  - n = nothing  
  - f = all columns  
  - i = index with indisreplident set, or default |
| relfrozenxid  | xid    |            | All transaction IDs before this one have been replaced with a permanent (“frozen”) transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to prevent transaction ID wraparound or to allow pg_clog to be shrunk.  
  - Zero (InvalidTransactionId) if the relation is not a table.  
  - 1916 (InvalidTransactionId) if the relation is not a table. |
Chapter 48. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>relminmxid</td>
<td>xid</td>
<td></td>
<td>All multixact IDs before this one have been replaced by a transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to prevent multixact ID wraparound or to allow pg_multixact to be shrunk. Zero (InvalidMultiXactId) if the relation is not a table.</td>
</tr>
<tr>
<td>relacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
<tr>
<td>reloptions</td>
<td>text[]</td>
<td></td>
<td>Access-method-specific options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

Several of the Boolean flags in pg_class are maintained lazily: they are guaranteed to be true if that’s the correct state, but may not be reset to false immediately when the condition is no longer true. For example, relhasindex is set by CREATE INDEX, but it is never cleared by DROP INDEX. Instead, VACUUM clears relhasindex if it finds the table has no indexes. This arrangement avoids race conditions and improves concurrency.

### 48.12. pg_collation

The catalog pg_collation describes the available collations, which are essentially mappings from an SQL name to operating system locale categories. See Section 22.2 for more information.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>collname</td>
<td>name</td>
<td></td>
<td>Collation name (unique per namespace and encoding)</td>
</tr>
</tbody>
</table>
Chapter 48. System Catalogs

### Table 48-12. System Catalog Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>collnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this collation</td>
</tr>
<tr>
<td>collowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the collation</td>
</tr>
<tr>
<td>collencoding</td>
<td>int4</td>
<td></td>
<td>Encoding in which the collation is applicable, or -1 if it works for any encoding</td>
</tr>
<tr>
<td>collcollate</td>
<td>name</td>
<td></td>
<td>LC_COLLATE for this collation object</td>
</tr>
<tr>
<td>collctype</td>
<td>name</td>
<td></td>
<td>LC_CTYPE for this collation object</td>
</tr>
</tbody>
</table>

Note that the unique key on this catalog is (collname, collencoding, collnamespace) not just (collname, collnamespace). PostgreSQL generally ignores all collations that do not have collencoding equal to either the current database’s encoding or -1, and creation of new entries with the same name as an entry with collencoding = -1 is forbidden. Therefore it is sufficient to use a qualified SQL name (schema.name) to identify a collation, even though this is not unique according to the catalog definition. The reason for defining the catalog this way is that initdb fills it in at cluster initialization time with entries for all locales available on the system, so it must be able to hold entries for all encodings that might ever be used in the cluster.

In the template0 database, it could be useful to create collations whose encoding does not match the database encoding, since they could match the encodings of databases later cloned from template0. This would currently have to be done manually.

### 48.13. pg_constraint

The catalog pg_constraint stores check, primary key, unique, foreign key, and exclusion constraints on tables. (Column constraints are not treated specially. Every column constraint is equivalent to some table constraint.) Not-null constraints are represented in the pg_attribute catalog, not here.

User-defined constraint triggers (created with CREATE CONSTRAINT TRIGGER) also give rise to an entry in this table.

Check constraints on domains are stored here, too.

<td>If a foreign key, list of the equality operators for FK = FK comparisons</td>
</tr>
<tr>
<td>conexclop</td>
<td>oid[]</td>
<td>pg_operator.oid</td>
<td>If an exclusion constraint, list of the per-column exclusion operators</td>
</tr>
</tbody>
</table>
### Chapter 48. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>conbin</td>
<td>pg_node_tree</td>
<td></td>
<td>If a check constraint, an internal representation of the expression</td>
</tr>
<tr>
<td>consrc</td>
<td>text</td>
<td></td>
<td>If a check constraint, a human-readable representation of the expression</td>
</tr>
</tbody>
</table>

In the case of an exclusion constraint, conkey is only useful for constraint elements that are simple column references. For other cases, a zero appears in conkey and the associated index must be consulted to discover the expression that is constrained. (conkey thus has the same contents as pg_index.indkey for the index.)

**Note**: consrc is not updated when referenced objects change; for example, it won’t track renaming of columns. Rather than relying on this field, it’s best to use pg_get_constraintdef() to extract the definition of a check constraint.

**Note**: pg_class.relchecks needs to agree with the number of check-constraint entries found in this table for each relation.

#### 48.14. pg_conversion

The catalog pg_conversion describes encoding conversion procedures. See CREATE CONVERSION for more information.

**Table 48-14. pg_conversion Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>

<td>Owner of the conversion</td>
</tr>
<tr>
<td>conforencoding</td>
<td>int4</td>
<td></td>
<td>Source encoding ID</td>
</tr>
</tbody>
</table>
48.15. pg_database

The catalog `pg_database` stores information about the available databases. Databases are created with the CREATE DATABASE command. Consult Chapter 21 for details about the meaning of some of the parameters.

Unlike most system catalogs, `pg_database` is shared across all databases of a cluster: there is only one copy of `pg_database` per cluster, not one per database.

Table 48-15. pg_database Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>datconnlimit</td>
<td>int4</td>
<td></td>
<td>Sets maximum number of concurrent connections that can be made to this database. -1 means no limit.</td>
</tr>
<tr>
<td>datlastsysoid</td>
<td>oid</td>
<td></td>
<td>Last system OID in the database; useful particularly to pg_dump</td>
</tr>
<tr>
<td>datfrozenxid</td>
<td>xid</td>
<td></td>
<td>All transaction IDs before this one have been replaced with a permanent (“frozen”) transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent transaction ID wraparound or to allow pg_clog to be shrunk. It is the minimum of the per-table pg_class.relfrozenxid values.</td>
</tr>
</tbody>
</table>
### 48.16. *pg_db_role_setting*

The catalog *pg_db_role_setting* records the default values that have been set for run-time configuration variables, for each role and database combination.

Unlike most system catalogs, *pg_db_role_setting* is shared across all databases of a cluster: there is only one copy of *pg_db_role_setting* per cluster, not one per database.

**Table 48-16. *pg_db_role_setting* Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>datminmxid</td>
<td>xid</td>
<td></td>
<td>All multixact IDs before this one have been replaced with a transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent multixact ID wraparound or to allow <em>pg_multixact</em> to be shrunk. It is the minimum of the per-table <em>pg_class.relminmxid</em> values.</td>
</tr>
<tr>
<td>datatablespace</td>
<td>oid</td>
<td><em>pg_tablespace.oid</em></td>
<td>The default tablespace for the database. Within this database, all tables for which <em>pg_class.reltablespace</em> is zero will be stored in this tablespace; in particular, all the non-shared system catalogs will be there.</td>
</tr>
<tr>

<td>pg_authid.oid</td>
<td>The OID of the role the setting is applicable to, or zero if not role-specific</td>
</tr>
<tr>
<td>setconfig</td>
<td>text[]</td>
<td></td>
<td>Defaults for run-time configuration variables</td>
</tr>
</tbody>
</table>

#### 48.17. pg_default_acl

The catalog `pg_default_acl` stores initial privileges to be assigned to newly created objects.

**Table 48-17. pg_default_acl Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>defaclrole</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>The OID of the role associated with this entry</td>
</tr>
<tr>
<td>defaclnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace associated with this entry, or 0 if none</td>
</tr>
<tr>
<td>defaclobjtype</td>
<td>char</td>
<td></td>
<td>Type of object this entry is for: r = relation (table, view), S = sequence, f = function, T = type</td>
</tr>
<tr>
<td>defaclacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges that this type of object should have on creation</td>
</tr>
</tbody>
</table>

A `pg_default_acl` entry shows the initial privileges to be assigned to an object belonging to the indicated user. There are currently two types of entry: “global” entries with `defaclnamespace` = 0, and “per-schema” entries that reference a particular schema. If a global entry is present then it overrides the normal hard-wired default privileges for the object type. A per-schema entry, if present, represents privileges to be added to the global or hard-wired default privileges.

Note that when an ACL entry in another catalog is null, it is taken to represent the hard-wired default
privileges for its object, *not* whatever might be in `pg_default_acl` at the moment. `pg_default_acl` is only consulted during object creation.

### 48.18. `pg_depend`

The catalog `pg_depend` records the dependency relationships between database objects. This information allows `DROP` commands to find which other objects must be dropped by `DROP CASCADE` or prevent dropping in the `DROP RESTRICT` case.

See also `pg_shdepend`, which performs a similar function for dependencies involving objects that are shared across a database cluster.

**Table 48-18. `pg_depend` Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>classid</td>
<td>oid</td>
<td><code>pg_class.oid</code></td>
<td>The OID of the system catalog the dependent object is in</td>
</tr>
<tr>
<td>objid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the specific dependent object</td>
</tr>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a table column, this is the column number (the <code>objid</code> and <code>classid</code> refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>refclassid</td>
<td>oid</td>
<td><code>pg_class.oid</code></td>
<td>The OID of the system catalog the referenced object is in</td>
</tr>
<tr>
<td>refobjid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the specific referenced object</td>
</tr>
<tr>
<td>refobjsubid</td>
<td>int4</td>
<td></td>
<td>For a table column, this is the column number (the <code>refobjid</code> and <code>refclassid</code> refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>deptype</td>
<td>char</td>
<td></td>
<td>A code defining the specific semantics of this dependency relationship; see text</td>
</tr>
</tbody>
</table>

In all cases, a `pg_depend` entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype:`
Chapter 48. System Catalogs

DEPENDECY_NORMAL (n)
A normal relationship between separately-created objects. The dependent object can be dropped without affecting the referenced object. The referenced object can only be dropped by specifying CASCADE, in which case the dependent object is dropped, too. Example: a table column has a normal dependency on its data type.

DEPENDECY_AUTO (a)
The dependent object can be dropped separately from the referenced object, and should be automatically dropped (regardless of RESTRICT or CASCADE mode) if the referenced object is dropped. Example: a named constraint on a table is made autodependent on the table, so that it will go away if the table is dropped.

DEPENDECY_INTERNAL (i)
The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation. A DROP of the dependent object will be disallowed outright (we’ll tell the user to issue a DROP against the referenced object, instead). A DROP of the referenced object will be propagated through to drop the dependent object whether CASCADE is specified or not. Example: a trigger that’s created to enforce a foreign-key constraint is made internally dependent on the constraint’s pg_constraint entry.

DEPENDECY_EXTENSION (e)
The dependent object is a member of the extension that is the referenced object (see pg_extension). The dependent object can be dropped only via DROP EXTENSION on the referenced object. Functionally this dependency type acts the same as an internal dependency, but it’s kept separate for clarity and to simplify pg_dump.

DEPENDECY_PIN (p)
There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by initdb. The columns for the dependent object contain zeroes.

Other dependency flavors might be needed in future.

48.19. pg_description

The catalog pg_description stores optional descriptions (comments) for each database object. Descriptions can be manipulated with the COMMENT command and viewed with psql’s \d commands. Descriptions of many built-in system objects are provided in the initial contents of pg_description.

See also pg_shdescription, which performs a similar function for descriptions involving objects that are shared across a database cluster.

Table 48-19. pg_description Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this description pertains to</td>
</tr>
</tbody>
</table>
Chapter 48. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>classoid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a comment on a table column, this is the column number (the objoid and classoid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>description</td>
<td>text</td>
<td></td>
<td>Arbitrary text that serves as the description of this object</td>
</tr>
</tbody>
</table>

48.20. pg_enum

The pg_enum catalog contains entries showing the values and labels for each enum type. The internal representation of a given enum value is actually the OID of its associated row in pg_enum.

Table 48-20. pg_enum Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>enumtypid</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>The OID of the pg_type entry owning this enum value</td>
</tr>
<tr>
<td>enumsortorder</td>
<td>float4</td>
<td></td>
<td>The sort position of this enum value within its enum type</td>
</tr>
<tr>
<td>enumlabel</td>
<td>name</td>
<td></td>
<td>The textual label for this enum value</td>
</tr>
</tbody>
</table>

The OIDs for pg_enum rows follow a special rule: even-numbered OIDs are guaranteed to be ordered in the same way as the sort ordering of their enum type. That is, if two even OIDs belong to the same enum type, the smaller OID must have the smaller enumsortorder value. Odd-numbered OID values need bear no relationship to the sort order. This rule allows the enum comparison routines to avoid catalog lookups in many common cases. The routines that create and alter enum types attempt to assign even OIDs to enum values whenever possible.

When an enum type is created, its members are assigned sort-order positions 1..n. But members added later might be given negative or fractional values of enumsortorder. The only requirement on these
values is that they be correctly ordered and unique within each enum type.

### 48.21. pg_event_trigger

The catalog `pg_event_trigger` stores event triggers. See Chapter 37 for more information.

#### Table 48-21. pg_event_trigger Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>evtname</td>
<td>name</td>
<td></td>
<td>Trigger name (must be unique)</td>
</tr>
<tr>
<td>evtevent</td>
<td>name</td>
<td></td>
<td>Identifies the event for which this trigger fires</td>
</tr>
<tr>
<td>evtowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the event trigger</td>
</tr>
<tr>
<td>evtfoid</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>The function to be called</td>
</tr>
<tr>
<td>evtenabled</td>
<td>char</td>
<td></td>
<td>Controls in which session_replication_role modes the event trigger fires. O = trigger fires in “origin” and “local” modes, D = trigger is disabled, R = trigger fires in “replica” mode, A = trigger fires always.</td>
</tr>
<tr>
<td>evttags</td>
<td>text[]</td>
<td></td>
<td>Command tags for which this trigger will fire. If NULL, the firing of this trigger is not restricted on the basis of the command tag.</td>
</tr>
</tbody>
</table>

### 48.22. pg_extension

The catalog `pg_extension` stores information about the installed extensions. See Section 35.15 for details about extensions.

#### Table 48-22. pg_extension Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
</table>

1929
Chapter 48. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>extname</td>
<td>name</td>
<td></td>
<td>Name of the extension</td>
</tr>
<tr>
<td>extowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the extension</td>
</tr>
<tr>
<td>extnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>Schema containing the extension’s exported objects</td>
</tr>
<tr>
<td>extrelocatable</td>
<td>bool</td>
<td></td>
<td>True if extension can be relocated to another schema</td>
</tr>
<tr>
<td>extversion</td>
<td>text</td>
<td></td>
<td>Version name for the extension</td>
</tr>
<tr>
<td>extconfig</td>
<td>oid[]</td>
<td>pg_class.oid</td>
<td>Array of regclass OIDs for the extension’s configuration table(s), or NULL if none</td>
</tr>
<tr>
<td>extcondition</td>
<td>text[]</td>
<td></td>
<td>Array of WHERE-clause filter conditions for the extension’s configuration table(s), or NULL if none</td>
</tr>
</tbody>
</table>

Note that unlike most catalogs with a “namespace” column, extnamespace is not meant to imply that the extension belongs to that schema. Extension names are never schema-qualified. Rather, extnamespace indicates the schema that contains most or all of the extension’s objects. If extrelocatable is true, then this schema must in fact contain all schema-qualifiable objects belonging to the extension.

48.23. `pg_foreign_data_wrapper`

The catalog `pg_foreign_data_wrapper` stores foreign-data wrapper definitions. A foreign-data wrapper is the mechanism by which external data, residing on foreign servers, is accessed.

Table 48-23. `pg_foreign_data_wrapper` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>

<td>Foreign server specific options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

48.25. pg_foreign_table

The catalog pg_foreign_table contains auxiliary information about foreign tables. A foreign table is primarily represented by a pg_class entry, just like a regular table. Its pg_foreign_table entry contains the information that is pertinent only to foreign tables and not any other kind of relation.

Table 48-25. pg_foreign_table Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ftrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>OID of the pg_class entry for this foreign table</td>

<td>OID of the foreign server for this foreign table</td>
</tr>
<tr>
<td>ftoptions</td>
<td>text[]</td>
<td></td>
<td>Foreign table options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

48.26. pg_index

The catalog pg_index contains part of the information about indexes. The rest is mostly in pg_class.

Table 48-26. pg_index Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>

</tr>
</tbody>
</table>

#### 48.28. `pg_language`

The catalog `pg_language` registers languages in which you can write functions or stored procedures. See `CREATE LANGUAGE` and Chapter 39 for more information about language handlers.

**Table 48-28. `pg_language` Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lanpltrusted</td>
<td>bool</td>
<td></td>
<td>True if this is a trusted language, which means that it is believed not to grant access to anything outside the normal SQL execution environment. Only superusers can create functions in untrusted languages.</td>
</tr>
<tr>
<td>lanplcallfoid</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>For noninternal languages this references the language handler, which is a special function that is responsible for executing all functions that are written in the particular language.</td>
</tr>
<tr>
<td>laninline</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>This references a function that is responsible for executing “inline” anonymous code blocks (DO blocks). Zero if inline blocks are not supported.</td>
</tr>
<tr>
<td>lanvalidator</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>This references a language validator function that is responsible for checking the syntax and validity of new functions when they are created. Zero if no validator is provided.</td>
</tr>
<tr>
<td>lanacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details.</td>
</tr>
</tbody>
</table>

#### 48.29. pg_largeobject

The catalog pg_largeobject holds the data making up “large objects”. A large object is identified by an OID assigned when it is created. Each large object is broken into segments or “pages” small enough to be conveniently stored as rows in pg_largeobject. The amount of data per page is defined to be 1937 bytes.
LOBLKSIZE (which is currently BLCKSZ/4, or typically 2 kB).

Prior to PostgreSQL 9.0, there was no permission structure associated with large objects. As a result, `pg_largeobject` was publicly readable and could be used to obtain the OIDs (and contents) of all large objects in the system. This is no longer the case; use `pg_largeobject_metadata` to obtain a list of large object OIDs.

Table 48-29. pg_largeobject Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>loid</td>
<td>oid</td>
<td>pg_largeobject_metadata.oid</td>
<td>Identifier of the large object that includes this page</td>
</tr>
<tr>
<td>pageno</td>
<td>int4</td>
<td></td>
<td>Page number of this page within its large object (counting from zero)</td>
</tr>
<tr>
<td>data</td>
<td>bytea</td>
<td></td>
<td>Actual data stored in the large object. This will never be more than LOBLKSIZE bytes and might be less.</td>
</tr>
</tbody>
</table>

Each row of `pg_largeobject` holds data for one page of a large object, beginning at byte offset (`pageno * LOBLKSIZE`) within the object. The implementation allows sparse storage: pages might be missing, and might be shorter than LOBLKSIZE bytes even if they are not the last page of the object. Missing regions within a large object read as zeroes.

48.30. pg_largeobject_metadata

The catalog `pg_largeobject_metadata` holds metadata associated with large objects. The actual large object data is stored in `pg_largeobject`.

Table 48-30. pg_largeobject_metadata Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>lomowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the large object</td>
</tr>
<tr>
<td>lomacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
</tbody>
</table>
48.31. pg_namespace

The catalog `pg_namespace` stores namespaces. A namespace is the structure underlying SQL schemas: each namespace can have a separate collection of relations, types, etc. without name conflicts.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>nspname</td>
<td>name</td>
<td></td>
<td>Name of the namespace</td>
</tr>
<tr>
<td>nspowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the namespace</td>
</tr>
<tr>
<td>nspacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
</tbody>
</table>

48.32. pg_opclass

The catalog `pg_opclass` defines index access method operator classes. Each operator class defines semantics for index columns of a particular data type and a particular index access method. An operator class essentially specifies that a particular operator family is applicable to a particular indexable column data type. The set of operators from the family that are actually usable with the indexed column are whichever ones accept the column’s data type as their left-hand input.

Operator classes are described at length in Section 35.14.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>opcmethod</td>
<td>oid</td>
<td>pg_am.oid</td>
<td>Index access method operator class is for</td>
</tr>
<tr>
<td>opcname</td>
<td>name</td>
<td></td>
<td>Name of this operator class</td>
</tr>
<tr>
<td>opcnameSpace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>Namespace of this operator class</td>
</tr>
<tr>
<td>opcowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the operator class</td>
</tr>
</tbody>
</table>
### 48.33. pg_operator

The catalog `pg_operator` stores information about operators. See CREATE OPERATOR and Section 35.12 for more information.

#### Table 48-33. pg_operator Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>oprname</td>
<td>name</td>
<td></td>
<td>Name of the operator</td>
</tr>
<tr>
<td>oprnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this operator</td>
</tr>
<tr>
<td>oprowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the operator</td>
</tr>
<tr>
<td>oprkind</td>
<td>char</td>
<td></td>
<td><code>b</code> = infix (“both”), <code>l</code> = prefix (“left”), <code>r</code> = postfix (“right”)</td>
</tr>
<tr>
<td>oprcanmerge</td>
<td>bool</td>
<td></td>
<td>This operator supports merge joins</td>
</tr>
<tr>
<td>oprcanhash</td>
<td>bool</td>
<td></td>
<td>This operator supports hash joins</td>
</tr>
<tr>
<td>oprleft</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Type of the left operand</td>
</tr>
<tr>
<td>oprright</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Type of the right operand</td>
</tr>
</tbody>
</table>

An operator class’s `opcmethod` must match the `opfmethod` of its containing operator family. Also, there must be no more than one `pg_opclass` row having `opcdefault` true for any given combination of `opcmethod` and `opcintype`. 
48.34. pg_opfamily

The catalog pg_opfamily defines operator families. Each operator family is a collection of operators and associated support routines that implement the semantics specified for a particular index access method. Furthermore, the operators in a family are all “compatible”, in a way that is specified by the access method. The operator family concept allows cross-data-type operators to be used with indexes and to be reasoned about using knowledge of access method semantics.

Operator families are described at length in Section 35.14.

Table 48-34. pg_opfamily Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>opfmethod</td>
<td>oid</td>
<td>pg_am.oid</td>
<td>Index access method operator family is for</td>
</tr>
<tr>
<td>opfname</td>
<td>name</td>
<td></td>
<td>Name of this operator family</td>
</tr>
<tr>
<td>opfnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>Namespace of this operator family</td>
</tr>
<tr>
<td>opfowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the operator family</td>
</tr>
</tbody>
</table>

The majority of the information defining an operator family is not in its pg_opfamily row, but in the associated rows in pg_amop, pg_amproc, and pg_opclass.
48.35. pg_pltemplate

The catalog `pg_pltemplate` stores “template” information for procedural languages. A template for a language allows the language to be created in a particular database by a simple `CREATE LANGUAGE` command, with no need to specify implementation details.

Unlike most system catalogs, `pg_pltemplate` is shared across all databases of a cluster: there is only one copy of `pg_pltemplate` per cluster, not one per database. This allows the information to be accessible in each database as it is needed.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tmplname</td>
<td>name</td>
<td>Name of the language this template is for</td>
</tr>
<tr>
<td>tmpltrusted</td>
<td>boolean</td>
<td>True if language is considered trusted</td>
</tr>
<tr>
<td>tmpldbcreate</td>
<td>boolean</td>
<td>True if language may be created by a database owner</td>
</tr>
<tr>
<td>tmplhandler</td>
<td>text</td>
<td>Name of call handler function</td>
</tr>
<tr>
<td>tmplinline</td>
<td>text</td>
<td>Name of anonymous-block handler function, or null if none</td>
</tr>
<tr>
<td>tmplvalidator</td>
<td>text</td>
<td>Name of validator function, or null if none</td>
</tr>
<tr>
<td>tmpllibrary</td>
<td>text</td>
<td>Path of shared library that implements language</td>
</tr>
<tr>
<td>tmplacl</td>
<td>aclitem[]</td>
<td>Access privileges for template (not actually used)</td>
</tr>
</tbody>
</table>

There are not currently any commands that manipulate procedural language templates; to change the built-in information, a superuser must modify the table using ordinary `INSERT`, `DELETE`, or `UPDATE` commands.

**Note:** It is likely that `pg_pltemplate` will be removed in some future release of PostgreSQL, in favor of keeping this knowledge about procedural languages in their respective extension installation scripts.

48.36. pg_proc

The catalog `pg_proc` stores information about functions (or procedures). See `CREATE FUNCTION` and Section 35.3 for more information.

The table contains data for aggregate functions as well as plain functions. If `proisagg` is true, there should be a matching row in `pg_aggregate`. 
### Table 48-36. pg_proc Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>proargtypes</td>
<td>oidvector</td>
<td>pg_type.oid</td>
<td>An array with the data types of the function arguments. This includes only input arguments (including INOUT and VARIADIC arguments), and thus represents the call signature of the function.</td>
</tr>
<tr>
<td>proallargtypes</td>
<td>oid[]</td>
<td>pg_type.oid</td>
<td>An array with the data types of the function arguments. This includes all arguments (including OUT and INOUT arguments); however, if all the arguments are IN arguments, this field will be null. Note that subscripting is 1-based, whereas for historical reasons proargtypes is subscripted from 0.</td>
</tr>
<tr>
<td>proargmodes</td>
<td>char[]</td>
<td></td>
<td>An array with the modes of the function arguments, encoded as i for IN arguments, o for OUT arguments, b for INOUT arguments, v for VARIADIC arguments, t for TABLE arguments. If all the arguments are IN arguments, this field will be null. Note that subscripts correspond to positions of proallargtypes not proargtypes.</td>
</tr>
</tbody>
</table>

1945
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proargnames</td>
<td>text[ ]</td>
<td></td>
<td>An array with the names of the function arguments. Arguments without a name are set to empty strings in the array. If none of the arguments have a name, this field will be null. Note that subscripts correspond to positions of proallargtypes not proargtypes.</td>
</tr>
<tr>
<td>proargdefaults</td>
<td>pg_node_tree</td>
<td></td>
<td>Expression trees (in nodeToString() representation) for default values. This is a list with pronargdefaults elements, corresponding to the last N input arguments (i.e., the last N proargtypes positions). If none of the arguments have defaults, this field will be null.</td>
</tr>
<tr>
<td>prosrc</td>
<td>text</td>
<td></td>
<td>This tells the function handler how to invoke the function. It might be the actual source code of the function for interpreted languages, a link symbol, a file name, or just about anything else, depending on the implementation language/call convention.</td>
</tr>
<tr>
<td>probin</td>
<td>text</td>
<td></td>
<td>Additional information about how to invoke the function. Again, the interpretation is language-specific.</td>
</tr>
<tr>
<td>proconfig</td>
<td>text[ ]</td>
<td></td>
<td>Function’s local settings for run-time configuration variables</td>
</tr>
</tbody>
</table>
Chapter 48. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
</tbody>
</table>

For compiled functions, both built-in and dynamically loaded, `prosrc` contains the function’s C-language name (link symbol). For all other currently-known language types, `prosrc` contains the function’s source text. `probin` is unused except for dynamically-loaded C functions, for which it gives the name of the shared library file containing the function.

### 48.37. pg_range

The catalog `pg_range` stores information about range types. This is in addition to the types’ entries in `pg_type`.

**Table 48-37. pg_range Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rngtypid</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>OID of the range type</td>
</tr>
<tr>
<td>rngsubtype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>OID of the element type (subtype) of this range type</td>
</tr>
<tr>
<td>rngcollation</td>
<td>oid</td>
<td>pg_collation.oid</td>
<td>OID of the collation used for range comparisons, or 0 if none</td>
</tr>
<tr>
<td>rngsubopc</td>
<td>oid</td>
<td>pg_opclass.oid</td>
<td>OID of the subtype’s operator class used for range comparisons</td>
</tr>
<tr>
<td>rngcanonical</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the function to convert a range value into canonical form, or 0 if none</td>
</tr>
<tr>
<td>rngsubdifff</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the function to return the difference between two element values as double precision, or 0 if none</td>
</tr>
</tbody>
</table>

`rngsubopc` (plus `rngcollation`, if the element type is collatable) determines the sort ordering used by the range type. `rngcanonical` is used when the element type is discrete. `rngsubdifff` is optional but should be supplied to improve performance of GiST indexes on the range type.

1947
48.38. **pg_rewrite**

The catalog `pg_rewrite` stores rewrite rules for tables and views.

**Table 48-38. pg_rewrite Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>

<td>Query tree (in the form of a nodeToString() representation) for the rule’s action</td>
</tr>
</tbody>
</table>

**Note:** `pg_class.relhasrules` must be true if a table has any rules in this catalog.

48.39. **pg_replication_slots**

The `pg_replication_slots` view provides a listing of all replication slots that currently exist on the database cluster, along with their current state.
For more on replication slots, see Section 25.2.6 and Chapter 46.

