any available procedural language, because they must access internal data structures of the planner/optimizer.

The index access costs should be computed using the parameters used by src/backend/optimizer/path/costsize.c: a sequential disk block fetch has cost seq_page_cost, a nonsequential fetch has cost random_page_cost, and the cost of processing one index row should usually be taken as cpu_index_tuple_cost. In addition, an appropriate multiple of cpu_operator_cost should be charged for any comparison operators invoked during index processing (especially evaluation of the indexquals themselves).

The access costs should include all disk and CPU costs associated with scanning the index itself, but not the costs of retrieving or processing the parent-table rows that are identified by the index.

The “start-up cost” is the part of the total scan cost that must be expended before we can begin to fetch the first row. For most indexes this can be taken as zero, but an index type with a high start-up cost might want to set it nonzero.

The indexSelectivity should be set to the estimated fraction of the parent table rows that will be retrieved during the index scan. In the case of a lossy query, this will typically be higher than the fraction of rows that actually pass the given qual conditions.

The indexCorrelation should be set to the correlation (ranging between -1.0 and 1.0) between the index order and the table order. This is used to adjust the estimate for the cost of fetching rows from the parent table.

When loop_count is greater than one, the returned numbers should be averages expected for any one scan of the index.

Cost Estimation

A typical cost estimator will proceed as follows:
1. Estimate and return the fraction of parent-table rows that will be visited based on the given
   qual conditions. In the absence of any index-type-specific knowledge, use the standard optimizer
   function `clauselist_selectivity()`:
   
   ```
   *indexSelectivity = clauselist_selectivity(root, path->indexquals,
   path->indexinfo->rel->relid,
   JOIN_INNER, NULL);
   ```

2. Estimate the number of index rows that will be visited during the scan. For many index types this
   is the same as `indexSelectivity` times the number of rows in the index, but it might be more.
   (Note that the index’s size in pages and rows is available from the `path->indexinfo struct`.)

3. Estimate the number of index pages that will be retrieved during the scan. This might be just
   `indexSelectivity` times the index’s size in pages.

4. Compute the index access cost. A generic estimator might do this:

   ```
   /*
   * Our generic assumption is that the index pages will be read
   * sequentially, so they cost seq_page_cost each, not random_page_cost.
   * Also, we charge for evaluation of the indexquals at each index row.
   * All the costs are assumed to be paid incrementally during the scan.
   */
   indexQualCost = cost_qual_eval(indexQualCost, path->indexquals, root);
   *indexStartupCost = indexQualCost.startup;
   *indexTotalCost = seq_page_cost * numIndexPages +
       (cpu_index_tuple_cost + indexQualCost.per_tuple) * numIndexTuples;
   ```
   However, the above does not account for amortization of index reads across repeated index scans.

5. Estimate the index correlation. For a simple ordered index on a single field, this can be retrieved
   from `pg_statistic`. If the correlation is not known, the conservative estimate is zero (no correla-
   tion).

Examples of cost estimator functions can be found in `src/backend/utils/adt/selfuncs.c`. 
Chapter 56. GiST Indexes

56.1. Introduction

GiST stands for Generalized Search Tree. It is a balanced, tree-structured access method, that acts as a base template in which to implement arbitrary indexing schemes. B-trees, R-trees and many other indexing schemes can be implemented in GiST.

One advantage of GiST is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from the University of California at Berkeley’s GiST Indexing Project web site¹ and Marcel Kornacker’s thesis, Access Methods for Next-Generation Database Systems². The GiST implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their web site³.

56.2. Built-in Operator Classes

The core PostgreSQL distribution includes the GiST operator classes shown in Table 56-1. (Some of the optional modules described in Appendix F provide additional GiST operator classes.)

Table 56-1. Built-in GiST Operator Classes

<table>
<thead>
<tr>
<th>Name</th>
<th>Indexed Data Type</th>
<th>Indexable Operators</th>
<th>Ordering Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td>box_ops</td>
<td>box</td>
<td>&amp;&amp; &amp;&gt; &amp;&lt; &amp;&lt;&lt; &amp;&gt;</td>
<td>&amp;&gt; &amp;&lt; &amp;&lt;&lt; &amp;&gt;</td>
</tr>
<tr>
<td>circle_ops</td>
<td>circle</td>
<td>&amp;&amp; &amp;&gt; &amp;&lt; &amp;&lt;&lt; &amp;&gt;</td>
<td>&amp;&gt; &amp;&lt; &amp;&lt;&lt; &amp;&gt;</td>
</tr>
<tr>
<td>inet_ops</td>
<td>inet, cidr</td>
<td>&amp;&amp; &gt;&gt; &gt;&gt; = &gt; = &lt;&lt;=</td>
<td>&lt;&lt;= &lt;&lt;= &lt;&lt;= &lt;&lt;=</td>
</tr>
<tr>
<td>point_ops</td>
<td>point</td>

<td>&lt; @ &lt; @ &lt; @ &lt; @</td>
</tr>
<tr>
<td>poly_ops</td>
<td>polygon</td>
<td>&amp;&amp; &amp;&gt; &amp;&lt; &amp;&lt;&lt; &amp;&gt;</td>
<td>&amp;&gt; &amp;&lt; &amp;&lt;&lt; &amp;&gt;</td>
</tr>
<tr>
<td>range_ops</td>
<td>any range type</td>
<td>&amp;&amp; &amp;&gt; &amp;&lt; &amp;&lt;&lt; &amp;&gt;</td>
<td>&amp;&gt; &amp;&lt; &amp;&lt;&lt; &amp;&gt;</td>
</tr>
<tr>
<td>tsquery_ops</td>
<td>tsquery</td>
<td>&lt; @ @</td>
<td>&lt; @ @</td>
</tr>
<tr>
<td>tsvector_ops</td>
<td>tsvector</td>
<td>@ @</td>
<td>@ @</td>
</tr>
</tbody>
</table>

¹. http://gist.cs.berkeley.edu/
For historical reasons, the `inet_ops` operator class is not the default class for types `inet` and `cidr`. To use it, mention the class name in `CREATE INDEX`, for example:

```
CREATE INDEX ON my_table USING gist (my_inet_column inet_ops);
```

### 56.3. Extensibility

Traditionally, implementing a new index access method meant a lot of difficult work. It was necessary to understand the inner workings of the database, such as the lock manager and Write-Ahead Log. The GiST interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GiST layer itself takes care of concurrency, logging and searching the tree structure.

This extensibility should not be confused with the extensibility of the other standard search trees in terms of the data they can handle. For example, PostgreSQL supports extensible B-trees and hash indexes. That means that you can use PostgreSQL to build a B-tree or hash over any data type you want. But B-trees only support range predicates (`<`, `=`, `>`), and hash indexes only support equality queries.

So if you index, say, an image collection with a PostgreSQL B-tree, you can only issue queries such as “is imagex equal to imagey”, “is imagex less than imagey” and “is imagex greater than imagey”. Depending on how you define “equals”, “less than” and “greater than” in this context, this could be useful. However, by using a GiST based index, you could create ways to ask domain-specific questions, perhaps “find all images of horses” or “find all over-exposed images”.

All it takes to get a GiST access method up and running is to implement several user-defined methods, which define the behavior of keys in the tree. Of course these methods have to be pretty fancy to support fancy queries, but for all the standard queries (B-trees, R-trees, etc.) they’re relatively straightforward. In short, GiST combines extensibility along with generality, code reuse, and a clean interface.

There are seven methods that an index operator class for GiST must provide, and an eighth that is optional. Correctness of the index is ensured by proper implementation of the `same`, `consistent` and `union` methods, while efficiency (size and speed) of the index will depend on the `penalty` and `picksplit` methods. The remaining two basic methods are `compress` and `decompress`, which allow an index to have internal tree data of a different type than the data it indexes. The leaves are to be of the indexed data type, while the other tree nodes can be of any C struct (but you still have to follow PostgreSQL data type rules here, see about `varlena` for variable sized data). If the tree’s internal data type exists at the SQL level, the `STORAGE` option of the `CREATE OPERATOR CLASS` command can be used. The optional eighth method is `distance`, which is needed if the operator class wishes to support ordered scans (nearest-neighbor searches).

**consistent**

Given an index entry $p$ and a query value $q$, this function determines whether the index entry is “consistent” with the query; that is, could the predicate “`indexed_column indexable_operator q`” be true for any row represented by the index entry? For a leaf index entry this is equivalent to testing the indexable condition, while for an internal tree node this determines whether it is necessary to scan the subtree of the index represented by the tree node. When the result is `true`, a `recheck` flag must also be returned. This indicates whether the predicate is certainly true or only possibly true. If `recheck = false` then the index has tested the predicate condition exactly, whereas if `recheck = true` the row is only a candidate match.
In that case the system will automatically evaluate the `indexable_operator` against the actual row value to see if it is really a match. This convention allows GiST to support both lossless and lossy index structures.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_consistent(internal, data_type, smallint, oid, internal) RETURNS bool
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```c
Datum my_consistent(PG_FUNCTION_ARGS);
PG_FUNCTION_INFO_V1(my_consistent);

Datum
my_consistent(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
data_type *query = PG_GETARG_DATA_TYPE_P(1);
StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
/* Oid subtype = PG_GETARG_OID(3); */
bool *recheck = (bool *) PG_GETARG_POINTER(4);
data_type *key = DatumGetDataType(entry->key);
bool retval;

    /*
    * determine return value as a function of strategy, key and query.
    * Use GIST_LEAF(entry) to know where you’re called in the index tree,
    * which comes handy when supporting the = operator for example (you could
    * check for non empty union() in non-leaf nodes and equality in leaf
    * nodes).
    */

    *recheck = true;  /* or false if check is exact */

    PG_RETURN_BOOL(retval);
}
```

Here, `key` is an element in the index and `query` the value being looked up in the index. The `StrategyNumber` parameter indicates which operator of your operator class is being applied — it matches one of the operator numbers in the `CREATE OPERATOR CLASS` command. Depending on what operators you have included in the class, the data type of `query` could vary with the operator, but the above skeleton assumes it doesn’t.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_union(internal, internal) RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```c
Datum my_union(PG_FUNCTION_ARGS);
PG_FUNCTION_INFO_V1(my_union);
```

This method consolidates information in the tree. Given a set of entries, this function generates a new index entry that represents all the given entries.
Datum
my_union(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
    GISTENTRY *ent = entryvec->vector;
    data_type *out,
            *tmp,
            *old;
    int numranges,
        i = 0;

    numranges = entryvec->n;
    tmp = DatumGetDataType(ent[0].key);
    out = tmp;

    if (numranges == 1)
    {
        out = data_type_deep_copy(tmp);

        PG_RETURN_DATA_TYPE_P(out);
    }

    for (i = 1; i < numranges; i++)
    {
        old = out;
        tmp = DatumGetDataType(ent[i].key);
        out = my_union_implementation(out, tmp);
    }

    PG_RETURN_DATA_TYPE_P(out);
}

As you can see, in this skeleton we’re dealing with a data type where union(X, Y, Z) = union(union(X, Y), Z). It’s easy enough to support data types where this is not the case, by implementing the proper union algorithm in this GiST support method.

The union implementation function should return a pointer to newly palloc()ed memory. You can’t just return whatever the input is.

compress

Converts the data item into a format suitable for physical storage in an index page.

The SQL declaration of the function must look like this:

CREATE OR REPLACE FUNCTION my_compress(internal)
RETURNS internal
AS ‘MODULE_PATHNAME’
LANGUAGE C STRICT;

And the matching code in the C module could then follow this skeleton:

Datum my_compress(PG_FUNCTION_ARGS);
PG_FUNCTION_INFO_V1(my_compress);

Datum my_compress(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *retval;

    return retval;
}
if (entry->leafkey) {
    /* replace entry->key with a compressed version */
    compressed_data_type *compressed_data = palloc(sizeof(compressed_data_type));
    /* fill *compressed_data from entry->key ... */
    retval = palloc(sizeof(GISTENTRY));
    gistentryinit(*retval, PointerGetDatum(compressed_data),
                  entry->rel, entry->page, entry->offset, FALSE);
} else {
    /* typically we needn’t do anything with non-leaf entries */
    retval = entry;
}
PG_RETURN_POINTER(retval);

You have to adapt compressed_data_type to the specific type you’re converting to in order to compress your leaf nodes, of course.

Depending on your needs, you could also need to care about compressing NULL values in there, storing for example (Datum) 0 like gist_circle_compress does.

decompress

The reverse of the compress method. Converts the index representation of the data item into a format that can be manipulated by the database.

The SQL declaration of the function must look like this:

CREATE OR REPLACE FUNCTION my_decompress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

And the matching code in the C module could then follow this skeleton:

Datum my_decompress(PG_FUNCTION_ARGS);
PG_FUNCTION_INFO_V1(my_decompress);

Datum my_decompress(PG_FUNCTION_ARGS)
{
    PG_RETURN_POINTER(PG_GETARG_POINTER(0));
}

The above skeleton is suitable for the case where no decompression is needed.

penalty

Returns a value indicating the “cost” of inserting the new entry into a particular branch of the tree. Items will be inserted down the path of least penalty in the tree. Values returned by penalty should be non-negative. If a negative value is returned, it will be treated as zero.

The SQL declaration of the function must look like this:

CREATE OR REPLACE FUNCTION my_penalty(internal, internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT; -- in some cases penalty functions need not be strict
And the matching code in the C module could then follow this skeleton:

```c
Datum my_penalty(PG_FUNCTION_ARGS);
PG_FUNCTION_INFO_V1(my_penalty);

Datum
my_penalty(PG_FUNCTION_ARGS)
{
    GISTENTRY *origentry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *newentry = (GISTENTRY *) PG_GETARG_POINTER(1);
    float *penalty = (float *) PG_GETARG_POINTER(2);
    data_type *orig = DatumGetDataType(origentry->key);
    data_type *new = DatumGetDataType(newentry->key);

    *penalty = my_penalty_implementation(orig, new);
    PG_RETURN_POINTER(penalty);
}
```

The **penalty** function is crucial to good performance of the index. It'll get used at insertion time to determine which branch to follow when choosing where to add the new entry in the tree. At query time, the more balanced the index, the quicker the lookup.

**picksplit**

When an index page split is necessary, this function decides which entries on the page are to stay on the old page, and which are to move to the new page.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_picksplit(internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```c
Datum my_picksplit(PG_FUNCTION_ARGS);
PG_FUNCTION_INFO_V1(my_picksplit);

Datum
my_picksplit(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
    OffsetNumber maxoff = entryvec->n - 1;
    GISTENTRY *ent = entryvec->vector;
    GIST_SPLITVEC *v = (GIST_SPLITVEC *) PG_GETARG_POINTER(1);
    int i,
        nbytes;
    OffsetNumber *left,
        *right;
    data_type *tmp_union;
    data_type *unionL;
    data_type *unionR;
    GISTENTRY **raw_entryvec;

    maxoff = entryvec->n - 1;
    nbytes = (maxoff + 1) * sizeof(OffsetNumber);

    v->spl_left = (OffsetNumber *) palloc(nbytes);
    left = v->spl_left;
    v->spl_nleft = 0;
```
Chapter 56. GiST Indexes

v->spl_right = (OffsetNumber *) palloc(nbytes);
right = v->spl_right;
v->spl_nright = 0;

unionL = NULL;
unionR = NULL;

/* Initialize the raw entry vector. */
raw_entryvec = (GISTENTRY **) malloc(entryvec->n * sizeof(void *));
for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
   raw_entryvec[i] = &(entryvec->vector[i]);

for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
{
    int real_index = raw_entryvec[i] - entryvec->vector;
    tmp_union = DatumGetDataType(entryvec->vector[real_index].key);
    Assert(tmp_union != NULL);

    /* Choose where to put the index entries and update unionL and unionR
     * accordingly. Append the entries to either v_spl_left or
     * v_spl_right, and care about the counters.
     */

    if (my_choice_is_left(unionL, curl, unionR, curr))
    {
        if (unionL == NULL)
            unionL = tmp_union;
        else
            unionL = my_union_implementation(unionL, tmp_union);

        *left = real_index;
        ++left;
        ++(v->spl_nleft);
    }
    else
    {
        /*
        * Same on the right
        */
    }
}

v->spl_ldatum = DataTypeGetDatum(unionL);
v->spl_rdatum = DataTypeGetDatum(unionR);
PG_RETURN_POINTER(v);

Like penalty, the picksplit function is crucial to good performance of the index. Designing suitable penalty and picksplit implementations is where the challenge of implementing well-performing GiST indexes lies.
same

Returns true if two index entries are identical, false otherwise.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_same(internal, internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```c
Datum my_same(PG_FUNCTION_ARGS);
PG_FUNCTION_INFO_V1(my_same);

Datum
my_same(PG_FUNCTION_ARGS)
{
    prefix_range *v1 = PG_GETARG_PREFIX_RANGE_P(0);
    prefix_range *v2 = PG_GETARG_PREFIX_RANGE_P(1);
    bool *result = (bool *) PG_GETARG_POINTER(2);
    *result = my_eq(v1, v2);
    PG_RETURN_POINTER(result);
}
```

For historical reasons, the `same` function doesn’t just return a Boolean result; instead it has to store the flag at the location indicated by the third argument.

distance

Given an index entry \( p \) and a query value \( q \), this function determines the index entry’s “distance” from the query value. This function must be supplied if the operator class contains any ordering operators. A query using the ordering operator will be implemented by returning index entries with the smallest “distance” values first, so the results must be consistent with the operator’s semantics. For a leaf index entry the result just represents the distance to the index entry; for an internal tree node, the result must be the smallest distance that any child entry could have.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_distance(internal, data_type, smallint, oid)
RETURNS float8
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```c
Datum my_distance(PG_FUNCTION_ARGS);
PG_FUNCTION_INFO_V1(my_distance);

Datum
my_distance(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    data_type *query = PG_GETARG_DATA_TYPE_P(1);
    StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
    /* Oid subtype = PG_GETARG_OID(3); */
    data_type *key = DatumGetDataType(entry->key);
    double retval;

    /*
    * determine return value as a function of strategy, key and query.
    */
```
The arguments to the distance function are identical to the arguments of the consistent function, except that no recheck flag is used. The distance to a leaf index entry must always be determined exactly, since there is no way to re-order the tuples once they are returned. Some approximation is allowed when determining the distance to an internal tree node, so long as the result is never greater than any child’s actual distance. Thus, for example, distance to a bounding box is usually sufficient in geometric applications. The result value can be any finite float8 value. (Infinity and minus infinity are used internally to handle cases such as nulls, so it is not recommended that distance functions return these values.)

All the GiST support methods are normally called in short-lived memory contexts; that is, CurrentMemoryContext will get reset after each tuple is processed. It is therefore not very important to worry about pfree’ing everything you palloc. However, in some cases it’s useful for a support method to cache data across repeated calls. To do that, allocate the longer-lived data in fcinfo->flinfo->fn_mctx, and keep a pointer to it in fcinfo->flinfo->fn_extra. Such data will survive for the life of the index operation (e.g., a single GiST index scan, index build, or index tuple insertion). Be careful to pfree the previous value when replacing a fn_extra value, or the leak will accumulate for the duration of the operation.

56.4. Implementation

56.4.1. GiST buffering build

Building large GiST indexes by simply inserting all the tuples tends to be slow, because if the index tuples are scattered across the index and the index is large enough to not fit in cache, the insertions need to perform a lot of random I/O. Beginning in version 9.2, PostgreSQL supports a more efficient method to build GiST indexes based on buffering, which can dramatically reduce the number of random I/Os needed for non-ordered data sets. For well-ordered data sets the benefit is smaller or non-existent, because only a small number of pages receive new tuples at a time, and those pages fit in cache even if the index as whole does not.

However, buffering index build needs to call the penalty function more often, which consumes some extra CPU resources. Also, the buffers used in the buffering build need temporary disk space, up to the size of the resulting index. Buffering can also influence the quality of the resulting index, in both positive and negative directions. That influence depends on various factors, like the distribution of the input data and the operator class implementation.

By default, a GiST index build switches to the buffering method when the index size reaches effective_cache_size. It can be manually turned on or off by the BUFFERING parameter to the CREATE INDEX command. The default behavior is good for most cases, but turning buffering off might speed up the build somewhat if the input data is ordered.

56.5. Examples

The PostgreSQL source distribution includes several examples of index methods implemented using GiST. The core system currently provides text search support (indexing for tsvector and tsquery) as well as R-Tree equivalent functionality for some of the built-in geometric data types.
(see src/backend/access/gist/gistproc.c). The following contrib modules also contain GiST operator classes:

- **btree_gist**
  - B-tree equivalent functionality for several data types
- **cube**
  - Indexing for multidimensional cubes
- **hstore**
  - Module for storing (key, value) pairs
- **intarray**
  - RD-Tree for one-dimensional array of int4 values
- **ltree**
  - Indexing for tree-like structures
- **pg_trgm**
  - Text similarity using trigram matching
- **seg**
  - Indexing for “float ranges”
Chapter 57. SP-GiST Indexes

57.1. Introduction

SP-GiST is an abbreviation for space-partitioned GiST. SP-GiST supports partitioned search trees, which facilitate development of a wide range of different non-balanced data structures, such as quad-trees, k-d trees, and radix trees (tries). The common feature of these structures is that they repeatedly divide the search space into partitions that need not be of equal size. Searches that are well matched to the partitioning rule can be very fast.

These popular data structures were originally developed for in-memory usage. In main memory, they are usually designed as a set of dynamically allocated nodes linked by pointers. This is not suitable for direct storing on disk, since these chains of pointers can be rather long which would require too many disk accesses. In contrast, disk-based data structures should have a high fanout to minimize I/O. The challenge addressed by SP-GiST is to map search tree nodes to disk pages in such a way that a search need access only a few disk pages, even if it traverses many nodes.

Like GiST, SP-GiST is meant to allow the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from Purdue University’s SP-GiST Indexing Project web site. The SP-GIST implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their web site.

57.2. Built-in Operator Classes

The core PostgreSQL distribution includes the SP-GiST operator classes shown in Table 57-1.

Table 57-1. Built-in SP-GiST Operator Classes

<table>
<thead>
<tr>
<th>Name</th>
<th>Indexed Data Type</th>
<th>Indexable Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>kd_point_ops</code></td>
<td>point</td>
<td><code>&lt;&lt;</code> <code>&lt;&gt;</code> <code>&lt;&lt;</code> <code>&gt;&gt;</code> <code>~&gt;</code> <code>~</code></td>
</tr>
<tr>
<td><code>quad_point_ops</code></td>
<td>point</td>
<td><code>&lt;&lt;</code> <code>&lt;&gt;</code> <code>&lt;&lt;</code> <code>&gt;&gt;</code> <code>~&gt;</code> <code>~</code></td>
</tr>
<tr>
<td><code>range_ops</code></td>
<td>any range type</td>
<td><code>&lt;=</code> <code>&lt;?</code> <code>&gt;=</code> <code>?&gt;</code> <code>~&gt;</code> <code>~</code></td>
</tr>
<tr>
<td><code>text_ops</code></td>
<td>text</td>
<td><code>&lt;=</code> <code>&lt;&gt;</code> <code>&gt;=</code> <code>~&gt;</code> <code>~</code> <code>~&gt;</code></td>
</tr>
</tbody>
</table>

Of the two operator classes for type `point`, `quad_point_ops` is the default. `kd_point_ops` supports the same operators but uses a different index data structure which may offer better performance in some applications.

57.3. Extensibility

SP-GiST offers an interface with a high level of abstraction, requiring the access method developer to implement only methods specific to a given data type. The SP-GiST core is responsible for efficient disk mapping and searching the tree structure. It also takes care of concurrency and logging considerations.

Leaf tuples of an SP-GiST tree contain values of the same data type as the indexed column. Leaf tuples at the root level will always contain the original indexed data value, but leaf tuples at lower levels might contain only a compressed representation, such as a suffix. In that case the operator class support functions must be able to reconstruct the original value using information accumulated from the inner tuples that are passed through to reach the leaf level.

Inner tuples are more complex, since they are branching points in the search tree. Each inner tuple contains a set of one or more nodes, which represent groups of similar leaf values. A node contains a downlink that leads to either another, lower-level inner tuple, or a short list of leaf tuples that all lie on the same index page. Each node has a label that describes it; for example, in a radix tree the node label could be the next character of the string value. Optionally, an inner tuple can have a prefix value that describes all its members. In a radix tree this could be the common prefix of the represented strings. The prefix value is not necessarily really a prefix, but can be any data needed by the operator class; for example, in a quad-tree it can store the central point that the four quadrants are measured with respect to. A quad-tree inner tuple would then also contain four nodes corresponding to the quadrants around this central point.

Some tree algorithms require knowledge of level (or depth) of the current tuple, so the SP-GiST core provides the possibility for operator classes to manage level counting while descending the tree. There is also support for incrementally reconstructing the represented value when that is needed.

Note: The SP-GiST core code takes care of null entries. Although SP-GiST indexes do store entries for nulls in indexed columns, this is hidden from the index operator class code: no null index entries or search conditions will ever be passed to the operator class methods. (It is assumed that SP-GiST operators are strict and so cannot succeed for null values.) Null values are therefore not discussed further here.

There are five user-defined methods that an index operator class for SP-GiST must provide. All five follow the convention of accepting two internal arguments, the first of which is a pointer to a C struct containing input values for the support method, while the second argument is a pointer to a C struct where output values must be placed. Four of the methods just return void, since all their results appear in the output struct; but leaf_consistent additionally returns a boolean result. The methods must not modify any fields of their input structs. In all cases, the output struct is initialized to zeroes before calling the user-defined method.

The five user-defined methods are:

config

Returns static information about the index implementation, including the data type OIDs of the prefix and node label data types.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_config(internal, internal) RETURNS void ...
```

The first argument is a pointer to a spgConfigIn C struct, containing input data for the function. The second argument is a pointer to a spgConfigOut C struct, which the function must fill with result data.
typedef struct spgConfigIn
{
    Oid attType; /* Data type to be indexed */
} spgConfigIn;

typedef struct spgConfigOut
{
    Oid prefixType; /* Data type of inner-tuple prefixes */
    Oid labelType; /* Data type of inner-tuple node labels */
    bool canReturnData; /* Opclass can reconstruct original data */
    bool longValuesOK; /* Opclass can cope with values > 1 page */
} spgConfigOut;

attType is passed in order to support polymorphic index operator classes; for ordinary fixed-data-type operator classes, it will always have the same value and so can be ignored.

For operator classes that do not use prefixes, prefixType can be set to VOIDOID. Likewise, for operator classes that do not use node labels, labelType can be set to VOIDOID. canReturnData should be set true if the operator class is capable of reconstructing the originally-supplied index value. longValuesOK should be set true only when the attType is of variable length and the operator class is capable of segmenting long values by repeated suffixing (see Section 57.4.1).

choose

Chooses a method for inserting a new value into an inner tuple.

The SQL declaration of the function must look like this:

CREATE FUNCTION my_choose(internal, internal) RETURNS void ...

The first argument is a pointer to a spgChooseIn C struct, containing input data for the function. The second argument is a pointer to a spgChooseOut C struct, which the function must fill with result data.

typedef struct spgChooseIn
{
    Datum datum; /* original datum to be indexed */
    Datum leafDatum; /* current datum to be stored at leaf */
    int level; /* current level (counting from zero) */

    /* Data from current inner tuple */
    bool allTheSame; /* tuple is marked all-the-same? */
    bool hasPrefix; /* tuple has a prefix? */
    Datum prefixDatum; /* if so, the prefix value */
    int nNodes; /* number of nodes in the inner tuple */
    Datum *nodeLabels; /* node label values (NULL if none) */
} spgChooseIn;

typedef enum spgChooseResultType
{
    spgMatchNode = 1, /* descend into existing node */
    spgAddNode, /* add a node to the inner tuple */
    spgSplitTuple /* split inner tuple (change its prefix) */
} spgChooseResultType;

typedef struct spgChooseOut
{
    spgChooseResultType resultType; /* action code, see above */
    union
    {
    }
}
```c
struct /* results for spgMatchNode */
{
    int nodeN; /* descend to this node (index from 0) */
    int levelAdd; /* increment level by this much */
    Datum restDatum; /* new leaf datum */
} matchNode;
struct /* results for spgAddNode */
{
    Datum nodeLabel; /* new node’s label */
    int nodeN; /* where to insert it (index from 0) */
} addNode;
struct /* results for spgSplitTuple */
{
    /* Info to form new inner tuple with one node */
    bool prefixHasPrefix; /* tuple should have a prefix? */
    Datum prefixPrefixDatum; /* if so, its value */
    Datum nodeLabel; /* node’s label */

    /* Info to form new lower-level inner tuple with all old nodes */
    bool postfixHasPrefix; /* tuple should have a prefix? */
    Datum postfixPrefixDatum; /* if so, its value */
} splitTuple;
}
result;
}

spgChooseOut;
datum is the original datum that was to be inserted into the index. leafDatum is initially the same as datum, but can change at lower levels of the tree if the choose or picksplit methods change it. When the insertion search reaches a leaf page, the current value of leafDatum is what will be stored in the newly created leaf tuple. level is the current inner tuple’s level, starting at zero for the root level. allTheSame is true if the current inner tuple is marked as containing multiple equivalent nodes (see Section 57.4.3). hasPrefix is true if the current inner tuple contains a prefix; if so, prefixDatum is its value. nNodes is the number of child nodes contained in the inner tuple, and nodeLabels is an array of their label values, or NULL if there are no labels.

The choose function can determine either that the new value matches one of the existing child nodes, or that a new child node must be added, or that the new value is inconsistent with the tuple prefix and so the inner tuple must be split to create a less restrictive prefix.

If the new value matches one of the existing child nodes, set resultType to spgMatchNode. Set nodeN to the index (from zero) of that node in the node array. Set levelAdd to the increment in level caused by descending through that node, or leave it as zero if the operator class does not use levels. Set restDatum to equal datum if the operator class does not modify datums from one level to the next, or otherwise set it to the modified value to be used as leafDatum at the next level.

If a new child node must be added, set resultType to spgAddNode. Set nodeLabel to the label to be used for the new node, and set nodeN to the index (from zero) at which to insert the node in the node array. After the node has been added, the choose function will be called again with the modified inner tuple; that call should result in an spgMatchNode result.

If the new value is inconsistent with the tuple prefix, set resultType to spgSplitTuple. This action moves all the existing nodes into a new lower-level inner tuple, and replaces the existing inner tuple with a tuple having a single node that links to the new lower-level inner tuple. Set prefixHasPrefix to indicate whether the new upper tuple should have a prefix, and if so set prefixPrefixDatum to the prefix value. This new prefix value must be sufficiently less restrictive than the original to accept the new value to be indexed, and it should be no longer
than the original prefix. Set nodeLabel to the label to be used for the node that will point to the new lower-level inner tuple. Set postfixHasPrefix to indicate whether the new lower-level inner tuple should have a prefix, and if so set postfixPrefixDatum to the prefix value. The combination of these two prefixes and the additional label must have the same meaning as the original prefix, because there is no opportunity to alter the node labels that are moved to the new lower-level tuple, nor to change any child index entries. After the node has been split, the choose function will be called again with the replacement inner tuple. That call will usually result in an spgAddNode result, since presumably the node label added in the split step will not match the new value; so after that, there will be a third call that finally returns spgMatchNode and allows the insertion to descend to the leaf level.

`picksplit` decides how to create a new inner tuple over a set of leaf tuples.

The SQL declaration of the function must look like this:

```sql
CREATE FUNCTION my_picksplit(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgPickSplitIn` C struct, containing input data for the function. The second argument is a pointer to a `spgPickSplitOut` C struct, which the function must fill with result data.

```c
typedef struct spgPickSplitIn {
    int nTuples; /* number of leaf tuples */
    Datum *datums; /* their datums (array of length nTuples) */
    int level; /* current level (counting from zero) */
} spgPickSplitIn;

typedef struct spgPickSplitOut {
    bool hasPrefix; /* new inner tuple should have a prefix? */
    Datum prefixDatum; /* if so, its value */
    int nNodes; /* number of nodes for new inner tuple */
    Datum *nodeLabels; /* their labels (or NULL for no labels) */
    int *mapTuplesToNodes; /* node index for each leaf tuple */
    Datum *leafTupleDatums; /* datum to store in each new leaf tuple */
} spgPickSplitOut;
```

`nTuples` is the number of leaf tuples provided. `datums` is an array of their datum values. `level` is the current level that all the leaf tuples share, which will become the level of the new inner tuple.

Set `hasPrefix` to indicate whether the new inner tuple should have a prefix, and if so set `prefixDatum` to the prefix value. Set `nNodes` to indicate the number of nodes that the new inner tuple will contain, and set `nodeLabels` to an array of their label values. (If the nodes do not require labels, set `nodeLabels` to NULL; see Section 57.4.2 for details.) Set `mapTuplesToNodes` to an array that gives the index (from zero) of the node that each leaf tuple should be assigned to. Set `leafTupleDatums` to an array of the values to be stored in the new leaf tuples (these will be the same as the input `datums` if the operator class does not modify datums from one level to the next). Note that the `picksplit` function is responsible for `palloc`ing the `nodeLabels`, `mapTuplesToNodes` and `leafTupleDatums` arrays.

If more than one leaf tuple is supplied, it is expected that the `picksplit` function will classify them into more than one node; otherwise it is not possible to split the leaf tuples across multiple pages, which is the ultimate purpose of this operation. Therefore, if the `picksplit` function ends up placing all the leaf tuples in the same node, the core SP-GiST code will override that
Chapter 57. SP-GiST Indexes

decision and generate an inner tuple in which the leaf tuples are assigned at random to several
identically-labeled nodes. Such a tuple is marked allTheSame to signify that this has happened.
The choose and inner_consistent functions must take suitable care with such inner tuples.
See Section 57.4.3 for more information.

picksplit can be applied to a single leaf tuple only in the case that the config function set
longValuesOK to true and a larger-than-a-page input value has been supplied. In this case the
point of the operation is to strip off a prefix and produce a new, shorter leaf datum value. The call
will be repeated until a leaf datum short enough to fit on a page has been produced. See Section
57.4.1 for more information.

inner_consistent

Returns set of nodes (branches) to follow during tree search.

The SQL declaration of the function must look like this:

CREATE FUNCTION my_inner_consistent(internal, internal) RETURNS void ...
The first argument is a pointer to a spgInnerConsistentIn C struct, containing input data for
the function. The second argument is a pointer to a spgInnerConsistentOut C struct, which
the function must fill with result data.

typedef struct spgInnerConsistentIn
{
    ScanKey    scankeys;    /* array of operators and comparison values */
    int        nkeys;       /* length of array */
    Datum      reconstructedValue; /* value reconstructed at parent */
    int        level;       /* current level (counting from zero) */
    bool       returnData;  /* original data must be returned? */
    /* Data from current inner tuple */
    bool       allTheSame;  /* tuple is marked all-the-same? */
    bool       hasPrefix;   /* tuple has a prefix? */
    Datum      prefixDatum; /* if so, the prefix value */
    int        nNodes;      /* number of nodes in the inner tuple */
    Datum      *nodeLabels; /* node label values (NULL if none) */
} spgInnerConsistentIn;

typedef struct spgInnerConsistentOut
{
    int        nNodes;      /* number of child nodes to be visited */
    int        *nodeNumbers; /* their indexes in the node array */
    int        *levelAdds;  /* increment level by this much for each */
    Datum      *reconstructedValues; /* associated reconstructed values */
} spgInnerConsistentOut;

The array scankeys, of length nkeys, describes the index search condition(s). These conditions
are combined with AND — only index entries that satisfy all of them are interesting. (Note that
nkeys = 0 implies that all index entries satisfy the query.) Usually the consistent function only
cares about the sk_strategy and sk_argument fields of each array entry, which respectively
give the indexable operator and comparison value. In particular it is not necessary to check
sk_flags to see if the comparison value is NULL, because the SP-GiST core code will filter
out such conditions. reconstructedValue is the value reconstructed for the parent tuple; it is
(Datum) 0 at the root level or if the inner_consistent function did not provide a value
at the parent level. level is the current inner tuple’s level, starting at zero for the root level.
returnData is true if reconstructed data is required for this query; this will only be so if the
config function asserted canReturnData. allTheSame is true if the current inner tuple is
marked “all-the-same”; in this case all the nodes have the same label (if any) and so either all

1974
or none of them match the query (see Section 57.4.3). 

hasPrefix is true if the current inner tuple contains a prefix; if so, prefixDatum is its value. nNodes is the number of child nodes contained in the inner tuple, and nodeLabels is an array of their label values, or NULL if the nodes do not have labels.

nNodes must be set to the number of child nodes that need to be visited by the search, and nodeNumbers must be set to an array of their indexes. If the operator class keeps track of levels, set levelAdds to an array of the level increments required when descending to each node to be visited. (Often these increments will be the same for all the nodes, but that’s not necessarily so, so an array is used.) If value reconstruction is needed, set reconstructedValues to an array of the values reconstructed for each child node to be visited; otherwise, leave reconstructedValues as NULL. Note that the inner_consistent function is responsible for palloc’ing the nodeNumbers, levelAdds and reconstructedValues arrays.

leaf_consistent

Returns true if a leaf tuple satisfies a query.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_leaf_consistent(internal, internal) RETURNS bool ...
```

The first argument is a pointer to a spgLeafConsistentIn C struct, containing input data for the function. The second argument is a pointer to a spgLeafConsistentOut C struct, which the function must fill with result data.

```
typedef struct spgLeafConsistentIn {
    ScanKey scankeys; /* array of operators and comparison values */
    int nkeys; /* length of array */
    Datum reconstructedValue; /* value reconstructed at parent */
    int level; /* current level (counting from zero) */
    bool returnData; /* original data must be returned? */
    Datum leafDatum; /* datum in leaf tuple */
} spgLeafConsistentIn;

typedef struct spgLeafConsistentOut {
    Datum leafValue; /* reconstructed original data, if any */
    bool recheck; /* set true if operator must be rechecked */
} spgLeafConsistentOut;
```

The array scankeys, of length nkeys, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them satisfy the query. (Note that nkeys = 0 implies that all index entries satisfy the query.) Usually the consistent function only cares about the sk_strategy and sk_argument fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check sk_flags to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. reconstructedValue is the value reconstructed for the parent tuple; it is (Datum) 0 at the root level or if the inner_consistent function did not provide a value at the parent level. level is the current leaf tuple’s level, starting at zero for the root level. returnData is true if reconstructed data is required for this query; this will only be so if the config function asserted canReturnData. leafDatum is the key value stored in the current leaf tuple.

The function must return true if the leaf tuple matches the query, or false if not. In the true case, if returnData is true then leafValue must be set to the value originally supplied to be
indexed for this leaf tuple. Also, recheck may be set to true if the match is uncertain and so the operator(s) must be re-applied to the actual heap tuple to verify the match.

All the SP-GiST support methods are normally called in a short-lived memory context; that is, CurrentMemoryContext will be reset after processing of each tuple. It is therefore not very important to worry about pfree’ing everything you palloc. (The config method is an exception; it should try to avoid leaking memory. But usually the config method need do nothing but assign constants into the passed parameter struct.)

If the indexed column is of a collatable data type, the index collation will be passed to all the support methods, using the standard PG_GET_COLLATION() mechanism.

57.4. Implementation

This section covers implementation details and other tricks that are useful for implementers of SP-GiST operator classes to know.

57.4.1. SP-GiST Limits

Individual leaf tuples and inner tuples must fit on a single index page (8KB by default). Therefore, when indexing values of variable-length data types, long values can only be supported by methods such as radix trees, in which each level of the tree includes a prefix that is short enough to fit on a page, and the final leaf level includes a suffix also short enough to fit on a page. The operator class should set longValuesOK to TRUE only if it is prepared to arrange for this to happen. Otherwise, the SP-GiST core will reject any request to index a value that is too large to fit on an index page.

Likewise, it is the operator class’s responsibility that inner tuples do not grow too large to fit on an index page; this limits the number of child nodes that can be used in one inner tuple, as well as the maximum size of a prefix value.

Another limitation is that when an inner tuple’s node points to a set of leaf tuples, those tuples must all be in the same index page. (This is a design decision to reduce seeking and save space in the links that chain such tuples together.) If the set of leaf tuples grows too large for a page, a split is performed and an intermediate inner tuple is inserted. For this to fix the problem, the new inner tuple must divide the set of leaf values into more than one node group. If the operator class’s picksplit function fails to do that, the SP-GiST core resorts to extraordinary measures described in Section 57.4.3.

57.4.2. SP-GiST Without Node Labels

Some tree algorithms use a fixed set of nodes for each inner tuple; for example, in a quad-tree there are always exactly four nodes corresponding to the four quadrants around the inner tuple’s centroid point. In such a case the code typically works with the nodes by number, and there is no need for explicit node labels. To suppress node labels (and thereby save some space), the picksplit function can return NULL for the nodeLabels array. This will in turn result in nodeLabels being NULL during subsequent calls to choose and inner_consistent. In principle, node labels could be used for some inner tuples and omitted for others in the same index.

When working with an inner tuple having unlabeled nodes, it is an error for choose to return spgAddNode, since the set of nodes is supposed to be fixed in such cases. Also, there is no provision for generating an unlabeled node in spgSplitTuple actions, since it is expected that an spgAddNode action will be needed as well.
57.4.3. “All-the-same” Inner Tuples

The SP-GiST core can override the results of the operator class’s `picksplit` function when `picksplit` fails to divide the supplied leaf values into at least two node categories. When this happens, the new inner tuple is created with multiple nodes that each have the same label (if any) that `picksplit` gave to the one node it did use, and the leaf values are divided at random among these equivalent nodes. The `allTheSame` flag is set on the inner tuple to warn the `choose` and `inner_consistent` functions that the tuple does not have the node set that they might otherwise expect.

When dealing with an `allTheSame` tuple, a `choose` result of `spgMatchNode` is interpreted to mean that the new value can be assigned to any of the equivalent nodes; the core code will ignore the supplied `nodeN` value and descend into one of the nodes at random (so as to keep the tree balanced). It is an error for `choose` to return `spgAddNode`, since that would make the nodes not all equivalent; the `spgSplitTuple` action must be used if the value to be inserted doesn’t match the existing nodes.

When dealing with an `allTheSame` tuple, the `inner_consistent` function should return either all or none of the nodes as targets for continuing the index search, since they are all equivalent. This may or may not require any special-case code, depending on how much the `inner_consistent` function normally assumes about the meaning of the nodes.

57.5. Examples

The PostgreSQL source distribution includes several examples of index operator classes for SP-GiST. The core system currently provides radix trees over text columns and two types of trees over points: quad-tree and k-d tree. Look into `src/backend/access/spgist/` to see the code.
Chapter 58. GIN Indexes

58.1. Introduction

GIN stands for Generalized Inverted Index. GIN is designed for handling cases where the items to be indexed are composite values, and the queries to be handled by the index need to search for element values that appear within the composite items. For example, the items could be documents, and the queries could be searches for documents containing specific words.

We use the word item to refer to a composite value that is to be indexed, and the word key to refer to an element value. GIN always stores and searches for keys, not item values per se.

A GIN index stores a set of (key, posting list) pairs, where a posting list is a set of row IDs in which the key occurs. The same row ID can appear in multiple posting lists, since an item can contain more than one key. Each key value is stored only once, so a GIN index is very compact for cases where the same key appears many times.

GIN is generalized in the sense that the GIN access method code does not need to know the specific operations that it accelerates. Instead, it uses custom strategies defined for particular data types. The strategy defines how keys are extracted from indexed items and query conditions, and how to determine whether a row that contains some of the key values in a query actually satisfies the query.

One advantage of GIN is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert. This is much the same advantage as using GiST.

The GIN implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov. There is more information about GIN on their website\(^1\).

58.2. Built-in Operator Classes

The core PostgreSQL distribution includes the GIN operator classes shown in Table 58-1. (Some of the optional modules described in Appendix F provide additional GIN operator classes.)

<table>

<td>&amp; &amp; &lt; @ = 0 &gt;</td>
</tr>
<tr>
<td><code>tsvector_ops</code></td>
<td>tsvector</td>
<td>@ @ @ @ @ &gt;</td>
</tr>
</tbody>
</table>

Of the two operator classes for type `jsonb`, `jsonb_ops` is the default. `jsonb_path_ops` supports fewer operators but offers better performance for those operators. See Section 8.14.4 for details.

### 58.3. Extensibility

The GIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GIN layer itself takes care of concurrency, logging and searching the tree structure.

All it takes to get a GIN access method working is to implement a few user-defined methods, which define the behavior of keys in the tree and the relationships between keys, indexed items, and indexable queries. In short, GIN combines extensibility with generality, code reuse, and a clean interface.

There are three methods that an operator class for GIN must provide:

```c
int compare(Datum a, Datum b)
```

Compares two keys (not indexed items!) and returns an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second. Null
keys are never passed to this function.

Datum *extractValue(Datum itemValue, int32 *nkeys, bool **nullFlags)

Returns a palloc’ed array of keys given an item to be indexed. The number of returned keys must be stored into *nkeys. If any of the keys can be null, also palloc an array of *nkeys bool fields, store its address at *nullFlags, and set these null flags as needed. *nullFlags can be left NULL (its initial value) if all keys are non-null. The return value can be NULL if the item contains no keys.

Datum *extractQuery(Datum query, int32 *nkeys, StrategyNumber n, bool **pmatch, Pointer **extra_data, bool **nullFlags, int32 *searchMode)

Returns a palloc’ed array of keys given a value to be queried; that is, query is the value on the right-hand side of an indexable operator whose left-hand side is the indexed column. n is the strategy number of the operator within the operator class (see Section 35.14.2). Often, extractQuery will need to consult n to determine the data type of query and the method it should use to extract key values. The number of returned keys must be stored into *nkeys. If any of the keys can be null, also palloc an array of *nkeys bool fields, store its address at *nullFlags, and set these null flags as needed. *nullFlags can be left NULL (its initial value) if all keys are non-null. The return value can be NULL if the query contains no keys.

searchMode is an output argument that allows extractQuery to specify details about how the search will be done. If *searchMode is set to GIN_SEARCH_MODE_DEFAULT (which is the value it is initialized to before call), only items that match at least one of the returned keys are considered candidate matches. If *searchMode is set to GIN_SEARCH_MODE_INCLUDE_EMPTY, then in addition to items containing at least one matching key, items that contain no keys at all are considered candidate matches. (This mode is useful for implementing is-subset-of operators, for example.) If *searchMode is set to GIN_SEARCH_MODE_ALL, then all non-null items in the index are considered candidate matches, whether they match any of the returned keys or not. (This mode is much slower than the other two choices, since it requires scanning essentially the entire index, but it may be necessary to implement corner cases correctly. An operator that needs this mode in most cases is probably not a good candidate for a GIN operator class.) The symbols to use for setting this mode are defined in access/gin.h.

pmatch is an output argument for use when partial match is supported. To use it, extractQuery must allocate an array of *nkeys booleans and store its address at *pmatch. Each element of the array should be set to TRUE if the corresponding key requires partial match, FALSE if not. If *pmatch is set to NULL then GIN assumes partial match is not required. The variable is initialized to NULL before call, so this argument can simply be ignored by operator classes that do not support partial match.

extra_data is an output argument that allows extractQuery to pass additional data to the consistent and comparePartial methods. To use it, extractQuery must allocate an array of *nkeys pointers and store its address at *extra_data, then store whatever it wants to into the individual pointers. The variable is initialized to NULL before call, so this argument can simply be ignored by operator classes that do not require extra data. If *extra_data is set, the whole array is passed to the consistent method, and the appropriate element to the comparePartial method.

An operator class must also provide a function to check if an indexed item matches the query. It comes in two flavors, a boolean consistent function, and a ternary triConsistent function. triConsistent covers the functionality of both, so providing triConsistent alone is sufficient. However, if the boolean variant is significantly cheaper to calculate, it can be advantageous to provide both. If only the boolean variant is provided, some optimizations that depend on refuting index items before fetching all the keys are disabled.
bool consistent(bool check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], bool *recheck, Datum queryKeys[], bool nullFlags[])

Returns TRUE if an indexed item satisfies the query operator with strategy number $n$ (or might satisfy it, if the recheck indication is returned). This function does not have direct access to the indexed item’s value, since GIN does not store items explicitly. Rather, what is available is knowledge about which key values extracted from the query appear in a given indexed item. The check array has length $nkeys$, which is the same as the number of keys previously returned by extractQuery for this query datum. Each element of the check array is TRUE if the indexed item contains the corresponding query key, i.e., if $(\text{check}[\text{i}] == \text{TRUE})$ the $i$-th key of the extractQuery result array is present in the indexed item. The original query datum is passed in case the consistent method needs to consult it, and so are the queryKeys[] and nullFlags[] arrays previously returned by extractQuery. extra_data is the extra-data array returned by extractQuery, or NULL if none.

When extractQuery returns a null key in queryKeys[], the corresponding check[] element is TRUE if the indexed item contains a null key; that is, the semantics of check[] are like IS NOT DISTINCT FROM. The consistent function can examine the corresponding nullFlags[] element if it needs to tell the difference between a regular value match and a null match.

On success, *recheck should be set to TRUE if the heap tuple needs to be rechecked against the query operator, or FALSE if the index test is exact. That is, a FALSE return value guarantees that the heap tuple does not match the query; a TRUE return value with *recheck set to FALSE guarantees that the heap tuple does match the query; and a TRUE return value with *recheck set to TRUE means that the heap tuple might match the query, so it needs to be fetched and rechecked by evaluating the query operator directly against the originally indexed item.

GinTernaryValue triConsistent(GinTernaryValue check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], Datum queryKeys[], bool nullFlags[])

triConsistent is similar to consistent, but instead of a boolean check[], there are three possible values for each key: GIN_TRUE, GIN_FALSE and GIN_MAYBE. GIN_FALSE and GIN_TRUE have the same meaning as regular boolean values. GIN_MAYBE means that the presence of that key is not known. When GIN_MAYBE values are present, the function should only return GIN_TRUE if the item matches whether or not the index item contains the corresponding query keys. Likewise, the function must return GIN_FALSE only if the item does not match, whether or not it contains the GIN_MAYBE keys. If the result depends on the GIN_MAYBE entries, i.e. the match cannot be confirmed or refuted based on the known query keys, the function must return GIN_MAYBE.

When there are no GIN_MAYBE values in the check vector, GIN_MAYBE return value is equivalent of setting recheck flag in the boolean consistent function.

Optionally, an operator class for GIN can supply the following method:

int comparePartial(Datum partial_key, Datum key, StrategyNumber n, Pointer extra_data)

Compare a partial-match query key to an index key. Returns an integer whose sign indicates the result: less than zero means the index key does not match the query, but the index scan should continue; zero means that the index key does match the query; greater than zero indicates that the index scan should stop because no more matches are possible. The strategy number $n$ of the operator that generated the partial match query is provided, in case its semantics are needed to determine when to end the scan. Also, extra_data is the corresponding element of the extra-data array made by extractQuery, or NULL if none. Null keys are never passed to this function.
To support “partial match” queries, an operator class must provide the comparePartial method, and its extractQuery method must set the pmatch parameter when a partial-match query is encountered. See Section 58.4.2 for details.

The actual data types of the various Datum values mentioned above vary depending on the operator class. The item values passed to extractValue are always of the operator class’s input type, and all key values must be of the class’s STORAGE type. The type of the query argument passed to extractQuery, consistent and triConsistent is whatever is specified as the right-hand input type of the class member operator identified by the strategy number. This need not be the same as the item type, so long as key values of the correct type can be extracted from it.

58.4. Implementation

Internally, a GIN index contains a B-tree index constructed over keys, where each key is an element of one or more indexed items (a member of an array, for example) and where each tuple in a leaf page contains either a pointer to a B-tree of heap pointers (a “posting tree”), or a simple list of heap pointers (a “posting list”) when the list is small enough to fit into a single index tuple along with the key value.

As of PostgreSQL 9.1, null key values can be included in the index. Also, placeholder nulls are included in the index for indexed items that are null or contain no keys according to extractValue. This allows searches that should find empty items to do so.

Multicolumn GIN indexes are implemented by building a single B-tree over composite values (column number, key value). The key values for different columns can be of different types.

58.4.1. GIN Fast Update Technique

Updating a GIN index tends to be slow because of the intrinsic nature of inverted indexes: inserting or updating one heap row can cause many inserts into the index (one for each key extracted from the indexed item). As of PostgreSQL 8.4, GIN is capable of postponing much of this work by inserting new tuples into a temporary, unsorted list of pending entries. When the table is vacuumed, or if the pending list becomes too large (larger than work_mem), the entries are moved to the main GIN data structure using the same bulk insert techniques used during initial index creation. This greatly improves GIN index update speed, even counting the additional vacuum overhead. Moreover the overhead work can be done by a background process instead of in foreground query processing.

The main disadvantage of this approach is that searches must scan the list of pending entries in addition to searching the regular index, and so a large list of pending entries will slow searches significantly. Another disadvantage is that, while most updates are fast, an update that causes the pending list to become “too large” will incur an immediate cleanup cycle and thus be much slower than other updates. Proper use of autovacuum can minimize both of these problems.

If consistent response time is more important than update speed, use of pending entries can be disabled by turning off the FASTUPDATE storage parameter for a GIN index. See CREATE INDEX for details.

58.4.2. Partial Match Algorithm

GIN can support “partial match” queries, in which the query does not determine an exact match for one or more keys, but the possible matches fall within a reasonably narrow range of key values (within
the key sorting order determined by the compare support method). The extractQuery method, instead of returning a key value to be matched exactly, returns a key value that is the lower bound of the range to be searched, and sets the pmatch flag true. The key range is then scanned using the comparePartial method. comparePartial must return zero for a matching index key, less than zero for a non-match that is still within the range to be searched, or greater than zero if the index key is past the range that could match.

58.5. GIN Tips and Tricks

Create vs. insert

Insertion into a GIN index can be slow due to the likelihood of many keys being inserted for each item. So, for bulk insertions into a table it is advisable to drop the GIN index and recreate it after finishing bulk insertion.

As of PostgreSQL 8.4, this advice is less necessary since delayed indexing is used (see Section 58.4.1 for details). But for very large updates it may still be best to drop and recreate the index.

maintenance_work_mem

Build time for a GIN index is very sensitive to the maintenance_work_mem setting; it doesn’t pay to skimp on work memory during index creation.

work_mem

During a series of insertions into an existing GIN index that has FASTUPDATE enabled, the system will clean up the pending-entry list whenever the list grows larger than work_mem. To avoid fluctuations in observed response time, it’s desirable to have pending-list cleanup occur in the background (i.e., via autovacuum). Foreground cleanup operations can be avoided by increasing work_mem or making autovacuum more aggressive. However, enlarging work_mem means that if a foreground cleanup does occur, it will take even longer.

gin_fuzzy_search_limit

The primary goal of developing GIN indexes was to create support for highly scalable full-text search in PostgreSQL, and there are often situations when a full-text search returns a very large set of results. Moreover, this often happens when the query contains very frequent words, so that the large result set is not even useful. Since reading many tuples from the disk and sorting them could take a lot of time, this is unacceptable for production. (Note that the index search itself is very fast.)

To facilitate controlled execution of such queries, GIN has a configurable soft upper limit on the number of rows returned: the gin_fuzzy_search_limit configuration parameter. It is set to 0 (meaning no limit) by default. If a non-zero limit is set, then the returned set is a subset of the whole result set, chosen at random.

“Soft” means that the actual number of returned results could differ somewhat from the specified limit, depending on the query and the quality of the system’s random number generator.

From experience, values in the thousands (e.g., 5000 — 20000) work well.
58.6. Limitations

GIN assumes that indexable operators are strict. This means that extractValue will not be called at all on a null item value (instead, a placeholder index entry is created automatically), and extractQuery will not be called on a null query value either (instead, the query is presumed to be unsatisfiable). Note however that null key values contained within a non-null composite item or query value are supported.

58.7. Examples

The PostgreSQL source distribution includes GIN operator classes for tsvector and for one-dimensional arrays of all internal types. Prefix searching in tsvector is implemented using the GIN partial match feature. The following contrib modules also contain GIN operator classes:

btree_gin
    B-tree equivalent functionality for several data types
hstore
    Module for storing (key, value) pairs
intarray
    Enhanced support for int[]
pg_trgm
    Text similarity using trigram matching
Chapter 59. Database Physical Storage

This chapter provides an overview of the physical storage format used by PostgreSQL databases.

59.1. Database File Layout

This section describes the storage format at the level of files and directories.

Traditionally, the configuration and data files used by a database cluster are stored together within the cluster’s data directory, commonly referred to as `PGDATA` (after the name of the environment variable that can be used to define it). A common location for `PGDATA` is `/var/lib/pgsql/data`. Multiple clusters, managed by different server instances, can exist on the same machine.

The `PGDATA` directory contains several subdirectories and control files, as shown in Table 59-1. In addition to these required items, the cluster configuration files `postgresql.conf`, `pg_hba.conf`, and `pg_ident.conf` are traditionally stored in `PGDATA`, although it is possible to place them elsewhere.

### Table 59-1. Contents of `PGDATA`

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>

<td>A file recording the command-line options the server was last started with</td>
</tr>
<tr>
<td>postmaster.pid</td>
<td>A lock file recording the current postmaster process ID (PID), cluster data directory path, postmaster start timestamp, port number, Unix-domain socket directory path (empty on Windows), first valid listen_address (IP address or *, or empty if not listening on TCP), and shared memory segment ID (this file is not present after server shutdown)</td>
</tr>
</tbody>
</table>

For each database in the cluster there is a subdirectory within PGDATA/base, named after the database’s OID in pg_database. This subdirectory is the default location for the database’s files; in particular, its system catalogs are stored there.

Each table and index is stored in a separate file. For ordinary relations, these files are named after the table or index’s filenode number, which can be found in pg_class.relfilenode. But for temporary relations, the file name is of the form tBBB_FFF, where BBB is the backend ID of the backend which created the file, and FFF is the filenode number. In either case, in addition to the main file (a/k/a main fork), each table and index has a free space map (see Section 59.3), which stores information about free space available in the relation. The free space map is stored in a file named with the filenode number plus the suffix _fsm. Tables also have a visibility map, stored in a fork with the suffix _vm, to track which pages are known to have no dead tuples. The visibility map is described further in Section 59.4. Unlogged tables and indexes have a third fork, known as the initialization fork, which is stored in a fork with the suffix _init (see Section 59.5).

Caution

Note that while a table’s filenode often matches its OID, this is not necessarily the case; some operations, like TRUNCATE, REINDEX, CLUSTER and some forms of ALTER TABLE, can change the filenode while preserving the OID. Avoid assuming that filenode and table OID are the same. Also, for certain system catalogs including pg_class itself, pg_class.relfilenode contains zero. The actual filenode number of these catalogs is stored in a lower-level data structure, and can be obtained using the pg_relation_filenode() function.

When a table or index exceeds 1 GB, it is divided into gigabyte-sized segments. The first segment’s file name is the same as the filenode; subsequent segments are named filenode.1, filenode.2, etc. This arrangement avoids problems on platforms that have file size limitations. (Actually, 1 GB is just the default segment size. The segment size can be adjusted using the configuration option...
A table that has columns with potentially large entries will have an associated TOAST table, which is used for out-of-line storage of field values that are too large to keep in the table rows proper. pg_class.reltoastrelid links from a table to its TOAST table, if any. See Section 59.2 for more information.

The contents of tables and indexes are discussed further in Section 59.6.

Tablespaces make the scenario more complicated. Each user-defined tablespace has a symbolic link inside the PGDATA/pg_tblspc directory, which points to the physical tablespace directory (i.e., the location specified in the tablespace’s CREATE TABLESPACE command). This symbolic link is named after the tablespace’s OID. Inside the physical tablespace directory there is a subdirectory with a name that depends on the PostgreSQL server version, such as PG_9.0_201008051. (The reason for using this subdirectory is so that successive versions of the database can use the same CREATE TABLESPACE location value without conflicts.) Within the version-specific subdirectory, there is a subdirectory for each database that has elements in the tablespace, named after the database’s OID. Tables and indexes are stored within that directory, using the filenode naming scheme. The pg_default tablespace is not accessed through pg_tblspc, but corresponds to PGDATA/base. Similarly, the pg_global tablespace is not accessed through pg_tblspc, but corresponds to PGDATA/global.

The pg_relation_filepath() function shows the entire path (relative to PGDATA) of any relation. It is often useful as a substitute for remembering many of the above rules. But keep in mind that this function just gives the name of the first segment of the main fork of the relation — you may need to append a segment number and/or _fsm, _vm, or _init to find all the files associated with the relation.

Temporary files (for operations such as sorting more data than can fit in memory) are created within PGDATA/base/pgsql_tmp, or within a pgsql_tmp subdirectory of a tablespace directory if a tablespace other than pg_default is specified for them. The name of a temporary file has the form pgsql_tmpPPP.NNN, where PPP is the PID of the owning backend and NNN distinguishes different temporary files of that backend.

59.2. TOAST

This section provides an overview of TOAST (The Oversized-Attribute Storage Technique).

PostgreSQL uses a fixed page size (commonly 8 kB), and does not allow tuples to span multiple pages. Therefore, it is not possible to store very large field values directly. To overcome this limitation, large field values are compressed and/or broken up into multiple physical rows. This happens transparently to the user, with only small impact on most of the backend code. The technique is affectionately known as TOAST (or “the best thing since sliced bread”).

Only certain data types support TOAST — there is no need to impose the overhead on data types that cannot produce large field values. To support TOAST, a data type must have a variable-length (varlena) representation, in which the first 32-bit word of any stored value contains the total length of the value in bytes (including itself). TOAST does not constrain the rest of the representation. All the C-level functions supporting a TOAST-able data type must be careful to handle TOASTed input values. (This is normally done by invoking PG_DETOAST_DATUM before doing anything with an input value, but in some cases more efficient approaches are possible.)

TOAST usurps two bits of the varlena length word (the high-order bits on big-endian machines, the low-order bits on little-endian machines), thereby limiting the logical size of any value of a TOAST-able data type to 1 GB ($2^{30} - 1$ bytes). When both bits are zero, the value is an ordinary un-TOASTed value of the data type, and the remaining bits of the length word give the total datum size (including...
length word) in bytes. When the highest-order or lowest-order bit is set, the value has only a single-byte header instead of the normal four-byte header, and the remaining bits give the total datum size (including length byte) in bytes. As a special case, if the remaining bits are all zero (which would be impossible for a self-inclusive length), the value is a pointer to out-of-line data stored in a separate TOAST table. (The size of a TOAST pointer is given in the second byte of the datum.) Values with single-byte headers aren’t aligned on any particular boundary, either. Lastly, when the highest-order or lowest-order bit is clear but the adjacent bit is set, the content of the datum has been compressed and must be decompressed before use. In this case the remaining bits of the length word give the total size of the compressed datum, not the original data. Note that compression is also possible for out-of-line data but the varlena header does not tell whether it has occurred — the content of the TOAST pointer tells that, instead.

If any of the columns of a table are TOAST-able, the table will have an associated TOAST table, whose OID is stored in the table’s `pg_class.reltoastrelid` entry. Out-of-line TOASTed values are kept in the TOAST table, as described in more detail below.

The compression technique used is a fairly simple and very fast member of the LZ family of compression techniques. See `src/backend/utils/adt/pg_lzcompress.c` for the details.

Out-of-line values are divided (after compression if used) into chunks of at most `TOAST_MAX_CHUNK_SIZE` bytes (by default this value is chosen so that four chunk rows will fit on a page, making it about 2000 bytes). Each chunk is stored as a separate row in the TOAST table for the owning table. Every TOAST table has the columns `chunk_id` (an OID identifying the particular TOASTed value), `chunk_seq` (a sequence number for the chunk within its value), and `chunk_data` (the actual data of the chunk). A unique index on `chunk_id` and `chunk_seq` provides fast retrieval of the values. A pointer datum representing an out-of-line TOASTed value therefore needs to store the OID of the TOAST table in which to look and the OID of the specific value (its `chunk_id`). For convenience, pointer datums also store the logical datum size (original uncompressed data length) and actual stored size (different if compression was applied). Allowing for the varlena header bytes, the total size of a TOAST pointer datum is therefore 18 bytes regardless of the actual size of the represented value.

The TOAST code is triggered only when a row value to be stored in a table is wider than `TOAST_TUPLE_THRESHOLD` bytes (normally 2 kB). The TOAST code will compress and/or move field values out-of-line until the row value is shorter than `TOAST_TUPLE_TARGET` bytes (also normally 2 kB) or no more gains can be had. During an UPDATE operation, values of unchanged fields are normally preserved as-is; so an UPDATE of a row with out-of-line values incurs no TOAST costs if none of the out-of-line values change.

The TOAST code recognizes four different strategies for storing TOAST-able columns:

- **PLAIN** prevents either compression or out-of-line storage; furthermore it disables use of single-byte headers for varlena types. This is the only possible strategy for columns of non-TOAST-able data types.
- **EXTENDED** allows both compression and out-of-line storage. This is the default for most TOAST-able data types. Compression will be attempted first, then out-of-line storage if the row is still too big.
- **EXTERNAL** allows out-of-line storage but not compression. Use of EXTERNAL will make substring operations on wide `text` and `bytea` columns faster (at the penalty of increased storage space) because these operations are optimized to fetch only the required parts of the out-of-line value when it is not compressed.
- **MAIN** allows compression but not out-of-line storage. (Actually, out-of-line storage will still be performed for such columns, but only as a last resort when there is no other way to make the row...
Each TOAST-able data type specifies a default strategy for columns of that data type, but the strategy for a given table column can be altered with \texttt{ALTER TABLE SET STORAGE}.

This scheme has a number of advantages compared to a more straightforward approach such as allowing row values to span pages. Assuming that queries are usually qualified by comparisons against relatively small key values, most of the work of the executor will be done using the main row entry. The big values of TOASTed attributes will only be pulled out (if selected at all) at the time the result set is sent to the client. Thus, the main table is much smaller and more of its rows fit in the shared buffer cache than would be the case without any out-of-line storage. Sort sets shrink also, and sorts will more often be done entirely in memory. A little test showed that a table containing typical HTML pages and their URLs was stored in about half of the raw data size including the TOAST table, and that the main table contained only about 10% of the entire data (the URLs and some small HTML pages). There was no run time difference compared to an un-TOASTed comparison table, in which all the HTML pages were cut down to 7 kB to fit.

59.3. Free Space Map

Each heap and index relation, except for hash indexes, has a Free Space Map (FSM) to keep track of available space in the relation. It's stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a \texttt{_fsm} suffix. For example, if the filenode of a relation is 12345, the FSM is stored in a file called \texttt{12345_fsm}, in the same directory as the main relation file.

The Free Space Map is organized as a tree of FSM pages. The bottom level FSM pages store the free space available on each heap (or index) page, using one byte to represent each such page. The upper levels aggregate information from the lower levels.

Within each FSM page is a binary tree, stored in an array with one byte per node. Each leaf node represents a heap page, or a lower level FSM page. In each non-leaf node, the higher of its children's values is stored. The maximum value in the leaf nodes is therefore stored at the root.

See \texttt{src/backend/storage/freespace/README} for more details on how the FSM is structured, and how it's updated and searched. The \texttt{pg_freespacemap} module can be used to examine the information stored in free space maps.

59.4. Visibility Map

Each heap relation has a Visibility Map (VM) to keep track of which pages contain only tuples that are known to be visible to all active transactions. It's stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a \texttt{_vm} suffix. For example, if the filenode of a relation is 12345, the VM is stored in a file called \texttt{12345_vm}, in the same directory as the main relation file. Note that indexes do not have VMs.

The visibility map simply stores one bit per heap page. A set bit means that all tuples on the page are known to be visible to all transactions. This means that the page does not contain any tuples that need to be vacuumed. This information can also be used by \texttt{index-only scans} to answer queries using only the index tuple.

The map is conservative in the sense that we make sure that whenever a bit is set, we know the condition is true, but if a bit is not set, it might or might not be true. Visibility map bits are only set by vacuum, but are cleared by any data-modifying operations on a page.
59.5. The Initialization Fork

Each unlogged table, and each index on an unlogged table, has an initialization fork. The initialization fork is an empty table or index of the appropriate type. When an unlogged table must be reset to empty due to a crash, the initialization fork is copied over the main fork, and any other forks are erased (they will be recreated automatically as needed).

59.6. Database Page Layout

This section provides an overview of the page format used within PostgreSQL tables and indexes. Sequences and TOAST tables are formatted just like a regular table.

In the following explanation, a byte is assumed to contain 8 bits. In addition, the term item refers to an individual data value that is stored on a page. In a table, an item is a row; in an index, an item is an index entry.

Every table and index is stored as an array of pages of a fixed size (usually 8 kB, although a different page size can be selected when compiling the server). In a table, all the pages are logically equivalent, so a particular item (row) can be stored in any page. In indexes, the first page is generally reserved as a metapage holding control information, and there can be different types of pages within the index, depending on the index access method.

Table 59-2 shows the overall layout of a page. There are five parts to each page.

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PageHeaderData</td>
<td>24 bytes long. Contains general information about the page, including free space pointers.</td>
</tr>
<tr>
<td>ItemIdData</td>
<td>Array of (offset,length) pairs pointing to the actual items. 4 bytes per item.</td>
</tr>
<tr>
<td>Free space</td>
<td>The unallocated space. New item pointers are allocated from the start of this area, new items from the end.</td>
</tr>
<tr>
<td>Items</td>
<td>The actual items themselves.</td>
</tr>
<tr>
<td>Special space</td>
<td>Index access method specific data. Different methods store different data. Empty in ordinary tables.</td>
</tr>
</tbody>
</table>

The first 24 bytes of each page consists of a page header (PageHeaderData). Its format is detailed in Table 59-3. The first field tracks the most recent WAL entry related to this page. The second field contains the page checksum if data checksums are enabled. Next is a 2-byte field containing flag bits. This is followed by three 2-byte integer fields (pd_lower, pd_upper, and pd_special). These contain byte offsets from the page start to the start of unallocated space, to the end of unallocated space, and to the start of the special space. The next 2 bytes of the page header, pd_pagesize_version, store both the page size and a version indicator. Beginning with PostgreSQL 8.3 the version number is 4; PostgreSQL 8.1 and 8.2 used version number 3; PostgreSQL 8.0 used version number 2; PostgreSQL 7.3 and 7.4 used version number 1; prior releases used version number 0. (The basic page layout and header format has not changed in most of these versions, but the layout of heap row headers has.)

1. Actually, index access methods need not use this page format. All the existing index methods do use this basic format, but the data kept on index metapages usually doesn’t follow the item layout rules.
The page size is basically only present as a cross-check; there is no support for having more than one page size in an installation. The last field is a hint that shows whether pruning the page is likely to be profitable: it tracks the oldest un-pruned XMAX on the page.

Table 59-3. PageHeaderData Layout

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Length</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pd_lsn</td>

<td>Oldest unpruned XMAX on page, or zero if none</td>
</tr>
</tbody>
</table>

All the details can be found in src/include/storage/bufpage.h.

Following the page header are item identifiers (ItemIdData), each requiring four bytes. An item identifier contains a byte-offset to the start of an item, its length in bytes, and a few attribute bits which affect its interpretation. New item identifiers are allocated as needed from the beginning of the unallocated space. The number of item identifiers present can be determined by looking at pd_lower, which is increased to allocate a new identifier. Because an item identifier is never moved until it is freed, its index can be used on a long-term basis to reference an item, even when the item itself is moved around on the page to compact free space. In fact, every pointer to an item (ItemPointer, also known as CTID) created by PostgreSQL consists of a page number and the index of an item identifier.

The items themselves are stored in space allocated backwards from the end of unallocated space. The exact structure varies depending on what the table is to contain. Tables and sequences both use a structure named HeapTupleHeaderData, described below.

The final section is the “special section” which can contain anything the access method wishes to store. For example, b-tree indexes store links to the page’s left and right siblings, as well as some other data relevant to the index structure. Ordinary tables do not use a special section at all (indicated by setting pd_special to equal the page size).

All table rows are structured in the same way. There is a fixed-size header (occupying 23 bytes on most machines), followed by an optional null bitmap, an optional object ID field, and the user data. The header is detailed in Table 59-4. The actual user data (columns of the row) begins at the offset indicated by t_hoff, which must always be a multiple of the MAXALIGN distance for the platform. The null bitmap is only present if the HEAP_HASNULL bit is set in t_infomask. If it is present it begins just after the fixed header and occupies enough bytes to have one bit per data column (that is,
In this list of bits, a 1 bit indicates not-null, a 0 bit is a null. When the bitmap is not present, all columns are assumed not-null. The object ID is only present if the `HEAP_HASOID` bit is set in `t_infomask`. If present, it appears just before the `t_hoff` boundary. Any padding needed to make `t_hoff` a MAXALIGN multiple will appear between the null bitmap and the object ID. (This in turn ensures that the object ID is suitably aligned.)

Table 59-4. HeapTupleHeaderData Layout

</tr>
</tbody>
</table>

All the details can be found in `src/include/access/htup_details.h`.

Interpreting the actual data can only be done with information obtained from other tables, mostly `pg_attribute`. The key values needed to identify field locations are `attlen` and `attalign`. There is no way to directly get a particular attribute, except when there are only fixed width fields and no null values. All this trickery is wrapped up in the functions `heap_getattr`, `fastgetattr` and `heap_getsysattr`.

To read the data you need to examine each attribute in turn. First check whether the field is NULL according to the null bitmap. If it is, go to the next. Then make sure you have the right alignment. If the field is a fixed width field, then all the bytes are simply placed. If it’s a variable length field (attlen = -1) then it’s a bit more complicated. All variable-length data types share the common header structure `struct varlena`, which includes the total length of the stored value and some flag bits. Depending on the flags, the data can be either inline or in a TOAST table; it might be compressed, too (see Section 59.2).
Chapter 60. BKI Backend Interface

Backend Interface (BKI) files are scripts in a special language that is understood by the PostgreSQL backend when running in the “bootstrap” mode. The bootstrap mode allows system catalogs to be created and filled from scratch, whereas ordinary SQL commands require the catalogs to exist already. BKI files can therefore be used to create the database system in the first place. (And they are probably not useful for anything else.)

initdb uses a BKI file to do part of its job when creating a new database cluster. The input file used by initdb is created as part of building and installing PostgreSQL by a program named genbki.pl, which reads some specially formatted C header files in the src/include/catalog/ directory of the source tree. The created BKI file is called postgres.bki and is normally installed in the share subdirectory of the installation tree.

Related information can be found in the documentation for initdb.

60.1. BKI File Format

This section describes how the PostgreSQL backend interprets BKI files. This description will be easier to understand if the postgres.bki file is at hand as an example.

BKI input consists of a sequence of commands. Commands are made up of a number of tokens, depending on the syntax of the command. Tokens are usually separated by whitespace, but need not be if there is no ambiguity. There is no special command separator; the next token that syntactically cannot belong to the preceding command starts a new one. (Usually you would put a new command on a new line, for clarity.) Tokens can be certain key words, special characters (parentheses, commas, etc.), numbers, or double-quoted strings. Everything is case sensitive.

Lines starting with # are ignored.

60.2. BKI Commands

create  tablename  tableoid  [bootstrap]  [shared_relation]  [without_oids]  [rowtype_oid oid]  (name1 = type1 [, name2 = type2, ...])

Create a table named tablename, and having the OID tableoid, with the columns given in parentheses.

The following column types are supported directly by bootstrap.c: bool, bytea, char (1 byte), name, int2, int4, regproc, regclass, regtype, text, oid, tid, xid, cid, int2vector, oidvector, _int4 (array), _text (array), _oid (array), _char (array), _aclitem (array). Although it is possible to create tables containing columns of other types, this cannot be done until after pg_type has been created and filled with appropriate entries. (That effectively means that only these column types can be used in bootstrapped tables, but non-bootstrap catalogs can contain any built-in type.)

When bootstrap is specified, the table will only be created on disk; nothing is entered into pg_class, pg_attribute, etc, for it. Thus the table will not be accessible by ordinary SQL
operations until such entries are made the hard way (with insert commands). This option is used for creating pg_class etc themselves.

The table is created as shared if shared_relation is specified. It will have OIDs unless without_oids is specified. The table’s row type OID (pg_type OID) can optionally be specified via the rowtype_oid clause; if not specified, an OID is automatically generated for it. (The rowtype_oid clause is useless if bootstrap is specified, but it can be provided anyway for documentation.)

```
open tablename
```

Open the table named tablename for insertion of data. Any currently open table is closed.

```
close [tablename]
```

Close the open table. The name of the table can be given as a cross-check, but this is not required.

```
insert [OID = oid_value] ( value1 value2 ... )
```

Insert a new row into the open table using value1, value2, etc., for its column values and oid_value for its OID. If oid_value is zero (0) or the clause is omitted, and the table has OIDs, then the next available OID is assigned.

NULL values can be specified using the special key word _null_. Values containing spaces must be double quoted.

```
declare [unique] index indexname indexoid on tablename using amname ( opclass1 name1 [, ...] )
```

Create an index named indexname, having OID indexoid, on the table named tablename, using the amname access method. The fields to index are called name1, name2 etc., and the operator classes to use are opclass1, opclass2 etc., respectively. The index file is created and appropriate catalog entries are made for it, but the index contents are not initialized by this command.

```
declare toast toasttableoid toastindexoid on tablename
```

Create a TOAST table for the table named tablename. The TOAST table is assigned OID toasttableoid and its index is assigned OID toastindexoid. As with declare index, filling of the index is postponed.