Table 48-39. **pg_replication_slots** Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>slot_name</td>
<td>name</td>
<td></td>
<td>A unique, cluster-wide identifier for the replication slot</td>
</tr>
<tr>
<td>plugin</td>
<td>name</td>
<td></td>
<td>The base name of the shared object containing the output plugin this logical slot is using, or null for physical slots.</td>
</tr>
<tr>
<td>slot_type</td>
<td>text</td>
<td></td>
<td>The slot type - physical or logical</td>
</tr>
<tr>
<td>datoid</td>
<td>oid</td>
<td>pg_database.oid</td>
<td>The OID of the database this slot is associated with, or null. Only logical slots have an associated database.</td>
</tr>
<tr>
<td>database</td>
<td>text</td>
<td>pg_database.datname</td>
<td>The name of the database this slot is associated with, or null. Only logical slots have an associated database.</td>
</tr>
<tr>
<td>active</td>
<td>boolean</td>
<td></td>
<td>True if this slot is currently actively being used</td>
</tr>
<tr>
<td>xmin</td>
<td>xid</td>
<td></td>
<td>The oldest transaction that this slot needs the database to retain. <strong>VACUUM</strong> cannot remove tuples deleted by any later transaction.</td>
</tr>
<tr>
<td>catalog_xmin</td>
<td>xid</td>
<td></td>
<td>The oldest transaction affecting the system catalogs that this slot needs the database to retain. <strong>VACUUM</strong> cannot remove catalog tuples deleted by any later transaction.</td>
</tr>
</tbody>
</table>
Chapter 48. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>restart_lsn</td>
<td>pg_lsn</td>
<td></td>
<td>The address (LSN) of oldest WAL which still might be required by the consumer of this slot and thus won’t be automatically removed during checkpoints.</td>
</tr>
</tbody>
</table>

48.40. pg_seclabel

The catalog pg_seclabel stores security labels on database objects. Security labels can be manipulated with the SECURITY LABEL command. For an easier way to view security labels, see Section 48.66.

See also pg_shseclabel, which performs a similar function for security labels of database objects that are shared across a database cluster.

Table 48-40. pg_seclabel Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this security label pertains to</td>
</tr>
<tr>
<td>classoid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a security label on a table column, this is the column number (the objoid and classoid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>provider</td>
<td>text</td>
<td></td>
<td>The label provider associated with this label.</td>
</tr>
<tr>
<td>label</td>
<td>text</td>
<td></td>
<td>The security label applied to this object.</td>
</tr>
</tbody>
</table>

48.41. pg_shdepend

The catalog pg_shdepend records the dependency relationships between database objects and shared
objects, such as roles. This information allows PostgreSQL to ensure that those objects are unreferenced before attempting to delete them.

See also `pg_depend`, which performs a similar function for dependencies involving objects within a single database.

Unlike most system catalogs, `pg_shdepend` is shared across all databases of a cluster: there is only one copy of `pg_shdepend` per cluster, not one per database.

### Table 48-41. `pg_shdepend` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbid</td>
<td>oid</td>
<td>pg_database.oid</td>
<td>The OID of the database the dependent object is in, or zero for a shared object</td>
</tr>
<tr>
<td>classid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog the dependent object is in</td>
</tr>
<tr>
<td>objid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the specific dependent object</td>
</tr>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a table column, this is the column number (the objid and classid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>refclassid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog the referenced object is in (must be a shared catalog)</td>
</tr>
<tr>
<td>refobjid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the specific referenced object</td>
</tr>
<tr>
<td>deptype</td>
<td>char</td>
<td></td>
<td>A code defining the specific semantics of this dependency relationship; see text</td>
</tr>
</tbody>
</table>

In all cases, a `pg_shdepend` entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

**SHARED_DEPENDENCY_OWNER (o)**

The referenced object (which must be a role) is the owner of the dependent object.

**SHARED_DEPENDENCY_ACL (a)**

The referenced object (which must be a role) is mentioned in the ACL (access control list, i.e.,
privileges list) of the dependent object. (A \texttt{SHARED\_DEPENDENCY\_ACL} entry is not made for the owner of the object, since the owner will have a \texttt{SHARED\_DEPENDENCY\_OWNER} entry anyway.)

\texttt{SHARED\_DEPENDENCY\_PIN} (p)

There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by \texttt{initdb}. The columns for the dependent object contain zeroes.

Other dependency flavors might be needed in future. Note in particular that the current definition only supports roles as referenced objects.

### 48.42. \texttt{pg\_shdescription}

The catalog \texttt{pg\_shdescription} stores optional descriptions (comments) for shared database objects. Descriptions can be manipulated with the \texttt{COMMENT} command and viewed with \texttt{psql}'s \texttt{\textbackslash d} commands.

See also \texttt{pg\_description}, which performs a similar function for descriptions involving objects within a single database.

Unlike most system catalogs, \texttt{pg\_shdescription} is shared across all databases of a cluster: there is only one copy of \texttt{pg\_shdescription} per cluster, not one per database.

<table>
<thead>
<tr>
<th>\textbf{Name}</th>
<th>\textbf{Type}</th>
<th>\textbf{References}</th>
<th>\textbf{Description}</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{objoid}</td>
<td>\texttt{oid}</td>
<td>any OID column</td>
<td>The OID of the object this description pertains to</td>
</tr>
<tr>
<td>\texttt{classoid}</td>
<td>\texttt{oid}</td>
<td>\texttt{pg_class_oid}</td>
<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>\texttt{description}</td>
<td>\texttt{text}</td>
<td></td>
<td>Arbitrary text that serves as the description of this object</td>
</tr>
</tbody>
</table>

### 48.43. \texttt{pg\_shseclabel}

The catalog \texttt{pg\_shseclabel} stores security labels on shared database objects. Security labels can be manipulated with the \texttt{SECURITY LABEL} command. For an easier way to view security labels, see Section 48.66.

See also \texttt{pg\_seclabel}, which performs a similar function for security labels involving objects within a single database.

Unlike most system catalogs, \texttt{pg\_shseclabel} is shared across all databases of a cluster: there is only one copy of \texttt{pg\_shseclabel} per cluster, not one per database.
Table 48-43. pg_shseclabel Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this security label pertains to</td>

<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>provider</td>
<td>text</td>
<td></td>
<td>The label provider associated with this label.</td>
</tr>
<tr>
<td>label</td>
<td>text</td>
<td></td>
<td>The security label applied to this object.</td>
</tr>
</tbody>
</table>

48.44. pg_statistic

The catalog pg_statistic stores statistical data about the contents of the database. Entries are created by ANALYZE and subsequently used by the query planner. Note that all the statistical data is inherently approximate, even assuming that it is up-to-date.

Normally there is one entry, with stainherit = false, for each table column that has been analyzed. If the table has inheritance children, a second entry with stainherit = true is also created. This row represents the column’s statistics over the inheritance tree, i.e., statistics for the data you’d see with SELECT column FROM table*, whereas the stainherit = false row represents the results of SELECT column FROM ONLY table.

pg_statistic also stores statistical data about the values of index expressions. These are described as if they were actual data columns; in particular, starelid references the index. No entry is made for an ordinary non-expression index column, however, since it would be redundant with the entry for the underlying table column. Currently, entries for index expressions always have stainherit = false.

Since different kinds of statistics might be appropriate for different kinds of data, pg_statistic is designed not to assume very much about what sort of statistics it stores. Only extremely general statistics (such as nullness) are given dedicated columns in pg_statistic. Everything else is stored in “slots”, which are groups of associated columns whose content is identified by a code number in one of the slot’s columns. For more information see src/include/catalog/pg_statistic.h.

pg_statistic should not be readable by the public, since even statistical information about a table’s contents might be considered sensitive. (Example: minimum and maximum values of a salary column might be quite interesting.) pg_stats is a publicly readable view on pg_statistic that only exposes information about those tables that are readable by the current user.

Table 48-44. pg_statistic Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------</td>
<td>---------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>starelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table or index that the described column belongs to</td>
</tr>
<tr>
<td>staattnum</td>
<td>int2</td>
<td>pg_attribute.attnum</td>
<td>The number of the described column</td>
</tr>
<tr>
<td>stainherit</td>
<td>bool</td>
<td></td>
<td>If true, the stats include inheritance child columns, not just the values in the specified relation</td>
</tr>
<tr>
<td>stanullfrac</td>
<td>float4</td>
<td></td>
<td>The fraction of the column’s entries that are null</td>
</tr>
<tr>
<td>stawidth</td>
<td>int4</td>
<td></td>
<td>The average stored width, in bytes, of nonnull entries</td>
</tr>
<tr>
<td>stadistinct</td>
<td>float4</td>
<td></td>
<td>The number of distinct nonnull data values in the column. A value greater than zero is the actual number of distinct values. A value less than zero is the negative of a multiplier for the number of rows in the table; for example, a column in which about 80% of the values are nonnull and each nonnull value appears about twice on average could be represented by stadistinct = -0.4. A zero value means the number of distinct values is unknown.</td>
</tr>
<tr>
<td>stakindN</td>
<td>int2</td>
<td></td>
<td>A code number indicating the kind of statistics stored in the Nth “slot” of the pg_statistic row.</td>
</tr>
</tbody>
</table>
### 48.45. `pg_tablespace`

The catalog `pg_tablespace` stores information about the available tablespaces. Tables can be placed in particular tablespaces to aid administration of disk layout.

Unlike most system catalogs, `pg_tablespace` is shared across all databases of a cluster: there is only one copy of `pg_tablespace` per cluster, not one per database.

**Table 48-45. `pg_tablespace` Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
</tbody>
</table>
### 48.46. pg_trigger

The catalog pg_trigger stores triggers on tables and views. See CREATE TRIGGER for more information.

#### Table 48-46. pg_trigger Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>

<td>oid</td>
<td>pg_class.oid</td>
<td>The table this trigger is on</td>
</tr>
<tr>
<td>tgname</td>
<td>name</td>
<td></td>
<td>Trigger name (must be unique among triggers of same table)</td>
</tr>
<tr>
<td>tgfoid</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>The function to be called</td>
</tr>
<tr>
<td>tgtype</td>
<td>int2</td>
<td></td>
<td>Bit mask identifying trigger firing conditions</td>
</tr>
<tr>
<td>tgenabled</td>
<td>char</td>
<td></td>
<td>Controls in which session_replication_role modes the trigger fires.</td>
</tr>
</tbody>
</table>

- ○ = trigger fires in “origin” and “local” modes
- D = trigger is disabled
- R = trigger fires in “replica” mode
- A = trigger fires always
### System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tgisinternal</td>
<td>bool</td>
<td></td>
<td>True if trigger is internally generated (usually, to enforce the constraint identified by tgconstraint)</td>
</tr>
<tr>
<td>tgconstrrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table referenced by a referential integrity constraint</td>
</tr>
<tr>
<td>tgconstrindid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The index supporting a unique, primary key, referential integrity, or exclusion constraint</td>
</tr>
<tr>
<td>tgconstraint</td>
<td>oid</td>
<td>pg_constraint.oid</td>
<td>The pg_constraint entry associated with the trigger, if any</td>
</tr>
<tr>
<td>tgdeferrable</td>
<td>bool</td>
<td></td>
<td>True if constraint trigger is deferrable</td>
</tr>
<tr>
<td>tgininitdeferred</td>
<td>bool</td>
<td></td>
<td>True if constraint trigger is initially deferred</td>
</tr>
<tr>
<td>tgnargs</td>
<td>int2</td>
<td></td>
<td>Number of argument strings passed to trigger function</td>
</tr>
<tr>
<td>tgattr</td>
<td>int2vector</td>
<td>pg_attribute.attnum</td>
<td>Column numbers, if trigger is column-specific; otherwise an empty array</td>
</tr>
<tr>
<td>tgargs</td>
<td>bytea</td>
<td></td>
<td>Argument strings to pass to trigger, each NULL-terminated</td>
</tr>
<tr>
<td>tqqual</td>
<td>pg_node_tree</td>
<td></td>
<td>Expression tree (in nodeToString() representation) for the trigger’s WHEN condition, or null if none</td>
</tr>
</tbody>
</table>

Currently, column-specific triggering is supported only for UPDATE events, and so `tgattr` is relevant only for that event type. `tgtype` might contain bits for other event types as well, but those are presumed to be table-wide regardless of what is in `tgattr`.

**Note:** When `tgconstraint` is nonzero, `tgconstrrelid`, `tgconstrindid`, `tgdeferrable`, and `tgininitdeferred` are largely redundant with the referenced `pg_constraint` entry. However, it is possible for a non-deferrable trigger to be associated with a deferrable constraint: foreign key constraints can have some deferrable and some non-deferrable triggers.
Note: `pg_class.relhastriggers` must be true if a relation has any triggers in this catalog.

### 48.47. `pg_ts_config`

The `pg_ts_config` catalog contains entries representing text search configurations. A configuration specifies a particular text search parser and a list of dictionaries to use for each of the parser’s output token types. The parser is shown in the `pg_ts_config` entry, but the token-to-dictionary mapping is defined by subsidiary entries in `pg_ts_config_map`.

PostgreSQL’s text search features are described at length in Chapter 12.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>cfgname</td>
<td>name</td>
<td></td>
<td>Text search configuration name</td>
</tr>
<tr>
<td>cfgnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this configuration</td>
</tr>
<tr>
<td>cfgowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the configuration</td>
</tr>
<tr>
<td>cfgparser</td>
<td>oid</td>
<td>pg_ts_parser.oid</td>
<td>The OID of the text search parser for this configuration</td>
</tr>
</tbody>
</table>

### 48.48. `pg_ts_config_map`

The `pg_ts_config_map` catalog contains entries showing which text search dictionaries should be consulted, and in what order, for each output token type of each text search configuration’s parser.

PostgreSQL’s text search features are described at length in Chapter 12.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
</table>

Chapter 48. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mapcfg</td>
<td>oid</td>
<td>pg_ts_config</td>
<td>The OID of the pg_ts_config entry owning this map entry</td>
</tr>
<tr>
<td>maptokentype</td>
<td>integer</td>
<td></td>
<td>A token type emitted by the configuration’s parser</td>
</tr>
<tr>
<td>mapseqno</td>
<td>integer</td>
<td></td>
<td>Order in which to consult this entry (lower mapseqnos first)</td>
</tr>
<tr>
<td>mapdict</td>
<td>oid</td>
<td>pg_ts_dict</td>
<td>The OID of the text search dictionary to consult</td>
</tr>
</tbody>
</table>

### 48.49. pg_ts_dict

The pg_ts_dict catalog contains entries defining text search dictionaries. A dictionary depends on a text search template, which specifies all the implementation functions needed; the dictionary itself provides values for the user-settable parameters supported by the template. This division of labor allows dictionaries to be created by unprivileged users. The parameters are specified by a text string dictinitoption, whose format and meaning vary depending on the template.

PostgreSQL’s text search features are described at length in Chapter 12.

Table 48-49. pg_ts_dict Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>dictname</td>
<td>name</td>
<td></td>
<td>Text search dictionary name</td>
</tr>
<tr>
<td>dictnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this dictionary</td>
</tr>
<tr>
<td>dictowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the dictionary</td>
</tr>
<tr>
<td>dicttemplate</td>
<td>oid</td>
<td>pg_ts_template.oid</td>
<td>The OID of the text search template for this dictionary</td>
</tr>
<tr>
<td>dictinitoption</td>
<td>text</td>
<td></td>
<td>Initialization option string for the template</td>
</tr>
</tbody>
</table>
48.50. **pg_ts_parser**

The `pg_ts_parser` catalog contains entries defining text search parsers. A parser is responsible for splitting input text into lexemes and assigning a token type to each lexeme. Since a parser must be implemented by C-language-level functions, creation of new parsers is restricted to database superusers.

PostgreSQL’s text search features are described at length in Chapter 12.

**Table 48-50. pg_ts_parser Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>prsname</td>
<td>name</td>
<td></td>
<td>Text search parser name</td>
</tr>
<tr>
<td>prsnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this parser</td>
</tr>
<tr>
<td>prsstart</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the parser’s startup function</td>
</tr>
<tr>
<td>prstoken</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the parser’s next-token function</td>
</tr>
<tr>
<td>prsend</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the parser’s shutdown function</td>
</tr>
<tr>
<td>prsheadline</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the parser’s headline function</td>
</tr>
<tr>
<td>prslextype</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the parser’s lextype function</td>
</tr>
</tbody>
</table>

48.51. **pg_ts_template**

The `pg_ts_template` catalog contains entries defining text search templates. A template is the implementation skeleton for a class of text search dictionaries. Since a template must be implemented by C-language-level functions, creation of new templates is restricted to database superusers.

PostgreSQL’s text search features are described at length in Chapter 12.

**Table 48-51. pg_ts_template Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>OID of the template’s initialization function</td>
</tr>
<tr>
<td>tmpllexize</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the template’s lexize function</td>
</tr>
</tbody>
</table>

#### 48.52. pg_type

The catalog `pg_type` stores information about data types. Base types and enum types (scalar types) are created with `CREATE TYPE`, and domains with `CREATE DOMAIN`. A composite type is automatically created for each table in the database, to represent the row structure of the table. It is also possible to create composite types with `CREATE TYPE AS`.

**Table 48-52. pg_type Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>

### Chapter 48. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>typbyval</td>
<td>bool</td>
<td></td>
<td><strong>typbyval</strong> determines whether internal routines pass a value of this type by value or by reference. <strong>typbyval</strong> had better be false if <strong>typlen</strong> is not 1, 2, or 4 (or 8 on machines where Datum is 8 bytes). Variable-length types are always passed by reference. Note that <strong>typbyval</strong> can be false even if the length would allow pass-by-value.</td>
</tr>
<tr>
<td>typtype</td>
<td>char</td>
<td></td>
<td><strong>typtype</strong> is <strong>b</strong> for a base type, <strong>c</strong> for a composite type (e.g., a table’s row type), <strong>d</strong> for a domain, <strong>e</strong> for an enum type, <strong>p</strong> for a pseudo-type, or <strong>r</strong> for a range type. See also <strong>typrelid</strong> and <strong>typbasetype</strong>.</td>
</tr>
<tr>
<td>typcategory</td>
<td>char</td>
<td></td>
<td><strong>typcategory</strong> is an arbitrary classification of data types that is used by the parser to determine which implicit casts should be “preferred”. See Table 48-53.</td>
</tr>
<tr>
<td>typispreferred</td>
<td>bool</td>
<td></td>
<td>True if the type is a preferred cast target within its <strong>typcategory</strong>.</td>
</tr>
<tr>
<td>typisdefined</td>
<td>bool</td>
<td></td>
<td>True if the type is defined, false if this is a placeholder entry for a not-yet-defined type. When <strong>typisdefined</strong> is false, nothing except the type name, namespace, and OID can be relied on.</td>
</tr>
</tbody>
</table>
## Chapter 48. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>typdelim</td>
<td>char</td>
<td></td>
<td>Character that separates two values of this type when parsing array input. Note that the delimiter is associated with the array element data type, not the array data type.</td>
</tr>
<tr>
<td>typrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>If this is a composite type (see typtype), then this column points to the pg_class entry that defines the corresponding table. (For a free-standing composite type, the pg_class entry doesn’t really represent a table, but it is needed anyway for the type’s pg_attribute entries to link to.) Zero for non-composite types.</td>

## Chapter 48. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| typalign | char | typalign is the alignment required when storing a value of this type. It applies to storage on disk as well as most representations of the value inside PostgreSQL. When multiple values are stored consecutively, such as in the representation of a complete row on disk, padding is inserted before a datum of this type so that it begins on the specified boundary. The alignment reference is the beginning of the first datum in the sequence. Possible values are:  
  - **c** = char alignment, i.e., no alignment needed.  
  - **s** = short alignment (2 bytes on most machines).  
  - **i** = int alignment (4 bytes on most machines).  
  - **d** = double alignment (8 bytes on many machines, but by no means all). |

*Note:* For types used in system tables, it is critical that the size and alignment defined in `pg_type` agree with the way that the compiler will lay out the column in a structure representing a table row.

</tbody>
</table>

48.54. **System Views**

In addition to the system catalogs, PostgreSQL provides a number of built-in views. Some system views provide convenient access to some commonly used queries on the system catalogs. Other views provide access to internal server state.

The information schema (Chapter 34) provides an alternative set of views which overlap the functionality of the system views. Since the information schema is SQL-standard whereas the views described here are PostgreSQL-specific, it’s usually better to use the information schema if it provides all the information you need.

Table 48-55 lists the system views described here. More detailed documentation of each view follows below. There are some additional views that provide access to the results of the statistics collector; they are described in Table 27-1.

Except where noted, all the views described here are read-only.

**Table 48-55. System Views**
Chapter 48. System Catalogs

</tr>
<tr>
<td>comment</td>
<td>text</td>
<td>Comment string from the extension’s control file</td>
</tr>
</tbody>
</table>

The `pg_available_extension_versions` view is read only.

48.57. **pg_cursors**

The `pg_cursors` view lists the cursors that are currently available. Cursors can be defined in several ways:

- via the DECLARE statement in SQL
- via the Bind message in the frontend/backend protocol, as described in Section 49.2.3
- via the Server Programming Interface (SPI), as described in Section 44.1

The `pg_cursors` view displays cursors created by any of these means. Cursors only exist for the duration of the transaction that defines them, unless they have been declared WITH HOLD. Therefore non-holdable cursors are only present in the view until the end of their creating transaction.

**Note:** Cursors are used internally to implement some of the components of PostgreSQL, such as procedural languages. Therefore, the `pg_cursors` view might include cursors that have not been explicitly created by the user.
Chapter 48. System Catalogs

Table 48-58. pg_cursors Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>

<td>true if the cursor is scrollable (that is, it allows rows to be retrieved in a nonsequential manner); false otherwise</td>
</tr>
<tr>
<td>creation_time</td>
<td>timestamptz</td>
<td>The time at which the cursor was declared</td>
</tr>
</tbody>
</table>

The pg_cursors view is read only.

48.58. pg_group

The view pg_group exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows the names and members of all roles that are marked as not rolcanlogin, which is an approximation to the set of roles that are being used as groups.

Table 48-59. pg_group Columns

<table>
<thead>
<tr>

<td>Index definition (a reconstructed CREATE INDEX command)</td>
</tr>
</tbody>
</table>

48.60. pg_locks

The view `pg_locks` provides access to information about the locks held by open transactions within the database server. See Chapter 13 for more discussion of locking.

`pg_locks` contains one row per active lockable object, requested lock mode, and relevant transaction. Thus, the same lockable object might appear many times, if multiple transactions are holding or waiting for locks on it. However, an object that currently has no locks on it will not appear at all.

There are several distinct types of lockable objects: whole relations (e.g., tables), individual pages of relations, individual tuples of relations, transaction IDs (both virtual and permanent IDs), and general database objects (identified by class OID and object OID, in the same way as in `pg_description` or `pg_depend`). Also, the right to extend a relation is represented as a separate lockable object. Also, “advisory” locks can be taken on numbers that have user-defined meanings.

Table 48-61. pg_locks Columns

<table>
<thead>
<tr>
<th>Name</th>

<tr>
<td>objsubid</td>
<td>smallint</td>
<td></td>
<td>Column number targeted by the lock (the classid and objid refer to the table itself), or zero if the target is some other general database object, or null if the target is not a general database object.</td>
</tr>
<tr>
<td>virtualtransaction</td>
<td>text</td>
<td></td>
<td>Virtual ID of the transaction that is holding or awaiting this lock.</td>
</tr>
<tr>
<td>pid</td>
<td>integer</td>
<td></td>
<td>Process ID of the server process holding or awaiting this lock, or null if the lock is held by a prepared transaction.</td>
</tr>
<tr>
<td>mode</td>
<td>text</td>
<td></td>
<td>Name of the lock mode held or desired by this process (see Section 13.3.1 and Section 13.2.3).</td>
</tr>
<tr>
<td>granted</td>
<td>boolean</td>
<td></td>
<td>True if lock is held, false if lock is awaited.</td>
</tr>
<tr>
<td>fastpath</td>
<td>boolean</td>
<td></td>
<td>True if lock was taken via fast path, false if taken via main lock table.</td>
</tr>
</tbody>
</table>

 granted is true in a row representing a lock held by the indicated transaction. False indicates that this transaction is currently waiting to acquire this lock, which implies that some other transaction is holding a conflicting lock mode on the same lockable object. The waiting transaction will sleep until the other lock is released (or a deadlock situation is detected). A single transaction can be waiting to acquire at most one lock at a time.

Every transaction holds an exclusive lock on its virtual transaction ID for its entire duration. If a permanent ID is assigned to the transaction (which normally happens only if the transaction changes the state of the database), it also holds an exclusive lock on its permanent transaction ID until it ends. When one transaction finds it necessary to wait specifically for another transaction, it does so by attempting to acquire share lock on the other transaction ID (either virtual or permanent ID depending on the situation). That will succeed only when the other transaction terminates and releases its locks.

Although tuples are a lockable type of object, information about row-level locks is stored on disk, not in memory, and therefore row-level locks normally do not appear in this view. If a transaction is waiting for a row-level lock, it will usually appear in the view as waiting for the permanent transaction ID of the current holder of that row lock.
Advisory locks can be acquired on keys consisting of either a single \texttt{bigint} value or two integer values. A \texttt{bigint} key is displayed with its high-order half in the \texttt{classid} column, its low-order half in the \texttt{objid} column, and \texttt{objsubid} equal to 1. The original \texttt{bigint} value can be reassembled with the expression \texttt{(classid::bigint \ll 32) | objid::bigint}. Integer keys are displayed with the first key in the \texttt{classid} column, the second key in the \texttt{objid} column, and \texttt{objsubid} equal to 2. The actual meaning of the keys is up to the user. Advisory locks are local to each database, so the \texttt{database} column is meaningful for an advisory lock.

\texttt{pg_locks} provides a global view of all locks in the database cluster, not only those relevant to the current database. Although its \texttt{relation} column can be joined against \texttt{pg_class.oid} to identify locked relations, this will only work correctly for relations in the current database (those for which the \texttt{database} column is either the current database’s OID or zero).

The \texttt{pid} column can be joined to the \texttt{pid} column of the \texttt{pg_stat_activity} view to get more information on the session holding or waiting to hold each lock, for example

\begin{verbatim}
SELECT * FROM pg_locks pl LEFT JOIN pg_stat_activity psa
  ON pl.pid = psa.pid;
\end{verbatim}

Also, if you are using prepared transactions, the \texttt{virtualtransaction} column can be joined to the \texttt{transaction} column of the \texttt{pg_prepared_xacts} view to get more information on prepared transactions that hold locks. (A prepared transaction can never be waiting for a lock, but it continues to hold the locks it acquired while running.) For example:

\begin{verbatim}
SELECT * FROM pg_locks pl LEFT JOIN pg_prepared_xacts ppx
  ON pl.virtualtransaction = '-1/' || ppx.transaction;
\end{verbatim}

The \texttt{pg_locks} view displays data from both the regular lock manager and the predicate lock manager, which are separate systems; in addition, the regular lock manager subdivides its locks into regular and \texttt{fast-path} locks. This data is not guaranteed to be entirely consistent. When the view is queried, data on fast-path locks (with \texttt{fastpath = true}) is gathered from each backend one at a time, without freezing the state of the entire lock manager, so it is possible for locks to be taken or released while information is gathered. Note, however, that these locks are known not to conflict with any other lock currently in place. After all backends have been queried for fast-path locks, the remainder of the regular lock manager is locked as a unit, and a consistent snapshot of all remaining locks is collected as an atomic action. After unlocking the regular lock manager, the predicate lock manager is similarly locked and all predicate locks are collected as an atomic action. Thus, with the exception of fast-path locks, each lock manager will deliver a consistent set of results, but as we do not lock both lock managers simultaneously, it is possible for locks to be taken or released after we interrogate the regular lock manager and before we interrogate the predicate lock manager.

Locking the regular and/or predicate lock manager could have some impact on database performance if this view is very frequently accessed. The locks are held only for the minimum amount of time necessary to obtain data from the lock managers, but this does not completely eliminate the possibility of a performance impact.
48.61. pg_matviews

The view `pg_matviews` provides access to useful information about each materialized view in the database.

Table 48-62. pg_matviews Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>

<td>boolean</td>
<td></td>
<td>True if materialized view has (or recently had) any indexes</td>
</tr>
<tr>
<td>ispopulated</td>
<td>boolean</td>
<td></td>
<td>True if materialized view is currently populated</td>
</tr>
<tr>
<td>definition</td>
<td>text</td>
<td></td>
<td>Materialized view definition (a reconstructed SELECT query)</td>
</tr>
</tbody>
</table>

48.62. pg_prepared_statements

The `pg_prepared_statements` view displays all the prepared statements that are available in the current session. See PREPARE for more information about prepared statements.

`pg_prepared_statements` contains one row for each prepared statement. Rows are added to the view when a new prepared statement is created and removed when a prepared statement is released (for example, via the DEALLOCATE command).

Table 48-63. pg_prepared_statements Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
<td>The identifier of the prepared statement</td>
</tr>
</tbody>
</table>
Chapter 48. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>statement</td>
<td>text</td>
<td>The query string submitted by the client to create this prepared statement. For prepared statements created via SQL, this is the PREPARE statement submitted by the client. For prepared statements created via the frontend/backend protocol, this is the text of the prepared statement itself.</td>
</tr>
<tr>
<td>prepare_time</td>
<td>timestamp</td>
<td>The time at which the prepared statement was created</td>
</tr>
<tr>
<td>parameter_types</td>
<td>regtype[]</td>
<td>The expected parameter types for the prepared statement in the form of an array of regtype. The OID corresponding to an element of this array can be obtained by casting the regtype value to oid.</td>
</tr>
<tr>
<td>from_sql</td>
<td>boolean</td>
<td>true if the prepared statement was created via the PREPARE SQL statement; false if the statement was prepared via the frontend/backend protocol</td>
</tr>
</tbody>
</table>

The `pg_prepared_statements` view is read only.

### 48.63. pg_prepared_xacts

The view `pg_prepared_xacts` displays information about transactions that are currently prepared for two-phase commit (see PREPARE TRANSACTION for details).

`pg_prepared_xacts` contains one row per prepared transaction. An entry is removed when the transaction is committed or rolled back.

**Table 48-64. pg_prepared_xacts Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>transaction</td>
<td>xid</td>
<td></td>
<td>Numeric transaction identifier of the prepared transaction</td>
</tr>
</tbody>
</table>
### Chapter 48. System Catalogs

#### Table 48-63. pg_prepared_xacts Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gid</td>
<td>text</td>
<td></td>
<td>Global transaction identifier that was assigned to the transaction</td>
</tr>
<tr>
<td>prepared</td>
<td>timestamp with time zone</td>
<td></td>
<td>Time at which the transaction was prepared for commit</td>
</tr>
<tr>
<td>owner</td>
<td>name</td>
<td>pg_authid.rolname</td>
<td>Name of the user that executed the transaction</td>
</tr>
<tr>
<td>database</td>
<td>name</td>
<td>pg_database.datname</td>
<td>Name of the database in which the transaction was executed</td>
</tr>
</tbody>
</table>

When the `pg_prepared_xacts` view is accessed, the internal transaction manager data structures are momentarily locked, and a copy is made for the view to display. This ensures that the view produces a consistent set of results, while not blocking normal operations longer than necessary. Nonetheless there could be some impact on database performance if this view is frequently accessed.

#### 48.64. pg_roles

The view `pg_roles` provides access to information about database roles. This is simply a publicly readable view of `pg_authid` that blanks out the password field.

This view explicitly exposes the OID column of the underlying table, since that is needed to do joins to other catalogs.

#### Table 48-65. pg_roles Columns

<td>bool</td>
<td></td>
<td>Role is a replication role. That is, this role can initiate streaming replication (see Section 25.2.5) and set/unset the system backup mode using <code>pg_start_backup</code> and <code>pg_stop_backup</code></td>
</tr>
<tr>
<td>rolconnlimit</td>
<td>int4</td>
<td></td>
<td>For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit.</td>
</tr>
<tr>
<td>rolpassword</td>
<td>text</td>
<td></td>
<td>Not the password (always reads as ********)</td>
</tr>
<tr>
<td>rolvaliduntil</td>
<td>timestampz</td>
<td></td>
<td>Password expiry time (only used for password authentication); null if no expiration</td>
</tr>
<tr>
<td>rolconfig</td>
<td>text[]</td>
<td></td>
<td>Role-specific defaults for run-time configuration variables</td>
</tr>
<tr>
<td>oid</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>ID of role</td>
</tr>
</tbody>
</table>

### 48.65. pg_rules

The view `pg_rules` provides access to useful information about query rewrite rules.

### Table 48-66. pg_rules Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>pg_authid.oid</td>
<td>ID of role</td>
</tr>
</tbody>
</table>
Chapter 48. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td>pg_namespace.nspname</td>
<td>Name of schema containing table</td>
</tr>
<tr>
<td>tablename</td>
<td>name</td>
<td>pg_class.relname</td>
<td>Name of table the rule is for</td>
</tr>
<tr>
<td>rulename</td>
<td>name</td>
<td>pg_rewrite.rulename</td>
<td>Name of rule</td>
</tr>
<tr>
<td>definition</td>
<td>text</td>
<td></td>
<td>Rule definition (a reconstructed creation command)</td>
</tr>
</tbody>
</table>

The `pg_rules` view excludes the ON SELECT rules of views and materialized views; those can be seen in `pg_views` and `pg_matviews`.

48.66. **pg_seclabels**

The view `pg_seclabels` provides information about security labels. It is an easier-to-query version of the `pg_seclabel` catalog.

**Table 48-67. pg_seclabels Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this security label pertains to</td>
</tr>
<tr>
<td>classoid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a security label on a table column, this is the column number (the objoid and classoid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>objtype</td>
<td>text</td>
<td></td>
<td>The type of object to which this label applies, as text.</td>
</tr>
<tr>
<td>objnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace for this object, if applicable; otherwise NULL.</td>
</tr>
</tbody>
</table>
### 48.67. `pg_settings`

The view `pg_settings` provides access to run-time parameters of the server. It is essentially an alternative interface to the SHOW and SET commands. It also provides access to some facts about each parameter that are not directly available from SHOW, such as minimum and maximum values.

**Table 48-68. `pg_settings` Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
<td>Run-time configuration parameter name</td>

<td>text</td>
<td>Minimum allowed value of the parameter (null for non-numeric values)</td>
</tr>
<tr>
<td>max_val</td>
<td>text</td>
<td>Maximum allowed value of the parameter (null for non-numeric values)</td>
</tr>
</tbody>
</table>
Chapter 48. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enumvals</td>
<td>text[]</td>
<td>Allowed values of an enum parameter (null for non-enum values)</td>
</tr>
<tr>
<td>boot_val</td>
<td>text</td>
<td>Parameter value assumed at server startup if the parameter is not otherwise set</td>
</tr>
<tr>
<td>reset_val</td>
<td>text</td>
<td>Value that RESET would reset the parameter to in the current session</td>
</tr>
<tr>
<td>sourcefile</td>
<td>text</td>
<td>Configuration file the current value was set in (null for values set from sources other than configuration files, or when examined by a non-superuser); helpful when using include directives in configuration files</td>
</tr>
<tr>
<td>sourceline</td>
<td>integer</td>
<td>Line number within the configuration file the current value was set at (null for values set from sources other than configuration files, or when examined by a non-superuser)</td>
</tr>
</tbody>
</table>

There are several possible values of context. In order of decreasing difficulty of changing the setting, they are:

**internal**

These settings cannot be changed directly; they reflect internally determined values. Some of them may be adjustable by rebuilding the server with different configuration options, or by changing options supplied to initdb.

**postmaster**

These settings can only be applied when the server starts, so any change requires restarting the server. Values for these settings are typically stored in the postgresql.conf file, or passed on the command line when starting the server. Of course, settings with any of the lower context types can also be set at server start time.

**sighup**

Changes to these settings can be made in postgresql.conf without restarting the server. Send a SIGHUP signal to the postmaster to cause it to re-read postgresql.conf and apply the changes. The postmaster will also forward the SIGHUP signal to its child processes so that they all pick up the new value.

**backend**

Changes to these settings can be made in postgresql.conf without restarting the server; they can also be set for a particular session in the connection request packet (for example, via libpq’s
POPTIONS environment variable). However, these settings never change in a session after it is started. If you change them in postgresql.conf, send a SIGHUP signal to the postmaster to cause it to re-read postgresql.conf. The new values will only affect subsequently-launched sessions.

superuser

These settings can be set from postgresql.conf, or within a session via the SET command; but only superusers can change them via SET. Changes in postgresql.conf will affect existing sessions only if no session-local value has been established with SET.

user

These settings can be set from postgresql.conf, or within a session via the SET command. Any user is allowed to change his session-local value. Changes in postgresql.conf will affect existing sessions only if no session-local value has been established with SET.

See Section 18.1 for more information about the various ways to change these parameters.

The pg_settings view cannot be inserted into or deleted from, but it can be updated. An UPDATE applied to a row of pg_settings is equivalent to executing the SET command on that named parameter. The change only affects the value used by the current session. If an UPDATE is issued within a transaction that is later aborted, the effects of the UPDATE command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another UPDATE or SET.

48.68. pg_shadow

The view pg_shadow exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows properties of all roles that are marked as rolcanlogin in pg_authid.

The name stems from the fact that this table should not be readable by the public since it contains passwords. pg_user is a publicly readable view on pg_shadow that blanks out the password field.

Table 48-69. pg_shadow Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>usename</td>
<td>name</td>

<td></td>
<td>User is a superuser</td>
</tr>
<tr>
<td>usecatupd</td>
<td>bool</td>
<td></td>
<td>User can update system catalogs. (Even a superuser cannot do this unless this column is true.)</td>
</tr>
</tbody>
</table>
### 48.69. `pg_stats`

The view `pg_stats` provides access to the information stored in the `pg_statistic` catalog. This view allows access only to rows of `pg_statistic` that correspond to tables the user has permission to read, and therefore it is safe to allow public read access to this view.

`pg_stats` is also designed to present the information in a more readable format than the underlying catalog — at the cost that its schema must be extended whenever new slot types are defined for `pg_statistic`.

#### Table 48-70. `pg_stats` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>

<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>avg_width</td>
<td>integer</td>
<td></td>
<td>Average width in bytes of column’s entries</td>
</tr>
<tr>
<td>n_distinct</td>
<td>real</td>
<td></td>
<td>If greater than zero, the estimated number of distinct values in the column. If less than zero, the negative of the number of distinct values divided by the number of rows. (The negated form is used when <code>ANALYZE</code> believes that the number of distinct values is likely to increase as the table grows; the positive form is used when the column seems to have a fixed number of possible values.) For example, -1 indicates a unique column in which the number of distinct values is the same as the number of rows.</td>
</tr>
<tr>
<td>most_common_vals</td>
<td>anyarray</td>
<td></td>
<td>A list of the most common values in the column. (Null if no values seem to be more common than any others.)</td>
</tr>
<tr>
<td>most_common_freqs</td>
<td>real[]</td>
<td></td>
<td>A list of the frequencies of the most common values, i.e., number of occurrences of each divided by total number of rows. (Null when <code>most_common_vals</code> is.)</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>histogram_bounds</td>
<td>anyarray</td>
<td></td>
<td>A list of values that divide the column’s values into groups of approximately equal population. The values in <code>most_common_vals</code>, if present, are omitted from this histogram calculation. (This column is null if the column data type does not have a <code>&lt;</code> operator or if the <code>most_common_vals</code> list accounts for the entire population.)</td>
</tr>
<tr>
<td>correlation</td>
<td>real</td>
<td></td>
<td>Statistical correlation between physical row ordering and logical ordering of the column values. This ranges from -1 to +1. When the value is near -1 or +1, an index scan on the column will be estimated to be cheaper than when it is near zero, due to reduction of random access to the disk. (This column is null if the column data type does not have a <code>&lt;</code> operator.)</td>
</tr>
<tr>
<td>most_common elems</td>
<td>anyarray</td>
<td></td>
<td>A list of non-null element values most often appearing within values of the column. (Null for scalar types.)</td>
</tr>
</tbody>
</table>
48.70. **pg_tables**

The view `pg_tables` provides access to useful information about each table in the database.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td>pg_namespace.nspname</td>
<td>Name of schema containing table</td>
</tr>
<tr>
<td>tablename</td>
<td>name</td>
<td>pg_class.relname</td>
<td>Name of table</td>
</tr>
<tr>
<td>tableowner</td>
<td>name</td>
<td>pg_authid rolname</td>
<td>Name of table’s owner</td>
</tr>
</tbody>
</table>
### 48.71. `pg_timezone_abbrevs`

The view `pg_timezone_abbrevs` provides a list of time zone abbreviations that are currently recognized by the datetime input routines. The contents of this view change when the `timezoneabbreviations` runtime parameter is modified.

**Table 48-72. pg_timezone_abbrevs Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>abbrev</td>
<td>text</td>
<td>Time zone abbreviation</td>
</tr>
<tr>
<td>utc_offset</td>
<td>interval</td>
<td>Offset from UTC (positive means east of Greenwich)</td>
</tr>
<tr>
<td>is_dst</td>
<td>boolean</td>
<td>True if this is a daylight-savings abbreviation</td>
</tr>
</tbody>
</table>

While most timezone abbreviations represent fixed offsets from UTC, there are some that have historically varied in value (see Section B.3 for more information). In such cases this view presents their current meaning.

### 48.72. `pg_timezone_names`

The view `pg_timezone_names` provides a list of time zone names that are recognized by `SET TIMEZONE`, along with their associated abbreviations, UTC offsets, and daylight-savings status. (Technically, PostgreSQL uses UT1 rather than UTC because leap seconds are not handled.) Unlike the abbreviations shown in `pg_timezone_abbrevs`, many of these names imply a set of daylight-savings transition date rules. Therefore, the associated information changes across local DST boundaries. The displayed information is computed based on the current value of `CURRENT_TIMESTAMP`.

**Table 48-73. pg_timezone_names Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>

---

1990
Chapter 48. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
<td>Time zone name</td>
</tr>
<tr>
<td>abbrev</td>
<td>text</td>
<td>Time zone abbreviation</td>
</tr>
<tr>
<td>utc_offset</td>
<td>interval</td>
<td>Offset from UTC (positive means east of Greenwich)</td>
</tr>
<tr>
<td>is_dst</td>
<td>boolean</td>
<td>True if currently observing daylight savings</td>
</tr>
</tbody>
</table>

### 48.73. pg_user

The view `pg_user` provides access to information about database users. This is simply a publicly readable view of `pg_shadow` that blanks out the password field.

**Table 48-74. pg_user Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>usename</td>
<td>name</td>
<td>User name</td>
</tr>
<tr>
<td>usesysid</td>
<td>oid</td>
<td>ID of this user</td>
</tr>
<tr>
<td>usecreatedb</td>
<td>bool</td>
<td>User can create databases</td>
</tr>
<tr>
<td>usesuper</td>
<td>bool</td>
<td>User is a superuser</td>
</tr>
<tr>
<td>usecatupd</td>
<td>bool</td>
<td>User can update system catalogs. (Even a superuser cannot do this unless this column is true.)</td>
</tr>
<tr>
<td>userepl</td>
<td>bool</td>
<td>User can initiate streaming replication and put the system in and out of backup mode.</td>
</tr>
<tr>
<td>passwd</td>
<td>text</td>
<td>Not the password (always reads as ********)</td>
</tr>
<tr>
<td>valuntil</td>
<td>abstime</td>
<td>Password expiry time (only used for password authentication)</td>
</tr>
<tr>
<td>useconfig</td>
<td>text[]</td>
<td>Session defaults for run-time configuration variables</td>
</tr>
</tbody>
</table>

### 48.74. pg_user_mappings

The view `pg_user_mappings` provides access to information about user mappings. This is essentially a publicly readable view of `pg_user_mapping` that leaves out the options field if the user has no rights to use it.

**Table 48-75. pg_user_mappings Columns**
### Chapter 48. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>umid</td>
<td>oid</td>
<td>pg_user_mapping.oid</td>
<td>OID of the user mapping</td>
</tr>
<tr>
<td>srvid</td>
<td>oid</td>
<td>pg_foreign_server.oid</td>
<td>The OID of the foreign server that contains this mapping</td>
</tr>
<tr>
<td>srvname</td>
<td>name</td>
<td>pg_foreign_server.srvname</td>
<td>Name of the foreign server</td>
</tr>
<tr>
<td>umuser</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>OID of the local role being mapped, 0 if the user mapping is public</td>
</tr>
<tr>
<td>usename</td>
<td>name</td>
<td></td>
<td>Name of the local user to be mapped</td>
</tr>
<tr>
<td>umoptions</td>
<td>text[]</td>
<td></td>
<td>User mapping specific options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

To protect password information stored as a user mapping option, the `umoptions` column will read as null unless one of the following applies:

- current user is the user being mapped, and owns the server or holds `USAGE` privilege on it
- current user is the server owner and mapping is for `PUBLIC`
- current user is a superuser

### 48.75. pg_views

The view `pg_views` provides access to useful information about each view in the database.

#### Table 48-76. pg_views Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td>pg_namespace.nspname</td>
<td>Name of schema containing view</td>
</tr>
<tr>
<td>viewname</td>
<td>name</td>
<td>pg_class.relname</td>
<td>Name of view</td>
</tr>
<tr>
<td>viewowner</td>
<td>name</td>
<td>pg_authid.rolname</td>
<td>Name of view’s owner</td>
</tr>
<tr>
<td>definition</td>
<td>text</td>
<td></td>
<td>View definition (a reconstructed <code>SELECT</code> query)</td>
</tr>
</tbody>
</table>
Chapter 49. Frontend/Backend Protocol

PostgreSQL uses a message-based protocol for communication between frontends and backends (clients and servers). The protocol is supported over TCP/IP and also over Unix-domain sockets. Port number 5432 has been registered with IANA as the customary TCP port number for servers supporting this protocol, but in practice any non-privileged port number can be used.

This document describes version 3.0 of the protocol, implemented in PostgreSQL 7.4 and later. For descriptions of the earlier protocol versions, see previous releases of the PostgreSQL documentation. A single server can support multiple protocol versions. The initial startup-request message tells the server which protocol version the client is attempting to use. If the major version requested by the client is not supported by the server, the connection will be rejected (for example, this would occur if the client requested protocol version 4.0, which does not exist as of this writing). If the minor version requested by the client is not supported by the server (e.g. the client requests version 3.1, but the server supports only 3.0), the server may either reject the connection or may respond with a NegotiateProtocolVersion message containing the highest minor protocol version which it supports. The client may then choose either to continue with the connection using the specified protocol version or to abort the connection.

In order to serve multiple clients efficiently, the server launches a new “backend” process for each client. In the current implementation, a new child process is created immediately after an incoming connection is detected. This is transparent to the protocol, however. For purposes of the protocol, the terms “backend” and “server” are interchangeable; likewise “frontend” and “client” are interchangeable.

49.1. Overview

The protocol has separate phases for startup and normal operation. In the startup phase, the frontend opens a connection to the server and authenticates itself to the satisfaction of the server. (This might involve a single message, or multiple messages depending on the authentication method being used.) If all goes well, the server then sends status information to the frontend, and finally enters normal operation. Except for the initial startup-request message, this part of the protocol is driven by the server.

During normal operation, the frontend sends queries and other commands to the backend, and the backend sends back query results and other responses. There are a few cases (such as NOTIFY) wherein the backend will send unsolicited messages, but for the most part this portion of a session is driven by frontend requests.

Termination of the session is normally by frontend choice, but can be forced by the backend in certain cases. In any case, when the backend closes the connection, it will roll back any open (incomplete) transaction before exiting.

Within normal operation, SQL commands can be executed through either of two sub-protocols. In the “simple query” protocol, the frontend just sends a textual query string, which is parsed and immediately executed by the backend. In the “extended query” protocol, processing of queries is separated into multiple steps: parsing, binding of parameter values, and execution. This offers flexibility and performance benefits, at the cost of extra complexity.

Normal operation has additional sub-protocols for special operations such as COPY.
49.1.1. Messaging Overview

All communication is through a stream of messages. The first byte of a message identifies the message type, and the next four bytes specify the length of the rest of the message (this length count includes itself, but not the message-type byte). The remaining contents of the message are determined by the message type. For historical reasons, the very first message sent by the client (the startup message) has no initial message-type byte.

To avoid losing synchronization with the message stream, both servers and clients typically read an entire message into a buffer (using the byte count) before attempting to process its contents. This allows easy recovery if an error is detected while processing the contents. In extreme situations (such as not having enough memory to buffer the message), the receiver can use the byte count to determine how much input to skip before it resumes reading messages.

Conversely, both servers and clients must take care never to send an incomplete message. This is commonly done by marshaling the entire message in a buffer before beginning to send it. If a communications failure occurs partway through sending or receiving a message, the only sensible response is to abandon the connection, since there is little hope of recovering message-boundary synchronization.

49.1.2. Extended Query Overview

In the extended-query protocol, execution of SQL commands is divided into multiple steps. The state retained between steps is represented by two types of objects: prepared statements and portals. A prepared statement represents the result of parsing and semantic analysis of a textual query string. A prepared statement is not in itself ready to execute, because it might lack specific values for parameters. A portal represents a ready-to-execute or already-partially-executed statement, with any missing parameter values filled in. (For SELECT statements, a portal is equivalent to an open cursor, but we choose to use a different term since cursors don’t handle non-SELECT statements.)

The overall execution cycle consists of a parse step, which creates a prepared statement from a textual query string; a bind step, which creates a portal given a prepared statement and values for any needed parameters; and an execute step that runs a portal’s query. In the case of a query that returns rows (SELECT, SHOW, etc), the execute step can be told to fetch only a limited number of rows, so that multiple execute steps might be needed to complete the operation.

The backend can keep track of multiple prepared statements and portals (but note that these exist only within a session, and are never shared across sessions). Existing prepared statements and portals are referenced by names assigned when they were created. In addition, an “unnamed” prepared statement and portal exist. Although these behave largely the same as named objects, operations on them are optimized for the case of executing a query only once and then discarding it, whereas operations on named objects are optimized on the expectation of multiple uses.

49.1.3. Formats and Format Codes

Data of a particular data type might be transmitted in any of several different formats. As of PostgreSQL 7.4 the only supported formats are “text” and “binary”, but the protocol makes provision for future extensions. The desired format for any value is specified by a format code. Clients can specify a format code for each transmitted parameter value and for each column of a query result. Text has format code zero, binary has format code one, and all other format codes are reserved for future definition.
The text representation of values is whatever strings are produced and accepted by the input/output conversion functions for the particular data type. In the transmitted representation, there is no trailing null character; the frontend must add one to received values if it wants to process them as C strings. (The text format does not allow embedded nulls, by the way.)

Binary representations for integers use network byte order (most significant byte first). For other data types consult the documentation or source code to learn about the binary representation. Keep in mind that binary representations for complex data types might change across server versions; the text format is usually the more portable choice.

49.2. Message Flow

This section describes the message flow and the semantics of each message type. (Details of the exact representation of each message appear in Section 49.5.) There are several different sub-protocols depending on the state of the connection: start-up, query, function call, COPY, and termination. There are also special provisions for asynchronous operations (including notification responses and command cancellation), which can occur at any time after the start-up phase.

49.2.1. Start-up

To begin a session, a frontend opens a connection to the server and sends a startup message. This message includes the names of the user and of the database the user wants to connect to; it also identifies the particular protocol version to be used. (Optionally, the startup message can include additional settings for run-time parameters.) The server then uses this information and the contents of its configuration files (such as pg_hba.conf) to determine whether the connection is provisionally acceptable, and what additional authentication is required (if any).

The server then sends an appropriate authentication request message, to which the frontend must reply with an appropriate authentication response message (such as a password). For all authentication methods except GSSAPI and SSPI, there is at most one request and one response. In some methods, no response at all is needed from the frontend, and so no authentication request occurs. For GSSAPI and SSPI, multiple exchanges of packets may be needed to complete the authentication.

The authentication cycle ends with the server either rejecting the connection attempt (ErrorResponse), or sending AuthenticationOk.

The possible messages from the server in this phase are:

ErrorResponse
   The connection attempt has been rejected. The server then immediately closes the connection.

AuthenticationOk
   The authentication exchange is successfully completed.

AuthenticationKerberosV5
   The frontend must now take part in a Kerberos V5 authentication dialog (not described here, part of the Kerberos specification) with the server. If this is successful, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. This is no longer supported.
AuthenticationCleartextPassword

The frontend must now send a PasswordMessage containing the password in clear-text form. If this is the correct password, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse.

AuthenticationMD5Password

The frontend must now send a PasswordMessage containing the password (with username) encrypted via MD5, then encrypted again using the 4-byte random salt specified in the AuthenticationMD5Password message. If this is the correct password, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. The actual PasswordMessage can be computed in SQL as `concat('md5', md5(concat(md5(concat(password, username)), random-salt)))`. (Keep in mind the `md5()` function returns its result as a hex string.)

AuthenticationSCMCredential

This response is only possible for local Unix-domain connections on platforms that support SCM credential messages. The frontend must issue an SCM credential message and then send a single data byte. (The contents of the data byte are uninteresting; it’s only used to ensure that the server waits long enough to receive the credential message.) If the credential is acceptable, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. (This message type is only issued by pre-9.1 servers. It may eventually be removed from the protocol specification.)

AuthenticationGSS

The frontend must now initiate a GSSAPI negotiation. The frontend will send a PasswordMessage with the first part of the GSSAPI data stream in response to this. If further messages are needed, the server will respond with AuthenticationGSSContinue.

AuthenticationSSPI

The frontend must now initiate a SSPI negotiation. The frontend will send a PasswordMessage with the first part of the SSPI data stream in response to this. If further messages are needed, the server will respond with AuthenticationGSSContinue.

AuthenticationGSSContinue

This message contains the response data from the previous step of GSSAPI or SSPI negotiation (AuthenticationGSS, AuthenticationSSPI or a previous AuthenticationGSSContinue). If the GSSAPI or SSPI data in this message indicates more data is needed to complete the authentication, the frontend must send that data as another PasswordMessage. If GSSAPI or SSPI authentication is completed by this message, the server will next send AuthenticationOk to indicate successful authentication or ErrorResponse to indicate failure.

NegotiateProtocolVersion

The server does not support the minor protocol version requested by the client, but does support an earlier version of the protocol; this message indicates the highest supported minor version. This message will also be sent if the client requested unsupported protocol options (i.e. beginning with `_pq_`) in the startup packet. This message will be followed by an ErrorResponse or a message indicating the success or failure of authentication.
If the frontend does not support the authentication method requested by the server, then it should immediately close the connection.

After having received AuthenticationOk, the frontend must wait for further messages from the server. In this phase a backend process is being started, and the frontend is just an interested bystander. It is still possible for the startup attempt to fail (ErrorResponse) or the server to decline support for the requested minor protocol version (NegotiateProtocolVersion), but in the normal case the backend will send some ParameterStatus messages, BackendKeyData, and finally ReadyForQuery.

During this phase the backend will attempt to apply any additional run-time parameter settings that were given in the startup message. If successful, these values become session defaults. An error causes ErrorResponse and exit.

The possible messages from the backend in this phase are:

**BackendKeyData**

This message provides secret-key data that the frontend must save if it wants to be able to issue cancel requests later. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

**ParameterStatus**

This message informs the frontend about the current (initial) setting of backend parameters, such as client_encoding or DateStyle. The frontend can ignore this message, or record the settings for its future use; see Section 49.2.6 for more details. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

**ReadyForQuery**

Start-up is completed. The frontend can now issue commands.

**ErrorResponse**

Start-up failed. The connection is closed after sending this message.

**NoticeResponse**

A warning message has been issued. The frontend should display the message but continue listening for ReadyForQuery or ErrorResponse.

The ReadyForQuery message is the same one that the backend will issue after each command cycle. Depending on the coding needs of the frontend, it is reasonable to consider ReadyForQuery as starting a command cycle, or to consider ReadyForQuery as ending the start-up phase and each subsequent command cycle.

### 49.2.2. Simple Query

A simple query cycle is initiated by the frontend sending a Query message to the backend. The message includes an SQL command (or commands) expressed as a text string. The backend then sends one or more response messages depending on the contents of the query command string, and finally a ReadyForQuery response message. ReadyForQuery informs the frontend that it can safely send a new command. (It is not actually necessary for the frontend to wait for ReadyForQuery before issuing another command, but
the frontend must then take responsibility for figuring out what happens if the earlier command fails and already-issued later commands succeed.

The possible response messages from the backend are:

**CommandComplete**
An SQL command completed normally.

**CopyInResponse**
The backend is ready to copy data from the frontend to a table; see Section 49.2.5.

**CopyOutResponse**
The backend is ready to copy data from a table to the frontend; see Section 49.2.5.

**RowDescription**
Indicates that rows are about to be returned in response to a `SELECT`, `FETCH`, etc query. The contents of this message describe the column layout of the rows. This will be followed by a `DataRow` message for each row being returned to the frontend.

**DataRow**
One of the set of rows returned by a `SELECT`, `FETCH`, etc query.

**EmptyQueryResponse**
An empty query string was recognized.

**ErrorResponse**
An error has occurred.

**ReadyForQuery**
Processing of the query string is complete. A separate message is sent to indicate this because the query string might contain multiple SQL commands. (CommandComplete marks the end of processing one SQL command, not the whole string.) ReadyForQuery will always be sent, whether processing terminates successfully or with an error.

**NoticeResponse**
A warning message has been issued in relation to the query. Notices are in addition to other responses, i.e., the backend will continue processing the command.

The response to a `SELECT` query (or other queries that return row sets, such as `EXPLAIN` or `SHOW`) normally consists of RowDescription, zero or more `DataRow` messages, and then CommandComplete. `COPY` to or from the frontend invokes special protocol as described in Section 49.2.5. All other query types normally produce only a CommandComplete message.

Since a query string could contain several queries (separated by semicolons), there might be several such response sequences before the backend finishes processing the query string. ReadyForQuery is issued when the entire string has been processed and the backend is ready to accept a new query string.