```
build indices
```

Fill in the indices that have previously been declared.

### 60.3. Structure of the Bootstrap BKI File

The open command cannot be used until the tables it uses exist and have entries for the table that is to be opened. (These minimum tables are pg_class, pg_attribute, pg_proc, and pg_type.) To allow those tables themselves to be filled, create with the bootstrap option implicitly opens the created table for data insertion.

Also, the declare index and declare toast commands cannot be used until the system catalogs they need have been created and filled in.

Thus, the structure of the postgres.bki file has to be:

1. create bootstrap one of the critical tables
2. insert data describing at least the critical tables
3. close
4. Repeat for the other critical tables.
5. create (without bootstrap) a noncritical table
6. open
7. insert desired data
8. close
9. Repeat for the other noncritical tables.
10. Define indexes and toast tables.
11. build indices

There are doubtless other, undocumented ordering dependencies.

### 60.4. Example

The following sequence of commands will create the table `test_table` with OID 420, having two columns `cola` and `colb` of type `int4` and `text`, respectively, and insert two rows into the table:

```sql
create test_table 420 (cola = int4, colb = text)
open test_table
insert OID=421 ( 1 "value1" )
insert OID=422 ( 2 _null_ )
close test_table
```
Chapter 61. How the Planner Uses Statistics

This chapter builds on the material covered in Section 14.1 and Section 14.2 to show some additional details about how the planner uses the system statistics to estimate the number of rows each part of a query might return. This is a significant part of the planning process, providing much of the raw material for cost calculation.

The intent of this chapter is not to document the code in detail, but to present an overview of how it works. This will perhaps ease the learning curve for someone who subsequently wishes to read the code.

61.1. Row Estimation Examples

The examples shown below use tables in the PostgreSQL regression test database. The outputs shown are taken from version 8.3. The behavior of earlier (or later) versions might vary. Note also that since ANALYZE uses random sampling while producing statistics, the results will change slightly after any new ANALYZE.

Let’s start with a very simple query:

```
EXPLAIN SELECT * FROM tenk1;
```

```
QUERY PLAN
----------------------------------------------
Seq Scan on tenk1 (cost=0.00..458.00 rows=10000 width=244)

How the planner determines the cardinality of tenk1 is covered in Section 14.2, but is repeated here for completeness. The number of pages and rows is looked up in pg_class:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 'tenk1';
```

```
relpages | reltuples
----------+-----------
358 | 10000
```

These numbers are current as of the last VACUUM or ANALYZE on the table. The planner then fetches the actual current number of pages in the table (this is a cheap operation, not requiring a table scan). If that is different from relpages then reltuples is scaled accordingly to arrive at a current number-of-rows estimate. In the example above, the value of relpages is up-to-date so the rows estimate is the same as reltuples.

Let’s move on to an example with a range condition in its WHERE clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000;
```

```
QUERY PLAN
--------------------------------------------------------------------------------
Bitmap Heap Scan on tenk1 (cost=24.06..394.64 rows=1007 width=244)
  Recheck Cond: (unique1 < 1000)
  -> Bitmap Index Scan on tenk1_unique1 (cost=0.00..23.80 rows=1007 width=0)
    Index Cond: (unique1 < 1000)
```

Chapter 61. How the Planner Uses Statistics

The planner examines the WHERE clause condition and looks up the selectivity function for the operator < in pg_operator. This is held in the column oprrest, and the entry in this case is scalarltsel. The scalarltsel function retrieves the histogram for uniquel from pg_statistics. For manual queries it is more convenient to look in the simpler pg_stats view:

```sql
SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='uniquel';
```

```
histogram_bounds
------------------------
(0,993,1997,3050,4040,5036,5957,7057,8029,9016,9995)
```

Next the fraction of the histogram occupied by “< 1000” is worked out. This is the selectivity. The histogram divides the range into equal frequency buckets, so all we have to do is locate the bucket that our value is in and count part of it and all of the ones before. The value 1000 is clearly in the second bucket (993-1997). Assuming a linear distribution of values inside each bucket, we can calculate the selectivity as:

```
selectivity = (1 + (1000 - bucket[2].min)/(bucket[2].max - bucket[2].min))/num_buckets
= (1 + (1000 - 993)/(1997 - 993))/10
= 0.100697
```

that is, one whole bucket plus a linear fraction of the second, divided by the number of buckets. The estimated number of rows can now be calculated as the product of the selectivity and the cardinality of tenk1:

```
rows = rel_cardinality * selectivity
= 10000 * 0.100697
= 1007 (rounding off)
```

Next let’s consider an example with an equality condition in its WHERE clause:

```sql
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'CRAAAA';
```

```
QUERY PLAN
----------------------------------------------------------
Seq Scan on tenk1 (cost=0.00..483.00 rows=30 width=244)
  Filter: (stringu1 = 'CRAAAA'::name)
```

Again the planner examines the WHERE clause condition and looks up the selectivity function for =, which is eqsel. For equality estimation the histogram is not useful; instead the list of most common values (MCVs) is used to determine the selectivity. Let’s have a look at the MCVs, with some additional columns that will be useful later:

```sql
SELECT null_frac, n_distinct, most_common_vals, most_common_freqs FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';
```

```
null_frac | 0
n_distinct | 676
most_common_vals | EJAAAA, BBAAAA, CRAAAA, FCAA, FEEAAA, GSAAA, JOAAA, MCAAA, NAAA, WGA
most_common_freqs | 0.00333333, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003
```

Since CRAAAA appears in the list of MCVs, the selectivity is merely the corresponding entry in the list of most common frequencies (MCFs):
Chapter 61. How the Planner Uses Statistics

```plaintext
selectivity = mcf[3]
    = 0.003
```

As before, the estimated number of rows is just the product of this with the cardinality of `tenk1`:

```plaintext
rows = 10000 * 0.003
    = 30
```

Now consider the same query, but with a constant that is not in the MCV list:

```sql
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'xxx';
```

```plaintext
QUERY PLAN
----------------------------------------------------------
Seq Scan on tenk1 (cost=0.00..483.00 rows=15 width=244)
Filter: (stringu1 = 'xxx '::name)
```

This is quite a different problem: how to estimate the selectivity when the value is *not* in the MCV list. The approach is to use the fact that the value is not in the list, combined with the knowledge of the frequencies for all of the MCVs:

```plaintext
selectivity = (1 - sum(mvf))/(num_distinct - num_mcv)
    = (1 - (0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003))/(676 - 10)
    = 0.0014559
```

That is, add up all the frequencies for the MCVs and subtract them from one, then divide by the number of *other* distinct values. This amounts to assuming that the fraction of the column that is not any of the MCVs is evenly distributed among all the other distinct values. Notice that there are no null values so we don’t have to worry about those (otherwise we’d subtract the null fraction from the numerator as well). The estimated number of rows is then calculated as usual:

```plaintext
rows = 10000 * 0.0014559
    = 15 (rounding off)
```

The previous example with `unique1 < 1000` was an oversimplification of what `scalarltsel` really does; now that we have seen an example of the use of MCVs, we can fill in some more detail. The example was correct as far as it went, because since `unique1` is a unique column it has no MCVs (obviously, no value is any more common than any other value). For a non-unique column, there will normally be both a histogram and an MCV list, and the histogram does not include the portion of the column population represented by the MCVs. We do things this way because it allows more precise estimation. In this situation `scalarltsel` directly applies the condition (e.g., "< 1000") to each value of the MCV list, and adds up the frequencies of the MCVs for which the condition is true. This gives an exact estimate of the selectivity within the portion of the table that is MCVs. The histogram is then used in the same way as above to estimate the selectivity in the portion of the table that is not MCVs, and then the two numbers are combined to estimate the overall selectivity. For example, consider

```sql
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 < 'IAAAAA';
```

```plaintext
QUERY PLAN
------------------------------------------------------------
Seq Scan on tenk1 (cost=0.00..483.00 rows=3077 width=244)
```

1998
Filter: (stringu1 < 'IAAAAA'::name)

We already saw the MCV information for stringu1, and here is its histogram:

```sql
SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';
```

```
histogram_bounds
--------------------------------------------------------------------------------
{AAAAAA, CQAAAA, FRAAAA, IBAAAA, KRAAAA, NFAAAA, PSAAAA, SGAAAA, VAAAAA, XLAAAA, ZZAAAA}
--------------------------------------------------------------------------------
```

Checking the MCV list, we find that the condition stringu1 < 'IAAAAA' is satisfied by the first six entries and not the last four, so the selectivity within the MCV part of the population is

\[
\text{selectivity} = \sum \text{relevant mvfs} = 0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 = 0.01833333
\]

Summing all the MCFs also tells us that the total fraction of the population represented by MCVs is 0.03033333, and therefore the fraction represented by the histogram is 0.96966667 (again, there are no nulls, else we’d have to exclude them here). We can see that the value IAAAAA falls nearly at the end of the third histogram bucket. Using some rather cheesy assumptions about the frequency of different characters, the planner arrives at the estimate 0.298387 for the portion of the histogram population that is less than IAAAAA. We then combine the estimates for the MCV and non-MCV populations:

\[
\text{selectivity} = \text{mcv selectivity} + \text{histogram selectivity} \times \text{histogram fraction} = 0.01833333 + 0.298387 \times 0.96966667 = 0.307669
\]

\[
\text{rows} = 10000 \times 0.307669 = 3077 \text{ (rounding off)}
\]

In this particular example, the correction from the MCV list is fairly small, because the column distribution is actually quite flat (the statistics showing these particular values as being more common than others are mostly due to sampling error). In a more typical case where some values are significantly more common than others, this complicated process gives a useful improvement in accuracy because the selectivity for the most common values is found exactly.

Now let’s consider a case with more than one condition in the `WHERE` clause:

```sql
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000 AND stringu1 = 'xxx';
```

```
QUERY PLAN
-----------------------------------------------------------------------------------
Bitmap Heap Scan on tenk1 (cost=23.80..396.91 rows=1 width=244)  
  Recheck Cond: (unique1 < 1000)  
  Filter: (stringu1 = 'xxx'::name)  
    -> Bitmap Index Scan on tenk1_unique1 (cost=0.00..23.80 rows=1007 width=0)  
      Index Cond: (unique1 < 1000)
```

The planner assumes that the two conditions are independent, so that the individual selectivities of the clauses can be multiplied together:

\[
\text{selectivity} = \text{selectivity(unique1 < 1000)} \times \text{selectivity(stringu1 = 'xxx')} = 0.100697 \times 0.0014559 = 0.0001466
\]
Chapter 61. How the Planner Uses Statistics

rows = 10000 * 0.0001466
= 1 (rounding off)

Notice that the number of rows estimated to be returned from the bitmap index scan reflects only the condition used with the index; this is important since it affects the cost estimate for the subsequent heap fetches.

Finally we will examine a query that involves a join:

EXPLAIN SELECT * FROM tenk1 t1, tenk2 t2
WHERE t1.unique1 < 50 AND t1.unique2 = t2.unique2;

<table>
<thead>
<tr>
<th>QUERY PLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nested Loop (cost=4.64..456.23 rows=50 width=488)</td>
</tr>
<tr>
<td>-&gt; Bitmap Heap Scan on tenk1 t1 (cost=4.64..142.17 rows=50 width=244)</td>
</tr>
<tr>
<td>Recheck Cond: (unique1 &lt; 50)</td>
</tr>
<tr>
<td>-&gt; Bitmap Index Scan on tenk1_unique1 (cost=0.00..4.63 rows=50 width=0)</td>
</tr>
<tr>
<td>Index Cond: (unique1 &lt; 50)</td>
</tr>
<tr>
<td>-&gt; Index Scan using tenk2_unique2 on tenk2 t2 (cost=0.00..6.27 rows=1 width=244)</td>
</tr>
<tr>
<td>Index Cond: (unique2 = t1.unique2)</td>
</tr>
</tbody>
</table>

The restriction on tenk1, unique1 < 50, is evaluated before the nested-loop join. This is handled analogously to the previous range example. This time the value 50 falls into the first bucket of the unique1 histogram:

\[
\text{selectivity} = \frac{(0 + (50 - \text{bucket}[1].\text{min})/(\text{bucket}[1].\text{max} - \text{bucket}[1].\text{min}))/\text{num}\_\text{buckets}}
\]
\[
= \frac{(0 + (50 - 0)/(993 - 0))/10}{0.005035}
\]

rows = 10000 * 0.005035
= 50 (rounding off)

The restriction for the join is t2.unique2 = t1.unique2. The operator is just our familiar \(\text{=}\), however the selectivity function is obtained from the \text{oprjoin} column of \text{pg_operator}, and is \text{eqjoinsel}. \text{eqjoinsel} looks up the statistical information for both \text{tenk2} and \text{tenk1}:

SELECT tablename, null_frac, n_distinct, most_common_vals FROM pg_stats
WHERE tablename IN ('tenk1', 'tenk2') AND attname='unique2';

<table>
<thead>
<tr>
<th>tablename</th>
<th>null_frac</th>
<th>n_distinct</th>
<th>most_common_vals</th>
</tr>
</thead>
<tbody>
<tr>
<td>tenk1</td>
<td>0</td>
<td>-1</td>
<td></td>
</tr>
<tr>
<td>tenk2</td>
<td>0</td>
<td>-1</td>
<td></td>
</tr>
</tbody>
</table>

In this case there is no MCV information for \text{unique2} because all the values appear to be unique, so we use an algorithm that relies only on the number of distinct values for both relations together with their null fractions:

\[
\text{selectivity} = (1 - \text{null}\_\text{frac1}) \times (1 - \text{null}\_\text{frac2}) \times \min(\frac{1}{\text{n}\_\text{distinct1}}, \frac{1}{\text{n}\_\text{distinct2}})
\]
\[
= (1 - 0) \times (1 - 0) / \max(10000, 10000)
\]
\[
= 0.0001
\]

This is, subtract the null fraction from one for each of the relations, and divide by the maximum of the numbers of distinct values. The number of rows that the join is likely to emit is calculated as the cardinality of the Cartesian product of the two inputs, multiplied by the selectivity:
Chapter 61. How the Planner Uses Statistics

rows = (outer_cardinality * inner_cardinality) * selectivity
= (50 * 10000) * 0.0001
= 50

Had there been MCV lists for the two columns, eqjoinSEL would have used direct comparison of the MCV lists to determine the join selectivity within the part of the column populations represented by the MCVs. The estimate for the remainder of the populations follows the same approach shown here.

Notice that we showed inner_cardinality as 10000, that is, the unmodified size of tenk2. It might appear from inspection of the EXPLAIN output that the estimate of join rows comes from 50 * 1, that is, the number of outer rows times the estimated number of rows obtained by each inner index scan on tenk2. But this is not the case: the join relation size is estimated before any particular join plan has been considered. If everything is working well then the two ways of estimating the join size will produce about the same answer, but due to round-off error and other factors they sometimes diverge significantly.

For those interested in further details, estimation of the size of a table (before any WHERE clauses) is done in src/backend/optimizer/util/plancat.c. The generic logic for clause selectivities is in src/backend/optimizer/path/clausesel.c. The operator-specific selectivity functions are mostly found in src/backend/utils/adt/selfuncs.c.

### 61.2. Planner Statistics and Security

Access to the table pg_statistic is restricted to superusers, so that ordinary users cannot learn about the contents of the tables of other users from it. Some selectivity estimation functions will use a user-provided operator (either the operator appearing in the query or a related operator) to analyze the stored statistics. For example, in order to determine whether a stored most common value is applicable, the selectivity estimator will have to run the appropriate operator to compare the constant in the query to the stored value. Thus the data in pg_statistic is potentially passed to user-defined operators. An appropriately crafted operator can intentionally leak the passed operands (for example, by logging them or writing them to a different table), or accidentally leak them by showing their values in error messages, in either case possibly exposing data from pg_statistic to a user who should not be able to see it.

In order to prevent this, the following applies to all built-in selectivity estimation functions. When planning a query, in order to be able to use stored statistics, the current user must either have SELECT privilege on the table or the involved columns, or the operator used must be LEAKPROOF (more accurately, the function that the operator is based on). If not, then the selectivity estimator will behave as if no statistics are available, and the planner will proceed with default or fall-back assumptions.

If a user does not have the required privilege on the table or columns, then in many cases the query will ultimately receive a permission-denied error, in which case this mechanism is invisible in practice. But if the user is reading from a security-barrier view, then the planner might wish to check the statistics of an underlying table that is otherwise inaccessible to the user. In that case, the operator should be leak-proof or the statistics will not be used. There is no direct feedback about that, except that the plan might be suboptimal. If one suspects that this is the case, one could try running the query as a more privileged user, to see if a different plan results.

This restriction applies only to cases where the planner would need to execute a user-defined operator on one or more values from pg_statistic. Thus the planner is permitted to use generic statistical
information, such as the fraction of null values or the number of distinct values in a column, regardless of access privileges.

Selectivity estimation functions contained in third-party extensions that potentially operate on statistics with user-defined operators should follow the same security rules. Consult the PostgreSQL source code for guidance.
VIII. Appendixes
Appendix A. PostgreSQL Error Codes

All messages emitted by the PostgreSQL server are assigned five-character error codes that follow the SQL standard’s conventions for “SQLSTATE” codes. Applications that need to know which error condition has occurred should usually test the error code, rather than looking at the textual error message. The error codes are less likely to change across PostgreSQL releases, and also are not subject to change due to localization of error messages. Note that some, but not all, of the error codes produced by PostgreSQL are defined by the SQL standard; some additional error codes for conditions not defined by the standard have been invented or borrowed from other databases.

According to the standard, the first two characters of an error code denote a class of errors, while the last three characters indicate a specific condition within that class. Thus, an application that does not recognize the specific error code might still be able to infer what to do from the error class.

Table A-1 lists all the error codes defined in PostgreSQL 9.4.22. (Some are not actually used at present, but are defined by the SQL standard.) The error classes are also shown. For each error class there is a “standard” error code having the last three characters 000. This code is used only for error conditions that fall within the class but do not have any more-specific code assigned.

The symbol shown in the column “Condition Name” is the condition name to use in PL/pgSQL. Condition names can be written in either upper or lower case. (Note that PL/pgSQL does not recognize warning, as opposed to error, condition names; those are classes 00, 01, and 02.)

For some types of errors, the server reports the name of a database object (a table, table column, data type, or constraint) associated with the error; for example, the name of the unique constraint that caused a unique_violation error. Such names are supplied in separate fields of the error report message so that applications need not try to extract them from the possibly-localized human-readable text of the message. As of PostgreSQL 9.3, complete coverage for this feature exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

Appendix B. Date/Time Support

PostgreSQL uses an internal heuristic parser for all date/time input support. Dates and times are input as strings, and are broken up into distinct fields with a preliminary determination of what kind of information can be in the field. Each field is interpreted and either assigned a numeric value, ignored, or rejected. The parser contains internal lookup tables for all textual fields, including months, days of the week, and time zones.

This appendix includes information on the content of these lookup tables and describes the steps used by the parser to decode dates and times.

B.1. Date/Time Input Interpretation

Date/time input strings are decoded using the following procedure.

1. Break the input string into tokens and categorize each token as a string, time, time zone, or number.
   a. If the numeric token contains a colon (:), this is a time string. Include all subsequent digits and colons.
   b. If the numeric token contains a dash (-), slash (/), or two or more dots (.), this is a date string which might have a text month. If a date token has already been seen, it is instead interpreted as a time zone name (e.g.,America/New_York).
   c. If the token is numeric only, then it is either a single field or an ISO 8601 concatenated date (e.g.,19990113 for January 13, 1999) or time (e.g.,141516 for 14:15:16).
   d. If the token starts with a plus (+) or minus (-), then it is either a numeric time zone or a special field.
2. If the token is an alphabetic string, match up with possible strings:
   a. See if the token matches any known time zone abbreviation. These abbreviations are supplied by the configuration file described in Section B.4.
   b. If not found, search an internal table to match the token as either a special string (e.g.,today), day (e.g.,Thursday), month (e.g.,January), or noise word (e.g.,at,on).
   c. If still not found, throw an error.
3. When the token is a number or number field:
   a. If there are eight or six digits, and if no other date fields have been previously read, then interpret as a “concatenated date” (e.g.,19990118 or 990118). The interpretation is YYYYMMDD or YMMDD.
   b. If the token is three digits and a year has already been read, then interpret as day of year.
   c. If four or six digits and a year has already been read, then interpret as a time (HHMM or HHMMSS).
Appendix B. Date/Time Support

d. If three or more digits and no date fields have yet been found, interpret as a year (this forces yy-mm-dd ordering of the remaining date fields).
e. Otherwise the date field ordering is assumed to follow the DateStyle setting: mm-dd-yy, dd-mm-yy, or yy-mm-dd. Throw an error if a month or day field is found to be out of range.

4. If BC has been specified, negate the year and add one for internal storage. (There is no year zero in the Gregorian calendar, so numerically 1 BC becomes year zero.)

5. If BC was not specified, and if the year field was two digits in length, then adjust the year to four digits. If the field is less than 70, then add 2000, otherwise add 1900.

Tip: Gregorian years AD 1-99 can be entered by using 4 digits with leading zeros (e.g., 0099 is AD 99).

B.2. Handling of Invalid or Ambiguous Timestamps

Ordinarily, if a date/time string is syntactically valid but contains out-of-range field values, an error will be thrown. For example, input specifying the 31st of February will be rejected.

During a daylight-savings-time transition, it is possible for a seemingly valid timestamp string to represent a nonexistent or ambiguous timestamp. Such cases are not rejected; the ambiguity is resolved by determining which UTC offset to apply. For example, supposing that the TimeZone parameter is set to America/New_York, consider

\[\text{SELECT ‘2018-03-11 02:30’::timestamptz; }\]
\[\text{timestamptz} \]
\[\text{------------------------} \]
\[2018-03-11 03:30:00-04 \]
\[\text{(1 row)} \]

Because that day was a spring-forward transition date in that time zone, there was no civil time instant 2:30AM; clocks jumped forward from 2AM EST to 3AM EDT. PostgreSQL interprets the given time as if it were standard time (UTC-5), which then renders as 3:30AM EDT (UTC-4).

Conversely, consider the behavior during a fall-back transition:

\[\text{SELECT ‘2018-11-04 02:30’::timestamptz; }\]
\[\text{timestamptz} \]
\[\text{------------------------} \]
\[2018-11-04 02:30:00-05 \]
\[\text{(1 row)} \]

On that date, there were two possible interpretations of 2:30AM; there was 2:30AM EDT, and then an hour later after the reversion to standard time, there was 2:30AM EST. Again, PostgreSQL interprets the given time as if it were standard time (UTC-5). We can force the matter by specifying daylight-savings time:

\[\text{SELECT ‘2018-11-04 02:30 EDT’::timestamptz; }\]
\[\text{timestamptz} \]
\[\text{------------------------} \]
This timestamp could validly be rendered as either 2:30 UTC-4 or 1:30 UTC-5; the timestamp output code chooses the latter.

The precise rule that is applied in such cases is that an invalid timestamp that appears to fall within a jump-forward daylight savings transition is assigned the UTC offset that prevailed in the time zone just before the transition, while an ambiguous timestamp that could fall on either side of a jump-back transition is assigned the UTC offset that prevailed just after the transition. In most time zones this is equivalent to saying that “the standard-time interpretation is preferred when in doubt”.

In all cases, the UTC offset associated with a timestamp can be specified explicitly, using either a numeric UTC offset or a time zone abbreviation that corresponds to a fixed UTC offset. The rule just given applies only when it is necessary to infer a UTC offset for a time zone in which the offset varies.

### B.3. Date/Time Key Words

Table B-1 shows the tokens that are recognized as names of months.

**Table B-1. Month Names**

<table>
<thead>
<tr>
<th>Month</th>
<th>Abbreviations</th>
</tr>
</thead>
<tbody>
<tr>
<td>January</td>
<td>Jan</td>
</tr>
<tr>
<td>February</td>

<tr>
<td>PM</td>
<td>Time is on or after 12:00</td>
</tr>
<tr>
<td>T</td>
<td>Next field is time</td>
</tr>
</tbody>
</table>

B.4. Date/Time Configuration Files

Since timezone abbreviations are not well standardized, PostgreSQL provides a means to customize the set of abbreviations accepted by the server. The timezone_abbreviations run-time parameter determines the active set of abbreviations. While this parameter can be altered by any database user, the possible values for it are under the control of the database administrator — they are in fact names of configuration files stored in .../share/timezonesets/ of the installation directory. By adding or altering files in that directory, the administrator can set local policy for timezone abbreviations.

timezone_abbreviations can be set to any file name found in .../share/timezonesets/, if the file’s name is entirely alphabetic. (The prohibition against non-alphabetic characters in timezone_abbreviations prevents reading files outside the intended directory, as well as reading editor backup files and other extraneous files.)

A timezone abbreviation file can contain blank lines and comments beginning with #. Non-comment lines must have one of these formats:

```
zone_abbreviation offset
zone_abbreviation offset D
zone_abbreviation time_zone_name
@INCLUDE file_name
@OVERRIDE
```

A zone_abbreviation is just the abbreviation being defined. An offset is an integer giving the equivalent offset in seconds from UTC, positive being east from Greenwich and negative being west. For example, -18000 would be five hours west of Greenwich, or North American east coast standard time. D indicates that the zone name represents local daylight-savings time rather than standard time.

Alternatively, a time_zone_name can be given, referencing a zone name defined in the IANA timezone database. The zone’s definition is consulted to see whether the abbreviation is or has been in use in that zone, and if so, the appropriate meaning is used — that is, the meaning that was currently in use at the timestamp whose value is being determined, or the meaning in use immediately before that if it wasn’t current at that time, or the oldest meaning if it was used only after that time. This behavior is essential for dealing with abbreviations whose meaning has historically varied. It is also allowed to define an abbreviation in terms of a zone name in which that abbreviation does not appear; then using the abbreviation is just equivalent to writing out the zone name.
Appendix B. Date/Time Support

**Tip:** Using a simple integer *offset* is preferred when defining an abbreviation whose offset from UTC has never changed, as such abbreviations are much cheaper to process than those that require consulting a time zone definition.

The `@INCLUDE` syntax allows inclusion of another file in the `.../share/timezonesets/` directory. Inclusion can be nested, to a limited depth.

The `@OVERRIDE` syntax indicates that subsequent entries in the file can override previous entries (typically, entries obtained from included files). Without this, conflicting definitions of the same timezone abbreviation are considered an error.

In an unmodified installation, the file `Default` contains all the non-conflicting time zone abbreviations for most of the world. Additional files `Australia` and `India` are provided for those regions: these files first include the `Default` file and then add or modify abbreviations as needed.

For reference purposes, a standard installation also contains files `Africa.txt`, `America.txt`, etc, containing information about every time zone abbreviation known to be in use according to the IANA timezone database. The zone name definitions found in these files can be copied and pasted into a custom configuration file as needed. Note that these files cannot be directly referenced as `timezone_abbreviations` settings, because of the dot embedded in their names.

**Note:** If an error occurs while reading the time zone abbreviation set, no new value is applied and the old set is kept. If the error occurs while starting the database, startup fails.

---

**Caution**

Time zone abbreviations defined in the configuration file override non-timezone meanings built into PostgreSQL. For example, the `Australia` configuration file defines `SAT` (for South Australian Standard Time). When this file is active, `SAT` will not be recognized as an abbreviation for Saturday.

---

**Caution**

If you modify files in `.../share/timezonesets/`, it is up to you to make backups — a normal database dump will not include this directory.

---

B.5. History of Units

The SQL standard states that “Within the definition of a ‘datetime literal’, the ‘datetime values’ are constrained by the natural rules for dates and times according to the Gregorian calendar”. PostgreSQL follows the SQL standard’s lead by counting dates exclusively in the Gregorian calendar, even for years before that calendar was in use. This rule is known as the *proleptic Gregorian calendar*.

The Julian calendar was introduced by Julius Caesar in 45 BC. It was in common use in the Western world until the year 1582, when countries started changing to the Gregorian calendar. In the Julian calendar, the tropical year is approximated as 365 1/4 days = 365.25 days. This gives an error of about 1 day in 128 years.

The accumulating calendar error prompted Pope Gregory XIII to reform the calendar in accordance with instructions from the Council of Trent. In the Gregorian calendar, the tropical year is approxi-
Appendix B. Date/Time Support

mated as 365 + 97 / 400 days = 365.2425 days. Thus it takes approximately 3300 years for the tropical year to shift one day with respect to the Gregorian calendar.

The approximation 365+97/400 is achieved by having 97 leap years every 400 years, using the following rules:

- Every year divisible by 4 is a leap year.
- However, every year divisible by 100 is not a leap year.
- However, every year divisible by 400 is a leap year after all.

So, 1700, 1800, 1900, 2100, and 2200 are not leap years. But 1600, 2000, and 2400 are leap years. By contrast, in the older Julian calendar all years divisible by 4 are leap years.

The papal bull of February 1582 decreed that 10 days should be dropped from October 1582 so that 15 October should follow immediately after 4 October. This was observed in Italy, Poland, Portugal, and Spain. Other Catholic countries followed shortly after, but Protestant countries were reluctant to change, and the Greek Orthodox countries didn’t change until the start of the 20th century. The reform was observed by Great Britain and its dominions (including what is now the USA) in 1752. Thus 2 September 1752 was followed by 14 September 1752. This is why Unix systems that have the cal program produce the following:

```
$ cal 9 1752
September 1752
 Su Mo Tu We Th Fr Sa
  1  2  14  15  16
 17  18  19  20  21  22  23
 24  25  26  27  28  29  30
```

But, of course, this calendar is only valid for Great Britain and dominions, not other places. Since it would be difficult and confusing to try to track the actual calendars that were in use in various places at various times, PostgreSQL does not try, but rather follows the Gregorian calendar rules for all dates, even though this method is not historically accurate.

Different calendars have been developed in various parts of the world, many predating the Gregorian system. For example, the beginnings of the Chinese calendar can be traced back to the 14th century BC. Legend has it that the Emperor Huangdi invented that calendar in 2637 BC. The People’s Republic of China uses the Gregorian calendar for civil purposes. The Chinese calendar is used for determining festivals.

The Julian Date system is another type of calendar, unrelated to the Julian calendar though it is confusingly named similarly to that calendar. The Julian Date system was invented by the French scholar Joseph Justus Scaliger (1540-1609) and probably takes its name from Scaliger’s father, the Italian scholar Julius Caesar Scaliger (1484-1558). In the Julian Date system, each day has a sequential number, starting from JD 0 (which is sometimes called the Julian Date). JD 0 corresponds to 1 January 4713 BC in the Julian calendar, or 24 November 4714 BC in the Gregorian calendar. Julian Date counting is most often used by astronomers for labeling their nightly observations, and therefore a date runs from noon UTC to the next noon UTC, rather than from midnight to midnight: JD 0 designates the 24 hours from noon UTC on 24 November 4714 BC to noon UTC on 25 November 4714 BC.

Although PostgreSQL supports Julian Date notation for input and output of dates (and also uses Julian dates for some internal datetime calculations), it does not observe the nicety of having dates run from noon to noon. PostgreSQL treats a Julian Date as running from midnight to midnight.
Appendix C. SQL Key Words

Table C-1 lists all tokens that are key words in the SQL standard and in PostgreSQL 9.4.22. Background information can be found in Section 4.1.1. (For space reasons, only the latest two versions of the SQL standard, and SQL-92 for historical comparison, are included. The differences between those and the other intermediate standard versions are small.)

SQL distinguishes between reserved and non-reserved key words. According to the standard, reserved key words are the only real key words; they are never allowed as identifiers. Non-reserved key words only have a special meaning in particular contexts and can be used as identifiers in other contexts. Most non-reserved key words are actually the names of built-in tables and functions specified by SQL. The concept of non-reserved key words essentially only exists to declare that some predefined meaning is attached to a word in some contexts.

In the PostgreSQL parser life is a bit more complicated. There are several different classes of tokens ranging from those that can never be used as an identifier to those that have absolutely no special status in the parser as compared to an ordinary identifier. (The latter is usually the case for functions specified by SQL.) Even reserved key words are not completely reserved in PostgreSQL, but can be used as column labels (for example, SELECT 55 AS CHECK, even though CHECK is a reserved key word).

In Table C-1 in the column for PostgreSQL we classify as “non-reserved” those key words that are explicitly known to the parser but are allowed as column or table names. Some key words that are otherwise non-reserved cannot be used as function or data type names and are marked accordingly. (Most of these words represent built-in functions or data types with special syntax. The function or type is still available but it cannot be redefined by the user.) Labeled “reserved” are those tokens that are not allowed as column or table names. Some reserved key words are allowable as names for functions or data types; this is also shown in the table. If not so marked, a reserved key word is only allowed as an “AS” column label name.

As a general rule, if you get spurious parser errors for commands that contain any of the listed key words as an identifier you should try to quote the identifier to see if the problem goes away.

It is important to understand before studying Table C-1 that the fact that a key word is not reserved in PostgreSQL does not mean that the feature related to the word is not implemented. Conversely, the presence of a key word does not indicate the existence of a feature.

Appendix D. SQL Conformance

This section attempts to outline to what extent PostgreSQL conforms to the current SQL standard. The following information is not a full statement of conformance, but it presents the main topics in as much detail as is both reasonable and useful for users.

The formal name of the SQL standard is ISO/IEC 9075 “Database Language SQL”. A revised version of the standard is released from time to time; the most recent update appearing in 2011. The 2011 version is referred to as ISO/IEC 9075:2011, or simply as SQL:2011. The versions prior to that were SQL:2008, SQL:2003, SQL:1999, and SQL-92. Each version replaces the previous one, so claims of conformance to earlier versions have no official merit. PostgreSQL development aims for conformance with the latest official version of the standard where such conformance does not contradict traditional features or common sense. Many of the features required by the SQL standard are supported, though sometimes with slightly differing syntax or function. Further moves towards conformance can be expected over time.

SQL-92 defined three feature sets for conformance: Entry, Intermediate, and Full. Most database management systems claiming SQL standard conformance were conforming at only the Entry level, since the entire set of features in the Intermediate and Full levels was either too voluminous or in conflict with legacy behaviors.

Starting with SQL:1999, the SQL standard defines a large set of individual features rather than the ineffectively broad three levels found in SQL-92. A large subset of these features represents the “Core” features, which every conforming SQL implementation must supply. The rest of the features are purely optional. Some optional features are grouped together to form “packages”, which SQL implementations can claim conformance to, thus claiming conformance to particular groups of features.

The standard versions beginning with SQL:2003 are also split into a number of parts. Each is known by a shorthand name. Note that these parts are not consecutively numbered.

- ISO/IEC 9075-1 Framework (SQL/Framework)
- ISO/IEC 9075-2 Foundation (SQL/Foundation)
- ISO/IEC 9075-3 Call Level Interface (SQL/CLI)
- ISO/IEC 9075-4 Persistent Stored Modules (SQL/PSM)
- ISO/IEC 9075-9 Management of External Data (SQL/MED)
- ISO/IEC 9075-10 Object Language Bindings (SQL/OLB)
- ISO/IEC 9075-11 Information and Definition Schemas (SQL/Schemata)
- ISO/IEC 9075-13 Routines and Types using the Java Language (SQL/JRT)
- ISO/IEC 9075-14 XML-related specifications (SQL/XML)

The PostgreSQL core covers parts 1, 2, 9, 11, and 14. Part 3 is covered by the ODBC driver, and part 13 is covered by the PL/Java plug-in, but exact conformance is currently not being verified for these components. There are currently no implementations of parts 4 and 10 for PostgreSQL.

PostgreSQL supports most of the major features of SQL:2011. Out of 179 mandatory features required for full Core conformance, PostgreSQL conforms to at least 160. In addition, there is a long list of
supported optional features. It might be worth noting that at the time of writing, no current version of any database management system claims full conformance to Core SQL:2011.

In the following two sections, we provide a list of those features that PostgreSQL supports, followed by a list of the features defined in SQL:2011 which are not yet supported in PostgreSQL. Both of these lists are approximate: There might be minor details that are nonconforming for a feature that is listed as supported, and large parts of an unsupported feature might in fact be implemented. The main body of the documentation always contains the most accurate information about what does and does not work.

**Note:** Feature codes containing a hyphen are subfeatures. Therefore, if a particular subfeature is not supported, the main feature is listed as unsupported even if some other subfeatures are supported.

### D.1. Supported Features

Appendix E. Release Notes

The release notes contain the significant changes in each PostgreSQL release, with major features and migration issues listed at the top. The release notes do not contain changes that affect only a few users or changes that are internal and therefore not user-visible. For example, the optimizer is improved in almost every release, but the improvements are usually observed by users as simply faster queries.

A complete list of changes for each release can be obtained by viewing the Git logs for each release. The `pgsql-committers` email list¹ records all source code changes as well. There is also a web interface² that shows changes to specific files.

The name appearing next to each item represents the major developer for that item. Of course all changes involve community discussion and patch review, so each item is truly a community effort.

E.1. Release 9.4.22

Release date: 2019-05-09

This release contains a variety of fixes from 9.4.21. For information about new features in the 9.4 major release, see Section E.23.

The PostgreSQL community will stop releasing updates for the 9.4.X release series in February 2020. Users are encouraged to update to a newer release branch soon.

E.1.1. Migration to Version 9.4.22

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.18, see Section E.5.

E.1.2. Changes

- Fix behavior for an `UPDATE` or `DELETE` on an inheritance tree or partitioned table in which every table can be excluded (Amit Langote, Tom Lane)
  
  In such cases, the query did not report the correct set of output columns when a `RETURNING` clause was present, and if there were any statement-level triggers that should be fired, it didn’t fire them.

- Fix handling of explicit `DEFAULT` items in an `INSERT ... VALUES` command with multiple `VALUES` rows, if the target relation is an updatable view (Amit Langote, Dean Rasheed)
  
  When the updatable view has no default for the column but its underlying table has one, a single-row `INSERT ... VALUES` will use the underlying table’s default. In the multi-row case, however, `NULL` was always used. Correct it to act like the single-row case.

- Fix `CREATE VIEW` to allow zero-column views (Ashutosh Sharma)

¹. https://archives.postgresql.org/pgsql-committers/
². https://git.postgresql.org/gitweb/?p=postgresql.git;a=summary
Appendix E. Release Notes

We should allow this for consistency with allowing zero-column tables. Since a table can be converted to a view, zero-column views could be created even with the restriction in place, leading to dump/reload failures.

- Accept XML documents as valid values of type xml when xmloption is set to content, as required by SQL:2006 and later (Chapman Flack)

Previously PostgreSQL followed the SQL:2003 definition, which doesn’t allow this. But that creates a serious problem for dump/restore: there is no setting of xmloption that will accept all valid XML data. Hence, switch to the 2006 definition.

pg_dump is also modified to emit SET xmloption = content while restoring data, ensuring that dump/restore works even if the prevailing setting is document.

- Improve server’s startup-time checks for whether a pre-existing shared memory segment is still in use (Noah Misch)

The postmaster is now more likely to detect that there are still active processes from a previous postmaster incarnation, even if the postmaster.pid file has been removed.

- Fix incompatibility of GIN-index WAL records (Alexander Korotkov)

A fix applied in February’s minor releases was not sufficiently careful about backwards compatibility, leading to problems if a standby server of that vintage reads GIN page-deletion WAL records generated by a primary server of a previous minor release.

- Tolerate EINVAL and ENOSYS error results, where appropriate, for fsync and sync_file_range calls (Thomas Munro, James Sewell)

The previous change to panic on file synchronization failures turns out to have been excessively paranoid for certain cases where a failure is predictable and essentially means “operation not supported”.

- Fix “failed to build any $N$-way joins” planner failures with lateral references leading out of FULL outer joins (Tom Lane)

- Check the appropriate user’s permissions when enforcing rules about letting a leaky operator see pg_statistic data (Dean Rasheed)

When an underlying table is being accessed via a view, consider the privileges of the view owner while deciding whether leaky operators may be applied to the table’s statistics data, rather than the privileges of the user making the query. This makes the planner’s rules about what data is visible match up with the executor’s, avoiding unnecessarily-poor plans.

- Avoid O(N^2) performance issue when rolling back a transaction that created many tables (Tomas Vondra)

- Fix race conditions in management of dynamic shared memory (Thomas Munro)

These could lead to “dsa_area could not attach to segment” or “cannot unpin a segment that is not pinned” errors.

- Fix race condition in which a hot-standby postmaster could fail to shut down after receiving a smart-shutdown request (Tom Lane)

- Tighten validation of encoded SCRAM-SHA-256 and MD5 passwords (Jonathan Katz)

A password string that had the right initial characters could be mistaken for one that is correctly hashed into SCRAM-SHA-256 or MD5 format. The password would be accepted but would be unusable later.

- Fix handling of lc_time settings that imply an encoding different from the database’s encoding (Juan José Santamaría Flecha, Tom Lane)

2073
Localized month or day names that include non-ASCII characters previously caused unexpected errors or wrong output in such locales.

- Disallow NaN as a value for floating-point server parameters (Tom Lane)
- Rearrange REINDEX processing to avoid assertion failures when reindexing individual indexes of pg_class (Andres Freund, Tom Lane)
- Fix planner assertion failure for parameterized dummy paths (Tom Lane)
- Insert correct test function in the result of SnapBuildInitialSnapshot() (Antonin Houska)
  No core code cares about this, but some extensions do.
- Fix intermittent “could not reattach to shared memory” session startup failures on Windows (Noah Misch)
  A previously unrecognized source of these failures is creation of thread stacks for a process’s default thread pool. Arrange for such stacks to be allocated in a different memory region.
- Fix error detection in directory scanning on Windows (Konstantin Knizhnik)
  Errors, such as lack of permissions to read the directory, were not detected or reported correctly; instead the code silently acted as though the directory were empty.
- Fix grammar problems in ecpg (Tom Lane)
  A missing semicolon led to mistranslation of SET variable = DEFAULT (but not SET variable TO DEFAULT) in ecpg programs, producing syntactically invalid output that the server would reject. Additionally, in a DROP TYPE or DROP DOMAIN command that listed multiple type names, only the first type name was actually processed.
- Fix possible buffer overruns in ecpg’s processing of include filenames (Liu Huailing, Fei Wu)
- Avoid crash in contrib/vacuumlo if an lo_unlink() call failed (Tom Lane)
- Sync our copy of the timezone library with IANA tzcode release 2019a (Tom Lane)
  This corrects a small bug in zic that caused it to output an incorrect year-2440 transition in the Africa/Casablanca zone, and adds support for zic’s new -r option.
- Update time zone data files to tzdata release 2019a for DST law changes in Palestine and Metlakatla, plus historical corrections for Israel.
  Etc/UCT is now a backward-compatibility link to Etc/UTC, instead of being a separate zone that generates the abbreviation UCT, which nowadays is typically a typo. PostgreSQL will still accept UCT as an input zone abbreviation, but it won’t output it.

E.2. Release 9.4.21

Release date: 2019-02-14

This release contains a variety of fixes from 9.4.20. For information about new features in the 9.4 major release, see Section E.23.

The PostgreSQL community will stop releasing updates for the 9.4.X release series in February 2020. Users are encouraged to update to a newer release branch soon.
E.2.1. Migration to Version 9.4.21

A dump/restore is not required for those running 9.4.X.
However, if you are upgrading from a version earlier than 9.4.18, see Section E.5.

E.2.2. Changes

• By default, panic instead of retrying after `fsync()` failure, to avoid possible data corruption (Craig Ringer, Thomas Munro)

  Some popular operating systems discard kernel data buffers when unable to write them out, reporting this as `fsync()` failure. If we reissue the `fsync()` request it will succeed, but in fact the data has been lost, so continuing risks database corruption. By raising a panic condition instead, we can replay from WAL, which may contain the only remaining copy of the data in such a situation. While this is surely ugly and inefficient, there are few alternatives, and fortunately the case happens very rarely.

  A new server parameter `data_sync_retry` has been added to control this; if you are certain that your kernel does not discard dirty data buffers in such scenarios, you can set `data_sync_retry` to `on` to restore the old behavior.

• Include each major release branch’s release notes in the documentation for only that branch, rather than that branch and all later ones (Tom Lane)

  The duplication induced by the previous policy was getting out of hand. Our plan is to provide a full archive of release notes on the project’s web site, but not duplicate it within each release.

• Avoid possible deadlock when acquiring multiple buffer locks (Nishant Fnu)

• Avoid deadlock between hot-standby queries and replay of GIN index page deletion (Alexander Korotkov)

• Fix possible crashes in logical replication when index expressions or predicates are in use (Peter Eisentraut)

• Avoid useless and expensive logical decoding of TOAST data during a table rewrite (Tomas Vondra)

• Fix logic for stopping a subset of WAL senders when synchronous replication is enabled (Paul Guo, Michael Paquier)

• Avoid possibly writing an incorrect replica identity field in a tuple deletion WAL record (Stas Kelvich)

• Avoid crash if libxml2 returns a null error message (Sergio Conde Gómez)

• Fix spurious grouping-related parser errors caused by inconsistent handling of collation assignment (Andrew Gierth)

  In some cases, expressions that should be considered to match were not seen as matching, if they included operations on collatable data types.

• Check whether the comparison function underlying `LEAST()` or `GREATEST()` is leakproof, rather than just assuming it is (Tom Lane)

  Actual information leaks from btree comparison functions are typically hard to provoke, but in principle they could happen.

• Fix incorrect planning of queries in which a lateral reference must be evaluated at a foreign table scan (Tom Lane)
Appendix E. Release Notes

• Fix corner-case underestimation of the cost of a merge join (Tom Lane)
  The planner could prefer a merge join when the outer key range is much smaller than the inner key range, even if there are so many duplicate keys on the inner side that this is a poor choice.

• Avoid \( O(N^2) \) planning time growth when a query contains many thousand indexable clauses (Tom Lane)

• Improve `ANALYZE`’s handling of concurrently-updated rows (Jeff Janes, Tom Lane)
  Previously, rows deleted by an in-progress transaction were omitted from `ANALYZE`’s sample, but this has been found to lead to more inconsistency than including them would do. In effect, the sample now corresponds to an MVCC snapshot as of `ANALYZE`’s start time.

• Make `TRUNCATE` ignore inheritance child tables that are temporary tables of other sessions (Amit Langote, Michael Paquier)
  This brings `TRUNCATE` into line with the behavior of other commands. Previously, such cases usually ended in failure.

• Allow `UNLISTEN` in hot-standby mode (Shay Rojansky)
  This is necessarily a no-op, because `LISTEN` isn’t allowed in hot-standby mode; but allowing the dummy operation simplifies session-state-reset logic in clients.

• Fix missing role dependencies in some schema and data type permissions lists (Tom Lane)
  In some cases it was possible to drop a role to which permissions had been granted. This caused no immediate problem, but a subsequent dump/reload or upgrade would fail, with symptoms involving attempts to grant privileges to all-numeric role names.

• Ensure relation caches are updated properly after renaming constraints (Amit Langote)

• Make autovacuum more aggressive about removing leftover temporary tables, and also remove leftover temporary tables during `DISCARD TEMP` (Álvaro Herrera)
  This helps ensure that remnants from a crashed session are cleaned up more promptly.

• Prevent empty GIN index pages from being reclaimed too quickly, causing failures of concurrent searches (Andrey Borodin, Alexander Korotkov)

• Fix edge-case failures in float-to-integer coercions (Andrew Gierth, Tom Lane)
  Values very slightly above the maximum valid integer value might not be rejected, and then would overflow, producing the minimum valid integer instead. Also, values that should round to the minimum or maximum integer value might be incorrectly rejected.

• Disallow setting `client_min_messages` higher than `ERROR` (Jonah Harris, Tom Lane)
  Previously, it was possible to set this variable to `FATAL` or `PANIC`, which had the effect of suppressing transmission of ordinary error messages to the client. However, that’s contrary to guarantees that are given in the PostgreSQL wire protocol specification, and it caused some clients to become very confused. In released branches, fix this by silently treating such settings as meaning `ERROR` instead. Version 12 and later will reject those alternatives altogether.

• Fix `ecpglib` to use `uselocale()` or `_configthreadlocale()` in preference to `setlocale()` (Michael Meskes, Tom Lane)
  Since `setlocale()` is not thread-local, and might not even be thread-safe, the previous coding caused problems in multi-threaded `ecpg` applications.

• Fix incorrect results for numeric data passed through an `ecpg` SQLDA (SQL Descriptor Area) (Daisuke Higuchi)
  Values with leading zeroes were not copied correctly.
• Make psql’s LaTeX output formats render special characters properly (Tom Lane)

Backslash and some other ASCII punctuation characters were not rendered correctly, leading to
document syntax errors or wrong characters in the output.

• Fix pg_dump’s handling of materialized views with indirect dependencies on primary keys (Tom
Lane)

This led to mis-labeling of such views’ dump archive entries, causing harmless warnings about
“archive items not in correct section order”; less harmlessly, selective-restore options depending on
those labels, such as --section, might misbehave.

• Avoid null-pointer-dereference crash on some platforms when pg_dump or pg_restore tries to report
an error (Tom Lane)

• Fix contrib/hstore to calculate correct hash values for empty hstore values that were created
in version 8.4 or before (Andrew Gierth)

The previous coding did not give the same result as for an empty hstore value created by a newer
version, thus potentially causing wrong results in hash joins or hash aggregation. It is advisable
to reindex any hash indexes built on hstore columns, if the table might contain data that was
originally stored as far back as 8.4 and was never dumped/reloaded since then.

• Avoid crashes and excessive runtime with large inputs to contrib/intarray’s gist__int_ops
index support (Andrew Gierth)

• Adjust configure’s selection of threading-related compiler flags and libraries to match what later
PostgreSQL releases do (Tom Lane)

The coding previously used in the 9.4 and 9.5 branches fails outright on some newer platforms, so
sync it with what 9.6 and later have been doing.

• Support new Makefile variables PG_CFLAGS, PG_CXXFLAGS, and PG_LDFLAGS in pgxs builds
(Christoph Berg)

This simplifies customization of extension build processes.

• Fix Perl-coded build scripts to not assume “.” is in the search path, since recent Perl versions don’t
include that (Andrew Dunstan)

• Fix server command-line option parsing problems on OpenBSD (Tom Lane)

• Update time zone data files to tzdata release 2018i for DST law changes in Kazakhstan, Metlakatla,
and Sao Tome and Principe. Kazakhstan’s Qyzylorda zone is split in two, creating a new zone
Asia/Qostanay, as some areas did not change UTC offset. Historical corrections for Hong Kong
and numerous Pacific islands.

E.3. Release 9.4.20

Release date: 2018-11-08

This release contains a variety of fixes from 9.4.19. For information about new features in the 9.4
major release, see Section E.23.

E.3.1. Migration to Version 9.4.20

A dump/restore is not required for those running 9.4.X.
However, if you are upgrading from a version earlier than 9.4.18, see Section E.5.
E.3.2. Changes

- Fix corner-case failures in `has_foo_privilege()` family of functions (Tom Lane)
  Return NULL rather than throwing an error when an invalid object OID is provided. Some of these functions got that right already, but not all. `has_column_privilege()` was additionally capable of crashing on some platforms.
- Avoid \( O(N^2) \) slowdown in regular expression match/split functions on long strings (Andrew Gierth)
- Avoid \( O(N^3) \) slowdown in lexer for long strings of + or - characters (Andrew Gierth)
- Fix mis-execution of SubPlans when the outer query is being scanned backwards (Andrew Gierth)
- Fix failure of `UPDATE/DELETE ... WHERE CURRENT OF ...` after rewinding the referenced cursor (Tom Lane)
  A cursor that scans multiple relations (particularly an inheritance tree) could produce wrong behavior if rewound to an earlier relation.
- Fix `EvalPlanQual` to handle conditionally-executed InitPlans properly (Andrew Gierth, Tom Lane)
  This resulted in hard-to-reproduce crashes or wrong answers in concurrent updates, if they contained code such as an uncorrelated sub-SELECT inside a `CASE` construct.
- Fix character-class checks to not fail on Windows for Unicode characters above U+FFFF (Tom Lane, Kenji Uno)
  This bug affected full-text-search operations, as well as `contrib/ltree` and `contrib/pg_trgm`.
- Ensure that sequences owned by a foreign table are processed by `ALTER OWNER` on the table (Peter Eisentraut)
  The ownership change should propagate to such sequences as well, but this was missed for foreign tables.
- Fix over-allocation of space for `array_out()`’s result string (Keiichi Hirobe)
- Fix memory leak in repeated SP-GiST index scans (Tom Lane)
  This is only known to amount to anything significant in cases where an exclusion constraint using SP-GiST receives many new index entries in a single command.
- Ensure that `ApplyLogicalMappingFile()` closes the mapping file when done with it (Tomas Vondra)
  Previously, the file descriptor was leaked, eventually resulting in failures during logical decoding.
- Fix logical decoding to handle cases where a mapped catalog table is repeatedly rewritten, e.g. by `VACUUM FULL` (Andres Freund)
- Prevent starting the server with `wal_level` set to too low a value to support an existing replication slot (Andres Freund)
- Avoid crash if a utility command causes infinite recursion (Tom Lane)
- When initializing a hot standby, cope with duplicate XIDs caused by two-phase transactions on the master (Michael Paquier, Konstantin Knizhnik)
- Randomize the `random()` seed in bootstrap and standalone backends, and in `initdb` (Noah Misch)
The main practical effect of this change is that it avoids a scenario where initdb might mistakenly conclude that POSIX shared memory is not available, due to name collisions caused by always using the same random seed.

- Allow DSM allocation to be interrupted (Chris Travers)
- Avoid possible buffer overrun when replaying GIN page recompression from WAL (Alexander Korotkov, Sivasubramanian Ramasubramanian)
- Fix missed fsync of a replication slot’s directory (Konstantin Knizhnik, Michael Paquier)
- Fix unexpected timeouts when using `wal_sender_timeout` on a slow server (Noah Misch)
- Ensure that hot standby processes use the correct WAL consistency point (Alexander Kukushkin, Michael Paquier)
  This prevents possible misbehavior just after a standby server has reached a consistent database state during WAL replay.
- Don’t run atexit callbacks when servicing `SIGQUIT` (Heikki Linnakangas)
- Don’t record foreign-server user mappings as members of extensions (Tom Lane)
  If `CREATE USER MAPPING` is executed in an extension script, an extension dependency was created for the user mapping, which is unexpected. Roles can’t be extension members, so user mappings shouldn’t be either.
- Make syslogger more robust against failures in opening CSV log files (Tom Lane)
- Fix possible inconsistency in `pg_dump`’s sorting of dissimilar object names (Jacob Champion)
- Ensure that `pg_restore` will schema-qualify the table name when emitting `DISABLE/ENABLE TRIGGER` commands (Tom Lane)
  This avoids failures due to the new policy of running restores with restrictive search path.
- Fix `pg_upgrade` to handle event triggers in extensions correctly (Haribabu Kommi)
  `pg_upgrade` failed to preserve an event trigger’s extension-membership status.
- Fix `pg_upgrade`’s cluster state check to work correctly on a standby server (Bruce Momijian)
- Enforce type `cube`’s dimension limit in all `contrib/cube` functions (Andrey Borodin)
  Previously, some cube-related functions could construct values that would be rejected by `cube_in()`, leading to dump/reload failures.
- Fix `contrib/unaccent`’s `unaccent()` function to use the `unaccent` text search dictionary that is in the same schema as the function (Tom Lane)
  Previously it tried to look up the dictionary using the search path, which could fail if the search path has a restrictive value.
- Fix build problems on macOS 10.14 (Mojave) (Tom Lane)
  Adjust configure to add an `-isysroot` switch to `CPPFLAGS`; without this, PL/Perl and PL/Tcl fail to configure or build on macOS 10.14. The specific sysroot used can be overridden at configure time or build time by setting the `PG_SYSROOT` variable in the arguments of configure or make.
  It is now recommended that Perl-related extensions write `$perl_includespec` rather than `-I$(perl_archlibexp)/CORE` in their compiler flags. The latter continues to work on most platforms, but not recent macOS.
  Also, it should no longer be necessary to specify `--with-tclconfig` manually to get PL/Tcl to build on recent macOS releases.
- Fix MSVC build and regression-test scripts to work on recent Perl versions (Andrew Dunstan)
Appendix E. Release Notes

Perl no longer includes the current directory in its search path by default; work around that.

- Support building on Windows with Visual Studio 2015 or Visual Studio 2017 (Michael Paquier, Haribabu Kommi)
- Allow btree comparison functions to return INT_MIN (Tom Lane)
  
  Up to now, we’ve forbidden datatype-specific comparison functions from returning INT_MIN, which allows callers to invert the sort order just by negating the comparison result. However, this was never safe for comparison functions that directly return the result of memcmp(), strcmp(), etc, as POSIX doesn’t place any such restriction on those functions. At least some recent versions of memcmp() can return INT_MIN, causing incorrect sort ordering. Hence, we’ve removed this restriction. Callers must now use the INVERT_COMPARE_RESULT() macro if they wish to invert the sort order.

- Fix recursion hazard in shared-invalidation message processing (Tom Lane)

  This error could, for example, result in failure to access a system catalog or index that had just been processed by VACUUM FULL.

  This change adds a new result code for LockAcquire, which might possibly affect external callers of that function, though only very unusual usage patterns would have an issue with it. The API of LockAcquireExtended is also changed.

- Save and restore SPI’s global variables during SPI_connect() and SPI_finish() (Chapman Flack, Tom Lane)

  This prevents possible interference when one SPI-using function calls another.

- Provide ALLOCSET_DEFAULT_SIZES and sibling macros in back branches (Tom Lane)

  These macros have existed since 9.6, but there were requests to add them to older branches to allow extensions to rely on them without branch-specific coding.

- Avoid using potentially-under-aligned page buffers (Tom Lane)

  Invent new union types PGAignedBlock and PGAignedXLogBlock, and use these in place of plain char arrays, ensuring that the compiler can’t place the buffer at a misaligned start address. This fixes potential core dumps on alignment-picky platforms, and may improve performance even on platforms that allow misalignment.

- Make src/port/snprintf.c follow the C99 standard’s definition of snprintf()’s result value (Tom Lane)

  On platforms where this code is used (mostly Windows), its pre-C99 behavior could lead to failure to detect buffer overrun, if the calling code assumed C99 semantics.

- When building on i386 with the clang compiler, require -msse2 to be used (Andres Freund)

  This avoids problems with missed floating point overflow checks.

- Fix configure’s detection of the result type of strerror_r() (Tom Lane)

  The previous coding got the wrong answer when building with icc on Linux (and perhaps in other cases), leading to libpq not returning useful error messages for system-reported errors.

- Update time zone data files to tzdata release 2018g for DST law changes in Chile, Fiji, Morocco, and Russia (Volgograd), plus historical corrections for China, Hawaii, Japan, Macau, and North Korea.
E.4. Release 9.4.19

Release date: 2018-08-09

This release contains a variety of fixes from 9.4.18. For information about new features in the 9.4 major release, see Section E.23.

E.4.1. Migration to Version 9.4.19

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.18, see Section E.5.

E.4.2. Changes

• Fix failure to reset libpq’s state fully between connection attempts (Tom Lane)

An unprivileged user of dblink or postgres_fdw could bypass the checks intended to prevent use of server-side credentials, such as a ~/.pgpass file owned by the operating-system user running the server. Servers allowing peer authentication on local connections are particularly vulnerable. Other attacks such as SQL injection into a postgres_fdw session are also possible. Attacking postgres_fdw in this way requires the ability to create a foreign server object with selected connection parameters, but any user with access to dblink could exploit the problem. In general, an attacker with the ability to select the connection parameters for a libpq-using application could cause mischief, though other plausible attack scenarios are harder to think of. Our thanks to Andrew Krasichkov for reporting this issue. (CVE-2018-10915)

• Ensure that updates to the relfrozenxid and relminmxid values for “nailed” system catalogs are processed in a timely fashion (Andres Freund)

Overoptimistic caching rules could prevent these updates from being seen by other sessions, leading to spurious errors and/or data corruption. The problem was significantly worse for shared catalogs, such as pg_authid, because the stale cache data could persist into new sessions as well as existing ones.

• Fix case where a freshly-promoted standby crashes before having completed its first post-recovery checkpoint (Michael Paquier, Kyotaro Horiguchi, Pavan Deolasee, Álvaro Herrera)

This led to a situation where the server did not think it had reached a consistent database state during subsequent WAL replay, preventing restart.

• Avoid emitting a bogus WAL record when recycling an all-zero btree page (Amit Kapila)

This mistake has been seen to cause assertion failures, and potentially it could result in unnecessary query cancellations on hot standby servers.

• Improve performance of WAL replay for transactions that drop many relations (Fujii Masao)

This change reduces the number of times that shared buffers are scanned, so that it is of most benefit when that setting is large.

• Improve performance of lock releasing in standby server WAL replay (Thomas Munro)

• Make logical WAL senders report streaming state correctly (Simon Riggs, Sawada Masahiko)

The code previously mis-detected whether or not it had caught up with the upstream server.
Appendix E. Release Notes

- Fix bugs in snapshot handling during logical decoding, allowing wrong decoding results in rare cases (Arseny Sher, Álvaro Herrera)
- Ensure a table’s cached index list is correctly rebuilt after an index creation fails partway through (Peter Geoghegan)
  
  Previously, the failed index’s OID could remain in the list, causing problems later in the same session.
- Fix mishandling of empty uncompressed posting pages in GIN indexes (Sivasubramanian Ramasubramanian, Alexander Korotkov)
  
  This could result in an assertion failure after pg_upgrade of a pre-9.4 GIN index (9.4 and later will not create such pages).
- Ensure that VACUUM will respond to signals within btree page deletion loops (Andres Freund)

  Corrupted btree indexes could result in an infinite loop here, and that previously wasn’t interruptible without forcing a crash.
- Fix misoptimization of equivalence classes involving composite-type columns (Tom Lane)

  This resulted in failure to recognize that an index on a composite column could provide the sort order needed for a mergejoin on that column.
- Fix SQL-standard FETCH FIRST syntax to allow parameters (\$n), as the standard expects (Andrew Gierth)
- Fix failure to schema-qualify some object names in getObjectDescription output (Kyotaro Horiguchi, Tom Lane)

  Names of collations, conversions, and text search objects were not schema-qualified when they should be.
- Widen COPY FROM’s current-line-number counter from 32 to 64 bits (David Rowley)

  This avoids two problems with input exceeding 4G lines: COPY FROM WITH HEADER would drop a line every 4G lines, not only the first line, and error reports could show a wrong line number.
- Add a string freeing function to ecpg’s pgtypes library, so that cross-module memory management problems can be avoided on Windows (Takayuki Tsunakawa)

  On Windows, crashes can ensue if the free call for a given chunk of memory is not made from the same DLL that malloc’ed the memory. The pgtypes library sometimes returns strings that it expects the caller to free, making it impossible to follow this rule. Add a PGTYPESchar_free() function that just wraps free, allowing applications to follow this rule.
- Fix ecpg’s support for long long variables on Windows, as well as other platforms that declare strtoll/strtoull nonstandardly or not at all (Dang Minh Huong, Tom Lane)
- Fix misidentification of SQL statement type in PL/pgSQL, when a rule change causes a change in the semantics of a statement intra-session (Tom Lane)

  This error led to assertion failures, or in rare cases, failure to enforce the INTO STRICT option as expected.
- Fix password prompting in client programs so that echo is properly disabled on Windows when stdin is not the terminal (Matthew Stickney)
- Further fix mis-quoting of values for list-valued GUC variables in dumps (Tom Lane)

  The previous fix for quoting of search_path and other list-valued variables in pg_dump output turned out to misbehave for empty-string list elements, and it risked truncation of long file paths.
- Fix pg_dump’s failure to dump REPLICA IDENTITY properties for constraint indexes (Tom Lane)
Manually created unique indexes were properly marked, but not those created by declaring `UNIQUE` or `PRIMARY KEY` constraints.

- Make `pg_upgrade` check that the old server was shut down cleanly (Bruce Momjian)
  The previous check could be fooled by an immediate-mode shutdown.
- Fix crash in `contrib/ltrie/lca()` function when the input array is empty (Pierre Ducroquet)
- Fix various error-handling code paths in which an incorrect error code might be reported (Michael Paquier, Tom Lane, Magnus Hagander)
- Rearrange makefiles to ensure that programs link to freshly-built libraries (such as `libpq.so`) rather than ones that might exist in the system library directories (Tom Lane)
  This avoids problems when building on platforms that supply old copies of PostgreSQL libraries.
- Update time zone data files to tzdata release 2018e for DST law changes in North Korea, plus historical corrections for Czechoslovakia.
  This update includes a redefinition of “daylight savings” in Ireland, as well as for some past years in Namibia and Czechoslovakia. In those jurisdictions, legally standard time is observed in summer, and daylight savings time in winter, so that the daylight savings offset is one hour behind standard time not one hour ahead. This does not affect either the actual UTC offset or the timezone abbreviations in use; the only known effect is that the `is_dst` column in the `pg_timezone_names` view will now be true in winter and false in summer in these cases.

### E.5. Release 9.4.18

**Release date:** 2018-05-10

This release contains a variety of fixes from 9.4.17. For information about new features in the 9.4 major release, see Section E.23.

### E.5.1. Migration to Version 9.4.18

A dump/restore is not required for those running 9.4.X.

However, if the function marking mistakes mentioned in the first changelog entry below affect you, you will want to take steps to correct your database catalogs.

Also, if you are upgrading from a version earlier than 9.4.17, see Section E.6.

### E.5.2. Changes

- Fix incorrect volatility markings on a few built-in functions (Thomas Munro, Tom Lane)

  The functions `query_to_xml`, `cursor_to_xml`, `cursor_to_xmlschema`, `query_to_xmlschema`, and `query_to_xml_and_xmlschema` should be marked volatile because they execute user-supplied queries that might contain volatile operations. They were not, leading to a risk of incorrect query optimization. This has been repaired for new installations by correcting the initial catalog data, but existing installations will continue to contain the incorrect markings. Practical use of these functions seems to pose little hazard, but in case of trouble, it can be fixed by manually updating these functions’ `pg_proc` entries, for example `ALTER FUNCTION`
Appendix E. Release Notes

pg_catalog.query_to_xml(text, boolean, boolean, text) VOLATILE. (Note that that will need to be done in each database of the installation.) Another option is to pg_upgrade the database to a version containing the corrected initial data.

- Avoid re-using TOAST value OIDs that match dead-but-not-yet-vacuumed TOAST entries (Pavan Deolasee)

Once the OID counter has wrapped around, it’s possible to assign a TOAST value whose OID matches a previously deleted entry in the same TOAST table. If that entry were not yet vacuumed away, this resulted in “unexpected chunk number 0 (expected 1) for toast value nnnnn” errors, which would persist until the dead entry was removed by VACUUM. Fix by not selecting such OIDs when creating a new TOAST entry.

- Change ANALYZE’s algorithm for updating pg_class.reltuples (David Gould)

Previously, pages not actually scanned by ANALYZE were assumed to retain their old tuple density. In a large table where ANALYZE samples only a small fraction of the pages, this meant that the overall tuple density estimate could not change very much, so that reltuples would change nearly proportionally to changes in the table’s physical size (retpages) regardless of what was actually happening in the table. This has been observed to result in reltuples becoming so much larger than reality as to effectively shut off autovacuuming. To fix, assume that ANALYZE’s sample is a statistically unbiased sample of the table (as it should be), and just extrapolate the density observed within those pages to the whole table.

- Avoid deadlocks in concurrent CREATE INDEX CONCURRENTLY commands that are run under SERIALIZABLE or REPEATABLE READ transaction isolation (Tom Lane)

- Fix possible slow execution of REFRESH MATERIALIZED VIEW CONCURRENTLY (Thomas Munro)

- Fix UPDATE/DELETE ... WHERE CURRENT OF to not fail when the referenced cursor uses an index-only-scan plan (Yugo Nagata, Tom Lane)

- Fix incorrect planning of join clauses pushed into parameterized paths (Andrew Gierth, Tom Lane)

This error could result in misclassifying a condition as a “join filter” for an outer join when it should be a plain “filter” condition, leading to incorrect join output.

- Fix misoptimization of CHECK constraints having provably-NULL subclauses of top-level AND/OR conditions (Tom Lane, Dean Rasheed)

This could, for example, allow constraint exclusion to exclude a child table that should not be excluded from a query.

- Avoid failure if a query-cancel or session-termination interrupt occurs while committing a prepared transaction (Stas Kelvich)

- Fix query-lifespan memory leakage in repeatedly executed hash joins (Tom Lane)

- Fix overly strict sanity check in heap_prepare_freeze_tuple (Álvaro Herrera)

This could result in incorrect “cannot freeze committed xmax” failures in databases that have been pg_upgrade’d from 9.2 or earlier.

- Prevent dangling-pointer dereference when a C-coded before-update row trigger returns the “old” tuple (Rushabh Lathia)

- Reduce locking during autovacuum worker scheduling (Jeff Janes)

The previous behavior caused drastic loss of potential worker concurrency in databases with many tables.
• Ensure client hostname is copied while copying pg_stat_activity data to local memory (Edmund Horner)

Previously the supposedly-local snapshot contained a pointer into shared memory, allowing the client hostname column to change unexpectedly if any existing session disconnected.

• Fix incorrect processing of multiple compound affixes in ispell dictionaries (Arthur Zakirov)

• Fix collation-aware searches (that is, indexscans using inequality operators) in SP-GiST indexes on text columns (Tom Lane)

Such searches would return the wrong set of rows in most non-C locales.

• Count the number of index tuples correctly during initial build of an SP-GiST index (Tomas Vondra)

Previously, the tuple count was reported to be the same as that of the underlying table, which is wrong if the index is partial.

• Count the number of index tuples correctly during vacuuming of a GiST index (Andrey Borodin)

Previously it reported the estimated number of heap tuples, which might be inaccurate, and is certainly wrong if the index is partial.

• Fix a corner case where a streaming standby gets stuck at a WAL continuation record (Kyotaro Horiguchi)

• In logical decoding, avoid possible double processing of WAL data when a walsender restarts (Craig Ringer)

• Allow scalarltsel and scalargtsel to be used on non-core datatypes (Tomas Vondra)

• Reduce libpq’s memory consumption when a server error is reported after a large amount of query output has been collected (Tom Lane)

Discard the previous output before, not after, processing the error message. On some platforms, notably Linux, this can make a difference in the application’s subsequent memory footprint.

• Fix double-free crashes in ecpg (Patrick Krecker, Jeevan Ladhe)

• Fix ecpg to handle long long int variables correctly in MSVC builds (Michael Meskes, Andrew Gierth)

• Fix mis-quoting of values for list-valued GUC variables in dumps (Michael Paquier, Tom Lane)

The local_preload_libraries, session_preload_libraries, shared_preload_libraries, and temp_tablespaces variables were not correctly quoted in pg_dump output. This would cause problems if settings for these variables appeared in CREATE FUNCTION ... SET or ALTER DATABASE/ROLE ... SET clauses.

• Fix pg_recvlogical to not fail against pre-v10 PostgreSQL servers (Michael Paquier)

A previous fix caused pg_recvlogical to issue a command regardless of server version, but it should only be issued to v10 and later servers.

• Fix overflow handling in PL/pgSQL integer FOR loops (Tom Lane)

The previous coding failed to detect overflow of the loop variable on some non-gcc compilers, leading to an infinite loop.

• Adjust PL/Python regression tests to pass under Python 3.7 (Peter Eisentraut)

• Support testing PL/Python and related modules when building with Python 3 and MSVC (Andrew Dunstan)

• Rename internal b64_encode and b64_decode functions to avoid conflict with Solaris 11.4 built-in functions (Rainer Orth)
• Sync our copy of the timezone library with IANA tzcode release 2018e (Tom Lane)
  This fixes the zic timezone data compiler to cope with negative daylight-savings offsets. While the PostgreSQL project will not immediately ship such timezone data, zic might be used with timezone data obtained directly from IANA, so it seems prudent to update zic now.

• Update time zone data files to tzdata release 2018d for DST law changes in Palestine and Antarctica (Casey Station), plus historical corrections for Portugal and its colonies, as well as Enderbury, Jamaica, Turks & Caicos Islands, and Uruguay.

E.6. Release 9.4.17

Release date: 2018-03-01

This release contains a variety of fixes from 9.4.16. For information about new features in the 9.4 major release, see Section E.23.

E.6.1. Migration to Version 9.4.17

A dump/restore is not required for those running 9.4.X. However, if you run an installation in which not all users are mutually trusting, or if you maintain an application or extension that is intended for use in arbitrary situations, it is strongly recommended that you read the documentation changes described in the first changelog entry below, and take suitable steps to ensure that your installation or code is secure.

Also, the changes described in the second changelog entry below may cause functions used in index expressions or materialized views to fail during auto-analyze, or when reloading from a dump. After upgrading, monitor the server logs for such problems, and fix affected functions.

Also, if you are upgrading from a version earlier than 9.4.13, see Section E.10.

E.6.2. Changes

• Document how to configure installations and applications to guard against search-path-dependent trojan-horse attacks from other users (Noah Misch)

Using a search_path setting that includes any schemas writable by a hostile user enables that user to capture control of queries and then run arbitrary SQL code with the permissions of the attacked user. While it is possible to write queries that are proof against such hijacking, it is notionally tedious, and it’s very easy to overlook holes. Therefore, we now recommend configurations in which no untrusted schemas appear in one’s search path. Relevant documentation appears in Section 5.7.6 (for database administrators and users), Section 31.1 (for application authors), Section 35.15.1 (for extension authors), and CREATE FUNCTION (for authors of SECURITY DEFINER functions). (CVE-2018-1058)

• Avoid use of insecure search_path settings in pg_dump and other client programs (Noah Misch, Tom Lane)

pg_dump, pg_upgrade, vacuumdb and other PostgreSQL-provided applications were themselves vulnerable to the type of hijacking described in the previous changelog entry; since these applications are commonly run by superusers, they present particularly attractive targets. To make them
secure whether or not the installation as a whole has been secured, modify them to include only the pg_catalog schema in their search_path settings. Autovacuum worker processes now do the same, as well.

In cases where user-provided functions are indirectly executed by these programs — for example, user-provided functions in index expressions — the tighter search_path may result in errors, which will need to be corrected by adjusting those user-provided functions to not assume anything about what search path they are invoked under. That has always been good practice, but now it will be necessary for correct behavior. (CVE-2018-1058)

- Fix misbehavior of concurrent-update rechecks with CTE references appearing in subplans (Tom Lane)
  
  If a CTE (WITH clause reference) is used in an InitPlan or SubPlan, and the query requires a recheck due to trying to update or lock a concurrently-updated row, incorrect results could be obtained.

- Fix planner failures with overlapping mergejoin clauses in an outer join (Tom Lane)
  
  These mistakes led to “left and right pathkeys do not match in mergejoin” or “outer pathkeys do not match mergeclauses” planner errors in corner cases.

- Repair pg_upgrade’s failure to preserve relfrozenxid for materialized views (Tom Lane, Andres Freund)
  
  This oversight could lead to data corruption in materialized views after an upgrade, manifesting as “could not access status of transaction” or “found xmin from before relfrozenxid” errors. The problem would be more likely to occur in seldom-refreshed materialized views, or ones that were maintained only with REFRESH MATERIALIZED VIEW CONCURRENTLY.

  If such corruption is observed, it can be repaired by refreshing the materialized view (without CONCURRENTLY).

- Fix incorrect reporting of PL/Python function names in error CONTEXT stacks (Tom Lane)
  
  An error occurring within a nested PL/Python function call (that is, one reached via a SPI query from another PL/Python function) would result in a stack trace showing the inner function’s name twice, rather than the expected results. Also, an error in a nested PL/Python DO block could result in a null pointer dereference crash on some platforms.

- Allow contrib/auto_explain’s log_min_duration setting to range up to INT_MAX, or about 24 days instead of 35 minutes (Tom Lane)

E.7. Release 9.4.16

Release date: 2018-02-08

This release contains a variety of fixes from 9.4.15. For information about new features in the 9.4 major release, see Section E.23.

E.7.1. Migration to Version 9.4.16

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.13, see Section E.10.
E.7.2. Changes

- Ensure that all temporary files made by pg_upgrade are non-world-readable (Tom Lane, Noah Misch)

  pg_upgrade normally restricts its temporary files to be readable and writable only by the calling user. But the temporary file containing pg_dumpall -g output would be group- or world-readable, or even writable, if the user’s umask setting allows. In typical usage on multi-user machines, the umask and/or the working directory’s permissions would be tight enough to prevent problems; but there may be people using pg_upgrade in scenarios where this oversight would permit disclosure of database passwords to unfriendly eyes. (CVE-2018-1053)

- Fix vacuuming of tuples that were updated while key-share locked (Andres Freund, Álvaro Herrera)

  In some cases VACUUM would fail to remove such tuples even though they are now dead, leading to assorted data corruption scenarios.

- Fix inadequate buffer locking in some LSN fetches (Jacob Champion, Asim Praveen, Ashwin Agrawal)

  These errors could result in misbehavior under concurrent load. The potential consequences have not been characterized fully.

- Avoid unnecessary failure in a query on an inheritance tree that occurs concurrently with some child table being removed from the tree by ALTER TABLE NO INHERIT (Tom Lane)

- Fix spurious deadlock failures when multiple sessions are running CREATE INDEX CONCURRENTLY (Jeff Janes)

- Repair failure with correlated sub-SELECT inside VALUES inside a LATERAL subquery (Tom Lane)

- Fix “could not devise a query plan for the given query” planner failure for some cases involving nested UNION ALL inside a lateral subquery (Tom Lane)

- Fix logical decoding to correctly clean up disk files for crashed transactions (Atsushi Torikoshi)

  Logical decoding may spill WAL records to disk for transactions generating many WAL records. Normally these files are cleaned up after the transaction’s commit or abort record arrives; but if no such record is ever seen, the removal code misbehaved.

- Fix walsender timeout failure and failure to respond to interrupts when processing a large transaction (Petr Jelinek)

- Fix has_sequence_privilege() to support WITH GRANT OPTION tests, as other privilege-testing functions do (Joe Conway)

- In databases using UTF8 encoding, ignore any XML declaration that asserts a different encoding (Pavel Stehule, Noah Misch)

  We always store XML strings in the database encoding, so allowing libxml to act on a declaration of another encoding gave wrong results. In encodings other than UTF8, we don’t promise to support non-ASCII XML data anyway, so retain the previous behavior for bug compatibility. This change affects only xpath() and related functions; other XML code paths already acted this way.

- Provide for forward compatibility with future minor protocol versions (Robert Haas, Badrul Chowdhury)

  Up to now, PostgreSQL servers simply rejected requests to use protocol versions newer than 3.0, so that there was no functional difference between the major and minor parts of the protocol version number. Allow clients to request versions 3.x without failing, sending back a message showing that
the server only understands 3.0. This makes no difference at the moment, but back-patching this change should allow speedier introduction of future minor protocol upgrades.

- Cope with failure to start a parallel worker process (Amit Kapila, Robert Haas)
  
  Parallel query previously tended to hang indefinitely if a worker could not be started, as the result of `fork()` failure or other low-probability problems.