If a completely empty (no contents other than whitespace) query string is received, the response is EmptyQueryResponse followed by ReadyForQuery.
In the event of an error, ErrorResponse is issued followed by ReadyForQuery. All further processing of the query string is aborted by ErrorResponse (even if more queries remained in it). Note that this might occur partway through the sequence of messages generated by an individual query.

In simple Query mode, the format of retrieved values is always text, except when the given command is a FETCH from a cursor declared with the BINARY option. In that case, the retrieved values are in binary format. The format codes given in the RowDescription message tell which format is being used.

A frontend must be prepared to accept ErrorResponse and NoticeResponse messages whenever it is expecting any other type of message. See also Section 49.2.6 concerning messages that the backend might generate due to outside events.

Recommended practice is to code frontends in a state-machine style that will accept any message type at any time that it could make sense, rather than wiring in assumptions about the exact sequence of messages.

### 49.2.3. Extended Query

The extended query protocol breaks down the above-described simple query protocol into multiple steps. The results of preparatory steps can be re-used multiple times for improved efficiency. Furthermore, additional features are available, such as the possibility of supplying data values as separate parameters instead of having to insert them directly into a query string.

In the extended protocol, the frontend first sends a Parse message, which contains a textual query string, optionally some information about data types of parameter placeholders, and the name of a destination prepared-statement object (an empty string selects the unnamed prepared statement). The response is either ParseComplete or ErrorResponse. Parameter data types can be specified by OID; if not given, the parser attempts to infer the data types in the same way as it would do for untyped literal string constants.

**Note:** A parameter data type can be left unspecified by setting it to zero, or by making the array of parameter type OIDs shorter than the number of parameter symbols ($n$) used in the query string. Another special case is that a parameter’s type can be specified as void (that is, the OID of the void pseudotype). This is meant to allow parameter symbols to be used for function parameters that are actually OUT parameters. Ordinarily there is no context in which a void parameter could be used, but if such a parameter symbol appears in a function’s parameter list, it is effectively ignored. For example, a function call such as `foo($1,$2,$3,$4)` could match a function with two IN and two OUT arguments, if $3$ and $4$ are specified as having type void.

**Note:** The query string contained in a Parse message cannot include more than one SQL statement; else a syntax error is reported. This restriction does not exist in the simple-query protocol, but it does exist in the extended protocol, because allowing prepared statements or portals to contain multiple commands would complicate the protocol unduly.

If successfully created, a named prepared-statement object lasts till the end of the current session, unless explicitly destroyed. An unnamed prepared statement lasts only until the next Parse statement specifying the unnamed statement as destination is issued. (Note that a simple Query message also destroys the unnamed statement.) Named prepared statements must be explicitly closed before they can be redefined.
by another Parse message, but this is not required for the unnamed statement. Named prepared statements
can also be created and accessed at the SQL command level, using PREPARE and EXECUTE.

Once a prepared statement exists, it can be readied for execution using a Bind message. The Bind message
gives the name of the source prepared statement (empty string denotes the unnamed prepared statement),
the name of the destination portal (empty string denotes the unnamed portal), and the values to use for
any parameter placeholders present in the prepared statement. The supplied parameter set must match
those needed by the prepared statement. (If you declared any void parameters in the Parse message, pass
NULL values for them in the Bind message.) Bind also specifies the format to use for any data returned
by the query; the format can be specified overall, or per-column. The response is either BindComplete or
ErrorResponse.

**Note:** The choice between text and binary output is determined by the format codes given in Bind,
regardless of the SQL command involved. The BINARY attribute in cursor declarations is irrelevant
when using extended query protocol.

Query planning typically occurs when the Bind message is processed. If the prepared statement has no
parameters, or is executed repeatedly, the server might save the created plan and re-use it during subse-
quent Bind messages for the same prepared statement. However, it will do so only if it finds that a generic
plan can be created that is not much less efficient than a plan that depends on the specific parameter values
supplied. This happens transparently so far as the protocol is concerned.

If successfully created, a named portal object lasts till the end of the current transaction, unless explicitly
destroyed. An unnamed portal is destroyed at the end of the transaction, or as soon as the next Bind
statement specifying the unnamed portal as destination is issued. (Note that a simple Query message also
destroys the unnamed portal.) Named portals must be explicitly closed before they can be redefined by
another Bind message, but this is not required for the unnamed portal. Named portals can also be created
and accessed at the SQL command level, using DECLARE CURSOR and FETCH.

Once a portal exists, it can be executed using an Execute message. The Execute message specifies the
portal name (empty string denotes the unnamed portal) and a maximum result-row count (zero meaning
"fetch all rows"). The result-row count is only meaningful for portals containing commands that return
row sets; in other cases the command is always executed to completion, and the row count is ignored. The
possible responses to Execute are the same as those described above for queries issued via simple query
protocol, except that Execute doesn’t cause ReadyForQuery or RowDescription to be issued.

If Execute terminates before completing the execution of a portal (due to reaching a nonzero result-row
count), it will send a PortalSuspended message; the appearance of this message tells the frontend that
another Execute should be issued against the same portal to complete the operation. The CommandCom-
plete message indicating completion of the source SQL command is not sent until the portal’s execution
is completed. Therefore, an Execute phase is always terminated by the appearance of exactly one of these
messages: CommandComplete, EmptyQueryResponse (if the portal was created from an empty query
string), ErrorResponse, or PortalSuspended.

At completion of each series of extended-query messages, the frontend should issue a Sync message.
This parameterless message causes the backend to close the current transaction if it’s not inside a
BEGIN/COMMIT transaction block (“close” meaning to commit if no error, or roll back if error). Then a
ReadyForQuery response is issued. The purpose of Sync is to provide a resynchronization point for error
recovery. When an error is detected while processing any extended-query message, the backend issues
ErrorResponse, then reads and discards messages until a Sync is reached, then issues ReadyForQuery
and returns to normal message processing. (But note that no skipping occurs if an error is detected while processing Sync — this ensures that there is one and only one ReadyForQuery sent for each Sync.)

**Note:** Sync does not cause a transaction block opened with `BEGIN` to be closed. It is possible to detect this situation since the ReadyForQuery message includes transaction status information.

In addition to these fundamental, required operations, there are several optional operations that can be used with extended-query protocol.

The Describe message (portal variant) specifies the name of an existing portal (or an empty string for the unnamed portal). The response is a RowDescription message describing the rows that will be returned by executing the portal; or a NoData message if the portal does not contain a query that will return rows; or ErrorResponse if there is no such portal.

The Describe message (statement variant) specifies the name of an existing prepared statement (or an empty string for the unnamed prepared statement). The response is a ParameterDescription message describing the parameters needed by the statement, followed by a RowDescription message describing the rows that will be returned when the statement is eventually executed (or a NoData message if the statement will not return rows). ErrorResponse is issued if there is no such prepared statement. Note that since Bind has not yet been issued, the formats to be used for returned columns are not yet known to the backend; the format code fields in the RowDescription message will be zeroes in this case.

**Tip:** In most scenarios the frontend should issue one or the other variant of Describe before issuing Execute, to ensure that it knows how to interpret the results it will get back.

The Close message closes an existing prepared statement or portal and releases resources. It is not an error to issue Close against a nonexistent statement or portal name. The response is normally CloseComplete, but could be ErrorResponse if some difficulty is encountered while releasing resources. Note that closing a prepared statement implicitly closes any open portals that were constructed from that statement.

The Flush message does not cause any specific output to be generated, but forces the backend to deliver any data pending in its output buffers. A Flush must be sent after any extended-query command except Sync, if the frontend wishes to examine the results of that command before issuing more commands. Without Flush, messages returned by the backend will be combined into the minimum possible number of packets to minimize network overhead.

**Note:** The simple Query message is approximately equivalent to the series Parse, Bind, portal Describe, Execute, Close, Sync, using the unnamed prepared statement and portal objects and no parameters. One difference is that it will accept multiple SQL statements in the query string, automatically performing the bind/describe/execute sequence for each one in succession. Another difference is that it will not return ParseComplete, BindComplete, CloseComplete, or NoData messages.
49.2.4. Function Call

The Function Call sub-protocol allows the client to request a direct call of any function that exists in the database’s pg_proc system catalog. The client must have execute permission for the function.

**Note:** The Function Call sub-protocol is a legacy feature that is probably best avoided in new code. Similar results can be accomplished by setting up a prepared statement that does `SELECT function($1, ...)`. The Function Call cycle can then be replaced with Bind/Execute.

A Function Call cycle is initiated by the frontend sending a FunctionCall message to the backend. The backend then sends one or more response messages depending on the results of the function call, and finally a ReadyForQuery response message. ReadyForQuery informs the frontend that it can safely send a new query or function call.

The possible response messages from the backend are:

- **ErrorResponse**
  
  An error has occurred.

- **FunctionCallResponse**
  
  The function call was completed and returned the result given in the message. (Note that the Function Call protocol can only handle a single scalar result, not a row type or set of results.)

- **ReadyForQuery**
  
  Processing of the function call is complete. ReadyForQuery will always be sent, whether processing terminates successfully or with an error.

- **NoticeResponse**
  
  A warning message has been issued in relation to the function call. Notices are in addition to other responses, i.e., the backend will continue processing the command.

49.2.5. COPY Operations

The **COPY** command allows high-speed bulk data transfer to or from the server. Copy-in and copy-out operations each switch the connection into a distinct sub-protocol, which lasts until the operation is completed.

Copy-in mode (data transfer to the server) is initiated when the backend executes a `COPY FROM STDIN` SQL statement. The backend sends a CopyInResponse message to the frontend. The frontend should then send zero or more CopyData messages, forming a stream of input data. (The message boundaries are not required to have anything to do with row boundaries, although that is often a reasonable choice.) The frontend can terminate the copy-in mode by sending either a CopyDone message (allowing successful termination) or a CopyFail message (which will cause the **COPY** SQL statement to fail with an error). The backend then reverts to the command-processing mode it was in before the **COPY** started, which will be either simple or extended query protocol. It will next send either CommandComplete (if successful) or ErrorResponse (if not).
In the event of a backend-detected error during copy-in mode (including receipt of a CopyFail message), the backend will issue an ErrorResponse message. If the COPY command was issued via an extended-query message, the backend will now discard frontend messages until a Sync message is received, then it will issue ReadyForQuery and return to normal processing. If the COPY command was issued in a simple Query message, the rest of that message is discarded and ReadyForQuery is issued. In either case, any subsequent CopyData, CopyDone, or CopyFail messages issued by the frontend will simply be dropped.

The backend will ignore Flush and Sync messages received during copy-in mode. Receipt of any other non-copy message type constitutes an error that will abort the copy-in state as described above. (The exception for Flush and Sync is for the convenience of client libraries that always send Flush or Sync after an Execute message, without checking whether the command to be executed is a COPY FROM STDIN.)

Copy-out mode (data transfer from the server) is initiated when the backend executes a COPY TO STDOUT SQL statement. The backend sends a CopyOutResponse message to the frontend, followed by zero or more CopyData messages (always one per row), followed by CopyDone. The backend then reverts to the command-processing mode it was in before the COPY started, and sends CommandComplete. The frontend cannot abort the transfer (except by closing the connection or issuing a Cancel request), but it can discard unwanted CopyData and CopyDone messages.

In the event of a backend-detected error during copy-out mode, the backend will issue an ErrorResponse message and revert to normal processing. The frontend should treat receipt of ErrorResponse as terminating the copy-out mode.

It is possible for NoticeResponse and ParameterStatus messages to be interspersed between CopyData messages; frontends must handle these cases, and should be prepared for other asynchronous message types as well (see Section 49.2.6). Otherwise, any message type other than CopyData or CopyDone may be treated as terminating copy-out mode.

There is another Copy-related mode called copy-both, which allows high-speed bulk data transfer to and from the server. Copy-both mode is initiated when a backend in walsender mode executes a START_REPLICATION statement. The backend sends a CopyBothResponse message to the frontend. Both the backend and the frontend may then send CopyData messages until either end sends a CopyDone message. After the client sends a CopyDone message, the connection goes from copy-both mode to copy-out mode, and the client may not send any more CopyData messages. Similarly, when the server sends a CopyDone message, the connection goes into copy-in mode, and the server may not send any more CopyData messages. After both sides have sent a CopyDone message, the copy mode is terminated, and the backend reverts to the command-processing mode. In the event of a backend-detected error during copy-both mode, the backend will issue an ErrorResponse message, discard frontend messages until a Sync message is received, and then issue ReadyForQuery and return to normal processing. The frontend should treat receipt of ErrorResponse as terminating the copy in both directions; no CopyDone should be sent in this case. See Section 49.3 for more information on the subprotocol transmitted over copy-both mode.

The CopyInResponse, CopyOutResponse and CopyBothResponse messages include fields that inform the frontend of the number of columns per row and the format codes being used for each column. (As of the present implementation, all columns in a given COPY operation will use the same format, but the message design does not assume this.)
49.2.6. Asynchronous Operations

There are several cases in which the backend will send messages that are not specifically prompted by the frontend’s command stream. Frontends must be prepared to deal with these messages at any time, even when not engaged in a query. At minimum, one should check for these cases before beginning to read a query response.

It is possible for NoticeResponse messages to be generated due to outside activity; for example, if the database administrator commands a “fast” database shutdown, the backend will send a NoticeResponse indicating this fact before closing the connection. Accordingly, frontends should always be prepared to accept and display NoticeResponse messages, even when the connection is nominally idle.

ParameterStatus messages will be generated whenever the active value changes for any of the parameters the backend believes the frontend should know about. Most commonly this occurs in response to a SET SQL command executed by the frontend, and this case is effectively synchronous — but it is also possible for parameter status changes to occur because the administrator changed a configuration file and then sent the SIGHUP signal to the server. Also, if a SET command is rolled back, an appropriate ParameterStatus message will be generated to report the current effective value.

At present there is a hard-wired set of parameters for which ParameterStatus will be generated: they are server_version, server_encoding, client_encoding, application_name, is_superuser, session_authorization, DateStyle, IntervalStyle, TimeZone, integer_datetimes, and standard_conforming_strings. (server_encoding, TimeZone, and integer_datetimes were not reported by releases before 8.0; standard_conforming_strings was not reported by releases before 8.1; IntervalStyle was not reported by releases before 8.4; application_name was not reported by releases before 9.0.) Note that server_version, server_encoding and integer_datetimes are pseudo-parameters that cannot change after startup. This set might change in the future, or even become configurable. Accordingly, a frontend should simply ignore ParameterStatus for parameters that it does not understand or care about.

If a frontend issues a LISTEN command, then the backend will send a NotificationResponse message (not to be confused with NoticeResponse!) whenever a NOTIFY command is executed for the same channel name.

Note: At present, NotificationResponse can only be sent outside a transaction, and thus it will not occur in the middle of a command-response series, though it might occur just before ReadyForQuery. It is unwise to design frontend logic that assumes that, however. Good practice is to be able to accept NotificationResponse at any point in the protocol.

49.2.7. Canceling Requests in Progress

During the processing of a query, the frontend might request cancellation of the query. The cancel request is not sent directly on the open connection to the backend for reasons of implementation efficiency: we don’t want to have the backend constantly checking for new input from the frontend during query processing. Cancel requests should be relatively infrequent, so we make them slightly cumbersome in order to avoid a penalty in the normal case.

To issue a cancel request, the frontend opens a new connection to the server and sends a CancelRequest message, rather than the StartupMessage message that would ordinarily be sent across a new connection.
Chapter 49. Frontend/Backend Protocol

The server will process this request and then close the connection. For security reasons, no direct reply is made to the cancel request message.

A CancelRequest message will be ignored unless it contains the same key data (PID and secret key) passed to the frontend during connection start-up. If the request matches the PID and secret key for a currently executing backend, the processing of the current query is aborted. (In the existing implementation, this is done by sending a special signal to the backend process that is processing the query.)

The cancellation signal might or might not have any effect — for example, if it arrives after the backend has finished processing the query, then it will have no effect. If the cancellation is effective, it results in the current command being terminated early with an error message.

The upshot of all this is that for reasons of both security and efficiency, the frontend has no direct way to tell whether a cancel request has succeeded. It must continue to wait for the backend to respond to the query. Issuing a cancel simply improves the odds that the current query will finish soon, and improves the odds that it will fail with an error message instead of succeeding.

Since the cancel request is sent across a new connection to the server and not across the regular frontend/backend communication link, it is possible for the cancel request to be issued by any process, not just the frontend whose query is to be canceled. This might provide additional flexibility when building multiple-process applications. It also introduces a security risk, in that unauthorized persons might try to cancel queries. The security risk is addressed by requiring a dynamically generated secret key to be supplied in cancel requests.

49.2.8. Termination

The normal, graceful termination procedure is that the frontend sends a Terminate message and immediately closes the connection. On receipt of this message, the backend closes the connection and terminates.

In rare cases (such as an administrator-commanded database shutdown) the backend might disconnect without any frontend request to do so. In such cases the backend will attempt to send an error or notice message giving the reason for the disconnection before it closes the connection.

Other termination scenarios arise from various failure cases, such as core dump at one end or the other, loss of the communications link, loss of message-boundary synchronization, etc. If either frontend or backend sees an unexpected closure of the connection, it should clean up and terminate. The frontend has the option of launching a new backend by recontacting the server if it doesn’t want to terminate itself. Closing the connection is also advisable if an unrecognizable message type is received, since this probably indicates loss of message-boundary sync.

For either normal or abnormal termination, any open transaction is rolled back, not committed. One should note however that if a frontend disconnects while a non-SELECT query is being processed, the backend will probably finish the query before noticing the disconnection. If the query is outside any transaction block (BEGIN ... COMMIT sequence) then its results might be committed before the disconnection is recognized.

49.2.9. SSL Session Encryption

If PostgreSQL was built with SSL support, frontend/backend communications can be encrypted using SSL. This provides communication security in environments where attackers might be able to capture the session traffic. For more information on encrypting PostgreSQL sessions with SSL, see Section 17.9.
To initiate an SSL-encrypted connection, the frontend initially sends an SSLRequest message rather than a StartupMessage. The server then responds with a single byte containing S or N, indicating that it is willing or unwilling to perform SSL, respectively. The frontend might close the connection at this point if it is dissatisfied with the response. To continue after S, perform an SSL startup handshake (not described here, part of the SSL specification) with the server. If this is successful, continue with sending the usual StartupMessage. In this case the StartupMessage and all subsequent data will be SSL-encrypted. To continue after N, send the usual StartupMessage and proceed without encryption.

The frontend should also be prepared to handle an ErrorMessage response to SSLRequest from the server. This would only occur if the server predates the addition of SSL support to PostgreSQL. (Such servers are now very ancient, and likely do not exist in the wild anymore.) In this case the connection must be closed, but the frontend might choose to open a fresh connection and proceed without requesting SSL.

An initial SSLRequest can also be used in a connection that is being opened to send a CancelRequest message.

While the protocol itself does not provide a way for the server to force SSL encryption, the administrator can configure the server to reject unencrypted sessions as a byproduct of authentication checking.

### 49.3. Streaming Replication Protocol

To initiate streaming replication, the frontend sends the replication parameter in the startup message. A Boolean value of true tells the backend to go into walsender mode, wherein a small set of replication commands can be issued instead of SQL statements. Only the simple query protocol can be used in walsender mode. Passing database as the value instructs walsender to connect to the database specified in the dbname parameter, which will allow the connection to be used for logical replication from that database.

For the purpose of testing replication commands, you can make a replication connection via psql or any other libpq-using tool with a connection string including the replication option, e.g.:

```bash
psql "dbname=postgres replication=database" -c "IDENTIFY_SYSTEM;"
```

However it is often more useful to use pg_receivexlog (for physical replication) or pg_recvlogical (for logical replication).

The commands accepted in walsender mode are:

**IDENTIFY_SYSTEM**

Requests the server to identify itself. Server replies with a result set of a single row, containing four fields:

- **systemid**
  - The unique system identifier identifying the cluster. This can be used to check that the base backup used to initialize the standby came from the same cluster.

- **timeline**
  - Current TimelineID. Also useful to check that the standby is consistent with the master.
Chapter 49. Frontend/Backend Protocol

xlogpos
Current xlog flush location. Useful to get a known location in the transaction log where streaming can start.

dbname
Database connected to or NULL.

TIMELINE_HISTORY tli
Requests the server to send over the timeline history file for timeline tli. Server replies with a result set of a single row, containing two fields:

filename
Filename of the timeline history file, e.g. 00000002.history.

content
Contents of the timeline history file.

CREATE_REPLICATION_SLOT slot_name { PHYSICAL | LOGICAL output_plugin }
Create a physical or logical replication slot. See Section 25.2.6 for more about replication slots.

slot_name
The name of the slot to create. Must be a valid replication slot name (see Section 25.2.6.1).

output_plugin
The name of the output plugin used for logical decoding (see Section 46.6).

START_REPLICATION [SLOT slot_name] [PHYSICAL] XXX/XXX [TIMELINE tli]
Instructs server to start streaming WAL, starting at WAL position XXX/XXX. If TIMELINE option is specified, streaming starts on timeline tli; otherwise, the server’s current timeline is selected. The server can reply with an error, e.g. if the requested section of WAL has already been recycled. On success, server responds with a CopyBothResponse message, and then starts to stream WAL to the frontend.

If a slot’s name is provided via slot_name, it will be updated as replication progresses so that the server knows which WAL segments, and if hot_standby_feedback is on which transactions, are still needed by the standby.

If the client requests a timeline that’s not the latest, but is part of the history of the server, the server will stream all the WAL on that timeline starting from the requested startpoint, up to the point where the server switched to another timeline. If the client requests streaming at exactly the end of an old timeline, the server responds immediately with CommandComplete without entering COPY mode.

After streaming all the WAL on a timeline that is not the latest one, the server will end streaming by exiting the COPY mode. When the client acknowledges this by also exiting COPY mode, the server sends a result set with one row and two columns, indicating the next timeline in this server’s history. The first column is the next timeline’s ID, and the second column is the XLOG position where the switch happened. Usually, the switch position is the end of the WAL that was streamed, but there
are corner cases where the server can send some WAL from the old timeline that it has not itself replayed before promoting. Finally, the server sends CommandComplete message, and is ready to accept a new command.

WAL data is sent as a series of CopyData messages. (This allows other information to be intermixed; in particular the server can send an ErrorResponse message if it encounters a failure after beginning to stream.) The payload of each CopyData message from server to the client contains a message of one of the following formats:

XLogData (B)

Byte1(‘w’)
Identifies the message as WAL data.

Int64
The starting point of the WAL data in this message.

Int64
The current end of WAL on the server.

Int64
The server’s system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte:
A section of the WAL data stream.
A single WAL record is never split across two XLogData messages. When a WAL record crosses a WAL page boundary, and is therefore already split using continuation records, it can be split at the page boundary. In other words, the first main WAL record and its continuation records can be sent in different XLogData messages.

Primary keepalive message (B)

Byte1(‘k’)
Identifies the message as a sender keepalive.

Int64
The current end of WAL on the server.

Int64
The server’s system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte1
1 means that the client should reply to this message as soon as possible, to avoid a timeout disconnect. 0 otherwise.
The receiving process can send replies back to the sender at any time, using one of the following message formats (also in the payload of a CopyData message):

**Standby status update (F)**

- Byte1 (‘r’)
  - Identifies the message as a receiver status update.
- Int64
  - The location of the last WAL byte + 1 received and written to disk in the standby.
- Int64
  - The location of the last WAL byte + 1 flushed to disk in the standby.
- Int64
  - The location of the last WAL byte + 1 applied in the standby.
- Int64
  - The client’s system clock at the time of transmission, as microseconds since midnight on 2000-01-01.
- Byte1
  - If 1, the client requests the server to reply to this message immediately. This can be used to ping the server, to test if the connection is still healthy.

**Hot Standby feedback message (F)**

- Byte1 (‘h’)
  - Identifies the message as a Hot Standby feedback message.
- Int64
  - The client’s system clock at the time of transmission, as microseconds since midnight on 2000-01-01.
- Int32
  - The standby’s current xmin. This may be 0, if the standby is sending notification that Hot Standby feedback will no longer be sent on this connection. Later non-zero messages may reinitiate the feedback mechanism.
- Int32
  - The standby’s current epoch.
START_REPLICATION SLOT slot_name LOGICAL XXX/XXX [(option_name [option_value] [,... ])]

Instructs server to start streaming WAL for logical replication, starting at WAL position XXX/XXX. The server can reply with an error, e.g. if the requested section of WAL has already been recycled. On success, server responds with a CopyBothResponse message, and then starts to stream WAL to the frontend.

The messages inside the CopyBothResponse messages are of the same format documented for START_REPLICATION ... PHYSICAL.

The output plugin associated with the selected slot is used to process the output for streaming.

SLOT slot_name

The name of the slot to stream changes from. This parameter is required, and must correspond to an existing logical replication slot created with CREATE_REPLICATION_SLOT in LOGICAL mode.

XXX/XXX

The WAL position to begin streaming at.

option_name

The name of an option passed to the slot’s logical decoding plugin.

option_value

Optional value, in the form of a string constant, associated with the specified option.

DROP_REPLICATION_SLOT slot_name

Drops a replication slot, freeing any reserved server-side resources. If the slot is currently in use by an active connection, this command fails.

slot_name

The name of the slot to drop.

BASE_BACKUP [LABEL 'label'] [PROGRESS] [FAST] [WAL] [NOWAIT] [MAX_RATE rate]

Instructs the server to start streaming a base backup. The system will automatically be put in backup mode before the backup is started, and taken out of it when the backup is complete. The following options are accepted:

LABEL 'label'

Sets the label of the backup. If none is specified, a backup label of base backup will be used. The quoting rules for the label are the same as a standard SQL string with standard_conforming_strings turned on.

PROGRESS

Request information required to generate a progress report. This will send back an approximate size in the header of each tablespace, which can be used to calculate how far along the stream is done. This is calculated by enumerating all the file sizes once before the transfer is even started, and may as such have a negative impact on the performance - in particular it may take longer before the first data is streamed. Since the database files can change during the backup, the size
is only approximate and may both grow and shrink between the time of approximation and the sending of the actual files.

**FAST**

Request a fast checkpoint.

**WAL**

Include the necessary WAL segments in the backup. This will include all the files between start and stop backup in the `pg_xlog` directory of the base directory tar file.

**NOWAIT**

By default, the backup will wait until the last required xlog segment has been archived, or emit a warning if log archiving is not enabled. Specifying `NOWAIT` disables both the waiting and the warning, leaving the client responsible for ensuring the required log is available.

**MAX_RATE rate**

Limit (throttle) the maximum amount of data transferred from server to client per unit of time. The expected unit is kilobytes per second. If this option is specified, the value must either be equal to zero or it must fall within the range from 32 kB through 1 GB (inclusive). If zero is passed or the option is not specified, no restriction is imposed on the transfer.

When the backup is started, the server will first send two ordinary result sets, followed by one or more CopyResponse results.

The first ordinary result set contains the starting position of the backup, in a single row with two columns. The first column contains the start position given in XLogRecPtr format, and the second column contains the corresponding timeline ID.

The second ordinary result set has one row for each tablespace. The fields in this row are:

- **spcoid**
  The oid of the tablespace, or `NULL` if it’s the base directory.

- **spclocation**
  The full path of the tablespace directory, or `NULL` if it’s the base directory.

- **size**
  The approximate size of the tablespace, if progress report has been requested; otherwise it’s `NULL`.

After the second regular result set, one or more CopyResponse results will be sent, one for PGDATA and one for each additional tablespace other than `pg_default` and `pg_global`. The data in the CopyResponse results will be a tar format (following the “ustar interchange format” specified in the POSIX 1003.1-2008 standard) dump of the tablespace contents, except that the two trailing blocks of zeroes specified in the standard are omitted. After the tar data is complete, a final ordinary result set will be sent, containing the WAL end position of the backup, in the same format as the start position.
Chapter 49. Frontend/Backend Protocol

The tar archive for the data directory and each tablespace will contain all files in the directories, regardless of whether they are PostgreSQL files or other files added to the same directory. The only excluded files are:

- `postmaster.pid`
- `postmaster.opts`
- various temporary files created during the operation of the PostgreSQL server
- `pg_xlog`, including subdirectories. If the backup is run with WAL files included, a synthesized version of `pg_xlog` will be included, but it will only contain the files necessary for the backup to work, not the rest of the contents.
- `pg_replslot` is copied as an empty directory.
- Files other than regular files and directories, such as symbolic links and special device files, are skipped. (Symbolic links in `pg_tblspc` are maintained.)

Owner, group and file mode are set if the underlying file system on the server supports it.

Once all tablespaces have been sent, a final regular result set will be sent. This result set contains the end position of the backup, given in XLogRecPtr format as a single column in a single row.

49.4. Message Data Types

This section describes the base data types used in messages.

\textbf{Int}n(i)

An \( n \)-bit integer in network byte order (most significant byte first). If \( i \) is specified it is the exact value that will appear, otherwise the value is variable. Eg. Int16, Int32(42).

\textbf{Int}n[k]

An array of \( k \) \( n \)-bit integers, each in network byte order. The array length \( k \) is always determined by an earlier field in the message. Eg. Int16[M].

\textbf{String}(s)

A null-terminated string (C-style string). There is no specific length limitation on strings. If \( s \) is specified it is the exact value that will appear, otherwise the value is variable. Eg. String, String("user").

\textbf{Note}: There is no predefined limit on the length of a string that can be returned by the backend. Good coding strategy for a frontend is to use an expandable buffer so that anything that fits in memory can be accepted. If that’s not feasible, read the full string and discard trailing characters that don’t fit into your fixed-size buffer.

\textbf{Byte}n(c)

Exactly \( n \) bytes. If the field width \( n \) is not a constant, it is always determinable from an earlier field in the message. If \( c \) is specified it is the exact value. Eg. Byte2, Byte1(‘\n’).
49.5. Message Formats

This section describes the detailed format of each message. Each is marked to indicate that it can be sent by a frontend (F), a backend (B), or both (F & B). Notice that although each message includes a byte count at the beginning, the message format is defined so that the message end can be found without reference to the byte count. This aids validity checking. (The CopyData message is an exception, because it forms part of a data stream; the contents of any individual CopyData message cannot be interpretable on their own.)

AuthenticationOk (B)

- Byte1(‘R’)
  - Identifies the message as an authentication request.
- Int32(8)
  - Length of message contents in bytes, including self.
- Int32(0)
  - Specifies that the authentication was successful.

AuthenticationKerberosV5 (B)

- Byte1(‘R’)
  - Identifies the message as an authentication request.
- Int32(8)
  - Length of message contents in bytes, including self.
- Int32(2)
  - Specifies that Kerberos V5 authentication is required.

AuthenticationCleartextPassword (B)

- Byte1(‘R’)
  - Identifies the message as an authentication request.
- Int32(8)
  - Length of message contents in bytes, including self.
- Int32(3)
  - Specifies that a clear-text password is required.

AuthenticationMD5Password (B)

- Byte1(‘R’)
  - Identifies the message as an authentication request.
Int32(12)
Length of message contents in bytes, including self.

Int32(5)
Specifies that an MD5-encrypted password is required.

Byte4
The salt to use when encrypting the password.

AuthenticationSCMCredential (B)

Byte1('R')
Identifies the message as an authentication request.

Int32(8)
Length of message contents in bytes, including self.

Int32(6)
Specifies that an SCM credentials message is required.

AuthenticationGSS (B)

Byte1('R')
Identifies the message as an authentication request.

Int32(8)
Length of message contents in bytes, including self.

Int32(7)
Specifies that GSSAPI authentication is required.

AuthenticationSSPI (B)

Byte1('R')
Identifies the message as an authentication request.

Int32(8)
Length of message contents in bytes, including self.

Int32(9)
Specifies that SSPI authentication is required.
Chapter 49. Frontend/Backend Protocol

AuthenticationGSSContinue (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(8)

Specifies that this message contains GSSAPI or SSPI data.

Byte

GSSAPI or SSPI authentication data.

BackendKeyData (B)

Byte1('K')

Identifies the message as cancellation key data. The frontend must save these values if it wishes to be able to issue CancelRequest messages later.

Int32(12)

Length of message contents in bytes, including self.

Int32

The process ID of this backend.

Int32

The secret key of this backend.

Bind (F)

Byte1('B')

Identifies the message as a Bind command.

Int32

Length of message contents in bytes, including self.

String

The name of the destination portal (an empty string selects the unnamed portal).

String

The name of the source prepared statement (an empty string selects the unnamed prepared statement).
Int16
The number of parameter format codes that follow (denoted \( C \) below). This can be zero to indicate that there are no parameters or that the parameters all use the default format (text); or one, in which case the specified format code is applied to all parameters; or it can equal the actual number of parameters.

Int16\([C]\)
The parameter format codes. Each must presently be zero (text) or one (binary).

Int16
The number of parameter values that follow (possibly zero). This must match the number of parameters needed by the query.

Next, the following pair of fields appear for each parameter:

Int32
The length of the parameter value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL parameter value. No value bytes follow in the NULL case.

Byte\( n \)
The value of the parameter, in the format indicated by the associated format code. \( n \) is the above length.

After the last parameter, the following fields appear:

Int16
The number of result-column format codes that follow (denoted \( R \) below). This can be zero to indicate that there are no result columns or that the result columns should all use the default format (text); or one, in which case the specified format code is applied to all result columns (if any); or it can equal the actual number of result columns of the query.

Int16\([R]\)
The result-column format codes. Each must presently be zero (text) or one (binary).

BindComplete (B)

Byte1(’2’)
Identifies the message as a Bind-complete indicator.

Int32(4)
Length of message contents in bytes, including self.

CancelRequest (F)

Int32(16)
Length of message contents in bytes, including self.
Int32(80877102)

The cancel request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5678 in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

Int32

The process ID of the target backend.

Int32

The secret key for the target backend.

Close (F)

Byte1('C')

Identifies the message as a Close command.

Int32

Length of message contents in bytes, including self.

Byte1

'S' to close a prepared statement; or 'P' to close a portal.

String

The name of the prepared statement or portal to close (an empty string selects the unnamed prepared statement or portal).

CloseComplete (B)

Byte1('3')

Identifies the message as a Close-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

CommandComplete (B)

Byte1('C')

Identifies the message as a command-completed response.

Int32

Length of message contents in bytes, including self.

String

The command tag. This is usually a single word that identifies which SQL command was completed.
For an INSERT command, the tag is INSERT oid rows, where rows is the number of rows inserted. oid is the object ID of the inserted row if rows is 1 and the target table has OIDs; otherwise oid is 0.

For a DELETE command, the tag is DELETE rows where rows is the number of rows deleted.

For an UPDATE command, the tag is UPDATE rows where rows is the number of rows updated.

For a SELECT or CREATE TABLE AS command, the tag is SELECT rows where rows is the number of rows retrieved.

For a MOVE command, the tag is MOVE rows where rows is the number of rows the cursor’s position has been changed by.

For a FETCH command, the tag is FETCH rows where rows is the number of rows that have been retrieved from the cursor.

For a COPY command, the tag is COPY rows where rows is the number of rows copied. (Note: the row count appears only in PostgreSQL 8.2 and later.)

CopyData (F & B)

Byte1(‘d’)
  Identifies the message as COPY data.

Int32
  Length of message contents in bytes, including self.

Byte
  Data that forms part of a COPY data stream. Messages sent from the backend will always correspond to single data rows, but messages sent by frontends might divide the data stream arbitrarily.

CopyDone (F & B)

Byte1(‘c’)
  Identifies the message as a COPY-complete indicator.

Int32(4)
  Length of message contents in bytes, including self.

CopyFail (F)

Byte1(‘f’)
  Identifies the message as a COPY-failure indicator.

Int32
  Length of message contents in bytes, including self.
String
An error message to report as the cause of failure.

CopyInResponse (B)

Byte1('G')
Identifies the message as a Start Copy In response. The frontend must now send copy-in data (if not prepared to do so, send a CopyFail message).

Int32
Length of message contents in bytes, including self.

Int8
0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16
The number of columns in the data to be copied (denoted \( N \) below).

Int16[\( N \)]
The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

CopyOutResponse (B)

Byte1('H')
Identifies the message as a Start Copy Out response. This message will be followed by copy-out data.

Int32
Length of message contents in bytes, including self.

Int8
0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16
The number of columns in the data to be copied (denoted \( N \) below).

Int16[\( N \)]
The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.
CopyBothResponse (B)

Byte1('W')
   Identifies the message as a Start Copy Both response. This message is used only for Streaming Replication.

Int32
   Length of message contents in bytes, including self.

Int8
   0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16
   The number of columns in the data to be copied (denoted $N$ below).

Int16[$N$]
   The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

DataRow (B)

Byte1('D')
   Identifies the message as a data row.

Int32
   Length of message contents in bytes, including self.

Int16
   The number of column values that follow (possibly zero).

Next, the following pair of fields appear for each column:

Int32
   The length of the column value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL column value. No value bytes follow in the NULL case.

Byte$n$
   The value of the column, in the format indicated by the associated format code. $n$ is the above length.

Describe (F)

Byte1('D')
   Identifies the message as a Describe command.
Chapter 49. Frontend/Backend Protocol

Int32
Length of message contents in bytes, including self.

Byte1
'S' to describe a prepared statement; or 'P' to describe a portal.

String
The name of the prepared statement or portal to describe (an empty string selects the unnamed prepared statement or portal).

EmptyQueryResponse (B)

Byte1('I')
Identifies the message as a response to an empty query string. (This substitutes for Command-Complete.)

Int32(4)
Length of message contents in bytes, including self.

ErrorResponse (B)

Byte1('E')
Identifies the message as an error.

Int32
Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:

Byte1
A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in Section 49.6. Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

String
The field value.

Execute (F)

Byte1('E')
Identifies the message as an Execute command.

Int32
Length of message contents in bytes, including self.
String
The name of the portal to execute (an empty string selects the unnamed portal).

Int32
Maximum number of rows to return, if portal contains a query that returns rows (ignored otherwise). Zero denotes “no limit”.

Flush (F)

Byte1(‘H’)
Identifies the message as a Flush command.

Int32(4)
Length of message contents in bytes, including self.

FunctionCall (F)

Byte1(‘F’)
Identifies the message as a function call.

Int32
Length of message contents in bytes, including self.

Int32
Specifies the object ID of the function to call.

Int16
The number of argument format codes that follow (denoted \( \mathbf{c} \) below). This can be zero to indicate that there are no arguments or that the arguments all use the default format (text); or one, in which case the specified format code is applied to all arguments; or it can equal the actual number of arguments.

Int16[\( \mathbf{c} \)]
The argument format codes. Each must presently be zero (text) or one (binary).

Int16
Specifies the number of arguments being supplied to the function.

Next, the following pair of fields appear for each argument:

Int32
The length of the argument value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL argument value. No value bytes follow in the NULL case.

Byte\( n \)
The value of the argument, in the format indicated by the associated format code. \( n \) is the above length.
Chapter 49. Frontend/Backend Protocol

After the last argument, the following field appears:

Int16

The format code for the function result. Must presently be zero (text) or one (binary).

FunctionCallResponse (B)

Byte1('V')

Identifies the message as a function call result.

Int32

Length of message contents in bytes, including self.

Int32

The length of the function result value, in bytes (this count does not include itself). Can be zero.
As a special case, -1 indicates a NULL function result. No value bytes follow in the NULL case.

Byte

The value of the function result, in the format indicated by the associated format code. \( n \) is the above length.

NegotiateProtocolVersion (B)

Byte1('v')

Identifies the message as a protocol version negotiation message.

Int32

Length of message contents in bytes, including self.

Int32

Newest minor protocol version supported by the server for the major protocol version requested by the client.

Int32

Number of protocol options not recognized by the server.

Then, for protocol option not recognized by the server, there is the following:

String

The option name.

NoData (B)

Byte1('n')

Identifies the message as a no-data indicator.
Chapter 49. Frontend/Backend Protocol

Int32(4)

Length of message contents in bytes, including self.

NoticeResponse (B)

Byte1('N')

Identifies the message as a notice.

Int32

Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:

Byte1

A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in Section 49.6. Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

String

The field value.

NotificationResponse (B)

Byte1('A')

Identifies the message as a notification response.

Int32

Length of message contents in bytes, including self.

Int32

The process ID of the notifying backend process.

String

The name of the channel that the notify has been raised on.

String

The “payload” string passed from the notifying process.

ParameterDescription (B)

Byte1('t')

Identifies the message as a parameter description.

Int32

Length of message contents in bytes, including self.
Chapter 49. Frontend/Backend Protocol

Int16
The number of parameters used by the statement (can be zero).

Then, for each parameter, there is the following:

Int32
Specifies the object ID of the parameter data type.

ParameterStatus (B)

Byte1('S')
Identifies the message as a run-time parameter status report.

Int32
Length of message contents in bytes, including self.

String
The name of the run-time parameter being reported.

String
The current value of the parameter.

Parse (F)

Byte1('P')
Identifies the message as a Parse command.

Int32
Length of message contents in bytes, including self.

String
The name of the destination prepared statement (an empty string selects the unnamed prepared statement).

String
The query string to be parsed.

Int16
The number of parameter data types specified (can be zero). Note that this is not an indication of the number of parameters that might appear in the query string, only the number that the frontend wants to prespecify types for.

Then, for each parameter, there is the following:
Int32
  Specifies the object ID of the parameter data type. Placing a zero here is equivalent to leaving
  the type unspecified.

ParseComplete (B)

Byte1('1')
  Identifies the message as a Parse-complete indicator.

Int32(4)
  Length of message contents in bytes, including self.

PasswordMessage (F)

Byte1('p')
  Identifies the message as a password response. Note that this is also used for GSSAPI and
  SSPI response messages (which is really a design error, since the contained data is not a null-
  terminated string in that case, but can be arbitrary binary data).

Int32
  Length of message contents in bytes, including self.

String
  The password (encrypted, if requested).

PortalSuspended (B)

Byte1('s')
  Identifies the message as a portal-suspended indicator. Note this only appears if an Execute
  message’s row-count limit was reached.

Int32(4)
  Length of message contents in bytes, including self.

Query (F)

Byte1('Q')
  Identifies the message as a simple query.

Int32
  Length of message contents in bytes, including self.
Chapter 49. Frontend/Backend Protocol

String
The query string itself.

ReadyForQuery (B)

Byte1('Z')
Identifies the message type. ReadyForQuery is sent whenever the backend is ready for a new
query cycle.

Int32(5)
Length of message contents in bytes, including self.

Byte1
Current backend transaction status indicator. Possible values are 'I' if idle (not in a transaction
block); 'T' if in a transaction block; or 'E' if in a failed transaction block (queries will be rejected
until block is ended).

RowDescription (B)

Byte1('T')
Identifies the message as a row description.

Int32
Length of message contents in bytes, including self.

Int16
Specifies the number of fields in a row (can be zero).

Then, for each field, there is the following:

String
The field name.

Int32
If the field can be identified as a column of a specific table, the object ID of the table; otherwise
zero.

Int16
If the field can be identified as a column of a specific table, the attribute number of the column;
otherwise zero.

Int32
The object ID of the field's data type.

Int16
The data type size (see \texttt{pg\_type\_typlen}). Note that negative values denote variable-width
types.
Chapter 49. Frontend/Backend Protocol

Int32

The type modifier (see pg_attribute.atttypmod). The meaning of the modifier is type-specific.

Int16

The format code being used for the field. Currently will be zero (text) or one (binary). In a RowDescription returned from the statement variant of Describe, the format code is not yet known and will always be zero.

SSLRequest (F)

Int32(8)

Length of message contents in bytes, including self.

Int32(80877103)

The SSL request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5679 in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

StartupMessage (F)

Int32

Length of message contents in bytes, including self.

Int32(196608)

The protocol version number. The most significant 16 bits are the major version number (3 for the protocol described here). The least significant 16 bits are the minor version number (0 for the protocol described here).

The protocol version number is followed by one or more pairs of parameter name and value strings. A zero byte is required as a terminator after the last name/value pair. Parameters can appear in any order. user is required, others are optional. Each parameter is specified as:

String

The parameter name. Currently recognized names are:

user

The database user name to connect as. Required; there is no default.

database

The database to connect to. Defaults to the user name.

options

Command-line arguments for the backend. (This is deprecated in favor of setting individual run-time parameters.)
In addition to the above, other parameters may be listed. Parameter names beginning with \_pq\_ are reserved for use as protocol extensions, while others are treated as run-time parameters to be set at backend start time. Such settings will be applied during backend start (after parsing the command-line arguments if any) and will act as session defaults.

String

The parameter value.

Sync (F)

Byte1('S')

Identifies the message as a Sync command.

Int32(4)

Length of message contents in bytes, including self.

Terminate (F)

Byte1('X')

Identifies the message as a termination.

Int32(4)

Length of message contents in bytes, including self.

49.6. Error and Notice Message Fields

This section describes the fields that can appear in ErrorResponse and NoticeResponse messages. Each field type has a single-byte identification token. Note that any given field type should appear at most once per message.

S

Severity: the field contents are ERROR, FATAL, or PANIC (in an error message), or WARNING, NOTICE, DEBUG, INFO, or LOG (in a notice message), or a localized translation of one of these. Always present.

C

Code: the SQLSTATE code for the error (see Appendix A). Not localizable. Always present.

M

Message: the primary human-readable error message. This should be accurate but terse (typically one line). Always present.
Chapter 49. Frontend/Backend Protocol

D
Detail: an optional secondary error message carrying more detail about the problem. Might run to multiple lines.

H
Hint: an optional suggestion what to do about the problem. This is intended to differ from Detail in that it offers advice (potentially inappropriate) rather than hard facts. Might run to multiple lines.

P
Position: the field value is a decimal ASCII integer, indicating an error cursor position as an index into the original query string. The first character has index 1, and positions are measured in characters not bytes.

P
Internal position: this is defined the same as the P field, but it is used when the cursor position refers to an internally generated command rather than the one submitted by the client. The q field will always appear when this field appears.

q
Internal query: the text of a failed internally-generated command. This could be, for example, a SQL query issued by a PL/pgSQL function.

W
Where: an indication of the context in which the error occurred. Presently this includes a call stack traceback of active procedural language functions and internally-generated queries. The trace is one entry per line, most recent first.

s
Schema name: if the error was associated with a specific database object, the name of the schema containing that object, if any.

t
Table name: if the error was associated with a specific table, the name of the table. (Refer to the schema name field for the name of the table’s schema.)

c
Column name: if the error was associated with a specific table column, the name of the column. (Refer to the schema and table name fields to identify the table.)

d
Data type name: if the error was associated with a specific data type, the name of the data type. (Refer to the schema name field for the name of the data type’s schema.)

n
Constraint name: if the error was associated with a specific constraint, the name of the constraint. Refer to fields listed above for the associated table or domain. (For this purpose, indexes are treated as constraints, even if they weren’t created with constraint syntax.)

F
File: the file name of the source-code location where the error was reported.
49.7. Summary of Changes since Protocol 2.0

This section provides a quick checklist of changes, for the benefit of developers trying to update existing client libraries to protocol 3.0.

The initial startup packet uses a flexible list-of-strings format instead of a fixed format. Notice that session default values for run-time parameters can now be specified directly in the startup packet. (Actually, you could do that before using the `options` field, but given the limited width of `options` and the lack of any way to quote whitespace in the values, it wasn’t a very safe technique.)

All messages now have a length count immediately following the message type byte (except for startup packets, which have no type byte). Also note that PasswordMessage now has a type byte.

ErrorResponse and NoticeResponse (‘E’ and ‘N’) messages now contain multiple fields, from which the client code can assemble an error message of the desired level of verbosity. Note that individual fields will typically not end with a newline, whereas the single string sent in the older protocol always did.

The ReadyForQuery (‘Z’) message includes a transaction status indicator.

The distinction between BinaryRow andDataRow message types is gone; the single DataRow message type serves for returning data in all formats. Note that the layout of DataRow has changed to make it easier to parse. Also, the representation of binary values has changed: it is no longer directly tied to the server’s internal representation.

There is a new “extended query” sub-protocol, which adds the frontend message types Parse, Bind, Execute, Describe, Close, Flush, and Sync, and the backend message types ParseComplete, BindComplete, PortalSuspended, ParameterDescription, NoData, and CloseComplete. Existing clients do not have to concern themselves with this sub-protocol, but making use of it might allow improvements in performance or functionality.

COPY data is now encapsulated into CopyData and CopyDone messages. There is a well-defined way to recover from errors during COPY. The special “\.” last line is not needed anymore, and is not sent during COPY OUT. (It is still recognized as a terminator during COPY IN, but its use is deprecated and...
will eventually be removed.) Binary COPY is supported. The CopyInResponse and CopyOutResponse messages include fields indicating the number of columns and the format of each column.

The layout of FunctionCall and FunctionCallResponse messages has changed. FunctionCall can now support passing NULL arguments to functions. It also can handle passing parameters and retrieving results in either text or binary format. There is no longer any reason to consider FunctionCall a potential security hole, since it does not offer direct access to internal server data representations.

The backend sends ParameterStatus (‘S’) messages during connection startup for all parameters it considers interesting to the client library. Subsequently, a ParameterStatus message is sent whenever the active value changes for any of these parameters.

The RowDescription (‘T’) message carries new table OID and column number fields for each column of the described row. It also shows the format code for each column.

The CursorResponse (‘P’) message is no longer generated by the backend.

The NotificationResponse (‘A’) message has an additional string field, which can carry a “payload” string passed from the NOTIFY event sender.

The EmptyQueryResponse (‘I’) message used to include an empty string parameter; this has been removed.
Chapter 50. PostgreSQL Coding Conventions

50.1. Formatting

Source code formatting uses 4 column tab spacing, with tabs preserved (i.e., tabs are not expanded to spaces). Each logical indentation level is one additional tab stop.

Layout rules (brace positioning, etc) follow BSD conventions. In particular, curly braces for the controlled blocks of if, while, switch, etc go on their own lines.

Limit line lengths so that the code is readable in an 80-column window. (This doesn’t mean that you must never go past 80 columns. For instance, breaking a long error message string in arbitrary places just to keep the code within 80 columns is probably not a net gain in readability.)

Do not use C++ style comments (/ / comments). Strict ANSI C compilers do not accept them. For the same reason, do not use C++ extensions such as declaring new variables mid-block.

The preferred style for multi-line comment blocks is

/*
 * comment text begins here
 * and continues here
 */

Note that comment blocks that begin in column 1 will be preserved as-is by pgindent, but it will re-flow indented comment blocks as though they were plain text. If you want to preserve the line breaks in an indented block, add dashes like this:

/----------
 * comment text begins here
 * and continues here
----------
 */

While submitted patches do not absolutely have to follow these formatting rules, it’s a good idea to do so. Your code will get run through pgindent before the next release, so there’s no point in making it look nice under some other set of formatting conventions. A good rule of thumb for patches is “make the new code look like the existing code around it”.

The src/tools directory contains sample settings files that can be used with the emacs, xemacs or vim editors to help ensure that they format code according to these conventions.

The text browsing tools more and less can be invoked as:

more -x4
less -x4

to make them show tabs appropriately.
50.2. Reporting Errors Within the Server

Error, warning, and log messages generated within the server code should be created using `ereport`, or its older cousin `elog`. The use of this function is complex enough to require some explanation.

There are two required elements for every message: a severity level (ranging from `DEBUG` to `PANIC`) and a primary message text. In addition there are optional elements, the most common of which is an error identifier code that follows the SQL spec’s SQLSTATE conventions. `ereport` itself is just a shell function, that exists mainly for the syntactic convenience of making message generation look like a function call in the C source code. The only parameter accepted directly by `ereport` is the severity level. The primary message text and any optional message elements are generated by calling auxiliary functions, such as `errmsg`, within the `ereport` call.

A typical call to `ereport` might look like this:

```c
ereport(ERROR,
            (errcode(ERRCODE_DIVISION_BY_ZERO),
                errmsg("division by zero")));
```

This specifies error severity level `ERROR` (a run-of-the-mill error). The `errcode` call specifies the SQLSTATE error code using a macro defined in `src/include/utils/errcodes.h`. The `errmsg` call provides the primary message text. Notice the extra set of parentheses surrounding the auxiliary function calls — these are annoying but syntactically necessary.

Here is a more complex example:

```c
ereport(ERROR,
            (errcode(ERRCODE_AMBIGUOUS_FUNCTION),
                errmsg("function %s is not unique",
                    func_signature_string(funcname, nargs, NIL, actual_arg_types)),
                errhint("Unable to choose a best candidate function. "
                    "You might need to add explicit typecasts.")));)
```

This illustrates the use of format codes to embed run-time values into a message text. Also, an optional “hint” message is provided.

If the severity level is `ERROR` or higher, `ereport` aborts the execution of the user-defined function and does not return to the caller. If the severity level is lower than `ERROR`, `ereport` returns normally.

The available auxiliary routines for `ereport` are:

- `errcode(sqlerrcode)` specifies the SQLSTATE error identifier code for the condition. If this routine is not called, the error identifier defaults to `ERRCODE_INTERNAL_ERROR` when the error severity level is `ERROR` or higher, `ERRCODE_WARNING` when the error level is `WARNING`, otherwise (for `NOTICE` and below) `ERRCODE_SUCCESSFUL_COMPLETION`. While these defaults are often convenient, always think whether they are appropriate before omitting the `errcode()` call.

- `errmsg(const char *msg, ...)` specifies the primary error message text, and possibly run-time values to insert into it. Insertions are specified by `sprintf`-style format codes. In addition to the standard format codes accepted by `sprintf`, the format code `%m` can be used to insert the error message
returned by `strerror` for the current value of `errno`.\(^1\) `\%m` does not require any corresponding entry in the parameter list for `errmsg`. Note that the message string will be run through `gettext` for possible localization before format codes are processed.

- `errmsg_internal(const char *msg, ...)` is the same as `errmsg`, except that the message string will not be translated nor included in the internationalization message dictionary. This should be used for “cannot happen” cases that are probably not worth expending translation effort on.

- `errmsg_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)` is like `errmsg`, but with support for various plural forms of the message. `fmt_singular` is the English singular format, `fmt_plural` is the English plural format, `n` is the integer value that determines which plural form is needed, and the remaining arguments are formatted according to the selected format string. For more information see Section 51.2.2.

- `errdetail(const char *msg, ...)` supplies an optional “detail” message; this is to be used when there is additional information that seems inappropriate to put in the primary message. The message string is processed in just the same way as for `errmsg`.

- `errdetail_internal(const char *msg, ...)` is the same as `errdetail`, except that the message string will not be translated nor included in the internationalization message dictionary. This should be used for detail messages that are not worth expending translation effort on, for instance because they are too technical to be useful to most users.

- `errdetail_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)` is like `errdetail`, but with support for various plural forms of the message. For more information see Section 51.2.2.

- `errdetail_log(const char *msg, ...)` is the same as `errdetail` except that this string goes only to the server log, never to the client. If both `errdetail` (or one of its equivalents above) and `errdetail_log` are used then one string goes to the client and the other to the log. This is useful for error details that are too security-sensitive or too bulky to include in the report sent to the client.

- `errdetail_log_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)` is like `errdetail_log`, but with support for various plural forms of the message. For more information see Section 51.2.2.

- `errhint(const char *msg, ...)` supplies an optional “hint” message; this is to be used when offering suggestions about how to fix the problem, as opposed to factual details about what went wrong. The message string is processed in just the same way as for `errmsg`.

- `errcontext(const char *msg, ...)` is not normally called directly from an `ereport` message site; rather it is used in `error_context_stack` callback functions to provide information about the context in which an error occurred, such as the current location in a PL function. The message string is processed in just the same way as for `errmsg`. Unlike the other auxiliary functions, this can be called more than once per `ereport` call; the successive strings thus supplied are concatenated with separating newlines.

- `errposition(int cursorpos)` specifies the textual location of an error within a query string. Currently it is only useful for errors detected in the lexical and syntactic analysis phases of query processing.

\(^1\) That is, the value that was current when the `ereport` call was reached; changes of `errno` within the auxiliary reporting routines will not affect it. That would not be true if you were to write `strerror(errno)` explicitly in `errmsg`'s parameter list; accordingly, do not do so.
Chapter 50. PostgreSQL Coding Conventions

- `errtable(Relation rel)` specifies a relation whose name and schema name should be included as auxiliary fields in the error report.
- `errtablecol(Relation rel, int attnum)` specifies a column whose name, table name, and schema name should be included as auxiliary fields in the error report.
- `errtableconstraint(Relation rel, const char *conname)` specifies a table constraint whose name, table name, and schema name should be included as auxiliary fields in the error report. Indexes should be considered to be constraints for this purpose, whether or not they have an associated `pg_constraint` entry. Be careful to pass the underlying heap relation, not the index itself, as `rel`.
- `errdatatype(Oid datatypeOid)` specifies a data type whose name and schema name should be included as auxiliary fields in the error report.
- `errdomainconstraint(Oid datatypeOid, const char *conname)` specifies a domain constraint whose name, domain name, and schema name should be included as auxiliary fields in the error report.
- `errcode_for_file_access()` is a convenience function that selects an appropriate SQLSTATE error identifier for a failure in a file-access-related system call. It uses the saved `errno` to determine which error code to generate. Usually this should be used in combination with `%m` in the primary error message text.
- `errcode_for_socket_access()` is a convenience function that selects an appropriate SQLSTATE error identifier for a failure in a socket-related system call.
- `errhidestmt(bool hide_stmt)` can be called to specify suppression of the `STATEMENT:` portion of a message in the postmaster log. Generally this is appropriate if the message text includes the current statement already.