- Prevent stack-overflow crashes when planning extremely deeply nested set operations (`UNION/INTERSECT/EXCEPT`) (Tom Lane)

- Fix null-pointer crashes for some types of LDAP URLs appearing in `pg_hba.conf` (Thomas Munro)

- Fix sample `INSTR()` functions in the PL/pgSQL documentation (Yugo Nagata, Tom Lane)

  These functions are stated to be Oracle® compatible, but they weren’t exactly. In particular, there was a discrepancy in the interpretation of a negative third parameter: Oracle thinks that a negative value indicates the last place where the target substring can begin, whereas our functions took it as the last place where the target can end. Also, Oracle throws an error for a zero or negative fourth parameter, whereas our functions returned zero.

  The sample code has been adjusted to match Oracle’s behavior more precisely. Users who have copied this code into their applications may wish to update their copies.

- Fix `pg_dump` to make ACL (permissions), comment, and security label entries reliably identifiable in archive output formats (Tom Lane)

  The “tag” portion of an ACL archive entry was usually just the name of the associated object. Make it start with the object type instead, bringing ACLs into line with the convention already used for comment and security label archive entries. Also, fix the comment and security label entries for the whole database, if present, to make their tags start with `DATABASE` so that they also follow this convention. This prevents false matches in code that tries to identify large-object-related entries by seeing if the tag starts with `LARGE OBJECT`. That could have resulted in misclassifying entries as data rather than schema, with undesirable results in a schema-only or data-only dump.

  Note that this change has user-visible results in the output of `pg_restore --list`.

- In `ecpg`, detect indicator arrays that do not have the correct length and report an error (David Rader)

- Avoid triggering a libc assertion in `contrib/hstore`, due to use of `memcpy()` with equal source and destination pointers (Tomas Vondra)

- Provide modern examples of how to auto-start Postgres on macOS (Tom Lane)

  The scripts in `contrib/start-scripts/osx` use infrastructure that’s been deprecated for over a decade, and which no longer works at all in macOS releases of the last couple of years. Add a new subdirectory `contrib/start-scripts/macos` containing scripts that use the newer launchd infrastructure.

- Fix incorrect selection of configuration-specific libraries for OpenSSL on Windows (Andrew Dunstan)

- Support linking to MinGW-built versions of libperl (Noah Misch)

  This allows building PL/Perl with some common Perl distributions for Windows.

- Fix MSVC build to test whether 32-bit `libperl` needs `#D_USE_32BIT_TIME_T` (Noah Misch)

  Available Perl distributions are inconsistent about what they expect, and lack any reliable means of reporting it, so resort to a build-time test on what the library being used actually does.

- On Windows, install the crash dump handler earlier in postmaster startup (Takayuki Tsunakawa)
This may allow collection of a core dump for some early-startup failures that did not produce a dump before.

- On Windows, avoid encoding-conversion-related crashes when emitting messages very early in postmaster startup (Takayuki Tsunakawa)
- Use our existing Motorola 68K spinlock code on OpenBSD as well as NetBSD (David Carlier)
- Add support for spinlocks on Motorola 88K (David Carlier)
- Update time zone data files to tzdata release 2018c for DST law changes in Brazil, Sao Tome and Principe, plus historical corrections for Bolivia, Japan, and South Sudan. The US/Pacific-New zone has been removed (it was only an alias for America/Los_Angeles anyway).

E.8. Release 9.4.15

Release date: 2017-11-09

This release contains a variety of fixes from 9.4.14. For information about new features in the 9.4 major release, see Section E.23.

E.8.1. Migration to Version 9.4.15

A dump/restore is not required for those running 9.4.X. However, if you are upgrading from a version earlier than 9.4.13, see Section E.10.

E.8.2. Changes

- Fix crash due to rowtype mismatch in \texttt{json(b)}\_\texttt{populate\_recordset()} (Michael Paquier, Tom Lane)
  
  These functions used the result rowtype specified in the \texttt{FROM} \ldots \texttt{AS} clause without checking that it matched the actual rowtype of the supplied tuple value. If it didn’t, that would usually result in a crash, though disclosure of server memory contents seems possible as well. (CVE-2017-15098)

- Fix sample server-start scripts to become $\texttt{PGUSER}$ before opening $\texttt{PGLOG}$ (Noah Misch)

  Previously, the postmaster log file was opened while still running as root. The database owner could therefore mount an attack against another system user by making $\texttt{PGLOG}$ be a symbolic link to some other file, which would then become corrupted by appending log messages.

  By default, these scripts are not installed anywhere. Users who have made use of them will need to manually recopy them, or apply the same changes to their modified versions. If the existing $\texttt{PGLOG}$ file is root-owned, it will need to be removed or renamed out of the way before restarting the server with the corrected script. (CVE-2017-12172)

- Fix crash when logical decoding is invoked from a SPI-using function, in particular any function written in a PL language (Tom Lane)

- Fix \texttt{json\_build\_array()}, \texttt{json\_build\_object()}, and their \texttt{jsonb} equivalents to handle explicit \texttt{VARIADIC} arguments correctly (Michael Paquier)

- Properly reject attempts to convert infinite float values to type \texttt{numeric} (Tom Lane, KaiGai Kohei)
Appendix E. Release Notes

Previously the behavior was platform-dependent.

- Fix corner-case crashes when columns have been added to the end of a view (Tom Lane)
- Record proper dependencies when a view or rule contains FieldSelect or FieldStore expression nodes (Tom Lane)

  Lack of these dependencies could allow a column or data type DROP to go through when it ought to fail, thereby causing later uses of the view or rule to get errors. This patch does not do anything to protect existing views/rules, only ones created in the future.

- Correctly detect hashability of range data types (Tom Lane)

  The planner mistakenly assumed that any range type could be hashed for use in hash joins or hash aggregation, but actually it must check whether the range’s subtype has hash support. This does not affect any of the built-in range types, since they’re all hashable anyway.

- Fix low-probability loss of NOTIFY messages due to XID wraparound (Marko Tiikkaja, Tom Lane)

  If a session executed no queries, but merely listened for notifications, for more than 2 billion transactions, it started to miss some notifications from concurrently-committing transactions.

- Avoid SIGBUS crash on Linux when a DSM memory request exceeds the space available in tmpfs (Thomas Munro)

- Prevent low-probability crash in processing of nested trigger firings (Tom Lane)

- Allow COPY’s FREEZE option to work when the transaction isolation level is REPEATABLE READ or higher (Noah Misch)

  This case was unintentionally broken by a previous bug fix.

- Correctly restore the umask setting when file creation fails in COPY or lo_export() (Peter Eisentraut)

- Give a better error message for duplicate column names in ANALYZE (Nathan Bossart)

- Fix mis-parsing of the last line in a non-newline-terminated pg_hba.conf file (Tom Lane)

- Fix libpq to not require user’s home directory to exist (Tom Lane)

  In v10, failure to find the home directory while trying to read ~/.pgpass was treated as a hard error, but it should just cause that file to not be found. Both v10 and previous release branches made the same mistake when reading ~/.pg_service.conf, though this was less obvious since that file is not sought unless a service name is specified.

- Fix libpq to guard against integer overflow in the row count of a PGresult (Michael Paquier)

- Fix ecpg’s handling of out-of-scope cursor declarations with pointer or array variables (Michael Meskes)

  In ecpglib, correctly handle backslashes in string literals depending on whether standard_conforming_strings is set (Tsunakawa Takayuki)

- Make ecpglib’s Informix-compatibility mode ignore fractional digits in integer input strings, as expected (Gao Zengqi, Michael Meskes)

- Sync our copy of the timezone library with IANA release tzcode2017c (Tom Lane)

  This fixes various issues; the only one likely to be user-visible is that the default DST rules for a POSIX-style zone name, if no posixrules file exists in the timezone data directory, now match current US law rather than what it was a dozen years ago.

- Update time zone data files to tzdata release 2017c for DST law changes in Fiji, Namibia, Northern Cyprus, Sudan, Tonga, and Turks & Caicos Islands, plus historical corrections for Alaska, Apia, Burma, Calcutta, Detroit, Ireland, Namibia, and Pago Pago.

2091
E.9. Release 9.4.14

Release date: 2017-08-31

This release contains a small number of fixes from 9.4.13. For information about new features in the 9.4 major release, see Section E.23.

E.9.1. Migration to Version 9.4.14

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.13, see Section E.10.

E.9.2. Changes

- Fix failure of walsender processes to respond to shutdown signals (Marco Nenciarini)
  A missed flag update resulted in walsenders continuing to run as long as they had a standby server connected, preventing primary-server shutdown unless immediate shutdown mode is used.

- Show foreign tables in information_schema.table_privileges view (Peter Eisentraut)
  All other relevant information_schema views include foreign tables, but this one ignored them.
  Since this view definition is installed by initdb, merely upgrading will not fix the problem. If you need to fix this in an existing installation, you can, as a superuser, do this in psql:

```sql
SET search_path TO information_schema;
CREATE OR REPLACE VIEW table_privileges AS
SELECT CAST(u_grantor.rolname AS sql_identifier) AS grantor,
       CAST(grantee.rolname AS sql_identifier) AS grantee,
       CAST(current_database() AS sql_identifier) AS table_catalog,
       CAST(nc.nspname AS sql_identifier) AS table_schema,
       CAST(c.relname AS sql_identifier) AS table_name,
       CAST(c.prtype AS character_data) AS privilege_type,
       CAST(CASE WHEN -- object owner always has grant options
                    pg_has_role(grantee.oid, c.relowner, 'USAGE')
                 OR c.grantable
                THEN 'YES' ELSE 'NO' END AS yes_or_no) AS is_grantable,
       CAST(CASE WHEN c.prtype = 'SELECT' THEN 'YES' ELSE 'NO' END AS yes_or_no) AS with_hierarchy
FROM (
    SELECT oid, relname, relnamespace, relkind, relowner, (aclexplode(coalesce(relacl, acldefault('r', relowner)))).* FROM pg_class
) AS c (oid, relname, relnamespace, relkind, relowner, grantor, grantee, prtype, grantable,
        pg_namespace nc,
        pg_authid u_grantor,
        (SELECT oid, rolname FROM pg_authid
         UNION ALL
         SELECT 0::oid, 'PUBLIC') AS grantee (oid, rolname)
WHERE c.relnamespace = nc.oid
    AND c.relkind IN ('r', 'v', 'f')
```

2092
AND c.grantee = grantee.oid  
AND c.grantor = u_grantor.oid  
AND c.prtype IN ('INSERT', 'SELECT', 'UPDATE', 'DELETE', 'TRUNCATE', 'REFERENCES', 'TRIGGER')  
AND (pg_has_role(u_grantor.oid, 'USAGE')  
OR pg_has_role(grantee.oid, 'USAGE')  
OR grantee.rolname = 'PUBLIC');

This must be repeated in each database to be fixed, including template0.

- Clean up handling of a fatal exit (e.g., due to receipt of SIGTERM) that occurs while trying to execute a ROLLBACK of a failed transaction (Tom Lane)
  This situation could result in an assertion failure. In production builds, the exit would still occur, but it would log an unexpected message about “cannot drop active portal”.
- Remove assertion that could trigger during a fatal exit (Tom Lane)
- Correctly identify columns that are of a range type or domain type over a composite type or domain type being searched for (Tom Lane)
  Certain ALTER commands that change the definition of a composite type or domain type are supposed to fail if there are any stored values of that type in the database, because they lack the infrastructure needed to update or check such values. Previously, these checks could miss relevant values that are wrapped inside range types or sub-domains, possibly allowing the database to become inconsistent.
- Fix crash in pg_restore when using parallel mode and using a list file to select a subset of items to restore (Fabrício de Royes Mello)
- Change ecpg’s parser to allow RETURNING clauses without attached C variables (Michael Meskes)
  This allows ecpg programs to contain SQL constructs that use RETURNING internally (for example, inside a CTE) rather than using it to define values to be returned to the client.
- Improve selection of compiler flags for PL/Perl on Windows (Tom Lane)
  This fix avoids possible crashes of PL/Perl due to inconsistent assumptions about the width of time_t values. A side-effect that may be visible to extension developers is that _USE_32BIT_TIME_T is no longer defined globally in PostgreSQL Windows builds. This is not expected to cause problems, because type time_t is not used in any PostgreSQL API definitions.

Release date: 2017-08-10

This release contains a variety of fixes from 9.4.12. For information about new features in the 9.4 major release, see Section E.23.

E.10.1. Migration to Version 9.4.13

A dump/restore is not required for those running 9.4.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.4.12, see Section E.11.
Appendix E. Release Notes

E.10.2. Changes

- Further restrict visibility of `pg_user_mappings.umoptions`, to protect passwords stored as user mapping options (Noah Misch)

The fix for CVE-2017-7486 was incorrect: it allowed a user to see the options in her own user mapping, even if she did not have `USAGE` permission on the associated foreign server. Such options might include a password that had been provided by the server owner rather than the user herself. Since `information_schema.user_mapping_options` does not show the options in such cases, `pg_user_mappings` should not either. (CVE-2017-7547)

By itself, this patch will only fix the behavior in newly initdb’d databases. If you wish to apply this change in an existing database, you will need to do the following:

1. Restart the postmaster after adding `allow_system_table_mods = true` to `postgresql.conf`. (In versions supporting `ALTER SYSTEM`, you can use that to make the configuration change, but you’ll still need a restart.)

2. In each database of the cluster, run the following commands as superuser:
   ```sql
   SET search_path = pg_catalog;
   CREATE OR REPLACE VIEW pg_user_mappings AS
   SELECT
       U.oid AS umid,
       S.oid AS srvid,
       S.srvname AS srvname,
       U.umuser AS umuser,
       CASE WHEN U.umuser = 0 THEN 'public' ELSE A.rolname END AS usename,
       CASE WHEN (U.umuser <> 0 AND A.rolname = current_user
       AND (pg_has_role(S.srvowner, 'USAGE')
       OR has_server_privilege(S.oid, 'USAGE')))
       OR (U.umuser = 0 AND pg_has_role(S.srvowner, 'USAGE'))
       OR (SELECT rolsuper FROM pg_authid WHERE rolname = current_user)
       THEN U.umoptions
       ELSE NULL END AS umoptions
   FROM pg_user_mapping U
   LEFT JOIN pg_authid A ON (A.oid = U.umuser) JOIN
   pg_foreign_server S ON (U.umserver = S.oid);
   ```

3. Do not forget to include the `template0` and `template1` databases, or the vulnerability will still exist in databases you create later. To fix `template0`, you’ll need to temporarily make it accept connections. In PostgreSQL 9.5 and later, you can use
   ```sql
   ALTER DATABASE template0 WITH ALLOW_CONNECTIONS true;
   ```
   and then after fixing `template0`, undo that with
   ```sql
   ALTER DATABASE template0 WITH ALLOW_CONNECTIONS false;
   ```
   In prior versions, instead use
   ```sql
   UPDATE pg_database SET datallowconn = true WHERE datname = 'template0';
   UPDATE pg_database SET datallowconn = false WHERE datname = 'template0';
   ```

4. Finally, remove the `allow_system_table_mods` configuration setting, and again restart the postmaster.
Appendix E. Release Notes

- Disallow empty passwords in all password-based authentication methods (Heikki Linnakangas)
  libpq ignores empty password specifications, and does not transmit them to the server. So, if a user’s password has been set to the empty string, it’s impossible to log in with that password via psql or other libpq-based clients. An administrator might therefore believe that setting the password to empty is equivalent to disabling password login. However, with a modified or non-libpq-based client, logging in could be possible, depending on which authentication method is configured. In particular the most common method, \texttt{md5}, accepted empty passwords. Change the server to reject empty passwords in all cases. (CVE-2017-7546)

- Make \texttt{lo_put()} check for \texttt{UPDATE} privilege on the target large object (Tom Lane, Michael Paquier)
  \texttt{lo_put()} should surely require the same permissions as \texttt{lowrite()}, but the check was missing, allowing any user to change the data in a large object. (CVE-2017-7548)

- Fix concurrent locking of tuple update chains (Álvaro Herrera)
  If several sessions concurrently lock a tuple update chain with nonconflicting lock modes using an old snapshot, and they all succeed, it was possible for some of them to nonetheless fail (and conclude there is no live tuple version) due to a race condition. This had consequences such as foreign-key checks failing to see a tuple that definitely exists but is being updated concurrently.

- Fix potential data corruption when freezing a tuple whose XMAX is a multixact with exactly one still-interesting member (Teodor Sigaev)

- Avoid integer overflow and ensuing crash when sorting more than one billion tuples in-memory (Sergey Koposov)

- On Windows, retry process creation if we fail to reserve the address range for our shared memory in the new process (Tom Lane, Amit Kapila)
  This is expected to fix infrequent child-process-launch failures that are probably due to interference from antivirus products.

- Fix low-probability corruption of shared predicate-lock hash table in Windows builds (Thomas Munro, Tom Lane)

- Avoid logging clean closure of an SSL connection as though it were a connection reset (Michael Paquier)

- Prevent sending SSL session tickets to clients (Tom Lane)
  This fix prevents reconnection failures with ticket-aware client-side SSL code.

- Fix code for setting tcp_keepalives_idle on Solaris (Tom Lane)

- Fix statistics collector to honor inquiry messages issued just after a postmaster shutdown and immediate restart (Tom Lane)
  Statistics inquiries issued within half a second of the previous postmaster shutdown were effectively ignored.

- Ensure that the statistics collector’s receive buffer size is at least 100KB (Tom Lane)
  This reduces the risk of dropped statistics data on older platforms whose default receive buffer size is less than that.

- Fix possible creation of an invalid WAL segment when a standby is promoted just after it processes an \texttt{XLOG\_SWITCH} WAL record (Andres Freund)

- Fix walsender to exit promptly when client requests shutdown (Tom Lane)
Appendix E. Release Notes

- Fix SIGHUP and SIGUSR1 handling in walsender processes (Petr Jelinek, Andres Freund)
- Prevent walsender-triggered panics during shutdown checkpoints (Andres Freund, Michael Paquier)
- Fix unnecessarily slow restarts of walreceiver processes due to race condition in postmaster (Tom Lane)
- Fix logical decoding failure with very wide tuples (Andres Freund)
  Logical decoding crashed on tuples that are wider than 64KB (after compression, but with all data in-line). The case arises only when `REPLICA IDENTITY FULL` is enabled for a table containing such tuples.
- Fix leakage of small subtransactions spilled to disk during logical decoding (Andres Freund)
  This resulted in temporary files consuming excessive disk space.
- Reduce the work needed to build snapshots during creation of logical-decoding slots (Andres Freund, Petr Jelinek)
  The previous algorithm was infeasibly expensive on a server with a lot of open transactions.
- Fix race condition that could indefinitely delay creation of logical-decoding slots (Andres Freund, Petr Jelinek)
- Reduce overhead in processing syscache invalidation events (Tom Lane)
  This is particularly helpful for logical decoding, which triggers frequent cache invalidation.
- Fix cases where an `INSERT` or `UPDATE` assigns to more than one element of a column that is of domain-over-array type (Tom Lane)
- Allow window functions to be used in `sub-SELECTs` that are within the arguments of an aggregate function (Tom Lane)
- Move autogenerated array types out of the way during `ALTER ... RENAME` (Vik Fearing)
  Previously, we would rename a conflicting autogenerated array type out of the way during `CREATE`; this fix extends that behavior to renaming operations.
- Ensure that `ALTER USER ... SET` accepts all the syntax variants that `ALTER ROLE ... SET` does (Peter Eisentraut)
- Properly update dependency info when changing a datatype I/O function’s argument or return type from `opaque` to the correct type (Heikki Linnakangas)
  `CREATE TYPE` updates I/O functions declared in this long-obsolete style, but it forgot to record a dependency on the type, allowing a subsequent `DROP TYPE` to leave broken function definitions behind.
- Reduce memory usage when `ANALYZE` processes a `tsvector` column (Heikki Linnakangas)
- Fix unnecessary precision loss and sloppy rounding when multiplying or dividing `money` values by integers or floats (Tom Lane)
- Tighten checks for whitespace in functions that parse identifiers, such as `regprocedurein()` (Tom Lane)
  Depending on the prevailing locale, these functions could misinterpret fragments of multibyte characters as whitespace.
- Use relevant `#define` symbols from Perl while compiling PL/Perl (Ashutosh Sharma, Tom Lane)
  This avoids portability problems, typically manifesting as a “handshake” mismatch during library load, when working with recent Perl versions.
• In libpq, reset GSS/SASL and SSPI authentication state properly after a failed connection attempt (Michael Paquier)

Failure to do this meant that when falling back from SSL to non-SSL connections, a GSS/SASL failure in the SSL attempt would always cause the non-SSL attempt to fail. SSPI did not fail, but it leaked memory.

• In psql, fix failure when COPY FROM STDIN is ended with a keyboard EOF signal and then another COPY FROM STDIN is attempted (Thomas Munro)

This misbehavior was observed on BSD-derived platforms (including macOS), but not on most others.

• Fix pg_dump and pg_restore to emit REFRESH MATERIALIZED VIEW commands last (Tom Lane)

This prevents errors during dump/restore when a materialized view refers to tables owned by a different user.

• Improve pg_dump/pg_restore’s reporting of error conditions originating in zlib (Vladimir Kunschikov, Álvaro Herrera)

• Fix pg_dump with the --clean option to drop event triggers as expected (Tom Lane)

It also now correctly assigns ownership of event triggers; before, they were restored as being owned by the superuser running the restore script.

• Fix pg_dump to not emit invalid SQL for an empty operator class (Daniel Gustafsson)

• Fix pg_dump output to stdout on Windows (Kuntal Ghosh)

A compressed plain-text dump written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

• Fix pg_get_ruledef() to print correct output for the ON SELECT rule of a view whose columns have been renamed (Tom Lane)

In some corner cases, pg_dump relies on pg_get_ruledef() to dump views, so that this error could result in dump/reload failures.

• Fix dumping of outer joins with empty constraints, such as the result of a NATURAL LEFT JOIN with no common columns (Tom Lane)

• Fix dumping of function expressions in the FROM clause in cases where the expression does not deparse into something that looks like a function call (Tom Lane)

• Fix pg_basebackup output to stdout on Windows (Haribabu Kommi)

A backup written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

• Fix pg_upgrade to ensure that the ending WAL record does not have wal_level = minimum (Bruce Momjian)

This condition could prevent upgraded standby servers from reconnecting.

• In postgres_fdw, re-establish connections to remote servers after ALTER SERVER or ALTER USER MAPPING commands (Kyotaro Horiguchi)

This ensures that option changes affecting connection parameters will be applied promptly.

• In postgres_fdw, allow cancellation of remote transaction control commands (Robert Haas, Rafia Sabih)

This change allows us to quickly escape a wait for an unresponsive remote server in many more cases than previously.
Appendix E. Release Notes

- Increase MAX_SYSCACHE_CALLBACKS to provide more room for extensions (Tom Lane)
- Always use `-fpic`, not `-fpic`, when building shared libraries with gcc (Tom Lane)
  This supports larger extension libraries on platforms where it makes a difference.
- Fix unescaped-braces issue in our build scripts for Microsoft MSVC, to avoid a warning or error from recent Perl versions (Andrew Dunstan)
- In MSVC builds, handle the case where the openssl library is not within a VC subdirectory (Andrew Dunstan)
- In MSVC builds, add proper include path for libxml2 header files (Andrew Dunstan)
  This fixes a former need to move things around in standard Windows installations of libxml2.
- In MSVC builds, recognize a Tcl library that is named tcl86.lib (Noah Misch)
- In MSVC builds, honor PROVE_FLAGS settings on vcregress.pl’s command line (Andrew Dunstan)

Release date: 2017-05-11

This release contains a variety of fixes from 9.4.11. For information about new features in the 9.4 major release, see Section E.23.

E.11.1. Migration to Version 9.4.12

A dump/restore is not required for those running 9.4.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are using third-party replication tools that depend on “logical decoding”, see the fourth changelog entry below.

Also, if you are upgrading from a version earlier than 9.4.11, see Section E.12.

E.11.2. Changes

- Restrict visibility of pg_user_mappings.umoptions, to protect passwords stored as user mapping options (Michael Paquier, Feike Steenbergen)

  The previous coding allowed the owner of a foreign server object, or anyone he has granted server usage permission to, to see the options for all user mappings associated with that server. This might well include passwords for other users. Adjust the view definition to match the behavior of information_schema.user_mapping_options, namely that these options are visible to the user being mapped, or if the mapping is for public and the current user is the server owner, or if the current user is a superuser. (CVE-2017-7486)

  By itself, this patch will only fix the behavior in newly initdb’d databases. If you wish to apply this change in an existing database, follow the corrected procedure shown in the changelog entry for CVE-2017-7547, in Section E.10.
Appendix E. Release Notes

• Prevent exposure of statistical information via leaky operators (Peter Eisentraut)

Some selectivity estimation functions in the planner will apply user-defined operators to values obtained from pg_statistic, such as most common values and histogram entries. This occurs before table permissions are checked, so a nefarious user could exploit the behavior to obtain these values for table columns he does not have permission to read. To fix, fall back to a default estimate if the operator’s implementation function is not certified leak-proof and the calling user does not have permission to read the table column whose statistics are needed. At least one of these criteria is satisfied in most cases in practice. (CVE-2017-7484)

• Restore libpq’s recognition of the PGREQUIRESSL environment variable (Daniel Gustafsson)

Processing of this environment variable was unintentionally dropped in PostgreSQL 9.3, but its documentation remained. This creates a security hazard, since users might be relying on the environment variable to force SSL-encrypted connections, but that would no longer be guaranteed. Restore handling of the variable, but give it lower priority than PGSSLMODE, to avoid breaking configurations that work correctly with post-9.3 code. (CVE-2017-7485)

• Fix possibly-invalid initial snapshot during logical decoding (Petr Jelinek, Andres Freund)

The initial snapshot created for a logical decoding replication slot was potentially incorrect. This could cause third-party tools that use logical decoding to copy incomplete/inconsistent initial data. This was more likely to happen if the source server was busy at the time of slot creation, or if another logical slot already existed.

If you are using a replication tool that depends on logical decoding, and it should have copied a nonempty data set at the start of replication, it is advisable to recreate the replica after installing this update, or to verify its contents against the source server.

• Fix possible corruption of “init forks” of unlogged indexes (Robert Haas, Michael Paquier)

This could result in an unlogged index being set to an invalid state after a crash and restart. Such a problem would persist until the index was dropped and rebuilt.

• Fix incorrect reconstruction of pg_subtrans entries when a standby server replays a prepared but uncommitted two-phase transaction (Tom Lane)

In most cases this turned out to have no visible ill effects, but in corner cases it could result in circular references in pg_subtrans, potentially causing infinite loops in queries that examine rows modified by the two-phase transaction.

• Avoid possible crash in walsender due to failure to initialize a string buffer (Stas Kelvich, Fujii Masao)

• Fix postmaster’s handling of fork() failure for a background worker process (Tom Lane)

Previously, the postmaster updated portions of its state as though the process had been launched successfully, resulting in subsequent confusion.

• Ensure parsing of queries in extension scripts sees the results of immediately-preceding DDL (Julien Rouhaut, Tom Lane)

Due to lack of a cache flush step between commands in an extension script file, non-utility queries might not see the effects of an immediately preceding catalog change, such as ALTER TABLE ... RENAME.

• Skip tablespace privilege checks when ALTER TABLE ... ALTER COLUMN TYPE rebuilds an existing index (Noah Misch)

The command failed if the calling user did not currently have CREATE privilege for the tablespace containing the index. That behavior seems unhelpful, so skip the check, allowing the index to be rebuilt where it is.
• Fix `ALTER TABLE ... VALIDATE CONSTRAINT` to not recurse to child tables when the constraint is marked `NO INHERIT` (Amit Langote)

This fix prevents unwanted “constraint does not exist” failures when no matching constraint is present in the child tables.

• Fix `VACUUM` to account properly for pages that could not be scanned due to conflicting page pins (Andrew Gierth)

This tended to lead to underestimation of the number of tuples in the table. In the worst case of a small heavily-contended table, `VACUUM` could incorrectly report that the table contained no tuples, leading to very bad planning choices.

• Ensure that bulk-tuple-transfer loops within a hash join are interruptible by query cancel requests (Tom Lane, Thomas Munro)

• Fix integer-overflow problems in `interval` comparison (Kyotaro Horiguchi, Tom Lane)

The comparison operators for type `interval` could yield wrong answers for intervals larger than about 296000 years. Indexes on columns containing such large values should be reindexed, since they may be corrupt.

• Fix `cursor_to_xml()` to produce valid output with `tableforest` = false (Thomas Munro, Peter Eisentraut)

Previously it failed to produce a wrapping `<table>` element.

• Fix roundoff problems in `float8_timestamptz()` and `make_interval()` (Tom Lane)

These functions truncated, rather than rounded, when converting a floating-point value to integer microseconds; that could cause unexpectedly off-by-one results.

• Improve performance of `pg_timezone_names` view (Tom Lane, David Rowley)

• Reduce memory management overhead for contexts containing many large blocks (Tom Lane)

• Fix sloppy handling of corner-case errors from `lseek()` and `close()` (Tom Lane)

Neither of these system calls are likely to fail in typical situations, but if they did, `fd.c` could get quite confused.

• Fix incorrect check for whether postmaster is running as a Windows service (Michael Paquier)

This could result in attempting to write to the event log when that isn’t accessible, so that no logging happens at all.

• Fix `ecpg` to support `COMMIT PREPARED` and `ROLLBACK PREPARED` (Masahiko Sawada)

• Fix a double-free error when processing dollar-quoted string literals in `ecpg` (Michael Meskes)

• In `pg_dump`, fix incorrect schema and owner marking for comments and security labels of some types of database objects (Giuseppe Broccolo, Tom Lane)

In simple cases this caused no ill effects; but for example, a schema-selective restore might omit comments it should include, because they were not marked as belonging to the schema of their associated object.

• Avoid emitting an invalid list file in `pg_restore -l` when SQL object names contain newlines (Tom Lane)

Replace newlines by spaces, which is sufficient to make the output valid for `pg_restore -L`’s purposes.

• Fix `pg_upgrade` to transfer comments and security labels attached to “large objects” (blobs) (Stephen Frost)
Previously, blobs were correctly transferred to the new database, but any comments or security labels attached to them were lost.

- Improve error handling in contrib/adminpack's pg_file_write() function (Noah Misch)
  Notably, it failed to detect errors reported by fclose().
- In contrib/dblink, avoid leaking the previous unnamed connection when establishing a new unnamed connection (Joe Conway)
- Fix contrib/pg_trgm's extraction of trigrams from regular expressions (Tom Lane)
  In some cases it would produce a broken data structure that could never match anything, leading to GIN or GiST indexscans that use a trigram index not finding any matches to the regular expression.
- In contrib/postgres_fdw, transmit query cancellation requests to the remote server (Michael Paquier, Etsuro Fujita)
  Previously, a local query cancellation request did not cause an already-sent remote query to terminate early. This is a back-patch of work originally done for 9.6.
- Support OpenSSL 1.1.0 (Heikki Linnakangas, Andreas Karlsson, Tom Lane)
  This is a back-patch of work previously done in newer branches; it’s needed since many platforms are adopting newer OpenSSL versions.
- Support Tcl 8.6 in MSVC builds (Álvaro Herrera)
- Sync our copy of the timezone library with IANA release tzcode2017b (Tom Lane)
  This fixes a bug affecting some DST transitions in January 2038.
- Update time zone data files to tzdata release 2017b for DST law changes in Chile, Haiti, and Mongolia, plus historical corrections for Ecuador, Kazakhstan, Liberia, and Spain. Switch to numeric abbreviations for numerous time zones in South America, the Pacific and Indian oceans, and some Asian and Middle Eastern countries.

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the pg_timezone_names view nor used for output.

- Use correct daylight-savings rules for POSIX-style time zone names in MSVC builds (David Rowley)
  The Microsoft MSVC build scripts neglected to install the posixrules file in the timezone directory tree. This resulted in the timezone code falling back to its built-in rule about what DST behavior to assume for a POSIX-style time zone name. For historical reasons that still corresponds to the DST rules the USA was using before 2007 (i.e., change on first Sunday in April and last Sunday in October). With this fix, a POSIX-style zone name will use the current and historical DST transition dates of the US/Eastern zone. If you don’t want that, remove the posixrules file, or replace it with a copy of some other zone file (see Section 8.5.3). Note that due to caching, you may need to restart the server to get such changes to take effect.
This release contains a variety of fixes from 9.4.10. For information about new features in the 9.4 major release, see Section E.23.

E.12.1. Migration to Version 9.4.11

A dump/restore is not required for those running 9.4.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted indexes.

Also, if you are upgrading from a version earlier than 9.4.10, see Section E.13.

E.12.2. Changes

- Fix a race condition that could cause indexes built with `CREATE INDEX CONCURRENTLY` to be corrupt (Pavan Deolasee, Tom Lane)

  If `CREATE INDEX CONCURRENTLY` was used to build an index that depends on a column not previously indexed, then rows updated by transactions that ran concurrently with the `CREATE INDEX` command could have received incorrect index entries. If you suspect this may have happened, the most reliable solution is to rebuild affected indexes after installing this update.

- Ensure that the special snapshot used for catalog scans is not invalidated by premature data pruning (Tom Lane)

  Backends failed to account for this snapshot when advertising their oldest xmin, potentially allowing concurrent vacuuming operations to remove data that was still needed. This led to transient failures along the lines of “cache lookup failed for relation 1255”.

- Unconditionally WAL-log creation of the “init fork” for an unlogged table (Michael Paquier)

  Previously, this was skipped when `wal_level = minimal`, but actually it’s necessary even in that case to ensure that the unlogged table is properly reset to empty after a crash.

- Reduce interlocking on standby servers during the replay of btree index vacuuming operations (Simon Riggs)

  This change avoids substantial replication delays that sometimes occurred while replaying such operations.

- If the stats collector dies during hot standby, restart it (Takayuki Tsunakawa)

- Ensure that hot standby feedback works correctly when it’s enabled at standby server start (Ants Aasma, Craig Ringer)

- Check for interrupts while hot standby is waiting for a conflicting query (Simon Riggs)

- Avoid constantly respawning the autovacuum launcher in a corner case (Amit Khandekar)

  This fix avoids problems when autovacuum is nominally off and there are some tables that require freezing, but all such tables are already being processed by autovacuum workers.

- Fix check for when an extension member object can be dropped (Tom Lane)

  Extension upgrade scripts should be able to drop member objects, but this was disallowed for serial-column sequences, and possibly other cases.

- Make sure `ALTER TABLE` preserves index tablespace assignments when rebuilding indexes (Tom Lane, Michael Paquier)
Previously, non-default settings of default_tablespace could result in broken indexes.

- Fix incorrect updating of trigger function properties when changing a foreign-key constraint’s deferrability properties with `ALTER TABLE ... ALTER CONSTRAINT` (Tom Lane)
  This led to odd failures during subsequent exercise of the foreign key, as the triggers were fired at the wrong times.

- Prevent dropping a foreign-key constraint if there are pending trigger events for the referenced relation (Tom Lane)
  This avoids “could not find trigger NNN” or “relation NNN has no triggers” errors.

- Fix processing of OID column when a table with OIDs is associated to a parent with OIDs via `ALTER TABLE ... INHERIT` (Amit Langote)
  The OID column should be treated the same as regular user columns in this case, but it wasn’t, leading to odd behavior in later inheritance changes.

- Fix `CREATE OR REPLACE VIEW` to update the view query before attempting to apply the new view options (Dean Rasheed)
  Previously the command would fail if the new options were inconsistent with the old view definition.

- Report correct object identity during `ALTER TEXT SEARCH CONFIGURATION` (Artur Zakirov)
  The wrong catalog OID was reported to extensions such as logical decoding.

- Check for serializability conflicts before reporting constraint-violation failures (Thomas Munro)
  When using serializable transaction isolation, it is desirable that any error due to concurrent transactions should manifest as a serialization failure, thereby cueing the application that a retry might succeed. Unfortunately, this does not reliably happen for duplicate-key failures caused by concurrent insertions. This change ensures that such an error will be reported as a serialization error if the application explicitly checked for the presence of a conflicting key (and did not find it) earlier in the transaction.

- Prevent multicolumn expansion of `foo.*` in an `UPDATE` source expression (Tom Lane)
  This led to “UPDATE target count mismatch --- internal error”. Now the syntax is understood as a whole-row variable, as it would be in other contexts.

- Ensure that column typmods are determined accurately for multi-row `VALUES` constructs (Tom Lane)
  This fixes problems occurring when the first value in a column has a determinable typmod (e.g., length for a `varchar` value) but later values don’t share the same limit.

- Throw error for an unfinished Unicode surrogate pair at the end of a Unicode string (Tom Lane)
  Normally, a Unicode surrogate leading character must be followed by a Unicode surrogate trailing character, but the check for this was missed if the leading character was the last character in a Unicode string literal (`U&'...'`) or Unicode identifier (`U&"..."`).

- Ensure that a purely negative text search query, such as `!foo`, matches empty `tsvectors` (Tom Dunstan)
  Such matches were found by GIN index searches, but not by sequential scans or GiST index searches.

- Prevent crash when `ts_rewrite()` replaces a non-top-level subtree with an empty query (Artur Zakirov)

- Fix performance problems in `ts_rewrite()` (Tom Lane)
• Fix ts_rewrite()’s handling of nested NOT operators (Tom Lane)
• Fix array_fill() to handle empty arrays properly (Tom Lane)
• Fix one-byte buffer overrun in quote_literal_cstr() (Heikki Linnakangas)
  The overrun occurred only if the input consisted entirely of single quotes and/or backslashes.
• Prevent multiple calls of pg_start_backup() and pg_stop_backup() from running concurrently (Michael Paquier)
  This avoids an assertion failure, and possibly worse things, if someone tries to run these functions in parallel.
• Avoid discarding interval-to-interval casts that aren’t really no-ops (Tom Lane)
  In some cases, a cast that should result in zeroing out low-order interval fields was mistakenly deemed to be a no-op and discarded. An example is that casting from INTERVAL MONTH to INTERVAL YEAR failed to clear the months field.
• Ensure that cached plans are invalidated by changes in foreign-table options (Amit Langote, Etsuro Fujita, Ashutosh Bapat)
• Fix pg_dump to dump user-defined casts and transforms that use built-in functions (Stephen Frost)
• Fix pg_restore with --create --if-exists to behave more sanely if an archive contains unrecognized DROP commands (Tom Lane)
  This doesn’t fix any live bug, but it may improve the behavior in future if pg_restore is used with an archive generated by a later pg_dump version.
• Fix pg_basebackup’s rate limiting in the presence of slow I/O (Antonin Houska)
  If disk I/O was transiently much slower than the specified rate limit, the calculation overflowed, effectively disabling the rate limit for the rest of the run.
• Fix pg_basebackup’s handling of symlinked pg_stat_tmp and pg_replslot subdirectories (Magnus Hagander, Michael Paquier)
• Fix possible pg_basebackup failure on standby server when including WAL files (Amit Kapila, Robert Haas)
• Ensure that the Python exception objects we create for PL/Python are properly reference-counted (Rafa de la Torre, Tom Lane)
  This avoids failures if the objects are used after a Python garbage collection cycle has occurred.
• Fix PL/Tcl to support triggers on tables that have .tupno as a column name (Tom Lane)
  This matches the (previously undocumented) behavior of PL/Tcl’s spi_exec and spi_execp commands, namely that a magic .tupno column is inserted only if there isn’t a real column named that.
• Allow DOS-style line endings in ~/.pgpass files, even on Unix (Vik Fearing)
  This change simplifies use of the same password file across Unix and Windows machines.
• Fix one-byte buffer overrun if ecpg is given a file name that ends with a dot (Takayuki Tsunakawa)
• Fix psql’s tab completion for ALTER DEFAULT PRIVILEGES (Gilles Darold, Stephen Frost)
• In psql, treat an empty or all-blank setting of the PAGER environment variable as meaning “no pager” (Tom Lane)
  Previously, such a setting caused output intended for the pager to vanish entirely.
• Improve contrib/dblink’s reporting of low-level libpq errors, such as out-of-memory (Joe Con-
• Teach contrib/dblink to ignore irrelevant server options when it uses a contrib/postgres_fdw foreign server as the source of connection options (Corey Huinker)

Previously, if the foreign server object had options that were not also libpq connection options, an error occurred.

• On Windows, ensure that environment variable changes are propagated to DLLs built with debug options (Christian Ullrich)

• Sync our copy of the timezone library with IANA release tzcode2016j (Tom Lane)

This fixes various issues, most notably that timezone data installation failed if the target directory didn’t support hard links.

• Update time zone data files to tzdata release 2016j for DST law changes in northern Cyprus (adding a new zone Asia/Famagusta), Russia (adding a new zone Europe/Saratov), Tonga, and Antarctica/Cas. Historical corrections for Italy, Kazakhstan, Malta, and Palestine. Switch to preferring numeric zone abbreviations for Tonga.

E.13. Release 9.4.10

Release date: 2016-10-27

This release contains a variety of fixes from 9.4.9. For information about new features in the 9.4 major release, see Section E.23.

E.13.1. Migration to Version 9.4.10

A dump/restore is not required for those running 9.4.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted free space maps.

Also, if you are upgrading from a version earlier than 9.4.6, see Section E.17.

E.13.2. Changes

• Fix WAL-logging of truncation of relation free space maps and visibility maps (Pavan Deolasee, Heikki Linnakangas)

It was possible for these files to not be correctly restored during crash recovery, or to be written incorrectly on a standby server. Bogus entries in a free space map could lead to attempts to access pages that have been truncated away from the relation itself, typically producing errors like “could not read block xxx: read only 0 of 8192 bytes”. Checksum failures in the visibility map are also possible, if checksumming is enabled.

Procedures for determining whether there is a problem and repairing it if so are discussed at https://wiki.postgresql.org/wiki/Free_Space_Map_Problems.

• Fix incorrect creation of GIN index WAL records on big-endian machines (Tom Lane)

The typical symptom was “unexpected GIN leaf action” errors during WAL replay.

• Fix SELECT FOR UPDATE/SHARE to correctly lock tuples that have been updated by a subsequently-aborted transaction (Álvaro Herrera)
Appendix E. Release Notes

In 9.5 and later, the `SELECT` would sometimes fail to return such tuples at all. A failure has not been proven to occur in earlier releases, but might be possible with concurrent updates.

- Fix EvalPlanQual rechecks involving CTE scans (Tom Lane)
  The recheck would always see the CTE as returning no rows, typically leading to failure to update rows that were recently updated.

- Fix improper repetition of previous results from hashed aggregation in a subquery (Andrew Gierth)
  The test to see if we can reuse a previously-computed hash table of the aggregate state values neglected the possibility of an outer query reference appearing in an aggregate argument expression. A change in the value of such a reference should lead to recalculating the hash table, but did not.

- Fix query-lifespan memory leak in a bulk `UPDATE` on a table with a `PRIMARY KEY` or `REPLICA IDENTITY` index (Tom Lane)

- Fix `EXPLAIN` to emit valid XML when `track_io_timing` is on (Markus Winand)
  Previously the XML output-format option produced syntactically invalid tags such as `<I/O-Read-Time>`. That is now rendered as `<I-O-Read-Time>`.

- Suppress printing of zeroes for unmeasured times in `EXPLAIN` (Maksim Milyutin)
  Certain option combinations resulted in printing zero values for times that actually aren’t ever measured in that combination. Our general policy in `EXPLAIN` is not to print such fields at all, so do that consistently in all cases.

- Fix timeout length when `VACUUM` is waiting for exclusive table lock so that it can truncate the table (Simon Riggs)
  The timeout was meant to be 50 milliseconds, but it was actually only 50 microseconds, causing `VACUUM` to give up on truncation much more easily than intended. Set it to the intended value.

- Fix bugs in merging inherited `CHECK` constraints while creating or altering a table (Tom Lane, Amit Langote)
  Allow identical `CHECK` constraints to be added to a parent and child table in either order. Prevent merging of a valid constraint from the parent table with a `NOT VALID` constraint on the child. Likewise, prevent merging of a `NO INHERIT` child constraint with an inherited constraint.

- Remove artificial restrictions on the values accepted by `numeric_in()` and `numeric_recv()` (Tom Lane)
  We allow numeric values up to the limit of the storage format (more than `1e100000`), so it seems fairly pointless that `numeric_in()` rejected scientific-notation exponents above 1000. Likewise, it was silly for `numeric_recv()` to reject more than 1000 digits in an input value.

- Avoid very-low-probability data corruption due to testing tuple visibility without holding buffer lock (Thomas Munro, Peter Geoghegan, Tom Lane)

- Fix logical WAL decoding to work properly when a subtransaction’s WAL output is large enough to spill to disk (Andres Freund)

- Fix buffer overread in logical WAL decoding (Tom Lane)
  Logical decoding of a tuple update record read 23 bytes too many, which was usually harmless but with very bad luck could result in a crash.

- Fix file descriptor leakage when truncating a temporary relation of more than 1GB (Andres Freund)

- Disallow starting a standalone backend with `standby_mode` turned on (Michael Paquier)
  This can’t do anything useful, since there will be no WAL receiver process to fetch more WAL data; and it could result in misbehavior in code that wasn’t designed with this situation in mind.
• Properly initialize replication slot state when recycling a previously-used slot (Michael Paquier)
  This failure to reset all of the fields of the slot could prevent VACUUM from removing dead tuples.
• Round shared-memory allocation request to a multiple of the actual huge page size when attempting to use huge pages on Linux (Tom Lane)
  This avoids possible failures during munmap() on systems with atypical default huge page sizes. Except in crash-recovery cases, there were no ill effects other than a log message.
• Use a more random value for the dynamic shared memory control segment’s ID (Robert Haas, Tom Lane)
  Previously, the same value would be chosen every time, because it was derived from random() but srand() had not yet been called. While relatively harmless, this was not the intended behavior.
• On Windows, retry creation of the dynamic shared memory control segment after an access-denied error (Kyotaro Horiguchi, Amit Kapila)
  Windows sometimes returns ERROR_ACCESS_DENIED rather than ERROR_ALREADY_EXISTS when there is an existing segment. This led to postmaster startup failure due to believing that the former was an unrecoverable error.
• Don’t try to share SSL contexts across multiple connections in libpq (Heikki Linnakangas)
  This led to assorted corner-case bugs, particularly when trying to use different SSL parameters for different connections.
• Avoid corner-case memory leak in libpq (Tom Lane)
  The reported problem involved leaking an error report during PQreset(), but there might be related cases.
• Make ecpg’s --help and --version options work consistently with our other executables (Haribabu Kommi)
• Fix pgbench’s calculation of average latency (Fabien Coelho)
  The calculation was incorrect when there were \sleep commands in the script, or when the test duration was specified in number of transactions rather than total time.
• In pg_dump, never dump range constructor functions (Tom Lane)
  This oversight led to pg_upgrade failures with extensions containing range types, due to duplicate creation of the constructor functions.
• In pg_xlogdump, retry opening new WAL segments when using --follow option (Magnus Hagander)
  This allows for a possible delay in the server’s creation of the next segment.
• Fix pg_xlogdump to cope with a WAL file that begins with a continuation record spanning more than one page (Pavan Deolasee)
• Fix contrib/pg_buffercache to work when shared_buffers exceeds 256GB (KaiGai Kohei)
• Fix contrib/intarray/bench/bench.pl to print the results of the EXPLAIN it does when given the -e option (Daniel Gustafsson)
• Install TAP test infrastructure so that it’s available for extension testing (Craig Ringer)
  When PostgreSQL has been configured with --enable-tap-tests, “make install” will now install the Perl support files for TAP testing where PGXS can find them. This allows non-core extensions to use $(prove_check) without extra tests.
• In MSVC builds, include pg_recvlogical in a client-only installation (MauMau)

• Update Windows time zone mapping to recognize some time zone names added in recent Windows versions (Michael Paquier)

• Prevent failure of obsolete dynamic time zone abbreviations (Tom Lane)

If a dynamic time zone abbreviation does not match any entry in the referenced time zone, treat it as equivalent to the time zone name. This avoids unexpected failures when IANA removes abbreviations from their time zone database, as they did in tzdata release 2016f and seem likely to do again in the future. The consequences were not limited to not recognizing the individual abbreviation; any mismatch caused the pg_timezone_abbr view to fail altogether.

• Update time zone data files to tzdata release 2016h for DST law changes in Palestine and Turkey, plus historical corrections for Turkey and some regions of Russia. Switch to numeric abbreviations for some time zones in Antarctica, the former Soviet Union, and Sri Lanka.

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the pg_timezone_names view nor used for output.

In this update, AMT is no longer shown as being in use to mean Armenia Time. Therefore, we have changed the Default abbreviation set to interpret it as Amazon Time, thus UTC-4 not UTC+4.

**E.14. Release 9.4.9**

**Release date:** 2016-08-11

This release contains a variety of fixes from 9.4.8. For information about new features in the 9.4 major release, see Section E.23.

**E.14.1. Migration to Version 9.4.9**

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.6, see Section E.17.

**E.14.2. Changes**

• Fix possible mis-evaluation of nested `CASE-WHEN` expressions (Heikki Linnakangas, Michael Paquier, Tom Lane)

A `CASE` expression appearing within the test value subexpression of another `CASE` could become confused about whether its own test value was null or not. Also, inlining of a SQL function implementing the equality operator used by a `CASE` expression could result in passing the wrong test value to functions called within a `CASE` expression in the SQL function’s body. If the test values were of different data types, a crash might result; moreover such situations could be abused to allow disclosure of portions of server memory. (CVE-2016-5423)
• Fix client programs’ handling of special characters in database and role names (Noah Misch, Nathan Bossart, Michael Paquier)

Numerous places in vacuumdb and other client programs could become confused by database and role names containing double quotes or backslashes. Tighten up quoting rules to make that safe. Also, ensure that when a conninfo string is used as a database name parameter to these programs, it is correctly treated as such throughout.

Fix handling of paired double quotes in psql’s \connect and \password commands to match the documentation.

Introduce a new -reuse-previous option in psql’s \connect command to allow explicit control of whether to re-use connection parameters from a previous connection. (Without this, the choice is based on whether the database name looks like a conninfo string, as before.) This allows secure handling of database names containing special characters in pg_dumpall scripts.

pg_dumpall now refuses to deal with database and role names containing carriage returns or newlines, as it seems impractical to quote those characters safely on Windows. In future we may reject such names on the server side, but that step has not been taken yet.

These are considered security fixes because crafted object names containing special characters could have been used to execute commands with superuser privileges the next time a superuser executes pg_dumpall or other routine maintenance operations. (CVE-2016-5424)

• Fix corner-case misbehaviors for IS NULL/IS NOT NULL applied to nested composite values (Andrew Gierth, Tom Lane)

The SQL standard specifies that IS NULL should return TRUE for a row of all null values (thus ROW(NULL,NULL) IS NULL yields TRUE), but this is not meant to apply recursively (thus ROW(NULL, ROW(NULL,NULL)) IS NULL yields FALSE). The core executor got this right, but certain planner optimizations treated the test as recursive (thus producing TRUE in both cases), and contrib/postgres_fdw could produce remote queries that misbehaved similarly.

• Make the inet and cidr data types properly reject IPv6 addresses with too many colon-separated fields (Tom Lane)

• Prevent crash in close_ps() (the point ## lseg operator) for NaN input coordinates (Tom Lane)

Make it return NULL instead of crashing.

• Avoid possible crash in pg_get_expr() when inconsistent values are passed to it (Michael Paquier, Thomas Munro)

• Fix several one-byte buffer over-reads in to_number() (Peter Eisentraut)

In several cases the to_number() function would read one more character than it should from the input string. There is a small chance of a crash, if the input happens to be adjacent to the end of memory.

• Do not run the planner on the query contained in CREATE MATERIALIZED VIEW or CREATE TABLE AS when WITH NO DATA is specified (Michael Paquier, Tom Lane)

This avoids some unnecessary failure conditions, for example if a stable function invoked by the materialized view depends on a table that doesn’t exist yet.

• Avoid unsafe intermediate state during expensive paths through heap_update() (Masahiko Sawada, Andres Freund)

Previously, these cases locked the target tuple (by setting its XMAX) but did not WAL-log that action, thus risking data integrity problems if the page were spilled to disk and then a database crash occurred before the tuple update could be completed.
Appendix E. Release Notes

• Fix hint bit update during WAL replay of row locking operations (Andres Freund)
  The only known consequence of this problem is that row locks held by a prepared, but uncommitted, transaction might fail to be enforced after a crash and restart.

• Avoid unnecessary “could not serialize access” errors when acquiring \texttt{FOR KEY SHARE} row locks in serializable mode (Álvaro Herrera)

• Avoid crash in \texttt{postgres -C} when the specified variable has a null string value (Michael Paquier)

• Fix possible loss of large subtransactions in logical decoding (Petru-Florin Mihancea)

• Fix failure of logical decoding when a subtransaction contains no actual changes (Marko Tiikkaja, Andrew Gierth)

• Ensure that backends see up-to-date statistics for shared catalogs (Tom Lane)
  The statistics collector failed to update the statistics file for shared catalogs after a request from a regular backend. This problem was partially masked because the autovacuum launcher regularly makes requests that did cause such updates; however, it became obvious with autovacuum disabled.

• Avoid redundant writes of the statistics files when multiple backends request updates close together (Tom Lane, Tomas Vondra)

• Avoid consuming a transaction ID during \texttt{VACUUM} (Alexander Korotkov)
  Some cases in \texttt{VACUUM} unnecessarily caused an XID to be assigned to the current transaction. Normally this is negligible, but if one is up against the XID wraparound limit, consuming more XIDs during anti-wraparound vacuums is a very bad thing.

• Avoid canceling hot-standby queries during \texttt{VACUUM FREEZE} (Simon Rüggs, Álvaro Herrera)
  \texttt{VACUUM FREEZE} on an otherwise-idle master server could result in unnecessary cancellations of queries on its standby servers.

• Prevent possible failure when vacuuming multixact IDs in an installation that has been \texttt{pg_upgrade’d} from pre-9.3 (Andrew Gierth, Álvaro Herrera)
  The usual symptom of this bug is errors like “MultiXactId \texttt{NNN} has not been created yet -- apparent wraparound”.

• When a manual \texttt{ANALYZE} specifies a column list, don’t reset the table’s \texttt{changes_since_analyze} counter (Tom Lane)
  If we’re only analyzing some columns, we should not prevent routine auto-analyze from happening for the other columns.

• Fix \texttt{ANALYZE}’s overestimation of \texttt{n\_distinct} for a unique or nearly-unique column with many null entries (Tom Lane)
  The nulls could get counted as though they were themselves distinct values, leading to serious planner misestimates in some types of queries.

• Prevent autovacuum from starting multiple workers for the same shared catalog (Álvaro Herrera)
  Normally this isn’t much of a problem because the vacuum doesn’t take long anyway; but in the case of a severely bloated catalog, it could result in all but one worker uselessly waiting instead of doing useful work on other tables.

• Avoid duplicate buffer lock release when abandoning a b-tree index page deletion attempt (Tom Lane)
  This mistake prevented \texttt{VACUUM} from completing in some cases involving corrupt b-tree indexes.

• Prevent infinite loop in GiST index build for geometric columns containing NaN component values (Tom Lane)
Appendix E. Release Notes

- Fix contrib/btree_gin to handle the smallest possible bigint value correctly (Peter Eisentraut)
- Teach libpq to correctly decode server version from future servers (Peter Eisentraut)
  It’s planned to switch to two-part instead of three-part server version numbers for releases after 9.6.
  Make sure that PQserverVersion() returns the correct value for such cases.
- Fix ecpg’s code for unsigned long long array elements (Michael Meskes)
- In pg_dump with both -c and -C options, avoid emitting an unwanted CREATE SCHEMA public
  command (David Johnston, Tom Lane)
- Improve handling of SIGTERM/control-C in parallel pg_dump and pg_restore (Tom Lane)
  Make sure that the worker processes will exit promptly, and also arrange to send query-cancel re-
  quests to the connected backends, in case they are doing something long-running such as a CREATE
  INDEX.
- Fix error reporting in parallel pg_dump and pg_restore (Tom Lane)
  Previously, errors reported by pg_dump or pg_restore worker processes might never make it to
  the user’s console, because the messages went through the master process, and there were various
deadlock scenarios that would prevent the master process from passing on the messages. Instead,
just print everything to stderr. In some cases this will result in duplicate messages (for instance,
if all the workers report a server shutdown), but that seems better than no message.
- Ensure that parallel pg_dump or pg_restore on Windows will shut down properly after an error
  (Kyotaro Horiguchi)
  Previously, it would report the error, but then just sit until manually stopped by the user.
- Make pg_dump behave better when built without zlib support (Kyotaro Horiguchi)
  It didn’t work right for parallel dumps, and emitted some rather pointless warnings in other cases.
- Make pg_basebackup accept -Z 0 as specifying no compression (Fujii Masao)
- Fix makefiles’ rule for building AIX shared libraries to be safe for parallel make (Noah Misch)
- Fix TAP tests and MSVC scripts to work when build directory’s path name contains spaces
  (Michael Paquier, Kyotaro Horiguchi)
- Be more predictable about reporting “statement timeout” versus “lock timeout” (Tom Lane)
  On heavily loaded machines, the regression tests sometimes failed due to reporting “lock timeout”
even though the statement timeout should have occurred first.
- Make regression tests safe for Danish and Welsh locales (Jeff Janes, Tom Lane)
  Change some test data that triggered the unusual sorting rules of these locales.
- Update our copy of the timezone code to match IANA’s tzcode release 2016c (Tom Lane)
  This is needed to cope with anticipated future changes in the time zone data files. It also fixes some
corner-case bugs in coping with unusual time zones.
- Update time zone data files to tzdata release 2016f for DST law changes in Kemerovo and Novoji-
birsk, plus historical corrections for Azerbaijan, Belarus, and Morocco.

E.15. Release 9.4.8

Release date: 2016-05-12
Appendix E. Release Notes

This release contains a variety of fixes from 9.4.7. For information about new features in the 9.4 major release, see Section E.23.

E.15.1. Migration to Version 9.4.8

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.6, see Section E.17.

E.15.2. Changes

- Clear the OpenSSL error queue before OpenSSL calls, rather than assuming it’s clear already, and make sure we leave it clear afterwards (Peter Geoghegan, Dave Vitek, Peter Eisentraut)

This change prevents problems when there are multiple connections using OpenSSL within a single process and not all the code involved follows the same rules for when to clear the error queue. Failures have been reported specifically when a client application uses SSL connections in libpq concurrently with SSL connections using the PHP, Python, or Ruby wrappers for OpenSSL. It’s possible for similar problems to arise within the server as well, if an extension module establishes an outgoing SSL connection.

- Fix “failed to build any n-way joins” planner error with a full join enclosed in the right-hand side of a left join (Tom Lane)

- Fix incorrect handling of equivalence-class tests in multilevel nestloop plans (Tom Lane)

Given a three-or-more-way equivalence class of variables, such as $X \cdot X = Y \cdot Y = Z \cdot Z$, it was possible for the planner to omit some of the tests needed to enforce that all the variables are actually equal, leading to join rows being output that didn’t satisfy the WHERE clauses. For various reasons, erroneous plans were seldom selected in practice, so that this bug has gone undetected for a long time.

- Fix query-lifespan memory leak in GIN index scans (Julien Rouhaud)

- Fix query-lifespan memory leak and potential index corruption hazard in GIN index insertion (Tom Lane)

The memory leak would typically not amount to much in simple queries, but it could be very substantial during a large GIN index build with high maintenance_work_mem.

- Fix possible misbehavior of TH, th, and Y, YYY format codes in to_timestamp() (Tom Lane)

These could advance off the end of the input string, causing subsequent format codes to read garbage.

- Fix dumping of rules and views in which the array argument of a value operator ANY (array) construct is a sub-SELECT (Tom Lane)

- Disallow newlines in ALTER SYSTEM parameter values (Tom Lane)

The configuration-file parser doesn’t support embedded newlines in string literals, so we mustn’t allow them in values to be inserted by ALTER SYSTEM.

- Fix ALTER TABLE ... REPLICA IDENTITY USING INDEX to work properly if an index on OID is selected (David Rowley)

- Fix crash in logical decoding on alignment-picky platforms (Tom Lane, Andres Freund)
The failure occurred only with a transaction large enough to spill to disk and a primary-key change within that transaction.

- Avoid repeated requests for feedback from receiver while shutting down walsender (Nick Cleaton)
- Make pg_regress use a startup timeout from the PGCTLTIMEOUT environment variable, if that’s set (Tom Lane)
  This is for consistency with a behavior recently added to pg_ctl; it eases automated testing on slow machines.
- Fix pg_upgrade to correctly restore extension membership for operator families containing only one operator class (Tom Lane)
  In such a case, the operator family was restored into the new database, but it was no longer marked as part of the extension. This had no immediate ill effects, but would cause later pg_dump runs to emit output that would cause (harmless) errors on restore.
- Fix pg_upgrade to not fail when new-cluster TOAST rules differ from old (Tom Lane)
  pg_upgrade had special-case code to handle the situation where the new PostgreSQL version thinks that a table should have a TOAST table while the old version did not. That code was broken, so remove it, and instead do nothing in such cases; there seems no reason to believe that we can’t get along fine without a TOAST table if that was okay according to the old version’s rules.
- Reduce the number of SysV semaphores used by a build configured with --disable-spinlocks (Tom Lane)
- Rename internal function strtoi() to strtoint() to avoid conflict with a NetBSD library function (Thomas Munro)
- Fix reporting of errors from bind() and listen() system calls on Windows (Tom Lane)
- Reduce verbosity of compiler output when building with Microsoft Visual Studio (Christian Ullrich)
- Fix putenv() to work properly with Visual Studio 2013 (Michael Paquier)
- Avoid possibly-unsafe use of Windows’ FormatMessage() function (Christian Ullrich)
  Use the FORMAT_MESSAGE_IGNORE_INSERTS flag where appropriate. No live bug is known to exist here, but it seems like a good idea to be careful.
- Update time zone data files to tzdata release 2016d for DST law changes in Russia and Venezuela. There are new zone names Europe/Kirov and Asia/Tomsk to reflect the fact that these regions now have different time zone histories from adjacent regions.

**E.16. Release 9.4.7**

**Release date:** 2016-03-31

This release contains a variety of fixes from 9.4.6. For information about new features in the 9.4 major release, see Section E.23.

**E.16.1. Migration to Version 9.4.7**

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.6, see Section E.17.
E.16.2. Changes

- Fix incorrect handling of NULL index entries in indexed \texttt{ROW()} comparisons (Tom Lane)
  An index search using a row comparison such as \texttt{ROW(a, b) > ROW('x', 'y')} would stop upon reaching a NULL entry in the \texttt{b} column, ignoring the fact that there might be non-NULL \texttt{b} values associated with later values of \texttt{a}.

- Avoid unlikely data-loss scenarios due to renaming files without adequate \texttt{fsync()} calls before and after (Michael Paquier, Tomas Vondra, Andres Freund)

- Fix bug in \texttt{json_to_record()} when a field of its input object contains a sub-object with a field name matching one of the requested output column names (Tom Lane)

- Fix misformatting of negative time zone offsets by \texttt{to_char()}’s \texttt{OF} format code (Thomas Munro, Tom Lane)

- Ignore recovery\_min\_apply\_delay parameter until recovery has reached a consistent state (Michael Paquier)
  Previously, standby servers would delay application of WAL records in response to \texttt{recovery\_min\_apply\_delay} even while replaying the initial portion of WAL needed to make their database state valid. Since the standby is useless until it’s reached a consistent database state, this was deemed unhelpful.

- Correctly handle cases where \texttt{pg\_subtrans} is close to XID wraparound during server startup (Jeff Janes)

- Fix assorted bugs in logical decoding (Andres Freund)
  Trouble cases included tuples larger than one page when replica identity is \texttt{FULL}, \texttt{UPDATES} that change a primary key within a transaction large enough to be spilled to disk, incorrect reports of “subxact logged without previous toplevel record”, and incorrect reporting of a transaction’s commit time.

- Fix planner error with nested security barrier views when the outer view has a \texttt{WHERE} clause containing a correlated subquery (Dean Rasheed)

- Fix corner-case crash due to trying to free \texttt{localeconv()} output strings more than once (Tom Lane)

- Fix parsing of affix files for \texttt{ispell} dictionaries (Tom Lane)
  The code could go wrong if the affix file contained any characters whose byte length changes during case-folding, for example \texttt{I} in Turkish UTF8 locales.

- Avoid use of \texttt{sscanf()} to parse \texttt{ispell} dictionary files (Artur Zakirov)
  This dodges a portability problem on FreeBSD-derived platforms (including macOS).

- Avoid a crash on old Windows versions (before 7SP1/2008R2SP1) with an AVX2-capable CPU and a Postgres build done with Visual Studio 2013 (Christian Ullrich)
  This is a workaround for a bug in Visual Studio 2013’s runtime library, which Microsoft have stated they will not fix in that version.

- Fix \texttt{psql}’s tab completion logic to handle multibyte characters properly (Kyotaro Horiguchi, Robert Haas)

- Fix \texttt{psql}’s tab completion for \texttt{SECURITY LABEL} (Tom Lane)
  Pressing \texttt{TAB} after \texttt{SECURITY LABEL} might cause a crash or offering of inappropriate keywords.
Appendix E. Release Notes

- Make pg_ctl accept a wait timeout from the `PGCTLTIMEOUT` environment variable, if none is specified on the command line (Noah Misch)
  This eases testing of slower buildfarm members by allowing them to globally specify a longer-than-normal timeout for postmaster startup and shutdown.
- Fix incorrect test for Windows service status in pg_ctl (Manuel Mathar)
  The previous set of minor releases attempted to fix pg_ctl to properly determine whether to send log messages to Window’s Event Log, but got the test backwards.
- Fix pgbench to correctly handle the combination of `-C` and `-M` prepared options (Tom Lane)
- In pg_upgrade, skip creating a deletion script when the new data directory is inside the old data directory (Bruce Momjian)
  Blind application of the script in such cases would result in loss of the new data directory.
- In PL/Perl, properly translate empty Postgres arrays into empty Perl arrays (Alex Hunsaker)
- Make PL/Python cope with function names that aren’t valid Python identifiers (Jim Nasby)
- Fix multiple mistakes in the statistics returned by contrib/pgstattuple’s `pgstatindex()` function (Tom Lane)
- Remove dependency on psed in MSVC builds, since it’s no longer provided by core Perl (Michael Paquier, Andrew Dunstan)
- Update time zone data files to tzdata release 2016c for DST law changes in Azerbaijan, Chile, Haiti, Palestine, and Russia (Altai, Astrakhan, Kirov, Sakhalin, Ulyanovsk regions), plus historical corrections for Lithuania, Moldova, and Russia (Kaliningrad, Samara, Volgograd).

E.17. Release 9.4.6

Release date: 2016-02-11

This release contains a variety of fixes from 9.4.5. For information about new features in the 9.4 major release, see Section E.23.

E.17.1. Migration to Version 9.4.6

A dump/restore is not required for those running 9.4.X. However, if you are upgrading an installation that contains any GIN indexes that use the (non-default) `jsonb_path_ops` operator class, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.4.4, see Section E.19.

E.17.2. Changes

- Fix inconsistent hash calculations in `jsonb_path_ops` GIN indexes (Tom Lane)
  When processing `jsonb` values that contain both scalars and sub-objects at the same nesting level, for example an array containing both scalars and sub-arrays, key hash values could be calculated differently than they would be for the same key in a different context. This could result in queries...
not finding entries that they should find. Fixing this means that existing indexes may now be inconsistent with the new hash calculation code. Users should `REINDEX jsonb_path_ops` GIN indexes after installing this update to make sure that all searches work as expected.

- Fix infinite loops and buffer-overrun problems in regular expressions (Tom Lane)
  Very large character ranges in bracket expressions could cause infinite loops in some cases, and memory overwrites in other cases. (CVE-2016-0773)

- Perform an immediate shutdown if the `postmaster.pid` file is removed (Tom Lane)
  The postmaster now checks every minute or so that `postmaster.pid` is still there and still contains its own PID. If not, it performs an immediate shutdown, as though it had received SIGQUIT. The main motivation for this change is to ensure that failed buildfarm runs will get cleaned up without manual intervention; but it also serves to limit the bad effects if a DBA forcibly removes `postmaster.pid` and then starts a new postmaster.

- In `SERIALIZABLE` transaction isolation mode, serialization anomalies could be missed due to race conditions during insertions (Kevin Grittner, Thomas Munro)

- Fix failure to emit appropriate WAL records when doing `ALTER TABLE ... SET TABLESPACE` for unlogged relations (Michael Paquier, Andres Freund)
  Even though the relation’s data is unlogged, the move must be logged or the relation will be inaccessible after a standby is promoted to master.

- Fix possible misinitialization of unlogged relations at the end of crash recovery (Andres Freund, Michael Paquier)

- Ensure walsender slots are fully re-initialized when being re-used (Magnus Hagander)

- Fix `ALTER COLUMN TYPE` to reconstruct inherited check constraints properly (Tom Lane)

- Fix `REASSIGN OWNED` to change ownership of composite types properly (Álvaro Herrera)

- Fix `REASSIGN OWNED` and `ALTER OWNER` to correctly update granted-permissions lists when changing owners of data types, foreign data wrappers, or foreign servers (Bruce Momjian, Álvaro Herrera)

- Fix `REASSIGN OWNED` to ignore foreign user mappings, rather than fail (Álvaro Herrera)

- Fix possible crash after doing query rewrite for an updatable view (Stephen Frost)

- Fix planner’s handling of `LATERAL` references (Tom Lane)
  This fixes some corner cases that led to “failed to build any N-way joins” or “could not devise a query plan” planner failures.

- Add more defenses against bad planner cost estimates for GIN index scans when the index’s internal statistics are very out-of-date (Tom Lane)

- Make planner cope with hypothetical GIN indexes suggested by an index advisor plug-in (Julien Rouhaud)

- Speed up generation of unique table aliases in `EXPLAIN` and rule dumping, and ensure that generated aliases do not exceed `NAMEDATALEN` (Tom Lane)

- Fix dumping of whole-row Vars in `ROW()` and `VALUES()` lists (Tom Lane)

- Translation of minus-infinity dates and timestamps to `json` or `jsonb` incorrectly rendered them as plus-infinity (Tom Lane)

- Fix possible internal overflow in `numeric` division (Dean Rasheed)

- Fix enforcement of restrictions inside parentheses within regular expression lookahead constraints (Tom Lane)
Appendix E. Release Notes

Lookahead constraints aren’t allowed to contain backrefs, and parentheses within them are always considered non-capturing, according to the manual. However, the code failed to handle these cases properly inside a parenthesized subexpression, and would give unexpected results.

- Conversion of regular expressions to indexscan bounds could produce incorrect bounds from regexps containing lookahead constraints (Tom Lane)
- Fix regular-expression compiler to handle loops of constraint arcs (Tom Lane)
The code added for CVE-2007-4772 was both incomplete, in that it didn’t handle loops involving more than one state, and incorrect, in that it could cause assertion failures (though there seem to be no bad consequences of that in a non-assert build). Multi-state loops would cause the compiler to run until the query was canceled or it reached the too-many-states error condition.
- Improve memory-usage accounting in regular-expression compiler (Tom Lane)

This causes the code to emit “regular expression is too complex” errors in some cases that previously used unreasonable amounts of time and memory.
- Improve performance of regular-expression compiler (Tom Lane)
- Make %h and %r escapes in log_line_prefix work for messages emitted due to log_connections (Tom Lane)

Previously, %h/%r started to work just after a new session had emitted the “connection received” log message; now they work for that message too.
- On Windows, ensure the shared-memory mapping handle gets closed in child processes that don’t need it (Tom Lane, Amit Kapila)

This oversight resulted in failure to recover from crashes whenever logging_collector is turned on.
- Fix possible failure to detect socket EOF in non-blocking mode on Windows (Tom Lane)

It’s not entirely clear whether this problem can happen in pre-9.5 branches, but if it did, the symptom would be that a walsender process would wait indefinitely rather than noticing a loss of connection.
- Avoid leaking a token handle during SSPI authentication (Christian Ullrich)
- In psql, ensure that libreadline’s idea of the screen size is updated when the terminal window size changes (Merlin Moncure)

Previously, libreadline did not notice if the window was resized during query output, leading to strange behavior during later input of multiline queries.
- Fix psql’s \det command to interpret its pattern argument the same way as other \d commands with potentially schema-qualified patterns do (Reece Hart)
- Avoid possible crash in psql’s \c command when previous connection was via Unix socket and command specifies a new hostname and same username (Tom Lane)
- In pg_ctl start -w, test child process status directly rather than relying on heuristics (Tom Lane, Michael Paquier)

Previously, pg_ctl relied on an assumption that the new postmaster would always create postmaster.pid within five seconds. But that can fail on heavily-loaded systems, causing pg_ctl to report incorrectly that the postmaster failed to start.

Except on Windows, this change also means that a pg_ctl start -w done immediately after another such command will now reliably fail, whereas previously it would report success if done within two seconds of the first command.
Appendix E. Release Notes

- In pg_ctl start -w, don’t attempt to use a wildcard listen address to connect to the postmaster (Kondo Yuta)

  On Windows, pg_ctl would fail to detect postmaster startup if listen_addresses is set to 0.0.0.0 or ::, because it would try to use that value verbatim as the address to connect to, which doesn’t work. Instead assume that 127.0.0.1 or ::1, respectively, is the right thing to use.

- In pg_ctl on Windows, check service status to decide where to send output, rather than checking if standard output is a terminal (Michael Paquier)

- In pg_dump and pg_basebackup, adopt the GNU convention for handling tar-archive members exceeding 8GB (Tom Lane)

  The POSIX standard for tar file format does not allow archive member files to exceed 8GB, but most modern implementations of tar support an extension that fixes that. Adopt this extension so that pg_dump with -Ft no longer fails on tables with more than 8GB of data, and so that pg_basebackup can handle files larger than 8GB. In addition, fix some portability issues that could cause failures for members between 4GB and 8GB on some platforms. Potentially these problems could cause unrecoverable data loss due to unreadable backup files.

- Fix assorted corner-case bugs in pg_dump’s processing of extension member objects (Tom Lane)

- Make pg_dump mark a view’s triggers as needing to be processed after its rule, to prevent possible failure during parallel pg_restore (Tom Lane)

- Ensure that relation option values are properly quoted in pg_dump (Kouhei Sutou, Tom Lane)

  A reloption value that isn’t a simple identifier or number could lead to dump/reload failures due to syntax errors in CREATE statements issued by pg_dump. This is not an issue with any reloption currently supported by core PostgreSQL, but extensions could allow reloptions that cause the problem.

- Avoid repeated password prompts during parallel pg_dump (Zeus Kronion)

- Fix pg_upgrd’s file-copying code to handle errors properly on Windows (Bruce Momjian)

- Install guards in pgbench against corner-case overflow conditions during evaluation of script-specified division or modulo operators (Fabien Coelho, Michael Paquier)

- Fix failure to localize messages emitted by pg_receivexlog and pg_recvlogical (Ioseph Kim)

- Avoid dump/reload problems when using both plpython2 and plpython3 (Tom Lane)

  In principle, both versions of PL/Python can be used in the same database, though not in the same session (because the two versions of libpython cannot safely be used concurrently). However, pg_restore and pg_upgrd both do things that can fall foul of the same-session restriction. Work around that by changing the timing of the check.

- Fix PL/Python regression tests to pass with Python 3.5 (Peter Eisentraut)

- Fix premature clearing of libpq’s input buffer when socket EOF is seen (Tom Lane)

  This mistake caused libpq to sometimes not report the backend’s final error message before reporting “server closed the connection unexpectedly”.

- Prevent certain PL/Java parameters from being set by non-superusers (Noah Misch)

  This change mitigates a PL/Java security bug (CVE-2016-0766), which was fixed in PL/Java by marking these parameters as superuser-only. To fix the security hazard for sites that update PostgreSQL more frequently than PL/Java, make the core code aware of them also.

- Improve libpq’s handling of out-of-memory situations (Michael Paquier, Amit Kapila, Heikki Linnakangas)
Appendix E. Release Notes

• Fix order of arguments in ecpg-generated typedef statements (Michael Meskes)
• Use %g not %f format in ecpg’s PGTYPESnumeric_from_double() (Tom Lane)
• Fix ecpg-supplied header files to not contain comments continued from a preprocessor directive line onto the next line (Michael Meskes)
  Such a comment is rejected by ecpg. It’s not yet clear whether ecpg itself should be changed.
• Fix hstore_to_json_loose()’s test for whether an hstore value can be converted to a JSON number (Tom Lane)
  Previously this function could be fooled by non-alphanumeric trailing characters, leading to emitting syntactically-invalid JSON.
• Ensure that contrib/pgcrypto’s crypt() function can be interrupted by query cancel (Andreas Karlsson)
• In contrib/postgres_fdw, fix bugs triggered by use of tableoid in data-modifying commands (Etsuro Fujita, Robert Haas)
• Accept flex versions later than 2.5.x (Tom Lane, Michael Paquier)
  Now that flex 2.6.0 has been released, the version checks in our build scripts needed to be adjusted.
• Improve reproducibility of build output by ensuring filenames are given to the linker in a fixed order (Christoph Berg)
  This avoids possible bitwise differences in the produced executable files from one build to the next.
• Install our missing script where PGXS builds can find it (Jim Nasby)
  This allows sane behavior in a PGXS build done on a machine where build tools such as bison are missing.
• Ensure that dynloader.h is included in the installed header files in MSVC builds (Bruce Momjian, Michael Paquier)
• Add variant regression test expected-output file to match behavior of current libxml2 (Tom Lane)
  The fix for libxml2’s CVE-2015-7499 causes it not to output error context reports in some cases where it used to do so. This seems to be a bug, but we’ll probably have to live with it for some time, so work around it.
• Update time zone data files to tzdata release 2016a for DST law changes in Cayman Islands, Metlakatla, and Trans-Baikal Territory (Zabaykalsky Krai), plus historical corrections for Pakistan.

E.18. Release 9.4.5

Release date: 2015-10-08

This release contains a variety of fixes from 9.4.4. For information about new features in the 9.4 major release, see Section E.23.

E.18.1. Migration to Version 9.4.5

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.4, see Section E.19.
Appendix E. Release Notes

E.18.2. Changes

- Guard against stack overflows in `json` parsing (Oskari Saarenmaa)
  If an application constructs PostgreSQL `json` or `jsonb` values from arbitrary user input, the application’s users can reliably crash the PostgreSQL server, causing momentary denial of service. (CVE-2015-5289)

- Fix `contrib/pgcrypto` to detect and report too-short `crypt()` salts (Josh Kupershmidt)
  Certain invalid salt arguments crashed the server or disclosed a few bytes of server memory. We have not ruled out the viability of attacks that arrange for presence of confidential information in the disclosed bytes, but they seem unlikely. (CVE-2015-5288)

- Fix subtransaction cleanup after a portal (cursor) belonging to an outer subtransaction fails (Tom Lane, Michael Paquier)
  A function executed in an outer-subtransaction cursor could cause an assertion failure or crash by referencing a relation created within an inner subtransaction.