**Note:** At most one of the functions `errtable`, `errtablecol`, `errtableconstraint`, `errdatatype`, or `errdomainconstraint` should be used in an `ereport` call. These functions exist to allow applications to extract the name of a database object associated with the error condition without having to examine the potentially-localized error message text. These functions should be used in error reports for which it's likely that applications would wish to have automatic error handling. As of PostgreSQL 9.3, complete coverage exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

There is an older function `elog` that is still heavily used. An `elog` call:

```c
elog(level, "format string", ...);
```

is exactly equivalent to:

```c
ereport(level, (errmsg_internal("format string", ...)));
```

Notice that the SQLSTATE error code is always defaulted, and the message string is not subject to translation. Therefore, `elog` should be used only for internal errors and low-level debug logging. Any message that is likely to be of interest to ordinary users should go through `ereport`. Nonetheless, there are enough internal “cannot happen” error checks in the system that `elog` is still widely used; it is preferred for those messages for its notational simplicity.
50.3. Error Message Style Guide

This style guide is offered in the hope of maintaining a consistent, user-friendly style throughout all the messages generated by PostgreSQL.

50.3.1. What Goes Where

The primary message should be short, factual, and avoid reference to implementation details such as specific function names. “Short” means “should fit on one line under normal conditions”. Use a detail message if needed to keep the primary message short, or if you feel a need to mention implementation details such as the particular system call that failed. Both primary and detail messages should be factual. Use a hint message for suggestions about what to do to fix the problem, especially if the suggestion might not always be applicable.

For example, instead of:

```
IpcMemoryCreate: shmget(key=%d, size=%u, 0%o) failed: %m
(plus a long addendum that is basically a hint)
```

write:

```
Primary: could not create shared memory segment: %m
Detail:   Failed syscall was shmget(key=%d, size=%u, 0%o).
Hint:    the addendum
```

Rationale: keeping the primary message short helps keep it to the point, and lets clients lay out screen space on the assumption that one line is enough for error messages. Detail and hint messages can be relegated to a verbose mode, or perhaps a pop-up error-details window. Also, details and hints would normally be suppressed from the server log to save space. Reference to implementation details is best avoided since users don’t know the details anyway.

50.3.2. Formatting

Don’t put any specific assumptions about formatting into the message texts. Expect clients and the server log to wrap lines to fit their own needs. In long messages, newline characters (\n) can be used to indicate suggested paragraph breaks. Don’t end a message with a newline. Don’t use tabs or other formatting characters. (In error context displays, newlines are automatically added to separate levels of context such as function calls.)

Rationale: Messages are not necessarily displayed on terminal-type displays. In GUI displays or browsers these formatting instructions are at best ignored.
50.3.3. Quotation Marks

English text should use double quotes when quoting is appropriate. Text in other languages should con-
sistently use one kind of quotes that is consistent with publishing customs and computer output of other
programs.

Rationale: The choice of double quotes over single quotes is somewhat arbitrary, but tends to be the
preferred use. Some have suggested choosing the kind of quotes depending on the type of object according
to SQL conventions (namely, strings single quoted, identifiers double quoted). But this is a language-
internal technical issue that many users aren’t even familiar with, it won’t scale to other kinds of quoted
terms, it doesn’t translate to other languages, and it’s pretty pointless, too.

50.3.4. Use of Quotes

Use quotes always to delimit file names, user-supplied identifiers, and other variables that might contain
words. Do not use them to mark up variables that will not contain words (for example, operator names).

There are functions in the backend that will double-quote their own output at need (for example,
format_type_be()). Do not put additional quotes around the output of such functions.

Rationale: Objects can have names that create ambiguity when embedded in a message. Be consistent
about denoting where a plugged-in name starts and ends. But don’t clutter messages with unnecessary or
duplicate quote marks.

50.3.5. Grammar and Punctuation

The rules are different for primary error messages and for detail/hint messages:

Primary error messages: Do not capitalize the first letter. Do not end a message with a period. Do not even
think about ending a message with an exclamation point.

Detail and hint messages: Use complete sentences, and end each with a period. Capitalize the first word
of sentences. Put two spaces after the period if another sentence follows (for English text; might be inap-
propriate in other languages).

Error context strings: Do not capitalize the first letter and do not end the string with a period. Context
strings should normally not be complete sentences.

Rationale: Avoiding punctuation makes it easier for client applications to embed the message into a variety
of grammatical contexts. Often, primary messages are not grammatically complete sentences anyway.
(And if they’re long enough to be more than one sentence, they should be split into primary and detail
parts.) However, detail and hint messages are longer and might need to include multiple sentences. For
consistency, they should follow complete-sentence style even when there’s only one sentence.

50.3.6. Upper Case vs. Lower Case

Use lower case for message wording, including the first letter of a primary error message. Use upper case
for SQL commands and key words if they appear in the message.
Rationale: It’s easier to make everything look more consistent this way, since some messages are complete sentences and some not.

50.3.7. Avoid Passive Voice

Use the active voice. Use complete sentences when there is an acting subject (“A could not do B”). Use telegram style without subject if the subject would be the program itself; do not use “I” for the program.

Rationale: The program is not human. Don’t pretend otherwise.

50.3.8. Present vs. Past Tense

Use past tense if an attempt to do something failed, but could perhaps succeed next time (perhaps after fixing some problem). Use present tense if the failure is certainly permanent.

There is a nontrivial semantic difference between sentences of the form:

could not open file "%s": %m

and:

cannot open file "%s"

The first one means that the attempt to open the file failed. The message should give a reason, such as “disk full” or “file doesn’t exist”. The past tense is appropriate because next time the disk might not be full anymore or the file in question might exist.

The second form indicates that the functionality of opening the named file does not exist at all in the program, or that it’s conceptually impossible. The present tense is appropriate because the condition will persist indefinitely.

Rationale: Granted, the average user will not be able to draw great conclusions merely from the tense of the message, but since the language provides us with a grammar we should use it correctly.

50.3.9. Type of the Object

When citing the name of an object, state what kind of object it is.

Rationale: Otherwise no one will know what “foo.bar.baz” refers to.

50.3.10. Brackets

Square brackets are only to be used (1) in command synopses to denote optional arguments, or (2) to denote an array subscript.

Rationale: Anything else does not correspond to widely-known customary usage and will confuse people.
50.3.11. Assembling Error Messages

When a message includes text that is generated elsewhere, embed it in this style:

could not open file %s: %m

Rationale: It would be difficult to account for all possible error codes to paste this into a single smooth sentence, so some sort of punctuation is needed. Putting the embedded text in parentheses has also been suggested, but it’s unnatural if the embedded text is likely to be the most important part of the message, as is often the case.

50.3.12. Reasons for Errors

Messages should always state the reason why an error occurred. For example:

BAD:   could not open file %s
BETTER: could not open file %s (I/O failure)

If no reason is known you better fix the code.

50.3.13. Function Names

Don’t include the name of the reporting routine in the error text. We have other mechanisms for finding that out when needed, and for most users it’s not helpful information. If the error text doesn’t make as much sense without the function name, reword it.

BAD:   pg_atoi: error in "z": cannot parse "z"
BETTER: invalid input syntax for integer: "z"

Avoid mentioning called function names, either; instead say what the code was trying to do:

BAD:   open() failed: %m
BETTER: could not open file %s: %m

If it really seems necessary, mention the system call in the detail message. (In some cases, providing the actual values passed to the system call might be appropriate information for the detail message.)
Rationale: Users don’t know what all those functions do.

50.3.14. Tricky Words to Avoid

Unable. “Unable” is nearly the passive voice. Better use “cannot” or “could not”, as appropriate.
Bad. Error messages like “bad result” are really hard to interpret intelligently. It’s better to write why the result is “bad”, e.g., “invalid format”.
Illegal. “Illegal” stands for a violation of the law, the rest is “invalid”. Better yet, say why it’s invalid.
**Unknown.** Try to avoid “unknown”. Consider “error: unknown response”. If you don’t know what the response is, how do you know it’s erroneous? “Unrecognized” is often a better choice. Also, be sure to include the value being complained of.

**BAD:** unknown node type  
**BETTER:** unrecognized node type: 42

**Find vs. Exists.** If the program uses a nontrivial algorithm to locate a resource (e.g., a path search) and that algorithm fails, it is fair to say that the program couldn’t “find” the resource. If, on the other hand, the expected location of the resource is known but the program cannot access it there then say that the resource doesn’t “exist”. Using “find” in this case sounds weak and confuses the issue.

**May vs. Can vs. Might.** “May” suggests permission (e.g., ”You may borrow my rake.”), and has little use in documentation or error messages. “Can” suggests ability (e.g., ”I can lift that log.”), and “might” suggests possibility (e.g., ”It might rain today.”). Using the proper word clarifies meaning and assists translation.

**Contractions.** Avoid contractions, like “can’t”; use “cannot” instead.

### 50.3.15. Proper Spelling

Spell out words in full. For instance, avoid:

- spec
- stats
- parens
- auth
- xact

**Rationale:** This will improve consistency.

### 50.3.16. Localization

Keep in mind that error message texts need to be translated into other languages. Follow the guidelines in Section 51.2.2 to avoid making life difficult for translators.
Chapter 51. Native Language Support

51.1. For the Translator

PostgreSQL programs (server and client) can issue their messages in your favorite language — if the messages have been translated. Creating and maintaining translated message sets needs the help of people who speak their own language well and want to contribute to the PostgreSQL effort. You do not have to be a programmer at all to do this. This section explains how to help.

51.1.1. Requirements

We won’t judge your language skills — this section is about software tools. Theoretically, you only need a text editor. But this is only in the unlikely event that you do not want to try out your translated messages. When you configure your source tree, be sure to use the --enable-nls option. This will also check for the libintl library and the msgfmt program, which all end users will need anyway. To try out your work, follow the applicable portions of the installation instructions.

If you want to start a new translation effort or want to do a message catalog merge (described later), you will need the programs xgettext and msgmerge, respectively, in a GNU-compatible implementation. Later, we will try to arrange it so that if you use a packaged source distribution, you won’t need xgettext. (If working from Git, you will still need it.) GNU Gettext 0.10.36 or later is currently recommended.

Your local gettext implementation should come with its own documentation. Some of that is probably duplicated in what follows, but for additional details you should look there.

51.1.2. Concepts

The pairs of original (English) messages and their (possibly) translated equivalents are kept in message catalogs, one for each program (although related programs can share a message catalog) and for each target language. There are two file formats for message catalogs: The first is the “PO” file (for Portable Object), which is a plain text file with special syntax that translators edit. The second is the “MO” file (for Machine Object), which is a binary file generated from the respective PO file and is used while the internationalized program is run. Translators do not deal with MO files; in fact hardly anyone does.

The extension of the message catalog file is to no surprise either .po or .mo. The base name is either the name of the program it accompanies, or the language the file is for, depending on the situation. This is a bit confusing. Examples are psql.po (PO file for psql) or fr.mo (MO file in French).

The file format of the PO files is illustrated here:

```
# comment
msgid "original string"
msgstr "translated string"
```
Chapter 51. Native Language Support

msgid "more original"
msgstr "another translated"
"string can be broken up like this"

... The msgid’s are extracted from the program source. (They need not be, but this is the most common way.) The msgstr lines are initially empty and are filled in with useful strings by the translator. The strings can contain C-style escape characters and can be continued across lines as illustrated. (The next line must start at the beginning of the line.)

The # character introduces a comment. If whitespace immediately follows the # character, then this is a comment maintained by the translator. There can also be automatic comments, which have a non-whitespace character immediately following the #. These are maintained by the various tools that operate on the PO files and are intended to aid the translator.

#. automatic comment
#: filename.c:1023
#, flags, flags

The #. style comments are extracted from the source file where the message is used. Possibly the programmer has inserted information for the translator, such as about expected alignment. The #: comment indicates the exact location(s) where the message is used in the source. The translator need not look at the program source, but he can if there is doubt about the correct translation. The #. comments contain flags that describe the message in some way. There are currently two flags: fuzzy is set if the message has possibly been outdated because of changes in the program source. The translator can then verify this and possibly remove the fuzzy flag. Note that fuzzy messages are not made available to the end user. The other flag is c-format, which indicates that the message is a printf-style format template. This means that the translation should also be a format string with the same number and type of placeholders. There are tools that can verify this, which key off the c-format flag.

51.1.3. Creating and Maintaining Message Catalogs

OK, so how does one create a “blank” message catalog? First, go into the directory that contains the program whose messages you want to translate. If there is a file nls.mk, then this program has been prepared for translation.

If there are already some .po files, then someone has already done some translation work. The files are named language.po, where language is the ISO 639-1 two-letter language code (in lower case)\(^1\), e.g., fr.po for French. If there is really a need for more than one translation effort per language then the files can also be named language_region.po where region is the ISO 3166-1 two-letter country code (in upper case)\(^2\), e.g., pt_BR.po for Portuguese in Brazil. If you find the language you wanted you can just start working on that file.

If you need to start a new translation effort, then first run the command:

make init-po

\(^2\) [http://www.iso.org/iso/country_names_and_code_elements](http://www.iso.org/iso/country_names_and_code_elements)
This will create a file `progname.pot`. (.pot to distinguish it from PO files that are “in production”. The T stands for “template.”) Copy this file to `language.po` and edit it. To make it known that the new language is available, also edit the file `nls.mk` and add the language (or language and country) code to the line that looks like:

```
AVAIL_LANGUAGES := de fr
```

(Other languages can appear, of course.)

As the underlying program or library changes, messages might be changed or added by the programmers. In this case you do not need to start from scratch. Instead, run the command:

```
make update-po
```

which will create a new blank message catalog file (the pot file you started with) and will merge it with the existing PO files. If the merge algorithm is not sure about a particular message it marks it “fuzzy” as explained above. The new PO file is saved with a `.po.new` extension.

### 51.1.4. Editing the PO Files

The PO files can be edited with a regular text editor. The translator should only change the area between the quotes after the `msgstr` directive, add comments, and alter the fuzzy flag. There is (unsurprisingly) a PO mode for Emacs, which I find quite useful.

The PO files need not be completely filled in. The software will automatically fall back to the original string if no translation (or an empty translation) is available. It is no problem to submit incomplete translations for inclusions in the source tree; that gives room for other people to pick up your work. However, you are encouraged to give priority to removing fuzzy entries after doing a merge. Remember that fuzzy entries will not be installed; they only serve as reference for what might be the right translation.

Here are some things to keep in mind while editing the translations:

- Make sure that if the original ends with a newline, the translation does, too. Similarly for tabs, etc.
- If the original is a `printf` format string, the translation also needs to be. The translation also needs to have the same format specifiers in the same order. Sometimes the natural rules of the language make this impossible or at least awkward. In that case you can modify the format specifiers like this:

  ```
  msgstr "Die Datei %2$s hat %1$u Zeichen."
  ```

  Then the first placeholder will actually use the second argument from the list. The `digits$` needs to follow the `%` immediately, before any other format manipulators. (This feature really exists in the `printf` family of functions. You might not have heard of it before because there is little use for it outside of message internationalization.)

- If the original string contains a linguistic mistake, report that (or fix it yourself in the program source) and translate normally. The corrected string can be merged in when the program sources have been updated. If the original string contains a factual mistake, report that (or fix it yourself) and do not translate it. Instead, you can mark the string with a comment in the PO file.

- Maintain the style and tone of the original string. Specifically, messages that are not sentences (cannot open file `%s`) should probably not start with a capital letter (if your language distinguishes letter
case) or end with a period (if your language uses punctuation marks). It might help to read Section 50.3.

- If you don’t know what a message means, or if it is ambiguous, ask on the developers’ mailing list. Chances are that English speaking end users might also not understand it or find it ambiguous, so it's best to improve the message.

51.2. For the Programmer

51.2.1. Mechanics

This section describes how to implement native language support in a program or library that is part of the PostgreSQL distribution. Currently, it only applies to C programs.

Adding NLS Support to a Program

1. Insert this code into the start-up sequence of the program:

```c
#ifdef ENABLE_NLS
#include <locale.h>
#endif

... 

#ifdef ENABLE_NLS
setlocale(LC_ALL, ""));
bindtextdomain("profilename", LOCALEDIR);
textdomain("profilename");
#endif

(The profilename can actually be chosen freely.)

2. Wherever a message that is a candidate for translation is found, a call to gettext() needs to be inserted. E.g.:

```c
fprintf(stderr, "panic level %d\n", lvl);
```would be changed to:

```c
fprintf(stderr, gettext("panic level %d\n"), lvl);
```

(gettext is defined as a no-op if NLS support is not configured.)

This tends to add a lot of clutter. One common shortcut is to use:

```c
#define _(x) gettext(x)
```

Another solution is feasible if the program does much of its communication through one or a few functions, such as ereport() in the backend. Then you make this function call gettext internally on all input strings.

3. Add a file nls.mk in the directory with the program sources. This file will be read as a makefile. The following variable assignments need to be made here:
Chapter 51. Native Language Support

CATALOG_NAME

The program name, as provided in the textdomain() call.

AVAIL_LANGUAGES

List of provided translations — initially empty.

GETTEXT_FILES

List of files that contain translatable strings, i.e., those marked with gettext or an alternative solution. Eventually, this will include nearly all source files of the program. If this list gets too long you can make the first “file” be a + and the second word be a file that contains one file name per line.

GETTEXT_TRIGGERS

The tools that generate message catalogs for the translators to work on need to know what function calls contain translatable strings. By default, only gettext() calls are known. If you used _ or other identifiers you need to list them here. If the translatable string is not the first argument, the item needs to be of the form func:2 (for the second argument). If you have a function that supports pluralized messages, the item should look like func:1,2 (identifying the singular and plural message arguments).

The build system will automatically take care of building and installing the message catalogs.

51.2.2. Message-writing Guidelines

Here are some guidelines for writing messages that are easily translatable.

• Do not construct sentences at run-time, like:

  printf("Files were %s.\n", flag ? "copied" : "removed");

  The word order within the sentence might be different in other languages. Also, even if you remember to call gettext() on each fragment, the fragments might not translate well separately. It’s better to duplicate a little code so that each message to be translated is a coherent whole. Only numbers, file names, and such-like run-time variables should be inserted at run time into a message text.

• For similar reasons, this won’t work:

  printf("copied %d file%s", n, n!=1 ? "s" : "");

  because it assumes how the plural is formed. If you figured you could solve it like this:

  if (n==1)
    printf("copied 1 file");
  else
    printf("copied %d files", n):

  then be disappointed. Some languages have more than two forms, with some peculiar rules. It’s often best to design the message to avoid the issue altogether, for instance like this:

  printf("number of copied files: %d", n);
Chapter 51. Native Language Support

If you really want to construct a properly pluralized message, there is support for this, but it’s a bit awkward. When generating a primary or detail error message in `ereport()`, you can write something like this:

```c
errmsg_plural("copied %d file",
    "copied %d files",
    n,
    n)
```

The first argument is the format string appropriate for English singular form, the second is the format string appropriate for English plural form, and the third is the integer control value that determines which plural form to use. Subsequent arguments are formatted per the format string as usual. (Normally, the pluralization control value will also be one of the values to be formatted, so it has to be written twice.) In English it only matters whether \( n \) is 1 or not 1, but in other languages there can be many different plural forms. The translator sees the two English forms as a group and has the opportunity to supply multiple substitute strings, with the appropriate one being selected based on the run-time value of \( n \).

If you need to pluralize a message that isn’t going directly to an `errmsg` or `errdetail` report, you have to use the underlying function `ngettext`. See the gettext documentation.

- If you want to communicate something to the translator, such as about how a message is intended to line up with other output, precede the occurrence of the string with a comment that starts with `translator`, e.g.:

  ```c
  /* translator: This message is not what it seems to be. */
  ```

These comments are copied to the message catalog files so that the translators can see them.
Chapter 52. Writing A Procedural Language Handler

All calls to functions that are written in a language other than the current “version 1” interface for compiled languages (this includes functions in user-defined procedural languages, functions written in SQL, and functions using the version 0 compiled language interface) go through a call handler function for the specific language. It is the responsibility of the call handler to execute the function in a meaningful way, such as by interpreting the supplied source text. This chapter outlines how a new procedural language’s call handler can be written.

The call handler for a procedural language is a “normal” function that must be written in a compiled language such as C, using the version-1 interface, and registered with PostgreSQL as taking no arguments and returning the type `language_handler`. This special pseudotype identifies the function as a call handler and prevents it from being called directly in SQL commands. For more details on C language calling conventions and dynamic loading, see Section 35.9.

The call handler is called in the same way as any other function: It receives a pointer to a `FunctionCallInfoData` struct containing argument values and information about the called function, and it is expected to return a `Datum` result (and possibly set the `isnull` field of the `FunctionCallInfoData` structure, if it wishes to return an SQL null result). The difference between a call handler and an ordinary callee function is that the `flinfo->fn_oid` field of the `FunctionCallInfoData` structure will contain the OID of the actual function to be called, not of the call handler itself. The call handler must use this field to determine which function to execute. Also, the passed argument list has been set up according to the declaration of the target function, not of the call handler.

It’s up to the call handler to fetch the entry of the function from the `pg_proc` system catalog and to analyze the argument and return types of the called function. The `AS` clause from the `CREATE FUNCTION` command for the function will be found in the `prosrc` column of the `pg_proc` row. This is commonly source text in the procedural language, but in theory it could be something else, such as a path name to a file, or anything else that tells the call handler what to do in detail.

Often, the same function is called many times per SQL statement. A call handler can avoid repeated lookups of information about the called function by using the `flinfo->fn_extra` field. This will initially be `NULL`, but can be set by the call handler to point at information about the called function. On subsequent calls, if `flinfo->fn_extra` is already non-`NULL` then it can be used and the information lookup step skipped. The call handler must make sure that `flinfo->fn_extra` is made to point at memory that will live at least until the end of the current query, since an `FmgrInfo` data structure could be kept that long. One way to do this is to allocate the extra data in the memory context specified by `flinfo->fn_mcxt`; such data will normally have the same lifespan as the `FmgrInfo` itself. But the handler could also choose to use a longer-lived memory context so that it can cache function definition information across queries.

When a procedural-language function is invoked as a trigger, no arguments are passed in the usual way, but the `FunctionCallInfoData's context` field points at a `TriggerData` structure, rather than being `NULL` as it is in a plain function call. A language handler should provide mechanisms for procedural-
language functions to get at the trigger information.

This is a template for a procedural-language handler written in C:

```c
#include "postgres.h"
#include "executor/spi.h"
#include "commands/trigger.h"
#include "fmgr.h"
#include "access/heapam.h"
#include "utils/syscache.h"
#include "catalog/pg_proc.h"
#include "catalog/pg_type.h"

#ifdef PG_MODULE_MAGIC
PG_MODULE_MAGIC;
#endif

PG_FUNCTION_INFO_V1(plsample_call_handler);

Datum
plsample_call_handler(PG_FUNCTION_ARGS)
{
    Datum retval;

    if (CALLED_AS_TRIGGER(fcinfo))
    {
        /*
         * Called as a trigger procedure
         */
        TriggerData *trigdata = (TriggerData *) fcinfo->context;
        retval = ...;
    }
    else
    {
        /*
         * Called as a function
         */
        retval = ...;
    }

    return retval;
}
```

Only a few thousand lines of code have to be added instead of the dots to complete the call handler. After having compiled the handler function into a loadable module (see Section 35.9.6), the following commands then register the sample procedural language:

```sql
CREATE FUNCTION plsample_call_handler() RETURNS language_handler
    AS 'filename'
    LANGUAGE C;
CREATE LANGUAGE plsample
```
Although providing a call handler is sufficient to create a minimal procedural language, there are two other functions that can optionally be provided to make the language more convenient to use. These are a validator and an inline handler. A validator can be provided to allow language-specific checking to be done during CREATE FUNCTION. An inline handler can be provided to allow the language to support anonymous code blocks executed via the DO command.

If a validator is provided by a procedural language, it must be declared as a function taking a single parameter of type oid. The validator’s result is ignored, so it is customarily declared to return void. The validator will be called at the end of a CREATE FUNCTION command that has created or updated a function written in the procedural language. The passed-in OID is the OID of the function’s pg_proc row. The validator must fetch this row in the usual way, and do whatever checking is appropriate. First, call CheckFunctionValidatorAccess() to diagnose explicit calls to the validator that the user could not achieve through CREATE FUNCTION. Typical checks then include verifying that the function’s argument and result types are supported by the language, and that the function’s body is syntactically correct in the language. If the validator finds the function to be okay, it should just return. If it finds an error, it should report that via the normal ereport() error reporting mechanism. Throwing an error will force a transaction rollback and thus prevent the incorrect function definition from being committed.

Validator functions should typically honor the check_function_bodies parameter: if it is turned off then any expensive or context-sensitive checking should be skipped. If the language provides for code execution at compilation time, the validator must suppress checks that would induce such execution. In particular, this parameter is turned off by pg_dump so that it can load procedural language functions without worrying about side effects or dependencies of the function bodies on other database objects. (Because of this requirement, the call handler should avoid assuming that the validator has fully checked the function. The point of having a validator is not to let the call handler omit checks, but to notify the user immediately if there are obvious errors in a CREATE FUNCTION command.) While the choice of exactly what to check is mostly left to the discretion of the validator function, note that the core CREATE FUNCTION code only executes SET clauses attached to a function when check_function_bodies is on. Therefore, checks whose results might be affected by GUC parameters definitely should be skipped when check_function_bodies is off, to avoid false failures when reloading a dump.

If an inline handler is provided by a procedural language, it must be declared as a function taking a single parameter of type internal. The inline handler’s result is ignored, so it is customarily declared to return void. The inline handler will be called when a DO statement is executed specifying the procedural language. The parameter actually passed is a pointer to an InlineCodeBlock struct, which contains information about the DO statement’s parameters, in particular the text of the anonymous code block to be executed. The inline handler should execute this code and return.

It’s recommended that you wrap all these function declarations, as well as the CREATE LANGUAGE command itself, into an extension so that a simple CREATE EXTENSION command is sufficient to install the language. See Section 35.15 for information about writing extensions.

The procedural languages included in the standard distribution are good references when trying to write your own language handler. Look into the src/pl subdirectory of the source tree. The CREATE LANGUAGE reference page also has some useful details.
Chapter 53. Writing A Foreign Data Wrapper

All operations on a foreign table are handled through its foreign data wrapper, which consists of a set of functions that the core server calls. The foreign data wrapper is responsible for fetching data from the remote data source and returning it to the PostgreSQL executor. If updating foreign tables is to be supported, the wrapper must handle that, too. This chapter outlines how to write a new foreign data wrapper.

The foreign data wrappers included in the standard distribution are good references when trying to write your own. Look into the contrib subdirectory of the source tree. The CREATE FOREIGN DATA WRAPPER reference page also has some useful details.

Note: The SQL standard specifies an interface for writing foreign data wrappers. However, PostgreSQL does not implement that API, because the effort to accommodate it into PostgreSQL would be large, and the standard API hasn't gained wide adoption anyway.

53.1. Foreign Data Wrapper Functions

The FDW author needs to implement a handler function, and optionally a validator function. Both functions must be written in a compiled language such as C, using the version-1 interface. For details on C language calling conventions and dynamic loading, see Section 35.9.

The handler function simply returns a struct of function pointers to callback functions that will be called by the planner, executor, and various maintenance commands. Most of the effort in writing an FDW is in implementing these callback functions. The handler function must be registered with PostgreSQL as taking no arguments and returning the special pseudo-type \texttt{fdw\_handler}. The callback functions are plain C functions and are not visible or callable at the SQL level. The callback functions are described in Section 53.2.

The validator function is responsible for validating options given in CREATE and ALTER commands for its foreign data wrapper, as well as foreign servers, user mappings, and foreign tables using the wrapper. The validator function must be registered as taking two arguments, a text array containing the options to be validated, and an OID representing the type of object the options are associated with (in the form of the OID of the system catalog the object would be stored in, either \texttt{ForeignDataWrapperRelationId}, \texttt{ForeignServerRelationId}, \texttt{UserMappingRelationId}, or \texttt{ForeignTableRelationId}). If no validator function is supplied, options are not checked at object creation time or object alteration time.

53.2. Foreign Data Wrapper Callback Routines

The FDW handler function returns a palloc’d \texttt{Fdw\_Routine} struct containing pointers to the callback functions described below. The scan-related functions are required, the rest are optional.
The FdwRoutine struct type is declared in src/include/foreign/fdwapi.h, which see for additional details.

**53.2.1. FDW Routines For Scanning Foreign Tables**

```c
void GetForeignRelSize (PlannerInfo *root,
            RelOptInfo *baserel,
            Oid foreigntableid);
```

Obtain relation size estimates for a foreign table. This is called at the beginning of planning for a query that scans a foreign table. root is the planner’s global information about the query; baserel is the planner’s information about this table; and foreigntableid is the pg_class OID of the foreign table. (foreigntableid could be obtained from the planner data structures, but it’s passed explicitly to save effort.)

This function should update baserel->rows to be the expected number of rows returned by the table scan, after accounting for the filtering done by the restriction quals. The initial value of baserel->rows is just a constant default estimate, which should be replaced if at all possible. The function may also choose to update baserel->width if it can compute a better estimate of the average result row width.

See Section 53.4 for additional information.

```c
void GetForeignPaths (PlannerInfo *root,
            RelOptInfo *baserel,
            Oid foreigntableid);
```

Create possible access paths for a scan on a foreign table. This is called during query planning. The parameters are the same as for GetForeignRelSize, which has already been called.

This function must generate at least one access path (ForeignPath node) for a scan on the foreign table and must call add_path to add each such path to baserel->pathlist. It’s recommended to use create_foreignscan_path to build the ForeignPath nodes. The function can generate multiple access paths, e.g., a path which has valid pathkeys to represent a pre-sorted result. Each access path must contain cost estimates, and can contain any FDW-private information that is needed to identify the specific scan method intended.

See Section 53.4 for additional information.

```c
ForeignScan *
GetForeignPlan (PlannerInfo *root,
            RelOptInfo *baserel,
            Oid foreigntableid,
            ForeignPath *best_path,
            List *tlist,
            List *scan_clauses);
```

Create a ForeignScan plan node from the selected foreign access path. This is called at the end of query planning. The parameters are as for GetForeignRelSize, plus the selected ForeignPath (previously
produced by GetForeignPaths), the target list to be emitted by the plan node, and the restriction clauses to be enforced by the plan node.

This function must create and return a ForeignScan plan node; it’s recommended to use make_foreignscan to build the ForeignScan node.

See Section 53.4 for additional information.

```c
void BeginForeignScan (ForeignScanState *node, int eflags);
```

Begin executing a foreign scan. This is called during executor startup. It should perform any initialization needed before the scan can start, but not start executing the actual scan (that should be done upon the first call to IterateForeignScan). The ForeignScanState node has already been created, but its fdw_state field is still NULL. Information about the table to scan is accessible through the ForeignScanState node (in particular, from the underlying ForeignScan plan node, which contains any FDW-private information provided by GetForeignPlan). eflags contains flag bits describing the executor's operating mode for this plan node.

Note that when (eflags & EXEC_FLAG_EXPLAIN_ONLY) is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for ExplainForeignScan and EndForeignScan.

```c
TupleTableSlot * IterateForeignScan (ForeignScanState *node);
```

Fetch one row from the foreign source, returning it in a tuple table slot (the node's ScanTupleSlot should be used for this purpose). Return NULL if no more rows are available. The tuple table slot infrastructure allows either a physical or virtual tuple to be returned; in most cases the latter choice is preferable from a performance standpoint. Note that this is called in a short-lived memory context that will be reset between invocations. Create a memory context in BeginForeignScan if you need longer-lived storage, or use the es_query_cxt of the node’s EState.

The rows returned must match the column signature of the foreign table being scanned. If you choose to optimize away fetching columns that are not needed, you should insert nulls in those column positions.

Note that PostgreSQL’s executor doesn’t care whether the rows returned violate any NOT NULL constraints that were defined on the foreign table columns — but the planner does care, and may optimize queries incorrectly if NULL values are present in a column declared not to contain them. If a NULL value is encountered when the user has declared that none should be present, it may be appropriate to raise an error (just as you would need to do in the case of a data type mismatch).

```c
void ReScanForeignScan (ForeignScanState *node);
```

Restart the scan from the beginning. Note that any parameters the scan depends on may have changed value, so the new scan does not necessarily return exactly the same rows.

```c
void EndForeignScan (ForeignScanState *node);
```
End the scan and release resources. It is normally not important to release palloc’d memory, but for example open files and connections to remote servers should be cleaned up.

53.2.2. FDW Routines For Updating Foreign Tables

If an FDW supports writable foreign tables, it should provide some or all of the following callback functions depending on the needs and capabilities of the FDW:

```c
void AddForeignUpdateTargets (Query *parsetree,
   RangeTblEntry *target_rte,
   Relation target_relation);
```

UPDATE and DELETE operations are performed against rows previously fetched by the table-scanning functions. The FDW may need extra information, such as a row ID or the values of primary-key columns, to ensure that it can identify the exact row to update or delete. To support that, this function can add extra hidden, or “junk”, target columns to the list of columns that are to be retrieved from the foreign table during an UPDATE or DELETE.

To do that, add TargetEntry items to parsetree->targetList, containing expressions for the extra values to be fetched. Each such entry must be marked resjunk = true, and must have a distinct resname that will identify it at execution time. Avoid using names matching ctidN, wholerow, or wholerowN, as the core system can generate junk columns of these names.

This function is called in the rewriter, not the planner, so the information available is a bit different from that available to the planning routines. parsetree is the parse tree for the UPDATE or DELETE command, while target_rte and target_relation describe the target foreign table.

If the AddForeignUpdateTargets pointer is set to NULL, no extra target expressions are added. (This will make it impossible to implement DELETE operations, though UPDATE may still be feasible if the FDW relies on an unchanging primary key to identify rows.)

```c
List * PlanForeignModify (PlannerInfo *root,
   ModifyTable *plan,
   Index resultRelation,
   int subplan_index);
```

Perform any additional planning actions needed for an insert, update, or delete on a foreign table. This function generates the FDW-private information that will be attached to the ModifyTable plan node that performs the update action. This private information must have the form of a List, and will be delivered to BeginForeignModify during the execution stage.

root is the planner’s global information about the query. plan is the ModifyTable plan node, which is complete except for the fdwPrivLists field. resultRelation identifies the target foreign table by its range table index. subplan_index identifies which target of the ModifyTable plan node this is, counting from zero; use this if you want to index into plan->plans or other substructure of the plan node.

See Section 53.4 for additional information.
If the PlanForeignModify pointer is set to NULL, no additional plan-time actions are taken, and the fdw_private list delivered to BeginForeignModify will be NIL.

```c
void
BeginForeignModify (ModifyTableState *mtstate,
                    ResultRelInfo *rinfo,
                    List *fdw_private,
                    int subplan_index,
                    int eflags);
```

Begin executing a foreign table modification operation. This routine is called during executor startup. It should perform any initialization needed prior to the actual table modifications. Subsequently, ExecForeignInsert, ExecForeignUpdate or ExecForeignDelete will be called for each tuple to be inserted, updated, or deleted.

*mtstate* is the overall state of the ModifyTable plan node being executed; global data about the plan and execution state is available via this structure. *rinfo* is the ResultRelInfo struct describing the target foreign table. (The ri_FdwState field of ResultRelInfo is available for the FDW to store any private state it needs for this operation.) *fdw_private* contains the private data generated by PlanForeignModify, if any. *subplan_index* identifies which target of the ModifyTable plan node this is. *eflags* contains flag bits describing the executor’s operating mode for this plan node.

Note that when *(eflags & EXEC_FLAG_EXPLAIN_ONLY)* is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for ExplainForeignModify and EndForeignModify.

If the BeginForeignModify pointer is set to NULL, no action is taken during executor startup.

```c
TupleTableSlot *
ExecForeignInsert (EState *estate,
                   ResultRelInfo *rinfo,
                   TupleTableSlot *slot,
                   TupleTableSlot *planSlot);
```

Insert one tuple into the foreign table. *estate* is global execution state for the query. *rinfo* is the ResultRelInfo struct describing the target foreign table. *slot* contains the tuple to be inserted; it will match the row-type definition of the foreign table. *planSlot* contains the tuple that was generated by the ModifyTable plan node’s subplan; it differs from *slot* in possibly containing additional “junk” columns. (The *planSlot* is typically of little interest for INSERT cases, but is provided for completeness.)

The return value is either a slot containing the data that was actually inserted (this might differ from the data supplied, for example as a result of trigger actions), or NULL if no row was actually inserted (again, typically as a result of triggers). The passed-in *slot* can be re-used for this purpose.

The data in the returned slot is used only if the INSERT query has a RETURNING clause or the foreign table has an AFTER ROW trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the RETURNING clause. Regardless, some slot must be returned to indicate success, or the query’s reported row count will be wrong.

If the ExecForeignInsert pointer is set to NULL, attempts to insert into the foreign table will fail with an error message.

```c
TupleTableSlot *
```
Chapter 53. Writing A Foreign Data Wrapper

ExecForeignUpdate (EState *estate,
    ResultRelInfo *rinfo,
    TupleTableSlot *slot,
    TupleTableSlot *planSlot);

Update one tuple in the foreign table. estate is global execution state for the query. rinfo is the ResultRelInfo struct describing the target foreign table. slot contains the new data for the tuple; it will match the row-type definition of the foreign table. planSlot contains the tuple that was generated by the ModifyTable plan node’s subplan; it differs from slot in possibly containing additional “junk” columns. In particular, any junk columns that were requested by AddForeignUpdateTargets will be available from this slot.

The return value is either a slot containing the row as it was actually updated (this might differ from the data supplied, for example as a result of trigger actions), or NULL if no row was actually updated (again, typically as a result of triggers). The passed-in slot can be re-used for this purpose.

The data in the returned slot is used only if the UPDATE query has a RETURNING clause or the foreign table has an AFTER ROW trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the RETURNING clause. Regardless, some slot must be returned to indicate success, or the query’s reported row count will be wrong.

If the ExecForeignUpdate pointer is set to NULL, attempts to update the foreign table will fail with an error message.

TupleTableSlot *
ExecForeignDelete (EState *estate,
    ResultRelInfo *rinfo,
    TupleTableSlot *slot,
    TupleTableSlot *planSlot);

Delete one tuple from the foreign table. estate is global execution state for the query. rinfo is the ResultRelInfo struct describing the target foreign table. slot contains nothing useful upon call, but can be used to hold the returned tuple. planSlot contains the tuple that was generated by the ModifyTable plan node’s subplan; in particular, it will carry any junk columns that were requested by AddForeignUpdateTargets. The junk column(s) must be used to identify the tuple to be deleted.

The return value is either a slot containing the row that was deleted, or NULL if no row was deleted (typically as a result of triggers). The passed-in slot can be used to hold the tuple to be returned.

The data in the returned slot is used only if the DELETE query has a RETURNING clause or the foreign table has an AFTER ROW trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the RETURNING clause. Regardless, some slot must be returned to indicate success, or the query’s reported row count will be wrong.

If the ExecForeignDelete pointer is set to NULL, attempts to delete from the foreign table will fail with an error message.

void
EndForeignModify (EState *estate,
    ResultRelInfo *rinfo);

End the table update and release resources. It is normally not important to release palloc’d memory, but for example open files and connections to remote servers should be cleaned up.
If the EndForeignModify pointer is set to NULL, no action is taken during executor shutdown.

```c
int IsForeignRelUpdatable (Relation rel);
```

Report which update operations the specified foreign table supports. The return value should be a bit mask of rule event numbers indicating which operations are supported by the foreign table, using the CmdType enumeration; that is, 

- `(1 << CMD_UPDATE) = 4` for UPDATE,
- `(1 << CMD_INSERT) = 8` for INSERT,
- `(1 << CMD_DELETE) = 16` for DELETE.

If the IsForeignRelUpdatable pointer is set to NULL, foreign tables are assumed to be insertable, updatable, or deletable if the FDW provides ExecForeignInsert, ExecForeignUpdate, or ExecForeignDelete respectively. This function is only needed if the FDW supports some tables that are updatable and some that are not. (Even then, it’s permissible to throw an error in the execution routine instead of checking in this function. However, this function is used to determine updatability for display in the information_schema views.)

### 53.2.3. FDW Routines for EXPLAIN

```c
void ExplainForeignScan (ForeignScanState *node,
                        ExplainState *es);
```

Print additional EXPLAIN output for a foreign table scan. This function can call ExplainPropertyText and related functions to add fields to the EXPLAIN output. The flag fields in `es` can be used to determine what to print, and the state of the ForeignScanState node can be inspected to provide run-time statistics in the EXPLAIN ANALYZE case.

If the ExplainForeignScan pointer is set to NULL, no additional information is printed during EXPLAIN.

```c
void ExplainForeignModify (ModifyTableState *mtstate,
                           ResultRelInfo *rinfo,
                           List *fdw_private,
                           int subplan_index,
                           struct ExplainState *es);
```

Print additional EXPLAIN output for a foreign table update. This function can call ExplainPropertyText and related functions to add fields to the EXPLAIN output. The flag fields in `es` can be used to determine what to print, and the state of the ModifyTableState node can be inspected to provide run-time statistics in the EXPLAIN ANALYZE case. The first four arguments are the same as for BeginForeignModify.

If the ExplainForeignModify pointer is set to NULL, no additional information is printed during EXPLAIN.
53.2.4. FDW Routines for ANALYZE

```c
bool
AnalyzeForeignTable (Relation relation,
   AcquireSampleRowsFunc *func,
   BlockNumber *totalpages);
```

This function is called when ANALYZE is executed on a foreign table. If the FDW can collect statistics for this foreign table, it should return `true`, and provide a pointer to a function that will collect sample rows from the table in `func`, plus the estimated size of the table in pages in `totalpages`. Otherwise, return `false`.

If the FDW does not support collecting statistics for any tables, the `AnalyzeForeignTable` pointer can be set to `NULL`.

If provided, the sample collection function must have the signature

```c
int
AcquireSampleRowsFunc (Relation relation, int elevel,
   HeapTuple *rows, int targrows,
   double *totalrows,
   double *totaldeadrows);
```

A random sample of up to `targrows` rows should be collected from the table and stored into the caller-provided `rows` array. The actual number of rows collected must be returned. In addition, store estimates of the total numbers of live and dead rows in the table into the output parameters `totalrows` and `totaldeadrows`. (Set `totaldeadrows` to zero if the FDW does not have any concept of dead rows.)

53.3. Foreign Data Wrapper Helper Functions

Several helper functions are exported from the core server so that authors of foreign data wrappers can get easy access to attributes of FDW-related objects, such as FDW options. To use any of these functions, you need to include the header file `foreign/foreign.h` in your source file. That header also defines the struct types that are returned by these functions.

```c
ForeignDataWrapper *
GetForeignDataWrapper(Oid fdwid);
```

This function returns a `ForeignDataWrapper` object for the foreign-data wrapper with the given OID. A `ForeignDataWrapper` object contains properties of the FDW (see `foreign/foreign.h` for details).

```c
ForeignServer *
GetForeignServer(Oid serverid);
```

This function returns a `ForeignServer` object for the foreign server with the given OID. A `ForeignServer` object contains properties of the server (see `foreign/foreign.h` for details).

```c
UserMapping *
```
Chapter 53. Writing A Foreign Data Wrapper

GetUserMapping(Oid userid, Oid serverid);

This function returns a UserMapping object for the user mapping of the given role on the given server. (If there is no mapping for the specific user, it will return the mapping for PUBLIC, or throw error if there is none.) A UserMapping object contains properties of the user mapping (see foreign/foreign.h for details).

ForeignTable *
GetForeignTable(Oid relid);

This function returns a ForeignTable object for the foreign table with the given OID. A ForeignTable object contains properties of the foreign table (see foreign/foreign.h for details).

List *
GetForeignColumnOptions(Oid relid, AttrNumber attnum);

This function returns the per-column FDW options for the column with the given foreign table OID and attribute number, in the form of a list of DefElem. NIL is returned if the column has no options.

Some object types have name-based lookup functions in addition to the OID-based ones:

ForeignDataWrapper *
GetForeignDataWrapperByName(const char *name, bool missing_ok);

This function returns a ForeignDataWrapper object for the foreign-data wrapper with the given name. If the wrapper is not found, return NULL if missing_ok is true, otherwise raise an error.

ForeignServer *
GetForeignServerByName(const char *name, bool missing_ok);

This function returns a ForeignServer object for the foreign server with the given name. If the server is not found, return NULL if missing_ok is true, otherwise raise an error.

53.4. Foreign Data Wrapper Query Planning

The FDW callback functions GetForeignRelSize, GetForeignPaths, GetForeignPlan, and PlanForeignModify must fit into the workings of the PostgreSQL planner. Here are some notes about what they must do.

The information in root and baserel can be used to reduce the amount of information that has to be fetched from the foreign table (and therefore reduce the cost). baserel->baserestrictinfo is particularly interesting, as it contains restriction quals (WHERE clauses) that should be used to filter the rows to be fetched. (The FDW itself is not required to enforce these quals, as the core executor can check them instead.) baserel->reltargetlist can be used to determine which columns need to be fetched; but note that it only lists columns that have to be emitted by the ForeignScan plan node, not columns that are used in qual evaluation but not output by the query.
Chapter 53. Writing A Foreign Data Wrapper

Various private fields are available for the FDW planning functions to keep information in. Generally, whatever you store in FDW private fields should be palloc’d, so that it will be reclaimed at the end of planning.

baserel->fdw_private is a void pointer that is available for FDW planning functions to store information relevant to the particular foreign table. The core planner does not touch it except to initialize it to NULL when the baserel node is created. It is useful for passing information forward from GetForeignRelSize to GetForeignPaths and/or GetForeignPaths to GetForeignPlan, thereby avoiding recalculation.

GetForeignPaths can identify the meaning of different access paths by storing private information in the fdw_private field of ForeignPath nodes. fdw_private is declared as a List pointer, but could actually contain anything since the core planner does not touch it. However, best practice is to use a representation that’s dumpable by nodeToString, for use with debugging support available in the backend.

GetForeignPlan can examine the fdw_private field of the selected ForeignPath node, and can generate fdw_exprs and fdw_private lists to be placed in the ForeignScan plan node, where they will be available at execution time. Both of these lists must be represented in a form that copyObject knows how to copy. The fdw_private list has no other restrictions and is not interpreted by the core backend in any way. The fdw_exprs list, if not NIL, is expected to contain expression trees that are intended to be executed at run time. These trees will undergo post-processing by the planner to make them fully executable.

In GetForeignPlan, generally the passed-in target list can be copied into the plan node as-is. The passed scan_clauses list contains the same clauses as baserel->baserestrictinfo, but may be re-ordered for better execution efficiency. In simple cases the FDW can just strip RestrictInfo nodes from the scan_clauses list (using extract_actual_clauses) and put all the clauses into the plan node’s qual list, which means that all the clauses will be checked by the executor at run time. More complex FDWs may be able to check some of the clauses internally, in which case those clauses can be removed from the plan node’s qual list so that the executor doesn’t waste time rechecking them.

As an example, the FDW might identify some restriction clauses of the form foreign_variable = sub_expression, which it determines can be executed on the remote server given the locally-evaluated value of the sub_expression. The actual identification of such a clause should happen during GetForeignPaths, since it would affect the cost estimate for the path. The path’s fdw_private field would probably include a pointer to the identified clause’s RestrictInfo node. Then GetForeignPlan would remove that clause from scan_clauses, but add the sub_expression to fdw_exprs to ensure that it gets massaged into executable form. It would probably also put control information into the plan node’s fdw_private field to tell the execution functions what to do at run time. The query transmitted to the remote server would involve something like WHERE foreign_variable = $1, with the parameter value obtained at run time from evaluation of the fdw_exprs expression tree.

The FDW should always construct at least one path that depends only on the table’s restriction clauses. In join queries, it might also choose to construct path(s) that depend on join clauses, for example foreign_variable = local_variable. Such clauses will not be found in baserel->baserestrictinfo but must be sought in the relation’s join lists. A path using such a clause is called a “parameterized path”. It must identify the other relations used in the selected join clause(s) with a suitable value of param_info; use get_baserel_parampathinfo to compute that value. In GetForeignPlan, the local_variable portion of the join clause would be added to
fdw_exprs, and then at run time the case works the same as for an ordinary restriction clause.

When planning an UPDATE or DELETE, PlanForeignModify can look up the RelOptInfo struct for the foreign table and make use of the baserel->fdw_private data previously created by the scan-planning functions. However, in INSERT the target table is not scanned so there is no RelOptInfo for it. The List returned by PlanForeignModify has the same restrictions as the fdw_private list of a ForeignScan plan node, that is it must contain only structures that copyObject knows how to copy.

For an UPDATE or DELETE against an external data source that supports concurrent updates, it is recommended that the ForeignScan operation lock the rows that it fetches, perhaps via the equivalent of SELECT FOR UPDATE. The FDW may also choose to lock rows at fetch time when the foreign table is referenced in a SELECT FOR UPDATE/SHARE; if it does not, the FOR UPDATE or FOR SHARE option is essentially a no-op so far as the foreign table is concerned. This behavior may yield semantics slightly different from operations on local tables, where row locking is customarily delayed as long as possible: remote rows may get locked even though they subsequently fail locally-applied restriction or join conditions. However, matching the local semantics exactly would require an additional remote access for every row, and might be impossible anyway depending on what locking semantics the external data source provides.
Chapter 54. Genetic Query Optimizer

Author: Written by Martin Utesch (<utesch@aut.tu-freiberg.de>) for the Institute of Automatic Control at the University of Mining and Technology in Freiberg, Germany.

54.1. Query Handling as a Complex Optimization Problem

Among all relational operators the most difficult one to process and optimize is the join. The number of possible query plans grows exponentially with the number of joins in the query. Further optimization effort is caused by the support of a variety of join methods (e.g., nested loop, hash join, merge join in PostgreSQL) to process individual joins and a diversity of indexes (e.g., B-tree, hash, GiST and GIN in PostgreSQL) as access paths for relations.

The normal PostgreSQL query optimizer performs a near-exhaustive search over the space of alternative strategies. This algorithm, first introduced in IBM’s System R database, produces a near-optimal join order, but can take an enormous amount of time and memory space when the number of joins in the query grows large. This makes the ordinary PostgreSQL query optimizer inappropriate for queries that join a large number of tables.

The Institute of Automatic Control at the University of Mining and Technology, in Freiberg, Germany, encountered some problems when it wanted to use PostgreSQL as the backend for a decision support knowledge based system for the maintenance of an electrical power grid. The DBMS needed to handle large join queries for the inference machine of the knowledge based system. The number of joins in these queries made using the normal query optimizer infeasible.

In the following we describe the implementation of a genetic algorithm to solve the join ordering problem in a manner that is efficient for queries involving large numbers of joins.

54.2. Genetic Algorithms

The genetic algorithm (GA) is a heuristic optimization method which operates through randomized search. The set of possible solutions for the optimization problem is considered as a population of individuals. The degree of adaptation of an individual to its environment is specified by its fitness.

The coordinates of an individual in the search space are represented by chromosomes, in essence a set of character strings. A gene is a subsection of a chromosome which encodes the value of a single parameter being optimized. Typical encodings for a gene could be binary or integer.
Chapter 54. Genetic Query Optimizer

Through simulation of the evolutionary operations recombination, mutation, and selection new generations of search points are found that show a higher average fitness than their ancestors.

According to the comp.ai.genetic FAQ it cannot be stressed too strongly that a GA is not a pure random search for a solution to a problem. A GA uses stochastic processes, but the result is distinctly non-random (better than random).

Figure 54-1. Structured Diagram of a Genetic Algorithm

P(t) generation of ancestors at a time t
P''(t) generation of descendants at a time t

54.3. Genetic Query Optimization (GEQO) in PostgreSQL

The GEQO module approaches the query optimization problem as though it were the well-known traveling salesman problem (TSP). Possible query plans are encoded as integer strings. Each string represents the join order from one relation of the query to the next. For example, the join tree

```
   /
  /\  2
 /\  3
4  1
```

is encoded by the integer string '4-1-3-2’, which means, first join relation '4' and '1’, then '3’, and then '2’, where 1, 2, 3, 4 are relation IDs within the PostgreSQL optimizer.

Specific characteristics of the GEQO implementation in PostgreSQL are:
• Usage of a steady state GA (replacement of the least fit individuals in a population, not whole-generational replacement) allows fast convergence towards improved query plans. This is essential for query handling with reasonable time;
• Usage of edge recombination crossover which is especially suited to keep edge losses low for the solution of the TSP by means of a GA;
• Mutation as genetic operator is deprecated so that no repair mechanisms are needed to generate legal TSP tours.

Parts of the GEQO module are adapted from D. Whitley’s Genitor algorithm.
The GEQO module allows the PostgreSQL query optimizer to support large join queries effectively through non-exhaustive search.

54.3.1. Generating Possible Plans with GEQO

The GEQO planning process uses the standard planner code to generate plans for scans of individual relations. Then join plans are developed using the genetic approach. As shown above, each candidate join plan is represented by a sequence in which to join the base relations. In the initial stage, the GEQO code simply generates some possible join sequences at random. For each join sequence considered, the standard planner code is invoked to estimate the cost of performing the query using that join sequence. (For each step of the join sequence, all three possible join strategies are considered; and all the initially-determined relation scan plans are available. The estimated cost is the cheapest of these possibilities.) Join sequences with lower estimated cost are considered “more fit” than those with higher cost. The genetic algorithm discards the least fit candidates. Then new candidates are generated by combining genes of more-fit candidates — that is, by using randomly-chosen portions of known low-cost join sequences to create new sequences for consideration. This process is repeated until a preset number of join sequences have been considered; then the best one found at any time during the search is used to generate the finished plan.

This process is inherently nondeterministic, because of the randomized choices made during both the initial population selection and subsequent “mutation” of the best candidates. To avoid surprising changes of the selected plan, each run of the GEQO algorithm restarts its random number generator with the current geqo_seed parameter setting. As long as geqo_seed and the other GEQO parameters are kept fixed, the same plan will be generated for a given query (and other planner inputs such as statistics). To experiment with different search paths, try changing geqo_seed.

54.3.2. Future Implementation Tasks for PostgreSQL GEQO

Work is still needed to improve the genetic algorithm parameter settings. In file src/backend/optimizer/geqo/geqo_main.c, routines gimme_pool_size and gimme_number_generations, we have to find a compromise for the parameter settings to satisfy two competing demands:

• Optimality of the query plan
• Computing time
In the current implementation, the fitness of each candidate join sequence is estimated by running the standard planner’s join selection and cost estimation code from scratch. To the extent that different candidates use similar sub-sequences of joins, a great deal of work will be repeated. This could be made significantly faster by retaining cost estimates for sub-joins. The problem is to avoid expending unreasonable amounts of memory on retaining that state.

At a more basic level, it is not clear that solving query optimization with a GA algorithm designed for TSP is appropriate. In the TSP case, the cost associated with any substring (partial tour) is independent of the rest of the tour, but this is certainly not true for query optimization. Thus it is questionable whether edge recombination crossover is the most effective mutation procedure.

### 54.4. Further Reading

The following resources contain additional information about genetic algorithms:

Chapter 55. Index Access Method Interface

Definition

This chapter defines the interface between the core PostgreSQL system and index access methods, which manage individual index types. The core system knows nothing about indexes beyond what is specified here, so it is possible to develop entirely new index types by writing add-on code.

All indexes in PostgreSQL are what are known technically as secondary indexes; that is, the index is physically separate from the table file that it describes. Each index is stored as its own physical relation and so is described by an entry in the `pg_class` catalog. The contents of an index are entirely under the control of its index access method. In practice, all index access methods divide indexes into standard-size pages so that they can use the regular storage manager and buffer manager to access the index contents. (All the existing index access methods furthermore use the standard page layout described in Section 59.6, and they all use the same format for index tuple headers; but these decisions are not forced on an access method.)

An index is effectively a mapping from some data key values to tuple identifiers, or TIDs, of row versions (tuples) in the index’s parent table. A TID consists of a block number and an item number within that block (see Section 59.6). This is sufficient information to fetch a particular row version from the table. Indexes are not directly aware that under MVCC, there might be multiple extant versions of the same logical row; to an index, each tuple is an independent object that needs its own index entry. Thus, an update of a row always creates all-new index entries for the row, even if the key values did not change. (HOT tuples are an exception to this statement; but indexes do not deal with those, either.) Index entries for dead tuples are reclaimed (by vacuuming) when the dead tuples themselves are reclaimed.

55.1. Catalog Entries for Indexes

Each index access method is described by a row in the `pg_am` system catalog (see Section 48.3). The principal contents of a `pg_am` row are references to `pg_proc` entries that identify the index access functions supplied by the access method. The APIs for these functions are defined later in this chapter. In addition, the `pg_am` row specifies a few fixed properties of the access method, such as whether it can support multi-column indexes. There is not currently any special support for creating or deleting `pg_am` entries; anyone able to write a new access method is expected to be competent to insert an appropriate row for themselves.

To be useful, an index access method must also have one or more `operator families` and `operator classes` defined in `pg_opfamily`, `pg_opclass`, `pg_amop`, and `pg_amproc`. These entries allow the planner to determine what kinds of query qualifications can be used with indexes of this access method. Operator families and classes are described in Section 35.14, which is prerequisite material for reading this chapter.

An individual index is defined by a `pg_class` entry that describes it as a physical relation, plus a `pg_index` entry that shows the logical content of the index — that is, the set of index columns it has and the semantics of those columns, as captured by the associated operator classes. The index columns (key values) can be either simple columns of the underlying table or expressions over the table rows. The index access method normally has no interest in where the index key values come from (it is al-
Chapter 55. Index Access Method Interface Definition

ways handed precomputed key values) but it will be very interested in the operator class information in
pg_index. Both of these catalog entries can be accessed as part of the Relation data structure that is
passed to all operations on the index.

Some of the flag columns of pg_am have nonobvious implications. The requirements of amcanunique are
discussed in Section 55.5. The amcanmulticol flag asserts that the access method supports multicolumn
indexes, while amoptionalkey asserts that it allows scans where no indexable restriction clause is given
for the first index column. When amcanmulticol is false, amoptionalkey essentially says whether
the access method supports full-index scans without any restriction clause. Access methods that support
multiple index columns must support scans that omit restrictions on any or all of the columns after the
first; however they are permitted to require some restriction to appear for the first index column, and this
is signaled by setting amoptionalkey false. One reason that an index AM might set amoptionalkey
false is if it doesn’t index null values. Since most indexable operators are strict and hence cannot return
true for null inputs, it is at first sight attractive to not store index entries for null values: they could never
be returned by an index scan anyway. However, this argument fails when an index scan has no restriction
clause for a given index column. In practice this means that indexes that have amoptionalkey true
must index nulls, since the planner might decide to use such an index with no scan keys at all. A related
restriction is that an index access method that supports multiple index columns must support indexing null
values in columns after the first, because the planner will assume the index can be used for queries that do
not restrict these columns. For example, consider an index on (a,b) and a query with WHERE a = 4. The
system will assume the index can be used to scan for rows with a = 4, which is wrong if the index omits
rows where b is null. It is, however, OK to omit rows where the first indexed column is null. An index
access method that does index nulls may also set amsearchnulls, indicating that it supports IS NULL
and IS NOT NULL clauses as search conditions.

55.2. Index Access Method Functions

The index construction and maintenance functions that an index access method must provide are:

IndexBuildResult *
ambuild (Relation heapRelation,
    Relation indexRelation,
    IndexInfo *indexInfo);

Build a new index. The index relation has been physically created, but is empty. It must be filled in with
whatever fixed data the access method requires, plus entries for all tuples already existing in the table.
Ordinarily the ambuild function will call IndexBuildHeapScan() to scan the table for existing tuples
and compute the keys that need to be inserted into the index. The function must return a palloc’d struct
containing statistics about the new index.

void
ambuildempty (Relation indexRelation);

Build an empty index, and write it to the initialization fork (INIT_FORKNUM) of the given relation. This
method is called only for unlogged tables; the empty index written to the initialization fork will be copied
over the main relation fork on each server restart.

bool
aminsert (Relation indexRelation,
    Datum *values,
    bool *isNull,
    ItemPointer heap_tid,
    Relation heapRelation,
    IndexUniqueCheck checkUnique);

Insert a new tuple into an existing index. The values and isnull arrays give the key values to be
indexed, and heap_tid is the TID to be indexed. If the access method supports unique indexes (its
pg_am.amcanunique flag is true) then checkUnique indicates the type of uniqueness check to perform.
This varies depending on whether the unique constraint is deferrable; see Section 55.5 for details. Nor-
mally the access method only needs the heapRelation parameter when performing uniqueness checking
(since then it will have to look into the heap to verify tuple liveness).

The function’s Boolean result value is significant only when checkUnique is UNIQUE_CHECK_PARTIAL.
In this case a TRUE result means the new entry is known unique, whereas FALSE means it might be non-
unique (and a deferred uniqueness check must be scheduled). For other cases a constant FALSE result is
recommended.

Some indexes might not index all tuples. If the tuple is not to be indexed, aminsert should just return
without doing anything.

IndexBulkDeleteResult *
ambulkdelete (IndexVacuumInfo *info,
    IndexBulkDeleteResult *stats,
    IndexBulkDeleteCallback callback,
    void *callback_state);

Delete tuple(s) from the index. This is a “bulk delete” operation that is intended to be implemented by
scanning the whole index and checking each entry to see if it should be deleted. The passed-in callback
function must be called, in the style callback(TID, callback_state) returns bool, to deter-
mine whether any particular index entry, as identified by its referenced TID, is to be deleted. Must return
either NULL or a palloc’d struct containing statistics about the effects of the deletion operation. It is OK
to return NULL if no information needs to be passed on to amvacuumcleanup.

Because of limited maintenance_work_mem, ambulkdelete might need to be called more than once
when many tuples are to be deleted. The stats argument is the result of the previous call for this index (it
is NULL for the first call within a VACUUM operation). This allows the AM to accumulate statistics across
the whole operation. Typically, ambulkdelete will modify and return the same struct if the passed stats
is not null.

IndexBulkDeleteResult *
amvacuumcleanup (IndexVacuumInfo *info,
    IndexBulkDeleteResult *stats);

Clean up after a VACUUM operation (zero or more ambulkdelete calls). This does not have to do anything
beyond returning index statistics, but it might perform bulk cleanup such as reclaiming empty index pages.
stats is whatever the last ambulkdelete call returned, or NULL if ambulkdelete was not called
because no tuples needed to be deleted. If the result is not NULL it must be a palloc’d struct. The statistics
it contains will be used to update pg_class, and will be reported by VACUUM if VERBOSE is given. It is
OK to return NULL if the index was not changed at all during the VACUUM operation, but otherwise correct stats should be returned.

As of PostgreSQL 8.4, amvacuumcleanup will also be called at completion of an ANALYZE operation. In this case stats is always NULL and any return value will be ignored. This case can be distinguished by checking info->analyze_only. It is recommended that the access method do nothing except post-insert cleanup in such a call, and that only in an autovacuum worker process.