- Fix possible deadlock during WAL insertion when `commit_delay` is set (Heikki Linnakangas)

- Ensure all relations referred to by an updatable view are properly locked during an update statement (Dean Rasheed)

- Fix insertion of relations into the relation cache “init file” (Tom Lane)
  An oversight in a patch in the most recent minor releases caused `pg_trigger_tgrelid_tgname_index` to be omitted from the init file. Subsequent sessions detected this, then deemed the init file to be broken and silently ignored it, resulting in a significant degradation in session startup time. In addition to fixing the bug, install some guards so that any similar future mistake will be more obvious.

- Avoid $O(N^2)$ behavior when inserting many tuples into a SPI query result (Neil Conway)

- Improve `LISTEN` startup time when there are many unread notifications (Matt Newell)

- Fix performance problem when a session alters large numbers of foreign key constraints (Jan Wieck, Tom Lane)
  This was seen primarily when restoring `pg_dump` output for databases with many thousands of tables.

- Disable SSL renegotiation by default (Michael Paquier, Andres Freund)
  While use of SSL renegotiation is a good idea in theory, we have seen too many bugs in practice, both in the underlying OpenSSL library and in our usage of it. Renegotiation will be removed entirely in 9.5 and later. In the older branches, just change the default value of `ssl_renegotiation_limit` to zero (disabled).

- Lower the minimum values of the `*_freeze_max_age` parameters (Andres Freund)
  This is mainly to make tests of related behavior less time-consuming, but it may also be of value for installations with limited disk space.

- Limit the maximum value of `wal_buffers` to 2GB to avoid server crashes (Josh Berkus)

- Avoid logging complaints when a parameter that can only be set at server start appears multiple times in `postgresql.conf`, and fix counting of line numbers after an `include_dir` directive (Tom Lane)

- Fix rare internal overflow in multiplication of `numeric` values (Dean Rasheed)
Appendix E. Release Notes

• Guard against hard-to-reach stack overflows involving record types, range types, json, jsonb, tsquery, ltxtquery and query_int (Noah Misch)

• Fix handling of DOW and DOY in datetime input (Greg Stark)
  These tokens aren’t meant to be used in datetime values, but previously they resulted in opaque internal error messages rather than “invalid input syntax”.

• Add more query-cancel checks to regular expression matching (Tom Lane)

• Add recursion depth protections to regular expression, SIMILAR TO, and LIKE matching (Tom Lane)
  Suitable search patterns and a low stack depth limit could lead to stack-overrun crashes.

• Fix potential infinite loop in regular expression execution (Tom Lane)
  A search pattern that can apparently match a zero-length string, but actually doesn’t match because of a back reference, could lead to an infinite loop.

• In regular expression execution, correctly record match data for capturing parentheses within a quantifier even when the match is zero-length (Tom Lane)

• Fix low-memory failures in regular expression compilation (Andreas Seltenreich)

• Fix low-probability memory leak during regular expression execution (Tom Lane)

• Fix rare low-memory failure in lock cleanup during transaction abort (Tom Lane)

• Fix “unexpected out-of-memory situation during sort” errors when using tuplestores with small work_mem settings (Tom Lane)

• Fix very-low-probability stack overrun in qsort (Tom Lane)

• Fix “invalid memory alloc request size” failure in hash joins with large work_mem settings (Tomas Vondra, Tom Lane)

• Fix assorted planner bugs (Tom Lane)
  These mistakes could lead to incorrect query plans that would give wrong answers, or to assertion failures in assert-enabled builds, or to odd planner errors such as “could not devise a query plan for the given query”, “could not find pathkey item to sort”, “plan should not reference subplan’s variable”, or “failed to assign all NestLoopParams to plan nodes”. Thanks are due to Andreas Seltenreich and Piotr Stefaniak for fuzz testing that exposed these problems.

• Improve planner’s performance for UPDATE/DELETE on large inheritance sets (Tom Lane, Dean Rasheed)

• Ensure standby promotion trigger files are removed at postmaster startup (Michael Paquier, Fujii Masao)
  This prevents unwanted promotion from occurring if these files appear in a database backup that is used to initialize a new standby server.

• During postmaster shutdown, ensure that per-socket lock files are removed and listen sockets are closed before we remove the postmaster.pid file (Tom Lane)
  This avoids race-condition failures if an external script attempts to start a new postmaster as soon as pg_ctl stop returns.

• Ensure that the postmaster does not exit until all its child processes are gone, even in an immediate shutdown (Tom Lane)
  Like the previous item, this avoids possible race conditions against a subsequently-started postmaster.
Appendix E. Release Notes

- Fix postmaster’s handling of a startup-process crash during crash recovery (Tom Lane)
  If, during a crash recovery cycle, the startup process crashes without having restored database consistency, we’d try to launch a new startup process, which typically would just crash again, leading to an infinite loop.
- Make emergency autovacuuming for multixact wraparound more robust (Andres Freund)
- Do not print a WARNING when an autovacuum worker is already gone when we attempt to signal it, and reduce log verbosity for such signals (Tom Lane)
- Prevent autovacuum launcher from sleeping unduly long if the server clock is moved backwards a large amount (Álvaro Herrera)
- Ensure that cleanup of a GIN index’s pending insertions list is interruptable by cancel requests (Jeff Janes)
- Allow all-zeroes pages in GIN indexes to be reused (Heikki Linnakangas)
  Such a page might be left behind after a crash.
- Fix handling of all-zeroes pages in SP-GiST indexes (Heikki Linnakangas)
  VACUUM attempted to recycle such pages, but did so in a way that wasn’t crash-safe.
- Fix off-by-one error that led to otherwise-harmless warnings about “apparent wraparound” in subtrans/multixact truncation (Thomas Munro)
- Fix misreporting of CONTINUE and MOVE statement types in PL/pgSQL’s error context messages (Pavel Stehule, Tom Lane)
- Fix PL/Perl to handle non-ASCII error message texts correctly (Alex Hunsaker)
- Fix PL/Python crash when returning the string representation of a record result (Tom Lane)
- Fix some places in PL/Tcl that neglected to check for failure of malloc() calls (Michael Paquier, Álvaro Herrera)
- In contrib/isn, fix output of ISBN-13 numbers that begin with 979 (Fabien Coelho)
  EANs beginning with 979 (but not 9790) are considered ISBNs, but they must be printed in the new 13-digit format, not the 10-digit format.
- Improve contrib/pg_stat_statements’ handling of query-text garbage collection (Peter Geoghegan)
  The external file containing query texts could bloat to very large sizes; once it got past 1GB attempts to trim it would fail, soon leading to situations where the file could not be read at all.
- Improve contrib/postgres_fdw’s handling of collation-related decisions (Tom Lane)
  The main user-visible effect is expected to be that comparisons involving varchar columns will be sent to the remote server for execution in more cases than before.
- Improve libpq’s handling of out-of-memory conditions (Michael Paquier, Heikki Linnakangas)
- Fix memory leaks and missing out-of-memory checks in ecpg (Michael Paquier)
- Fix psql’s code for locale-aware formatting of numeric output (Tom Lane)
  The formatting code invoked by \pset numericlocale on did the wrong thing for some uncommon cases such as numbers with an exponent but no decimal point. It could also mangle already-localized output from the money data type.
- Prevent crash in psql’s \c command when there is no current connection (Noah Misch)
- Make pg_dump handle inherited NOT VALID check constraints correctly (Tom Lane)
Appendix E. Release Notes

- Fix selection of default zlib compression level in pg_dump’s directory output format (Andrew Dunstan)
- Ensure that temporary files created during a pg_dump run with tar-format output are not world-readable (Michael Paquier)
- Fix pg_dump and pg_upgrade to support cases where the postgres or template1 database is in a non-default tablespace (Marti Raudsepp, Bruce Momjian)
- Fix pg_dump to handle object privileges sanely when dumping from a server too old to have a particular privilege type (Tom Lane)
  When dumping data types from pre-9.2 servers, and when dumping functions or procedural languages from pre-7.3 servers, pg_dump would produce GRANT/REVOKE commands that revoked the owner’s grantable privileges and instead granted all privileges to PUBLIC. Since the privileges involved are just USAGE and EXECUTE, this isn’t a security problem, but it’s certainly a surprising representation of the older systems’ behavior. Fix it to leave the default privilege state alone in these cases.
- Fix pg_dump to dump shell types (Tom Lane)
  Shell types (that is, not-yet-fully-defined types) aren’t useful for much, but nonetheless pg_dump should dump them.
- Fix assorted minor memory leaks in pg_dump and other client-side programs (Michael Paquier)
- Fix pgbench’s progress-report behavior when a query, or pgbench itself, gets stuck (Fabien Coelho)
- Fix spinlock assembly code for Alpha hardware (Tom Lane)
- Fix spinlock assembly code for PPC hardware to be compatible with AIX’s native assembler (Tom Lane)
  Building with gcc didn’t work if gcc had been configured to use the native assembler, which is becoming more common.
- On AIX, test the --qlonglong compiler option rather than just assuming it’s safe to use (Noah Misch)
- On AIX, use -Wl,-brtllib link option to allow symbols to be resolved at runtime (Noah Misch)
  Perl relies on this ability in 5.8.0 and later.
- Avoid use of inline functions when compiling with 32-bit xlc, due to compiler bugs (Noah Misch)
- Use librt for sched_yield() when necessary, which it is on some Solaris versions (Oskari Saarenmaa)
- Translate encoding UHC as Windows code page 949 (Noah Misch)
  This fixes presentation of non-ASCII log messages from processes that are not attached to any particular database, such as the postmaster.
- On Windows, avoid failure when doing encoding conversion to UTF16 outside a transaction, such as for log messages (Noah Misch)
- Fix postmaster startup failure due to not copying setlocale()’s return value (Noah Misch)
  This has been reported on Windows systems with the ANSI code page set to CP936 (“Chinese (Simplified, PRC)”), and may occur with other multibyte code pages.
- Fix Windows install.bat script to handle target directory names that contain spaces (Heikki Linnakangas)
- Make the numeric form of the PostgreSQL version number (e.g., 90405) readily available to extension Makefiles, as a variable named VERSION_NUM (Michael Paquier)
Appendix E. Release Notes

- Update time zone data files to tzdata release 2015g for DST law changes in Cayman Islands, Fiji, Moldova, Morocco, Norfolk Island, North Korea, Turkey, and Uruguay. There is a new zone name America/Fort_Nelson for the Canadian Northern Rockies.

E.19. Release 9.4.4

Release date: 2015-06-12

This release contains a small number of fixes from 9.4.3. For information about new features in the 9.4 major release, see Section E.23.

E.19.1. Migration to Version 9.4.4

A dump/restore is not required for those running 9.4.X. However, if you are upgrading an installation that was previously upgraded using a pg_upgrade version between 9.3.0 and 9.3.4 inclusive, see the first changelog entry below. Also, if you are upgrading from a version earlier than 9.4.2, see Section E.21.

E.19.2. Changes

- Fix possible failure to recover from an inconsistent database state (Robert Haas)

Recent PostgreSQL releases introduced mechanisms to protect against multixact wraparound, but some of that code did not account for the possibility that it would need to run during crash recovery, when the database may not be in a consistent state. This could result in failure to restart after a crash, or failure to start up a secondary server. The lingering effects of a previously-fixed bug in pg_upgrade could also cause such a failure, in installations that had used pg_upgrade versions between 9.3.0 and 9.3.4.

The pg_upgrade bug in question was that it would set oldestMultiXid to 1 in pg_control even if the true value should be higher. With the fixes introduced in this release, such a situation will result in immediate emergency autovacuuming until a correct oldestMultiXid value can be determined. If that would pose a hardship, users can avoid it by doing manual vacuuming before upgrading to this release. In detail:

1. Check whether pg_controldata reports “Latest checkpoint’s oldestMultiXid” to be 1. If not, there’s nothing to do.

2. Look in PGDATA/pg_multixact/offsets to see if there’s a file named 0000. If there is, there’s nothing to do.

3. Otherwise, for each table that has pg_class.relminmxid equal to 1, VACUUM that table with both vacuum_multixact_freeze_min_age and vacuum_multixact_freeze_table_age set to zero. (You can use the vacuum cost delay parameters described in Section 18.4.4 to reduce the performance consequences for concurrent sessions.)

- Fix rare failure to invalidate relation cache init file (Tom Lane)
With just the wrong timing of concurrent activity, a VACUUM FULL on a system catalog might fail to update the “init file” that’s used to avoid cache-loading work for new sessions. This would result in later sessions being unable to access that catalog at all. This is a very ancient bug, but it’s so hard to trigger that no reproducible case had been seen until recently.

- Avoid deadlock between incoming sessions and CREATE/DROP DATABASE (Tom Lane)

A new session starting in a database that is the target of a DROP DATABASE command, or is the template for a CREATE DATABASE command, could cause the command to wait for five seconds and then fail, even if the new session would have exited before that.

- Improve planner’s cost estimates for semi-joins and anti-joins with inner indexscans (Tom Lane, Tomas Vondra)

This type of plan is quite cheap when all the join clauses are used as index scan conditions, even if the inner scan would nominally fetch many rows, because the executor will stop after obtaining one row. The planner only partially accounted for that effect, and would therefore overestimate the cost, leading it to possibly choose some other much less efficient plan type.

E.20. Release 9.4.3

Release date: 2015-06-04

This release contains a small number of fixes from 9.4.2. For information about new features in the 9.4 major release, see Section E.23.

E.20.1. Migration to Version 9.4.3

A dump/restore is not required for those running 9.4.X. However, if you are upgrading from a version earlier than 9.4.2, see Section E.21.

E.20.2. Changes

- Avoid failures while fsync’ing data directory during crash restart (Abhijit Menon-Sen, Tom Lane)

In the previous minor releases we added a patch to fsync everything in the data directory after a crash. Unfortunately its response to any error condition was to fail, thereby preventing the server from starting up, even when the problem was quite harmless. An example is that an unwritable file in the data directory would prevent restart on some platforms; but it is common to make SSL certificate files unwritable by the server. Revise this behavior so that permissions failures are ignored altogether, and other types of failures are logged but do not prevent continuing. Also apply the same rules in initdb --sync-only. This case is less critical but it should act similarly.

- Fix pg_get_functiondef() to show functions’ LEAKPROOF property, if set (Jeevan Chalke)

- Fix pushJsonbValue() to unpack jbvBinary objects (Andrew Dunstan)

This change does not affect any behavior in the core code as of 9.4, but it avoids a corner case for possible third-party callers.

- Remove configure’s check prohibiting linking to a threaded libpython on OpenBSD (Tom Lane)
The failure this restriction was meant to prevent seems to not be a problem anymore on current OpenBSD versions.

### E.21. Release 9.4.2

**Release date:** 2015-05-22

This release contains a variety of fixes from 9.4.1. For information about new features in the 9.4 major release, see Section E.23.

#### E.21.1. Migration to Version 9.4.2

A dump/restore is not required for those running 9.4.X.

However, if you use `contrib/citext`'s `regexp_matches()` functions, see the changelog entry below about that.

Also, if you are upgrading from a version earlier than 9.4.1, see Section E.22.

#### E.21.2. Changes

- Avoid possible crash when client disconnects just before the authentication timeout expires (Benkocs Norbert Attila)
  
  If the timeout interrupt fired partway through the session shutdown sequence, SSL-related state would be freed twice, typically causing a crash and hence denial of service to other sessions. Experimentation shows that an unauthenticated remote attacker could trigger the bug somewhat consistently, hence treat as security issue. (CVE-2015-3165)

- Improve detection of system-call failures (Noah Misch)
  
  Our replacement implementation of `snprintf()` failed to check for errors reported by the underlying system library calls; the main case that might be missed is out-of-memory situations. In the worst case this might lead to information exposure, due to our code assuming that a buffer had been overwritten when it hadn’t been. Also, there were a few places in which security-relevant calls of other system library functions did not check for failure.

  It remains possible that some calls of the `*printf()` family of functions are vulnerable to information disclosure if an out-of-memory error occurs at just the wrong time. We judge the risk to not be large, but will continue analysis in this area. (CVE-2015-3166)

- In `contrib/pgcrypto`, uniformly report decryption failures as “Wrong key or corrupt data” (Noah Misch)
  
  Previously, some cases of decryption with an incorrect key could report other error message texts. It has been shown that such variance in error reports can aid attackers in recovering keys from other systems. While it’s unknown whether `pgcrypto`’s specific behaviors are likewise exploitable, it seems better to avoid the risk by using a one-size-fits-all message. (CVE-2015-3167)

- Protect against wraparound of multixact member IDs (Álvaro Herrera, Robert Haas, Thomas Munro)
Under certain usage patterns, the existing defenses against this might be insufficient, allowing `pg_multixact/members` files to be removed too early, resulting in data loss. The fix for this includes modifying the server to fail transactions that would result in overwriting old multixact member ID data, and improving autovacuum to ensure it will act proactively to prevent multixact member ID wraparound, as it does for transaction ID wraparound.

- Fix incorrect declaration of `contrib/citext`'s `regexp_matches()` functions (Tom Lane)
  These functions should return `setof text[]`, like the core functions they are wrappers for; but they were incorrectly declared as returning just `text[]`. This mistake had two results: first, if there was no match you got a scalar null result, whereas what you should get is an empty set (zero rows). Second, the `g` flag was effectively ignored, since you would get only one result array even if there were multiple matches.

While the latter behavior is clearly a bug, there might be applications depending on the former behavior; therefore the function declarations will not be changed by default until PostgreSQL 9.5. In pre-9.5 branches, the old behavior exists in version 1.0 of the `citext` extension, while we have provided corrected declarations in version 1.1 (which is not installed by default). To adopt the fix in pre-9.5 branches, execute `ALTER EXTENSION citext UPDATE TO '1.1'` in each database in which `citext` is installed. (You can also “update” back to 1.0 if you need to undo that.) Be aware that either update direction will require dropping and recreating any views or rules that use `citext`'s `regexp_matches()` functions.

- Render infinite dates and timestamps as `infinity` when converting to `json`, rather than throwing an error (Andrew Dunstan)
- Fix `json/jsonb`'s `populate_record()` and `to_record()` functions to handle empty input properly (Andrew Dunstan)
- Fix incorrect checking of deferred exclusion constraints after a HOT update (Tom Lane)
  If a new row that potentially violates a deferred exclusion constraint is HOT-updated (that is, no indexed columns change and the row can be stored back onto the same table page) later in the same transaction, the exclusion constraint would be reported as violated when the check finally occurred, even if the row(s) the new row originally conflicted with had been deleted.
- Fix behavior when changing foreign key constraint deferrability status with `ALTER TABLE ... ALTER CONSTRAINT` (Tom Lane)
  Operations later in the same session or concurrent sessions might not honor the status change promptly.
- Fix planning of star-schema-style queries (Tom Lane)
  Sometimes, efficient scanning of a large table requires that index parameters be provided from more than one other table (commonly, dimension tables whose keys are needed to index a large fact table). The planner should be able to find such plans, but an overly restrictive search heuristic prevented it.
- Prevent improper reordering of antijoins (NOT EXISTS joins) versus other outer joins (Tom Lane)
  This oversight in the planner has been observed to cause “could not find RelOptInfo for given relids” errors, but it seems possible that sometimes an incorrect query plan might get past that consistency check and result in silently-wrong query output.
- Fix incorrect matching of subexpressions in outer-join plan nodes (Tom Lane)
  Previously, if textually identical non-strict subexpressions were used both above and below an outer join, the planner might try to re-use the value computed below the join, which would be incorrect because the executor would force the value to `NULL` in case of an unmatched outer row.
• Fix GEQO planner to cope with failure of its join order heuristic (Tom Lane)

This oversight has been seen to lead to “failed to join all relations together” errors in queries involving LATERAL, and that might happen in other cases as well.

• Ensure that row locking occurs properly when the target of an UPDATE or DELETE is a security-barrier view (Stephen Frost)

• Use a file opened for read/write when syncing replication slot data during database startup (Andres Freund)

On some platforms, the previous coding could result in errors like “could not fsync file "pg_replslot/...": Bad file descriptor”.

• Fix possible deadlock at startup when max_prepared_transactions is too small (Heikki Linnakangas)

• Don’t archive useless preallocated WAL files after a timeline switch (Heikki Linnakangas)

• Recursively fsync() the data directory after a crash (Abhijit Menon-Sen, Robert Haas)

This ensures consistency if another crash occurs shortly later. (The second crash would have to be a system-level crash, not just a database crash, for there to be a problem.)

• Fix autovacuum launcher’s possible failure to shut down, if an error occurs after it receives SIGTERM (Álvaro Herrera)

• Fix failure to handle invalidation messages for system catalogs early in session startup (Tom Lane)

This oversight could result in failures in sessions that start concurrently with a VACUUM FULL on a system catalog.

• Fix crash in BackendIdGetTransactionIds() when trying to get status for a backend process that just exited (Tom Lane)

• Cope with unexpected signals in LockBufferForCleanup() (Andres Freund)

This oversight could result in spurious errors about “multiple backends attempting to wait for pin-count 1”.

• Fix crash when doing COPY IN to a table with check constraints that contain whole-row references (Tom Lane)

The known failure case only crashes in 9.4 and up, but there is very similar code in 9.3 and 9.2, so back-patch those branches as well.

• Avoid waiting for WAL flush or synchronous replication during commit of a transaction that was read-only so far as the user is concerned (Andres Freund)

Previously, a delay could occur at commit in transactions that had written WAL due to HOT page pruning, leading to undesirable effects such as sessions getting stuck at startup if all synchronous replicas are down. Sessions have also been observed to get stuck in catchup interrupt processing when using synchronous replication; this will fix that problem as well.

• Avoid busy-waiting with short recovery_min_apply_delay values (Andres Freund)

• Fix crash when manipulating hash indexes on temporary tables (Heikki Linnakangas)

• Fix possible failure during hash index bucket split, if other processes are modifying the index concurrently (Tom Lane)

• Fix memory leaks in GIN index vacuum (Heikki Linnakangas)

• Check for interrupts while analyzing index expressions (Jeff Janes)
Appendix E. Release Notes

**ANALYZE** executes index expressions many times; if there are slow functions in such an expression, it’s desirable to be able to cancel the **ANALYZE** before that loop finishes.

- Ensure `tableoid` of a foreign table is reported correctly when a *READ COMMITTED* recheck occurs after locking rows in **SELECT FOR UPDATE**, **UPDATE**, or **DELETE** (Etsuro Fujita)
- Add the name of the target server to object description strings for foreign-server user mappings (Álvaro Herrera)
- Include the schema name in object identity strings for conversions (Álvaro Herrera)
- Recommend setting `include_realm` to 1 when using Kerberos/GSSAPI/SSPI authentication (Stephen Frost)
  
  Without this, identically-named users from different realms cannot be distinguished. For the moment this is only a documentation change, but it will become the default setting in PostgreSQL 9.5.

- Remove code for matching IPv4 `pg_hba.conf` entries to IPv4-in-IPv6 addresses (Tom Lane)
  
  This hack was added in 2003 in response to a report that some Linux kernels of the time would report IPv4 connections as having IPv4-in-IPv6 addresses. However, the logic was accidentally broken in 9.0. The lack of any field complaints since then shows that it’s not needed anymore. Now we have reports that the broken code causes crashes on some systems, so let’s just remove it rather than fix it. (Had we chosen to fix it, that would make for a subtle and potentially security-sensitive change in the effective meaning of IPv4 `pg_hba.conf` entries, which does not seem like a good thing to do in minor releases.)

- Fix status reporting for terminated background workers that were never actually started (Robert Haas)
- After a database crash, don’t restart background workers that are marked `BGW_NEVER_RESTART` (Amit Khandekar)
- Report WAL flush, not insert, position in IDENTIFY_SYSTEM replication command (Heikki Linnakangas)
  
  This avoids a possible startup failure in `pg_receivexlog`.

- While shutting down service on Windows, periodically send status updates to the Service Control Manager to prevent it from killing the service too soon; and ensure that `pg_ctl` will wait for shutdown (Krystian Bigaj)
- Reduce risk of network deadlock when using libpq’s non-blocking mode (Heikki Linnakangas)
  
  When sending large volumes of data, it’s important to drain the input buffer every so often, in case the server has sent enough response data to cause it to block on output. (A typical scenario is that the server is sending a stream of NOTICE messages during COPY FROM STDIN.) This worked properly in the normal blocking mode, but not so much in non-blocking mode. We’ve modified libpq to opportunistically drain input when it can, but a full defense against this problem requires application cooperation: the application should watch for socket read-ready as well as write-ready conditions, and be sure to call `PQconsumeInput()` upon read-ready.

- In libpq, fix misparsing of empty values in URI connection strings (Thomas Fanghaenel)
- Fix array handling in ecpg (Michael Meskes)
- Fix `psql` to sanely handle URIs and conninfo strings as the first parameter to `\connect` (David Fetter, Andrew Dunstan, Álvaro Herrera)
  
  This syntax has been accepted (but undocumented) for a long time, but previously some parameters might be taken from the old connection instead of the given string, which was agreed to be undesirable.
Appendix E. Release Notes

- Suppress incorrect complaints from psql on some platforms that it failed to write
  ~/.psql_history at exit (Tom Lane)
  This misbehavior was caused by a workaround for a bug in very old (pre-2006) versions of libedit.
  We fixed it by removing the workaround, which will cause a similar failure to appear for anyone
  still using such versions of libedit. Recommendation: upgrade that library, or use libreadline.

- Fix pg_dump’s rule for deciding which casts are system-provided casts that should not be dumped
  (Tom Lane)

- In pg_dump, fix failure to honor -z compression level option together with -Fd (Michael Paquier)

- Make pg_dump consider foreign key relationships between extension configuration tables while
  choosing dump order (Gilles Darold, Michael Paquier, Stephen Frost)
  This oversight could result in producing dumps that fail to reload because foreign key constraints
  are transiently violated.

- Avoid possible pg_dump failure when concurrent sessions are creating and dropping temporary
  functions (Tom Lane)

- Fix dumping of views that are just VALUES(. . .) but have column aliases (Tom Lane)

- Ensure that a view’s replication identity is correctly set to nothing during dump/restore (Marko
  Tiikkaja)
  Previously, if the view was involved in a circular dependency, it might wind up with an incorrect
  replication identity property.

- In pg_upgrade, force timeline 1 in the new cluster (Bruce Momjian)
  This change prevents upgrade failures caused by bogus complaints about missing WAL history
  files.

- In pg_upgrade, check for improperly non-connectable databases before proceeding (Bruce
  Momjian)

- In pg_upgrade, quote directory paths properly in the generated delete_old_cluster script
  (Bruce Momjian)

- In pg_upgrade, preserve database-level freezing info properly (Bruce Momjian)
  This oversight could cause missing-clog-file errors for tables within the postgres and template1
  databases.

- Run pg_upgrade and pg_resetxlog with restricted privileges on Windows, so that they don’t fail
  when run by an administrator (Muhammad Asif Naeem)

- Improve handling of readdir() failures when scanning directories in initdb and pg_basebackup
  (Marco Nenciarini)

- Fix slow sorting algorithm in contrib/intarray (Tom Lane)

- Fix compile failure on Sparc V8 machines (Rob Rowan)

- Silence some build warnings on macOS (Tom Lane)

- Update time zone data files to tzdata release 2015d for DST law changes in Egypt, Mongolia, and
  Palestine, plus historical changes in Canada and Chile. Also adopt revised zone abbreviations for
  the America/Adak zone (HST/HDT not HAST/HADT).
E.22. Release 9.4.1

Release date: 2015-02-05
This release contains a variety of fixes from 9.4.0. For information about new features in the 9.4 major release, see Section E.23.

E.22.1. Migration to Version 9.4.1

A dump/restore is not required for those running 9.4.X.

However, if you are a Windows user and are using the “Norwegian (Bokmål)“ locale, manual action is needed after the upgrade to replace any “Norwegian (Bokmål)_Norway“ or “norwegian-bokmal“ locale names stored in PostgreSQL system catalogs with the plain-ASCII alias “Norwegian_Norway“.

For details see http://wiki.postgresql.org/wiki/Changes_To_Norwegian_Locale

E.22.2. Changes

• Fix buffer overruns in to_char() (Bruce Momjian)

When to_char() processes a numeric formatting template calling for a large number of digits, PostgreSQL would read past the end of a buffer. When processing a crafted timestamp formatting template, PostgreSQL would write past the end of a buffer. Either case could crash the server. We have not ruled out the possibility of attacks that lead to privilege escalation, though they seem unlikely. (CVE-2015-0241)

• Fix buffer overrun in replacement *printf() functions (Tom Lane)

PostgreSQL includes a replacement implementation of printf and related functions. This code will overrun a stack buffer when formatting a floating point number (conversion specifiers e, E, f, F, g or G) with requested precision greater than about 500. This will crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. A database user can trigger such a buffer overrun through the to_char() SQL function. While that is the only affected core PostgreSQL functionality, extension modules that use printf-family functions may be at risk as well.

This issue primarily affects PostgreSQL on Windows. PostgreSQL uses the system implementation of these functions where adequate, which it is on other modern platforms. (CVE-2015-0242)

• Fix buffer overruns in contrib/pgcrypto (Marko Tiikkaja, Noah Misch)

Errors in memory size tracking within the pgcrypto module permitted stack buffer overruns and improper dependence on the contents of uninitialized memory. The buffer overrun cases can crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. (CVE-2015-0243)

• Fix possible loss of frontend/backend protocol synchronization after an error (Heikki Linnakangas)

If any error occurred while the server was in the middle of reading a protocol message from the client, it could lose synchronization and incorrectly try to interpret part of the message’s data as a new protocol message. An attacker able to submit crafted binary data within a command parameter might succeed in injecting his own SQL commands this way. Statement timeout and query cancellation are the most likely sources of errors triggering this scenario. Particularly vulnerable are applications that use a timeout and also submit arbitrary user-crafted data as binary query param-
Appendix E. Release Notes

eters. Disabling statement timeout will reduce, but not eliminate, the risk of exploit. Our thanks to Emil Lenngren for reporting this issue. (CVE-2015-0244)

• Fix information leak via constraint-violation error messages (Stephen Frost)
  Some server error messages show the values of columns that violate a constraint, such as a unique constraint. If the user does not have SELECT privilege on all columns of the table, this could mean exposing values that the user should not be able to see. Adjust the code so that values are displayed only when they came from the SQL command or could be selected by the user. (CVE-2014-8161)

• Lock down regression testing’s temporary installations on Windows (Noah Misch)
  Use SSPI authentication to allow connections only from the OS user who launched the test suite. This closes on Windows the same vulnerability previously closed on other platforms, namely that other users might be able to connect to the test postmaster. (CVE-2014-0067)

• Cope with the Windows locale named “Norwegian (Bokmål)” (Heikki Linnakangas)
  Non-ASCII locale names are problematic since it’s not clear what encoding they should be represented in. Map the troublesome locale name to a plain-ASCII alias, “Norwegian_Norway”. 9.4.0 mapped the troublesome name to “norwegian-bokmal”, but that turns out not to work on all Windows configurations. “Norwegian_Norway” is now recommended instead.

• Fix use-of-already-freed-memory problem in EvalPlanQual processing (Tom Lane)
  In READ COMMITTED mode, queries that lock or update recently-updated rows could crash as a result of this bug.

• Avoid possible deadlock while trying to acquire tuple locks in EvalPlanQual processing (Álvaro Herrera, Mark Kirkwood)

• Fix failure to wait when a transaction tries to acquire a FOR NO KEY EXCLUSIVE tuple lock, while multiple other transactions currently hold FOR SHARE locks (Álvaro Herrera)

• Improve performance of EXPLAIN with large range tables (Tom Lane)

• Fix jsonb Unicode escape processing, and in consequence disallow \u0000 (Tom Lane)
  Previously, the JSON Unicode escape \u0000 was accepted and was stored as those six characters; but that is indistinguishable from what is stored for the input \"\u0000", resulting in ambiguity. Moreover, in cases where de-escaped textual output is expected, such as the \r \n operator, the sequence was printed as \u0000, which does not meet the expectation that JSON escaping would be removed. (Consistent behavior would require emitting a zero byte, but PostgreSQL does not support zero bytes embedded in text strings.) 9.4.0 included an ill-advised attempt to improve this situation by adjusting JSON output conversion rules; but of course that could not fix the fundamental ambiguity, and it turned out to break other usages of Unicode escape sequences. Revert that, and to avoid the core problem, reject \u0000 in jsonb input.

  If a jsonb column contains a \u0000 value stored with 9.4.0, it will henceforth read out as though it were \u0000, which is the other valid interpretation of the data stored by 9.4.0 for this case.

  The json type did not have the storage-ambiguity problem, but it did have the problem of inconsistent de-escaped textual output. Therefore \u0000 will now also be rejected in json values when conversion to de-escaped form is required. This change does not break the ability to store \u0000 in json columns so long as no processing is done on the values. This is exactly parallel to the cases in which non-ASCII Unicode escapes are allowed when the database encoding is not UTF8.

• Fix namespace handling in xpath() (Ali Akbar)
  Previously, the xml value resulting from an xpath() call would not have namespace declarations if the namespace declarations were attached to an ancestor element in the input xml value, rather
than to the specific element being returned. Propagate the ancestral declaration so that the result is
correct when considered in isolation.

- Fix assorted oversights in range-operator selectivity estimation (Emre Hasegeli)
  This patch fixes corner-case “unexpected operator NNNN” planner errors, and improves the selec-
tivity estimates for some other cases.

- Revert unintended reduction in maximum size of a GIN index item (Heikki Linnakangas)
  9.4.0 could fail with “index row size exceeds maximum” errors for data that previous versions
  would accept.

- Fix query-duration memory leak during repeated GIN index rescans (Heikki Linnakangas)

- Fix possible crash when using nonzero gin_fuzzy_search_limit (Heikki Linnakangas)

- Assorted fixes for logical decoding (Andres Freund)

- Fix incorrect replay of WAL parameter change records that report changes in the wal_log_hints
  setting (Petr Jelinek)

- Change “pgstat wait timeout” warning message to be LOG level, and rephrase it to be more under-
  standable (Tom Lane)
  This message was originally thought to be essentially a can’t-happen case, but it occurs often
  enough on our slower buildfarm members to be a nuisance. Reduce it to LOG level, and expend a
  bit more effort on the wording: it now reads “using stale statistics instead of current ones because
  stats collector is not responding”.

- Warn if macOS’s setlocale() starts an unwanted extra thread inside the postmaster (Noah
  Misch)

- Fix libpq’s behavior when /etc/passwd isn’t readable (Tom Lane)
  While doing PQsetdbLogin(), libpq attempts to ascertain the user’s operating system name,
  which on most Unix platforms involves reading /etc/passwd. As of 9.4, failure to do that was
  treated as a hard error. Restore the previous behavior, which was to fail only if the application does
  not provide a database role name to connect as. This supports operation in chroot environments that
  lack an /etc/passwd file.

- Improve consistency of parsing of psql’s special variables (Tom Lane)
  Allow variant spellings of on and off (such as 1/0) for ECHO_HIDDEN and ON_ERROR_ROLLBACK.
  Report a warning for unrecognized values for COMP_KEYWORD_CASE, ECHO, ECHO_HIDDEN,
  HISTCONTROL, ON_ERROR_ROLLBACK, and VERBOSITY. Recognize all values for all
  these variables case-insensitively; previously there was a mishmash of case-sensitive and
  case-insensitive behaviors.

- Fix pg_dump to handle comments on event triggers without failing (Tom Lane)

- Allow parallel pg_dump to use --serializable-deferrable (Kevin Grittner)

- Prevent WAL files created by pg_basebackup -x/-X from being archived again when the
  standby is promoted (Andres Freund)

- Handle unexpected query results, especially NULLs, safely in contrib/tablefunc’s
  connectby() (Michael Paquier)
  connectby() previously crashed if it encountered a NULL key value. It now prints that row but
  doesn’t recurse further.

- Numerous cleanups of warnings from Coverity static code analyzer (Andres Freund, Tatsuo Ishii,
  Marko Kreen, Tom Lane, Michael Paquier)
These changes are mostly cosmetic but in some cases fix corner-case bugs, for example a crash rather than a proper error report after an out-of-memory failure. None are believed to represent security issues.

- Allow `CFLAGS` from configure’s environment to override automatically-supplied `CFLAGS` (Tom Lane)

  Previously, configure would add any switches that it chose of its own accord to the end of the user-specified `CFLAGS` string. Since most compilers process switches left-to-right, this meant that configure’s choices would override the user-specified flags in case of conflicts. That should work the other way around, so adjust the logic to put the user’s string at the end not the beginning.

- Make `pg_regress` remove any temporary installation it created upon successful exit (Tom Lane)

  This results in a very substantial reduction in disk space usage during `make check-world`, since that sequence involves creation of numerous temporary installations.

- Add CST (China Standard Time) to our lists of timezone abbreviations (Tom Lane)

- Update time zone data files to tzdata release 2015a for DST law changes in Chile and Mexico, plus historical changes in Iceland.

---

**E.23. Release 9.4**

**Release date:** 2014-12-18

**E.23.1. Overview**

Major enhancements in PostgreSQL 9.4 include:

- Add `jsonb`, a more capable and efficient data type for storing JSON data
- Add new SQL command `ALTER SYSTEM` for changing `postgresql.conf` configuration file entries
- Reduce lock strength for some `ALTER TABLE` commands
- Allow materialized views to be refreshed without blocking concurrent reads
- Add support for logical decoding of WAL data, to allow database changes to be streamed out in a customizable format
- Allow background worker processes to be dynamically registered, started and terminated

The above items are explained in more detail in the sections below.

**E.23.2. Migration to Version 9.4**

A dump/restore using `pg_dumpall`, or use of `pg_upgrade`, is required for those wishing to migrate data from any previous release.

Version 9.4 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- Tighten checks for multidimensional array input (Bruce Momjian)
Previously, an input array string that started with a single-element sub-array could later contain multi-element sub-arrays, e.g. `{ {1}, {2,3} } :: int []` would be accepted.

- When converting values of type `date`, `timestamp` or `timestamptz` to JSON, render the values in a format compliant with ISO 8601 (Andrew Dunstan)

  Previously such values were rendered according to the current DateStyle setting; but many JSON processors require timestamps to be in ISO 8601 format. If necessary, the previous behavior can be obtained by explicitly casting the datetime value to `text` before passing it to the JSON conversion function.

- The `json #> text []` path extraction operator now returns its lefthand input, not NULL, if the array is empty (Tom Lane)

  This is consistent with the notion that this represents zero applications of the simple field/element extraction operator `->`. Similarly, `json #>> text []` with an empty array merely coerces its lefthand input to `text`.

- Corner cases in the JSON field/element/path extraction operators now return NULL rather than raising an error (Tom Lane)

  For example, applying field extraction to a JSON array now yields NULL not an error. This is more consistent (since some comparable cases such as no-such-field already returned NULL), and it makes it safe to create expression indexes that use these operators, since they will now not throw errors for any valid JSON input.

- Cause consecutive whitespace in `to_timestamp()` and `to_date()` format strings to consume a corresponding number of characters in the input string (whitespace or not), then conditionally consume adjacent whitespace, if not in FX mode (Jeevan Chalke)

  Previously, consecutive whitespace characters in a non-FX format string behaved like a single whitespace character and consumed all adjacent whitespace in the input string. For example, previously a format string of three spaces would consume only the first space in `' 12'`, but it will now consume all three characters.

- Fix `ts_rank_cd()` to ignore stripped lexemes (Alex Hill)

  Previously, stripped lexemes were treated as if they had a default location, producing a rank of dubious usefulness.

- For functions declared to take `VARIADIC "any"`, an actual parameter marked as `VARIADIC` must be of a determinable array type (Pavel Stehule)

  Such parameters can no longer be written as an undecorated string literal or `NULL`; a cast to an appropriate array data type will now be required. Note that this does not affect parameters not marked `VARIADIC`.

- Ensure that whole-row variables expose the expected column names to functions that pay attention to column names within composite arguments (Tom Lane)

  Constructs like `row_to_json(tab.*)` now always emit column names that match the column aliases visible for table `tab` at the point of the call. In previous releases the emitted column names would sometimes be the table’s actual column names regardless of any aliases assigned in the query.

- DISCARD now also discards sequence-related state (Fabrício de Royes Mello, Robert Haas)

- Rename `EXPLAIN ANALYZE`’s “total runtime” output to “execution time” (Tom Lane)

  Now that planning time is also reported, the previous name was confusing.

- `SHOW TIME ZONE` now outputs simple numeric UTC offsets in POSIX timezone format (Tom Lane)
Previously, such timezone settings were displayed as `interval` values. The new output is properly interpreted by `SET TIME ZONE` when passed as a simple string, whereas the old output required special treatment to be re-parsed correctly.

- **Foreign data wrappers that support updating foreign tables must consider the possible presence of `AFTER ROW` triggers (Noah Misch)**

  When an `AFTER ROW` trigger is present, all columns of the table must be returned by updating actions, since the trigger might inspect any or all of them. Previously, foreign tables never had triggers, so the FDW might optimize away fetching columns not mentioned in the `RETURNING` clause (if any).

- **Prevent `CHECK` constraints from referencing system columns, except `tableoid` (Amit Kapila)**

  Previously such check constraints were allowed, but they would often cause errors during restores.

- **Use the last specified recovery target parameter if multiple target parameters are specified (Heikki Linnakangas)**

  Previously, there was an undocumented precedence order among the `recovery_target_xxx` parameters.

- **On Windows, automatically preserve quotes in command strings supplied by the user (Heikki Linnakangas)**

  User commands that did their own quote preservation might need adjustment. This is likely to be an issue for commands used in `archive_command`, `restore_command`, and `COPY TO/FROM PROGRAM`.

- **Remove catalog column `pg_class.reltoastidxid` (Michael Paquier)**

- **Remove catalog column `pg_rewrite.ev_attr` (Kevin Grittner)**

  Per-column rules have not been supported since PostgreSQL 7.3.

- **Remove native support for Kerberos authentication (`--with-krb5`, etc) (Magnus Hagander)**

  The supported way to use Kerberos authentication is with GSSAPI. The native code has been deprecated since PostgreSQL 8.3.

- **In PL/Python, handle domains over arrays like the underlying array type (Rodolfo Campero)**

  Previously such values were treated as strings.

- **Make `libpq`'s `PQconnectdbParams()` and `PQpingParams()` functions process zero-length strings as defaults (Adrian Vondendriesch)**

  Previously, these functions treated zero-length string values as selecting the default in only some cases.

- **Change empty arrays returned by the intarray module to be zero-dimensional arrays (Bruce Momjian)**

  Previously, empty arrays were returned as zero-length one-dimensional arrays, whose text representation looked the same as zero-dimensional arrays ({}), but they acted differently in array operations. intarray’s behavior in this area now matches the built-in array operators.

- **`pg_upgrade` now uses `-U` or `--username` to specify the user name (Bruce Momjian)**

  Previously this option was spelled `-u` or `--user`, but that was inconsistent with other tools.

### E.23.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 9.4 and the previous major release.
E.23.3.1. Server

- Allow background worker processes to be dynamically registered, started and terminated (Robert Haas)
  The new `worker_spi` module shows an example of use of this feature.
- Allow dynamic allocation of shared memory segments (Robert Haas, Amit Kapila)
  This feature is illustrated in the `test_shm mq` module.
- During crash recovery or immediate shutdown, send uncatchable termination signals (SIGKILL) to child processes that do not shut down promptly (MauMau, Álvaro Herrera)
  This reduces the likelihood of leaving orphaned child processes behind after postmaster shutdown, as well as ensuring that crash recovery can proceed if some child processes have become “stuck”.
- Improve randomness of the database system identifier (Tom Lane)
- Make VACUUM properly report dead but not-yet-removable rows to the statistics collector (Hari Babu)
  Previously these were reported as live rows.

E.23.3.1.1. Indexes

- Reduce GIN index size (Alexander Korotkov, Heikki Linnakangas)
  Indexes upgraded via `pg_upgrade` will work fine but will still be in the old, larger GIN format. Use `REINDEX` to recreate old GIN indexes in the new format.
- Improve speed of multi-key GIN lookups (Alexander Korotkov, Heikki Linnakangas)
- Add GiST index support for `inet` and `cidr` data types (Emre Hasegeli)
  Such indexes improve subnet and supernet lookups and ordering comparisons.
- Fix rare race condition in B-tree page deletion (Heikki Linnakangas)
- Make the handling of interrupted B-tree page splits more robust (Heikki Linnakangas)

E.23.3.1.2. General Performance

- Allow multiple backends to insert into WAL buffers concurrently (Heikki Linnakangas)
  This improves parallel write performance.
- Conditionally write only the modified portion of updated rows to WAL (Amit Kapila)
- Improve performance of aggregate functions used as window functions (David Rowley, Florian Pflug, Tom Lane)
- Improve speed of aggregates that use numeric state values (Hadi Moshayedi)
- Attempt to freeze tuples when tables are rewritten with `CLUSTER` or `VACUUM FULL` (Robert Haas, Andres Freund)
  This can avoid the need to freeze the tuples in the future.
- Improve speed of COPY with default `nextval()` columns (Simon Riggs)
- Improve speed of accessing many different sequences in the same session (David Rowley)
• Raise hard limit on the number of tuples held in memory during sorting and B-tree index builds (Noah Misch)

• Reduce memory allocated by PL/pgSQL DO blocks (Tom Lane)

• Make the planner more aggressive about extracting restriction clauses from mixed AND/OR clauses (Tom Lane)

• Disallow pushing volatile WHERE clauses down into DISTINCT subqueries (Tom Lane)

Pushing down a WHERE clause can produce a more efficient plan overall, but at the cost of evaluating the clause more often than is implied by the text of the query; so don’t do it if the clause contains any volatile functions.

• Auto-resize the catalog caches (Heikki Linnakangas)

This reduces memory consumption for sessions accessing only a few tables, and improves performance for sessions accessing many tables.

E.23.3.1.3. Monitoring

• Add pg_stat_archiver system view to report WAL archiver activity (Gabriele Bartolini)

• Add n_mod_since_analyze columns to pg_stat_all_tables and related system views (Mark Kirkwood)

These columns expose the system’s estimate of the number of changed tuples since the table’s last ANALYZE. This estimate drives decisions about when to auto-analyze.

• Add backend_xid and backend_xmin columns to the system view pg_stat_activity, and a backend_xmin column to pg_stat_replication (Christian Kruse)

E.23.3.1.4. SSL

• Add support for SSL ECDH key exchange (Marko Kreen)

This allows use of Elliptic Curve keys for server authentication. Such keys are faster and have better security than RSA keys. The new configuration parameter ssl_ecdh_curve controls which curve is used for ECDH.

• Improve the default ssl_ciphers setting (Marko Kreen)

• By default, the server not the client now controls the preference order of SSL ciphers (Marko Kreen)

Previously, the order specified by ssl_ciphers was usually ignored in favor of client-side defaults, which are not configurable in most PostgreSQL clients. If desired, the old behavior can be restored via the new configuration parameter ssl_prefer_server_ciphers.

• Make log_connections show SSL encryption information (Andreas Kunert)

• Improve SSL renegotiation handling (Álvaro Herrera)

E.23.3.1.5. Server Settings

• Add new SQL command ALTER SYSTEM for changing postgresql.conf configuration file entries (Amit Kapila)
Previously such settings could only be changed by manually editing `postgresql.conf`.

- Add autovacuum_work_mem configuration parameter to control the amount of memory used by autovacuum workers (Peter Geoghegan)
- Add huge_pages parameter to allow using huge memory pages on Linux (Christian Kruse, Richard Poole, Abhijit Menon-Sen)
  
  This can improve performance on large-memory systems.
- Add max_worker_processes parameter to limit the number of background workers (Robert Haas)
  
  This is helpful in configuring a standby server to have the required number of worker processes (the same as the primary).
- Add superuser-only session_preload_libraries parameter to load libraries at session start (Peter Eisentraut)
  
  In contrast to local_preload_libraries, this parameter can load any shared library, not just those in the `@libdir/plugins` directory.
- Add wal_log_hints parameter to enable WAL logging of hint-bit changes (Sawada Masahiko)
  
  Hint bit changes are not normally logged, except when checksums are enabled. This is useful for external tools like pg_rewind.
- Increase the default settings of work_mem and maintenance_work_mem by four times (Bruce Momjian)
  
  The new defaults are 4MB and 64MB respectively.
- Increase the default setting of effective_cache_size to 4GB (Bruce Momjian, Tom Lane)
- Allow printf-style space padding to be specified in log_line_prefix (David Rowley)
- Allow terabyte units (TB) to be used when specifying configuration variable values (Simon Riggs)
- Show PIDs of lock holders and waiters and improve information about relations in log_lock_waits log messages (Christian Kruse)
- Reduce server logging level when loading shared libraries (Peter Geoghegan)
  
  The previous level was LOG, which was too verbose for libraries loaded per-session.
- On Windows, make SQL_ASCII-encoded databases and server processes (e.g., postmaster) emit messages in the character encoding of the server’s Windows user locale (Alexander Law, Noah Misch)
  
  Previously these messages were output in the Windows ANSI code page.

**E.23.3.2. Replication and Recovery**

- Add replication slots to coordinate activity on streaming standbys with the node they are streaming from (Andres Freund, Robert Haas)
  
  Replication slots allow preservation of resources like WAL files on the primary until they are no longer needed by standby servers.
- Add recovery parameter recovery_min_apply_delay to delay replication (Robert Haas, Fabrízio de Royes Mello, Simon Riggs)
  
  Delaying replay on standby servers can be useful for recovering from user errors.
• Add recovery_target option immediate to stop WAL recovery as soon as a consistent state is reached (MauMau, Heikki Linnakangas)

• Improve recovery target processing (Heikki Linnakangas)
  The timestamp reported by pg_last_xact_replay_timestamp() now reflects already-committed records, not transactions about to be committed. Recovering to a restore point now replays the restore point, rather than stopping just before the restore point.

• pg_switch_xlog() now clears any unused trailing space in the old WAL file (Heikki Linnakangas)
  This improves the compression ratio for WAL files.

• Report failure return codes from external recovery commands (Peter Eisentraut)
• Reduce spinlock contention during WAL replay (Heikki Linnakangas)
• Write WAL records of running transactions more frequently (Andres Freund)
  This allows standby servers to start faster and clean up resources more aggressively.

E.23.3.2.1. Logical Decoding

Logical decoding allows database changes to be streamed in a configurable format. The data is read from the WAL and transformed into the desired target format. To implement this feature, the following changes were made:

• Add support for logical decoding of WAL data, to allow database changes to be streamed out in a customizable format (Andres Freund)
• Add new wal_level setting logical to enable logical change-set encoding in WAL (Andres Freund)
• Add table-level parameter REPLICA IDENTITY to control logical replication (Andres Freund)
• Add relation option user_catalog_table to identify user-created tables involved in logical change-set encoding (Andres Freund)
• Add pg_recvlogical application to receive logical-decoding data (Andres Freund)
• Add test_decoding module to illustrate logical decoding at the SQL level (Andres Freund)

E.23.3.3. Queries

• Add WITH ORDINALITY syntax to number the rows returned from a set-returning function in the FROM clause (Andrew Gierth, David Fetter)
  This is particularly useful for functions like unnest().
• Add ROWS FROM() syntax to allow horizontal concatenation of set-returning functions in the FROM clause (Andrew Gierth)
• Allow SELECT to have an empty target list (Tom Lane)
  This was added so that views that select from a table with zero columns can be dumped and restored correctly.
• Ensure that SELECT ... FOR UPDATE NOWAIT does not wait in corner cases involving already-concurrently-updated tuples (Craig Ringer and Thomas Munro)
E.23.3.4. Utility Commands

- Add `DISCARD SEQUENCES` command to discard cached sequence-related state (Fabrízio de Royes Mello, Robert Haas)
  
  `DISCARD ALL` will now also discard such information.

- Add `FORCE NULL` option to `COPY FROM`, which causes quoted strings matching the specified null string to be converted to NULLs in `CSV` mode (Ian Barwick, Michael Paquier)
  
  Without this option, only unquoted matching strings will be imported as null values.

- Issue warnings for commands used outside of transaction blocks when they can have no effect (Bruce Momjian)

  New warnings are issued for `SET LOCAL`, `SET CONSTRAINTS`, `SET TRANSACTION` and `ABORT` when used outside a transaction block.

E.23.3.4.1. EXPLAIN

- Make `EXPLAIN ANALYZE` show planning time (Andreas Karlsson)

- Make `EXPLAIN` show the grouping columns in Agg and Group nodes (Tom Lane)

- Make `EXPLAIN ANALYZE` show exact and lossy block counts in bitmap heap scans (Etsuro Fujita)

E.23.3.4.2. Views

- Allow a materialized view to be refreshed without blocking other sessions from reading the view meanwhile (Kevin Grittner)

  This is done with `REFRESH MATERIALIZED VIEW CONCURRENTLY`.

- Allow views to be automatically updated even if they contain some non-updatable columns (Dean Rasheed)

  Previously the presence of non-updatable output columns such as expressions, literals, and function calls prevented automatic updates. Now `INSERTS`, `UPDATES` and `DELETES` are supported, provided that they do not attempt to assign new values to any of the non-updatable columns.

- Allow control over whether `INSERTS` and `UPDATES` can add rows to an auto-updatable view that would not appear in the view (Dean Rasheed)

  This is controlled with the new `CREATE VIEW` clause `WITH CHECK OPTION`.

- Allow security barrier views to be automatically updatable (Dean Rasheed)

E.23.3.5. Object Manipulation

- Support triggers on foreign tables (Ronan Dunklau)

- Allow moving groups of objects from one tablespace to another using the `ALL IN TABLESPACE` ...

  `... SET TABLESPACE` form of `ALTER TABLE`, `ALTER INDEX`, or `ALTER MATERIALIZED VIEW` (Stephen Frost)

- Allow changing foreign key constraint deferrability via `ALTER TABLE` ...

  `ALTER CONSTRAINT` (Simon Riggs)
Appendix E. Release Notes

• Reduce lock strength for some ALTER TABLE commands (Simon Riggs, Noah Misch, Robert Haas)
  
  Specifically, VALIDATE CONSTRAINT, CLUSTER ON, SET WITHOUT CLUSTER, ALTER COLUMN SET STATISTICS, ALTER COLUMN SET (attribute_option), ALTER COLUMN RESET (attribute_option) no longer require ACCESS EXCLUSIVE locks.

• Allow tablespace options to be set in CREATE TABLESPACE (Vik Fearing)
  Formerly these options could only be set via ALTER TABLESPACE.

• Allow CREATE AGGREGATE to define the estimated size of the aggregate’s transition state data (Hadi Moshayedi)
  Proper use of this feature allows the planner to better estimate how much memory will be used by aggregates.

• Fix DROP IF EXISTS to avoid errors for non-existent objects in more cases (Pavel Stehule, Dean Rasheed)

• Improve how system relations are identified (Andres Freund, Robert Haas)
  Previously, relations once moved into the pg_catalog schema could no longer be modified or dropped.

E.23.3.6. Data Types

• Fully implement the line data type (Peter Eisentraut)
  The line segment data type (lseg) has always been fully supported. The previous line data type (which was enabled only via a compile-time option) is not binary or dump-compatible with the new implementation.

• Add pg_lsn data type to represent a WAL log sequence number (LSN) (Robert Haas, Michael Paquier)

• Allow single-point polygons to be converted to circles (Bruce Momjian)

• Support time zone abbreviations that change UTC offset from time to time (Tom Lane)
  Previously, PostgreSQL assumed that the UTC offset associated with a time zone abbreviation (such as EST) never changes in the usage of any particular locale. However this assumption fails in the real world, so introduce the ability for a zone abbreviation to represent a UTC offset that sometimes changes. Update the zone abbreviation definition files to make use of this feature in timezone locales that have changed the UTC offset of their abbreviations since 1970 (according to the IANA timezone database). In such timezones, PostgreSQL will now associate the correct UTC offset with the abbreviation depending on the given date.

• Allow 5+ digit years for non-ISO timestamp and date strings, where appropriate (Bruce Momjian)

• Add checks for overflow/underflow of interval values (Bruce Momjian)

E.23.3.6.1. JSON

• Add jsonb, a more capable and efficient data type for storing JSON data (Oleg Bartunov, Teodor Sigaev, Alexander Korotkov, Peter Geoghegan, Andrew Dunstan)
Appendix E. Release Notes

This new type allows faster access to values within a JSON document, and faster and more useful
indexing of JSON columns. Scalar values in jsonb documents are stored as appropriate scalar
SQL types, and the JSON document structure is pre-parsed rather than being stored as text as in the
original json data type.

- Add new JSON functions to allow for the construction of arbitrarily complex JSON trees (Andrew
  Dunstan, Laurence Rowe)
  
  New functions include json_array_elements_text(), json_build_array(),
  json_object(), json_object_agg(), json_to_record(), and json_to_recordset().

- Add json_typeof() to return the data type of a json value (Andrew Tipton)

E.23.3.7. Functions

- Add pg_sleep_for(interval) and pg_sleep_until(timestamp) to specify delays more
  flexibly (Vik Fearing, Julien Rouhaud)
  
  The existing pg_sleep() function only supports delays specified in seconds.

- Add cardinality() function for arrays (Marko Tiikkaja)
  
  This returns the total number of elements in the array, or zero for an array with no elements.

- Add SQL functions to allow large object reads/writes at arbitrary offsets (Pavel Stehule)

- Add unnest() to take multiple arguments, which are individually unnested then horizontally
  concatenated (Andrew Gierth)

- Add functions to construct times, dates, timestamps, timestamptzs, and intervals from
  individual values, rather than strings (Pavel Stehule)
  
  These functions’ names are prefixed with make_, e.g. make_date().

- Make to_char()’s TZ format specifier return a useful value for simple numeric time zone offsets
  (Tom Lane)
  
  Previously, to_char(CURRENT_TIMESTAMP, ’TZ’) returned an empty string if the timezone
  was set to a constant like -4.

- Add timezone offset format specifier OF to to_char() (Bruce Momjian)

- Improve the random seed used for random() (Honza Horak)

- Tighten validity checking for Unicode code points in chr(int) (Tom Lane)
  
  This function now only accepts values that are valid UTF8 characters according to RFC 3629.

E.23.3.7.1. System Information Functions

- Add functions for looking up objects in pg_class, pg_proc, pg_type, and pg_operator that
do not generate errors for non-existent objects (Yugo Nagata, Nozomi Anzai, Robert Haas)
  
  For example, to_regclass() does a lookup in pg_class similarly to the regclass input func-
tion, but it returns NULL for a non-existent object instead of failing.

- Add function pg_filenode_relation() to allow for more efficient lookup of relation names
  from filenodes (Andres Freund)
• Add parameter_default column to information_schema.parameters view (Peter Eisentraut)
• Make information_schema.schemata show all accessible schemas (Peter Eisentraut)
  Previously it only showed schemas owned by the current user.

**E.23.3.7.2. Aggregates**

• Add control over which rows are passed into aggregate functions via the FILTER clause (David Fetter)
• Support ordered-set (WITHIN GROUP) aggregates (Atri Sharma, Andrew Gierth, Tom Lane)
• Add standard ordered-set aggregates percentile_cont(), percentile_disc(), mode(), rank(), dense_rank(), percent_rank(), and cume_dist() (Atri Sharma, Andrew Gierth)
• Support VARIADIC aggregate functions (Tom Lane)
• Allow polymorphic aggregates to have non-polymorphic state data types (Tom Lane)
  This allows proper declaration in SQL of aggregates like the built-in aggregate array_agg().

**E.23.3.8. Server-Side Languages**

• Add event trigger support to PL/Perl and PL/Tcl (Dimitri Fontaine)
• Convert numeric values to decimal in PL/Python (Szymon Guz, Ronan Dunklau)
  Previously such values were converted to Python float values, risking loss of precision.

**E.23.3.8.1. PL/pgSQL Server-Side Language**

• Add ability to retrieve the current PL/pgSQL call stack using GET DIAGNOSTICS (Pavel Stehule, Stephen Frost)
• Add option print_strict_params to display the parameters passed to a query that violated a STRICT constraint (Marko Tiikkaja)
• Add variables plpgsql.extra_warnings and plpgsql.extra_errors to enable additional PL/pgSQL warnings and errors (Marko Tiikkaja, Petr Jelinek)
  Currently only warnings/errors about shadowed variables are available.

**E.23.3.9. libpq**

• Make libpq’s PQconndefaults() function ignore invalid service files (Steve Singer, Bruce Momjian)
  Previously it returned NULL if an incorrect service file was encountered.
• Accept TLS protocol versions beyond TLSv1 in libpq (Marko Kreen)
E.23.3.10. Client Applications

- Add createuser option `-g` to specify role membership (Christopher Browne)
- Add vacuumdb option `--analyze-in-stages` to analyze in stages of increasing granularity (Peter Eisentraut)
  This allows minimal statistics to be created quickly.
- Make `pg_resetxlog` with option `-n` output current and potentially changed values (Rajeev Rastogi)
- Make initdb throw error for incorrect locale settings, rather than silently falling back to a default choice (Tom Lane)
- Make `pg_ctl` return exit code 4 for an inaccessible data directory (Amit Kapila, Bruce Momjian)
  This behavior more closely matches the Linux Standard Base (LSB) Core Specification.
- On Windows, ensure that a non-absolute `-D` path specification is interpreted relative to `pg_ctl`’s current directory (Kumar Rajeev Rastogi)
  Previously it would be interpreted relative to whichever directory the underlying Windows service was started in.
- Allow `sizeof()` in ECPG C array definitions (Michael Meskes)
- Make ECPG properly handle nesting of C-style comments in both C and SQL text (Michael Meskes)

E.23.3.10.1. psql

- Suppress “No rows” output in `psql` expanded mode when the footer is disabled (Bruce Momjian)
- Allow Control-C to abort `psql` when it’s hung at connection startup (Peter Eisentraut)

E.23.3.10.1.1. Backslash Commands

- Make `psql`’s `\db+` show tablespace options (Magnus Hagander)
- Make `\do+` display the functions that implement the operators (Marko Tiikkaja)
- Make `\d+` output an OID line only if an oid column exists in the table (Bruce Momjian)
  Previously, the presence or absence of an oid column was always reported.
- Make `\d` show disabled system triggers (Bruce Momjian)
  Previously, if you disabled all triggers, only user triggers would show as disabled.
- Fix `\copy` to no longer require a space between stdin and a semicolon (Etsuro Fujita)
- Output the row count at the end of `\copy`, just like `COPY` already did (Kumar Rajeev Rastogi)
- Fix `\conninfo` to display the server’s IP address for connections using `hostaddr` (Fujii Masao)
  Previously `\conninfo` could not display the server’s IP address in such cases.
- Show the SSL protocol version in `\conninfo` (Marko Kreen)
- Add tab completion for `\pset` (Pavel Stehule)
- Allow `\pset` with no arguments to show all settings (Gilles Darold)
- Make `\a` display the name of the history file it wrote without converting it to an absolute path (Tom Lane)
The code previously attempted to convert a relative file name to an absolute path for display, but frequently got it wrong.

**E.23.3.10.2. pg_dump**

- Allow pg_restore options `-I`, `-P`, `-T` and `-n` to be specified multiple times (Heikki Linnakangas)
  This allows multiple objects to be restored in one operation.
- Optionally add `IF EXISTS` clauses to the `DROP` commands emitted when removing old objects during a restore (Pavel Stehule)
  This change prevents unnecessary errors when removing old objects. The new `--if-exists` option for `pg_dump`, `pg_dumpall`, and `pg_restore` is only available when `--clean` is also specified.

**E.23.3.10.3. pg_basebackup**

- Add `pg_basebackup` option `--xlogdir` to specify the `pg_xlog` directory location (Haribabu Kommi)
- Allow `pg_basebackup` to relocate tablespaces in the backup copy (Steeve Lennmark)
  This is particularly useful for using `pg_basebackup` on the same machine as the primary.
- Allow network-stream base backups to be throttled (Antonin Houska)
  This can be controlled with the `pg_basebackup` `--max-rate` parameter.

**E.23.3.11. Source Code**

- Improve the way tuples are frozen to preserve forensic information (Robert Haas, Andres Freund)
  This change removes the main objection to freezing tuples as soon as possible. Code that inspects tuple flag bits will need to be modified.
- No longer require function prototypes for functions marked with the `PG_FUNCTION_INFO_V1` macro (Peter Eisentraut)
  This change eliminates the need to write boilerplate prototypes. Note that the `PG_FUNCTION_INFO_V1` macro must appear before the corresponding function definition to avoid compiler warnings.
- Remove `SnapshotNow` and `HeapTupleSatisfiesNow()` (Robert Haas)
  All existing uses have been switched to more appropriate snapshot types. Catalog scans now use MVCC snapshots.
- Add an API to allow memory allocations over one gigabyte (Noah Misch)
- Add `psprintf()` to simplify memory allocation during string composition (Peter Eisentraut, Tom Lane)
- Support `printf()` size modifier `z` to print `size_t` values (Andres Freund)
- Change API of `appendStringInfoVA()` to better use `vsnprintf()` (David Rowley, Tom Lane)
- Allow new types of external toast datums to be created (Andres Freund)
Appendix E. Release Notes

- Add single-reader, single-writer, lightweight shared message queue (Robert Haas)
- Improve spinlock speed on x86_64 CPUs (Heikki Linnakangas)
- Remove spinlock support for unsupported platforms SINIX, Sun3, and NS32K (Robert Haas)
- Remove IRIX port (Robert Haas)
- Reduce the number of semaphores required by --disable-spinlocks builds (Robert Haas)
- Rewrite duplicate_oids Unix shell script in Perl (Andrew Dunstan)
- Add Test Anything Protocol (TAP) tests for client programs (Peter Eisentraut)
  Currently, these tests are run by make check-world only if the --enable-tap-tests option was given to configure. This might become the default behavior in some future release.
- Add make targets check-tests and installcheck-tests, which allow selection of individual tests to be run (Andrew Dunstan)
- Remove maintainer-check makefile rule (Peter Eisentraut)
  The default build rules now include all the formerly-optional tests.
- Improve support for VPATH builds of PGXS modules (Cédric Villemain, Andrew Dunstan, Peter Eisentraut)
- Upgrade to Autoconf 2.69 (Peter Eisentraut)
- Add a configure flag that appends custom text to the PG_VERSION string (Oskari Saarenmaa)
  This is useful for packagers building custom binaries.
- Improve DocBook XML validity (Peter Eisentraut)
- Fix various minor security and sanity issues reported by the Coverity scanner (Stephen Frost)
- Improve detection of invalid memory usage when testing PostgreSQL with Valgrind (Noah Misch)
- Improve sample Emacs configuration file emacs.samples (Peter Eisentraut)
  Also add .dir-locals.el to the top of the source tree.
- Allow pgindent to accept a command-line list of typedefs (Bruce Momjian)
- Make pgindent smarter about blank lines around preprocessor conditionals (Bruce Momjian)
- Avoid most uses of dlltool in Cygwin and Mingw builds (Marco Atzeri, Hiroshi Inoue)
- Support client-only installs in MSVC (Windows) builds (MauMau)

E.23.3.12. Additional Modules

- Add pg_prewarm extension to preload relation data into the shared buffer cache at server start (Robert Haas)
  This allows reaching full operating performance more quickly.
- Add UUID random number generator gen_random_uuid() to pgcrypto (Oskari Saarenmaa)
  This allows creation of version 4 UUIDs without requiring installation of uuid-ossp.
- Allow uuid-ossp to work with the BSD or e2fsprogs UUID libraries, not only the OSSP UUID library (Matteo Beccati)
  This improves the uuid-ossp module’s portability since it no longer has to have the increasingly-obsolete OSSP library. The module’s name is now rather a misnomer, but we won’t change it.
• Add option to auto_explain to include trigger execution time (Horiguchi Kyotaro)
• Fix pgstattuple to not report rows from uncommitted transactions as dead (Robert Haas)
• Make pgstattuple functions use regclass-type arguments (Satoshi Nagayasu)
  While text-type arguments are still supported, they may be removed in a future major release.
• Improve consistency of pgrowlocks output to honor snapshot rules more consistently (Robert Haas)
• Improve pg_trgm’s choice of trigrams for indexed regular expression searches (Alexander Kotrotkov)
  This change discourages use of trigrams containing whitespace, which are usually less selective.
• Allow pg_xlogdump to report a live log stream with --follow (Heikki Linnakangas)
• Store cube data more compactly (Stas Kelvich)
  Existing data must be dumped/restore to use the new format. The old format can still be read.
• Reduce vacuumlo client-side memory usage by using a cursor (Andrew Dunstan)
• Dramatically reduce memory consumption in pg_upgrade (Bruce Momjian)
• Pass pg_upgrade’s user name (-U) option to generated analyze scripts (Bruce Momjian)

E.23.3.12.1. pgbench

• Remove line length limit for pgbench scripts (Sawada Masahiko)
  The previous line limit was BUFSIZ.
• Add long option names to pgbench (Fabien Coelho)
• Add pgbench option --rate to control the transaction rate (Fabien Coelho)
• Add pgbench option --progress to print periodic progress reports (Fabien Coelho)

E.23.3.12.2. pg_stat_statements

• Make pg_stat_statements use a file, rather than shared memory, for query text storage (Peter Geoghegan)
  This removes the previous limitation on query text length, and allows a higher number of unique
  statements to be tracked by default.
• Allow reporting of pg_stat_statements’s internal query hash identifier (Daniel Farina, Sameer
  Thakur, Peter Geoghegan)
• Add the ability to retrieve all pg_stat_statements information except the query text (Peter Geoghegan)
  This allows monitoring tools to fetch query text only for just-created entries, improving performance
  during repeated querying of the statistics.
• Make pg_stat_statements ignore DEALLOCATE commands (Fabien Coelho)
  It already ignored PREPARE, as well as planning time in general, so this seems more consistent.
• Save the statistics file into $PGDATA/pg_stat at server shutdown, rather than $PGDATA/global
  (Fujii Masao)
E.24. Prior Releases

Release notes for prior release branches can be found at
https://www.postgresql.org/docs/release/
Appendix F. Additional Supplied Modules

This appendix and the next one contain information regarding the modules that can be found in the contrib directory of the PostgreSQL distribution. These include porting tools, analysis utilities, and plug-in features that are not part of the core PostgreSQL system, mainly because they address a limited audience or are too experimental to be part of the main source tree. This does not preclude their usefulness.

This appendix covers extensions and other server plug-in modules found in contrib. Appendix G covers utility programs.

When building from the source distribution, these components are not built automatically, unless you build the "world" target (see step 2). You can build and install all of them by running:

```
make
make install
```

in the contrib directory of a configured source tree; or to build and install just one selected module, do the same in that module’s subdirectory. Many of the modules have regression tests, which can be executed by running:

```
make check
```

before installation or

```
make installcheck
```

once you have a PostgreSQL server running.

If you are using a pre-packaged version of PostgreSQL, these modules are typically made available as a separate subpackage, such as postgresql-contrib.

Many modules supply new user-defined functions, operators, or types. To make use of one of these modules, after you have installed the code you need to register the new SQL objects in the database system. In PostgreSQL 9.1 and later, this is done by executing a CREATE EXTENSION command. In a fresh database, you can simply do

```
CREATE EXTENSION module_name;
```

This command must be run by a database superuser. This registers the new SQL objects in the current database only, so you need to run this command in each database that you want the module’s facilities to be available in. Alternatively, run it in database template1 so that the extension will be copied into subsequently-created databases by default.

Many modules allow you to install their objects in a schema of your choice. To do that, add SCHEMA schema_name to the CREATE EXTENSION command. By default, the objects will be placed in your current creation target schema, which in turn defaults to public.

If your database was brought forward by dump and reload from a pre-9.1 version of PostgreSQL, and you had been using the pre-9.1 version of the module in it, you should instead do

```
CREATE EXTENSION module_name FROM unpackaged;
```
This will update the pre-9.1 objects of the module into a proper extension object. Future updates to the module will be managed by ALTER EXTENSION. For more information about extension updates, see Section 35.15.

Note, however, that some of these modules are not “extensions” in this sense, but are loaded into the server in some other way, for instance by way of shared_preload_libraries. See the documentation of each module for details.

F.1. adminpack

adminpack provides a number of support functions which pgAdmin and other administration and management tools can use to provide additional functionality, such as remote management of server log files. Use of all these functions is restricted to superusers.

The functions shown in Table F-1 provide write access to files on the machine hosting the server. (See also the functions in Table 9-72, which provide read-only access.) Only files within the database cluster directory can be accessed, but either a relative or absolute path is allowable.

Table F-1. adminpack Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pg_catalog.pg_file_write(filename text, data text, append boolean)</code></td>
<td>bigint</td>
<td>Write, or append to, a text file</td>
</tr>
<tr>
<td><code>pg_catalog.pg_file_rename(oldname text, newname text [, archivename text])</code></td>
<td>boolean</td>
<td>Rename a file</td>
</tr>
<tr>
<td><code>pg_catalog.pg_file_unlink(filename text)</code></td>
<td>boolean</td>
<td>Remove a file</td>
</tr>
<tr>
<td><code>pg_catalog.pg_logdir_ls()</code></td>
<td>setof record</td>
<td>List the log files in the log_directory directory</td>
</tr>
</tbody>
</table>

`pg_file_write` writes the specified data into the file named by filename. If append is false, the file must not already exist. If append is true, the file can already exist, and will be appended to if so. Returns the number of bytes written.

`pg_file_rename` renames a file. If archivename is omitted or NULL, it simply renames oldname to newname (which must not already exist). If archivename is provided, it first renames newname to archivename (which must not already exist), and then renames oldname to newname. In event of failure of the second rename step, it will try to rename archivename back to newname before reporting the error. Returns true on success, false if the source file(s) are not present or not writable; other cases throw errors.

`pg_file_unlink` removes the specified file. Returns true on success, false if the specified file is not present or the unlink() call fails; other cases throw errors.

`pg_logdir_ls` returns the start timestamps and path names of all the log files in the log_directory directory. The log_filename parameter must have its default setting (postgresql-%Y-%m-%d_%H%M%S.log) to use this function.

The functions shown in Table F-2 are deprecated and should not be used in new applications; instead use those shown in Table 9-64 and Table 9-72. These functions are provided in adminpack only for compatibility with old versions of pgAdmin.
Table F-2. Deprecated adminpack Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pg_catalog.pg_file_read(filename text, offset bigint, nbytes bigint)</td>
<td>text</td>
<td>Alternate name for pg_read_file()</td>
</tr>
<tr>
<td>pg_catalog.pg_file_length(filename text)</td>
<td>bigint</td>
<td>Same as size column returned by pg_stat_file()</td>
</tr>
<tr>
<td>pg_catalog.pg_logfile_rotate()</td>
<td>integer</td>
<td>Alternate name for pg_rotate_logfile(), but note that it returns integer 0 or 1 rather than boolean</td>
</tr>
</tbody>
</table>

**F.2. auth_delay**

auth_delay causes the server to pause briefly before reporting authentication failure, to make brute-force attacks on database passwords more difficult. Note that it does nothing to prevent denial-of-service attacks, and may even exacerbate them, since processes that are waiting before reporting authentication failure will still consume connection slots.

In order to function, this module must be loaded via shared_preload_libraries in postgresql.conf.

**F.2.1. Configuration Parameters**

auth_delay.milliseconds (int)

The number of milliseconds to wait before reporting an authentication failure. The default is 0.

These parameters must be set in postgresql.conf, Typical usage might be:

```sql
# postgresql.conf
shared_preload_libraries = 'auth_delay'
auth_delay.milliseconds = '500'
```

**F.2.2. Author**

KaiGai Kohei <kaigai@ak.jp.nec.com>

**F.3. auto_explain**

The auto_explain module provides a means for logging execution plans of slow statements automatically, without having to run EXPLAIN by hand. This is especially helpful for tracking down un-optimized queries in large applications.

The module provides no SQL-accessible functions. To use it, simply load it into the server. You can load it into an individual session:
LOAD 'auto_explain';

(You must be superuser to do that.) More typical usage is to preload it into some or all sessions by including `auto_explain` in `session_preload_libraries` or `shared_preload_libraries` in `postgresql.conf`. Then you can track unexpectedly slow queries no matter when they happen. Of course there is a price in overhead for that.

### F.3.1. Configuration Parameters

There are several configuration parameters that control the behavior of `auto_explain`. Note that the default behavior is to do nothing, so you must set at least `auto_explain.log_min_duration` if you want any results.

- **`auto_explain.log_min_duration`**: (integer)
  
  `auto_explain.log_min_duration` is the minimum statement execution time, in milliseconds, that will cause the statement’s plan to be logged. Setting this to zero logs all plans. Minus-one (the default) disables logging of plans. For example, if you set it to 250ms then all statements that run 250ms or longer will be logged. Only superusers can change this setting.

- **`auto_explain.log_analyze`**: (boolean)
  
  `auto_explain.log_analyze` causes `EXPLAIN ANALYZE` output, rather than just `EXPLAIN` output, to be printed when an execution plan is logged. This parameter is off by default. Only superusers can change this setting.

  **Note**: When this parameter is on, per-plan-node timing occurs for all statements executed, whether or not they run long enough to actually get logged. This can have an extremely negative impact on performance. Turning off `auto_explain.log_timing` ameliorates the performance cost, at the price of obtaining less information.

- **`auto_explain.log_buffers`**: (boolean)
  
  `auto_explain.log_buffers` controls whether buffer usage statistics are printed when an execution plan is logged; it’s equivalent to the `BUFFERS` option of `EXPLAIN`. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

- **`auto_explain.log_timing`**: (boolean)
  
  `auto_explain.log_timing` controls whether per-node timing information is printed when an execution plan is logged; it’s equivalent to the `TIMING` option of `EXPLAIN`. The overhead of repeatedly reading the system clock can slow down queries significantly on some systems, so it may be useful to set this parameter to off when only actual row counts, and not exact times, are needed. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is on by default. Only superusers can change this setting.

- **`auto_explain.log_triggers`**: (boolean)
  
  `auto_explain.log_triggers` causes trigger execution statistics to be included when an execution plan is logged. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.
auto_explain.logVerbose (boolean)

auto_explain.logVerbose controls whether verbose details are printed when an execution plan is logged; it’s equivalent to the VERBOSE option of EXPLAIN. This parameter is off by default. Only superusers can change this setting.

auto_explain.logFormat (enum)

auto_explain.logFormat selects the EXPLAIN output format to be used. The allowed values are text, xml, json, and yaml. The default is text. Only superusers can change this setting.

auto_explain.logNestedStatements (boolean)

auto_explain.logNestedStatements causes nested statements (statements executed inside a function) to be considered for logging. When it is off, only top-level query plans are logged. This parameter is off by default. Only superusers can change this setting.

In ordinary usage, these parameters are set in postgresql.conf, although superusers can alter them on-the-fly within their own sessions. Typical usage might be:

```plaintext
# postgresql.conf
session_preload_libraries = 'auto_explain'
auto_explain.log_min_duration = '3s'
```

F.3.2. Example

postgres=# LOAD 'auto_explain';
postgres=# SET auto_explain.log_min_duration = 0;
postgres=# SET auto_explain.log_analyze = true;
postgres=# SELECT count(*)
FROM pg_class, pg_index
WHERE oid = indrelid AND indisunique;

This might produce log output such as:

```
LOG: duration: 3.651 ms plan:
Query Text: SELECT count(*)
FROM pg_class, pg_index
WHERE oid = indrelid AND indisunique;

F.3.3. Author

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>
F.4. btree_gin

btree_gin provides sample GIN operator classes that implement B-tree equivalent behavior for the data types int2, int4, int8, float4, float8, timestamp with time zone, timestamp without time zone, time with time zone, time without time zone, date, interval, oid, money, "char", varchar, text, bytea, bit, varbit, macaddr, inet, and cidr.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they are useful for GIN testing and as a base for developing other GIN operator classes. Also, for queries that test both a GIN-indexable column and a B-tree-indexable column, it might be more efficient to create a multicolumn GIN index that uses one of these operator classes than to create two separate indexes that would have to be combined via bitmap ANDing.

F.4.1. Example Usage

CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING gin (a);
-- query
SELECT * FROM test WHERE a < 10;

F.4.2. Authors

Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See http://www.sai.msu.su/~megera/oddmuse/index.cgi/Gin for additional information.

F.5. btree_gist

btree_gist provides GiST index operator classes that implement B-tree equivalent behavior for the data types int2, int4, int8, float4, float8, numeric, timestamp with time zone, timestamp without time zone, time with time zone, time without time zone, date, interval, oid, money, char, varchar, text, bytea, bit, varbit, macaddr, inet, and cidr.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they provide some other features that are not available with a B-tree index, as described below. Also, these operator classes are useful when a multicolumn GiST index is needed, wherein some of the columns are of data types that are only indexable with GiST but other columns are just simple data types. Lastly, these operator classes are useful for GiST testing and as a base for developing other GiST operator classes.

In addition to the typical B-tree search operators, btree_gist also provides index support for <> (“not equals”). This may be useful in combination with an exclusion constraint, as described below. Also, for data types for which there is a natural distance metric, btree_gist defines a distance operator <~>, and provides GiST index support for nearest-neighbor searches using this operator. Distance operators are provided for int2, int4, int8, float4, float8, timestamp with...
time zone, timestamp without time zone, time without time zone, date, interval, oid, and money.

F.5.1. Example Usage

Simple example using btree_gist instead of btree:

CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING gist (a);
-- query
SELECT * FROM test WHERE a < 10;
-- nearest-neighbor search: find the ten entries closest to 42
SELECT *, a <-> 42 AS dist FROM test ORDER BY a <-> 42 LIMIT 10;

Use an exclusion constraint to enforce the rule that a cage at a zoo can contain only one kind of animal:

=> CREATE TABLE zoo (  
cage INTEGER,
   animal TEXT,
   EXCLUDE USING gist (cage WITH =, animal WITH <>)
);

=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'lion');
ERROR: conflicting key value violates exclusion constraint "zoo_cage_animal_excl"
DETAIL: Key (cage, animal)=(123, lion) conflicts with existing key (cage, animal)=(123, zebra).
=> INSERT INTO zoo VALUES(124, 'lion');
INSERT 0 1

F.5.2. Authors

Teodor Sigaev (<teodor@stack.net>), Oleg Bartunov (<oleg@sai.msu.su>), and Janko Richter (<jankorichter@yahoo.de>). See http://www.sai.msu.su/~megera/postgres/gist/ for additional information.

F.6. chkpass

This module implements a data type chkpass that is designed for storing encrypted passwords. Each password is automatically converted to encrypted form upon entry, and is always stored encrypted. To compare, simply compare against a clear text password and the comparison function will encrypt it before comparing.

There are provisions in the code to report an error if the password is determined to be easily crackable. However, this is currently just a stub that does nothing.
If you precede an input string with a colon, it is assumed to be an already-encrypted password, and is stored without further encryption. This allows entry of previously-encrypted passwords.

On output, a colon is prepended. This makes it possible to dump and reload passwords without re-encrypting them. If you want the encrypted password without the colon then use the `raw()` function. This allows you to use the type with things like Apache's `Auth_PostgreSQL` module.

The encryption uses the standard Unix function `crypt()`, and so it suffers from all the usual limitations of that function; notably that only the first eight characters of a password are considered.

Note that the `chkpass` data type is not indexable.

Sample usage:

```sql
test=# create table test (p chkpass);
CREATE TABLE

test=# insert into test values ('hello');
INSERT 0 1

test=# select * from test;
p
-------------
:dVGkpXdOrE3ko
(1 row)

test=# select raw(p) from test;
raw
-------------
dVGkpXdOrE3ko
(1 row)

test=# select p = 'hello' from test;
?column?
----------
t
(1 row)

test=# select p = 'goodbye' from test;
?column?
----------
f
(1 row)
```

**F.6.1. Author**

D'Arcy J.M. Cain (<darcy@druid.net>)

**F.7. citext**

The `citext` module provides a case-insensitive character string type, `citext`. Essentially, it internally calls `lower` when comparing values. Otherwise, it behaves almost exactly like `text`. 
F.7.1. Rationale

The standard approach to doing case-insensitive matches in PostgreSQL has been to use the lower function when comparing values, for example

```
SELECT * FROM tab WHERE lower(col) = LOWER(?);
```

This works reasonably well, but has a number of drawbacks:

- It makes your SQL statements verbose, and you always have to remember to use lower on both the column and the query value.
- It won’t use an index, unless you create a functional index using lower.
- If you declare a column as UNIQUE or PRIMARY KEY, the implicitly generated index is case-sensitive. So it’s useless for case-insensitive searches, and it won’t enforce uniqueness case-insensitively.

The citext data type allows you to eliminate calls to lower in SQL queries, and allows a primary key to be case-insensitive. citext is locale-aware, just like text, which means that the matching of upper case and lower case characters is dependent on the rules of the database’s LC_CTYPE setting. Again, this behavior is identical to the use of lower in queries. But because it’s done transparently by the data type, you don’t have to remember to do anything special in your queries.

F.7.2. How to Use It

Here’s a simple example of usage:

```
CREATE TABLE users (  
  nick CITEXT PRIMARY KEY,  
  pass TEXT NOT NULL
);
```

```
INSERT INTO users VALUES ( 'larry', md5(random()::text) );
INSERT INTO users VALUES ( 'Tom', md5(random()::text) );
INSERT INTO users VALUES ( 'Damian', md5(random()::text) );
INSERT INTO users VALUES ( 'NEAL', md5(random()::text) );
INSERT INTO users VALUES ( 'Bjørn', md5(random()::text) );
```

```
SELECT * FROM users WHERE nick = 'Larry';
```

The select statement will return one tuple, even though the nick column was set to larry and the query was for Larry.

F.7.3. String Comparison Behavior

citext performs comparisons by converting each string to lower case (as though lower were called) and then comparing the results normally. Thus, for example, two strings are considered equal if lower would produce identical results for them.

In order to emulate a case-insensitive collation as closely as possible, there are citext-specific versions of a number of string-processing operators and functions. So, for example, the regular expression operators ~ and ~* exhibit the same behavior when applied to citext: they both match case-
insensitively. The same is true for !~ and !~*, as well as for the LIKE operators ~~ and ~~~*, and !~~ and !~~*. If you’d like to match case-sensitively, you can cast the operator’s arguments to text.

Similarly, all of the following functions perform matching case-insensitively if their arguments are citext:

- `regexp_matches()`
- `regexp_replace()`
- `regexp_split_to_array()`
- `regexp_split_to_table()`
- `replace()`
- `split_part()`
- `strpos()`
- `translate()`

For the regex functions, if you want to match case-sensitively, you can specify the “c” flag to force a case-sensitive match. Otherwise, you must cast to text before using one of these functions if you want case-sensitive behavior.

### F.7.4. Limitations

- `citext`’s case-folding behavior depends on the `LC_CTYPE` setting of your database. How it compares values is therefore determined when the database is created. It is not truly case-insensitive in the terms defined by the Unicode standard. Effectively, what this means is that, as long as you’re happy with your collation, you should be happy with `citext`’s comparisons. But if you have data in different languages stored in your database, users of one language may find their query results are not as expected if the collation is for another language.

- As of PostgreSQL 9.1, you can attach a `COLLATE` specification to `citext` columns or data values. Currently, `citext` operators will honor a non-default `COLLATE` specification while comparing case-folded strings, but the initial folding to lower case is always done according to the database’s `LC_CTYPE` setting (that is, as though `COLLATE "default"` were given). This may be changed in a future release so that both steps follow the input `COLLATE` specification.

- `citext` is not as efficient as `text` because the operator functions and the B-tree comparison functions must make copies of the data and convert it to lower case for comparisons. It is, however, slightly more efficient than using `lower` to get case-insensitive matching.

- `citext` doesn’t help much if you need data to compare case-sensitively in some contexts and case-insensitively in other contexts. The standard answer is to use the `text` type and manually use the `lower` function when you need to compare case-insensitively; this works all right if case-insensitive comparison is needed only infrequently. If you need case-insensitive behavior most of the time and case-sensitive infrequently, consider storing the data as `citext` and explicitly casting the column to `text` when you want case-sensitive comparison. In either situation, you will need two indexes if you want both types of searches to be fast.

- The schema containing the `citext` operators must be in the current `search_path` (typically `public`); if it is not, the normal case-sensitive `text` operators will be invoked instead.
F.7.5. Author

David E. Wheeler <david@kineticode.com>
Inspired by the original citext module by Donald Fraser.

F.8. cube

This module implements a data type cube for representing multidimensional cubes.

F.8.1. Syntax

Table F-3 shows the valid external representations for the cube type. x, y, etc. denote floating-point numbers.

<table>
<thead>
<tr>
<th>Representation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>A one-dimensional point (or, zero-length one-dimensional interval)</td>
</tr>
<tr>
<td>(x)</td>
<td>Same as above</td>
</tr>
<tr>
<td>x1, x2, ..., xn</td>
<td>A point in n-dimensional space, represented internally as a zero-volume cube</td>
</tr>
<tr>
<td>(x1, x2, ..., xn)</td>
<td>Same as above</td>
</tr>
<tr>
<td>(x), (y)</td>
<td>A one-dimensional interval starting at x and ending at y or vice versa; the order does not matter</td>
</tr>
<tr>
<td>[(x), (y)]</td>
<td>Same as above</td>
</tr>
<tr>
<td>(x1, ..., xn), (y1, ..., yn)</td>
<td>An n-dimensional cube represented by a pair of its diagonally opposite corners</td>
</tr>
<tr>
<td>[(x1, ..., xn), (y1, ..., yn)]</td>
<td>Same as above</td>
</tr>
</tbody>
</table>

It does not matter which order the opposite corners of a cube are entered in. The cube functions automatically swap values if needed to create a uniform “lower left — upper right” internal representation. White space is ignored, so [(x), (y)] is the same as [(x), (y)].

F.8.2. Precision

Values are stored internally as 64-bit floating point numbers. This means that numbers with more than about 16 significant digits will be truncated.

F.8.3. Usage

The cube module includes a GiST index operator class for cube values. The operators supported by the GiST operator class are shown in Table F-4.
Table F-4. Cube GiST Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a = b</td>
<td>The cubes a and b are identical.</td>
</tr>
<tr>
<td>a &amp;a b</td>
<td>The cubes a and b overlap.</td>
</tr>
<tr>
<td>a @&gt; b</td>
<td>The cube a contains the cube b.</td>
</tr>
<tr>
<td>a &lt;@ b</td>
<td>The cube a is contained in the cube b.</td>
</tr>
</tbody>
</table>

(Before PostgreSQL 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

The standard B-tree operators are also provided, for example

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[a, b] &lt; [c, d]</td>
<td>Less than</td>
</tr>
<tr>
<td>[a, b] &gt; [c, d]</td>
<td>Greater than</td>
</tr>
</tbody>
</table>

These operators do not make a lot of sense for any practical purpose but sorting. These operators first compare (a) to (c), and if these are equal, compare (b) to (d). That results in reasonably good sorting in most cases, which is useful if you want to use ORDER BY with this type.

Table F-5 shows the available functions.

Table F-5. Cube Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cube(float8) returns cube</code></td>
<td>Makes a one dimensional cube with both coordinates the same. <code>cube(1) == '(1)'</code></td>
</tr>
<tr>
<td><code>cube(float8, float8) returns cube</code></td>
<td>Makes a one dimensional cube. <code>cube(1,2) == '(1,2)'</code></td>
</tr>
<tr>
<td><code>cube(float8[]) returns cube</code></td>
<td>Makes a zero-volume cube using the coordinates defined by the array. <code>cube(ARRAY[1,2]) == '(1,2)'</code></td>
</tr>
<tr>
<td><code>cube(float8[], float8[]) returns cube</code></td>
<td>Makes a cube with upper right and lower left coordinates as defined by the two arrays, which must be of the same length. <code>cube('{1,2}':float[], '{3,4}':float[]) == '(1,2),(3,4)'</code></td>
</tr>
<tr>
<td><code>cube(cube, float8) returns cube</code></td>
<td>Makes a new cube by adding a dimension on to an existing cube with the same values for both parts of the new coordinate. This is useful for building cubes piece by piece from calculated values. <code>cube('(1)',2) == '(1,2),(1,2)'</code></td>
</tr>
<tr>
<td><code>cube(cube, float8, float8) returns cube</code></td>
<td>Makes a new cube by adding a dimension on to an existing cube. This is useful for building cubes piece by piece from calculated values. <code>cube('(1,2)',3,4) == '(1,3),(2,4)'</code></td>
</tr>
<tr>
<td><code>cube_dim(cube) returns int</code></td>
<td>Returns the number of dimensions of the cube</td>
</tr>
</tbody>
</table>
## Appendix F. Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cube_ll_coord(cube, int) returns double</td>
<td>Returns the n’th coordinate value for the lower left corner of a cube</td>
</tr>
<tr>
<td>cube_ur_coord(cube, int) returns double</td>
<td>Returns the n’th coordinate value for the upper right corner of a cube</td>
</tr>
<tr>
<td>cube_is_point(cube) returns bool</td>
<td>Returns true if a cube is a point, that is, the two defining corners are the same.</td>
</tr>
<tr>
<td>cube_distance(cube, cube) returns double</td>
<td>Returns the distance between two cubes. If both cubes are points, this is the normal distance function.</td>
</tr>
<tr>
<td>cube_subset(cube, int[]) returns cube</td>
<td>Makes a new cube from an existing cube, using a list of dimension indexes from an array. Can be used to find both the LL and UR coordinates of a single dimension, e.g. cube_subset(cube(’(1,3,5),(6,7,8)’), ARRAY[2]) = ’(3),(7)’. Or can be used to drop dimensions, or reorder them as desired, e.g. cube_subset(cube(’(1,3,5),(6,7,8)’), ARRAY[3,2,1,1]) = ’(5, 3, 1, 1),(8, 7, 6, 6)’.</td>
</tr>
<tr>
<td>cube_union(cube, cube) returns cube</td>
<td>Produces the union of two cubes</td>
</tr>
<tr>
<td>cube_inter(cube, cube) returns cube</td>
<td>Produces the intersection of two cubes</td>
</tr>
<tr>
<td>cube_enlarge(cube c, double r, int n) returns cube</td>
<td>Increases the size of a cube by a specified radius in at least n dimensions. If the radius is negative the cube is shrunk instead. This is useful for creating bounding boxes around a point for searching for nearby points. All defined dimensions are changed by the radius r. LL coordinates are decreased by r and UR coordinates are increased by r. If a LL coordinate is increased to larger than the corresponding UR coordinate (this can only happen when r &lt; 0) than both coordinates are set to their average. If n is greater than the number of defined dimensions and the cube is being increased (r &gt;= 0) then 0 is used as the base for the extra coordinates.</td>
</tr>
</tbody>
</table>

### F.8.4. Defaults

I believe this union:

```sql
select cube_union(’(0,5,2),(2,3,1)’, ’0’);
cube_union
-------------------
(0, 0, 0),(2, 5, 2)
(1 row)
```

does not contradict common sense, neither does the intersection.
select cube_inter('(0,-1),(1,1)', '(-2),(2)');
cube_inter
-------------
(0, 0),(1, 0)
(1 row)

In all binary operations on differently-dimensioned cubes, I assume the lower-dimensional one to be a Cartesian projection, i.e., having zeroes in place of coordinates omitted in the string representation. The above examples are equivalent to:
cube_union('(0,5,2),(2,3,1)','(0,0,0),(0,0,0)');
cube_inter('(0,-1),(1,1)', '(-2,0),(2,0)');

The following containment predicate uses the point syntax, while in fact the second argument is internally represented by a box. This syntax makes it unnecessary to define a separate point type and functions for (box,point) predicates.

select cube_contains('(0,0),(1,1)', '0.5,0.5');
cube_contains
-------------
t
(1 row)

F.8.5. Notes

For examples of usage, see the regression test sql/cube.sql.

To make it harder for people to break things, there is a limit of 100 on the number of dimensions of cubes. This is set in cubedata.h if you need something bigger.

F.8.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (http://db.cs.berkeley.edu/jmh/) for elucidating the gist of the GiST (http://gist.cs.berkeley.edu/), and to his former student, Andy Dong (http://best.me.berkeley.edu/~adong/), for his example written for Illustra, http://best.berkeley.edu/~adong/rtree/index.html. I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

Minor updates to this package were made by Bruno Wolff III <bruno@wolff.to> in August/September of 2002. These include changing the precision from single precision to double precision and adding some new functions.

Additional updates were made by Joshua Reich <josh@root.net> in July 2006. These include cube(float8[], float8[]) and cleaning up the code to use the V1 call protocol instead of the deprecated V0 protocol.
F.9. dblink

dblink is a module that supports connections to other PostgreSQL databases from within a database session.

See also postgres_fdw, which provides roughly the same functionality using a more modern and standards-compliant infrastructure.

dblink_connect

Name
dblink_connect — opens a persistent connection to a remote database

Synopsis
dblink_connect(text connstr) returns text
dblink_connect(text connname, text connstr) returns text

Description
dblink_connect() establishes a connection to a remote PostgreSQL database. The server and database to be contacted are identified through a standard libpq connection string. Optionally, a name can be assigned to the connection. Multiple named connections can be open at once, but only one unnamed connection is permitted at a time. The connection will persist until closed or until the database session is ended.

The connection string may also be the name of an existing foreign server. It is recommended to use the foreign-data wrapper dblink_fdw when defining the foreign server. See the example below, as well as CREATE SERVER and CREATE USER MAPPING.

Arguments

connname

The name to use for this connection; if omitted, an unnamed connection is opened, replacing any existing unnamed connection.

connstr

libpq-style connection info string, for example hostaddr=127.0.0.1 port=5432 dbname=mydb user=postgres password=mypassword options=-csearch_path=. For details see Section 31.1.1. Alternatively, the name of a foreign server.

Return Value

Returns status, which is always OK (since any error causes the function to throw an error instead of returning).
Notes
If untrusted users have access to a database that has not adopted a secure schema usage pattern, begin
each session by removing publicly-writable schemas from search_path. One could, for example,
add options=-csearch_path= to connstr. This consideration is not specific to dblink; it applies
to every interface for executing arbitrary SQL commands.

Only superusers may use dblink_connect to create non-password-authenticated connections. If
non-superusers need this capability, use dblink_connect_u instead.

It is unwise to choose connection names that contain equal signs, as this opens a risk of confusion
with connection info strings in other dblink functions.

Examples
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
  dblink_connect
----------------
  OK
  (1 row)

SELECT dblink_connect('myconn', 'dbname=postgres options=-csearch_path=');
  dblink_connect
----------------
  OK
  (1 row)

-- FOREIGN DATA WRAPPER functionality
-- Note: local connection must require password authentication for this to work properly
-- Otherwise, you will receive the following error from dblink_connect():
-- ----------------------------------------------------------------------
-- ERROR: password is required
-- DETAIL: Non-superuser cannot connect if the server does not request a password
-- HINT: Target server’s authentication method must be changed.

CREATE SERVER fdtest FOREIGN DATA WRAPPER dblink_fdw OPTIONS (hostaddr '127.0.0.1', dbname
CREATE USER dblink_regression_test WITH PASSWORD 'secret';
CREATE USER MAPPING FOR dblink_regression_test SERVER fdtest OPTIONS (user 'dblink_regression_test', password 'secret');
GRANT USAGE ON FOREIGN SERVER fdtest TO dblink_regression_test;
GRANT SELECT ON TABLE foo TO dblink_regression_test;
\set ORIGINAL_USER :USER
\c - dblink_regression_test
SELECT dblink_connect('myconn', 'fdtest');
  dblink_connect
----------------
  OK
  (1 row)

SELECT * FROM dblink('myconn','SELECT * FROM foo') AS t(a int, b text, c text[]);
  a  | b  | c
-------------
 0  | a  | {a0,b0,c0}
 1  | b  | {a1,b1,c1}
 2  | c  | {a2,b2,c2}

**dblink_connect_u**

**Name**

dblink_connect_u — opens a persistent connection to a remote database, insecurely

**Synopsis**

dblink_connect_u(text connstr) returns text

dblink_connect_u(text connname, text connstr) returns text

**Description**

dblink_connect_u() is identical to dblink_connect(), except that it will allow non-superusers to connect using any authentication method.

If the remote server selects an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur, because the session will appear to have originated from the user as which the local PostgreSQL server runs. Also, even if the remote server does demand a password, it is possible for the password to be supplied from the server environment, such as a ~/.pgpass file belonging to the server’s user. This opens not only a risk of impersonation, but the possibility of exposing a password to an untrustworthy remote server. Therefore, dblink_connect_u() is initially installed with all privileges revoked from PUBLIC, making it un-callable except by superusers. In some situations it may be appropriate to grant EXECUTE permission for dblink_connect_u() to specific users who are considered trustworthy, but this should be done with care. It is also recommended that any ~/.pgpass file belonging to the server’s user not contain any records specifying a wildcard host name.

For further details see dblink_connect().
dblink_disconnect

Name
dblink_disconnect — closes a persistent connection to a remote database

Synopsis
dblink_disconnect() returns text
dblink_disconnect(text connname) returns text

Description
dblink_disconnect() closes a connection previously opened by dblink_connect(). The form with no arguments closes an unnamed connection.

Arguments

cconnname
The name of a named connection to be closed.

Return Value
Returns status, which is always OK (since any error causes the function to throw an error instead of returning).

Examples

```sql
SELECT dblink_disconnect();
dblink_disconnect
-------------------
   OK
   (1 row)
```

```sql
SELECT dblink_disconnect('myconn');
dblink_disconnect
-------------------
   OK
   (1 row)
```
**dblink**

**Name**
dblink — executes a query in a remote database

**Synopsis**
dblink(text connname, text sql [, bool fail_on_error]) returns setof record
dblink(text connstr, text sql [, bool fail_on_error]) returns setof record
dblink(text sql [, bool fail_on_error]) returns setof record

**Description**
dblink executes a query (usually a SELECT, but it can be any SQL statement that returns rows) in a remote database.

When two text arguments are given, the first one is first looked up as a persistent connection’s name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for dblink_connect, and the indicated connection is made just for the duration of this command.

**Arguments**

**connname**
Name of the connection to use; omit this parameter to use the unnamed connection.

**connstr**
A connection info string, as previously described for dblink_connect.

**sql**
The SQL query that you wish to execute in the remote database, for example select * from foo.

**fail_on_error**
If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

**Return Value**
The function returns the row(s) produced by the query. Since dblink can be used with any query, it is declared to return record, rather than specifying any particular set of columns. This means that you must specify the expected set of columns in the calling query — otherwise PostgreSQL would not know what to expect. Here is an example:

```
SELECT *
FROM dblink('dbname=mydb options=--csearch_path=',
```
The “alias” part of the FROM clause must specify the column names and types that the function will return. (Specifying column names in an alias is actually standard SQL syntax, but specifying column types is a PostgreSQL extension.) This allows the system to understand what * should expand to, and what proname in the WHERE clause refers to, in advance of trying to execute the function. At runtime, an error will be thrown if the actual query result from the remote database does not have the same number of columns shown in the FROM clause. The column names need not match, however, and dblink does not insist on exact type matches either. It will succeed so long as the returned data strings are valid input for the column type declared in the FROM clause.

Notes

A convenient way to use dblink with predetermined queries is to create a view. This allows the column type information to be buried in the view, instead of having to spell it out in every query. For example,

```
CREATE VIEW myremote_pg_proc AS
    SELECT *
    FROM dblink('dbname=postgres options=-csearch_path=',
                'select proname, prosrc from pg_proc')
    AS t1(proname name, prosrc text);
SELECT * FROM myremote_pg_proc WHERE proname LIKE 'bytea%';
```

Examples

```
SELECT * FROM dblink('dbname=postgres options=-csearch_path=',
                      'select proname, prosrc from pg_proc')
AS t1(proname name, prosrc text) WHERE proname LIKE 'bytea%';
```

<table>

(14 rows)
**dblink_exec**

**Name**

dblink_exec — executes a command in a remote database

**Synopsis**

dblink_exec(text connname, text sql [, bool fail_on_error]) returns text
dblink_exec(text connstr, text sql [, bool fail_on_error]) returns text
dblink_exec(text sql [, bool fail_on_error]) returns text

**Description**

dblink_exec executes a command (that is, any SQL statement that doesn’t return rows) in a remote database.

When two text arguments are given, the first one is first looked up as a persistent connection’s name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for dblink_connect, and the indicated connection is made just for the duration of this command.

**Arguments**

**connname**

Name of the connection to use; omit this parameter to use the unnamed connection.

**connstr**

A connection info string, as previously described for dblink_connect.

**sql**

The SQL command that you wish to execute in the remote database, for example insert into foo values(0,’a’,’{"a0","b0","c0"}’).

**fail_on_error**

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function’s return value is set to ERROR.

**Return Value**

Returns status, either the command’s status string or ERROR.

**Examples**

SELECT dblink_connect('dbname=dblink_test_standby');
dblink_connect
----------------
OK (1 row)

SELECT dblink_exec('insert into foo values(21,"z","{"a0","b0","c0"}"");');
  dblink_exec
----------------
INSERT 943366 1 (1 row)

SELECT dblink_connect('myconn', 'dbname=regression');
  dblink_connect
----------------
OK (1 row)

SELECT dblink_exec('myconn', 'insert into foo values(21,"z","{"a0","b0","c0"}"");');
    dblink_exec
----------------
INSERT 6432584 1 (1 row)

SELECT dblink_exec('myconn', 'insert into pg_class values ("foo"),false);'
    dblink_exec
----------------
ERROR (1 row)

NOTICE: sql error
DETAIL: ERROR: null value in column "relnamespace" violates not-null constraint
**dblink_open**

**Name**

dblink_open — opens a cursor in a remote database

**Synopsis**

dblink_open(text cursorname, text sql [, bool fail_on_error]) returns text
dblink_open(text connname, text cursorname, text sql [, bool fail_on_error]) returns text

**Description**

dblink_open() opens a cursor in a remote database. The cursor can subsequently be manipulated with dblink_fetch() and dblink_close().

**Arguments**

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name to assign to this cursor.

sql

The SELECT statement that you wish to execute in the remote database, for example select * from pg_class.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function’s return value is set to ERROR.

**Return Value**

Returns status, either OK or ERROR.

**Notes**

Since a cursor can only persist within a transaction, dblink_open starts an explicit transaction block (BEGIN) on the remote side, if the remote side was not already within a transaction. This transaction will be closed again when the matching dblink_close is executed. Note that if you use dblink_exec to change data between dblink_open and dblink_close, and then an error occurs or you use dblink_disconnect before dblink_close, your change will be lost because the transaction will be aborted.
Examples

SELECT dblink_connect('dbname=postgres options=-csearch_path=');
  dblink_connect
----------------
  OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
  dblink_open
--------------
  OK
(1 row)
**dblink_fetch**

**Name**

`dblink_fetch` — returns rows from an open cursor in a remote database

**Synopsis**

```sql
dblink_fetch(text cursorname, int howmany [, bool fail_on_error]) returns setof record
dblink_fetch(text connname, text cursorname, int howmany [, bool fail_on_error]) returns setof record
```

**Description**

`dblink_fetch` fetches rows from a cursor previously established by `dblink_open`.

**Arguments**

- **connname**
  
  Name of the connection to use; omit this parameter to use the unnamed connection.

- **cursorname**
  
  The name of the cursor to fetch from.

- **howmany**
  
  The maximum number of rows to retrieve. The next `howmany` rows are fetched, starting at the current cursor position, moving forward. Once the cursor has reached its end, no more rows are produced.

- **fail_on_error**
  
  If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NO- NOTICE, and the function returns no rows.

**Return Value**

The function returns the row(s) fetched from the cursor. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

**Notes**

On a mismatch between the number of return columns specified in the `FROM` clause, and the actual number of columns returned by the remote cursor, an error will be thrown. In this event, the remote cursor is still advanced by as many rows as it would have been if the error had not occurred. The same is true for any other error occurring in the local query after the remote `FETCH` has been done.
Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
----------------
OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc where proname like "bytea%"');
dblink_open
-------------
OK
(1 row)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
  funcname | source
----------+----------
 byteacat  | byteacat
 byteacmp  | byteacmp
 byteaeq   | byteaeq
 byteage   | byteage
 byteagt   | byteagt
(5 rows)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
  funcname | source
----------+----------
 byteain   | byteain
 byteale   | byteale
 bytealike | bytealike
 bytealt   | bytealt
 byteane   | byteane
(5 rows)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
  funcname | source
----------+----------
 byteanlike | byteanlike
 byteaout   | byteaout
(2 rows)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
  funcname | source
----------+----------
(0 rows)
```
**dblink_close**

**Name**

`dblink_close` — closes a cursor in a remote database

**Synopsis**

```
dblink_close(text cursorname [, bool fail_on_error]) returns text
```

```
dblink_close(text connname, text cursorname [, bool fail_on_error]) returns text
```

**Description**

`dblink_close` closes a cursor previously opened with `dblink_open`.

**Arguments**

- **connname**
  
  Name of the connection to use; omit this parameter to use the unnamed connection.

- **cursorname**
  
  The name of the cursor to close.

- **fail_on_error**
  
  If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function’s return value is set to `ERROR`.

**Return Value**

Returns status, either `OK` or `ERROR`.

**Notes**

If `dblink_open` started an explicit transaction block, and this is the last remaining open cursor in this connection, `dblink_close` will issue the matching COMMIT.

**Examples**

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
----------------
OK
(1 row)
```
SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
dblink_open
-------------
  OK
(1 row)

SELECT dblink_close('foo');
dblink_close
-------------
  OK
(1 row)
**dblink_get_connections**

**Name**

dblink_get_connections — returns the names of all open named dblink connections

**Synopsis**

dblink_get_connections() returns text[]

**Description**

dblink_get_connections returns an array of the names of all open named dblink connections.

**Return Value**

Returns a text array of connection names, or NULL if none.

**Examples**

SELECT dblink_get_connections();
**dblink_error_message**

**Name**

`dblink_error_message` — gets last error message on the named connection

**Synopsis**

`dblink_error_message(text connname) returns text`

**Description**

`dblink_error_message` fetches the most recent remote error message for a given connection.

**Arguments**

`connname`

Name of the connection to use.

**Return Value**

Returns last error message, or `OK` if there has been no error in this connection.

**Notes**

When asynchronous queries are initiated by `dblink_send_query`, the error message associated with the connection might not get updated until the server’s response message is consumed. This typically means that `dblink_is_busy` or `dblink_get_result` should be called prior to `dblink_error_message`, so that any error generated by the asynchronous query will be visible.

**Examples**

```
SELECT dblink_error_message('dtest1');
```
dblink_send_query

Name

`dblink_send_query`— sends an async query to a remote database

Synopsis

`dblink_send_query(text connname, text sql) returns int`

Description

`dblink_send_query` sends a query to be executed asynchronously, that is, without immediately waiting for the result. There must not be an async query already in progress on the connection.

After successfully dispatching an async query, completion status can be checked with `dblink_is_busy`, and the results are ultimately collected with `dblink_get_result`. It is also possible to attempt to cancel an active async query using `dblink_cancel_query`.

Arguments

- `connname`
  
  Name of the connection to use.

- `sql`
  
  The SQL statement that you wish to execute in the remote database, for example `select * from pg_class`.

Return Value

Returns 1 if the query was successfully dispatched, 0 otherwise.

Examples

```
SELECT dblink_send_query('dtest1', 'SELECT * FROM foo WHERE f1 < 3');
```
**dblink_is_busy**

**Name**

dblink_is_busy — checks if connection is busy with an async query

**Synopsis**

dblink_is_busy(text connname) returns int

**Description**

dblink_is_busy tests whether an async query is in progress.

**Arguments**

connname

Name of the connection to check.

**Return Value**

Returns 1 if connection is busy, 0 if it is not busy. If this function returns 0, it is guaranteed that dblink_get_result will not block.

**Examples**

SELECT dblink_is_busy('dtest1');
**dblink_get_notify**

**Name**

`dblink_get_notify` — retrieve async notifications on a connection

**Synopsis**

`dblink_get_notify()` returns setof (notify_name text, be_pid int, extra text)

`dblink_get_notify(text connname)` returns setof (notify_name text, be_pid int, extra text)

**Description**

`dblink_get_notify` retrieves notifications on either the unnamed connection, or on a named connection if specified. To receive notifications via `dblink`, `LISTEN` must first be issued, using `dblink_exec`. For details see `LISTEN` and `NOTIFY`.

**Arguments**

connname

The name of a named connection to get notifications on.

**Return Value**

Returns setof (notify_name text, be_pid int, extra text), or an empty set if none.

**Examples**

```sql
SELECT dblink_exec('LISTEN virtual');

---

LISTEN

---

(1 row)

SELECT * FROM dblink_get_notify();

---

notify_name | be_pid | extra
---

---

(0 rows)

NOTIFY virtual;

---

NOTIFY

---

SELECT * FROM dblink_get_notify();

---

notify_name | be_pid | extra
---

---

virtual | 1229 |

---

(1 row)
```
**dblink_get_result**

**Name**
dblink_get_result — gets an async query result

**Synopsis**
dblink_get_result(text connname [, bool fail_on_error]) returns setof record

**Description**
dblink_get_result collects the results of an asynchronous query previously sent with dblink_send_query. If the query is not already completed, dblink_get_result will wait until it is.

**Arguments**

- **connname**
  
  Name of the connection to use.

- **fail_on_error**
  
  If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

**Return Value**

For an async query (that is, a SQL statement returning rows), the function returns the row(s) produced by the query. To use this function, you will need to specify the expected set of columns, as previously discussed for dblink.

For an async command (that is, a SQL statement not returning rows), the function returns a single row with a single text column containing the command’s status string. It is still necessary to specify that the result will have a single text column in the calling FROM clause.

**Notes**

This function must be called if dblink_send_query returned 1. It must be called once for each query sent, and one additional time to obtain an empty set result, before the connection can be used again.

When using dblink_send_query and dblink_get_result, dblink fetches the entire remote query result before returning any of it to the local query processor. If the query returns a large number of rows, this can result in transient memory bloat in the local session. It may be better to open such
a query as a cursor with `dblink_open` and then fetch a manageable number of rows at a time. Alternatively, use plain `dblink()`, which avoids memory bloat by spooling large result sets to disk.

**Examples**

```sql
contrib_regression=# SELECT dblink_connect('dtest1', 'dbname=contrib_regression');
dblink_connect
----------------
OK
(1 row)

contrib_regression=# SELECT * FROM contrib_regression-
dblink_send_query('dtest1', 'select * from foo where f1 < 3') AS t1;
t1
----
1
(1 row)

contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text, f3 text[]);
f1 | f2 | f3
----+----+---------------
0 | a | {a0,b0,c0}
1 | b | {a1,b1,c1}
2 | c | {a2,b2,c2}
(3 rows)

contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text, f3 text[]);
f1 | f2 | f3
----+----+---------------
0 | a | {a0,b0,c0}
1 | b | {a1,b1,c1}
2 | c | {a2,b2,c2}
(3 rows)

contrib_regression=# SELECT * FROM contrib_regression-
dblink_send_query('dtest1', 'select * from foo where f1 < 3; select * from foo where f1 > 6') AS t1;
t1
----
1
(1 row)

contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text, f3 text[]);
f1 | f2 | f3
----+----+---------------
0 | a | {a0,b0,c0}
1 | b | {a1,b1,c1}
2 | c | {a2,b2,c2}
(3 rows)

contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text, f3 text[]);
f1 | f2 | f3
----+----+---------------
7 | h | {a7,b7,c7}
8 | i | {a8,b8,c8}
9 | j | {a9,b9,c9}
10 | k | {a10,b10,c10}
(4 rows)
```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text, f3 text)  
  f1 | f2 | f3  
-----+----+----  
(0 rows)
dblink_cancel_query

Name

dblink_cancel_query — cancels any active query on the named connection

Synopsis

dblink_cancel_query(text connname) returns text

Description

dblink_cancel_query attempts to cancel any query that is in progress on the named connection. Note that this is not certain to succeed (since, for example, the remote query might already have finished). A cancel request simply improves the odds that the query will fail soon. You must still complete the normal query protocol, for example by calling dblink_get_result.

Arguments

connname

Name of the connection to use.

Return Value

Returns OK if the cancel request has been sent, or the text of an error message on failure.

Examples

SELECT dblink_cancel_query('dtest1');
**dblink_get_pkey**

**Name**

dblink_get_pkey — returns the positions and field names of a relation’s primary key fields

**Synopsis**

dblink_get_pkey(text relname) returns setof dblink_pkey_results

**Description**
dblink_get_pkey provides information about the primary key of a relation in the local database. This is sometimes useful in generating queries to be sent to remote databases.

**Arguments**

relayname

Name of a local relation, for example foobar or myschema.mytab. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

**Return Value**

Returns one row for each primary key field, or no rows if the relation has no primary key. The result row type is defined as

```
CREATE TYPE dblink_pkey_results AS (position int, colname text);
```

The position column simply runs from 1 to $n$; it is the number of the field within the primary key, not the number within the table’s columns.

**Examples**

```
CREATE TABLE foobar (  
  f1 int,  
  f2 int,  
  f3 int,  
  PRIMARY KEY (f1, f2, f3)  
);  
CREATE TABLE

SELECT * FROM dblink_get_pkey('foobar');
```

<table>
<thead>
<tr>
<th>position</th>
<th>colname</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>f1</td>
</tr>
<tr>
<td>2</td>
<td>f2</td>
</tr>
<tr>
<td>3</td>
<td>f3</td>
</tr>
<tr>
<td>---</td>
<td>----</td>
</tr>
</tbody>
</table>

(3 rows)
**dlink_build_sql_insert**

**Name**

`dlink_build_sql_insert` — builds an INSERT statement using a local tuple, replacing the primary key field values with alternative supplied values.

**Synopsis**

```sql
dlink_build_sql_insert(text relname,
        int2vector primary_key_attnums,
        integer num_primary_key_atts,
        text[] src_pk_att_vals_array,
        text[] tgt_pk_att_vals_array) returns text
```

**Description**

`dlink_build_sql_insert` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds a SQL `INSERT` command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.)

**Arguments**

- **relname**
  
  Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

- **primary_key_attnums**
  
  Attribute numbers (1-based) of the primary key fields, for example 1 2.

- **num_primary_key_atts**
  
  The number of primary key fields.

- **src_pk_att_vals_array**
  
  Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

- **tgt_pk_att_vals_array**
  
  Values of the primary key fields to be placed in the resulting `INSERT` command. Each field is represented in text form.

**Return Value**

Returns the requested SQL statement as text.
Notes

As of PostgreSQL 9.0, the attribute numbers in primary_key_attnums are interpreted as logical column numbers, corresponding to the column’s position in SELECT * FROM relname. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_insert('foo', '1 2', 2, '{"1", "a"}', '{"1", "b"a"}');
```

```
---
INSERT INTO foo(f1,f2,f3) VALUES('1','b"a"','1')
(1 row)
```
dblink_build_sql_delete

Name
dblink_build_sql_delete — builds a DELETE statement using supplied values for primary key field values

Synopsis
dblink_build_sql_delete(text relname,
                 int2vector primary_key_attnums,
                 integer num_primary_key_atts,
                 text[] tgt_pk_att_vals_array) returns text

Description
dblink_build_sql_delete can be useful in doing selective replication of a local table to a remote database. It builds a SQL DELETE command that will delete the row with the given primary key values.

Arguments

rename
  Name of a local relation, for example foo or myschema.mytab. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

primary_key_attnums
  Attribute numbers (1-based) of the primary key fields, for example 1 2.

num_primary_key_atts
  The number of primary key fields.

tgt_pk_att_vals_array
  Values of the primary key fields to be used in the resulting DELETE command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in primary_key_attnums are interpreted as logical column numbers, corresponding to the column’s position in SELECT * FROM relname. Previous
versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

SELECT dblink_build_sql_delete('"MyFoo"', '1 2', 2, '{"1", "b"}');
                        dblink_build_sql_delete
---------------------------------------------------------------
    DELETE FROM "MyFoo" WHERE f1='1' AND f2='b'
(1 row)
**dblink_build_sql_update**

**Name**

dblink_build_sql_update — builds an UPDATE statement using a local tuple, replacing the primary key field values with alternative supplied values

**Synopsis**

```
dblink_build_sql_update(text relname, 
    int2vector primary_key_attnums, 
    integer num_primary_key_atts, 
    text[] src_pk_att_vals_array, 
    text[] tgt_pk_att_vals_array) returns text
```

**Description**

dblink_build_sql_update can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds a SQL UPDATE command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.) The UPDATE command always assigns all fields of the row — the main difference between this and dblink_build_sql_insert is that it’s assumed that the target row already exists in the remote table.

**Arguments**

**relname**

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

**primary_key_attnums**

Attribute numbers (1-based) of the primary key fields, for example 1 2.

**num_primary_key_atts**

The number of primary key fields.

**src_pk_att_vals_array**

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

**tgt_pk_att_vals_array**

Values of the primary key fields to be placed in the resulting UPDATE command. Each field is represented in text form.
dblink_build_sql_update

Return Value
Returns the requested SQL statement as text.

Notes
As of PostgreSQL 9.0, the attribute numbers in primary_key_attnums are interpreted as logical
column numbers, corresponding to the column’s position in SELECT * FROM relname. Previous
versions interpreted the numbers as physical column positions. There is a difference if any column(s)
to the left of the indicated column have been dropped during the lifetime of the table.

Examples
SELECT dblink_build_sql_update(’foo’, ’1 2’, 2, ’{"1", "a"}’, ’{"1", "b"}’);
dblink_build_sql_update
------------------------------------------------------------UPDATE foo SET f1=’1’,f2=’b’,f3=’1’ WHERE f1=’1’ AND f2=’b’
(1 row)

F.10. dict_int

dict_int is an example of an add-on dictionary template for full-text search. The motivation for this example dictionary is to control the indexing of integers (signed and unsigned), allowing such numbers to be indexed while preventing excessive growth in the number of unique words, which greatly affects the performance of searching.

F.10.1. Configuration

The dictionary accepts two options:

- The maxlen parameter specifies the maximum number of digits allowed in an integer word. The default value is 6.
- The rejectlong parameter specifies whether an overlength integer should be truncated or ignored. If rejectlong is false (the default), the dictionary returns the first maxlen digits of the integer. If rejectlong is true, the dictionary treats an overlength integer as a stop word, so that it will not be indexed. Note that this also means that such an integer cannot be searched for.

F.10.2. Usage

Installing the dict_int extension creates a text search template intdict_template and a dictionary intdict based on it, with the default parameters. You can alter the parameters, for example

mydb# ALTER TEXT SEARCH DICTIONARY intdict (MAXLEN = 4, REJECTLONG = true);
ALTER TEXT SEARCH DICTIONARY

or create new dictionaries based on the template.

To test the dictionary, you can try

mydb# select ts_lexize('intdict', '12345678');
ts_lexize
---
{123456}

but real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:

ALTER TEXT SEARCH CONFIGURATION english
  ALTER MAPPING FOR int, uint WITH intdict;

F.11. dict_xsyn

dict_xsyn (Extended Synonym Dictionary) is an example of an add-on dictionary template for full-text search. This dictionary type replaces words with groups of their synonyms, and so makes it possible to search for a word using any of its synonyms.
F.11.1. Configuration

A dict_xsyn dictionary accepts the following options:

- `matchorig` controls whether the original word is accepted by the dictionary. Default is true.
- `matchsynonyms` controls whether the synonyms are accepted by the dictionary. Default is false.
- `keeporig` controls whether the original word is included in the dictionary’s output. Default is true.
- `keepsynonyms` controls whether the synonyms are included in the dictionary’s output. Default is true.
- `rules` is the base name of the file containing the list of synonyms. This file must be stored in `$SHAREDIR/tsearch_data/` (where `$SHAREDIR` means the PostgreSQL installation’s shared-data directory). Its name must end in `.rules` (which is not to be included in the `rules` parameter).

The rules file has the following format:

- Each line represents a group of synonyms for a single word, which is given first on the line. Synonyms are separated by whitespace, thus:
  ```
  word syn1 syn2 syn3
  ```
- The sharp (`#`) sign is a comment delimiter. It may appear at any position in a line. The rest of the line will be skipped.

Look at `xsyn_sample.rules`, which is installed in `$SHAREDIR/tsearch_data/`, for an example.

F.11.2. Usage

Installing the dict_xsyn extension creates a text search template `xsyn_template` and a dictionary `xsyn` based on it, with default parameters. You can alter the parameters, for example

```sql
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false);
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```sql
mydb# SELECT ts_lexize('xsyn', 'word');
```

```sql
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true);
```

mydb# SELECT ts_lexize('xsyn', 'word');

```sql
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false, MATCHSYNONYMS=true);
```

mydb# SELECT ts_lexize('xsyn', 'syn1');

```sql
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false, MATCHSYNONYMS=true, KEEPORIG=false, MATCHSYNONYMS=true);
```

mydb# SELECT ts_lexize('xsyn', 'syn1');
Appendix F: Additional Supplied Modules

---

{syn1,syn2,syn3}

```sql
mydb=# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true, MATCHORIG=false, KEEPSYNONYMS=false);
mydb=# SELECT ts_lexize('xsyn', 'syn1');
```

Real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:

```sql
ALTER TEXT SEARCH CONFIGURATION english
    ALTER MAPPING FOR word, asciiword WITH xsyn, english_stem;
```

F.12. dummy_seclabel

The dummy_seclabel module exists only to support regression testing of the SECURITY LABEL statement. It is not intended to be used in production.

F.12.1. Rationale

The SECURITY LABEL statement allows the user to assign security labels to database objects; however, security labels can only be assigned when specifically allowed by a loadable module, so this module is provided to allow proper regression testing.

Security label providers intended to be used in production will typically be dependent on a platform-specific feature such as SE-Linux. This module is platform-independent, and therefore better-suited to regression testing.

F.12.2. Usage

Here’s a simple example of usage:

```ini
# postgresql.conf
shared_preload_libraries = 'dummy_seclabel'
```

```sql
postgres=# CREATE TABLE t (a int, b text);
CREATE TABLE
postgres=# SECURITY LABEL ON TABLE t IS 'classified';
SECURITY LABEL
```

The dummy_seclabel module provides only four hardcoded labels: unclassified, classified, secret, and top secret. It does not allow any other strings as security labels.

These labels are not used to enforce access controls. They are only used to check whether the SECURITY LABEL statement works as expected, or not.
F.13. earthdistance

The earthdistance module provides two different approaches to calculating great circle distances on the surface of the Earth. The one described first depends on the cube module (which must be installed before earthdistance can be installed). The second one is based on the built-in point data type, using longitude and latitude for the coordinates.

In this module, the Earth is assumed to be perfectly spherical. (If that’s too inaccurate for you, you might want to look at the PostGIS\(^1\) project.)

F.13.1. Cube-based Earth Distances

Data is stored in cubes that are points (both corners are the same) using 3 coordinates representing the x, y, and z distance from the center of the Earth. A domain earth over cube is provided, which includes constraint checks that the value meets these restrictions and is reasonably close to the actual surface of the Earth.

The radius of the Earth is obtained from the earth() function. It is given in meters. But by changing this one function you can change the module to use some other units, or to use a different value of the radius that you feel is more appropriate.

This package has applications to astronomical databases as well. Astronomers will probably want to change earth() to return a radius of \(180/\pi()\) so that distances are in degrees.

Functions are provided to support input in latitude and longitude (in degrees), to support output of latitude and longitude, to calculate the great circle distance between two points and to easily specify a bounding box usable for index searches.

The provided functions are shown in Table F-6.

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>earth()</td>
<td>float8</td>
<td>Returns the assumed radius of the Earth.</td>
</tr>
<tr>
<td>sec_to_gc(float8)</td>
<td>float8</td>
<td>Converts the normal straight line (secant) distance between two points on the Earth to the great circle distance between them.</td>
</tr>
<tr>
<td>gc_to_sec(float8)</td>
<td>float8</td>
<td>Converts the great circle distance between two points on the surface of the Earth to the normal straight line (secant) distance between them.</td>
</tr>
</tbody>
</table>

1. http://postgis.net/
Appendix F. Additional Supplied Modules

### Function

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ll_to_earth(float8, float8)</td>
<td>earth</td>
<td>Returns the location of a point on the surface of the Earth given its latitude (argument 1) and longitude (argument 2) in degrees.</td>
</tr>
<tr>
<td>latitude(earth)</td>
<td>float8</td>
<td>Returns the latitude in degrees of a point on the surface of the Earth.</td>
</tr>
<tr>
<td>longitude(earth)</td>
<td>float8</td>
<td>Returns the longitude in degrees of a point on the surface of the Earth.</td>
</tr>
<tr>
<td>earth_distance(earth, earth)</td>
<td>float8</td>
<td>Returns the great circle distance between two points on the surface of the Earth.</td>
</tr>
<tr>
<td>earth_box(earth, float8)</td>
<td>cube</td>
<td>Returns a box suitable for an indexed search using the cube @&gt; operator for points within a given great circle distance of a location. Some points in this box are further than the specified great circle distance from the location, so a second check using earth_distance should be included in the query.</td>
</tr>
</tbody>
</table>

### F.13.2. Point-based Earth Distances

The second part of the module relies on representing Earth locations as values of type point, in which the first component is taken to represent longitude in degrees, and the second component is taken to represent latitude in degrees. Points are taken as (longitude, latitude) and not vice versa because longitude is closer to the intuitive idea of x-axis and latitude to y-axis.

A single operator is provided, shown in Table F-7.

### Table F-7. Point-based Earthdistance Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>point &lt;@&gt; point</td>
<td>float8</td>
<td>Gives the distance in statute miles between two points on the Earth’s surface.</td>
</tr>
</tbody>
</table>

Note that unlike the cube-based part of the module, units are hardwired here: changing the earth() function will not affect the results of this operator.

One disadvantage of the longitude/latitude representation is that you need to be careful about the edge conditions near the poles and near +/- 180 degrees of longitude. The cube-based representation avoids these discontinuities.
Appendix F. Additional Supplied Modules

F.14. file_fdw

The file_fdw module provides the foreign-data wrapper file_fdw, which can be used to access data files in the server’s file system. Data files must be in a format that can be read by COPY FROM; see COPY for details. Access to such data files is currently read-only.

A foreign table created using this wrapper can have the following options:

filename

Specifies the file to be read. Required. Must be an absolute path name.

format

Specifies the file’s format, the same as COPY’s FORMAT option.

header

Specifies whether the file has a header line, the same as COPY’s HEADER option.

delimiter

Specifies the file’s delimiter character, the same as COPY’s DELIMITER option.

quote

Specifies the file’s quote character, the same as COPY’s QUOTE option.

escape

Specifies the file’s escape character, the same as COPY’s ESCAPE option.

null

Specifies the file’s null string, the same as COPY’s NULL option.

encoding

Specifies the file’s encoding, the same as COPY’s ENCODING option.

Note that while COPY allows options such as OIDS and HEADER to be specified without a corresponding value, the foreign data wrapper syntax requires a value to be present in all cases. To activate COPY options normally supplied without a value, you can instead pass the value TRUE.

A column of a foreign table created using this wrapper can have the following options:

force_not_null

This is a Boolean option. If true, it specifies that values of the column should not be matched against the null string (that is, the file-level null option). This has the same effect as listing the column in COPY’s FORCE_NOT_NULL option.

force_null

This is a Boolean option. If true, it specifies that values of the column which match the null string are returned as NULL even if the value is quoted. Without this option, only unquoted values matching the null string are returned as NULL. This has the same effect as listing the column in COPY’s FORCE_NULL option.

COPY’s OIDS and FORCE_QUOTE options are currently not supported by file_fdw.

These options can only be specified for a foreign table or its columns, not in the options of the file_fdw foreign-data wrapper, nor in the options of a server or user mapping using the wrapper.

Changing table-level options requires superuser privileges, for security reasons: only a superuser should be able to determine which file is read. In principle non-superusers could be allowed to change the other options, but that’s not supported at present.
For a foreign table using `file_fdw`, `EXPLAIN` shows the name of the file to be read. Unless `COSTS OFF` is specified, the file size (in bytes) is shown as well.

**Example F-1. Create a Foreign Table for PostgreSQL CSV Logs**

One of the obvious uses for the `file_fdw` is to make the PostgreSQL activity log available as a table for querying. To do this, first you must be logging to a CSV file, which here we will call `pglog.csv`. First, install `file_fdw` as an extension:

```
CREATE EXTENSION file_fdw;
```

Then create a foreign server:

```
CREATE SERVER pglog FOREIGN DATA WRAPPER file_fdw;
```

Now you are ready to create the foreign data table. Using the `CREATE FOREIGN TABLE` command, you will need to define the columns for the table, the CSV file name, and its format:

```
CREATE FOREIGN TABLE pglog (
    log_time timestamp(3) with time zone,
    user_name text,
    database_name text,
    process_id integer,
    connection_from text,
    session_id text,
    session_line_num bigint,
    command_tag text,
    session_start_time timestamp with time zone,
    virtual_transaction_id text,
    transaction_id bigint,
    error_severity text,
    sql_state_code text,
    message text,
    detail text,
    hint text,
    internal_query text,
    internal_query_pos integer,
    context text,
    query text,
    query_pos integer,
    location text,
    application_name text
) SERVER pglog
OPTIONS ( filename '/home/josh/9.1/data/pg_log/pglog.csv', format 'csv' );
```

That’s it — now you can query your log directly. In production, of course, you would need to define some way to deal with log rotation.

**F.15. fuzzystrmatch**

The `fuzzystrmatch` module provides several functions to determine similarities and distance between strings.
F.15.1. Soundex

The Soundex system is a method of matching similar-sounding names by converting them to the same code. It was initially used by the United States Census in 1880, 1900, and 1910. Note that Soundex is not very useful for non-English names.

The `fuzzystrmatch` module provides two functions for working with Soundex codes:

```
soundex(text) returns text
difference(text, text) returns int
```

The `soundex` function converts a string to its Soundex code. The `difference` function converts two strings to their Soundex codes and then reports the number of matching code positions. Since Soundex codes have four characters, the result ranges from zero to four, with zero being no match and four being an exact match. (Thus, the function is misnamed — similarity would have been a better name.)

Here are some usage examples:

```
SELECT soundex('hello world!');
SELECT soundex('Anne'), soundex('Ann'), difference('Anne', 'Ann');
SELECT soundex('Anne'), soundex('Andrew'), difference('Anne', 'Andrew');
SELECT soundex('Anne'), soundex('Margaret'), difference('Anne', 'Margaret');
```

```
CREATE TABLE s (nm text);
INSERT INTO s VALUES ('john');
INSERT INTO s VALUES ('joan');
INSERT INTO s VALUES ('wobbly');
INSERT INTO s VALUES ('jack');
SELECT * FROM s WHERE soundex(nm) = soundex('john');
SELECT * FROM s WHERE difference(s.nm, 'john') > 2;
```

F.15.2. Levenshtein

This function calculates the Levenshtein distance between two strings:

```
levenshtein(text source, text target, int ins_cost, int del_cost, int sub_cost) returns int
levenshtein_less_equal(text source, text target, int max_d) returns int
```

Both `source` and `target` can be any non-null string, with a maximum of 255 bytes. The cost parameters specify how much to charge for a character insertion, deletion, or substitution, respectively. You can omit the cost parameters, as in the second version of the function; in that case they all default to 1. `levenshtein_less_equal` is accelerated version of `levenshtein` function for low values.
of distance. If actual distance is less or equal then max_d, then `levenshtein_less_equal` returns accurate value of it. Otherwise this function returns value which is greater than max_d.

Examples:

```sql
test=# SELECT levenshtein('GUMBO', 'GAMBOL');
levenshtein
---------
 2
(1 row)
```

```sql
test=# SELECT levenshtein('GUMBO', 'GAMBOL', 2,1,1);
levenshtein
---------
 3
(1 row)
```

```sql
test=# SELECT levenshtein_less_equal('extensive', 'exhaustive',2);
levenshtein_less_equal
----------------------
 3
(1 row)
```

```sql
test=# SELECT levenshtein_less_equal('extensive', 'exhaustive',4);
levenshtein_less_equal
----------------------
 4
(1 row)
```

F.15.3. Metaphone

Metaphone, like Soundex, is based on the idea of constructing a representative code for an input string. Two strings are then deemed similar if they have the same codes.

This function calculates the metaphone code of an input string:

```
metaphone(text source, int max_output_length) returns text
```

`source` has to be a non-null string with a maximum of 255 characters. `max_output_length` sets the maximum length of the output metaphone code; if longer, the output is truncated to this length.

Example:

```sql
test=# SELECT metaphone('GUMBO', 4);
metaphone
---------
KM
(1 row)
```

F.15.4. Double Metaphone

The Double Metaphone system computes two “sounds like” strings for a given input string — a “primary” and an “alternate”. In most cases they are the same, but for non-English names especially they can be a bit different, depending on pronunciation. These functions compute the primary and alternate codes:
Appendix F. Additional Supplied Modules

\texttt{dmetaphone(text source)} returns text

\texttt{dmetaphone\_alt(text source)} returns text

There is no length limit on the input strings.

Example:

\begin{verbatim}
  test=# select dmetaphone('gumbo');
dmetaphone
  ------------
    KMP
(1 row)
\end{verbatim}

F.16. \texttt{hstore}

This module implements the \texttt{hstore} data type for storing sets of key/value pairs within a single PostgreSQL value. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data. Keys and values are simply text strings.

F.16.1. \texttt{hstore} External Representation

The text representation of an \texttt{hstore}, used for input and output, includes zero or more \texttt{key => value} pairs separated by commas. Some examples:

\begin{verbatim}
  k => v
  foo => bar, baz => whatever
  "1-a" => "anything at all"
\end{verbatim}

The order of the pairs is not significant (and may not be reproduced on output). Whitespace between pairs or around the \texttt{=>} sign is ignored. Double-quote keys and values that include whitespace, commas, =s or >s. To include a double quote or a backslash in a key or value, escape it with a backslash.

Each key in an \texttt{hstore} is unique. If you declare an \texttt{hstore} with duplicate keys, only one will be stored in the \texttt{hstore} and there is no guarantee as to which will be kept:

\begin{verbatim}
  SELECT 'a=>1,a=>2'::hstore;
  hstore
  ------------
    "a"=>"1"
\end{verbatim}

A value (but not a key) can be an SQL \texttt{NULL}. For example:

\begin{verbatim}
  key => NULL
\end{verbatim}

The \texttt{NULL} keyword is case-insensitive. Double-quote the \texttt{NULL} to treat it as the ordinary string “\texttt{NULL}”.

\textbf{Note:} Keep in mind that the \texttt{hstore} text format, when used for input, applies \textit{before} any required quoting or escaping. If you are passing an \texttt{hstore} literal via a parameter, then no additional processing is needed. But if you're passing it as a quoted literal constant, then any single-quote characters and (depending on the setting of the \texttt{standard\_conforming\_strings} configuration...
parameter) backslash characters need to be escaped correctly. See Section 4.1.2.1 for more on the handling of string constants.

On output, double quotes always surround keys and values, even when it’s not strictly necessary.

**F.16.2. hstore Operators and Functions**

The operators provided by the hstore module are shown in Table F-8, the functions in Table F-9.

### Table F-8. hstore Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>hstore -&gt; text</td>
<td>get value for key (NULL if not present)</td>
<td>’a’-&gt;'x, b-&gt;'y': hstore -&gt;</td>
<td>x</td>
</tr>
<tr>
<td></td>
<td></td>
<td>’a’</td>
<td></td>
</tr>
<tr>
<td>hstore -&gt; text[]</td>
<td>get values for keys (NULL if not present)</td>
<td>’a’-&gt;'x, b-&gt;'y, c-&gt;'z': hstore -&gt; ARRAY[‘c’, ‘a’]</td>
<td>{“z”, “x”}</td>
</tr>
<tr>
<td>hstore</td>
<td></td>
<td>hstore</td>
<td>concatenate hstores</td>
</tr>
<tr>
<td>hstore ? text</td>
<td>does hstore contain key?</td>
<td>’a’-&gt;1’: hstore ? ’a’</td>
<td>t</td>
</tr>
<tr>
<td>hstore ?&amp; text[]</td>
<td>does hstore contain all specified keys?</td>
<td>’a’-&gt;1, b-&gt;2’::hstore ?&amp; ARRAY[‘a’, ‘b’]</td>
<td>t</td>
</tr>
<tr>
<td>hstore ?</td>
<td>text[]</td>
<td>does hstore contain any of the specified keys?</td>
<td>’a’-&gt;1, b-&gt;2’::hstore ?</td>
</tr>
<tr>
<td>hstore @@ hstore</td>
<td>does left operand contain right?</td>
<td>’a’-&gt;b, b-&gt;1, c-&gt;NULL’: hstore @@ ’b’-&gt;1’</td>
<td>t</td>
</tr>
<tr>
<td>hstore &lt;@ hstore</td>
<td>is left operand contained in right?</td>
<td>’a’-&gt;c’: hstore &lt;@ ’a’-&gt;b, b-&gt;1, c-&gt;NULL’</td>
<td>f</td>
</tr>
<tr>
<td>hstore - text</td>
<td>delete key from left operand</td>
<td>’a’-&gt;1, b-&gt;2, c-&gt;’3’: hstore - ’b’: text</td>
<td>“a”-&gt;“1”, “c”-&gt;“3”</td>
</tr>
<tr>
<td>hstore - text[]</td>
<td>delete keys from left operand</td>
<td>’a’-&gt;1, b-&gt;2, c-&gt;’3’: hstore - ARRAY[‘a’, ‘b’]</td>
<td>“c”-&gt;“3”</td>
</tr>
<tr>
<td>hstore - hstore</td>
<td>delete matching pairs from left operand</td>
<td>’a’-&gt;1, b-&gt;2, c-&gt;’3’: hstore - ’a’-&gt;4, b-&gt;2’: hstore</td>
<td>“a”-&gt;“1”, “c”-&gt;“3”</td>
</tr>
<tr>
<td>Operator</td>
<td>Description</td>
<td>Example</td>
<td>Result</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
<td>---------</td>
<td>--------</td>
</tr>
<tr>
<td>record $##=$ hstore</td>
<td>replace fields in record with matching values from hstore</td>
<td>see Examples section</td>
<td></td>
</tr>
<tr>
<td>%% hstore</td>
<td>convert hstore to array of alternating keys and values</td>
<td>%% ‘a=&gt;foo, b=&gt;bar’::hstore</td>
<td>{a,foo,b,bar}</td>
</tr>
<tr>
<td>%# hstore</td>
<td>convert hstore to two-dimensional key/value array</td>
<td>%# ‘a=&gt;foo, b=&gt;bar’::hstore</td>
<td>{{a,foo},{b,bar}}</td>
</tr>
</tbody>
</table>

**Note:** Prior to PostgreSQL 8.2, the containment operators $\@>$ and $\<@<$ were called $@$ and $\sim$, respectively. These names are still available, but are deprecated and will eventually be removed. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!

### Table F-9. hstore Functions

<table>

</table>
### Appendix F. Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>each(hstore)</code></td>
<td><code>setof(key text, value text)</code></td>
<td>get hstore’s keys and values as a set</td>
<td>select * from each('a&gt;=1,b=&gt;2')</td>
<td>key</td>
</tr>
<tr>
<td><code>exist(hstore, text)</code></td>
<td></td>
<td>does hstore contain key?</td>
<td>exist('a=&gt;1','a')</td>
<td>t</td>
</tr>
<tr>
<td><code>defined(hstore, test)</code></td>
<td></td>
<td>does hstore contain non-NULL value for key?</td>
<td>defined('a=&gt;NULL','a')</td>
<td>f</td>
</tr>
<tr>
<td><code>delete(hstore, test)</code></td>
<td></td>
<td>delete pair with matching key</td>
<td>delete('a=&gt;1,b=&gt;2','b')</td>
<td>&quot;a&quot; =&gt; 1</td>
</tr>
<tr>
<td><code>delete(hstore, test)</code></td>
<td></td>
<td>delete pairs with matching keys</td>
<td>delete('a=&gt;1,b=&gt;2','b','a')</td>
<td>&quot;b&quot; =&gt; 2</td>
</tr>
<tr>
<td><code>delete(hstore, hstore)</code></td>
<td></td>
<td>delete pairs matching those in the second argument</td>
<td>delete('a=&gt;1,b=&gt;2','b','a')</td>
<td>&quot;b&quot; =&gt; 2</td>
</tr>
<tr>
<td><code>populate_record(record, hstore)</code></td>
<td></td>
<td>replace fields in record with matching values from hstore</td>
<td>see Examples section</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** The function `hstore_to_json` is used when an `hstore` value is cast to `json`. Likewise, `hstore_to_jsonb` is used when an `hstore` value is cast to `jsonb`.

**Note:** The function `populate_record` is actually declared with `anyelement`, not `record`, as its first argument, but it will reject non-record types with a run-time error.

### F.16.3. Indexes

`hstore` has GiST and GIN index support for the `@>`, `?`, `?&` and `?|` operators. For example:

```sql
CREATE INDEX hidx ON testhstore USING GIST (h);
```

```sql
CREATE INDEX hidx ON testhstore USING GIN (h);
```

`hstore` also supports `btree` or `hash` indexes for the `=` operator. This allows `hstore` columns to be declared `UNIQUE`, or to be used in `GROUP` BY, `ORDER` BY or `DISTINCT` expressions. The sort ordering for `hstore` values is not particularly useful, but these indexes may be useful for equivalence lookups. Create indexes for `=` comparisons as follows:

```sql
CREATE INDEX hidx ON testhstore USING BTREE (h);
```

```sql
CREATE INDEX hidx ON testhstore USING HASH (h);
```
F.16.4. Examples

Add a key, or update an existing key with a new value:

```
UPDATE tab SET h = h || hstore('c', '3');
```

Delete a key:

```
UPDATE tab SET h = delete(h, 'k1');
```

Convert a record to an hstore:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');

SELECT hstore(t) FROM test AS t;

<table>
<thead>
<tr>
<th>hstore</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;col1&quot;=&gt;&quot;123&quot;, &quot;col2&quot;=&gt;&quot;foo&quot;, &quot;col3&quot;=&gt;&quot;bar&quot;</td>
</tr>
</tbody>
</table>
```

Convert an hstore to a predefined record type:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);

SELECT * FROM populate_record(null::test, '"col1"=>"456", "col2"=>"zzz"');

<table>
<thead>
<tr>
<th>col1</th>
<th>col2</th>
<th>col3</th>
</tr>
</thead>
<tbody>
<tr>
<td>456</td>
<td>zzz</td>
<td></td>
</tr>
</tbody>
</table>
```

Modify an existing record using the values from an hstore:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');

SELECT (r).* FROM (SELECT t #= '"col3"=>"baz"' AS r FROM test t) s;

<table>
<thead>
<tr>
<th>col1</th>
<th>col2</th>
<th>col3</th>
</tr>
</thead>
<tbody>
<tr>
<td>123</td>
<td>foo</td>
<td>baz</td>
</tr>
</tbody>
</table>
```

F.16.5. Statistics

The hstore type, because of its intrinsic liberality, could contain a lot of different keys. Checking for valid keys is the task of the application. The following examples demonstrate several techniques for checking keys and obtaining statistics.
Simple example:

```
SELECT * FROM each('aaa=>bq, b=>NULL, ""=>1');
```

Using a table:

```
SELECT (each(h)).key, (each(h)).value INTO stat FROM testhstore;
```

Online statistics:

```
SELECT key, count(*) FROM (SELECT (each(h)).key FROM testhstore) AS stat
GROUP BY key
ORDER BY count DESC, key;
```

<table>
<thead>
<tr>
<th>key</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>line</td>
<td>883</td>
</tr>
<tr>
<td>query</td>
<td>207</td>
</tr>
<tr>
<td>pos</td>
<td>203</td>
</tr>
<tr>
<td>node</td>
<td>202</td>
</tr>
<tr>
<td>space</td>
<td>197</td>
</tr>
<tr>
<td>status</td>
<td>195</td>
</tr>
<tr>
<td>public</td>
<td>194</td>
</tr>
<tr>
<td>title</td>
<td>190</td>
</tr>
<tr>
<td>org</td>
<td>189</td>
</tr>
</tbody>
</table>

F.16.6. Compatibility

As of PostgreSQL 9.0, `hstore` uses a different internal representation than previous versions. This presents no obstacle for dump/restore upgrades since the text representation (used in the dump) is unchanged.

In the event of a binary upgrade, upward compatibility is maintained by having the new code recognize old-format data. This will entail a slight performance penalty when processing data that has not yet been modified by the new code. It is possible to force an upgrade of all values in a table column by doing an `UPDATE` statement as follows:

```
UPDATE tablename SET hstorecol = hstorecol || "";
```

Another way to do it is:

```
ALTER TABLE tablename ALTER hstorecol TYPE hstore USING hstorecol || "";
```

The `ALTER TABLE` method requires an exclusive lock on the table, but does not result in bloating the table with old row versions.
F.16.7. Authors

Oleg Bartunov <oleg@sai.msu.su>, Moscow, Moscow University, Russia
Teodor Sigaev <teodor@sigaev.ru>, Moscow, Delta-Soft Ltd., Russia

F.17. intagg

The intagg module provides an integer aggregator and an enumerator. intagg is now obsolete, because there are built-in functions that provide a superset of its capabilities. However, the module is still provided as a compatibility wrapper around the built-in functions.

F.17.1. Functions

The aggregator is an aggregate function `int_array_aggregate(integer)` that produces an integer array containing exactly the integers it is fed. This is a wrapper around `array_agg`, which does the same thing for any array type.

The enumerator is a function `int_array_enum(integer[])` that returns `setof integer`. It is essentially the reverse operation of the aggregator: given an array of integers, expand it into a set of rows. This is a wrapper around `unnest`, which does the same thing for any array type.

F.17.2. Sample Uses

Many database systems have the notion of a one to many table. Such a table usually sits between two indexed tables, for example:

```
CREATE TABLE left (id INT PRIMARY KEY, ...);
CREATE TABLE right (id INT PRIMARY KEY, ...);
CREATE TABLE one_to_many(left INT REFERENCES left, right INT REFERENCES right);
```

It is typically used like this:

```
SELECT right.* from right JOIN one_to_many ON (right.id = one_to_many.right)
  WHERE one_to_many.left = item;
```

This will return all the items in the right hand table for an entry in the left hand table. This is a very common construct in SQL.

Now, this methodology can be cumbersome with a very large number of entries in the `one_to_many` table. Often, a join like this would result in an index scan and a fetch for each right hand entry in the table for a particular left hand entry. If you have a very dynamic system, there is not much you can do. However, if you have some data which is fairly static, you can create a summary table with the aggregator.

```
CREATE TABLE summary AS
  SELECT left, int_array_aggregate(right) AS right
  FROM one_to_many
  GROUP BY left;
```
This will create a table with one row per left item, and an array of right items. Now this is pretty useless without some way of using the array; that’s why there is an array enumerator. You can do

```sql
SELECT left, int_array_enum(right) FROM summary WHERE left = item;
```

The above query using `int_array_enum` produces the same results as

```sql
SELECT left, right FROM one_to_many WHERE left = item;
```

The difference is that the query against the summary table has to get only one row from the table, whereas the direct query against `one_to_many` must index scan and fetch a row for each entry.

On one system, an `EXPLAIN` showed a query with a cost of 8488 was reduced to a cost of 329. The original query was a join involving the `one_to_many` table, which was replaced by:

```sql
SELECT right, count(right) FROM
( SELECT left, int_array_enum(right) AS right
  FROM summary JOIN (SELECT left FROM left_table WHERE left = item) AS lefts
  ON (summary.left = lefts.left)
) AS list
GROUP BY right
ORDER BY count DESC;
```

---

**F.18. intarray**

The `intarray` module provides a number of useful functions and operators for manipulating null-free arrays of integers. There is also support for indexed searches using some of the operators.

All of these operations will throw an error if a supplied array contains any NULL elements.

Many of these operations are only sensible for one-dimensional arrays. Although they will accept input arrays of more dimensions, the data is treated as though it were a linear array in storage order.

### F.18.1. intarray Functions and Operators

The functions provided by the `intarray` module are shown in Table F-10, the operators in Table F-11.

#### Table F-10. intarray Functions

</tr>
<tr>
<td>query_int ~~ int[]</td>
<td>boolean</td>
<td>true if array satisfies query (commutator of @@)</td>
</tr>
</tbody>
</table>

(Before PostgreSQL 8.2, the containment operators @> and <@ were respectively called @ and ~.)
These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!

The operators \&\&, \(\geq\), and \(<\) are equivalent to PostgreSQL’s built-in operators of the same names, except that they work only on integer arrays that do not contain nulls, while the built-in operators work for any array type. This restriction makes them faster than the built-in operators in many cases.

The \(\bowtie\) and \(\sim\) operators test whether an array satisfies a query, which is expressed as a value of a specialized data type \texttt{query\_int}. A query consists of integer values that are checked against the elements of the array, possibly combined using the operators \& (AND), | (OR), and ! (NOT). Parentheses can be used as needed. For example, the query \(1\&(2|3)\) matches arrays that contain 1 and also contain either 2 or 3.

### F.18.2. Index Support

\texttt{intarray} provides index support for the \&\&, \(\geq\), \(<\), and \(\bowtie\) operators, as well as regular array equality.

Two GiST index operator classes are provided: \texttt{gist\_int\_ops} (used by default) is suitable for small- to medium-size data sets, while \texttt{gist\_intbig\_ops} uses a larger signature and is more suitable for indexing large data sets (i.e., columns containing a large number of distinct array values). The implementation uses an RD-tree data structure with built-in lossy compression.

There is also a non-default GIN operator class \texttt{gin\_int\_ops} supporting the same operators.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere. As a rule of thumb, a GIN index is faster to search than a GiST index, but slower to build or update; so GIN is better suited for static data and GiST for often-updated data.

### F.18.3. Example

-- a message can be in one or more “sections”
CREATE TABLE message (mid INT PRIMARY KEY, sections INT[][], ...);

-- create specialized index
CREATE INDEX message_rdtree_idx ON message USING GIST (sections gist\_int\_ops);

-- select messages in section 1 OR 2 - OVERLAP operator
SELECT message.mid FROM message WHERE message.sections \&\& '{1,2}';

-- select messages in sections 1 AND 2 - CONTAINS operator
SELECT message.mid FROM message WHERE message.sections \(\geq\) '{1,2}';

-- the same, using QUERY operator
SELECT message.mid FROM message WHERE message.sections \(\bowtie\) '1&2'::query\_int;

### F.18.4. Benchmark

The source directory \texttt{contrib/intarray/bench} contains a benchmark test suite. To run:

```
cd .../bench
createdb TEST
```
psql TEST < ../_int.sql
./create_test.pl | psql TEST
./bench.pl

The `bench.pl` script has numerous options, which are displayed when it is run without any arguments.

### F.18.5. Authors

All work was done by Teodor Sigaev (<teodor@sigaev.ru>) and Oleg Bartunov (<oleg@sai.msu.su>). See http://www.sai.msu.su/~megera/postgres/gist/ for additional information. Andrey Oktyabrski did a great work on adding new functions and operations.

### F.19. isn

The `isn` module provides data types for the following international product numbering standards: EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials). Numbers are validated on input according to a hard-coded list of prefixes; this list of prefixes is also used to hyphenate numbers on output. Since new prefixes are assigned from time to time, the list of prefixes may be out of date. It is hoped that a future version of this module will obtained the prefix list from one or more tables that can be easily updated by users as needed; however, at present, the list can only be updated by modifying the source code and recompiling. Alternatively, prefix validation and hyphenation support may be dropped from a future version of this module.

#### F.19.1. Data Types

Table F-12 shows the data types provided by the `isn` module.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAN13</td>
<td>European Article Numbers, always displayed in the EAN13 display format</td>
</tr>
<tr>
<td>ISBN13</td>
<td>International Standard Book Numbers to be displayed in the new EAN13 display format</td>
</tr>
<tr>
<td>ISMN13</td>
<td>International Standard Music Numbers to be displayed in the new EAN13 display format</td>
</tr>
<tr>
<td>ISSN13</td>
<td>International Standard Serial Numbers to be displayed in the new EAN13 display format</td>
</tr>
<tr>
<td>ISBN</td>
<td>International Standard Book Numbers to be displayed in the old short display format</td>
</tr>
<tr>
<td>ISMN</td>
<td>International Standard Music Numbers to be displayed in the old short display format</td>
</tr>
<tr>
<td>ISSN</td>
<td>International Standard Serial Numbers to be displayed in the old short display format</td>
</tr>
<tr>
<td>UPC</td>
<td>Universal Product Codes</td>
</tr>
</tbody>
</table>
Some notes:

1. ISBN13, ISMN13, ISSN13 numbers are all EAN13 numbers.
2. EAN13 numbers aren’t always ISBN13, ISMN13 or ISSN13 (some are).
3. Some ISBN13 numbers can be displayed as ISBN.
4. Some ISMN13 numbers can be displayed as ISMN.
5. Some ISSN13 numbers can be displayed as ISSN.
6. UPC numbers are a subset of the EAN13 numbers (they are basically EAN13 without the first 0 digit).
7. All UPC, ISBN, ISMN and ISSN numbers can be represented as EAN13 numbers.

Internally, all these types use the same representation (a 64-bit integer), and all are interchangeable. Multiple types are provided to control display formatting and to permit tighter validity checking of input that is supposed to denote one particular type of number.

The ISBN, ISMN, and ISSN types will display the short version of the number (ISxN 10) whenever it’s possible, and will show ISxN 13 format for numbers that do not fit in the short version. The EAN13, ISBN13, ISMN13 and ISSN13 types will always display the long version of the ISxN (EAN13).

F.19.2. Casts

The isn module provides the following pairs of type casts:

- ISBN13 <=> EAN13
- ISMN13 <=> EAN13
- ISSN13 <=> EAN13
- ISBN <=> EAN13
- ISMN <=> EAN13
- ISSN <=> EAN13
- UPC <=> EAN13
- ISMN <=> ISMN13
- ISSN <=> ISSN13

When casting from EAN13 to another type, there is a run-time check that the value is within the domain of the other type, and an error is thrown if not. The other casts are simply relabelings that will always succeed.

F.19.3. Functions and Operators

The isn module provides the standard comparison operators, plus B-tree and hash indexing support for all these data types. In addition there are several specialized functions; shown in Table F-13. In this table, isn means any one of the module’s data types.
Table F-13. isn Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>isn_weak(boolean)</td>
<td>boolean</td>
<td>Sets the weak input mode (returns new setting)</td>
</tr>
<tr>
<td>isn_weak()</td>
<td>boolean</td>
<td>Gets the current status of the weak mode</td>
</tr>
<tr>
<td>make_valid(isn)</td>
<td>isn</td>
<td>Validates an invalid number (clears the invalid flag)</td>
</tr>
<tr>
<td>is_valid(isn)</td>
<td>boolean</td>
<td>Checks for the presence of the invalid flag</td>
</tr>
</tbody>
</table>

Weak mode is used to be able to insert invalid data into a table. Invalid means the check digit is wrong, not that there are missing numbers.

Why would you want to use the weak mode? Well, it could be that you have a huge collection of ISBN numbers, and that there are so many of them that for weird reasons some have the wrong check digit (perhaps the numbers were scanned from a printed list and the OCR got the numbers wrong, perhaps the numbers were manually captured... who knows). Anyway, the point is you might want to clean the mess up, but you still want to be able to have all the numbers in your database and maybe use an external tool to locate the invalid numbers in the database so you can verify the information and validate it more easily; so for example you’d want to select all the invalid numbers in the table.

When you insert invalid numbers in a table using the weak mode, the number will be inserted with the corrected check digit, but it will be displayed with an exclamation mark (!) at the end, for example 0-11-000322-5!. This invalid marker can be checked with the is_valid function and cleared with the make_valid function.

You can also force the insertion of invalid numbers even when not in the weak mode, by appending the ! character at the end of the number.

Another special feature is that during input, you can write ? in place of the check digit, and the correct check digit will be inserted automatically.

F.19.4. Examples

--Using the types directly:
SELECT isbn('978-0-393-04002-9');
SELECT isbn13('0901690546');
SELECT issn('1436-4522');

--Casting types:
-- note that you can only cast from ean13 to another type when the
-- number would be valid in the realm of the target type;
-- thus, the following will NOT work: select isbn(ean13('0220356483481'));
-- but these will:
SELECT upc(ean13('0220356483481'));
SELECT ean13(upc('220356483481'));

--Create a table with a single column to hold ISBN numbers:
CREATE TABLE test (id isbn);
INSERT INTO test VALUES('9780393040029');

--Automatically calculate check digits (observe the '?'):

```
INSERT INTO test VALUES('220500896?');
INSERT INTO test VALUES('978055215372?');

SELECT issn('3251231?');
SELECT ismn('979047213542?');

-- Using the weak mode:
SELECT isn_weak(true);
INSERT INTO test VALUES('978-0-11-000533-4');
INSERT INTO test VALUES('9780141219307?');
INSERT INTO test VALUES('2-205-00876-X');
SELECT isn_weak(false);

SELECT id FROM test WHERE NOT is_valid(id);
UPDATE test SET id = make_valid(id) WHERE id = '2-205-00876-X!';

SELECT * FROM test;
SELECT isbn13(id) FROM test;
```

**F.19.5. Bibliography**

The information to implement this module was collected from several sites, including:

- [http://www.isbn-international.org/](http://www.isbn-international.org/)
- [http://www.ismn-international.org/](http://www.ismn-international.org/)

The prefixes used for hyphenation were also compiled from:

- [http://www.gs1.org/productssolutions/idkeys/support/prefix_list.html](http://www.gs1.org/productssolutions/idkeys/support/prefix_list.html)
- [https://www.isbn-international.org/content/isbn-users-manual](https://www.isbn-international.org/content/isbn-users-manual)
- [http://www.ismn-international.org/ranges.html](http://www.ismn-international.org/ranges.html)

Care was taken during the creation of the algorithms and they were meticulously verified against the suggested algorithms in the official ISBN, ISMN, ISSN User Manuals.

**F.19.6. Author**

Germán Méndez Bravo (Kronuz), 2004 - 2006

This module was inspired by Garrett A. Wollman’s `isbn_issn` code.
F.20. lo

The lo module provides support for managing Large Objects (also called LOs or BLOBs). This includes a data type lo and a trigger lo_manage.

F.20.1. Rationale

One of the problems with the JDBC driver (and this affects the ODBC driver also), is that the specification assumes that references to BLOBs (Binary Large OBjects) are stored within a table, and if that entry is changed, the associated BLOB is deleted from the database.

As PostgreSQL stands, this doesn’t occur. Large objects are treated as objects in their own right; a table entry can reference a large object by OID, but there can be multiple table entries referencing the same large object OID, so the system doesn’t delete the large object just because you change or remove one such entry.

Now this is fine for PostgreSQL-specific applications, but standard code using JDBC or ODBC won’t delete the objects, resulting in orphan objects — objects that are not referenced by anything, and simply occupy disk space.

The lo module allows fixing this by attaching a trigger to tables that contain LO reference columns. The trigger essentially just does a lo_unlink whenever you delete or modify a value referencing a large object. When you use this trigger, you are assuming that there is only one database reference to any large object that is referenced in a trigger-controlled column!

The module also provides a data type lo, which is really just a domain of the oid type. This is useful for differentiating database columns that hold large object references from those that are OIDs of other things. You don’t have to use the lo type to use the trigger, but it may be convenient to use it to keep track of which columns in your database represent large objects that you are managing with the trigger. It is also rumored that the ODBC driver gets confused if you don’t use lo for BLOB columns.

F.20.2. How to Use It

Here’s a simple example of usage:

```sql
CREATE TABLE image (title TEXT, raster lo);
```

```sql
CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON image
    FOR EACH ROW EXECUTE PROCEDURE lo_manage(raster);
```

For each column that will contain unique references to large objects, create a BEFORE UPDATE OR DELETE trigger, and give the column name as the sole trigger argument. You can also restrict the trigger to only execute on updates to the column by using BEFORE UPDATE OF column_name. If you need multiple lo columns in the same table, create a separate trigger for each one, remembering to give a different name to each trigger on the same table.

F.20.3. Limitations

- Dropping a table will still orphan any objects it contains, as the trigger is not executed. You can avoid this by preceding the DROP TABLE with DELETE FROM table. TRUNCATE has the same hazard.
Appendix F. Additional Supplied Modules

If you already have, or suspect you have, orphaned large objects, see the vacuumlo module to help you clean them up. It’s a good idea to run vacuumlo occasionally as a back-stop to the lo_manage trigger.

- Some frontends may create their own tables, and will not create the associated trigger(s). Also, users may not remember (or know) to create the triggers.

F.20.4. Author

Peter Mount <peter@retep.org.uk>

F.21. ltree

This module implements a data type `ltree` for representing labels of data stored in a hierarchical tree-like structure. Extensive facilities for searching through label trees are provided.

F.21.1. Definitions

A `label` is a sequence of alphanumeric characters and underscores (for example, in C locale the characters A-Za-z0-9_ are allowed). Labels must be less than 256 bytes long.

Examples: 42, Personal_Services

A `label path` is a sequence of zero or more labels separated by dots, for example L1.L2.L3, representing a path from the root of a hierarchical tree to a particular node. The length of a label path must be less than 65Kb, but keeping it under 2Kb is preferable.

Example: Top.Countries.Europe.Russia

The `ltree` module provides several data types:

- `ltree` stores a label path.
- `lquery` represents a regular-expression-like pattern for matching `ltree` values. A simple word matches that label within a path. A star symbol (*) matches zero or more labels. For example:

  ```
  foo          Match the exact label path foo
  *.foo.*      Match any label path containing the label foo
  *.foo        Match any label path whose last label is foo
  ```

Star symbols can also be quantified to restrict how many labels they can match:

```
*{n}            Match exactly n labels
*{n,}           Match at least n labels
*{n,m}          Match at least n but not more than m labels
*{,m}           Match at most m labels -- same as *{0,m}
```

There are several modifiers that can be put at the end of a non-star label in `lquery` to make it match more than just the exact match:

```
@                Match case-insensitively, for example a@ matches A
*                Match any label with this prefix, for example foo* matches foobar
%                Match initial underscore-separated words
```

The behavior of % is a bit complicated. It tries to match words rather than the entire label. For example `foo_bar%` matches `foo_bar_baz` but not `foo_barbaz`. If combined with *, prefix match-
ing applies to each word separately, for example `foo_bar%` matches `fool_bar2_baz` but not `fool_br2_baz`.

Also, you can write several possibly-modified labels separated with | (OR) to match any of those labels, and you can put ! (NOT) at the start to match any label that doesn’t match any of the alternatives.

Here’s an annotated example of lquery:

```
Top.*(0,2).sport@.football|tennis.Russ*|Spain
```

This query will match any label path that:

a. begins with the label Top
b. and next has zero to two labels before
c. a label beginning with the case-insensitive prefix sport
d. then a label not matching football nor tennis
e. and then ends with a label beginning with Russ or exactly matching Spain.

- `ltxtquery` represents a full-text-search-like pattern for matching `ltree` values. An `ltxtquery` value contains words, possibly with the modifiers @, *, % at the end; the modifiers have the same meanings as in `lquery`. Words can be combined with & (AND), | (OR), ! (NOT), and parentheses. The key difference from `lquery` is that `ltxtquery` matches words without regard to their position in the label path.

Here’s an example `ltxtquery`:

```
Europe & Russia@ & !Transportation
```

This will match paths that contain the label `Europe` and any label beginning with `Russia` (case-insensitive), but not paths containing the label `Transportation`. The location of these words within the path is not important. Also, when % is used, the word can be matched to any underscore-separated word within a label, regardless of position.

Note: `ltxtquery` allows whitespace between symbols, but `ltree` and `lquery` do not.

## F.21.2. Operators and Functions

Type `ltree` has the usual comparison operators =, <>, <=, >=. Comparison sorts in the order of a tree traversal, with the children of a node sorted by label text. In addition, the specialized operators shown in Table F-14 are available.

### Table F-14. `ltree` Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ltree @ ltree</code></td>

<td>boolean</td>
<td>does array contain an ancestor of \texttt{ltree}?</td>
</tr>
<tr>
<td>\texttt{ltree} &lt;@ \texttt{ltree[]}</td>
<td>boolean</td>
<td>does array contain an ancestor of \texttt{ltree}?</td>
</tr>
<tr>
<td>\texttt{ltree[]} &lt;@ \texttt{ltree}</td>
<td>boolean</td>
<td>does array contain a descendant of \texttt{ltree}?</td>
</tr>
<tr>
<td>\texttt{ltree} @\texttt{ltree[]}</td>
<td>boolean</td>
<td>does array contain a descendant of \texttt{ltree}?</td>
</tr>
<tr>
<td>\texttt{ltree[]} ~ \texttt{lquery}</td>
<td>boolean</td>
<td>does array contain any path matching \texttt{lquery}?</td>
</tr>
<tr>
<td>\texttt{lquery} ~ \texttt{ltree[]}</td>
<td>boolean</td>
<td>does array contain any path matching \texttt{lquery}?</td>
</tr>
<tr>
<td>\texttt{ltree[]} ? \texttt{lquery[]}</td>
<td>boolean</td>
<td>does \texttt{ltree} array contain any path matching any \texttt{lquery}?</td>
</tr>
<tr>
<td>\texttt{lquery[]} ? \texttt{ltree[]}</td>
<td>boolean</td>
<td>does \texttt{ltree} array contain any path matching any \texttt{lquery}?</td>
</tr>
<tr>
<td>\texttt{ltree[]} @ \texttt{ltxtquery}</td>
<td>boolean</td>
<td>does array contain any path matching \texttt{ltxtquery}?</td>
</tr>
<tr>
<td>\texttt{ltxtquery} @ \texttt{ltree[]}</td>
<td>boolean</td>
<td>does array contain any path matching \texttt{ltxtquery}?</td>
</tr>
<tr>
<td>\texttt{ltree[]} ?@ \texttt{ltree}</td>
<td>\texttt{ltree}</td>
<td>first array entry that is an ancestor of \texttt{ltree}; NULL if none</td>
</tr>
<tr>
<td>\texttt{ltree[]} &lt;@ \texttt{ltree}</td>
<td>\texttt{ltree}</td>
<td>first array entry that is a descendant of \texttt{ltree}; NULL if none</td>
</tr>
<tr>
<td>\texttt{ltree} ~ \texttt{lquery}</td>
<td>\texttt{ltree}</td>
<td>first array entry that matches \texttt{lquery}; NULL if none</td>
</tr>
<tr>
<td>\texttt{ltree} ?@ \texttt{ltxtquery}</td>
<td>\texttt{ltree}</td>
<td>first array entry that matches \texttt{ltxtquery}; NULL if none</td>
</tr>
</tbody>
</table>

The operators <@, @, >, and ~ have analogues ^<@, ^@, ^>, which are the same except they do not use indexes. These are useful only for testing purposes.

The available functions are shown in Table F-15.
# Table F-15. `ltree` Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>subltree(ltree, int start, int end)</code></td>
<td><code>ltree</code></td>
<td>subpath of <code>ltree</code> from position start to position end-1 (counting from 0)</td>
<td><code>subltree('Top.Child1.Child2',1,2)</code></td>
<td>-1</td>
</tr>
<tr>
<td><code>subpath(ltree, int offset, int len)</code></td>
<td><code>ltree</code></td>
<td>subpath of <code>ltree</code> starting at position offset, length len. If offset is negative, subpath starts that far from the end of the path. If len is negative, leaves that many labels off the end of the path.</td>
<td><code>subpath('Top.Child1.Child2',0,2)</code></td>
<td><code>Child1</code></td>
</tr>
<tr>
<td><code>subpath(ltree, int offset)</code></td>
<td><code>ltree</code></td>
<td>subpath of <code>ltree</code> starting at position offset, extending to end of path. If offset is negative, subpath starts that far from the end of the path.</td>
<td><code>subpath('Top.Child1.Child2',1)</code></td>
<td><code>Child1.Child2</code></td>
</tr>
<tr>
<td><code>nlevel(ltree)</code></td>
<td>integer</td>

</tr>
</tbody>
</table>
### Appendix F. Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>lca(ltree, ltree, ...)</td>
<td>ltree</td>
<td>longest common ancestor of paths (up to 8 arguments supported)</td>
<td>lca('1.2.3', '1.2.4.5.6')</td>
<td></td>
</tr>
<tr>
<td>lca(ltree[])</td>
<td>ltree</td>
<td>longest common ancestor of paths in array</td>
<td>lca(array['1.2', '1.2.3:ltree', '1.2 3.4'])</td>
<td></td>
</tr>
</tbody>
</table>

#### F.21.3. Indexes

`ltree` supports several types of indexes that can speed up the indicated operators:

- **B-tree index over `ltree:<,<=,=,>**
- **GiST index over `ltree:<,<=,=,>,@>,<@,>,~,?**

Example of creating such an index:

```
CREATE INDEX path_gist_idx ON test USING GIST (path);
```

Example of creating such an index:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path);
```

Note: This index type is lossy.

#### F.21.4. Example

This example uses the following data (also available in file `contrib/ltree/ltreetest.sql` in the source distribution):

```sql
CREATE TABLE test (path ltree);
INSERT INTO test VALUES ('Top');
INSERT INTO test VALUES ('Top.Science');
INSERT INTO test VALUES ('Top.Science.Astronomy');
INSERT INTO test VALUES ('Top.Science.Astronomy.Astrophysics');
INSERT INTO test VALUES ('Top.Science.Astronomy.Cosmology');
INSERT INTO test VALUES ('Top.Hobbies');
INSERT INTO test VALUES ('Top.Hobbies.Amateurs_Astronomy');
INSERT INTO test VALUES ('Top.Collections');
INSERT INTO test VALUES ('Top.Collections.Pictures');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Astronauts');
CREATE INDEX path_gist_idx ON test USING gist(path);
CREATE INDEX path_idx ON test USING btree(path);
```

Now, we have a table `test` populated with data describing the hierarchy shown below:

```
Top
  / | \
Science Hobbies Collections
```
Appendix F: Additional Supplied Modules

-- / \  
  Astronomy Amateurs_Astronomy Pictures

-- / \  |
  Astrophysics Cosmology Astronomy

-- / \  |
  Galaxies Stars Astronauts

We can do inheritance:

\$ltreetest\$=> SELECT path FROM test WHERE path <@ 'Top.Science';
path
------------------------------------
Top.Science
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
(4 rows)

Here are some examples of path matching:

\$ltreetest\$=> SELECT path FROM test WHERE path ~ '*.Astronomy.*';
path
-----------------------------------------------
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Collections.Pictures.Astronomy
(7 rows)

\$ltreetest\$=> SELECT path FROM test WHERE path ~ '*.!pictures@.*.Astronomy.*';
path
------------------------------------
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
(3 rows)

Here are some examples of full text search:

\$ltreetest\$=> SELECT path FROM test WHERE path @ 'Astro*% & !pictures@';
path
------------------------------------
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Hobbies.Amateurs_Astronomy
(4 rows)

\$ltreetest\$=> SELECT path FROM test WHERE path @ 'Astro* & !pictures@';
path
------------------------------------
Top.Science.Astronomy
2227
Appendix F. Additional Supplied Modules

Path construction using functions:

```sql
ltreetest=> SELECT subpath(path,0,2)||'Space'||subpath(path,2) FROM test WHERE path &@ 'Top.Science.Astronomy';

------------------------------------------
|                                      |
| Top.Science.Space.Astronomy          |
| (3 rows)                             |
```

We could simplify this by creating a SQL function that inserts a label at a specified position in a path:

```sql
CREATE FUNCTION ins_label(ltree, int, text) RETURNS ltree
AS 'select subpath($1,0,$2) || $3 || subpath($1,$2);'
LANGUAGE SQL IMMUTABLE;

ltreetest=> SELECT ins_label(path,2,'Space') FROM test WHERE path &@ 'Top.Science.Astronomy';

------------------------------------------
|                                      |
| Top.Science.Space.Astronomy          |
| (3 rows)                             |
```

F.21.5. Authors

All work was done by Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See http://www.sai.msu.su/~megera/postgres/gist/ for additional information. Authors would like to thank Eugeny Rodichev for helpful discussions. Comments and bug reports are welcome.

F.22. pageinspect

The pageinspect module provides functions that allow you to inspect the contents of database pages at a low level, which is useful for debugging purposes. All of these functions may be used only by superusers.
F.22.1. Functions

get_raw_page(relname text, fork text, blkno int) returns bytea

get_raw_page reads the specified block of the named relation and returns a copy as a bytea value. This allows a single time-consistent copy of the block to be obtained. fork should be ‘main’ for the main data fork, ‘fsm’ for the free space map, ‘vm’ for the visibility map, or ‘init’ for the initialization fork.

get_raw_page(relname text, blkno int) returns bytea

A shorthand version of get_raw_page, for reading from the main fork. Equivalent to get_raw_page(relname, ‘main’, blkno)

page_header(page bytea) returns record

page_header shows fields that are common to all PostgreSQL heap and index pages.

A page image obtained with get_raw_page should be passed as argument. For example:

test=# SELECT * FROM page_header(get_raw_page('pg_class', 0));

lsn | checksum | flags | lower | upper | special | pagesize | version | prune_xid
----------+----------+--------+-------+-------+---------+----------+---------+-----------
0/24A1B50 | 1 | 1 | 232 | 368 | 8192 | 8192 | 4 | 0

The returned columns correspond to the fields in the PageHeaderData struct. See src/include/storage/bufpage.h for details.

heap_page_items(page bytea) returns setof record

heap_page_items shows all line pointers on a heap page. For those line pointers that are in use, tuple headers are also shown. All tuples are shown, whether or not the tuples were visible to an MVCC snapshot at the time the raw page was copied.

A heap page image obtained with get_raw_page should be passed as argument. For example:

test=# SELECT * FROM heap_page_items(get_raw_page('pg_class', 0));

See src/include/storage/itemid.h and src/include/access/htup_details.h for explanations of the fields returned.

bt_metap(relname text) returns record

bt_metap returns information about a B-tree index’s metapage. For example:

test=# SELECT * FROM bt_metap('pg_cast_oid_index');

magic | 340322
version | 2
root | 1
level | 0
fastroot | 1
fastlevel | 0

bt_page_stats(relname text, blkno int) returns record

bt_page_stats returns summary information about single pages of B-tree indexes. For example:

test=# SELECT * FROM bt_page_stats('pg_cast_oid_index’, 1);

blkno | 1
type | 1
live_items | 256
dead_items | 0
avg_item_size | 12
Appendix F. Additional Supplied Modules

```
page_size | 8192
free_size | 4056
btpo_prev | 0
btpo_next | 0
btpo     | 0
btpo_flags | 3
```

\[\text{bt\_page\_items}(\text{relname text}, \text{blkno int}) \text{ returns setof record}\]

**bt_page_items** returns detailed information about all of the items on a B-tree index page. For example:

```
test=# SELECT * FROM bt_page_items('pg_cast_oid_index', 1);
itemoffset | ctid | itemlen | nulls | vars | data
------------+----------+---------+-------+------+-------------
       1 | (0,1) | 12 | f | f | 23 27 00 00
       2 | (0,2) | 12 | f | f | 24 27 00 00
       3 | (0,3) | 12 | f | f | 25 27 00 00
       4 | (0,4) | 12 | f | f | 26 27 00 00
       5 | (0,5) | 12 | f | f | 27 27 00 00
       6 | (0,6) | 12 | f | f | 28 27 00 00
       7 | (0,7) | 12 | f | f | 29 27 00 00
       8 | (0,8) | 12 | f | f | 2a 27 00 00
```

\[\text{fsm\_page\_contents}(\text{page bytea}) \text{ returns text}\]

**fsm_page_contents** shows the internal node structure of a FSM page. The output is a multiline string, with one line per node in the binary tree within the page. Only those nodes that are not zero are printed. The so-called "next" pointer, which points to the next slot to be returned from the page, is also printed.

See [src/backend/storage/freespace/README](http://www.postgresql.org) for more information on the structure of an FSM page.

### F.23. passwordcheck

The **passwordcheck** module checks users’ passwords whenever they are set with CREATE ROLE or ALTER ROLE. If a password is considered too weak, it will be rejected and the command will terminate with an error.

To enable this module, add `$libdir/passwordcheck` to shared_preload_libraries in `postgresql.conf`, then restart the server.

You can adapt this module to your needs by changing the source code. For example, you can use CrackLib2 to check passwords — this only requires uncommenting two lines in the Makefile and rebuilding the module. (We cannot include CrackLib by default for license reasons.) Without CrackLib, the module enforces a few simple rules for password strength, which you can modify or extend as you see fit.

---

Caution

To prevent unencrypted passwords from being sent across the network, written to the server log or otherwise stolen by a database administrator, PostgreSQL allows the user to supply pre-encrypted passwords. Many client programs make use of this functionality and encrypt the password before sending it to the server.

This limits the usefulness of the passwordcheck module, because in that case it can only try to guess the password. For this reason, passwordcheck is not recommended if your security requirements are high. It is more secure to use an external authentication method such as GSSAPI (see Chapter 19) than to rely on passwords within the database.

Alternatively, you could modify passwordcheck to reject pre-encrypted passwords, but forcing users to set their passwords in clear text carries its own security risks.

F.24. pg_buffercache

The pg_buffercache module provides a means for examining what’s happening in the shared buffer cache in real time.

The module provides a C function pg_buffercache_pages that returns a set of records, plus a view pg_buffercache that wraps the function for convenient use.

By default public access is revoked from both of these, just in case there are security issues lurking.

F.24.1. The pg_buffercache View

The definitions of the columns exposed by the view are shown in Table F-16.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bufferid</td>
<td>integer</td>
<td></td>
<td>ID, in the range 1..shared_buffers</td>

<td></td>
<td>Is the page dirty?</td>
</tr>
</tbody>
</table>
### Name

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>usagecount</td>
<td>smallint</td>
<td></td>
<td>Clock-sweep access count</td>
</tr>
</tbody>
</table>

There is one row for each buffer in the shared cache. Unused buffers are shown with all fields null except bufferid. Shared system catalogs are shown as belonging to database zero.

Because the cache is shared by all the databases, there will normally be pages from relations not belonging to the current database. This means that there may not be matching join rows in pg_class for some rows, or that there could even be incorrect joins. If you are trying to join against pg_class, it’s a good idea to restrict the join to rows having reldatabase equal to the current database’s OID or zero.

When the pg_buffercache view is accessed, internal buffer manager locks are taken for long enough to copy all the buffer state data that the view will display. This ensures that the view produces a consistent set of results, while not blocking normal buffer activity longer than necessary. Nonetheless there could be some impact on database performance if this view is read often.

### F.24.2. Sample Output

```
regression=# SELECT c.relname, count(*) AS buffers
             FROM pg_buffercache b INNER JOIN pg_class c
             ON b.relfilenode = pg_relation_filenode(c.oid) AND
                b.reldatabase IN (0, (SELECT oid FROM pg_database
                                      WHERE datname = current_database()))
             GROUP BY c.relname
             ORDER BY 2 DESC
             LIMIT 10;

relname | buffers
---------+--------

### F.24.3. Authors

Mark Kirkwood <markir@paradise.net.nz>

Design suggestions: Neil Conway <neilc@samurai.com>

Debugging advice: Tom Lane <tgl@sss.pgh.pa.us>
F.25. pgcrypto

The pgcrypto module provides cryptographic functions for PostgreSQL.

F.25.1. General Hashing Functions

F.25.1.1. digest()

digest(data text, type text) returns bytea
digest(data bytea, type text) returns bytea

Computes a binary hash of the given data. type is the algorithm to use. Standard algorithms are md5, sha1, sha224, sha256, sha384 and sha512. If pgcrypto was built with OpenSSL, more algorithms are available, as detailed in Table F-20.

If you want the digest as a hexadecimal string, use encode() on the result. For example:

```
CREATE OR REPLACE FUNCTION sha1(bytea) returns text AS $$
    SELECT encode(digest($1, 'sha1'), 'hex')
$$ LANGUAGE SQL STRICT IMMUTABLE;
```

F.25.1.2. hmac()

hmac(data text, key text, type text) returns bytea
hmac(data bytea, key bytea, type text) returns bytea

Calculates hashed MAC for data with key. type is the same as in digest().

This is similar to digest() but the hash can only be recalculated knowing the key. This prevents the scenario of someone altering data and also changing the hash to match.

If the key is larger than the hash block size it will first be hashed and the result will be used as key.

F.25.2. Password Hashing Functions

The functions crypt() and gen_salt() are specifically designed for hashing passwords. crypt() does the hashing and gen_salt() prepares algorithm parameters for it.

The algorithms in crypt() differ from the usual MD5 or SHA1 hashing algorithms in the following respects:

1. They are slow. As the amount of data is so small, this is the only way to make brute-forcing passwords hard.
2. They use a random value, called the salt, so that users having the same password will have different encrypted passwords. This is also an additional defense against reversing the algorithm.
3. They include the algorithm type in the result, so passwords hashed with different algorithms can co-exist.
4. Some of them are adaptive — that means when computers get faster, you can tune the algorithm to be slower, without introducing incompatibility with existing passwords.

Table F-17 lists the algorithms supported by the crypt() function.

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Max Password Length</th>
<th>Adaptive?</th>
<th>Salt Bits</th>
<th>Output Length</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bf</td>
<td>72</td>
<td>yes</td>
<td>128</td>
<td>60</td>
<td>Blowfish-based, variant 2a</td>
</tr>
<tr>
<td>md5</td>
<td>unlimited</td>
<td>no</td>
<td>48</td>
<td>34</td>
<td>MD5-based crypt</td>
</tr>
<tr>
<td>xdes</td>
<td>8</td>
<td>yes</td>
<td>24</td>
<td>20</td>
<td>Extended DES</td>
</tr>
<tr>
<td>des</td>
<td>8</td>
<td>no</td>
<td>12</td>
<td>13</td>
<td>Original UNIX crypt</td>
</tr>
</tbody>
</table>

F.25.2.1. crypt()

crypt(password text, salt text) returns text

Calculates a crypt(3)-style hash of password. When storing a new password, you need to use gen_salt() to generate a new salt value. To check a password, pass the stored hash value as salt, and test whether the result matches the stored value.

Example of setting a new password:

UPDATE ... SET pswhash = crypt('new password', gen_salt('md5'));

Example of authentication:

SELECT (pswhash = crypt('entered password', pswhash)) AS pswmatch FROM ... ;

This returns true if the entered password is correct.

F.25.2.2. gen_salt()

gen_salt(type text [, iter_count integer ]) returns text

Generates a new random salt string for use in crypt(). The salt string also tells crypt() which algorithm to use.

The type parameter specifies the hashing algorithm. The accepted types are: des, xdes, md5 and bf.

The iter_count parameter lets the user specify the iteration count, for algorithms that have one. The higher the count, the more time it takes to hash the password and therefore the more time to break it. Although with too high a count the time to calculate a hash may be several years — which is somewhat impractical. If the iter_count parameter is omitted, the default iteration count is used. Allowed values for iter_count depend on the algorithm and are shown in Table F-18.
Table F-18. Iteration Counts for `crypt()`

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Default</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>xdes</td>
<td>725</td>
<td>1</td>
<td>16777215</td>
</tr>
<tr>
<td>bf</td>
<td>6</td>
<td>4</td>
<td>31</td>
</tr>
</tbody>
</table>

For `xdes`, there is an additional limitation that the iteration count must be an odd number.

To pick an appropriate iteration count, consider that the original DES crypt was designed to have the speed of 4 hashes per second on the hardware of that time. Slower than 4 hashes per second would probably dampen usability. Faster than 100 hashes per second is probably too fast.

Table F-19 gives an overview of the relative slowness of different hashing algorithms. The table shows how much time it would take to try all combinations of characters in an 8-character password, assuming that the password contains either only lower case letters, or upper- and lower-case letters and numbers. In the `crypt-bf` entries, the number after a slash is the `iter_count` parameter of `gen_salt`.

Table F-19. Hash Algorithm Speeds

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Hashes/sec</th>
<th>For [a-z]</th>
<th>For [A-Za-z0-9]</th>
<th>Duration relative to md5 hash</th>
</tr>
</thead>
<tbody>

<td>22.5 minutes</td>
<td>17 days</td>
<td>1</td>
</tr>
</tbody>
</table>

Notes:

- The machine used is an Intel Mobile Core i3.
- `crypt-des` and `crypt-md5` algorithm numbers are taken from John the Ripper v1.6.38 `-test` output.
- `md5` hash numbers are from mdcrack 1.2.
- `sha1` numbers are from lcrack-20031130-beta.
- `crypt-bf` numbers are taken using a simple program that loops over 1000 8-character passwords.
  That way I can show the speed with different numbers of iterations. For reference: `john -test` shows 213 loops/sec for `crypt-bf/5`. (The very small difference in results is in accordance with the fact that the `crypt-bf` implementation in `pgcrypto` is the same one used in John the Ripper.)

Note that “try all combinations” is not a realistic exercise. Usually password cracking is done with the help of dictionaries, which contain both regular words and various mutations of them. So, even somewhat word-like passwords could be cracked much faster than the above numbers suggest, while a 6-character non-word-like password may escape cracking. Or not.
F.25.3. PGP Encryption Functions

The functions here implement the encryption part of the OpenPGP (RFC 4880) standard. Supported are both symmetric-key and public-key encryption.

An encrypted PGP message consists of 2 parts, or packets:

- Packet containing a session key — either symmetric-key or public-key encrypted.
- Packet containing data encrypted with the session key.

When encrypting with a symmetric key (i.e., a password):

1. The given password is hashed using a String2Key (S2K) algorithm. This is rather similar to crypt() algorithms — purposefully slow and with random salt — but it produces a full-length binary key.
2. If a separate session key is requested, a new random key will be generated. Otherwise the S2K key will be used directly as the session key.
3. If the S2K key is to be used directly, then only S2K settings will be put into the session key packet. Otherwise the session key will be encrypted with the S2K key and put into the session key packet.

When encrypting with a public key:

1. A new random session key is generated.
2. It is encrypted using the public key and put into the session key packet.

In either case the data to be encrypted is processed as follows:

1. Optional data-manipulation: compression, conversion to UTF-8, and/or conversion of line-endings.
2. The data is prefixed with a block of random bytes. This is equivalent to using a random IV.
3. An SHA1 hash of the random prefix and data is appended.
4. All this is encrypted with the session key and placed in the data packet.

F.25.3.1. pgp_sym_encrypt()

pgp_sym_encrypt(data text, psw text [, options text ]) returns bytea
pgp_sym_encrypt_bytea(data bytea, psw text [, options text ]) returns bytea

Encrypt data with a symmetric PGP key psw. The options parameter can contain option settings, as described below.

F.25.3.2. pgp_sym_decrypt()

pgp_sym_decrypt(msg bytea, psw text [, options text ]) returns text
pgp_sym_decrypt_bytea(msg bytea, psw text [, options text ]) returns bytea

Decrypt a symmetric-key-encrypted PGP message.

Decrypting bytea data with pgp_sym_decrypt is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with pgp_sym_decrypt_bytea is fine.
The `options` parameter can contain option settings, as described below.

### F.25.3.3. `pgp_pub_encrypt()`

```sql
pgp_pub_encrypt(data text, key bytea [, options text ]) returns bytea
pgp_pub_encrypt_bytea(data bytea, key bytea [, options text ]) returns bytea
```

Encrypt `data` with a public PGP key `key`. Giving this function a secret key will produce an error.

The `options` parameter can contain option settings, as described below.

### F.25.3.4. `pgp_pub_decrypt()`

```sql
pgp_pub_decrypt(msg bytea, key bytea [, psw text [, options text ]]) returns text
pgp_pub_decrypt_bytea(msg bytea, key bytea [, psw text [, options text ]]) returns bytea
```

Decrypt a public-key-encrypted message. `key` must be the secret key corresponding to the public key that was used to encrypt. If the secret key is password-protected, you must give the password in `psw`. If there is no password, but you want to specify options, you need to give an empty password.

Decrypting `bytea` data with `pgp_pub_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_pub_decrypt_bytea` is fine.

The `options` parameter can contain option settings, as described below.

### F.25.3.5. `pgp_key_id()`

```sql
pgp_key_id(bytea) returns text
```

`pgp_key_id` extracts the key ID of a PGP public or secret key. Or it gives the key ID that was used for encrypting the data, if given an encrypted message.

It can return 2 special key IDs:

- **SYMKEY**
  
The message is encrypted with a symmetric key.

- **ANYKEY**
  
The message is public-key encrypted, but the key ID has been removed. That means you will need to try all your secret keys on it to see which one decrypts it. `pgcrypto` itself does not produce such messages.

Note that different keys may have the same ID. This is rare but a normal event. The client application should then try to decrypt with each one, to see which fits — like handling ANYKEY.

### F.25.3.6. `armor()`, `dearmor()`

```sql
armor(data bytea) returns text
dearmor(data text) returns bytea
```

These functions wrap/unwrap binary data into PGP ASCII-armor format, which is basically Base64 with CRC and additional formatting.
F.25.3.7. Options for PGP Functions

Options are named to be similar to GnuPG. An option’s value should be given after an equal sign; separate options from each other with commas. For example:

```plaintext
gpg_sym_encrypt(data, psw, ‘compress-algo=1, cipher-algo=aes256’)
```

All of the options except `convert-crlf` apply only to encrypt functions. Decrypt functions get the parameters from the PGP data.

The most interesting options are probably `compress-algo` and `unicode-mode`. The rest should have reasonable defaults.

F.25.3.7.1. cipher-algo

Which cipher algorithm to use.

Values: bf, aes128, aes192, aes256 (OpenSSL-only: 3des, cast5)

Default: aes128

Applies to: `gpg_sym_encrypt`, `gpg_pub_encrypt`

F.25.3.7.2. compress-algo

Which compression algorithm to use. Only available if PostgreSQL was built with zlib.

Values:
- 0 - no compression
- 1 - ZIP compression
- 2 - ZLIB compression (= ZIP plus meta-data and block CRCs)

Default: 0

Applies to: `gpg_sym_encrypt`, `gpg_pub_encrypt`

F.25.3.7.3. compress-level

How much to compress. Higher levels compress smaller but are slower. 0 disables compression.

Values: 0, 1-9

Default: 6

Applies to: `gpg_sym_encrypt`, `gpg_pub_encrypt`

F.25.3.7.4. convert-crlf

Whether to convert \n into \r\n when encrypting and \r\n to \n when decrypting. RFC 4880 specifies that text data should be stored using \r\n line-feeds. Use this to get fully RFC-compliant behavior.

Values: 0, 1

Default: 0

Applies to: `gpg_sym_encrypt`, `gpg_pub_encrypt`, `gpg_sym_decrypt`, `gpg_pub_decrypt`
**F.25.3.7.5. disable-mdc**

Do not protect data with SHA-1. The only good reason to use this option is to achieve compatibility with ancient PGP products, predating the addition of SHA-1 protected packets to RFC 4880. Recent gnupg.org and pgp.com software supports it fine.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

**F.25.3.7.6. sess-key**

Use separate session key. Public-key encryption always uses a separate session key; this option is for symmetric-key encryption, which by default uses the S2K key directly.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt

**F.25.3.7.7. s2k-mode**

Which S2K algorithm to use.

Values:
- 0 - Without salt. Dangerous!
- 1 - With salt but with fixed iteration count.
- 3 - Variable iteration count.
Default: 3
Applies to: pgp_sym_encrypt

**F.25.3.7.8. s2k-digest-algo**

Which digest algorithm to use in S2K calculation.

Values: md5, sha1
Default: sha1
Applies to: pgp_sym_encrypt

**F.25.3.7.9. s2k-cipher-algo**

Which cipher to use for encrypting separate session key.

Values: bf, aes, aes128, aes192, aes256
Default: use cipher-algo
Applies to: pgp_sym_encrypt
F.25.3.7.10. unicode-mode

Whether to convert textual data from database internal encoding to UTF-8 and back. If your database already is UTF-8, no conversion will be done, but the message will be tagged as UTF-8. Without this option it will not be.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.25.3.8. Generating PGP Keys with GnuPG

To generate a new key:

gpg --gen-key

The preferred key type is “DSA and Elgamal”.

For RSA encryption you must create either DSA or RSA sign-only key as master and then add an RSA encryption subkey with gpg --edit-key.

To list keys:

gpg --list-secret-keys

To export a public key in ASCII-armor format:

gpg -a --export KEYID > public.key

To export a secret key in ASCII-armor format:

gpg -a --export-secret-keys KEYID > secret.key

You need to use dearmor() on these keys before giving them to the PGP functions. Or if you can handle binary data, you can drop -a from the command.

For more details see man gpg, The GNU Privacy Handbook\textsuperscript{3} and other documentation on http://www.gnupg.org.

F.25.3.9. Limitations of PGP Code

- No support for signing. That also means that it is not checked whether the encryption subkey belongs to the master key.
- No support for encryption key as master key. As such practice is generally discouraged, this should not be a problem.

\textsuperscript{3} http://www.gnupg.org/gph/en/manual.html
Appendix F. Additional Supplied Modules

- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with `pgcrypto`, but create new ones, as the usage scenario is rather different.

### F.25.4. Raw Encryption Functions

These functions only run a cipher over data; they don’t have any advanced features of PGP encryption. Therefore they have some major problems:

1. They use user key directly as cipher key.
2. They don’t provide any integrity checking, to see if the encrypted data was modified.
3. They expect that users manage all encryption parameters themselves, even IV.
4. They don’t handle text.

So, with the introduction of PGP encryption, usage of raw encryption functions is discouraged.

```sql
encrypt(data bytea, key bytea, type text) returns bytea
decrypt(data bytea, key bytea, type text) returns bytea

encrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
decrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
```

Encrypt/decrypt data using the cipher method specified by `type`. The syntax of the `type` string is:

```sql
algorithm [ - mode ] [ /pad: padding ]
```

where `algorithm` is one of:

- `bf` — Blowfish
- `aes` — AES (Rijndael-128, -192 or -256)

and `mode` is one of:

- `cbc` — next block depends on previous (default)
- `ecb` — each block is encrypted separately (for testing only)

and `padding` is one of:

- `pkcs` — data may be any length (default)
- `none` — data must be multiple of cipher block size

So, for example, these are equivalent:

```sql
encrypt(data, 'fooz', 'bf')
encrypt(data, 'fooz', 'bf-cbc/pad:pkcs')
```
In `encrypt_iv` and `decrypt_iv`, the `iv` parameter is the initial value for the CBC mode; it is ignored for ECB. It is clipped or padded with zeroes if not exactly block size. It defaults to all zeroes in the functions without this parameter.

### F.25.5. Random-Data Functions

```
gen_random_bytes(count integer) returns bytea
```

Returns `count` cryptographically strong random bytes. At most 1024 bytes can be extracted at a time. This is to avoid draining the randomness generator pool.

```
gen_random_uuid() returns uuid
```

Returns a version 4 (random) UUID.

### F.25.6. Notes

#### F.25.6.1. Configuration

`pgcrypto` configures itself according to the findings of the main PostgreSQL `configure` script. The options that affect it are `--with-zlib` and `--with-openssl`.

When compiled with zlib, PGP encryption functions are able to compress data before encrypting.

When compiled with OpenSSL, there will be more algorithms available. Also public-key encryption functions will be faster as OpenSSL has more optimized BIGNUM functions.

#### Table F-20. Summary of Functionality with and without OpenSSL

<table>
<thead>
<tr>
<th>Functionality</th>
<th>Built-in</th>
<th>With OpenSSL</th>
</tr>
</thead>
<tbody>
<tr>

<td>yes</td>
</tr>
</tbody>
</table>

Notes:

1. SHA2 algorithms were added to OpenSSL in version 0.9.8. For older versions, `pgcrypto` will use built-in code.

2. Any digest algorithm OpenSSL supports is automatically picked up. This is not possible with ciphers, which need to be supported explicitly.

3. AES is included in OpenSSL since version 0.9.7. For older versions, `pgcrypto` will use built-in
Appendix F. Additional Supplied Modules

code.

F.25.6.2. NULL Handling
As is standard in SQL, all functions return NULL, if any of the arguments are NULL. This may create security risks on careless usage.

F.25.6.3. Security Limitations
All pgcrypto functions run inside the database server. That means that all the data and passwords move between pgcrypto and client applications in clear text. Thus you must:

1. Connect locally or use SSL connections.
2. Trust both system and database administrator.
If you cannot, then better do crypto inside client application.
The implementation does not resist side-channel attacks\(^4\). For example, the time required for a pgcrypto decryption function to complete varies among ciphertexts of a given size.

F.25.6.4. Useful Reading

  The GNU Privacy Handbook.
- http://www.openwall.com/crypt/
  Describes the crypt-blowfish algorithm.
  How to choose a good password.
  Interesting idea for picking passwords.
- http://www.interhack.net/people/cmcurtin/snake-oil-faq.html
  Describes good and bad cryptography.

F.26. pg_freespacemap

The pg_freespacemap module provides a means for examining the free space map (FSM). It provides a function called pg_free space, or two overloaded functions, to be precise. The functions show the value recorded in the free space map for a given page, or for all pages in the relation.

By default public access is revoked from the functions, just in case there are security issues lurking.

F.26.1. Functions

pg_freespace(rel regclass IN, blkno bigint IN) returns int2

Returns the amount of free space on the page of the relation, specified by blkno, according to the FSM.

pg_freespace(rel regclass IN, blkno OUT bigint, avail OUT int2)

Displays the amount of free space on each page of the relation, according to the FSM. A set of (blkno bigint, avail int2) tuples is returned, one tuple for each page in the relation.

The values stored in the free space map are not exact. They’re rounded to precision of 1/256th of BLCKSZ (32 bytes with default BLCKSZ), and they’re not kept fully up-to-date as tuples are inserted and updated.
For indexes, what is tracked is entirely-unused pages, rather than free space within pages. Therefore, the values are not meaningful, just whether a page is full or empty.

Note: The interface was changed in version 8.4, to reflect the new FSM implementation introduced in the same version.

F.26.2. Sample Output

```
postgres=# SELECT * FROM pg_freespace('foo');
    blkno |  avail
----------+--------
         0 |      0
         1 |      0
         2 |      0
         3 |      32
         4 |    704
         5 |    704
         6 |    704
         7 |   1216
         8 |    704
         9 |    704
        10 |    704
        11 |    704
        12 |    704
        13 |    704
        14 |    704
        15 |    704
        16 |    704
        17 |    704
        18 |    704
        19 |  3648
(20 rows)
```

```
postgres=# SELECT * FROM pg_freespace('foo', 7);
pg_freespace
----------
     1216
(1 row)
```

F.26.3. Author

Original version by Mark Kirkwood <markir@paradise.net.nz>. Rewritten in version 8.4 to suit new FSM implementation by Heikki Linnakangas <heikki@enterprisedb.com>
F.27. pg_prewarm

The `pg_prewarm` module provides a convenient way to load relation data into either the operating system buffer cache or the PostgreSQL buffer cache.

F.27.1. Functions

```sql
pg_prewarm(regclass, mode text default 'buffer', fork text default 'main',
    first_block int8 default null,
    last_block int8 default null) RETURNS int8
```

The first argument is the relation to be prewarmed. The second argument is the prewarming method to be used, as further discussed below; the third is the relation fork to be prewarmed, usually `main`. The fourth argument is the first block number to prewarm (`NULL` is accepted as a synonym for zero). The fifth argument is the last block number to prewarm (`NULL` means prewarm through the last block in the relation). The return value is the number of blocks prewarmed.

There are three available prewarming methods. `prefetch` issues asynchronous prefetch requests to the operating system, if this is supported, or throws an error otherwise. `read` reads the requested range of blocks; unlike `prefetch`, this is synchronous and supported on all platforms and builds, but may be slower. `buffer` reads the requested range of blocks into the database buffer cache.

Note that with any of these methods, attempting to prewarm more blocks than can be cached — by the OS when using `prefetch` or `read`, or by PostgreSQL when using `buffer` — will likely result in lower-numbered blocks being evicted as higher numbered blocks are read in. Prewarmed data also enjoys no special protection from cache evictions, so it is possible for other system activity may evict the newly prewarmed blocks shortly after they are read; conversely, prewarming may also evict other data from cache. For these reasons, prewarming is typically most useful at startup, when caches are largely empty.

F.27.2. Author

Robert Haas <rhaas@postgresql.org>

F.28. pgrowlocks

The `pgrowlocks` module provides a function to show row locking information for a specified table.

F.28.1. Overview

```sql
pgrowlocks(text) returns setof record
```

The parameter is the name of a table. The result is a set of records, with one row for each locked row within the table. The output columns are shown in Table F-21.

Table F-21. pgrowlocks Output Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
Appendix F. Additional Supplied Modules

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>locked_row</td>
<td>tid</td>
<td>Tuple ID (TID) of locked row</td>
</tr>
<tr>
<td>locker</td>
<td>xid</td>
<td>Transaction ID of locker, or multixact ID if multitransaction</td>
</tr>
<tr>
<td>multi</td>
<td>boolean</td>
<td>True if locker is a multitransaction</td>
</tr>
<tr>
<td>xids</td>
<td>xid[]</td>
<td>Transaction IDs of lockers (more than one if multitransaction)</td>
</tr>
<tr>
<td>modes</td>
<td>text[]</td>
<td>Lock mode of lockers (more than one if multitransaction), an array of key share, share, for no key update, no key update, for update, update.</td>
</tr>
<tr>
<td>pids</td>
<td>integer[]</td>
<td>Process IDs of locking backends (more than one if multitransaction)</td>
</tr>
</tbody>
</table>

`pgrowlocks` takes `AccessShareLock` for the target table and reads each row one by one to collect the row locking information. This is not very speedy for a large table. Note that:

1. If the table as a whole is exclusive-locked by someone else, `pgrowlocks` will be blocked.
2. `pgrowlocks` is not guaranteed to produce a self-consistent snapshot. It is possible that a new row lock is taken, or an old lock is freed, during its execution.

`pgrowlocks` does not show the contents of locked rows. If you want to take a look at the row contents at the same time, you could do something like this:

```
SELECT * FROM accounts AS a, pgrowlocks('accounts') AS p
WHERE p.locked_row = a.ctid;
```

Be aware however that such a query will be very inefficient.

F.28.2. Sample Output

```
=# SELECT * FROM pgrowlocks('t1');
 locked_row | locker | multi | xids | modes       | pids
-----------------------------------------------
 (0,1)       | 609    | f     | {609} | {"For Share"} | {3161}
 (0,2)       | 609    | f     | {609} | {"For Share"} | {3161}
 (0,3)       | 607    | f     | {607} | {"For Update"} | {3107}
 (0,4)       | 607    | f     | {607} | {"For Update"} | {3107}
(4 rows)
```

F.29. pg_stat_statements

The `pg_stat_statements` module provides a means for tracking execution statistics of all SQL statements executed by a server.

The module must be loaded by adding `pg_stat_statements` to `shared_preload_libraries` in `postgresql.conf`, because it requires additional shared memory. This means that a server restart is needed to add or remove the module.

F.29.1. The `pg_stat_statements` View

The statistics gathered by the module are made available via a system view named `pg_stat_statements`. This view contains one row for each distinct database ID, user ID and query ID (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in Table F-22.

Table F-22. `pg_stat_statements` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>userid</td>

</tbody>
</table>

This view, and the functions `pg_stat_statements_reset` and `pg_stat_statements`, are available only in databases they have been specifically installed into by installing the `pg_stat_statements` extension. However, statistics are tracked across all databases of the server whenever the `pg_stat_statements` module is loaded into the server, regardless of presence of the view.

For security reasons, non-superusers are not allowed to see the SQL text or `queryid` of queries executed by other users. They can see the statistics, however, if the view has been installed in their database.

Plannable queries (that is, `SELECT`, `INSERT`, `UPDATE`, and `DELETE`) are combined into a single `pg_stat_statements` entry whenever they have identical query structures according to an internal hash calculation. Typically, two queries will be considered the same for this purpose if they are semantically equivalent except for the values of literal constants appearing in the query. Utility commands (that is, all other commands) are compared strictly on the basis of their textual query strings, however.

When a constant’s value has been ignored for purposes of matching the query to other queries, the constant is replaced by `?` in the `pg_stat_statements` display. The rest of the query text is that of the first query that had the particular `queryid` hash value associated with the `pg_stat_statements` view.

2249
entry.

In some cases, queries with visibly different texts might get merged into a single `pg_stat_statements` entry. Normally this will happen only for semantically equivalent queries, but there is a small chance of hash collisions causing unrelated queries to be merged into one entry. (This cannot happen for queries belonging to different users or databases, however.)

Since the `queryid` hash value is computed on the post-parse-analysis representation of the queries, the opposite is also possible: queries with identical texts might appear as separate entries, if they have different meanings as a result of factors such as different `search_path` settings.

Consumers of `pg_stat_statements` may wish to use `queryid` (perhaps in combination with `dbid` and `userid`) as a more stable and reliable identifier for each entry than its query text. However, it is important to understand that there are only limited guarantees around the stability of the `queryid` hash value. Since the identifier is derived from the post-parse-analysis tree, its value is a function of, among other things, the internal object identifiers appearing in this representation. This has some counterintuitive implications. For example, `pg_stat_statements` will consider two apparently-identical queries to be distinct, if they reference a table that was dropped and recreated between the executions of the two queries. The hashing process is also sensitive to differences in machine architecture and other facets of the platform. Furthermore, it is not safe to assume that `queryid` will be stable across major versions of PostgreSQL.

As a rule of thumb, `queryid` values can be assumed to be stable and comparable only so long as the underlying server version and catalog metadata details stay exactly the same. Two servers participating in replication based on physical WAL replay can be expected to have identical `queryid` values for the same query. However, logical replication schemes do not promise to keep replicas identical in all relevant details, so `queryid` will not be a useful identifier for accumulating costs across a set of logical replicas. If in doubt, direct testing is recommended.

The representative query texts are kept in an external disk file, and do not consume shared memory. Therefore, even very lengthy query texts can be stored successfully. However, if many long query texts are accumulated, the external file might grow unmanageably large. As a recovery method if that happens, `pg_stat_statements` may choose to discard the query texts, whereupon all existing entries in the `pg_stat_statements` view will show null `query` fields, though the statistics associated with each `queryid` are preserved. If this happens, consider reducing `pg_stat_statements.max` to prevent recurrences.

F.29.2. Functions

```sql
pg_stat_statements_reset() returns void
```

`pg_stat_statements_reset` discards all statistics gathered so far by `pg_stat_statements`. By default, this function can only be executed by superusers.

```sql
pg_stat_statements(showtext boolean) returns setof record
```

The `pg_stat_statements` view is defined in terms of a function also named `pg_stat_statements`. It is possible for clients to call the `pg_stat_statements` function directly, and by specifying `showtext := false` have query text be omitted (that is, the `OUT` argument that corresponds to the view’s `query` column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all `pg_stat_statements` itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the `pg_stat_statements` data.
Appendix F. Additional Supplied Modules

F.29.3. Configuration Parameters

pg_stat_statements.max (integer)

pg_stat_statements.max is the maximum number of statements tracked by the module (i.e., the maximum number of rows in the pg_stat_statements view). If more distinct statements than that are observed, information about the least-executed statements is discarded. The default value is 5000. This parameter can only be set at server start.

pg_stat_statements.track (enum)

pg_stat_statements.track controls which statements are counted by the module. Specify top to track top-level statements (those issued directly by clients), all to also track nested statements (such as statements invoked within functions), or none to disable statement statistics collection. The default value is top. Only superusers can change this setting.

pg_stat_statements.track_utility (boolean)

pg_stat_statements.track_utility controls whether utility commands are tracked by the module. Utility commands are all those other than SELECT, INSERT, UPDATE and DELETE. The default value is on. Only superusers can change this setting.

pg_stat_statements.save (boolean)

pg_stat_statements.save specifies whether to save statement statistics across server shutdowns. If it is off then statistics are not saved at shutdown nor reloaded at server start. The default value is on. This parameter can only be set in the postgresql.conf file or on the server command line.

The module requires additional shared memory proportional to pg_stat_statements.max. Note that this memory is consumed whenever the module is loaded, even if pg_stat_statements.track is set to none.

These parameters must be set in postgresql.conf. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'pg_stat_statements'
pg_stat_statements.max = 10000
pg_stat_statements.track = all
```

F.29.4. Sample Output

bench=# SELECT pg_stat_statements_reset();
$ pgbench -i bench
$ pgbench -c10 -t300 bench

bench=# \x
bench=# SELECT query, calls, total_time, rows, 100.0 * shared_blks_hit / nullif(shared_blks_hit + shared_blks_read, 0) AS hit_percent FROM pg_stat_statements ORDER BY total_time DESC LIMIT 5;

<table>
<thead>
<tr>
<th>query</th>
<th>calls</th>
<th>total_time</th>
<th>rows</th>
</tr>
</thead>
<tbody>
<tr>
<td>UPDATE pgbench_branches SET bbalance = bbalance + ? WHERE bid = ?;</td>
<td>3000</td>
<td>9609.001000000002</td>
<td></td>
</tr>
</tbody>
</table>
F.29.5. Authors

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>. Query normalization added by Peter Geoghegan <peter@2ndquadrant.com>.

F.30. pgstattuple

The pgstattuple module provides various functions to obtain tuple-level statistics.

F.30.1. Functions

pgstattuple(regclass) returns record

pgstattuple returns a relation’s physical length, percentage of “dead” tuples, and other info. This may help users to determine whether vacuum is necessary or not. The argument is the target relation’s name (optionally schema-qualified) or OID. For example:

test=> SELECT * FROM pgstattuple('pg_catalog.pg_proc');

- [ RECORD 1 ]------------------------
table_len | 458752
tuple_count | 1470
tuple_len | 438896
tuple_percent | 95.67
dead_tuple_count | 11

dead_tuple_len | 3157
dead_tuple_percent | 0.69
free_space | 8932
free_percent | 1.95
The output columns are described in Table F-23.

Table F-23. pgstattuple Output Columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_len</td>
<td>bigint</td>
<td>Physical relation length in bytes</td>
</tr>
<tr>
<td>tuple_count</td>
<td>bigint</td>
<td>Number of live tuples</td>
</tr>
<tr>
<td>tuple_len</td>
<td>bigint</td>
<td>Total length of live tuples in bytes</td>
</tr>
<tr>
<td>tuple_percent</td>
<td>float8</td>
<td>Percentage of live tuples</td>
</tr>
<tr>
<td>dead_tuple_count</td>
<td>bigint</td>
<td>Number of dead tuples</td>
</tr>
<tr>
<td>dead_tuple_len</td>
<td>bigint</td>
<td>Total length of dead tuples in bytes</td>
</tr>
<tr>
<td>dead_tuple_percent</td>
<td>float8</td>
<td>Percentage of dead tuples</td>
</tr>
<tr>
<td>free_space</td>
<td>bigint</td>
<td>Total free space in bytes</td>
</tr>
<tr>
<td>free_percent</td>
<td>float8</td>
<td>Percentage of free space</td>
</tr>
</tbody>
</table>

*Note:* The table_len will always be greater than the sum of the tuple_len, dead_tuple_len and free_space. The difference is accounted for by fixed page overhead, the per-page table of pointers to tuples, and padding to ensure that tuples are correctly aligned.

pgstattuple acquires only a read lock on the relation. So the results do not reflect an instantaneous snapshot; concurrent updates will affect them.

pgstattuple judges a tuple is “dead” if HeapTupleSatisfiesDirty returns false.

pgstattuple(text) returns record

This is the same as pgstattuple(regclass), except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

pgstatindex(regclass) returns record

pgstatindex returns a record showing information about a B-tree index. For example:

test=> SELECT * FROM pgstatindex('pg_cast_oid_index');
-[
  RECORD 1 ]---------------
  version | 2
  tree_level | 0
  index_size | 16384
  root_block_no | 1
  internal_pages | 0
  leaf_pages | 1
  empty_pages | 0
  deleted_pages | 0
  avg_leaf_density | 54.27
  leaf_fragmentation | 0

Appendix F. Additional Supplied Modules

The output columns are:

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>integer</td>
<td>B-tree version number</td>
</tr>
<tr>
<td>tree_level</td>
<td>integer</td>
<td>Tree level of the root page</td>
</tr>
<tr>
<td>index_size</td>
<td>bigint</td>
<td>Total index size in bytes</td>
</tr>
<tr>
<td>root_block_no</td>
<td>bigint</td>
<td>Location of root page (zero if none)</td>
</tr>
<tr>
<td>internal_pages</td>
<td>bigint</td>
<td>Number of “internal” (upper-level) pages</td>
</tr>
<tr>
<td>leaf_pages</td>
<td>bigint</td>
<td>Number of leaf pages</td>
</tr>
<tr>
<td>empty_pages</td>
<td>bigint</td>
<td>Number of empty pages</td>
</tr>
<tr>
<td>deleted_pages</td>
<td>bigint</td>
<td>Number of deleted pages</td>
</tr>
<tr>
<td>avg_leaf_density</td>
<td>float8</td>
<td>Average density of leaf pages</td>
</tr>
<tr>
<td>leaf_fragmentation</td>
<td>float8</td>
<td>Leaf page fragmentation</td>
</tr>
</tbody>
</table>

The reported `index_size` will normally correspond to one more page than is accounted for by `internal_pages + leaf_pages + empty_pages + deleted_pages`, because it also includes the index’s metapage.

As with `pgstattuple`, the results are accumulated page-by-page, and should not be expected to represent an instantaneous snapshot of the whole index.

`pgstatindex(TEXT)` returns record

This is the same as `pgstatindex(regclass)`, except that the target index is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatginindex(regclass)` returns record

`pgstatginindex` returns a record showing information about a GIN index. For example:

```
 test=> SELECT * FROM pgstatginindex('test_gin_index');
  -[ RECORD 1 ]--+-
    version  | 1
    pending_pages  | 0
    pending_tuples  | 0
```

The output columns are:

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>integer</td>
<td>GIN version number</td>
</tr>
<tr>
<td>pending_pages</td>
<td>integer</td>
<td>Number of pages in the pending list</td>
</tr>
<tr>
<td>pending_tuples</td>
<td>bigint</td>
<td>Number of tuples in the pending list</td>
</tr>
</tbody>
</table>

`pg_relpages(regclass)` returns bigint

`pg_relpages` returns the number of pages in the relation.
pg_relpages(text) returns bigint

This is the same as pg_relpages(regclass), except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

F.30.2. Authors
Tatsuo Ishii and Satoshi Nagayasu

F.31. pg_trgm

The pg_trgm module provides functions and operators for determining the similarity of alphanumeric text based on trigram matching, as well as index operator classes that support fast searching for similar strings.

F.31.1. Trigram (or Trigraph) Concepts

A trigram is a group of three consecutive characters taken from a string. We can measure the similarity of two strings by counting the number of trigrams they share. This simple idea turns out to be very effective for measuring the similarity of words in many natural languages.

Note: pg_trgm ignores non-word characters (non-alphanumeric) when extracting trigrams from a string. Each word is considered to have two spaces prefixed and one space suffixed when determining the set of trigrams contained in the string. For example, the set of trigrams in the string “cat” is “ c”, “ ca”, “ cat”, and “ at ”. The set of trigrams in the string “foo|bar” is “ f”, “ fo”, “foo”, “ oo ”, “ o”, “ ba”, “bar”, and “ar ”.

F.31.2. Functions and Operators

The functions provided by the pg_trgm module are shown in Table F-24, the operators in Table F-25.

Table F-24. pg_trgm Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>similarity(text, text)</td>
<td>real</td>
<td>Returns a number that indicates how similar the two arguments are. The range of the result is zero (indicating that the two strings are completely dissimilar) to one (indicating that the two strings are identical).</td>
</tr>
</tbody>
</table>
### Appendix F. Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show_trgm(text)</code></td>
<td><code>text[]</code></td>
<td>Returns an array of all the trigrams in the given string. (In practice this is seldom useful except for debugging.)</td>
</tr>
<tr>
<td><code>show_limit()</code></td>
<td><code>real</code></td>
<td>Returns the current similarity threshold used by the <code>%</code> operator. This sets the minimum similarity between two words for them to be considered similar enough to be misspellings of each other, for example.</td>
</tr>
<tr>
<td><code>set_limit(real)</code></td>
<td><code>real</code></td>
<td>Sets the current similarity threshold that is used by the <code>%</code> operator. The threshold must be between 0 and 1 (default is 0.3). Returns the same value passed in.</td>
</tr>
</tbody>
</table>

#### Table F-25. pg_trgm Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>text % text</code></td>
<td><code>boolean</code></td>
<td>Returns <code>true</code> if its arguments have a similarity that is greater than the current similarity threshold set by <code>set_limit</code>.</td>
</tr>
<tr>
<td><code>text &lt;-&gt; text</code></td>
<td><code>real</code></td>
<td>Returns the “distance” between the arguments, that is one minus the <code>similarity()</code> value.</td>
</tr>
</tbody>
</table>

### F.31.3. Index Support

The `pg_trgm` module provides GiST and GIN index operator classes that allow you to create an index over a text column for the purpose of very fast similarity searches. These index types support the above-described similarity operators, and additionally support trigram-based index searches for `LIKE`, `ILIKE`, `~` and `~*` queries. (These indexes do not support equality nor simple comparison operators, so you may need a regular B-tree index too.)

Example:

```sql
CREATE TABLE test_trgm (t text);
CREATE INDEX trgm_idx ON test_trgm USING gist (t gist_trgm_ops);

or

CREATE INDEX trgm_idx ON test_trgm USING gin (t gin_trgm_ops);
```
Appendix F. Additional Supplied Modules

At this point, you will have an index on the \( t \) column that you can use for similarity searching. A typical query is

```sql
SELECT t, similarity(t, 'word') AS sml
FROM test_trgm
WHERE t % 'word'
ORDER BY sml DESC, t;
```

This will return all values in the text column that are sufficiently similar to \textit{word}, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

A variant of the above query is

```sql
SELECT t, t <-> 'word' AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes. It will usually beat the first formulation when only a small number of the closest matches is wanted.

Beginning in PostgreSQL 9.1, these index types also support index searches for \texttt{LIKE} and \texttt{ILIKE}, for example

```sql
SELECT * FROM test_trgm WHERE t LIKE '%foo%bar';
```

The index search works by extracting trigrams from the search string and then looking these up in the index. The more trigrams in the search string, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

Beginning in PostgreSQL 9.3, these index types also support index searches for regular-expression matches (\texttt{~} and \texttt{~*} operators), for example

```sql
SELECT * FROM test_trgm WHERE t ~ '(foo|bar)';
```

The index search works by extracting trigrams from the regular expression and then looking these up in the index. The more trigrams that can be extracted from the regular expression, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

For both \texttt{LIKE} and regular-expression searches, keep in mind that a pattern with no extractable trigrams will degenerate to a full-index scan.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere. As a rule of thumb, a GIN index is faster to search than a GiST index, but slower to build or update; so GIN is better suited for static data and GiST for often-updated data.

### F.31.4. Text Search Integration

Trigram matching is a very useful tool when used in conjunction with a full text index. In particular it can help to recognize misspelled input words that will not be matched directly by the full text search mechanism.

The first step is to generate an auxiliary table containing all the unique words in the documents:

```sql
CREATE TABLE words AS SELECT word FROM
ts_stat('SELECT to_tsvector("simple", bodytext) FROM documents');
```
where documents is a table that has a text field bodytext that we wish to search. The reason for using the simple configuration with the to_tsvector function, instead of using a language-specific configuration, is that we want a list of the original (unstemmed) words.

Next, create a trigram index on the word column:

```sql
CREATE INDEX words_idx ON words USING gin(word gin_trgm_ops);
```

Now, a SELECT query similar to the previous example can be used to suggest spellings for misspelled words in user search terms. A useful extra test is to require that the selected words are also of similar length to the misspelled word.

**Note:** Since the words table has been generated as a separate, static table, it will need to be periodically regenerated so that it remains reasonably up-to-date with the document collection. Keeping it exactly current is usually unnecessary.

### F.32. postgres_fdw

The postgres_fdw module provides the foreign-data wrapper postgres_fdw, which can be used to access data stored in external PostgreSQL servers.

The functionality provided by this module overlaps substantially with the functionality of the older dblink module. But postgres_fdw provides more transparent and standards-compliant syntax for accessing remote tables, and can give better performance in many cases.

To prepare for remote access using postgres_fdw:

1. Install the postgres_fdw extension using CREATE EXTENSION.
2. Create a foreign server object, using CREATE SERVER, to represent each remote database you want to connect to. Specify connection information, except user and password, as options of the server object.
3. Create a user mapping, using CREATE USER MAPPING, for each database user you want to allow to access each foreign server. Specify the remote user name and password to use as user and password options of the user mapping.
4. Create a foreign table, using CREATE FOREIGN TABLE, for each remote table you want to access. The columns of the foreign table must match the referenced remote table. You can, however, use table and/or column names different from the remote table’s, if you specify the correct remote names as options of the foreign table object.

Now you need only SELECT from a foreign table to access the data stored in its underlying remote table. You can also modify the remote table using INSERT, UPDATE, or DELETE. (Of course, the remote user you have specified in your user mapping must have privileges to do these things.)

It is generally recommended that the columns of a foreign table be declared with exactly the same data types, and collations if applicable, as the referenced columns of the remote table. Although postgres_fdw is currently rather forgiving about performing data type conversions at need, surprising semantic anomalies may arise when types or collations do not match, due to the remote server interpreting WHERE clauses slightly differently from the local server.

Note that a foreign table can be declared with fewer columns, or with a different column order, than its underlying remote table has. Matching of columns to the remote table is by name, not position.

**F.32.1. FDW Options of postgres_fdw**

**F.32.1.1. Connection Options**

A foreign server using the postgres_fdw foreign data wrapper can have the same options that libpq accepts in connection strings, as described in Section 31.1.2, except that these options are not allowed:

- user and password (specify these for a user mapping, instead)
- client_encoding (this is automatically set from the local server encoding)
- fallback_application_name (always set to postgres_fdw)

Only superusers may connect to foreign servers without password authentication, so always specify the password option for user mappings belonging to non-superusers.

**F.32.1.2. Object Name Options**

These options can be used to control the names used in SQL statements sent to the remote PostgreSQL server. These options are needed when a foreign table is created with names different from the underlying remote table’s names.

`schema_name`

This option, which can be specified for a foreign table, gives the schema name to use for the foreign table on the remote server. If this option is omitted, the name of the foreign table’s schema is used.

`table_name`

This option, which can be specified for a foreign table, gives the table name to use for the foreign table on the remote server. If this option is omitted, the foreign table’s name is used.
Appendix F. Additional Supplied Modules

This option, which can be specified for a column of a foreign table, gives the column name to use for the column on the remote server. If this option is omitted, the column’s name is used.

F.32.1.3. Cost Estimation Options

`postgres_fdw` retrieves remote data by executing queries against remote servers, so ideally the estimated cost of scanning a foreign table should be whatever it costs to be done on the remote server, plus some overhead for communication. The most reliable way to get such an estimate is to ask the remote server and then add something for overhead — but for simple queries, it may not be worth the cost of an additional remote query to get a cost estimate. So `postgres_fdw` provides the following options to control how cost estimation is done:

`use_remote_estimate`

This option, which can be specified for a foreign table or a foreign server, controls whether `postgres_fdw` issues remote EXPLAIN commands to obtain cost estimates. A setting for a foreign table overrides any setting for its server, but only for that table. The default is `false`.

`fdw_startup_cost`

This option, which can be specified for a foreign server, is a numeric value that is added to the estimated startup cost of any foreign-table scan on that server. This represents the additional overhead of establishing a connection, parsing and planning the query on the remote side, etc. The default value is 100.

`fdw_tuple_cost`

This option, which can be specified for a foreign server, is a numeric value that is used as extra cost per-tuple for foreign-table scans on that server. This represents the additional overhead of data transfer between servers. You might increase or decrease this number to reflect higher or lower network delay to the remote server. The default value is 0.01.

When `use_remote_estimate` is `true`, `postgres_fdw` obtains row count and cost estimates from the remote server and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. When `use_remote_estimate` is `false`, `postgres_fdw` performs local row count and cost estimation and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. This local estimation is unlikely to be very accurate unless local copies of the remote table’s statistics are available. Running `ANALYZE` on the foreign table is the way to update the local statistics; this will perform a scan of the remote table and then calculate and store statistics just as though the table were local. Keeping local statistics can be a useful way to reduce per-query planning overhead for a remote table — but if the remote table is frequently updated, the local statistics will soon be obsolete.

F.32.1.4. Updatability Options

By default all foreign tables using `postgres_fdw` are assumed to be updatable. This may be overridden using the following option:

`updatable`

This option controls whether `postgres_fdw` allows foreign tables to be modified using INSERT, UPDATE and DELETE commands. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`. 2260
Of course, if the remote table is not in fact updatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server. Note however that the information_schema views will report a postgres_fdw foreign table to be updatable (or not) according to the setting of this option, without any check of the remote server.

F.32.2. Connection Management

postgres_fdw establishes a connection to a foreign server during the first query that uses a foreign table associated with the foreign server. This connection is kept and re-used for subsequent queries in the same session. However, if multiple user identities (user mappings) are used to access the foreign server, a connection is established for each user mapping.

F.32.3. Transaction Management

During a query that references any remote tables on a foreign server, postgres_fdw opens a transaction on the remote server if one is not already open corresponding to the current local transaction. The remote transaction is committed or aborted when the local transaction commits or aborts. Savepoints are similarly managed by creating corresponding remote savepoints.

The remote transaction uses SERIALIZABLE isolation level when the local transaction has SERIALIZABLE isolation level; otherwise it uses REPEATABLE READ isolation level. This choice ensures that if a query performs multiple table scans on the remote server, it will get snapshot-consistent results for all the scans. A consequence is that successive queries within a single transaction will see the same data from the remote server, even if concurrent updates are occurring on the remote server due to other activities. That behavior would be expected anyway if the local transaction uses SERIALIZABLE or REPEATABLE READ isolation level, but it might be surprising for a READ COMMITTED local transaction. A future PostgreSQL release might modify these rules.

F.32.4. Remote Query Optimization

postgres_fdw attempts to optimize remote queries to reduce the amount of data transferred from foreign servers. This is done by sending query WHERE clauses to the remote server for execution, and by not retrieving table columns that are not needed for the current query. To reduce the risk of misexecution of queries, WHERE clauses are not sent to the remote server unless they use only built-in data types, operators, and functions. Operators and functions in the clauses must be IMMUTABLE as well.

The query that is actually sent to the remote server for execution can be examined using EXPLAIN VERbose.

F.32.5. Remote Query Execution Environment

In the remote sessions opened by postgres_fdw, the search_path parameter is set to just pg_catalog, so that only built-in objects are visible without schema qualification. This is not an issue for queries generated by postgres_fdw itself, because it always supplies such qualification. However, this can pose a hazard for functions that are executed on the remote server via triggers or rules on remote tables. For example, if a remote table is actually a view, any functions used in that view will be executed with the restricted search path. It is recommended to schema-qualify all names
in such functions, or else attach `SET search_path` options (see `CREATE FUNCTION`) to such functions to establish their expected search path environment.

`postgres_fdw` likewise establishes remote session settings for the parameters TimeZone, DateStyle, IntervalStyle, and extra_float_digits. These are less likely to be problematic than `search_path`, but can be handled with function `SET` options if the need arises.

It is not recommended that you override this behavior by changing the session-level settings of these parameters; that is likely to cause `postgres_fdw` to malfunction.

### F.32.6. Cross-Version Compatibility

`postgres_fdw` can be used with remote servers dating back to PostgreSQL 8.3. Read-only capability is available back to 8.1. A limitation however is that `postgres_fdw` generally assumes that immutable built-in functions and operators are safe to send to the remote server for execution, if they appear in a `WHERE` clause for a foreign table. Thus, a built-in function that was added since the remote server’s release might be sent to it for execution, resulting in “function does not exist” or a similar error. This type of failure can be worked around by rewriting the query, for example by embedding the foreign table reference in a sub-`SELECT` with `OFFSET 0` as an optimization fence, and placing the problematic function or operator outside the sub-`SELECT`.

### F.32.7. Examples

Here is an example of creating a foreign table with `postgres_fdw`. First install the extension:

```sql
CREATE EXTENSION postgres_fdw;
```

Then create a foreign server using `CREATE SERVER`. In this example we wish to connect to a PostgreSQL server on host `192.83.123.89` listening on port `5432`. The database to which the connection is made is named `foreign_db` on the remote server:

```sql
CREATE SERVER foreign_server
FOREIGN DATA WRAPPER postgres_fdw
OPTIONS (host '192.83.123.89', port '5432', dbname 'foreign_db');
```

A user mapping, defined with `CREATE USER MAPPING`, is needed as well to identify the role that will be used on the remote server:

```sql
CREATE USER MAPPING FOR local_user
SERVER foreign_server
OPTIONS (user 'foreign_user', password 'password');
```

Now it is possible to create a foreign table with `CREATE FOREIGN TABLE`. In this example we wish to access the table named `some_schema.some_table` on the remote server. The local name for it will be `foreign_table`:

```sql
CREATE FOREIGN TABLE foreign_table
(id serial NOT NULL,
 data text
)
SERVER foreign_server
```
OPTIONS (schema_name 'some_schema', table_name 'some_table');

It’s essential that the data types and other properties of the columns declared in `CREATE FOREIGN TABLE` match the actual remote table. Column names must match as well, unless you attach `column_name` options to the individual columns to show how they are named in the remote table.

**F.32.8. Author**

Shigeru Hanada <shigeru.hanada@gmail.com>

**F.33. seg**

This module implements a data type `seg` for representing line segments, or floating point intervals. `seg` can represent uncertainty in the interval endpoints, making it especially useful for representing laboratory measurements.

**F.33.1. Rationale**

The geometry of measurements is usually more complex than that of a point in a numeric continuum. A measurement is usually a segment of that continuum with somewhat fuzzy limits. The measurements come out as intervals because of uncertainty and randomness, as well as because the value being measured may naturally be an interval indicating some condition, such as the temperature range of stability of a protein.

Using just common sense, it appears more convenient to store such data as intervals, rather than pairs of numbers. In practice, it even turns out more efficient in most applications.

Further along the line of common sense, the fuzziness of the limits suggests that the use of traditional numeric data types leads to a certain loss of information. Consider this: your instrument reads 6.50, and you input this reading into the database. What do you get when you fetch it? Watch:

```
test=> select 6.50 :: float8 as "pH";
   pH
---
   6.5
(1 row)
```

In the world of measurements, 6.50 is not the same as 6.5. It may sometimes be critically different. The experimenters usually write down (and publish) the digits they trust. 6.50 is actually a fuzzy interval contained within a bigger and even fuzzier interval, 6.5, with their center points being (probably) the only common feature they share. We definitely do not want such different data items to appear the same.

Conclusion? It is nice to have a special data type that can record the limits of an interval with arbitrarily variable precision. Variable in the sense that each data element records its own precision.

Check this out:

```
test=> select '6.25 .. 6.50'::seg as "pH";
   pH
-------------
   6.25 .. 6.50
```

2263
F.33.2. Syntax

The external representation of an interval is formed using one or two floating-point numbers joined by the range operator (.. or ...). Alternatively, it can be specified as a center point plus or minus a deviation. Optional certainty indicators (<, > or ~) can be stored as well. (Certainty indicators are ignored by all the built-in operators, however.) Table F-26 gives an overview of allowed representations; Table F-27 shows some examples.

In Table F-26, \(x, y\), and \(\delta\) denote floating-point numbers. \(x\) and \(y\), but not \(\delta\), can be preceded by a certainty indicator.

Table F-26. \texttt{seg} External Representations

| \(x\) | Single value (zero-length interval) |
| \(x..y\) | Interval from \(x\) to \(y\) |
| \(x(+-)\delta\) | Interval from \(x-\delta\) to \(x+\delta\) |
| \(x..\) | Open interval with lower bound \(x\) |
| ..\(x\) | Open interval with upper bound \(x\) |

Table F-27. Examples of Valid \texttt{seg} Input

| \(5.0\) | Creates a zero-length segment (a point, if you will) |
| \(~5.0\) | Creates a zero-length segment and records ~ in the data. ~ is ignored by \texttt{seg} operations, but is preserved as a comment. |
| \(<5.0\) | Creates a point at 5.0. < is ignored but is preserved as a comment. |
| \(>5.0\) | Creates a point at 5.0. > is ignored but is preserved as a comment. |
| \(5(+-)0.3\) | Creates an interval 4.7 .. 5.3. Note that the \((+-)\) notation isn’t preserved. |
| \(50..\) | Everything that is greater than or equal to 50 |
| \(..0\) | Everything that is less than or equal to 0 |
| \(1.5e-2..2e-2\) | Creates an interval 0.015 .. 0.02 |
| \(1...2\) | The same as 1...2, or 1 .. 2, or 1..2 (spaces around the range operator are ignored) |

Because ... is widely used in data sources, it is allowed as an alternative spelling of ... Unfortunately, this creates a parsing ambiguity: it is not clear whether the upper bound in 0...23 is meant to be 23 or 0.23. This is resolved by requiring at least one digit before the decimal point in all numbers in \texttt{seg} input.

As a sanity check, \texttt{seg} rejects intervals with the lower bound greater than the upper, for example 5 .. 2.
F.33.3. Precision

`seg` values are stored internally as pairs of 32-bit floating point numbers. This means that numbers with more than 7 significant digits will be truncated.

Numbers with 7 or fewer significant digits retain their original precision. That is, if your query returns 0.00, you will be sure that the trailing zeroes are not the artifacts of formatting: they reflect the precision of the original data. The number of leading zeroes does not affect precision: the value 0.0067 is considered to have just 2 significant digits.

F.33.4. Usage

The `seg` module includes a GiST index operator class for `seg` values. The operators supported by the GiST operator class are shown in Table F-28.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[a, b] &lt;&lt; [c, d]</code></td>
<td><code>[a, b]</code> is entirely to the left of <code>[c, d]</code>. That is, <code>[a, b] &lt;&lt; [c, d]</code> is true if <code>b &lt; c</code> and false otherwise.</td>
</tr>
<tr>
<td><code>[a, b] &gt;&gt; [c, d]</code></td>
<td><code>[a, b]</code> is entirely to the right of <code>[c, d]</code>. That is, <code>[a, b] &gt;&gt; [c, d]</code> is true if <code>a &gt; d</code> and false otherwise.</td>
</tr>
<tr>
<td><code>[a, b] &amp;&lt; [c, d]</code></td>
<td>Overlaps or is left of — This might be better read as “does not extend to right of”. It is true when <code>b &lt;= d</code>.</td>
</tr>
<tr>
<td><code>[a, b] &amp;&gt; [c, d]</code></td>
<td>Overlaps or is right of — This might be better read as “does not extend to left of”. It is true when <code>a &gt;= c</code>.</td>
</tr>
<tr>
<td><code>[a, b] = [c, d]</code></td>
<td>Same as — The segments <code>[a, b]</code> and <code>[c, d]</code> are identical, that is, <code>a = c</code> and <code>b = d</code>.</td>
</tr>
<tr>
<td><code>[a, b] &amp;&amp; [c, d]</code></td>
<td>The segments <code>[a, b]</code> and <code>[c, d]</code> overlap.</td>
</tr>
<tr>
<td><code>[a, b] @&gt; [c, d]</code></td>
<td>The segment <code>[a, b]</code> contains the segment <code>[c, d]</code>, that is, <code>a &lt;= c</code> and <code>b &gt;= d</code>.</td>
</tr>
<tr>
<td><code>[a, b] &lt;@ [c, d]</code></td>
<td>The segment <code>[a, b]</code> is contained in <code>[c, d]</code>, that is, <code>a &gt;= c</code> and <code>b &lt;= d</code>.</td>
</tr>
</tbody>
</table>

(Before PostgreSQL 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

The standard B-tree operators are also provided, for example

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[a, b] &lt; [c, d]</code></td>
<td>Less than</td>
</tr>
<tr>
<td><code>[a, b] &gt; [c, d]</code></td>
<td>Greater than</td>
</tr>
</tbody>
</table>

These operators do not make a lot of sense for any practical purpose but sorting. These operators first compare (a) to (c), and if these are equal, compare (b) to (d). That results in reasonably good sorting in most cases, which is useful if you want to use ORDER BY with this type.
F.33.5. Notes

For examples of usage, see the regression test sql/seg.sql.

The mechanism that converts \((+-)\) to regular ranges isn’t completely accurate in determining the number of significant digits for the boundaries. For example, it adds an extra digit to the lower boundary if the resulting interval includes a power of ten:

```
postgres=> select '10(+-)1'::seg as seg;
seg
---------
9.0 .. 11 -- should be: 9 .. 11
```

The performance of an R-tree index can largely depend on the initial order of input values. It may be very helpful to sort the input table on the `seg` column; see the script `sort-segments.pl` for an example.

F.33.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (http://db.cs.berkeley.edu/jmh/) for elucidating the gist of the GiST (http://gist.cs.berkeley.edu/). I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

F.34. sepgsql

`sepgsql` is a loadable module that supports label-based mandatory access control (MAC) based on SELinux security policy.

**Warning**

The current implementation has significant limitations, and does not enforce mandatory access control for all actions. See Section F.34.7.

F.34.1. Overview

This module integrates with SELinux to provide an additional layer of security checking above and beyond what is normally provided by PostgreSQL. From the perspective of SELinux, this module allows PostgreSQL to function as a user-space object manager. Each table or function access initiated by a DML query will be checked against the system security policy. This check is in addition to the usual SQL permissions checking performed by PostgreSQL.

SELinux access control decisions are made using security labels, which are represented by strings such as `system_u:object_r:sepgsql_table_t:s0`. Each access control decision involves two labels: the label of the subject attempting to perform the action, and the label of the object on which
the operation is to be performed. Since these labels can be applied to any sort of object, access control
decisions for objects stored within the database can be (and, with this module, are) subjected to the
same general criteria used for objects of any other type, such as files. This design is intended to allow
a centralized security policy to protect information assets independent of the particulars of how those
assets are stored.

The SECURITY LABEL statement allows assignment of a security label to a database object.

F.34.2. Installation

sepgsql can only be used on Linux 2.6.28 or higher with SELinux enabled. It is not available on
any other platform. You will also need libselinux 2.1.10 or higher and selinux-policy 3.9.13 or higher
(although some distributions may backport the necessary rules into older policy versions).

The sestatus command allows you to check the status of SELinux. A typical display is:

```
$ sestatus
SELinux status: enabled
SELinuxfs mount: /selinux
Current mode: enforcing
Mode from config file: enforcing
Policy version: 24
Policy from config file: targeted
```

If SELinux is disabled or not installed, you must set that product up first before installing this module.

To build this module, include the option `--with-selinux` in your PostgreSQL configure command. Be sure that the libselinux-devel RPM is installed at build time.

To use this module, you must include sepgsql in the shared_preload_libraries parameter in postgresql.conf. The module will not function correctly if loaded in any other manner. Once the module is loaded, you should execute sepgsql.sql in each database. This will install functions needed for security label management, and assign initial security labels.

Here is an example showing how to initialize a fresh database cluster with sepgsql functions and security labels installed. Adjust the paths shown as appropriate for your installation:

```
$ export PGDATA=/path/to/data/directory
$ initdb
$ vi $PGDATA/postgresql.conf
    change
    #shared_preload_libraries = " # (change requires restart)
    to
    shared_preload_libraries = 'sepgsql' # (change requires restart)
$ for DBNAME in template0 template1 postgres; do
    postgres --single -F -c exit_on_error=true $DBNAME "
    < /usr/local/pgsql/share/contrib/sepgsql.sql >/dev/null
    done
```

Please note that you may see some or all of the following notifications depending on the particular
versions you have of libselinux and selinux-policy:

```
/etc/selinux/targeted/contexts/sepgsql_contexts: line 33 has invalid object type db_blobs
/etc/selinux/targeted/contexts/sepgsql_contexts: line 36 has invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 37 has invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 38 has invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 39 has invalid object type db_language
```

2267
These messages are harmless and should be ignored.
If the installation process completes without error, you can now start the server normally.

**F.34.3. Regression Tests**

Due to the nature of SELinux, running the regression tests for `sepgsql` requires several extra configuration steps, some of which must be done as root. The regression tests will not be run by an ordinary `make check` or `make installcheck` command; you must set up the configuration and then invoke the test script manually. The tests must be run in the contrib/sepgsql directory of a configured PostgreSQL build tree. Although they require a build tree, the tests are designed to be executed against an installed server, that is they are comparable to `make installcheck` not `make check`.

First, set up `sepgsql` in a working database according to the instructions in Section F.34.2. Note that the current operating system user must be able to connect to the database as superuser without password authentication.

Second, build and install the policy package for the regression test. The `sepgsql-regtest` policy is a special purpose policy package which provides a set of rules to be allowed during the regression tests. It should be built from the policy source file `sepgsql-regtest.te`, which is done using `make` with a Makefile supplied by SELinux. You will need to locate the appropriate Makefile on your system; the path shown below is only an example. Once built, install this policy package using the `semodule` command, which loads supplied policy packages into the kernel. If the package is correctly installed, `semodule -l` should list `sepgsql-regtest` as an available policy package:

```
$ cd .../contrib/sepgsql
$ make -f /usr/share/selinux/devel/Makefile
$ sudo semodule -u sepgsql-regtest.pp
$ sudo semodule -l | grep sepgsql
sepgsql-regtest 1.07
```

Third, turn on `sepgsql_regression_test_mode`. For security reasons, the rules in `sepgsql-regtest` are not enabled by default; the `sepgsql_regression_test_mode` parameter enables the rules needed to launch the regression tests. It can be turned on using the `setsebool` command:

```
$ sudo setsebool sepgsql_regression_test_mode on
$ getsebool sepgsql_regression_test_mode
sepgsql_regression_test_mode --> on
```

Fourth, verify your shell is operating in the `unconfined_t` domain:

```
$ id -Z
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
```

See Section F.34.8 for details on adjusting your working domain, if necessary.

Finally, run the regression test script:

```
$ ./test_sepgsql
```

This script will attempt to verify that you have done all the configuration steps correctly, and then it will run the regression tests for the `sepgsql` module.
After completing the tests, it’s recommended you disable the `sepgsql_regression_test_mode` parameter:

```
$ sudo setsebool sepgsql_regression_test_mode off
```

You might prefer to remove the `sepgsql-regtest` policy entirely:

```
$ sudo semodule -r sepgsql-regtest
```

### F.34.4. GUC Parameters

**sepgsql.permissive (boolean)**

This parameter enables `sepgsql` to function in permissive mode, regardless of the system setting. The default is off. This parameter can only be set in the `postgresql.conf` file or on the server command line.

When this parameter is on, `sepgsql` functions in permissive mode, even if SELinux in general is working in enforcing mode. This parameter is primarily useful for testing purposes.

**sepgsql.debug_audit (boolean)**

This parameter enables the printing of audit messages regardless of the system policy settings. The default is off, which means that messages will be printed according to the system settings.

The security policy of SELinux also has rules to control whether or not particular accesses are logged. By default, access violations are logged, but allowed accesses are not.

This parameter forces all possible logging to be turned on, regardless of the system policy.

### F.34.5. Features

#### F.34.5.1. Controlled Object Classes

The security model of SELinux describes all the access control rules as relationships between a subject entity (typically, a client of the database) and an object entity (such as a database object), each of which is identified by a security label. If access to an unlabeled object is attempted, the object is treated as if it were assigned the label `unlabeled_t`.

Currently, `sepgsql` allows security labels to be assigned to schemas, tables, columns, sequences, views, and functions. When `sepgsql` is in use, security labels are automatically assigned to supported database objects at creation time. This label is called a default security label, and is decided according to the system security policy, which takes as input the creator’s label, the label assigned to the new object’s parent object and optionally name of the constructed object.

A new database object basically inherits the security label of the parent object, except when the security policy has special rules known as type-transition rules, in which case a different label may be applied. For schemas, the parent object is the current database; for tables, sequences, views, and functions, it is the containing schema; for columns, it is the containing table.
F.34.5.2. DML Permissions

For tables, \texttt{db\_table:select, db\_table:insert, db\_table:update} or \texttt{db\_table:delete} are checked for all the referenced target tables depending on the kind of statement; in addition, \texttt{db\_table:select} is also checked for all the tables that contain columns referenced in the \texttt{WHERE} or \texttt{RETURNING} clause, as a data source for \texttt{UPDATE}, and so on.

Column-level permissions will also be checked for each referenced column. \texttt{db\_column:select} is checked on not only the columns being read using \texttt{SELECT}, but those being referenced in other DML statements; \texttt{db\_column:update} or \texttt{db\_column:insert} will also be checked for columns being modified by \texttt{UPDATE} or \texttt{INSERT}.

For example, consider:

\begin{verbatim}
UPDATE t1 SET x = 2, y = md5sum(y) WHERE z = 100;
\end{verbatim}

Here, \texttt{db\_column:update} will be checked for \texttt{t1.x}, since it is being updated, \texttt{db\_column:{select update}} will be checked for \texttt{t1.y}, since it is both updated and referenced, and \texttt{db\_column:select} will be checked for \texttt{t1.z}, since it is only referenced. \texttt{db\_table:{select update}} will also be checked at the table level.

For sequences, \texttt{db\_sequence:get\_value} is checked when we reference a sequence object using \texttt{SELECT}; however, note that we do not currently check permissions on execution of corresponding functions such as \texttt{lastval()}.

For views, \texttt{db\_view:expand} will be checked, then any other required permissions will be checked on the objects being expanded from the view, individually.

For functions, \texttt{db\_procedure:{execute}} will be checked when user tries to execute a function as a part of query, or using fast-path invocation. If this function is a trusted procedure, it also checks \texttt{db\_procedure:{entrypoint}} permission to check whether it can perform as entry point of trusted procedure.

In order to access any schema object, \texttt{db\_schema:search} permission is required on the containing schema. When an object is referenced without schema qualification, schemas on which this permission is not present will not be searched (just as if the user did not have \texttt{USAGE} privilege on the schema). If an explicit schema qualification is present, an error will occur if the user does not have the requisite permission on the named schema.

The client must be allowed to access all referenced tables and columns, even if they originated from views which were then expanded, so that we apply consistent access control rules independent of the manner in which the table contents are referenced.

The default database privilege system allows database superusers to modify system catalogs using DML commands, and reference or modify toast tables. These operations are prohibited when \texttt{sepgsql} is enabled.

F.34.5.3. DDL Permissions

SELinux defines several permissions to control common operations for each object type; such as creation, alter, drop and relabel of security label. In addition, several object types have special permissions to control their characteristic operations; such as addition or deletion of name entries within a particular schema.

Creating a new database object requires \texttt{create} permission. SE Linux will grant or deny this permission based on the client’s security label and the proposed security label for the new object. In some cases, additional privileges are required:
• CREATE DATABASE additionally requires `getattr` permission for the source or template database.

• Creating a schema object additionally requires `add_name` permission on the parent schema.

• Creating a table additionally requires permission to create each individual table column, just as if each table column were a separate top-level object.

• Creating a function marked as `LEAKPROOF` additionally requires `install` permission. (This permission is also checked when `LEAKPROOF` is set for an existing function.)

When DROP command is executed, `drop` will be checked on the object being removed. Permissions will be also checked for objects dropped indirectly via CASCADE. Deletion of objects contained within a particular schema (tables, views, sequences and procedures) additionally requires `remove_name` on the schema.

When ALTER command is executed, `setattr` will be checked on the object being modified for each object types, except for subsidiary objects such as the indexes or triggers of a table, where permissions are instead checked on the parent object. In some cases, additional permissions are required:

• Moving an object to a new schema additionally requires `remove_name` permission on the old schema and `add_name` permission on the new one.

• Setting the `LEAKPROOF` attribute on a function requires `install` permission.

• Using SECURITY LABEL on an object additionally requires `relabelfrom` permission for the object in conjunction with its old security label and `relabelto` permission for the object in conjunction with its new security label. (In cases where multiple label providers are installed and the user tries to set a security label, but it is not managed by SELinux, only `setattr` should be checked here. This is currently not done due to implementation restrictions.)

F.34.5.4. Trusted Procedures

Trusted procedures are similar to security definer functions or setuid commands. SELinux provides a feature to allow trusted code to run using a security label different from that of the client, generally for the purpose of providing highly controlled access to sensitive data (e.g. rows might be omitted, or the precision of stored values might be reduced). Whether or not a function acts as a trusted procedure is controlled by its security label and the operating system security policy. For example:

```sql
postgres=# CREATE TABLE customer (cid int primary key, cname text, credit text);
CREATE TABLE
postgres=# SECURITY LABEL ON COLUMN customer.credit IS 'system_u:object_r:sepgsql_secret_table_t:s0';
SECURITY LABEL
postgres=# CREATE FUNCTION show_credit(int) RETURNS text AS 'SELECT regexp_replace(credit, "-\[0-9]+\", "-xxxx", "g") FROM customer WHERE cid = $1'
LANGUAGE sql;
CREATE FUNCTION
postgres=# SECURITY LABEL ON FUNCTION show_credit(int) IS 'system_u:object_r:sepgsql_trusted_proc_exec_t:s0';
SECURITY LABEL
```
The above operations should be performed by an administrative user.

```sql
postgres=# SELECT * FROM customer;
ERROR: SELinux: security policy violation
```

```sql
postgres=# SELECT cid, cname, show_credit(cid) FROM customer;
```

<table>
<thead>
<tr>
<th>cid</th>
<th>cname</th>
<th>show_credit</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>taro</td>
<td>1111-2222-3333-xxxx</td>
</tr>
<tr>
<td>2</td>
<td>hanako</td>
<td>5555-6666-7777-xxxx</td>
</tr>
</tbody>
</table>

(2 rows)

In this case, a regular user cannot reference `customer.credit` directly, but a trusted procedure `show_credit` allows him to print the credit card numbers of customers with some of the digits masked out.

### F.34.5.5. Dynamic Domain Transitions

It is possible to use SELinux’s dynamic domain transition feature to switch the security label of the client process, the client domain, to a new context, if that is allowed by the security policy. The client domain needs the `setcurrent` permission and also `dyntransition` from the old to the new domain.

Dynamic domain transitions should be considered carefully, because they allow users to switch their label, and therefore their privileges, at their option, rather than (as in the case of a trusted procedure) as mandated by the system. Thus, the `dyntransition` permission is only considered safe when used to switch to a domain with a smaller set of privileges than the original one. For example:

```sql
regression=# select sepgsql_getcon();

<table>
<thead>
<tr>
<th>sepgsql_getcon</th>
</tr>
</thead>
<tbody>
<tr>
<td>unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023</td>
</tr>
</tbody>
</table>

(1 row)
```

```sql
regression=# SELECT sepgsql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-s0:c1.c4');

<table>
<thead>
<tr>
<th>sepgsql_setcon</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
</tr>
</tbody>
</table>

(1 row)
```

```sql
regression=# SELECT sepgsql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-s0:c1.c1023');
ERROR: SELinux: security policy violation
```

In this example above we were allowed to switch from the larger MCS range `c1.c1023` to the smaller range `c1.c4`, but switching back was denied.

A combination of dynamic domain transition and trusted procedure enables an interesting use case that fits the typical process life-cycle of connection pooling software. Even if your connection pooling software is not allowed to run most of SQL commands, you can allow it to switch the security label of the client using the `sepgsql_setcon()` function from within a trusted procedure; that should take some credential to authorize the request to switch the client label. After that, this session will have the privileges of the target user, rather than the connection pooler. The connection pooler can later revert the security label change by again using `sepgsql_setcon()` with `NULL` argument, again invoked from within a trusted procedure with appropriate permissions checks. The point here is that only the trusted procedure actually has permission to change the effective security label, and only does so.

2272
when given proper credentials. Of course, for secure operation, the credential store (table, procedure definition, or whatever) must be protected from unauthorized access.

**F.34.5.6. Miscellaneous**

We reject the LOAD command across the board, because any module loaded could easily circumvent security policy enforcement.

**F.34.6. Sepgsql Functions**

Table F-29 shows the available functions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sepgsql_getcon()</code> returns <code>text</code></td>
<td>Returns the client domain, the current security label of the client.</td>
</tr>
<tr>
<td><code>sepgsql_setcon(text)</code> returns <code>bool</code></td>
<td>Switches the client domain of the current session to the new domain, if allowed by the security policy. It also accepts <code>NULL</code> input as a request to transition to the client’s original domain.</td>
</tr>
<tr>
<td><code>sepgsql_mcstrans_in(text)</code> returns <code>text</code></td>
<td>Translates the given qualified MLS/MCS range into raw format if the mcstrans daemon is running.</td>
</tr>
<tr>
<td><code>sepgsql_mcstrans_out(text)</code> returns <code>text</code></td>
<td>Translates the given raw MLS/MCS range into qualified format if the mcstrans daemon is running.</td>
</tr>
<tr>
<td><code>sepgsql_restorecon(text)</code> returns <code>bool</code></td>
<td>Sets up initial security labels for all objects within the current database. The argument may be <code>NULL</code>, or the name of a specfile to be used as alternative of the system default.</td>
</tr>
</tbody>
</table>

**F.34.7. Limitations**

Data Definition Language (DDL) Permissions

Due to implementation restrictions, some DDL operations do not check permissions.

Data Control Language (DCL) Permissions

Due to implementation restrictions, DCL operations do not check permissions.

Row-level access control

PostgreSQL does not support row-level access; therefore, `sepgsql` does not support it either.

Covert channels

`sepgsql` does not try to hide the existence of a certain object, even if the user is not allowed to reference it. For example, we can infer the existence of an invisible object as a result of primary key conflicts, foreign key violations, and so on, even if we cannot obtain the contents
of the object. The existence of a top secret table cannot be hidden; we only hope to conceal its contents.

KaiGai Kohei <kaigai@ak.jp.nec.com>

F.35. spi

The spi module provides several workable examples of using the Server Programming Interface (SPI) and triggers. While these functions are of some value in their own right, they are even more useful as examples to modify for your own purposes. The functions are general enough to be used with any table, but you have to specify table and field names (as described below) while creating a trigger. Each of the groups of functions described below is provided as a separately-installable extension.

F.35.1. refint — Functions for Implementing Referential Integrity

check_primary_key() and check_foreign_key() are used to check foreign key constraints. (This functionality is long since superseded by the built-in foreign key mechanism, of course, but the module is still useful as an example.)

check_primary_key() checks the referencing table. To use, create a BEFORE INSERT OR UPDATE trigger using this function on a table referencing another table. Specify as the trigger arguments: the referencing table’s column name(s) which form the foreign key, the referenced table name, and the column names in the referenced table which form the primary/unique key. To handle multiple foreign keys, create a trigger for each reference.

check_foreign_key() checks the referenced table. To use, create a BEFORE DELETE OR UPDATE trigger using this function on a table referenced by other table(s). Specify as the trigger arguments:

7. http://docs.fedoraproject.org/selinux-faq
the number of referencing tables for which the function has to perform checking, the action if a referencing key is found (\textit{cascade} — to delete the referencing row, \textit{restrict} — to abort transaction if referencing keys exist, \textit{setnull} — to set referencing key fields to null), the triggered table’s column names which form the primary/unique key, then the referencing table name and column names (repeated for as many referencing tables as were specified by first argument). Note that the primary/unique key columns should be marked \texttt{NOT NULL} and should have a unique index.

There are examples in \texttt{refint.example}.

\textbf{F.35.2. timetravel — Functions for Implementing Time Travel}

Long ago, PostgreSQL had a built-in time travel feature that kept the insert and delete times for each tuple. This can be emulated using these functions. To use these functions, you must add to a table two columns of \texttt{abstime} type to store the date when a tuple was inserted (\texttt{start\_date}) and changed/deleted (\texttt{stop\_date}):

\begin{verbatim}
CREATE TABLE mytab {
  ... ...
  start\_date  abstime,
  stop\_date  abstime
  ... ...
};
\end{verbatim}

The columns can be named whatever you like, but in this discussion we’ll call them \texttt{start\_date} and \texttt{stop\_date}.

When a new row is inserted, \texttt{start\_date} should normally be set to current time, and \texttt{stop\_date} to \texttt{infinity}. The trigger will automatically substitute these values if the inserted data contains nulls in these columns. Generally, inserting explicit non-null data in these columns should only be done when re-loading dumped data.

Tuples with \texttt{stop\_date} equal to \texttt{infinity} are “valid now”, and can be modified. Tuples with a finite \texttt{stop\_date} cannot be modified anymore — the trigger will prevent it. (If you need to do that, you can turn off time travel as shown below.)

For a modifiable row, on update only the \texttt{stop\_date} in the tuple being updated will be changed (to current time) and a new tuple with the modified data will be inserted. \texttt{Start\_date} in this new tuple will be set to current time and \texttt{stop\_date} to \texttt{infinity}.

A delete does not actually remove the tuple but only sets its \texttt{stop\_date} to current time.

To query for tuples “valid now”, include \texttt{stop\_date = ‘infinity’} in the query’s \texttt{WHERE} condition. (You might wish to incorporate that in a view.) Similarly, you can query for tuples valid at any past time with suitable conditions on \texttt{start\_date} and \texttt{stop\_date}.

\texttt{timetravel()} is the general trigger function that supports this behavior. Create a \texttt{BEFORE INSERT OR UPDATE OR DELETE} trigger using this function on each time-traveled table. Specify two trigger arguments: the actual names of the \texttt{start\_date} and \texttt{stop\_date} columns. Optionally, you can specify one to three more arguments, which must refer to columns of type \texttt{text}. The trigger will store the name of the current user into the first of these columns during \texttt{INSERT}, the second column during \texttt{UPDATE}, and the third during \texttt{DELETE}.

\texttt{set\_timetravel()} allows you to turn time-travel on or off for a table. \texttt{set\_timetravel(‘mytab’, 1)} will turn TT ON for table \texttt{mytab}. \texttt{set\_timetravel(‘mytab’, 0)} will turn TT OFF for table \texttt{mytab}. In both cases the old status is reported. While TT is off, you
can modify the start_date and stop_date columns freely. Note that the on/off status is local to the
current database session — fresh sessions will always start out with TT ON for all tables.

get_timetravel() returns the TT state for a table without changing it.

There is an example in timetravel.example.

F.35.3. autoinc — Functions for Autoincrementing Fields

autoinc() is a trigger that stores the next value of a sequence into an integer field. This has some
overlap with the built-in “serial column” feature, but it is not the same: autoinc() will override
attempts to substitute a different field value during inserts, and optionally it can be used to increment the field during updates, too.

To use, create a BEFORE INSERT (or optionally BEFORE INSERT OR UPDATE) trigger using this function. Specify two trigger arguments: the name of the integer column to be modified, and the name of the sequence object that will supply values. (Actually, you can specify any number of pairs of such names, if you’d like to update more than one autoincrementing column.)

There is an example in autoinc.example.

F.35.4. insert_username — Functions for Tracking Who Changed a Table

insert_username() is a trigger that stores the current user’s name into a text field. This can be
useful for tracking who last modified a particular row within a table.

To use, create a BEFORE INSERT and/or UPDATE trigger using this function. Specify a single trigger argument: the name of the text column to be modified.

There is an example in insert_username.example.

F.35.5. moddatetime — Functions for Tracking Last Modification Time

moddatetime() is a trigger that stores the current time into a timestamp field. This can be useful
for tracking the last modification time of a particular row within a table.

To use, create a BEFORE UPDATE trigger using this function. Specify a single trigger argument: the name of the column to be modified. The column must be of type timestamp or timestamp with time zone.

There is an example in moddatetime.example.

F.36. sslinfo

The sslinfo module provides information about the SSL certificate that the current client provided
when connecting to PostgreSQL. The module is useless (most functions will return NULL) if the
current connection does not use SSL.

This extension won’t build at all unless the installation was configured with --with-openssl.
F.36.1. Functions Provided

ssl_is_used() returns boolean

Returns TRUE if current connection to server uses SSL, and FALSE otherwise.

ssl_version() returns text

Returns the name of the protocol used for the SSL connection (e.g. SSLv2, SSLv3, or TLSv1).

ssl_cipher() returns text

Returns the name of the cipher used for the SSL connection (e.g. DHE-RSA-AES256-SHA).

ssl_client_cert_present() returns boolean

Returns TRUE if current client has presented a valid SSL client certificate to the server, and FALSE otherwise. (The server might or might not be configured to require a client certificate.)

ssl_client_serial() returns numeric

Returns serial number of current client certificate. The combination of certificate serial number and certificate issuer is guaranteed to uniquely identify a certificate (but not its owner — the owner ought to regularly change his keys, and get new certificates from the issuer).

So, if you run your own CA and allow only certificates from this CA to be accepted by the server, the serial number is the most reliable (albeit not very mnemonic) means to identify a user.

ssl_client_dn() returns text

Returns the full subject of the current client certificate, converting character data into the current database encoding. It is assumed that if you use non-ASCII characters in the certificate names, your database is able to represent these characters, too. If your database uses the SQL_ASCII encoding, non-ASCII characters in the name will be represented as UTF-8 sequences.

The result looks like /CN=Somebody /C=Some country/O=Some organization.

ssl_issuer_dn() returns text

Returns the full issuer name of the current client certificate, converting character data into the current database encoding. Encoding conversions are handled the same as for ssl_client_dn.

The combination of the return value of this function with the certificate serial number uniquely identifies the certificate.

This function is really useful only if you have more than one trusted CA certificate in your server’s root.crt file, or if this CA has issued some intermediate certificate authority certificates.

ssl_client_dn_field(fieldname text) returns text

This function returns the value of the specified field in the certificate subject, or NULL if the field is not present. Field names are string constants that are converted into ASN1 object identifiers using the OpenSSL object database. The following values are acceptable:

commonName (alias CN)
surname (alias SN)
name
givenName (alias GN)
countryName (alias C)
localityName (alias L)
stateOrProvinceName (alias ST)
organizationName (alias O)
organizationUnitName (alias OU)
title
description
initials
postalCode
streetAddress
generationQualifier
description
dnQualifier
x500UniqueIdentifier
pseudonym
role
e-mailAddress

All of these fields are optional, except commonName. It depends entirely on your CA’s policy which of them would be included and which wouldn’t. The meaning of these fields, however, is strictly defined by the X.500 and X.509 standards, so you cannot just assign arbitrary meaning to them.

ssl_issuer_field(fieldname text) returns text

Same as ssl_client_dn_field, but for the certificate issuer rather than the certificate subject.

F.37. tablefunc

The tablefunc module includes various functions that return tables (that is, multiple rows). These functions are useful both in their own right and as examples of how to write C functions that return multiple rows.

F.37.1. Functions Provided
Table F-30 shows the functions provided by the tablefunc module.

Table F-30. tablefunc Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>normal_rand(int numvals, float8 mean, float8 stddev)</td>
<td>setof float8</td>
<td>Produces a set of normally distributed random values</td>
</tr>
<tr>
<td>crosstab(text sql)</td>
<td>setof record</td>
<td>Produces a “pivot table” containing row names plus ( N ) value columns, where ( N ) is determined by the row type specified in the calling query</td>
</tr>
</tbody>
</table>
Appendix F: Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>crosstabN(text sql)</td>
<td>setof table_crosstab_N</td>
<td>Produces a “pivot table” containing row names plus N value columns. crosstab2, crosstab3, and crosstab4 are predefined, but you can create additional crosstabN functions as described below.</td>
</tr>
<tr>
<td>crosstab(text source_sql, text category_sql)</td>
<td>setof record</td>
<td>Produces a “pivot table” with the value columns specified by a second query.</td>
</tr>
<tr>
<td>crosstab(text sql, int N)</td>
<td>setof record</td>
<td>Obsolete version of crosstab(text). The parameter N is now ignored, since the number of value columns is always determined by the calling query.</td>
</tr>
<tr>
<td>connectby(text relname, text keyid_fld, text parent_keyid_fld [, text orderby_fld ], text start_with, int max_depth [, text branch_delim ])</td>
<td>setof record</td>
<td>Produces a representation of a hierarchical tree structure.</td>
</tr>
</tbody>
</table>

F.37.1.1. normal_rand

normal_rand(int numvals, float8 mean, float8 stddev) returns setof float8

normal_rand produces a set of normally distributed random values (Gaussian distribution).

numvals is the number of values to be returned from the function. mean is the mean of the normal distribution of values and stddev is the standard deviation of the normal distribution of values.

For example, this call requests 1000 values with a mean of 5 and a standard deviation of 3:

test=# SELECT * FROM normal_rand(1000, 5, 3);

```
+------------------+
<table>
<thead>
<tr>
<th>normal_rand</th>
</tr>

</tr>
<tr>
<td>9.71308014517282</td>
</tr>
<tr>
<td>2.49639286969028</td>
</tr>
</tbody>
</table>
+------------------+
```

(1000 rows)
F.37.1.2. **crosstab**(text)

```plaintext
(crosstab(text sql))
crosstab(text sql, int N)
```

The **crosstab** function is used to produce “pivot” displays, wherein data is listed across the page rather than down. For example, we might have data like

```
row1  val11
row1  val12
row1  val13
...
row2  val21
row2  val22
row2  val23
...
```

which we wish to display like

```
row1  val11  val12  val13  ...
row2  val21  val22  val23  ...
```

The **crosstab** function takes a text parameter that is a SQL query producing raw data formatted in the first way, and produces a table formatted in the second way.

The `sql` parameter is a SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. `N` is an obsolete parameter, ignored if supplied (formerly this had to match the number of output value columns, but now that is determined by the calling query).

For example, the provided query might produce a set something like:

```
row_name  cat  value
----------+-------+-------
row1      cat1  val1
row1      cat2  val2
row1      cat3  val3
row1      cat4  val4
row2      cat1  val5
row2      cat2  val6
row2      cat3  val7
row2      cat4  val8
```

The **crosstab** function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the **FROM** clause of the calling **SELECT** statement, for example:

```
SELECT * FROM crosstab('...') AS ct(row_name text, category_1 text, category_2 text);
```

This example produces a set something like:

```
<== value columns ==>  
row_name  category_1  category_2
----------+-------------------
row1      val1        val2
row2      val5        val6
```

2280
The **FROM** clause must define the output as one row_name column (of the same data type as the first result column of the SQL query) followed by N value columns (all of the same data type as the third result column of the SQL query). You can set up as many output value columns as you wish. The names of the output columns are up to you.

The crosstab function produces one output row for each consecutive group of input rows with the same row_name value. It fills the output value columns, left to right, with the value fields from these rows. If there are fewer rows in a group than there are output value columns, the extra output columns are filled with nulls; if there are more rows, the extra input rows are skipped.

In practice the SQL query should always specify ORDER BY 1,2 to ensure that the input rows are properly ordered, that is, values with the same row_name are brought together and correctly ordered within the row. Notice that crosstab itself does not pay any attention to the second column of the query result; it’s just there to be ordered by, to control the order in which the third-column values appear across the page.

Here is a complete example:

```sql
CREATE TABLE ct(id SERIAL, rowid TEXT, attribute TEXT, value TEXT);
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att1','val1');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att2','val2');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att3','val3');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att4','val4');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att1','val5');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att2','val6');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att3','val7');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att4','val8');

SELECT *
FROM crosstab(
    'select rowid, attribute, value
    from ct
    where attribute = "att2" or attribute = "att3"
    order by 1,2')
AS ct(row_name text, category_1 text, category_2 text, category_3 text);
```

<table>
<thead>
<tr>
<th>row_name</th>
<th>category_1</th>
<th>category_2</th>
<th>category_3</th>
</tr>
</thead>
<tbody>
<tr>
<td>test1</td>
<td>val2</td>
<td>val3</td>
<td></td>
</tr>
<tr>
<td>test2</td>
<td>val6</td>
<td>val7</td>
<td></td>
</tr>
</tbody>
</table>

(2 rows)

You can avoid always having to write out a **FROM** clause to define the output columns, by setting up a custom crosstab function that has the desired output row type wired into its definition. This is described in the next section. Another possibility is to embed the required **FROM** clause in a view definition.

### F.37.1.3. crosstabN (text)

crosstabN(text sql)

The crosstabN functions are examples of how to set up custom wrappers for the general crosstab function, so that you need not write out column names and types in the calling **SELECT** query. The
The `tablefunc` module includes `crosstab2`, `crosstab3`, and `crosstab4`, whose output row types are defined as

```sql
CREATE TYPE tablefunc_crosstab_N AS (
    row_name TEXT,
    category_1 TEXT,
    category_2 TEXT,
    ...
    category_N TEXT
);
```

Thus, these functions can be used directly when the input query produces `row_name` and `value` columns of type `text`, and you want 2, 3, or 4 output values columns. In all other ways they behave exactly as described above for the general `crosstab` function.

For instance, the example given in the previous section would also work as

```sql
SELECT *
FROM crosstab3(
    'select rowid, attribute, value
    from ct
    where attribute = "att2" or attribute = "att3"
    order by 1,2');
```

These functions are provided mostly for illustration purposes. You can create your own return types and functions based on the underlying `crosstab()` function. There are two ways to do it:

- Create a composite type describing the desired output columns, similar to the examples in `contrib/tablefunc/tablefunc--1.0.sql`. Then define a unique function name accepting one `text` parameter and returning `setof your_type_name`, but linking to the same underlying `crosstab` C function. For example, if your source data produces row names that are `text`, and values that are `float8`, and you want 5 value columns:

```sql
CREATE TYPE my_crosstab_float8_5_cols AS (
    my_row_name text,
    my_category_1 float8,
    my_category_2 float8,
    my_category_3 float8,
    my_category_4 float8,
    my_category_5 float8
);
CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(text)
RETURNS setof my_crosstab_float8_5_cols
AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;
```

- Use `OUT` parameters to define the return type implicitly. The same example could also be done this way:

```sql
CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(
    IN text,
    OUT my_row_name text,
    OUT my_category_1 float8,
    OUT my_category_2 float8,
    OUT my_category_3 float8,
```
Appendix F. Additional Supplied Modules

OUT my_category_4 float8,
OUT my_category_5 float8)
RETURNS setof record
AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;

F.37.1.4. crosstab(text, text)
crosstab(text source_sql, text category_sql)

The main limitation of the single-parameter form of crosstab is that it treats all values in a group alike, inserting each value into the first available column. If you want the value columns to correspond to specific categories of data, and some groups might not have data for some of the categories, that doesn’t work well. The two-parameter form of crosstab handles this case by providing an explicit list of the categories corresponding to the output columns.

source_sql is a SQL statement that produces the source set of data. This statement must return one row_name column, one category column, and one value column. It may also have one or more “extra” columns. The row_name column must be first. The category and value columns must be the last two columns, in that order. Any columns between row_name and category are treated as “extra”. The “extra” columns are expected to be the same for all rows with the same row_name value.

For example, source_sql might produce a set something like:

```
SELECT row_name, extra_col, cat, value FROM foo ORDER BY 1;
```

<table>
<thead>
<tr>
<th>row_name</th>
<th>extra_col</th>
<th>cat</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>row1</td>
<td>extra1</td>
<td>cat1</td>
<td>val1</td>
</tr>
<tr>
<td>row1</td>
<td>extra1</td>
<td>cat2</td>
<td>val2</td>
</tr>
<tr>
<td>row1</td>
<td>extra1</td>
<td>cat4</td>
<td>val4</td>
</tr>
<tr>
<td>row2</td>
<td>extra2</td>
<td>cat1</td>
<td>val5</td>
</tr>
<tr>
<td>row2</td>
<td>extra2</td>
<td>cat2</td>
<td>val6</td>
</tr>
<tr>
<td>row2</td>
<td>extra2</td>
<td>cat3</td>
<td>val7</td>
</tr>
<tr>
<td>row2</td>
<td>extra2</td>
<td>cat4</td>
<td>val8</td>
</tr>
</tbody>
</table>

category_sql is a SQL statement that produces the set of categories. This statement must return only one column. It must produce at least one row, or an error will be generated. Also, it must not produce duplicate values, or an error will be generated. category_sql might be something like:

```
SELECT DISTINCT cat FROM foo ORDER BY 1;
```

<table>
<thead>
<tr>
<th>cat</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat1</td>
</tr>
<tr>
<td>cat2</td>
</tr>
<tr>
<td>cat3</td>
</tr>
<tr>
<td>cat4</td>
</tr>
</tbody>
</table>

The crosstab function is declared to return setof record, so the actual names and types of the output columns must be defined in the FROM clause of the calling SELECT statement, for example:

```
SELECT * FROM crosstab('...', '...')
AS ct(row_name text, extra text, cat1 text, cat2 text, cat3 text, cat4 text);
```
Appendix F. Additional Supplied Modules

This will produce a result something like:

```
<== value columns ==>  
row_name  extra  cat1  cat2  cat3  cat4  
----------------+-------+------+------+------+------
row1           extra1  val1  val2  val4   
row2           extra2  val5  val6  val7  val8   
```

The `FROM` clause must define the proper number of output columns of the proper data types. If there are \( N \) columns in the `source_sql` query’s result, the first \( N-2 \) of them must match up with the first \( N-2 \) output columns. The remaining output columns must have the type of the last column of the `source_sql` query’s result, and there must be exactly as many of them as there are rows in the `category_sql` query’s result.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. The output `row_name` column, plus any “extra” columns, are copied from the first row of the group. The output `value` columns are filled with the `value` fields from rows having matching `category` values. If a row’s `category` does not match any output of the `category_sql` query, its `value` is ignored. Output columns whose matching `category` is not present in any input row of the group are filled with nulls.

In practice the `source_sql` query should always specify `ORDER BY 1` to ensure that values with the same `row_name` are brought together. However, ordering of the categories within a group is not important. Also, it is essential to be sure that the order of the `category_sql` query’s output matches the specified output column order.

Here are two complete examples:

```sql
create table sales(year int, month int, qty int);
insert into sales values(2007, 1, 1000);
insert into sales values(2007, 2, 1500);
insert into sales values(2007, 7, 500);
insert into sales values(2007, 11, 1500);
insert into sales values(2007, 12, 2000);
insert into sales values(2008, 1, 1000);

select * from crosstab(
  'select year, month, qty from sales order by 1',
  'select m from generate_series(1,12) m'
) as ( 
  year int,
  "Jan" int,
  "Feb" int,
  "Mar" int,
  "Apr" int,
  "May" int,
  "Jun" int,
  "Jul" int,
  "Aug" int,
  "Sep" int,
  "Oct" int,
  "Nov" int,
  "Dec" int
);
```

<table>
<thead>
<tr>
<th>year</th>
<th>Jan</th>
<th>Feb</th>
<th>Mar</th>
<th>Apr</th>
<th>May</th>
<th>Jun</th>
<th>Jul</th>
<th>Aug</th>
<th>Sep</th>
<th>Oct</th>
<th>Nov</th>
<th>Dec</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
CREATE TABLE cth(rowid text, rowdt timestamp, attribute text, val text);
INSERT INTO cth VALUES('test1','01 March 2003','temperature','42');
INSERT INTO cth VALUES('test1','01 March 2003','test_result','PASS');
INSERT INTO cth VALUES('test1','01 March 2003','volts','2.6987');
INSERT INTO cth VALUES('test2','02 March 2003','temperature','53');
INSERT INTO cth VALUES('test2','02 March 2003','test_result','FAIL');
INSERT INTO cth VALUES('test2','02 March 2003','test_startdate','01 March 2003');
INSERT INTO cth VALUES('test2','02 March 2003','volts','3.1234');

SELECT * FROM crosstab
(  
'SELECT rowid, rowdt, attribute, val FROM cth ORDER BY 1',  
'SELECT DISTINCT attribute FROM cth ORDER BY 1'
)
AS
(
  rowid text,  
  rowdt timestamp,  
  temperature int4,  
  test_result text,  
  test_startdate timestamp,  
  volts float8
);

(2 rows)

You can create predefined functions to avoid having to write out the result column names and types in each query. See the examples in the previous section. The underlying C function for this form of crosstab is named crosstab_hash.

F.37.1.5. connectby

connectby(text relname, text keyid_fld, text parent_keyid_fld
  [, text orderby_fld ], text start_with, int max_depth
  [, text branch_delim ])

The connectby function produces a display of hierarchical data that is stored in a table. The table must have a key field that uniquely identifies rows, and a parent-key field that references the parent (if any) of each row. connectby can display the sub-tree descending from any row.

Table F-31 explains the parameters.
### Table F-31. `connectby` Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>relname</code></td>
<td>Name of the source relation</td>
</tr>
<tr>
<td><code>keyid fld</code></td>
<td>Name of the key field</td>
</tr>
<tr>
<td><code>parent_keyid fld</code></td>
<td>Name of the parent-key field</td>
</tr>
<tr>
<td><code>orderby fld</code></td>
<td>Name of the field to order siblings by (optional)</td>
</tr>
<tr>
<td><code>start with</code></td>
<td>Key value of the row to start at</td>
</tr>
<tr>
<td><code>max_depth</code></td>
<td>Maximum depth to descend to, or zero for unlimited depth</td>
</tr>
<tr>
<td><code>branch delim</code></td>
<td>String to separate keys with in branch output (optional)</td>
</tr>
</tbody>
</table>

The key and parent-key fields can be any data type, but they must be the same type. Note that the `start with` value must be entered as a text string, regardless of the type of the key field.

The `connectby` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```sql
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0, '~')
AS t(keyid text, parent_keyid text, level int, branch text, pos int);
```

The first two output columns are used for the current row’s key and its parent row’s key; they must match the type of the table’s key field. The third output column is the depth in the tree and must be of type `integer`. If a `branch delim` parameter was given, the next output column is the branch display and must be of type `text`. Finally, if an `orderby fld` parameter was given, the last output column is a serial number, and must be of type `integer`.

The “branch” output column shows the path of keys taken to reach the current row. The keys are separated by the specified `branch delim` string. If no branch display is wanted, omit both the `branch delim` parameter and the branch column in the output column list.

If the ordering of siblings of the same parent is important, include the `orderby fld` parameter to specify which field to order siblings by. This field can be of any sortable data type. The output column list must include a final integer serial-number column, if and only if `orderby fld` is specified.

The parameters representing table and field names are copied as-is into the SQL queries that `connectby` generates internally. Therefore, include double quotes if the names are mixed-case or contain special characters. You may also need to schema-qualify the table name.

In large tables, performance will be poor unless there is an index on the parent-key field.

It is important that the `branch delim` string not appear in any key values, else `connectby` may incorrectly report an infinite-recursion error. Note that if `branch delim` is not provided, a default value of `~` is used for recursion detection purposes.

Here is an example:

```sql
CREATE TABLE connectby_tree(keyid text, parent_keyid text, pos int);

INSERT INTO connectby_tree VALUES('row1',NULL, 0);
INSERT INTO connectby_tree VALUES('row2','row1', 0);
INSERT INTO connectby_tree VALUES('row3','row1', 0);
INSERT INTO connectby_tree VALUES('row4','row2', 1);
INSERT INTO connectby_tree VALUES('row5','row2', 0);
```
INSERT INTO connectby_tree VALUES('row6', 'row4', 0);
INSERT INTO connectby_tree VALUES('row7', 'row3', 0);
INSERT INTO connectby_tree VALUES('row8', 'row6', 0);
INSERT INTO connectby_tree VALUES('row9', 'row5', 0);

-- with branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0, '~')
AS t(keyid text, parent_keyid text, level int, branch text);

<table>
<thead>
<tr>
<th>keyid</th>
<th>parent_keyid</th>
<th>level</th>
<th>branch</th>
</tr>
</thead>
<tbody>
<tr>
<td>row2</td>
<td></td>
<td>0</td>
<td>row2</td>
</tr>
<tr>
<td>row4</td>
<td>row2</td>
<td>1</td>
<td>row2~row4</td>
</tr>
<tr>
<td>row6</td>
<td>row4</td>
<td>2</td>
<td>row2<del>row4</del>row6</td>
</tr>
<tr>
<td>row8</td>
<td>row6</td>
<td>3</td>
<td>row2<del>row4</del>row6~row8</td>
</tr>
<tr>
<td>row5</td>
<td>row2</td>
<td>1</td>
<td>row2~row5</td>
</tr>
<tr>
<td>row9</td>
<td>row5</td>
<td>2</td>
<td>row2<del>row5</del>row9</td>
</tr>
</tbody>
</table>

(6 rows)

-- without branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0)
AS t(keyid text, parent_keyid text, level int);

<table>

F.37.2. Author

Joe Conway

F.38. tcn

The tcn module provides a trigger function that notifies listeners of changes to any table on which it is attached. It must be used as an \textit{AFTER} trigger \textit{FOR EACH ROW}.

Only one parameter may be supplied to the function in a \texttt{CREATE TRIGGER} statement, and that is optional. If supplied it will be used for the channel name for the notifications. If omitted tcn will be used for the channel name.

The payload of the notifications consists of the table name, a letter to indicate which type of operation was performed, and column name/value pairs for primary key columns. Each part is separated from the next by a comma. For ease of parsing using regular expressions, table and column names are always wrapped in double quotes, and data values are always wrapped in single quotes. Embedded quotes are doubled.

A brief example of using the extension follows.

```
test=# create table tcndata
(test=#   (a int not null,
(test=#      b date not null,
(test=#      c text,
(test=#      primary key (a, b)
(test=#   );

CREATE TABLE

test=# create trigger tcndata_tcn_trigger
(test=#   after insert or update or delete on tcndata
(test=#     for each row execute procedure triggered_change_notification();

CREATE TRIGGER

test=# listen tcn;
LISTEN

test=# insert into tcndata values (1, date '2012-12-22', 'one'),
(test=#   (1, date '2012-12-23', 'another'),
(test=#   (2, date '2012-12-23', 'two');

INSERT 0 3

Asynchronous notification "tcn" with payload ""tcndata"",I,"a"='1',"b"='2012-12-22'" received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata"",I,"a"='1',"b"='2012-12-23'" received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata"",I,"a"='2',"b"='2012-12-23'" received from server process with PID 22770.

test=# update tcndata set c = 'uno' where a = 1;
UPDATE 2

Asynchronous notification "tcn" with payload ""tcndata"",U,"a"='1',"b"='2012-12-22'" received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata"",U,"a"='1',"b"='2012-12-23'" received from server process with PID 22770.

test=# delete from tcndata where a = 1 and b = date '2012-12-22';
DELETE 1

Asynchronous notification "tcn" with payload ""tcndata"",D,"a"='1',"b"='2012-12-22'" received from server process with PID 22770.
```
F.39. test_decoding

test_decoding is an example of a logical decoding output plugin. It doesn’t do anything especially useful, but can serve as a starting point for developing your own output plugin.

test_decoding receives WAL through the logical decoding mechanism and decodes it into text representations of the operations performed.

Typical output from this plugin, used over the SQL logical decoding interface, might be:

```
postgres=# SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'include-xids', '0');

location | xid | data
-----------+-----+--------------------------------------------------
0/16D30F8 | 691 | BEGIN
0/16D32A0 | 691 | table public.data: INSERT: id[int4]:2 data[text]:'arg'
0/16D32A0 | 691 | table public.data: INSERT: id[int4]:3 data[text]:'demo'
0/16D32A0 | 691 | COMMIT
0/16D32D8 | 692 | BEGIN
0/16D3398 | 692 | table public.data: DELETE: id[int4]:2
0/16D3398 | 692 | table public.data: DELETE: id[int4]:3
0/16D3398 | 692 | COMMIT
(8 rows)
```

F.40. test_parser

test_parser is an example of a custom parser for full-text search. It doesn’t do anything especially useful, but can serve as a starting point for developing your own parser.

test_parser recognizes words separated by white space, and returns just two token types:

```
mydb=# SELECT * FROM ts_token_type('testparser');
tokid | alias | description
-------+-------+---------------
3 | word | Word
12 | blank | Space symbols
(2 rows)
```

These token numbers have been chosen to be compatible with the default parser’s numbering. This allows us to use its headline() function, thus keeping the example simple.

F.40.1. Usage

Installing the test_parser extension creates a text search parser testparser. It has no user-configurable parameters.

You can test the parser with, for example,

```
mydb=# SELECT * FROM ts_parse('testparser', 'That”s my first own parser');
tokid | token
-------+--------
3 | That’s
12 |
3 | my
12 |
```
Real-world use requires setting up a text search configuration that uses the parser. For example,

```sql
mydb=# CREATE TEXT SEARCH CONFIGURATION testcfg (PARSER = testparser);
CREATE TEXT SEARCH CONFIGURATION
mydb=# ALTER TEXT SEARCH CONFIGURATION testcfg
mydb=# ADD MAPPING FOR word WITH english_stem;
ALTER TEXT SEARCH CONFIGURATION
mydb=# SELECT to_tsvector('testcfg', 'That’s my first own parser');
to_tsvector
| 'that':1 'first':3 'parser':5 |
(1 row)
mydb=# SELECT ts_headline('testcfg', 'Supernovae stars are the brightest phenomena in galaxies',
mydb(# to_tsquery('testcfg', 'star'));
ts_headline
| Supernovae <b>stars</b> are the brightest phenomena in galaxies |
(1 row)
```

### F.41. test_shm_mq

test_shm_mq is an example of how to use dynamic shared memory and the shared memory message queue facilities to coordinate a user backend with the efforts of one or more background workers. It is not intended to do anything useful on its own; rather, it is a demonstration of how these facilities can be used, and a unit test of those facilities.

The function is this extension send the same message repeatedly through a loop of processes. The message payload, the size of the message queue through which it is sent, and the number of processes in the loop are configurable. At the end, the message may be verified to ensure that it has not been corrupted in transmission.

#### F.41.1. Functions

test_shm_mq(queue_size int8, message text,
repeat_count int4 default 1, num_workers int4 default 1)
RETURNS void

This function sends and receives messages synchronously. The user backend sends the provided message to the first background worker using a message queue of the given size. The first background worker sends the message to the second background worker, if the number of workers is greater than
one, and so forth. Eventually, the last background worker sends the message back to the user back-
end. If the repeat count is greater than one, the user backend then sends the message back to the first
worker. Once the message has been sent and received by all the coordinating processes a number of
times equal to the repeat count, the user backend verifies that the message finally received matches
the one originally sent and throws an error if not.

test_shm_mq_pipelined(queue_size int8, message text,
    repeat_count int4 default 1, num_workers int4 default 1,
    verify bool default true)

RETURNS void

This function sends the same message multiple times, as specified by the repeat count, to the first
background worker using a queue of the given size. These messages are then forwarded to each
background worker in turn, in each case using a queue of the given size. Finally, the last background
worker sends the messages back to the user backend. The user backend uses non-blocking sends
and receives, so that it may begin receiving copies of the message before it has finished sending all
copies of the message. The verify argument controls whether or not the received copies are checked
against the message that was sent. (This takes nontrivial time so it may be useful to disable it for
benchmarking purposes.)

F.42. tsearch2

The tsearch2 module provides backwards-compatible text search functionality for applications that
used tsearch2 before text searching was integrated into core PostgreSQL in release 8.3.

F.42.1. Portability Issues

Although the built-in text search features were based on tsearch2 and are largely similar to it, there
are numerous small differences that will create portability issues for existing applications:

- Some functions’ names were changed, for example rank to ts_rank. The replacement tsearch2
  module provides aliases having the old names.

- The built-in text search data types and functions all exist within the system schema pg_catalog.
  In an installation using tsearch2, these objects would usually have been in the public schema,
  though some users chose to place them in a separate schema of their own. Explicitly schema-
  qualified references to the objects will therefore fail in either case. The replacement tsearch2
  module provides alias objects that are stored in public (or another schema if necessary) so that
  such references will still work.

- There is no concept of a “current parser” or “current dictionary” in the built-in text search features,
  only of a current search configuration (set by the default_text_search_config parameter).
  While the current parser and current dictionary were used only by functions intended for debug-
  ging, this might still pose a porting obstacle in some cases. The replacement tsearch2 module
  emulates these additional state variables and provides backwards-compatible functions for setting
  and retrieving them.

There are some issues that are not addressed by the replacement tsearch2 module, and will therefore
require application code changes in any case:
• The old `tsearch2` trigger function allowed items in its argument list to be names of functions to be invoked on the text data before it was converted to `tsvector` format. This was removed as being a security hole, since it was not possible to guarantee that the function invoked was the one intended. The recommended approach if the data must be massaged before being indexed is to write a custom trigger that does the work for itself.

• Text search configuration information has been moved into core system catalogs that are noticeably different from the tables used by `tsearch2`. Any applications that examined or modified those tables will need adjustment.

• If an application used any custom text search configurations, those will need to be set up in the core catalogs using the new text search configuration SQL commands. The replacement `tsearch2` module offers a little bit of support for this by making it possible to load an old set of `tsearch2` configuration tables into PostgreSQL 8.3. (Without the module, it is not possible to load the configuration data because values in the `regprocedure` columns cannot be resolved to functions.) While those configuration tables won’t actually do anything, at least their contents will be available to be consulted while setting up an equivalent custom configuration in 8.3.

• The old `reset_tsearch()` and `get_covers()` functions are not supported.

• The replacement `tsearch2` module does not define any alias operators, relying entirely on the built-in ones. This would only pose an issue if an application used explicitly schema-qualified operator names, which is very uncommon.

**F.42.2. Converting a pre-8.3 Installation**

The recommended way to update a pre–8.3 installation that uses `tsearch2` is:

1. Make a dump from the old installation in the usual way, but be sure not to use `-c` (``--clean``) option of `pg_dump` or `pg_dumpall`.

2. In the new installation, create empty database(s) and install the replacement `tsearch2` module into each database that will use text search. This must be done before loading the dump data! If your old installation had the `tsearch2` objects in a schema other than `public`, be sure to adjust the `CREATE EXTENSION` command so that the replacement objects are created in that same schema.

3. Load the dump data. There will be quite a few errors reported due to failure to recreate the original `tsearch2` objects. These errors can be ignored, but this means you cannot restore the dump in a single transaction (eg, you cannot use `pg_restore`’s `-1` switch).

4. Examine the contents of the restored `tsearch2` configuration tables (`pg_ts_cfg` and so on), and create equivalent built-in text search configurations as needed. You may drop the old configuration tables once you've extracted all the useful information from them.

5. Test your application.

At a later time you may wish to rename application references to the alias text search objects, so that you can eventually uninstall the replacement `tsearch2` module.

Appendix F. Additional Supplied Modules

F.43. unaccent

unaccent is a text search dictionary that removes accents (diacritic signs) from lexemes. It’s a filtering dictionary, which means its output is always passed to the next dictionary (if any), unlike the normal behavior of dictionaries. This allows accent-insensitive processing for full text search.

The current implementation of unaccent cannot be used as a normalizing dictionary for the thesaurus dictionary.

F.43.1. Configuration

An unaccent dictionary accepts the following options:

- **RULES** is the base name of the file containing the list of translation rules. This file must be stored in `$SHAREDIR/tsearch_data/` (where `SHAREDIR` means the PostgreSQL installation’s shared-data directory). Its name must end in `.rules` (which is not to be included in the RULES parameter).

The rules file has the following format:

- Each line represents a pair, consisting of a character with accent followed by a character without accent. The first is translated into the second. For example,

  A
  À A
  Ä A
  Å A
  Á A
  Æ A

A more complete example, which is directly useful for most European languages, can be found in `unaccent.rules`, which is installed in `$SHAREDIR/tsearch_data/` when the unaccent module is installed.

F.43.2. Usage

Installing the unaccent extension creates a text search template unaccent and a dictionary unaccent based on it. The unaccent dictionary has the default parameter setting RULES=‘unaccent’, which makes it immediately usable with the standard unaccent.rules file. If you wish, you can alter the parameter, for example

```
mydb=# ALTER TEXT SEARCH DICTIONARY unaccent (RULES='my_rules');
```

or create new dictionaries based on the template.

To test the dictionary, you can try:

```
mydb=# select ts_lexize('unaccent','Hôtel');
```

Here is an example showing how to insert the unaccent dictionary into a text search configuration:
Appendix F. Additional Supplied Modules

mydb=# CREATE TEXT SEARCH CONFIGURATION fr ( COPY = french );
mydb=# ALTER TEXT SEARCH CONFIGURATION fr
ALTER MAPPING FOR hword, hword_part, word
     WITH unaccent, french_stem;
mydb=# select to_tsvector('fr','Hôtels de la Mer');
to_tsvector
---------------
 'hotel':1 'mer':4
(1 row)
mydb=# select to_tsvector('fr','Hôtel de la Mer') @@ to_tsquery('fr','Hotels');
?column?
--------
t
(1 row)
mydb=# select ts_headline('fr','Hôtel de la Mer',to_tsquery('fr','Hotels'));
 ts_headline
------------------------
 <b>Hôtel</b> de la Mer
(1 row)

F.43.3. Functions

The unaccent() function removes accents (diacritic signs) from a given string. Basically, it’s a wrapper around the unaccent dictionary, but it can be used outside normal text search contexts.

unaccent([dictionary regdictionary, ] string text) returns text

If the dictionary argument is omitted, the text search dictionary named unaccent and appearing in the same schema as the unaccent() function itself is used.

For example:

SELECT unaccent('unaccent', 'Hôtel');
SELECT unaccent('Hôtel');

F.44. uuid-ossp

The uuid-ossp module provides functions to generate universally unique identifiers (UUIDs) using one of several standard algorithms. There are also functions to produce certain special UUID constants.

F.44.1. uuid-ossp Functions

Table F-32 shows the functions available to generate UUIDs. The relevant standards ITU-T Rec. X.667, ISO/IEC 9834-8:2005, and RFC 4122 specify four algorithms for generating UUIDs, identi-
fied by the version numbers 1, 3, 4, and 5. (There is no version 2 algorithm.) Each of these algorithms could be suitable for a different set of applications.

Table F-32. Functions for UUID Generation

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uuid_generate_v1()</td>
<td>This function generates a version 1 UUID. This involves the MAC address of the computer and a time stamp. Note that UUIDs of this kind reveal the identity of the computer that created the identifier and the time at which it did so, which might make it unsuitable for certain security-sensitive applications.</td>
</tr>
<tr>
<td>uuid_generate_v1mc()</td>
<td>This function generates a version 1 UUID but uses a random multicast MAC address instead of the real MAC address of the computer.</td>
</tr>
<tr>
<td>uuid_generate_v3(namespace uuid, name text)</td>
<td>This function generates a version 3 UUID in the given namespace using the specified input name. The namespace should be one of the special constants produced by the uuid_ns_*() functions shown in Table F-33. (It could be any UUID in theory.) The name is an identifier in the selected namespace. For example: SELECT uuid_generate_v3(uuid_ns_url(), '<a href="http://www.postgresql.org">http://www.postgresql.org</a>'); The name parameter will be MD5-hashed, so the cleartext cannot be derived from the generated UUID. The generation of UUIDs by this method has no random or environment-dependent element and is therefore reproducible.</td>
</tr>
<tr>
<td>uuid_generate_v4()</td>
<td>This function generates a version 4 UUID, which is derived entirely from random numbers.</td>
</tr>
<tr>
<td>uuid_generate_v5(namespace uuid, name text)</td>
<td>This function generates a version 5 UUID, which works like a version 3 UUID except that SHA-1 is used as a hashing method. Version 5 should be preferred over version 3 because SHA-1 is thought to be more secure than MD5.</td>
</tr>
</tbody>
</table>

Table F-33. Functions Returning UUID Constants

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uuid_nil()</td>
<td>A “nil” UUID constant, which does not occur as a real UUID.</td>
</tr>
<tr>
<td>uuid_ns_dns()</td>
<td>Constant designating the DNS namespace for UUIDs.</td>
</tr>
<tr>
<td>uuid_ns_url()</td>
<td>Constant designating the URL namespace for UUIDs.</td>
</tr>
</tbody>
</table>
Appendix F. Additional Supplied Modules

<table>
<thead>
<tr>
<th>uuid_ns_oid()</th>
<th>Constant designating the ISO object identifier (OID) namespace for UUIDs. (This pertains to ASN.1 OIDs, which are unrelated to the OIDs used in PostgreSQL.)</th>
</tr>
</thead>
<tbody>
<tr>
<td>uuid_ns_x500()</td>
<td>Constant designating the X.500 distinguished name (DN) namespace for UUIDs.</td>
</tr>
</tbody>
</table>

F.44.2. Building `uuid-ossp`

Historically this module depended on the OSSP UUID library, which accounts for the module’s name. While the OSSP UUID library can still be found at http://www.osspe.org/pkg/lib/uuid/, it is not well maintained, and is becoming increasingly difficult to port to newer platforms. `uuid-ossp` can now be built without the OSSP library on some platforms. On FreeBSD, NetBSD, and some other BSD-derived platforms, suitable UUID creation functions are included in the core libc library. On Linux, OS X, and some other platforms, suitable functions are provided in the libuuid library, which originally came from the e2fsprogs project (though on modern Linux it is considered part of util-linux-ng). When invoking configure, specify `--with-uuid=bsd` to use the BSD functions, or `--with-uuid=e2fs` to use e2fsprogs’ libuuid, or `--with-uuid=ossp` to use the OSSP UUID library. More than one of these libraries might be available on a particular machine, so configure does not automatically choose one.

Note: If you only need randomly-generated (version 4) UUIDs, consider using the `gen_random_uuid()` function from the pgcrypto module instead.

F.44.3. Author

Peter Eisentraut <peter_e@gmx.net>

F.45. xml2

The xml2 module provides XPath querying and XSLT functionality.

F.45.1. Deprecation Notice

From PostgreSQL 8.3 on, there is XML-related functionality based on the SQL/XML standard in the core server. That functionality covers XML syntax checking and XPath queries, which is what this module does, and more, but the API is not at all compatible. It is planned that this module will be removed in a future version of PostgreSQL in favor of the newer standard API, so you are encouraged to try converting your applications. If you find that some of the functionality of this module is not available in an adequate form with the newer API, please explain your issue to <pgsql-hackers@lists.postgresql.org> so that the deficiency can be addressed.
## F.45.2. Description of Functions

Table F-34 shows the functions provided by this module. These functions provide straightforward XML parsing and XPath queries. All arguments are of type `text`, so for brevity that is not shown.

### Table F-34. Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xml_is_well_formed(document)</code></td>
<td><code>bool</code></td>
<td>This parses the document text in its parameter and returns true if the document is well-formed XML. (Note: before PostgreSQL 8.2, this function was called <code>xml_valid()</code>. That is the wrong name since validity and well-formedness have different meanings in XML. The old name is still available, but is deprecated.)</td>
</tr>
<tr>
<td><code>xpath_string(document, query)</code></td>
<td><code>text</code></td>
<td>These functions evaluate the XPath query on the supplied document, and cast the result to the specified type.</td>
</tr>
<tr>
<td><code>xpath_number(document, query)</code></td>
<td><code>float4</code></td>
<td></td>
</tr>
<tr>
<td><code>xpath_bool(document, query)</code></td>
<td><code>bool</code></td>
<td></td>
</tr>
<tr>
<td><code>xpath_nodeset(document, query, toptag, itemtag)</code></td>
<td><code>text</code></td>
<td>This evaluates query on document and wraps the result in XML tags. If the result is multivalued, the output will look like: <code>&lt;toptag&gt;&lt;itemtag&gt;Value 1 which could be an XML fragment&lt;/itemtag&gt;&lt;itemtag&gt;Value 2....&lt;/itemtag&gt;&lt;/toptag&gt;</code>. If either <code>toptag</code> or <code>itemtag</code> is an empty string, the relevant tag is omitted.</td>
</tr>
<tr>
<td><code>xpath_nodeset(document, query)</code></td>
<td><code>text</code></td>
<td>Like <code>xpath_nodeset(document, query, toptag, itemtag)</code> but result omits both tags.</td>
</tr>
<tr>
<td><code>xpath_nodeset(document, query, itemtag)</code></td>
<td><code>text</code></td>
<td>Like <code>xpath_nodeset(document, query, toptag, itemtag)</code> but result omits <code>toptag</code>.</td>
</tr>
<tr>
<td><code>xpath_list(document, query, separator)</code></td>
<td><code>text</code></td>
<td>This function returns multiple values separated by the specified separator, for example <code>Value 1,Value 2,Value 3</code> if separator is <code>,</code>.</td>
</tr>
</tbody>
</table>
Appendix F. Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xpath_list(document, query)</td>
<td>text</td>
<td>This is a wrapper for the above function that uses _, as the separator.</td>
</tr>
</tbody>
</table>

**F.45.3. xpath_table**

xpath_table(text key, text document, text relation, text xpaths, text criteria) returns setof record

xpath_table is a table function that evaluates a set of XPath queries on each of a set of documents and returns the results as a table. The primary key field from the original document table is returned as the first column of the result so that the result set can readily be used in joins. The parameters are described in Table F-35.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>the name of the “key” field — this is just a field to be used as the first column of the output table, i.e., it identifies the record from which each output row came (see note below about multiple values)</td>
</tr>
<tr>
<td>document</td>
<td>the name of the field containing the XML document</td>
</tr>
<tr>
<td>relation</td>
<td>the name of the table or view containing the documents</td>
</tr>
<tr>
<td>xpaths</td>
<td>one or more XPath expressions, separated by</td>
</tr>
<tr>
<td>criteria</td>
<td>the contents of the WHERE clause. This cannot be omitted, so use true or 1=1 if you want to process all the rows in the relation</td>
</tr>
</tbody>
</table>

These parameters (except the XPath strings) are just substituted into a plain SQL SELECT statement, so you have some flexibility — the statement is

```
SELECT <key>, <document> FROM <relation> WHERE <criteria>
```

so those parameters can be anything valid in those particular locations. The result from this SELECT needs to return exactly two columns (which it will unless you try to list multiple fields for key or document). Beware that this simplistic approach requires that you validate any user-supplied values to avoid SQL injection attacks.

The function has to be used in a FROM expression, with an AS clause to specify the output columns; for example

```
SELECT * FROM
xpath_table(’article_id’,
 ’article_xml’,
 ’articles’,
 ’/article/author[/article/pages]/article/title’,
 ’date_entered > “2003-01-01” ‘)
AS t(article_id integer, author text, page_count integer, title text);
```

2298
The AS clause defines the names and types of the columns in the output table. The first is the “key” field and the rest correspond to the XPath queries. If there are more XPath queries than result columns, the extra queries will be ignored. If there are more result columns than XPath queries, the extra columns will be NULL.

Notice that this example defines the page_count result column as an integer. The function deals internally with string representations, so when you say you want an integer in the output, it will take the string representation of the XPath result and use PostgreSQL input functions to transform it into an integer (or whatever type the AS clause requests). An error will result if it can’t do this — for example if the result is empty — so you may wish to just stick to text as the column type if you think your data has any problems.

The calling SELECT statement doesn’t necessarily have be just SELECT * — it can reference the output columns by name or join them to other tables. The function produces a virtual table with which you can perform any operation you wish (e.g. aggregation, joining, sorting etc). So we could also have:

```sql
SELECT t.title, p.fullname, p.email
FROM xpath_table('article_id', 'article_xml', 'articles',
    '/article/title|/article/author/@id',
    'xpath_string(article_xml,"/article/@date") > "2003-03-20" ')
AS t(article_id integer, title text, author_id integer),
    tblPeopleInfo AS p
WHERE t.author_id = p.person_id;
```

as a more complicated example. Of course, you could wrap all of this in a view for convenience.

### F.45.3.1. Multivalued Results

The xpath_table function assumes that the results of each XPath query might be multivalued, so the number of rows returned by the function may not be the same as the number of input documents. The first row returned contains the first result from each query, the second row the second result from each query. If one of the queries has fewer values than the others, null values will be returned instead.

In some cases, a user will know that a given XPath query will return only a single result (perhaps a unique document identifier) — if used alongside an XPath query returning multiple results, the single-valued result will appear only on the first row of the result. The solution to this is to use the key field as part of a join against a simpler XPath query. As an example:

```sql
CREATE TABLE test (id int PRIMARY KEY, xml text);

INSERT INTO test VALUES (1, '<doc num="C1">
  <line num="L1"><a>1</a><b>2</b><c>3</c></line>
  <line num="L2"><a>11</a><b>22</b><c>33</c></line>
</doc>');

INSERT INTO test VALUES (2, '<doc num="C2">
  <line num="L1"><a>111</a><b>222</b><c>333</c></line>
  <line num="L2"><a>111</a><b>222</b><c>333</c></line>
</doc>');

SELECT * FROM
    xpath_table('id','xml','test',
    '/article/title|/article/author/@id',
    'xpath_string(article_xml,"/article/@date") > "2003-03-20" ')
AS t(article_id integer, title text, author_id integer),
    tblPeopleInfo AS p
WHERE t.author_id = p.person_id;
```
Appendix F: Additional Supplied Modules

```
AS t(id int, doc_num varchar(10), line_num varchar(10), val1 int, val2 int, val3 int)
WHERE id = 1 ORDER BY doc_num, line_num
```

id | doc_num | line_num | val1 | val2 | val3
---+---------+----------+------+------+------
1  | C1      | L1       | 1    | 2    | 3
1  |         | L2       | 11   | 22   | 33

To get `doc_num` on every line, the solution is to use two invocations of `xpath_table` and join the results:

```
SELECT t.*, i.doc_num FROM
  xpath_table('id', 'xml', 'test',
    '/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
    'true')
AS t(id int, line_num varchar(10), val1 int, val2 int, val3 int),
  xpath_table('id', 'xml', 'test', '/doc/@num', 'true')
AS i(id int, doc_num varchar(10))
WHERE i.id = t.id AND i.id = 1
ORDER BY doc_num, line_num;
```

id | line_num | val1 | val2 | val3 | doc_num
---+----------+------+------+------+---------
1  | L1       | 1    | 2    | 3    | C1
1  | L2       | 11   | 22   | 33   | C1

(2 rows)

F.45.4. XSLT Functions

The following functions are available if libxslt is installed:

F.45.4.1. xslt_process

```
xslt_process(text document, text stylesheet, text paramlist) returns text
```

This function applies the XSL stylesheet to the document and returns the transformed result. The `paramlist` is a list of parameter assignments to be used in the transformation, specified in the form `a=1,b=2`. Note that the parameter parsing is very simple-minded: parameter values cannot contain commas!

There is also a two-parameter version of `xslt_process` which does not pass any parameters to the transformation.
F.45.5. Author

John Gray <jgray@azuli.co.uk>

Development of this module was sponsored by Torchbox Ltd. (www.torchbox.com). It has the same BSD license as PostgreSQL.
Appendix G. Additional Supplied Programs

This appendix and the previous one contain information regarding the modules that can be found in the contrib directory of the PostgreSQL distribution. See Appendix F for more information about the contrib section in general and server extensions and plug-ins found in contrib specifically.

This appendix covers utility programs found in contrib. Once installed, either from source or a packaging system, they are found in the bin directory of the PostgreSQL installation and can be used like any other program.

G.1. Client Applications

This section covers PostgreSQL client applications in contrib. They can be run from anywhere, independent of where the database server resides. See also Reference II, PostgreSQL Client Applications for information about client applications that part of the core PostgreSQL distribution.

oid2name

Name

oid2name — resolve OIDs and file nodes in a PostgreSQL data directory

Synopsis

oid2name [option...]

Description

oid2name is a utility program that helps administrators to examine the file structure used by PostgreSQL. To make use of it, you need to be familiar with the database file structure, which is described in Chapter 59.

Note: The name “oid2name” is historical, and is actually rather misleading, since most of the time when you use it, you will really be concerned with tables’ filenode numbers (which are the file names visible in the database directories). Be sure you understand the difference between table OIDs and table filenodes!

oid2name connects to a target database and extracts OID, filenode, and/or table name information. You can also have it show database OIDs or tablespace OIDs.
Options

oid2name accepts the following command-line arguments:

-\(-f\) filenode
  show info for table with filenode \textit{filenode}

-\(-i\)
  include indexes and sequences in the listing

-\(-o\) oid
  show info for table with OID \textit{oid}

-\(-q\)
  omit headers (useful for scripting)

-\(-s\)
  show tablespace OIDs

-\(-S\)
  include system objects (those in information_schema, pg_toast and pg_catalog schemas)

-\(-t\) \textit{tablename_pattern}
  show info for table(s) matching \textit{tablename_pattern}

-\(-V\)
  --version
  Print the oid2name version and exit.

-\(-x\)
  display more information about each object shown: tablespace name, schema name, and OID

-\(-?\)
  --help
  Show help about oid2name command line arguments, and exit.

oid2name also accepts the following command-line arguments for connection parameters:

-\(-d\) \textit{database}
  database to connect to

-\(-H\) host
  database server’s host

-\(-p\) port
  database server’s port

-\(-U\) username
  user name to connect as
oid2name

-P password

password (deprecated — putting this on the command line is a security hazard)

To display specific tables, select which tables to show by using -o, -f and/or -t. -o takes an OID, -f takes a filenode, and -t takes a table name (actually, it’s a LIKE pattern, so you can use things like foo%). You can use as many of these options as you like, and the listing will include all objects matched by any of the options. But note that these options can only show objects in the database given by -d.

If you don’t give any of -o, -f or -t, but do give -d, it will list all tables in the database named by -d. In this mode, the -S and -i options control what gets listed.

If you don’t give -d either, it will show a listing of database OIDs. Alternatively you can give -s to get a tablespace listing.

Notes

oid2name requires a running database server with non-corrupt system catalogs. It is therefore of only limited use for recovering from catastrophic database corruption situations.

Examples

Author

B. Palmer <bpalmer@crimelabs.net>
pgbench

Name

pgbench — run a benchmark test on PostgreSQL

Synopsis

pgbench -i [option...] [dbname]

pgbench [option...] [dbname]

Description

pgbench is a simple program for running benchmark tests on PostgreSQL. It runs the same sequence of SQL commands over and over, possibly in multiple concurrent database sessions, and then calculates the average transaction rate (transactions per second). By default, pgbench tests a scenario that is loosely based on TPC-B, involving five SELECT, UPDATE, and INSERT commands per transaction. However, it is easy to test other cases by writing your own transaction script files.

Typical output from pgbench looks like:

transaction type: TPC-B (sort of)
scaling factor: 10
query mode: simple
number of clients: 10
number of threads: 1
number of transactions per client: 1000
number of transactions actually processed: 10000/10000
tps = 85.184871 (including connections establishing)
tps = 85.296346 (excluding connections establishing)

The first six lines report some of the most important parameter settings. The next line reports the number of transactions completed and intended (the latter being just the product of number of clients and number of transactions per client); these will be equal unless the run failed before completion. (In -T mode, only the actual number of transactions is printed.) The last two lines report the number of transactions per second, figured with and without counting the time to start database sessions.

The default TPC-B-like transaction test requires specific tables to be set up beforehand. pgbench should be invoked with the -i (initialize) option to create and populate these tables. (When you are testing a custom script, you don’t need this step, but will instead need to do whatever setup your test needs.) Initialization looks like:

pgbench -i [ other-options ] dbname

where dbname is the name of the already-created database to test in. (You may also need -h, -p, and/or -U options to specify how to connect to the database server.)
Caution

pgbench -i creates four tables pgbench_accounts, pgbench_branches, pgbench_history, and pgbench_tellers, destroying any existing tables of these names. Be very careful to use another database if you have tables having these names!

At the default “scale factor” of 1, the tables initially contain this many rows:

<table>
<thead>
<tr>
<th>table</th>
<th># of rows</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgbench_branches</td>
<td>1</td>
</tr>
<tr>
<td>pgbench_tellers</td>
<td>10</td>
</tr>
<tr>
<td>pgbench_accounts</td>
<td>100000</td>
</tr>
<tr>
<td>pgbench_history</td>
<td>0</td>
</tr>
</tbody>
</table>

You can (and, for most purposes, probably should) increase the number of rows by using the -s (scale factor) option. The -F (fillfactor) option might also be used at this point.

Once you have done the necessary setup, you can run your benchmark with a command that doesn’t include -i, that is

```
pgbench [ options ] dbname
```

In nearly all cases, you’ll need some options to make a useful test. The most important options are -c (number of clients), -t (number of transactions), -T (time limit), and -f (specify a custom script file). See below for a full list.

Options

The following is divided into three subsections: Different options are used during database initialization and while running benchmarks, some options are useful in both cases.

Initialization Options

pgbench accepts the following command-line initialization arguments:

- i
  --initialize
  
  Required to invoke initialization mode.

- F fillfactor
  --fillfactor=fillfactor

  Create the pgbench_accounts, pgbench_tellers and pgbench_branches tables with the given fillfactor. Default is 100.

- n
  --no-vacuum

  Perform no vacuuming after initialization.
-q
--quiet

Switch logging to quiet mode, producing only one progress message per 5 seconds. The default logging prints one message each 100000 rows, which often outputs many lines per second (especially on good hardware).

-s scale_factor
--scale=scale_factor

Multiply the number of rows generated by the scale factor. For example, -s 100 will create 10,000,000 rows in the pgbench_accounts table. Default is 1. When the scale is 20,000 or larger, the columns used to hold account identifiers (aid columns) will switch to using larger integers (bigint), in order to be big enough to hold the range of account identifiers.

--foreign-keys

Create foreign key constraints between the standard tables.

--index-tablespace=index_tablespace

Create indexes in the specified tablespace, rather than the default tablespace.

--tablespace=tablespace

Create tables in the specified tablespace, rather than the default tablespace.

--unlogged-tables

Create all tables as unlogged tables, rather than permanent tables.

Benchmarking Options

pgbench accepts the following command-line benchmarking arguments:

-c clients
--client=clients

Number of clients simulated, that is, number of concurrent database sessions. Default is 1.

-C
--connect

Establish a new connection for each transaction, rather than doing it just once per client session. This is useful to measure the connection overhead.

-d
--debug

Print debugging output.

-D varname=value
--define=varname=value

Define a variable for use by a custom script (see below). Multiple -D options are allowed.

-f filename
--file=filename

Read transaction script from filename. See below for details. -N, -S, and -f are mutually exclusive.
-j threads
--jobs=threads

Number of worker threads within pgbench. Using more than one thread can be helpful on multi-
CPU machines. The number of clients must be a multiple of the number of threads, since each
thread is given the same number of client sessions to manage. Default is 1.

-l
--log

Write the time taken by each transaction to a log file. See below for details.

-M querymode
--protocol=querymode

Protocol to use for submitting queries to the server:

• simple: use simple query protocol.
• extended: use extended query protocol.
• prepared: use extended query protocol with prepared statements.

The default is simple query protocol. (See Chapter 49 for more information.)

-n
--no-vacuum

Perform no vacuuming before running the test. This option is necessary if you are running
a custom test scenario that does not include the standard tables pgbench_accounts,
pgbench_branches, pgbench_history, and pgbench_tellers.

-N
--skip-some-updates

Do not update pgbench_tellers and pgbench_branches. This will avoid update contention
on these tables, but it makes the test case even less like TPC-B.

-P sec
--progress=sec

Show progress report every sec seconds. The report includes the time since the beginning of
the run, the tps since the last report, and the transaction latency average and standard deviation
since the last report. Under throttling (-R), the latency is computed with respect to the transaction
scheduled start time, not the actual transaction beginning time, thus it also includes the average
schedule lag time.

-r
--report-latencies

Report the average per-statement latency (execution time from the perspective of the client) of
each command after the benchmark finishes. See below for details.

-R rate
--rate=rate

Execute transactions targeting the specified rate instead of running as fast as possible (the de-
fault). The rate is given in transactions per second. If the targeted rate is above the maximum
possible rate, the rate limit won’t impact the results.

The rate is targeted by starting transactions along a Poisson-distributed schedule time line. The
expected start time schedule moves forward based on when the client first started, not when the
previous transaction ended. That approach means that when transactions go past their original
scheduled end time, it is possible for later ones to catch up again.
When throttling is active, the transaction latency reported at the end of the run is calculated from the scheduled start times, so it includes the time each transaction had to wait for the previous transaction to finish. The wait time is called the schedule lag time, and its average and maximum are also reported separately. The transaction latency with respect to the actual transaction start time, i.e. the time spent executing the transaction in the database, can be computed by subtracting the schedule lag time from the reported latency.

A high schedule lag time is an indication that the system cannot process transactions at the specified rate, with the chosen number of clients and threads. When the average transaction execution time is longer than the scheduled interval between each transaction, each successive transaction will fall further behind, and the schedule lag time will keep increasing the longer the test run is. When that happens, you will have to reduce the specified transaction rate.

-s scale_factor
--scale=scale_factor

Report the specified scale factor in pgbench’s output. With the built-in tests, this is not necessary; the correct scale factor will be detected by counting the number of rows in the pgbench_branches table. However, when testing custom benchmarks (-f option), the scale factor will be reported as 1 unless this option is used.

-S
--select-only

Perform select-only transactions instead of TPC-B-like test.

-t transactions
--transactions=transactions

Number of transactions each client runs. Default is 10.

-T seconds
--time=seconds

Run the test for this many seconds, rather than a fixed number of transactions per client. -t and -T are mutually exclusive.

-v
--vacuum-all

Vacuum all four standard tables before running the test. With neither -n nor -v, pgbench will vacuum the pgbench_tellers and pgbench_branches tables, and will truncate pgbench_history.

--aggregate-interval=seconds

Length of aggregation interval (in seconds). May be used only together with -l - with this option, the log contains per-interval summary (number of transactions, min/max latency and two additional fields useful for variance estimation).

This option is not currently supported on Windows.

--sampling-rate=rate

Sampling rate, used when writing data into the log, to reduce the amount of log generated. If this option is given, only the specified fraction of transactions are logged. 1.0 means all transactions will be logged, 0.05 means only 5% of the transactions will be logged.

Remember to take the sampling rate into account when processing the log file. For example, when computing tps values, you need to multiply the numbers accordingly (e.g. with 0.01 sample rate, you’ll only get 1/100 of the actual tps).
Common Options

pgbench accepts the following command-line common arguments:

-\texttt{-h\ hostname}
-\texttt{--host=\ hostname}

The database server’s host name

-\texttt{-p\ port}
-\texttt{--port=\ port}

The database server’s port number

-\texttt{-U\ login}
-\texttt{--username=\ login}

The user name to connect as

-\texttt{-V}
-\texttt{--version}

Print the pgbench version and exit.

-\texttt{-?}
-\texttt{--help}

Show help about pgbench command line arguments, and exit.

Notes

What is the “Transaction” Actually Performed in pgbench?

The default transaction script issues seven commands per transaction:

1. \texttt{BEGIN;}
2. \texttt{UPDATE \textit{pgbench\_accounts} SET \textit{abalance} = \textit{abalance} + :delta WHERE \textit{aid} = :aid;}
3. \texttt{SELECT \textit{abalance} FROM \textit{pgbench\_accounts} WHERE \textit{aid} = :aid;}
4. \texttt{UPDATE \textit{pgbench\_tellers} SET \textit{tbalance} = \textit{tbalance} + :delta WHERE \textit{tid} = :tid;}
5. \texttt{UPDATE \textit{pgbench\_branches} SET \textit{bbalance} = \textit{bbalance} + :delta WHERE \textit{bid} = :bid;}
6. \texttt{INSERT INTO \textit{pgbench\_history} (tid, bid, aid, delta, mtime) VALUES (:tid, :bid, :aid, :delta, CURRENT\_TIMESTAMP);} 
7. \texttt{END;}

If you specify \texttt{-N}, steps 4 and 5 aren’t included in the transaction. If you specify \texttt{-S}, only the \texttt{SELECT} is issued.
Custom Scripts

gbench has support for running custom benchmark scenarios by replacing the default transaction script (described above) with a transaction script read from a file (-f option). In this case a “transaction” counts as one execution of a script file. You can even specify multiple scripts (multiple -f options), in which case a random one of the scripts is chosen each time a client session starts a new transaction.

The format of a script file is one SQL command per line; multiline SQL commands are not supported. Empty lines and lines beginning with -- are ignored. Script file lines can also be “meta commands”, which are interpreted by gbench itself, as described below.

There is a simple variable-substitution facility for script files. Variables can be set by the command-line -D option, explained above, or by the meta commands explained below. In addition to any variables preset by -D command-line options, there are a few variables that are preset automatically, listed in Table G-1. A value specified for these variables using -D takes precedence over the automatic preset. Once set, a variable’s value can be inserted into a SQL command by writing :varianlename.

When running more than one client session, each session has its own set of variables.

Table G-1. Automatic variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scale</td>
<td>current scale factor</td>
</tr>
<tr>
<td>client_id</td>
<td>unique number identifying the client session (starts from zero)</td>
</tr>
</tbody>
</table>

Script file meta commands begin with a backslash (\). Arguments to a meta command are separated by white space. These meta commands are supported:

\set varname operand1 [ operator operand2 ]

Sets variable varname to a calculated integer value. Each operand is either an integer constant or a :varianlename reference to a variable having an integer value. The operator can be +, -, *, or /.

Example:
\set ntellers 10 * :scale

\setrandom varname min max

Sets variable varname to a random integer value between the limits min and max inclusive. Each limit can be either an integer constant or a :varianlename reference to a variable having an integer value.

Example:
\setrandom aid 1 :naccounts

\sleep number [ us | ms | s ]

Causes script execution to sleep for the specified duration in microseconds (us), milliseconds (ms) or seconds (s). If the unit is omitted then seconds are the default. number can be either an integer constant or a :varianlename reference to a variable having an integer value.

Example:
\sleep 10 ms
Sets variable `varname` to the result of the shell command `command`. The command must return an integer value through its standard output.

`argument` can be either a text constant or a `:variablename` reference to a variable of any types. If you want to use `argument` starting with colons, you need to add an additional colon at the beginning of `argument`.

Example:

```
\setshell variable_to_be_assigned command literal_argument :variable ::literal_starting_with_colon
```

Same as `\setshell`, but the result is ignored.

Example:

```
\shell command literal_argument :variable ::literal_starting_with_colon
```

As an example, the full definition of the built-in TPC-B-like transaction is:

```
\set nbranches :scale
\set ntellers 10 * :scale
\set naccounts 100000 * :scale
\setrandom aid 1 :naccounts
\setrandom bid 1 :nbranches
\setrandom tid 1 :ntellers
\setrandom delta -5000 5000
BEGIN;
UPDATE pgbench_accounts SET abalance = abalance + :delta WHERE aid = :aid;
SELECT abalance FROM pgbench_accounts WHERE aid = :aid;
UPDATE pgbench_tellers SET tbalance = tbalance + :delta WHERE tid = :tid;
UPDATE pgbench_branches SET bbalance = bbalance + :delta WHERE bid = :bid;
INSERT INTO pgbench_history (tid, bid, aid, delta, mtime) VALUES (:tid, :bid, :aid, :delta, CURRENT_TIMESTAMP);
END;
```

This script allows each iteration of the transaction to reference different, randomly-chosen rows. (This example also shows why it’s important for each client session to have its own variables — otherwise they’d not be independently touching different rows.)

**Per-Transaction Logging**

With the `-l` option but without the `--aggregate-interval`, `pgbench` writes the time taken by each transaction to a log file. The log file will be named `pgbench_log.nnn`, where `nnn` is the PID of the `pgbench` process. If the `-j` option is 2 or higher, creating multiple worker threads, each will have its own log file. The first worker will use the same name for its log file as in the standard single worker case. The additional log files for the other workers will be named `pgbench_log.nnn.mmm`, where `mmm` is a sequential number for each worker starting with 1.

The format of the log is:

```
client_id transaction_no time file_no time_epoch time_us [schedule_lag]
```

where `time` is the total elapsed transaction time in microseconds, `file_no` identifies which script file was used (useful when multiple scripts were specified with `-f`), and `time_epoch/time_us` are a UNIX epoch format timestamp and an offset in microseconds (suitable for creating an ISO 8601 timestamp with fractional seconds) showing when the transaction completed. The last field,
schedule_lag, is the difference between the transaction’s scheduled start time, and the time it actually started, in microseconds. It is only present when the --rate option is used.

Here are example outputs:

0 199 2241 0 1175850568 995598
0 200 2465 0 1175850568 998079
0 201 2513 0 1175850569 608
0 202 2038 0 1175850569 2663

When running a long test on hardware that can handle a lot of transactions, the log files can become very large. The --sampling-rate option can be used to log only a random sample of transactions.

Aggregated Logging

With the --aggregate-interval option, the logs use a bit different format:

interval_start num_of_transactions latency_sum latency_2_sum min_latency max_latency [lag_sum lag_2_sum min_lag max_lag]

where interval_start is the start of the interval (UNIX epoch format timestamp), num_of_transactions is the number of transactions within the interval, latency_sum is a sum of latencies (so you can compute average latency easily). The following two fields are useful for variance estimation - latency_sum is a sum of latencies and latency_2_sum is a sum of 2nd powers of latencies. The next two fields are min_latency - a minimum latency within the interval, and max_latency - maximum latency within the interval. A transaction is counted into the interval when it was committed. The last four fields, lag_sum, lag_2_sum, min_lag, and max_lag, are only present if the --rate option is used. They are calculated from the time each transaction had to wait for the previous one to finish, i.e. the difference between each transaction’s scheduled start time and the time it actually started.

Here is example output:

1345828501 5601 1542744 483552416 61 2573
1345828503 7884 1979812 565806736 60 1479
1345828505 7208 1979422 567277552 59 1391
1345828507 7685 1980268 569784714 60 1398
1345828509 7073 1979779 573489941 236 1411

Notice that while the plain (unaggregated) log file contains a reference to the custom script files, the aggregated log does not. Therefore if you need per script data, you need to aggregate the data on your own.

Per-Statement Latencies

With the -r option, pgbench collects the elapsed transaction time of each statement executed by every client. It then reports an average of those values, referred to as the latency for each statement, after the benchmark has finished.

For the default script, the output will look similar to this:

starting vacuum...end.
transaction type: TPC-B (sort of)
scaling factor: 1
query mode: simple
number of clients: 10
number of threads: 1
number of transactions per client: 1000
number of transactions actually processed: 10000/10000
tps = 618.764555 (including connections establishing)
tps = 622.977698 (excluding connections establishing)

statement latencies in milliseconds:
0.004386 \set nbranches 1 * :scale
0.001343 \set ntellers 10 * :scale
0.001212 \set naccounts 100000 * :scale
0.001310 \setrandom aid 1 :naccounts
0.001073 \setrandom bid 1 :nbranches
0.001005 \setrandom tid 1 :ntellers
0.001078 \setrandom delta -5000 5000
0.326152 BEGIN;
0.603376 UPDATE pgbench_accounts SET abalance = abalance + :delta WHERE aid = :aid;
0.454643 SELECT abalance FROM pgbench_accounts WHERE aid = :aid;
5.528491 UPDATE pgbench_tellers SET tbalance = tbalance + :delta WHERE tid = :tid;
7.335435 UPDATE pgbench_branches SET bbalance = bbalance + :delta WHERE bid = :bid;
0.371851 INSERT INTO pgbench_history (tid, bid, aid, delta, mtime) VALUES (:tid, :bid, :aid, :delta, CURRENT_TIMESTAMP);
1.212976 END;

If multiple script files are specified, the averages are reported separately for each script file.

Note that collecting the additional timing information needed for per-statement latency computation adds some overhead. This will slow average execution speed and lower the computed TPS. The amount of slowdown varies significantly depending on platform and hardware. Comparing average TPS values with and without latency reporting enabled is a good way to measure if the timing overhead is significant.

**Good Practices**

It is very easy to use pgbench to produce completely meaningless numbers. Here are some guidelines to help you get useful results.

In the first place, *never* believe any test that runs for only a few seconds. Use the `-t` or `-T` option to make the run last at least a few minutes, so as to average out noise. In some cases you could need hours to get numbers that are reproducible. It’s a good idea to try the test run a few times, to find out if your numbers are reproducible or not.

For the default TPC-B-like test scenario, the initialization scale factor (`-s`) should be at least as large as the largest number of clients you intend to test (`-c`); else you’ll mostly be measuring update contention. There are only `-s` rows in the `pgbench_branches` table, and every transaction wants to update one of them, so `-c` values in excess of `-s` will undoubtedly result in lots of transactions blocked waiting for other transactions.

The default test scenario is also quite sensitive to how long it’s been since the tables were initialized: accumulation of dead rows and dead space in the tables changes the results. To understand the results you must keep track of the total number of updates and when vacuuming happens. If autovacuum is enabled it can result in unpredictable changes in measured performance.

A limitation of pgbench is that it can itself become the bottleneck when trying to test a large number of client sessions. This can be alleviated by running pgbench on a different machine from the database.
server, although low network latency will be essential. It might even be useful to run several pgbench instances concurrently, on several client machines, against the same database server.

Security

If untrusted users have access to a database that has not adopted a secure schema usage pattern, do not run pgbench in that database. pgbench uses unqualified names and does not manipulate the search path.
vacuumlo

Name
vacuumlo — remove orphaned large objects from a PostgreSQL database

Synopsis
vacuumlo [option...] dbname...

Description
vacuumlo is a simple utility program that will remove any "orphaned" large objects from a PostgreSQL database. An orphaned large object (LO) is considered to be any LO whose OID does not appear in any oid or lo data column of the database.

If you use this, you may also be interested in the lo_manage trigger in the lo module. lo_manage is useful to try to avoid creating orphaned LOs in the first place.

All databases named on the command line are processed.

Options
vacuumlo accepts the following command-line arguments:

- l limit
  Remove no more than limit large objects per transaction (default 1000). Since the server acquires a lock per LO removed, removing too many LOs in one transaction risks exceeding max_locks_per_transaction. Set the limit to zero if you want all removals done in a single transaction.

- n
  Don’t remove anything, just show what would be done.

- v
  Write a lot of progress messages.

- V
  --version
  Print the vacuumlo version and exit.

- ?
  --help
  Show help about vacuumlo command line arguments, and exit.

vacuumlo also accepts the following command-line arguments for connection parameters:
vacuumlo

- **h hostname**
  Database server’s host.

- **p port**
  Database server’s port.

- **U username**
  User name to connect as.

- **w**
  **--no-password**
  Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

- **W**
  Force vacuumlo to prompt for a password before connecting to a database.
  This option is never essential, since vacuumlo will automatically prompt for a password if the server demands password authentication. However, vacuumlo will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

**Notes**

vacuumlo works by the following method: First, vacuumlo builds a temporary table which contains all of the OIDs of the large objects in the selected database. It then scans through all columns in the database that are of type `oid` or `lo`, and removes matching entries from the temporary table. (Note: Only types with these names are considered; in particular, domains over them are not considered.) The remaining entries in the temporary table identify orphaned LOs. These are removed.

**Author**

Peter Mount <peter@retep.org.uk>
G.2. Server Applications

This section covers PostgreSQL server-related applications in contrib. They are typically run on the host where the database server resides. See also Reference III, PostgreSQL Server Applications for information about server applications that part of the core PostgreSQL distribution.

pg_archivecleanup

Name

pg_archivecleanup — clean up PostgreSQL WAL archive files

Synopsis

pg_archivecleanup [option...] archivelocation oldestkeptwalfile

Description

pg_archivecleanup is designed to be used as an archive_cleanup_command to clean up WAL file archives when running as a standby server (see Section 25.2). pg_archivecleanup can also be used as a standalone program to clean WAL file archives.

To configure a standby server to use pg_archivecleanup, put this into its recovery.conf configuration file:

archive_cleanup_command = 'pg_archivecleanup archivelocation %r'

where archivelocation is the directory from which WAL segment files should be removed.

When used within archive_cleanup_command, all WAL files logically preceding the value of the %r argument will be removed from archivelocation. This minimizes the number of files that need to be retained, while preserving crash-restart capability. Use of this parameter is appropriate if the archivelocation is a transient staging area for this particular standby server, but not when the archivelocation is intended as a long-term WAL archive area, or when multiple standby servers are recovering from the same archivelocation.

When used as a standalone program all WAL files logically preceding the oldestkeptwalfile will be removed from archivelocation. In this mode, if you specify a .backup file name, then only the file prefix will be used as the oldestkeptwalfile. This allows you to remove all WAL files archived prior to a specific base backup without error. For example, the following example will remove all files older than WAL file name 0000000100000037000000010:

pg_archivecleanup -d archive 0000000100000037000000010.00000020.backup

pg_archivecleanup: keep WAL file "archive/0000000100000037000000010" and later
pg_archivecleanup: removing file "archive/00000001000000370000000F"
pg_archivecleanup: removing file "archive/00000001000000370000000E"
pg_archivecleanup assumes that `archivelocation` is a directory readable and writable by the server-owning user.

Options

pg_archivecleanup accepts the following command-line arguments:

-d
Print lots of debug logging output on `stderr`.

-n
Print the names of the files that would have been removed on `stdout` (performs a dry run).

-V
--version
Print the pg_archivecleanup version and exit.

-x extension
When using the program as a standalone utility, provide an extension that will be stripped from all file names before deciding if they should be deleted. This is typically useful for cleaning up archives that have been compressed during storage, and therefore have had an extension added by the compression program. For example: `-x .gz`.

-?
--help
Show help about pg_archivecleanup command line arguments, and exit.

Notes

pg_archivecleanup is designed to work with PostgreSQL 8.0 and later when used as a standalone utility, or with PostgreSQL 9.0 and later when used as an archive cleanup command.

pg_archivecleanup is written in C and has an easy-to-modify source code, with specifically designated sections to modify for your own needs.

Examples

On Linux or Unix systems, you might use:

```
archive_cleanup_command = 'pg_archivecleanup -d /mnt/standby/archive %r 2>>cleanup.log'
```

where the archive directory is physically located on the standby server, so that the `archive_command` is accessing it across NFS, but the files are local to the standby. This will:

- produce debugging output in `cleanup.log`
- remove no-longer-needed files from the archive directory

pg_standby
pg_standby

Name

pg_standby — supports the creation of a PostgreSQL warm standby server

Synopsis

pg_standby[option...] archivelocation nextwalfile xlogfilepath [restartwalfile]

Description

pg_standby supports creation of a “warm standby” database server. It is designed to be a production-ready program, as well as a customizable template should you require specific modifications.

pg_standby is designed to be a waiting restore_command, which is needed to turn a standard archive recovery into a warm standby operation. Other configuration is required as well, all of which is described in the main server manual (see Section 25.2).

To configure a standby server to use pg_standby, put this into its recovery.conf configuration file:

```
restore_command = 'pg_standby archiveDir %f %p %r'
```

where `archiveDir` is the directory from which WAL segment files should be restored.

If `restartwalfile` is specified, normally by using the `%r` macro, then all WAL files logically preceding this file will be removed from `archivelocation`. This minimizes the number of files that need to be retained, while preserving crash-restart capability. Use of this parameter is appropriate if the `archivelocation` is a transient staging area for this particular standby server, but not when the `archivelocation` is intended as a long-term WAL archive area.

pg_standby assumes that `archivelocation` is a directory readable by the server-owning user. If `restartwalfile` (or `-k`) is specified, the `archivelocation` directory must be writable too.

There are two ways to fail over to a “warm standby” database server when the master server fails:

Smart Failover

In smart failover, the server is brought up after applying all WAL files available in the archive. This results in zero data loss, even if the standby server has fallen behind, but if there is a lot of unapplied WAL it can be a long time before the standby server becomes ready. To trigger a smart failover, create a trigger file containing the word `smart`, or just create it and leave it empty.

Fast Failover

In fast failover, the server is brought up immediately. Any WAL files in the archive that have not yet been applied will be ignored, and all transactions in those files are lost. To trigger a fast failover, create a trigger file and write the word `fast` into it. pg_standby can also be configured to execute a fast failover automatically if no new WAL file appears within a defined interval.
Options

pg_standby accepts the following command-line arguments:

- **c**
  
  Use `cp` or `copy` command to restore WAL files from archive. This is the only supported behavior so this option is useless.

- **d**
  
  Print lots of debug logging output on `stderr`.

- **k**
  
  Remove files from `archivelocation` so that no more than this many WAL files before the current one are kept in the archive. Zero (the default) means not to remove any files from `archivelocation`. This parameter will be silently ignored if `restartwalfile` is specified, since that specification method is more accurate in determining the correct archive cut-off point. Use of this parameter is deprecated as of PostgreSQL 8.3; it is safer and more efficient to specify a `restartwalfile` parameter. A too small setting could result in removal of files that are still needed for a restart of the standby server, while a too large setting wastes archive space.

- **r** `maxretries`
  
  Set the maximum number of times to retry the copy command if it fails (default 3). After each failure, we wait for `sleeptime * num_retries` so that the wait time increases progressively. So by default, we will wait 5 secs, 10 secs, then 15 secs before reporting the failure back to the standby server. This will be interpreted as end of recovery and the standby will come up fully as a result.

- **s** `sleeptime`
  
  Set the number of seconds (up to 60, default 5) to sleep between tests to see if the WAL file to be restored is available in the archive yet. The default setting is not necessarily recommended; consult Section 25.2 for discussion.

- **t** `triggerfile`
  
  Specify a trigger file whose presence should cause failover. It is recommended that you use a structured file name to avoid confusion as to which server is being triggered when multiple servers exist on the same system; for example `/tmp/pgsql.trigger.5432`.

- **V**
  
  --version
  
  Print the pg_standby version and exit.

- **w** `maxwaittime`
  
  Set the maximum number of seconds to wait for the next WAL file, after which a fast failover will be performed. A setting of zero (the default) means wait forever. The default setting is not necessarily recommended; consult Section 25.2 for discussion.

- **?**
  
  --help
  
  Show help about pg_standby command line arguments, and exit.
Notes

pg_standby is designed to work with PostgreSQL 8.2 and later.
PostgreSQL 8.3 provides the %r macro, which is designed to let pg_standby know the last file it needs to keep. With PostgreSQL 8.2, the -k option must be used if archive cleanup is required. This option remains available in 8.3, but its use is deprecated.
PostgreSQL 8.4 provides the recovery_end_command option. Without this option a leftover trigger file can be hazardous.

pg_standby is written in C and has an easy-to-modify source code, with specifically designated sections to modify for your own needs

Examples

On Linux or Unix systems, you might use:

archive_command = ‘cp $p .../archive/%f’
restore_command = ‘pg_standby -d -s 2 -t /tmp/pgsql.trigger.5442 .../archive %f $p $r 2>>standby.log’
recovery_end_command = ‘rm -f /tmp/pgsql.trigger.5442’

where the archive directory is physically located on the standby server, so that the archive_command is accessing it across NFS, but the files are local to the standby (enabling use of ln). This will:

- produce debugging output in standby.log
- sleep for 2 seconds between checks for next WAL file availability
- stop waiting only when a trigger file called /tmp/pgsql.trigger.5442 appears, and perform failover according to its content
- remove the trigger file when recovery ends
- remove no-longer-needed files from the archive directory

On Windows, you might use:

archive_command = ‘copy $p ...\archive\%f’
restore_command = ‘pg_standby -d -s 5 -t C:\pgsql.trigger.5442 ...\archive %f $p $r 2>>standby.log’
recovery_end_command = ‘del C:\pgsql.trigger.5442’

Note that backslashes need to be doubled in the archive_command, but not in the restore_command or recovery_end_command. This will:

- use the copy command to restore WAL files from archive
- produce debugging output in standby.log
- sleep for 5 seconds between checks for next WAL file availability
• stop waiting only when a trigger file called C:\pgsql.trigger.5442 appears, and perform failover according to its content
• remove the trigger file when recovery ends
• remove no-longer-needed files from the archive directory

The `copy` command on Windows sets the final file size before the file is completely copied, which would ordinarily confuse `pg_standby`. Therefore `pg_standby` waits `sleeptime` seconds once it sees the proper file size. GNUWin32’s `cp` sets the file size only after the file copy is complete.

Since the Windows example uses `copy` at both ends, either or both servers might be accessing the archive directory across the network.

pg_test_fsync

Name

pg_test_fsync — determine fastest wal_sync_method for PostgreSQL

Synopsis

pg_test_fsync [option...]

Description

pg_test_fsync is intended to give you a reasonable idea of what the fastest wal_sync_method is on your specific system, as well as supplying diagnostic information in the event of an identified I/O problem. However, differences shown by pg_test_fsync might not make any significant difference in real database throughput, especially since many database servers are not speed-limited by their transaction logs. pg_test_fsync reports average file sync operation time in microseconds for each wal_sync_method, which can also be used to inform efforts to optimize the value of commit_delay.

Options

pg_test_fsync accepts the following command-line options:

- **-f**
  --filename
  Specifies the file name to write test data in. This file should be in the same file system that the pg_xlog directory is or will be placed in. (pg_xlog contains the WAL files.) The default is pg_test_fsync.out in the current directory.

- **-s**
  --secs-per-test
  Specifies the number of seconds for each test. The more time per test, the greater the test’s accuracy, but the longer it takes to run. The default is 5 seconds, which allows the program to complete in under 2 minutes.

- **-V**
  --version
  Print the pg_test_fsync version and exit.

- **-?**
  --help
  Show help about pg_test_fsync command line arguments, and exit.

**pg_test_timing**

**Name**

`pg_test_timing` — measure timing overhead

**Synopsis**

`pg_test_timing [option...]`

**Description**

`pg_test_timing` is a tool to measure the timing overhead on your system and confirm that the system time never moves backwards. Systems that are slow to collect timing data can give less accurate `EXPLAIN ANALYZE` results.

**Options**

`pg_test_timing` accepts the following command-line options:

- `-d duration`
  `-d duration=duration`

  Specifies the test duration, in seconds. Longer durations give slightly better accuracy, and are more likely to discover problems with the system clock moving backwards. The default test duration is 3 seconds.

- `-V`
  `-V version`

  Print the `pg_test_timing` version and exit.

- `?`
  `-? help`

  Show help about `pg_test_timing` command line arguments, and exit.

**Usage**

**Interpreting results**

Good results will show most (>90%) individual timing calls take less than one microsecond. Average per loop overhead will be even lower, below 100 nanoseconds. This example from an Intel i7-860 system using a TSC clock source shows excellent performance:

```
Testing timing overhead for 3 seconds.
Per loop time including overhead: 35.96 nsec
Histogram of timing durations:
```

```
Note that different units are used for the per loop time than the histogram. The loop can have resolution within a few nanoseconds (nsec), while the individual timing calls can only resolve down to one microsecond (usec).

### Measuring executor timing overhead

When the query executor is running a statement using `EXPLAIN ANALYZE`, individual operations are timed as well as showing a summary. The overhead of your system can be checked by counting rows with the `psql` program:

```sql
cREATE TABLE t AS SELECT * FROM generate_series(1,100000);
\timing
SELECT COUNT(*) FROM t;
EXPLAIN ANALYZE SELECT COUNT(*) FROM t;
```

The i7-860 system measured runs the count query in 9.8 ms while the `EXPLAIN ANALYZE` version takes 16.6 ms, each processing just over 100,000 rows. That 6.8 ms difference means the timing overhead per row is 68 nsec, about twice what `pg_test_timing` estimated it would be. Even that relatively small amount of overhead is making the fully timed count statement take almost 70% longer. On more substantial queries, the timing overhead would be less problematic.

### Changing time sources

On some newer Linux systems, it’s possible to change the clock source used to collect timing data at any time. A second example shows the slowdown possible from switching to the slower `acpi_pm` time source, on the same system used for the fast results above:

```bash
# cat /sys/devices/system/clocksource/clocksource0/available_clocksource
tsc hpet acpi_pm
# echo acpi_pm > /sys/devices/system/clocksource/clocksource0/current_clocksource
# pg_test_timing
Per loop time including overhead: 722.92 nsec
```

Histogram of timing durations:

```
< usec  % of total  count
 1  27.84870  1155682
 2  72.05956  2990371
 4  0.07810  3241
 8  0.01357  563
16  0.00007   3
```

In this configuration, the sample `EXPLAIN ANALYZE` above takes 115.9 ms. That’s 1061 nsec of timing overhead, again a small multiple of what’s measured directly by this utility. That much timing
overhead means the actual query itself is only taking a tiny fraction of the accounted for time, most of it is being consumed in overhead instead. In this configuration, any EXPLAIN ANALYZE totals involving many timed operations would be inflated significantly by timing overhead.

FreeBSD also allows changing the time source on the fly, and it logs information about the timer selected during boot:

```
# dmesg | grep "Timecounter"
Timecounter "ACPI-fast" frequency 3579545 Hz quality 900
Timecounter "i8254" frequency 1193182 Hz quality 0
Timecounters tick every 10.000 msec
Timecounter "TSC" frequency 2531787134 Hz quality 800
# sysctl kern.timecounter.hardware=TSC
kern.timecounter.hardware: ACPI-fast -> TSC
```

Other systems may only allow setting the time source on boot. On older Linux systems the "clock" kernel setting is the only way to make this sort of change. And even on some more recent ones, the only option you’ll see for a clock source is "jiffies". Jiffies are the older Linux software clock implementation, which can have good resolution when it’s backed by fast enough timing hardware, as in this example:

```
$ cat /sys/devices/system/clocksource/clocksource0/available_clocksource
jiffies
$ dmesg | grep time.c
time.c: Using 3.579545 MHz WALL PM GTOD PIT/TSC timer.
time.c: Detected 2400.153 MHz processor.
$ pg_test_timing
Testing timing overhead for 3 seconds.
Per timing duration including loop overhead: 97.75 ns
Histogram of timing durations:
< usec  % of total  count
  1  90.23734   27694571
  2  9.75277    2993204
  4  0.00981    3010
  8  0.00007    22
16  0.00000    1
32  0.00000    1
```

Clock hardware and timing accuracy

Collecting accurate timing information is normally done on computers using hardware clocks with various levels of accuracy. With some hardware the operating systems can pass the system clock time almost directly to programs. A system clock can also be derived from a chip that simply provides timing interrupts, periodic ticks at some known time interval. In either case, operating system kernels provide a clock source that hides these details. But the accuracy of that clock source and how quickly it can return results varies based on the underlying hardware.

Inaccurate time keeping can result in system instability. Test any change to the clock source very carefully. Operating system defaults are sometimes made to favor reliability over best accuracy. And if you are using a virtual machine, look into the recommended time sources compatible with it. Virtual hardware faces additional difficulties when emulating timers, and there are often per operating system settings suggested by vendors.
The Time Stamp Counter (TSC) clock source is the most accurate one available on current generation CPUs. It’s the preferred way to track the system time when it’s supported by the operating system and the TSC clock is reliable. There are several ways that TSC can fail to provide an accurate timing source, making it unreliable. Older systems can have a TSC clock that varies based on the CPU temperature, making it unusable for timing. Trying to use TSC on some older multicore CPUs can give a reported time that’s inconsistent among multiple cores. This can result in the time going backwards, a problem this program checks for. And even the newest systems can fail to provide accurate TSC timing with very aggressive power saving configurations.

Newer operating systems may check for the known TSC problems and switch to a slower, more stable clock source when they are seen. If your system supports TSC time but doesn’t default to that, it may be disabled for a good reason. And some operating systems may not detect all the possible problems correctly, or will allow using TSC even in situations where it’s known to be inaccurate.

The High Precision Event Timer (HPET) is the preferred timer on systems where it’s available and TSC is not accurate. The timer chip itself is programmable to allow up to 100 nanosecond resolution, but you may not see that much accuracy in your system clock.

Advanced Configuration and Power Interface (ACPI) provides a Power Management (PM) Timer, which Linux refers to as the acpi_pm. The clock derived from acpi_pm will at best provide 300 nanosecond resolution.

Timers used on older PC hardware include the 8254 Programmable Interval Timer (PIT), the real-time clock (RTC), the Advanced Programmable Interrupt Controller (APIC) timer, and the Cyclone timer. These timers aim for millisecond resolution.

EXPLAIN
pg_upgrade

Name

pg_upgrade — upgrade a PostgreSQL server instance

Synopsis

pg_upgrade -b oldbindir -B newbindir -d olddatadir -D newdatadir [option...]

Description

pg_upgrade (formerly called pg_migrator) allows data stored in PostgreSQL data files to be upgraded to a later PostgreSQL major version without the data dump/reload typically required for major version upgrades, e.g. from 8.4.7 to the current major release of PostgreSQL. It is not required for minor version upgrades, e.g. from 9.0.1 to 9.0.4.

Major PostgreSQL releases regularly add new features that often change the layout of the system tables, but the internal data storage format rarely changes. pg_upgrade uses this fact to perform rapid upgrades by creating new system tables and simply reusing the old user data files. If a future major release ever changes the data storage format in a way that makes the old data format unreadable, pg_upgrade will not be usable for such upgrades. (The community will attempt to avoid such situations.)

pg_upgrade does its best to make sure the old and new clusters are binary-compatible, e.g. by checking for compatible compile-time settings, including 32/64-bit binaries. It is important that any external modules are also binary compatible, though this cannot be checked by pg_upgrade.

pg_upgrade supports upgrades from 8.3.X and later to the current major release of PostgreSQL, including snapshot and alpha releases.

Options

pg_upgrade accepts the following command-line arguments:

- `--old-bindir=bindir`
- `--new-bindir=bindir`
- `--check`

the old PostgreSQL executable directory; environment variable PGBINOLD

the new PostgreSQL executable directory; environment variable PGBINNEW

check clusters only, don’t change any data
pg_upgrade

-d datadir
   --old-datadir=datadir
       the old cluster data directory; environment variable PGDATAOLD

-D datadir
   --new-datadir=datadir
       the new cluster data directory; environment variable PGDATANEW

-j
   --jobs
       number of simultaneous processes or threads to use

-k
   --link
       use hard links instead of copying files to the new cluster

-o options
   --old-options options
       options to be passed directly to the old postgres command

-O options
   --new-options options
       options to be passed directly to the new postgres command

-p port
   --old-port=port
       the old cluster port number; environment variable PGPORTOLD

-P port
   --new-port=port
       the new cluster port number; environment variable PGPORTNEW

-r
   --retain
       retain SQL and log files even after successful completion

-U username
   --username=username
       cluster’s super user name; environment variable PGUSER

-v
   --verbose
       enable verbose internal logging

-V
   --version
       display version information, then exit

-?
   --help
       show help, then exit
Usage

These are the steps to perform an upgrade with `pg_upgrade`:

1. Optionally move the old cluster
   
   If you are using a version-specific installation directory, e.g. `/opt/PostgreSQL/9.1`, you do not need to move the old cluster. The graphical installers all use version-specific installation directories.

   If your installation directory is not version-specific, e.g. `/usr/local/pgsql`, it is necessary to move the current PostgreSQL install directory so it does not interfere with the new PostgreSQL installation. Once the current PostgreSQL server is shut down, it is safe to rename the PostgreSQL installation directory; assuming the old directory is `/usr/local/pgsql`, you can do:
   
   ```
   mv /usr/local/pgsql /usr/local/pgsql.old
   ```

2. For source installs, build the new version

   Build the new PostgreSQL source with `configure` flags that are compatible with the old cluster. `pg_upgrade` will check `pg_controldata` to make sure all settings are compatible before starting the upgrade.

3. Install the new PostgreSQL binaries

   Install the new server’s binaries and support files.

   For source installs, if you wish to install the new server in a custom location, use the `prefix` variable:
   
   ```
   make prefix=/usr/local/pgsql.new install
   ```

4. Install `pg_upgrade` and `pg_upgrade_support`

   Install the `pg_upgrade` binary and `pg_upgrade_support` library in the new PostgreSQL installation.

5. Initialize the new PostgreSQL cluster

   Initialize the new cluster using `initdb`. Again, use compatible `initdb` flags that match the old cluster. Many prebuilt installers do this step automatically. There is no need to start the new cluster.

6. Install custom shared object files

   Install any custom shared object files (or DLLs) used by the old cluster into the new cluster, e.g. `pgcrypto.so`, whether they are from `contrib` or some other source. Do not install the schema definitions, e.g. `CREATE EXTENSION pgcrypto`, because these will be upgraded from the old cluster. Also, any custom full text search files (dictionary, synonym, thesaurus, stop words) must also be copied to the new cluster.

7. Adjust authentication

   `pg_upgrade` will connect to the old and new servers several times, so you might want to set authentication to `peer` in `pg_hba.conf` or use a `~/.pgpass` file (see Section 31.15).

8. Stop both servers

   Make sure both database servers are stopped using, on Unix, e.g.:
   
   ```
   pg_ctl -D /opt/PostgreSQL/8.4 stop
   pg_ctl -D /opt/PostgreSQL/9.0 stop
   ```

   or on Windows, using the proper service names:
9. Run pg_upgrade

Always run the pg_upgrade binary of the new server, not the old one. pg_upgrade requires the specification of the old and new cluster's data and executable (bin) directories. You can also specify user and port values, and whether you want the data linked instead of copied (the default).

If you use link mode, the upgrade will be much faster (no file copying) and use less disk space, but you will not be able to access your old cluster once you start the new cluster after the upgrade. Link mode also requires that the old and new cluster data directories be in the same file system. (Tablespaces and pg_xlog can be on different file systems.) See pg_upgrade --help for a full list of options.

The --jobs option allows multiple CPU cores to be used for copying/linking of files and to dump and reload database schemas in parallel; a good place to start is the maximum of the number of CPU cores and tablespaces. This option can dramatically reduce the time to upgrade a multi-database server running on a multiprocessor machine.

For Windows users, you must be logged into an administrative account, and then start a shell as the postgres user and set the proper path:

```bash
RUNAS /USER:postgres "CMD.EXE" SET PATH=%PATH%;C:\Program Files\PostgreSQL\9.0\bin;
```

and then run pg_upgrade with quoted directories, e.g.:

```bash
pg_upgrade.exe
   --old-datadir "C:/Program Files/PostgreSQL/8.4/data"
   --new-datadir "C:/Program Files/PostgreSQL/9.0/data"
   --old-bindir "C:/Program Files/PostgreSQL/8.4/bin"
   --new-bindir "C:/Program Files/PostgreSQL/9.0/bin"
```

Once started, pg_upgrade will verify the two clusters are compatible and then do the upgrade. You can use pg_upgrade --check to perform only the checks, even if the old server is still running. pg_upgrade --check will also outline any manual adjustments you will need to make after the upgrade. If you are going to be using link mode, you should use the --link option with --check to enable link-mode-specific checks. pg_upgrade requires write permission in the current directory.

Obviously, no one should be accessing the clusters during the upgrade. pg_upgrade defaults to running servers on port 50432 to avoid unintended client connections. You can use the same port number for both clusters when doing an upgrade because the old and new clusters will not be running at the same time. However, when checking an old running server, the old and new port numbers must be different.

If an error occurs while restoring the database schema, pg_upgrade will exit and you will have to revert to the old cluster as outlined in step 14 below. To try pg_upgrade again, you will need to modify the old cluster so the pg_upgrade schema restore succeeds. If the problem is a contrib module, you might need to uninstall the contrib module from the old cluster and install it in the new cluster after the upgrade, assuming the module is not being used to store user data.

10. Restore pg_hba.conf

If you modified pg_hba.conf, restore its original settings. It might also be necessary to adjust other configuration files in the new cluster to match the old cluster, e.g. postgresql.conf.

11. Post-Upgrade processing
If any post-upgrade processing is required, pg_upgrade will issue warnings as it completes. It will also generate script files that must be run by the administrator. The script files will connect to each database that needs post-upgrade processing. Each script should be run using:

```sql
psql --username postgres --file script.sql postgres
```

The scripts can be run in any order and can be deleted once they have been run.

**Caution**

In general it is unsafe to access tables referenced in rebuild scripts until the rebuild scripts have run to completion; doing so could yield incorrect results or poor performance. Tables not referenced in rebuild scripts can be accessed immediately.

12. Statistics

Because optimizer statistics are not transferred by pg_upgrade, you will be instructed to run a command to regenerate that information at the end of the upgrade. You might need to set connection parameters to match your new cluster.

13. Delete old cluster

Once you are satisfied with the upgrade, you can delete the old cluster’s data directories by running the script mentioned when pg_upgrade completes. (Automatic deletion is not possible if you have user-defined tablespaces inside the old data directory.) You can also delete the old installation directories (e.g. bin, share).

14. Reverting to old cluster

If, after running pg_upgrade, you wish to revert to the old cluster, there are several options:

- If the --check option was used, the old cluster was unmodified; it can be restarted.
- If the --link option was *not* used, the old cluster was unmodified; it can be restarted.
- If the --link option was used, the data files might be shared between the old and new cluster:
  - If pg_upgrade aborted before linking started, the old cluster was unmodified; it can be restarted.
  - If you did *not* start the new cluster, the old cluster was unmodified except that, when linking started, a .old suffix was appended to $PGDATA/global/pg_control. To reuse the old cluster, remove the .old suffix from $PGDATA/global/pg_control; you can then restart the old cluster.
  - If you did start the new cluster, it has written to shared files and it is unsafe to use the old cluster. The old cluster will need to be restored from backup in this case.

**Notes**

pg_upgrade does not support upgrading of databases containing these reg* OID-referencing system data types: regproc, regprocedure, regoper, regoperator, regconfig, and regdictionary. (regtype can be upgraded.)

All failure, rebuild, and reindex cases will be reported by pg_upgrade if they affect your installation; post-upgrade scripts to rebuild tables and indexes will be generated automatically. If you are trying to automate the upgrade of many clusters, you should find that clusters with identical database schemas
require the same post-upgrade steps for all cluster upgrades; this is because the post-upgrade steps are based on the database schemas, and not user data.

For deployment testing, create a schema-only copy of the old cluster, insert dummy data, and upgrade that.

If you are upgrading a pre-PostgreSQL 9.2 cluster that uses a configuration-file-only directory, you must pass the real data directory location to `pg_upgrade`, and pass the configuration directory location to the server, e.g. `-d /real-data-directory -o ’-D /configuration-directory’`. If using a pre-9.1 old server that is using a non-default Unix-domain socket directory or a default that differs from the default of the new cluster, set `PGHOST` to point to the old server’s socket location. (This is not relevant on Windows.)

A Log-Shipping Standby Server (Section 25.2) cannot be upgraded because the server must allow writes. The simplest way is to upgrade the primary and use `rsync` to rebuild the standbys. You can run `rsync` while the primary is down, or as part of a base backup (Section 24.3.2) which overwrites the old standby cluster.

If you want to use link mode and you do not want your old cluster to be modified when the new cluster is started, make a copy of the old cluster and upgrade that in link mode. To make a valid copy of the old cluster, use `rsync` to create a dirty copy of the old cluster while the server is running, then shut down the old server and run `rsync` again to update the copy with any changes to make it consistent. You might want to exclude some files, e.g. `postmaster.pid`, as documented in Section 24.3.3. If your file system supports file system snapshots or copy-on-write file copies, you can use that to make a backup of the old cluster and tablespaces, though the snapshot and copies must be created simultaneously or while the database server is down.

**Limitations in Upgrading from PostgreSQL 8.3**

Upgrading *from* PostgreSQL 8.3 has additional restrictions not present when upgrading from later PostgreSQL releases. For example, `pg_upgrade` will not work for upgrading from 8.3 if a user column is defined as:

- a `tsquery` data type
- data type name and is not the first column

You must drop any such columns and upgrade them manually.

`pg_upgrade` will not work if the `ltree` contrib module is installed in a database.

`pg_upgrade` will require a table rebuild if:

- a user column is of data type `tsvector`

`pg_upgrade` will require a reindex if:

- an index is of type hash or GIN
- an index uses `bpchar_pattern_ops`
Also, the default datetime storage format changed to integer after PostgreSQL 8.3. `pg_upgrade` will check that the datetime storage format used by the old and new clusters match. Make sure your new cluster is built with the configure flag `--disable-integer-datetimes`.

For Windows users, note that due to different integer datetimes settings used by the graphical installer and the MSI installer, it is only possible to upgrade from version 8.3 of the installer distribution to version 8.4 or later of the installer distribution. It is not possible to upgrade from the MSI installer to the new graphical installer.

**Name**

pg_xlogdump — display a human-readable rendering of the write-ahead log of a PostgreSQL database cluster

**Synopsis**

```
pg_xlogdump [option...][startseg [endseg]]
```

**Description**

pg_xlogdump displays the write-ahead log (WAL) and is mainly useful for debugging or educational purposes. This utility can only be run by the user who installed the server, because it requires read-only access to the data directory.

**Options**

The following command-line options control the location and format of the output:

- `startseg`
  - Start reading at the specified log segment file. This implicitly determines the path in which files will be searched for, and the timeline to use.

- `endseg`
  - Stop after reading the specified log segment file.

- `-b`
  - `--bkp-details`
    - Output detailed information about backup blocks.

- `-e end`
  - `--end=end`
    - Stop reading at the specified log position, instead of reading to the end of the log stream.

- `-f`
  - `--follow`
    - After reaching the end of valid WAL, keep polling once per second for new WAL to appear.

- `-n limit`
  - `--limit=limit`
    - Display the specified number of records, then stop.
pg_xlogdump

-p path
--path=path

Directory in which to find log segment files. The default is to search for them in the pg_xlog subdirectory of the current directory.

-r rmgr
--rmgr=rmgr

Only display records generated by the specified resource manager. If list is passed as name, print a list of valid resource manager names, and exit.

-s start
--start=start

Log position at which to start reading. The default is to start reading the first valid log record found in the earliest file found.

-t timeline
--timeline=timeline

Timeline from which to read log records. The default is to use the value in startseg, if that is specified; otherwise, the default is 1.

-V
--version

Print the pg_xlogdump version and exit.

-x xid
--xid=xid

Only display records marked with the given TransactionId.

-?
--help

Show help about pg_xlogdump command line arguments, and exit.

Notes

Can give wrong results when the server is running.

Only the specified timeline is displayed (or the default, if none is specified). Records in other timelines are ignored.

Appendix H. External Projects

PostgreSQL is a complex software project, and managing the project is difficult. We have found that many enhancements to PostgreSQL can be more efficiently developed separately from the core project.

H.1. Client Interfaces

There are only two client interfaces included in the base PostgreSQL distribution:

- libpq is included because it is the primary C language interface, and because many other client interfaces are built on top of it.
- ECPG is included because it depends on the server-side SQL grammar, and is therefore sensitive to changes in PostgreSQL itself.

All other language interfaces are external projects and are distributed separately. Table H-1 includes a list of some of these projects. Note that some of these packages might not be released under the same license as PostgreSQL. For more information on each language interface, including licensing terms, refer to its website and documentation.

H.2. Administration Tools

There are several administration tools available for PostgreSQL. The most popular is pgAdmin¹, and there are several commercially available ones as well.

H.3. Procedural Languages

PostgreSQL includes several procedural languages with the base distribution: PL/pgSQL, PL/Tcl, PL/Perl, and PL/Python.

In addition, there are a number of procedural languages that are developed and maintained outside the core PostgreSQL distribution. Table H-2 lists some of these packages. Note that some of these projects might not be released under the same license as PostgreSQL. For more information on each procedural language, including licensing information, refer to its website and documentation.

H.4. Extensions

PostgreSQL is designed to be easily extensible. For this reason, extensions loaded into the database can function just like features that are built in. The contrib/ directory shipped with the source code contains several extensions, which are described in Appendix F. Other extensions are developed independently, like PostGIS². Even PostgreSQL replication solutions can be developed externally. For example, Slony-I³ is a popular master/standby replication solution that is developed independently from the core project.

¹. http://www.pgadmin.org/
². http://postgis.net/
Appendix I. The Source Code Repository

The PostgreSQL source code is stored and managed using the Git version control system. A public mirror of the master repository is available; it is updated within a minute of any change to the master repository.

Our wiki, https://wiki.postgresql.org/wiki/Working_with_Git, has some discussion on working with Git.

Note that building PostgreSQL from the source repository requires reasonably up-to-date versions of bison, flex, and Perl. These tools are not needed to build from a distribution tarball, because the files that these tools are used to build are included in the tarball. Other tool requirements are the same as shown in Section 15.2.

I.1. Getting The Source via Git

With Git you will make a copy of the entire code repository on your local machine, so you will have access to all history and branches offline. This is the fastest and most flexible way to develop or test patches.

**Git**

1. You will need an installed version of Git, which you can get from https://git-scm.com. Many systems already have a recent version of Git installed by default, or available in their package distribution system.

2. To begin using the Git repository, make a clone of the official mirror:

   ```bash
   git clone https://git.postgresql.org/git/postgresql.git
   ```

   This will copy the full repository to your local machine, so it may take a while to complete, especially if you have a slow Internet connection. The files will be placed in a new subdirectory `postgresql` of your current directory.

   The Git mirror can also be reached via the Git protocol. Just change the URL prefix to `git`, as in:

   ```bash
   git clone git://git.postgresql.org/git/postgresql.git
   ```

3. Whenever you want to get the latest updates in the system, `cd` into the repository, and run:

   ```bash
   git fetch
   ```

   Git can do a lot more things than just fetch the source. For more information, consult the Git man pages, or see the website at https://git-scm.com.
Appendix J. Documentation

PostgreSQL has four primary documentation formats:

- Plain text, for pre-installation information
- HTML, for on-line browsing and reference
- PDF or PostScript, for printing
- man pages, for quick reference.

Additionally, a number of plain-text README files can be found throughout the PostgreSQL source tree, documenting various implementation issues.

HTML documentation and man pages are part of a standard distribution and are installed by default. PDF and PostScript format documentation is available separately for download.

J.1. DocBook

The documentation sources are written in DocBook, which is a markup language superficially similar to HTML. Both of these languages are applications of the Standard Generalized Markup Language, SGML, which is essentially a language for describing other languages. In what follows, the terms DocBook and SGML are both used, but technically they are not interchangeable.

DocBook allows an author to specify the structure and content of a technical document without worrying about presentation details. A document style defines how that content is rendered into one of several final forms. DocBook is maintained by the OASIS group. The official DocBook site has good introductory and reference documentation and a complete O’Reilly book for your online reading pleasure. The NewbieDoc Docbook Guide is very helpful for beginners. The FreeBSD Documentation Project also uses DocBook and has some good information, including a number of style guidelines that might be worth considering.

J.2. Tool Sets

The following tools are used to process the documentation. Some might be optional, as noted.

DocBook DTD

This is the definition of DocBook itself. We currently use version 4.2; you cannot use later or earlier versions. You need the SGML variant of the DocBook DTD, but to build man pages you also need the XML variant of the same version.

ISO 8879 character entities

These are required by DocBook but are distributed separately because they are maintained by ISO.

DocBook DSSSL Stylesheets

These contain the processing instructions for converting the DocBook sources to other formats, such as HTML.

DocBook XSL Stylesheets

This is another stylesheet for converting DocBook to other formats. We currently use this to produce man pages and optionally HTMLHelp. You can also use this toolchain to produce HTML or PDF output, but official PostgreSQL releases use the DSSSL stylesheets for that.

The minimum required version is currently 1.74.0.

OpenJade

This is the base package of SGML processing. It contains an SGML parser, a DSSSL processor (that is, a program to convert SGML to other formats using DSSSL stylesheets), as well as a number of related tools. Jade is now being maintained by the OpenJade group, no longer by James Clark.

Libxslt for xsltproc

This is the processing tool to use with the XSLT stylesheets (like jade is the processing tool for DSSSL stylesheets).

JadeTeX

If you want to, you can also install JadeTeX to use TeX as a formatting backend for Jade. JadeTeX can create PostScript or PDF files (the latter with bookmarks).

However, the output from JadeTeX is inferior to what you get from the RTF backend. Particular problem areas are tables and various artifacts of vertical and horizontal spacing. Also, there is no opportunity to manually polish the results.

We have documented experience with several installation methods for the various tools that are needed to process the documentation. These will be described below. There might be some other packaged distributions for these tools. Please report package status to the documentation mailing list, and we will include that information here.

J.2.1. Linux RPM Installation

Most vendors provide a complete RPM set for DocBook processing in their distribution. Look for an “SGML” option while installing, or the following packages: sgml-common, docbook, stylesheets, openjade (or jade). You may also need sgml-tools and either xsltproc or libxslt. If your distributor does not provide these then you should be able to make use of the packages from some other, reasonably compatible vendor.

Appendix J. Documentation

J.2.2. FreeBSD Installation

The FreeBSD Documentation Project is itself a heavy user of DocBook, so it comes as no surprise that there is a full set of “ports” of the documentation tools available on FreeBSD. The following ports need to be installed to build the documentation on FreeBSD.

- textproc/sp
- textproc/openjade
- textproc/iso8879
- textproc/dsssl-docbook-modular
- textproc/docbook-420

A number of things from /usr/ports/print (tex, jadetex) might also be of interest.

It’s possible that the ports do not update the main catalog file in /usr/local/share/sgml/catalog.ports or that the order isn’t proper. Be sure to have the following lines in the beginning of the file:

CATALOG "openjade/catalog"
CATALOG "iso8879/catalog"
CATALOG "docbook/dsssl/modular/catalog"
CATALOG "docbook/4.2/catalog"

If you do not want to edit the file you can also set the environment variable SGML_CATALOG_FILES to a colon-separated list of catalog files (such as the one above).

More information about the FreeBSD documentation tools can be found in the FreeBSD Documentation Project’s instructions\(^\text{12}\).

J.2.3. Debian Packages

There is a full set of packages of the documentation tools available for Debian GNU/Linux. To install, simply use:

```
apt-get install docbook docbook-dsssl docbook-xsl openjade1.3 opensp xsltproc
```

J.2.4. OS X

If you use MacPorts, the following will get you set up:

```
sudo port install docbook-dsssl docbook-sgml-4.2 docbook-xmldoc docbook-xsl libxml2 librext
```

Appendix J. Documentation

J.2.5. Manual Installation from Source

The manual installation process of the DocBook tools is somewhat complex, so if you have pre-built packages available, use them. We describe here only a standard setup, with reasonably standard installation paths, and no “fancy” features. For details, you should study the documentation of the respective package, and read SGML introductory material.

J.2.5.1. Installing OpenJade

1. The installation of OpenJade offers a GNU-style 
   
   ./configure; make; make install build
   
   process. Details can be found in the OpenJade source distribution. In a nutshell:

   ./configure --enable-default-catalog=/usr/local/share/sgml/catalog
   make
   make install

   Be sure to remember where you put the “default catalog”; you will need it below. You can also leave it off, but then you will have to set the environment variable

   SGML_CATALOG_FILES

   to point to the file whenever you use jade later on. (This method is also an option if OpenJade is already installed and you want to install the rest of the toolchain locally.)

   Note: Some users have reported encountering a segmentation fault using OpenJade 1.4dev to build the PDFs, with a message like:

   openjade:./stylesheet.dsl:664:2:E: flow object not accepted by port; only display flow obj
   Downgrading to OpenJade 1.3 should get rid of this error.

2. Additionally, you should install the files dsssl.dtd, fot.dtd, style-sheet.dtd, and catalog from the dsssl directory somewhere, perhaps into /usr/local/share/sgml/dsssl. It’s probably easiest to copy the entire directory:

   cp -R dsssl /usr/local/share/sgml

3. Finally, create the file /usr/local/share/sgml/catalog and add this line to it:

   CATALOG "dsssl/catalog"

   (This is a relative path reference to the file installed in step 2. Be sure to adjust it if you chose your installation layout differently.)

J.2.5.2. Installing the DocBook DTD Kit

1. Obtain the DocBook V4.2 distribution.13

2. Create the directory /usr/local/share/sgml/docbook-4.2 and change to it. (The exact location is irrelevant, but this one is reasonable within the layout we are following here.)

   $ mkdir /usr/local/share/sgml/docbook-4.2
   $ cd /usr/local/share/sgml/docbook-4.2

3. Unpack the archive:

   $ unzip -a ...../docbook-4.2.zip

   (The archive will unpack its files into the current directory.)

Appendix J. Documentation

4. Edit the file /usr/local/share/sgml/catalog (or whatever you told jade during installation) and put a line like this into it:

```
CATALOG "docbook-4.2/docbook.cat"
```

5. Download the ISO 8879 character entities archive\footnote{http://www.oasis-open.org/cover/ISOEnts.zip}, unpack it, and put the files in the same directory you put the DocBook files in:

```
$ cd /usr/local/share/sgml/docbook-4.2
$ unzip ...../ISOEnts.zip
```

6. Run the following command in the directory with the DocBook and ISO files:

```
perl -pi -e 's/iso-(.*).gml/ISO\1/g' docbook.cat
```

(This fixes a mixup between the names used in the DocBook catalog file and the actual names of the ISO character entity files.)

### J.2.5.3. Installing the DocBook DSSSL Style Sheets

To install the style sheets, unzip and untar the distribution and move it to a suitable place, for example /usr/local/share/sgml. (The archive will automatically create a subdirectory.)

```
$ gunzip docbook-dsssl-1.xx.tar.gz
$ tar -C /usr/local/share/sgml -xf docbook-dsssl-1.xx.tar
```

The usual catalog entry in /usr/local/share/sgml/catalog can also be made:

\[
\text{CATALOG "docbook-dsssl-1.xx/catalog"}
\]

Because stylesheets change rather often, and it’s sometimes beneficial to try out alternative versions, PostgreSQL doesn’t use this catalog entry. See Section J.2.6 for information about how to select the stylesheets instead.

### J.2.5.4. Installing JadeTeX

To install and use JadeTeX, you will need a working installation of TeX and LaTeX2e, including the supported tools and graphics packages, Babel, AMS fonts and AMS-LaTeX, the PSNFSS extension and companion kit of “the 35 fonts”, the dvips program for generating PostScript, the macro packages fancyhdr, hyperref, minitoc, url and ot2enc. All of these can be found on your friendly neighborhood CTAN site\footnote{http://www.ctan.org}. The installation of the TeX base system is far beyond the scope of this introduction. Binary packages should be available for any system that can run TeX.

Before you can use JadeTeX with the PostgreSQL documentation sources, you will need to increase the size of TeX’s internal data structures. Details on this can be found in the JadeTeX installation instructions.

Once that is finished you can install JadeTeX:

```
$ gunzip jadetex-xxx.tar.gz
$ tar xf jadetex-xxx.tar
$ cd jadetex
$ make install
$ mktexlsr
```

The last two need to be done as root.

**J.2.6. Detection by `configure`**

Before you can build the documentation you need to run the `configure` script as you would when building the PostgreSQL programs themselves. Check the output near the end of the run, it should look something like this:

- checking for onsgmls... onsgmls
- checking for openjade... openjade
- checking for DocBook V4.2... yes
- checking for DocBook stylesheets... /usr/share/sgml/docbook/stylesheet/dsssl/modular
- checking for collateindex.pl... /usr/bin/collateindex.pl
- checking for xsltproc... xsltproc
- checking for osx... osx

If neither onsgmls nor nsgmls were found then some of the following tests will be skipped. `nsgmls` is part of the Jade package. You can pass the environment variables `JADE` and `NSGMLS` to `configure` to point to the programs if they are not found automatically. If “DocBook V4.2” was not found then you did not install the DocBook DTD kit in a place where Jade can find it, or you have not set up the catalog files correctly. See the installation hints above. The DocBook stylesheets are looked for in a number of relatively standard places, but if you have them some other place then you should set the environment variable `DOCBOOKSTYLE` to the location and rerun `configure` afterwards.

**J.3. Building The Documentation**

Once you have everything set up, change to the directory `doc/src/sgml` and run one of the commands described in the following subsections to build the documentation. (Remember to use GNU `make`).

**J.3.1. HTML**

To build the HTML version of the documentation:

```
doc/src/sgml$ make html
```

This is also the default target. The output appears in the subdirectory `html`.

To create a proper index, the build might process several identical stages. If you do not care about the index, and just want to proof-read the output, use `draft`:

```
doc/src/sgml$ make draft
```

To build the documentation as a single HTML page, use:

```
doc/src/sgml$ make postgres.html
```
J.3.2. Manpages

We use the DocBook XSL stylesheets to convert DocBook refentry pages to *roff output suitable for man pages. The man pages are also distributed as a tar archive, similar to the HTML version. To create the man pages, use the commands:

```
cd doc/src/sgml
make man
```

J.3.3. Print Output via JadeTeX

If you want to use JadeTeX to produce a printable rendition of the documentation, you can use one of the following commands:

- To generate PostScript via DVI in A4 format:
  
  `doc/src/sgml$ make postgres-A4.ps`
  
  In U.S. letter format:
  
  `doc/src/sgml$ make postgres-US.ps`

- To make a PDF:
  
  `doc/src/sgml$ make postgres-A4.pdf`
  
  or:
  
  `doc/src/sgml$ make postgres-US.pdf`

(Of course you can also make a PDF version from the PostScript, but if you generate PDF directly, it will have hyperlinks and other enhanced features.)

When using JadeTeX to build the PostgreSQL documentation, you will probably need to increase some of TeX’s internal parameters. These can be set in the file `texmf.cnf`. The following settings worked at the time of this writing:

```
hash_extra.jadetex = 200000
hash_extra.pdfjadetex = 200000
pool_size.jadetex = 2000000
pool_size.pdfjadetex = 2000000
string_vacancies.jadetex = 150000
string_vacancies.pdfjadetex = 150000
max_strings.jadetex = 300000
max_strings.pdfjadetex = 300000
save_size.jadetex = 15000
save_size.pdfjadetex = 15000
```

J.3.4. Overflow Text

Occasionally text is too wide for the printed margins, and in extreme cases, too wide for the printed page, e.g. non-wrapped text, wide tables. Overly wide text generates “Overfull hbox” messages in the TeX log output file, e.g. `postgres-US.log` or `postgres-A4.log`. There are 72 points in an inch.
so anything reported as over 72 points too wide will probably not fit on the printed page (assuming one inch margins). To find the SGML text causing the overflow, find the first page number mentioned above the overflow message, e.g. [50 ###] (page 50), and look at the page after that (e.g. page 51) in the PDF file to see the overflow text and adjust the SGML accordingly.

J.3.5. Print Output via RTF

You can also create a printable version of the PostgreSQL documentation by converting it to RTF and applying minor formatting corrections using an office suite. Depending on the capabilities of the particular office suite, you can then convert the documentation to PostScript or PDF. The procedure below illustrates this process using Applixware.

Note: It appears that current versions of the PostgreSQL documentation trigger some bug in or exceed the size limit of OpenJade. If the build process of the RTF version hangs for a long time and the output file still has size 0, then you might have hit that problem. (But keep in mind that a normal build takes 5 to 10 minutes, so don’t abort too soon.)

Applixware RTF Cleanup

OpenJade omits specifying a default style for body text. In the past, this undiagnosed problem led to a long process of table of contents generation. However, with great help from the Applixware folks the symptom was diagnosed and a workaround is available.

1. Generate the RTF version by typing:
   ```
doc/src/sgml$ make postgres.rtf
   ```

2. Repair the RTF file to correctly specify all styles, in particular the default style. If the document contains refentry sections, one must also replace formatting hints which tie a preceding paragraph to the current paragraph, and instead tie the current paragraph to the following one. A utility, fixrtf, is available in doc/src/sgml to accomplish these repairs:
   ```
doc/src/sgml$ ./fixrtf --refentry postgres.rtf
   ```
   The script adds \s0 Normal; as the zeroth style in the document. According to Applixware, the RTF standard would prohibit adding an implicit zeroth style, though Microsoft Word happens to handle this case. For repairing refentry sections, the script replaces \keepn tags with \keep.

3. Open a new document in Applixware Words and then import the RTF file.

4. Generate a new table of contents (ToC) using Applixware.
   a. Select the existing ToC lines, from the beginning of the first character on the first line to the last character of the last line.
   b. Build a new ToC using Tools → Book Building → Create Table of Contents. Select the first three levels of headers for inclusion in the ToC. This will replace the existing lines imported in the RTF with a native Applixware ToC.
   c. Adjust the ToC formatting by using Format → Style, selecting each of the three ToC styles, and adjusting the indents for First and Left. Use the following values:

<table>
<thead>
<tr>
<th>Style</th>
<th>First Indent (inches)</th>
<th>Left Indent (inches)</th>
</tr>
</thead>
<tbody>
<tr>
<td>TOC-Heading 1</td>
<td>0.4</td>
<td>0.4</td>
</tr>
</tbody>
</table>

2352
Appendix J. Documentation

<table>
<thead>
<tr>
<th>Style</th>
<th>First Indent (inches)</th>
<th>Left Indent (inches)</th>
</tr>
</thead>
<tbody>
<tr>
<td>TOC-Heading 2</td>
<td>0.8</td>
<td>0.8</td>
</tr>
<tr>
<td>TOC-Heading 3</td>
<td>1.2</td>
<td>1.2</td>
</tr>
</tbody>
</table>

5. Work through the document to:
   - Adjust page breaks.
   - Adjust table column widths.

6. Replace the right-justified page numbers in the Examples and Figures portions of the ToC with correct values. This only takes a few minutes.

7. Delete the index section from the document if it is empty.

8. Regenerate and adjust the table of contents.
   a. Select the ToC field.
   b. Select Tools → Book Building → Create Table of Contents.
   c. Unbind the ToC by selecting Tools → Field Editing → Unprotect.
   d. Delete the first line in the ToC, which is an entry for the ToC itself.

9. Save the document as native Applixware Words format to allow easier last minute editing later.

10. “Print” the document to a file in PostScript format.

J.3.6. Plain Text Files

The installation instructions are also distributed as plain text, in case they are needed in a situation where better reading tools are not available. The INSTALL file corresponds to Chapter 15, with some minor changes to account for the different context. To recreate the file, change to the directory doc/src/sgml and enter make INSTALL.

In the past, the release notes and regression testing instructions were also distributed as plain text, but this practice has been discontinued.

J.3.7. Syntax Check

Building the documentation can take very long. But there is a method to just check the correct syntax of the documentation files, which only takes a few seconds:

doc/src/sgml$ make check
J.4. Documentation Authoring

SGML and DocBook do not suffer from an oversupply of open-source authoring tools. The most common tool set is the Emacs/XEmacs editor with appropriate editing mode. On some systems these tools are provided in a typical full installation.

J.4.1. Emacs/PSGML

PSGML is the most common and most powerful mode for editing SGML documents. When properly configured, it will allow you to use Emacs to insert tags and check markup consistency. You could use it for HTML as well. Check the PSGML web site for downloads, installation instructions, and detailed documentation.

There is one important thing to note with PSGML: its author assumed that your main SGML DTD directory would be /usr/local/lib/sgml. If, as in the examples in this chapter, you use /usr/local/share/sgml, you have to compensate for this, either by setting SGML_CATALOG_FILES environment variable, or you can customize your PSGML installation (its manual tells you how).

Put the following in your ~/.emacs environment file (adjusting the path names to be appropriate for your system):

```
; ********** for SGML mode (psgml)
(setq sgml-omittag t)
(setq sgml-shorttag t)
(setq sgml-minimize-attributes nil)
(setq sgml-always-quote-attributes t)
(setq sgml-indent-step 1)
(setq sgml-indent-data t)
(setq sgml-parent-document nil)
(setq sgml-exposed-tags nil)
(setq sgml-catalog-files ‘("/usr/local/share/sgml/catalog")

(autoload ‘sgml-mode "psgml" "Major mode to edit SGML files." t )
```

and in the same file add an entry for SGML into the (existing) definition for auto-mode-alist:

```
(setq
  auto-mode-alist
  ’(("\.sgml$" . sgml-mode)
))
```

You might find that when using PSGML, a comfortable way of working with these separate files of book parts is to insert a proper DOCTYPE declaration while you’re editing them. If you are working on this source, for instance, it is an appendix chapter, so you would specify the document as an “appendix” instance of a DocBook document by making the first line look like this:

```
<!DOCTYPE appendix PUBLIC "-/OASIS//DTD DocBook V4.2//EN">
```

This means that anything and everything that reads SGML will get it right, and I can verify the document with nsgmls -s docguide.sgml. (But you need to take out that line before building the entire documentation set.)

J.4.2. Other Emacs Modes

GNU Emacs ships with a different SGML mode, which is not quite as powerful as PSGML, but it’s less confusing and lighter weight. Also, it offers syntax highlighting (font lock), which can be very helpful. src/tools/editors/emacs.samples contains sample settings for this mode.

Norm Walsh offers a major mode specifically for DocBook which also has font-lock and a number of features to reduce typing.

J.5. Style Guide

J.5.1. Reference Pages

Reference pages should follow a standard layout. This allows users to find the desired information more quickly, and it also encourages writers to document all relevant aspects of a command. Consistency is not only desired among PostgreSQL reference pages, but also with reference pages provided by the operating system and other packages. Hence the following guidelines have been developed. They are for the most part consistent with similar guidelines established by various operating systems.

Reference pages that describe executable commands should contain the following sections, in this order. Sections that do not apply can be omitted. Additional top-level sections should only be used in special circumstances; often that information belongs in the “Usage” section.

Name

This section is generated automatically. It contains the command name and a half-sentence summary of its functionality.

Synopsis

This section contains the syntax diagram of the command. The synopsis should normally not list each command-line option; that is done below. Instead, list the major components of the command line, such as where input and output files go.

Description

Several paragraphs explaining what the command does.

Options

A list describing each command-line option. If there are a lot of options, subsections can be used.

Exit Status

If the program uses 0 for success and non-zero for failure, then you do not need to document it. If there is a meaning behind the different non-zero exit codes, list them here.

Usage

Describe any sublanguage or run-time interface of the program. If the program is not interactive, this section can usually be omitted. Otherwise, this section is a catch-all for describing run-time features. Use subsections if appropriate.

Appendix J. Documentation

Environment

List all environment variables that the program might use. Try to be complete; even seemingly
trivial variables like SHELL might be of interest to the user.

Files

List any files that the program might access implicitly. That is, do not list input and output files
that were specified on the command line, but list configuration files, etc.

Diagnostics

Explain any unusual output that the program might create. Refrain from listing every possible
error message. This is a lot of work and has little use in practice. But if, say, the error messages
have a standard format that the user can parse, this would be the place to explain it.

Notes

Anything that doesn’t fit elsewhere, but in particular bugs, implementation flaws, security con-
considerations, compatibility issues.

Examples

Examples

History

If there were some major milestones in the history of the program, they might be listed here.
Usually, this section can be omitted.

Author

Author (only used in the contrib section)

See Also

Cross-references, listed in the following order: other PostgreSQL command reference pages,
PostgreSQL SQL command reference pages, citation of PostgreSQL manuals, other reference
pages (e.g., operating system, other packages), other documentation. Items in the same group
are listed alphabetically.

Reference pages describing SQL commands should contain the following sections: Name, Synopsis,
Description, Parameters, Outputs, Notes, Examples, Compatibility, History, See Also. The Parameters
section is like the Options section, but there is more freedom about which clauses of the command can
be listed. The Outputs section is only needed if the command returns something other than a default
command-completion tag. The Compatibility section should explain to what extent this command
conforms to the SQL standard(s), or to which other database system it is compatible. The See Also
section of SQL commands should list SQL commands before cross-references to programs.
Appendix K. Acronyms

This is a list of acronyms commonly used in the PostgreSQL documentation and in discussions about PostgreSQL.

Bibliography

Selected references and readings for SQL and PostgreSQL.
Some white papers and technical reports from the original POSTGRES development team are available at the University of California, Berkeley, Computer Science Department web site\(^1\).

**SQL Reference Books**

**PostgreSQL-specific Documentation**

Discusses SQL history and syntax, and describes the addition of `INTERSECT` and `EXCEPT` constructs into PostgreSQL. Prepared as a Master’s Thesis with the support of O. Univ. Prof. Dr. Georg Gottlob and Univ. Ass. Mag. Katrin Seyr at Vienna University of Technology.

Zelaine Fong. *The design and implementation of the POSTGRES query optimizer*\(^2\), University of California, Berkeley, Computer Science Department.