```c
bool amcanreturn (Relation indexRelation);
```

Check whether the index can support index-only scans by returning the indexed column values for an index entry in the form of an IndexTuple. Return TRUE if so, else FALSE. If the index AM can never support index-only scans (an example is hash, which stores only the hash values not the original data), it is sufficient to set its amcanreturn field to zero in pg_am.

```c
void amcostestimate (PlannerInfo *root, IndexPath *path, double loop_count, Cost *indexStartupCost, Cost *indexTotalCost, Selectivity *indexSelectivity, double *indexCorrelation);
```

Estimate the costs of an index scan. This function is described fully in Section 55.6, below.

```c
bytea * amoptions (ArrayType *reloptions, bool validate);
```

Parse and validate the reloptions array for an index. This is called only when a non-null reloptions array exists for the index. reloptions is a text array containing entries of the form name=value. The function should construct a bytea value, which will be copied into the rd_options field of the index’s relcache entry. The data contents of the bytea value are open for the access method to define; most of the standard access methods use struct StdRdOptions. When validate is true, the function should report a suitable error message if any of the options are unrecognized or have invalid values; when validate is false, invalid entries should be silently ignored. (validate is false when loading options already stored in pg_catalog; an invalid entry could only be found if the access method has changed its rules for options, and in that case ignoring obsolete entries is appropriate.) It is OK to return NULL if default behavior is wanted.

The purpose of an index, of course, is to support scans for tuples matching an indexable WHERE condition, often called a qualifier or scan key. The semantics of index scanning are described more fully in Section 55.3, below. An index access method can support “plain” index scans, “bitmap” index scans, or both. The scan-related functions that an index access method must or may provide are:

```c
IndexScanDesc ambeginscan (Relation indexRelation, int nkeys, int norderbys);
```
Prepare for an index scan. The \texttt{nkeys} and \texttt{norderbys} parameters indicate the number of quals and ordering operators that will be used in the scan; these may be useful for space allocation purposes. Note that the actual values of the scan keys aren’t provided yet. The result must be a \texttt{palloc’d} struct. For implementation reasons the index access method must create this struct by calling \texttt{RelationGetIndexScan()}. In most cases \texttt{ambeginscan} does little beyond making that call and perhaps acquiring locks; the interesting parts of index-scan startup are in \texttt{amrescan}.

```c
void
amrescan (IndexScanDesc scan,
            ScanKey keys,
            int nkeys,
            ScanKey orderbys,
            int norderbys);
```

Start or restart an index scan, possibly with new scan keys. (To restart using previously-passed keys, \texttt{NULL} is passed for \texttt{keys} and/or \texttt{orderbys}.) Note that it is not allowed for the number of keys or order-by operators to be larger than what was passed to \texttt{ambeginscan}. In practice the restart feature is used when a new outer tuple is selected by a nested-loop join and so a new key comparison value is needed, but the scan key structure remains the same.

```c
boolean
amgettuple (IndexScanDesc scan,
             ScanDirection direction);
```

Fetch the next tuple in the given scan, moving in the given direction (forward or backward in the index). Returns \texttt{TRUE} if a tuple was obtained, \texttt{FALSE} if no matching tuples remain. In the \texttt{TRUE} case the tuple TID is stored into the \texttt{scan} structure. Note that “success” means only that the index contains an entry that matches the scan keys, not that the tuple necessarily still exists in the heap or will pass the caller’s snapshot test. On success, \texttt{amgettuple} must also set \texttt{scan->xs_recheck} to \texttt{TRUE} or \texttt{FALSE}. \texttt{FALSE} means it is certain that the index entry matches the scan keys. \texttt{TRUE} means this is not certain, and the conditions represented by the scan keys must be rechecked against the heap tuple after fetching it. This provision supports “lossy” index operators. Note that rechecking will extend only to the scan conditions; a partial index predicate (if any) is never rechecked by \texttt{amgettuple} callers.

If the index supports index-only scans (i.e., \texttt{amcanreturn} returns \texttt{TRUE} for it), then on success the AM must also check \texttt{scan->xs.want_itup}, and if that is true it must return the original indexed data for the index entry, in the form of an \texttt{IndexTuple} pointer stored at \texttt{scan->xs.itup}, with tuple descriptor \texttt{scan->xs.itupdesc}. (Management of the data referenced by the pointer is the access method’s responsibility. The data must remain good at least until the next \texttt{amgettuple, amrescan, or amendscan} call for the scan.)

The \texttt{amgettuple} function need only be provided if the access method supports “plain” index scans. If it doesn’t, the \texttt{amgettuple} field in its \texttt{pg_am} row must be set to zero.

```c
int64
amgetbitmap (IndexScanDesc scan,
              TIDBitmap *tbm);
```

Fetch all tuples in the given scan and add them to the caller-supplied \texttt{TIDBitmap} (that is, OR the set of tuple IDs into whatever set is already in the bitmap). The number of tuples fetched is returned (this might
be just an approximate count, for instance some AMs do not detect duplicates). While inserting tuple IDs into the bitmap, amgetbitmap can indicate that rechecking of the scan conditions is required for specific tuple IDs. This is analogous to the xs_recheck output parameter of amgettuple. Note: in the current implementation, support for this feature is conflated with support for lossy storage of the bitmap itself, and therefore callers recheck both the scan conditions and the partial index predicate (if any) for recheckable tuples. That might not always be true, however. amgetbitmap and amgettuple cannot be used in the same index scan; there are other restrictions too when using amgetbitmap, as explained in Section 55.3.

The amgetbitmap function need only be provided if the access method supports “bitmap” index scans. If it doesn’t, the amgetbitmap field in its pg_am row must be set to zero.

```c
void amendscan (IndexScanDesc scan);
```

End a scan and release resources. The scan struct itself should not be freed, but any locks or pins taken internally by the access method must be released, as well as any other memory allocated by ambeginscan and other scan-related functions.

```c
void ammarkpos (IndexScanDesc scan);
```

Mark current scan position. The access method need only support one remembered scan position per scan.

```c
void amrestrpos (IndexScanDesc scan);
```

Restore the scan to the most recently marked position.

By convention, the pg_proc entry for an index access method function should show the correct number of arguments, but declare them all as type internal (since most of the arguments have types that are not known to SQL, and we don’t want users calling the functions directly anyway). The return type is declared as void, internal, or boolean as appropriate. The only exception is amoptions, which should be correctly declared as taking text[] and bool and returning bytea. This provision allows client code to execute amoptions to test validity of options settings.

55.3. Index Scanning

In an index scan, the index access method is responsible for regurgitating the TIDs of all the tuples it has been told about that match the scan keys. The access method is not involved in actually fetching those tuples from the index’s parent table, nor in determining whether they pass the scan’s time qualification test or other conditions.

A scan key is the internal representation of a WHERE clause of the form index_key operator constant, where the index key is one of the columns of the index and the operator is one of the members of the operator family associated with that index column. An index scan has zero or more scan keys, which are implicitly ANDed — the returned tuples are expected to satisfy all the indicated conditions.

The access method can report that the index is lossy, or requires rechecks, for a particular query. This implies that the index scan will return all the entries that pass the scan key, plus possibly additional entries
that do not. The core system’s index-scan machinery will then apply the index conditions again to the
heap tuple to verify whether or not it really should be selected. If the recheck option is not specified, the
index scan must return exactly the set of matching entries.

Note that it is entirely up to the access method to ensure that it correctly finds all and only the entries
passing all the given scan keys. Also, the core system will simply hand off all the WHERE clauses that
match the index keys and operator families, without any semantic analysis to determine whether they
are redundant or contradictory. As an example, given WHERE x > 4 AND x > 14 where x is a b-tree
indexed column, it is left to the b-tree amrescan function to realize that the first scan key is redundant
and can be discarded. The extent of preprocessing needed during amrescan will depend on the extent to
which the index access method needs to reduce the scan keys to a “normalized” form.

Some access methods return index entries in a well-defined order, others do not. There are actually two
different ways that an access method can support sorted output:

• Access methods that always return entries in the natural ordering of their data (such as btree) should
  set pg_am.amcanorder to true. Currently, such access methods must use btree-compatible strategy
  numbers for their equality and ordering operators.

• Access methods that support ordering operators should set pg_am.amcanorderbyop to true. This in-
  dicates that the index is capable of returning entries in an order satisfying ORDER BY index_key
  operator constant. Scan modifiers of that form can be passed to amrescan as described previ-
  ously.

The amgettuple function has a direction argument, which can be either ForwardScanDirection
(the normal case) or BackwardScanDirection. If the first call after amrescan specifies
BackwardScanDirection, then the set of matching index entries is to be scanned back-to-front rather
than in the normal front-to-back direction, so amgettuple must return the last matching tuple in the
index, rather than the first one as it normally would. (This will only occur for access methods that set
amcanorder to true.) After the first call, amgettuple must be prepared to advance the scan in either
direction from the most recently returned entry. (But if pg_am.amcanbackward is false, all subsequent
calls will have the same direction as the first one.)

Access methods that support ordered scans must support “marking” a position in a scan and later returning
to the marked position. The same position might be restored multiple times. However, only one position
need be remembered per scan; a new ammarkpos call overrides the previously marked position. An access
method that does not support ordered scans should still provide mark and restore functions in pg_am, but
it is sufficient to have them throw errors if called.

Both the scan position and the mark position (if any) must be maintained consistently in the face of
concurrent insertions or deletions in the index. It is OK if a freshly-inserted entry is not returned by a
scan that would have found the entry if it had existed when the scan started, or for the scan to return
such an entry upon rescanning or backing up even though it had not been returned the first time through.
Similarly, a concurrent delete might or might not be reflected in the results of a scan. What is important is
that insertions or deletions not cause the scan to miss or multiply return entries that were not themselves
being inserted or deleted.

If the index stores the original indexed data values (and not some lossy representation of them), it is useful
to support index-only scans, in which the index returns the actual data not just the TID of the heap tuple.
This will only work if the visibility map shows that the TID is on an all-visible page; else the heap tuple
must be visited anyway to check MVCC visibility. But that is no concern of the access method’s.
Instead of using `amgettuple`, an index scan can be done with `amgetbitmap` to fetch all tuples in one call. This can be noticeably more efficient than `amgettuple` because it allows avoiding lock/unlock cycles within the access method. In principle `amgetbitmap` should have the same effects as repeated `amgettuple` calls, but we impose several restrictions to simplify matters. First of all, `amgetbitmap` returns all tuples at once and marking or restoring scan positions isn’t supported. Secondly, the tuples are returned in a bitmap which doesn’t have any specific ordering, which is why `amgetbitmap` doesn’t take a direction argument. (Ordering operators will never be supplied for such a scan, either.) Also, there is no provision for index-only scans with `amgetbitmap`, since there is no way to return the contents of index tuples. Finally, `amgetbitmap` does not guarantee any locking of the returned tuples, with implications spelled out in Section 55.4.

Note that it is permitted for an access method to implement only `amgetbitmap` and not `amgettuple`, or vice versa, if its internal implementation is unsuited to one API or the other.

### 55.4. Index Locking Considerations

Index access methods must handle concurrent updates of the index by multiple processes. The core PostgreSQL system obtains `AccessShareLock` on the index during an index scan, and `RowExclusiveLock` when updating the index (including plain `VACUUM`). Since these lock types do not conflict, the access method is responsible for handling any fine-grained locking it might need. An exclusive lock on the index as a whole will be taken only during index creation, destruction, or `REINDEX`.

Building an index type that supports concurrent updates usually requires extensive and subtle analysis of the required behavior. For the b-tree and hash index types, you can read about the design decisions involved in `src/backend/access/nbtree/README` and `src/backend/access/hash/README`.

Aside from the index’s own internal consistency requirements, concurrent updates create issues about consistency between the parent table (the `heap`) and the index. Because PostgreSQL separates accesses and updates of the heap from those of the index, there are windows in which the index might be inconsistent with the heap. We handle this problem with the following rules:

- A new heap entry is made before making its index entries. (Therefore a concurrent index scan is likely to fail to see the heap entry. This is okay because the index reader would be uninterested in an uncommitted row anyway. But see Section 55.5.)
- When a heap entry is to be deleted (by `VACUUM`), all its index entries must be removed first.
- An index scan must maintain a pin on the index page holding the item last returned by `amgettuple`, and `ambulkdelete` cannot delete entries from pages that are pinned by other backends. The need for this rule is explained below.

Without the third rule, it is possible for an index reader to see an index entry just before it is removed by `VACUUM`, and then to arrive at the corresponding heap entry after that was removed by `VACUUM`. This creates no serious problems if that item number is still unused when the reader reaches it, since an empty item slot will be ignored by `heap_fetch()`. But what if a third backend has already re-used the item slot for something else? When using an MVCC-compliant snapshot, there is no problem because the new occupant of the slot is certain to be too new to pass the snapshot test. However, with a non-MVCC-compliant snapshot (such as `SnapshotAny`), it would be possible to accept and return a row that does not in fact match the scan keys. We could defend against this scenario by requiring the scan keys to be rechecked against the heap row in all cases, but that is too expensive. Instead, we use a pin on an index
page as a proxy to indicate that the reader might still be “in flight” from the index entry to the matching heap entry. Making `bulkdelete` block on such a pin ensures that `VACUUM` cannot delete the heap entry before the reader is done with it. This solution costs little in run time, and adds blocking overhead only in the rare cases where there actually is a conflict.

This solution requires that index scans be “synchronous”: we have to fetch each heap tuple immediately after scanning the corresponding index entry. This is expensive for a number of reasons. An “asynchronous” scan in which we collect many TIDs from the index, and only visit the heap tuples sometime later, requires much less index locking overhead and can allow a more efficient heap access pattern. Per the above analysis, we must use the synchronous approach for non-MVCC-compliant snapshots, but an asynchronous scan is workable for a query using an MVCC snapshot.

In an `amgetbitmap` index scan, the access method does not keep an index pin on any of the returned tuples. Therefore it is only safe to use such scans with MVCC-compliant snapshots.

When the `ampredlocks` flag is not set, any scan using that index access method within a serializable transaction will acquire a nonblocking predicate lock on the full index. This will generate a read-write conflict with the insert of any tuple into that index by a concurrent serializable transaction. If certain patterns of read-write conflicts are detected among a set of concurrent serializable transactions, one of those transactions may be canceled to protect data integrity. When the flag is set, it indicates that the index access method implements finer-grained predicate locking, which will tend to reduce the frequency of such transaction cancellations.

### 55.5. Index Uniqueness Checks

PostgreSQL enforces SQL uniqueness constraints using `unique indexes`, which are indexes that disallow multiple entries with identical keys. An access method that supports this feature sets `pg_am.amcanunique` true. (At present, only b-tree supports it.)

Because of MVCC, it is always necessary to allow duplicate entries to exist physically in an index: the entries might refer to successive versions of a single logical row. The behavior we actually want to enforce is that no MVCC snapshot could include two rows with equal index keys. This breaks down into the following cases that must be checked when inserting a new row into a unique index:

- If a conflicting valid row has been deleted by the current transaction, it’s okay. (In particular, since an UPDATE always deletes the old row version before inserting the new version, this will allow an UPDATE on a row without changing the key.)
- If a conflicting row has been inserted by an as-yet-uncommitted transaction, the would-be inserter must wait to see if that transaction commits. If it rolls back then there is no conflict. If it commits without deleting the conflicting row again, there is a uniqueness violation. (In practice we just wait for the other transaction to end and then redo the visibility check in toto.)
- Similarly, if a conflicting valid row has been deleted by an as-yet-uncommitted transaction, the would-be inserter must wait for that transaction to commit or abort, and then repeat the test.

Furthermore, immediately before reporting a uniqueness violation according to the above rules, the access method must recheck the liveness of the row being inserted. If it is committed dead then no violation should be reported. (This case cannot occur during the ordinary scenario of inserting a row that’s just
been created by the current transaction. It can happen during `CREATE UNIQUE INDEX CONCURRENTLY`, however."

We require the index access method to apply these tests itself, which means that it must reach into the heap to check the commit status of any row that is shown to have a duplicate key according to the index contents. This is without a doubt ugly and non-modular, but it saves redundant work: if we did a separate probe then the index lookup for a conflicting row would be essentially repeated while finding the place to insert the new row’s index entry. What’s more, there is no obvious way to avoid race conditions unless the conflict check is an integral part of insertion of the new index entry.

If the unique constraint is deferrable, there is additional complexity: we need to be able to insert an index entry for a new row, but defer any uniqueness-violation error until end of statement or even later. To avoid unnecessary repeat searches of the index, the index access method should do a preliminary uniqueness check during the initial insertion. If this shows that there is definitely no conflicting live tuple, we are done. Otherwise, we schedule a recheck to occur when it is time to enforce the constraint. If, at the time of the recheck, both the inserted tuple and some other tuple with the same key are live, then the error must be reported. (Note that for this purpose, “live” actually means “any tuple in the index entry’s HOT chain is live”.) To implement this, the `aminsert` function is passed a `checkUnique` parameter having one of the following values:

- `UNIQUE_CHECK_NO` indicates that no uniqueness checking should be done (this is not a unique index).
- `UNIQUE_CHECK_YES` indicates that this is a non-deferrable unique index, and the uniqueness check must be done immediately, as described above.
- `UNIQUE_CHECK_PARTIAL` indicates that the unique constraint is deferrable. PostgreSQL will use this mode to insert each row’s index entry. The access method must allow duplicate entries into the index, and report any potential duplicates by returning `FALSE` from `aminsert`. For each row for which `FALSE` is returned, a deferred recheck will be scheduled.

The access method must identify any rows which might violate the unique constraint, but it is not an error for it to report false positives. This allows the check to be done without waiting for other transactions to finish; conflicts reported here are not treated as errors and will be rechecked later, by which time they may no longer be conflicts.

- `UNIQUE_CHECK_EXISTING` indicates that this is a deferred recheck of a row that was reported as a potential uniqueness violation. Although this is implemented by calling `aminsert`, the access method must not insert a new index entry in this case. The index entry is already present. Rather, the access method must check to see if there is another live index entry. If so, and if the target row is also still live, report error.

It is recommended that in a `UNIQUE_CHECK_EXISTING` call, the access method further verify that the target row actually does have an existing entry in the index, and report error if not. This is a good idea because the index tuple values passed to `aminsert` will have been recomputed. If the index definition involves functions that are not really immutable, we might be checking the wrong area of the index. Checking that the target row is found in the recheck verifies that we are scanning for the same tuple values as were used in the original insertion.
55.6. Index Cost Estimation Functions

The `amcostestimate` function is given information describing a possible index scan, including lists of WHERE and ORDER BY clauses that have been determined to be usable with the index. It must return estimates of the cost of accessing the index and the selectivity of the WHERE clauses (that is, the fraction of parent-table rows that will be retrieved during the index scan). For simple cases, nearly all the work of the cost estimator can be done by calling standard routines in the optimizer; the point of having an `amcostestimate` function is to allow index access methods to provide index-type-specific knowledge, in case it is possible to improve on the standard estimates.

Each `amcostestimate` function must have the signature:

```c
void amcostestimate (PlannerInfo *root,
                    IndexPath *path,
                    double loop_count,
                    Cost *indexStartupCost,
                    Cost *indexTotalCost,
                    Selectivity *indexSelectivity,
                    double *indexCorrelation);
```

The first three parameters are inputs:

- `root`  
  The planner’s information about the query being processed.
- `path`  
  The index access path being considered. All fields except cost and selectivity values are valid.
- `loop_count`  
  The number of repetitions of the index scan that should be factored into the cost estimates. This will typically be greater than one when considering a parameterized scan for use in the inside of a nestloop join. Note that the cost estimates should still be for just one scan; a larger `loop_count` means that it may be appropriate to allow for some caching effects across multiple scans.

The last four parameters are pass-by-reference outputs:

- `*indexStartupCost`  
  Set to cost of index start-up processing
- `*indexTotalCost`  
  Set to total cost of index processing
- `*indexSelectivity`  
  Set to index selectivity
- `*indexCorrelation`  
  Set to correlation coefficient between index scan order and underlying table’s order
Chapter 55. Index Access Method Interface Definition

Note that cost estimate functions must be written in C, not in SQL or any available procedural language, because they must access internal data structures of the planner/optimizer.

The index access costs should be computed using the parameters used by src/backend/optimizer/path/costsize.c: a sequential disk block fetch has cost seq_page_cost, a nonsequential fetch has cost random_page_cost, and the cost of processing one index row should usually be taken as cpu_index_tuple_cost. In addition, an appropriate multiple of cpu_operator_cost should be charged for any comparison operators invoked during index processing (especially evaluation of the indexquals themselves).

The access costs should include all disk and CPU costs associated with scanning the index itself, but not the costs of retrieving or processing the parent-table rows that are identified by the index.

The “start-up cost” is the part of the total scan cost that must be expended before we can begin to fetch the first row. For most indexes this can be taken as zero, but an index type with a high start-up cost might want to set it nonzero.

The indexSelectivity should be set to the estimated fraction of the parent table rows that will be retrieved during the index scan. In the case of a lossy query, this will typically be higher than the fraction of rows that actually pass the given qual conditions.

The indexCorrelation should be set to the correlation (ranging between -1.0 and 1.0) between the index order and the table order. This is used to adjust the estimate for the cost of fetching rows from the parent table.

When loop_count is greater than one, the returned numbers should be averages expected for any one scan of the index.

Cost Estimation

A typical cost estimator will proceed as follows:

1. Estimate and return the fraction of parent-table rows that will be visited based on the given qual conditions. In the absence of any index-type-specific knowledge, use the standard optimizer function clauselist_selectivity():

   ```c
   *indexSelectivity = clauselist_selectivity(root, path->indexquals,
       path->indexinfo->rel->relid,
       JOIN_INNER, NULL);
   ```

2. Estimate the number of index rows that will be visited during the scan. For many index types this is the same as indexSelectivity times the number of rows in the index, but it might be more. (Note that the index’s size in pages and rows is available from the path->indexinfo struct.)

3. Estimate the number of index pages that will be retrieved during the scan. This might be just indexSelectivity times the index’s size in pages.

4. Compute the index access cost. A generic estimator might do this:

   ```c
   /*
   * Our generic assumption is that the index pages will be read
   * sequentially, so they cost seq_page_cost each, not random_page_cost.
   * Also, we charge for evaluation of the indexquals at each index row.
   * All the costs are assumed to be paid incrementally during the scan.
   */
   cost_qual_eval(&index_qual_cost, path->indexquals, root);
   ```
*indexStartupCost = index_qual_cost.startup;
*indexTotalCost = seq_page_cost * numIndexPages +
    (cpu_index_tuple_cost + index_qual_cost.per_tuple) * numIndexTuples;

However, the above does not account for amortization of index reads across repeated index scans.

5. Estimate the index correlation. For a simple ordered index on a single field, this can be retrieved from pg_statistic. If the correlation is not known, the conservative estimate is zero (no correlation).

Examples of cost estimator functions can be found in src/backend/utils/adt/selfuncs.c.
Chapter 56. GiST Indexes

56.1. Introduction

GiST stands for Generalized Search Tree. It is a balanced, tree-structured access method, that acts as a base template in which to implement arbitrary indexing schemes. B-trees, R-trees and many other indexing schemes can be implemented in GiST.

One advantage of GiST is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from the University of California at Berkeley’s GiST Indexing Project web site1 and Marcel Kornacker’s thesis, Access Methods for Next-Generation Database Systems2. The GiST implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their web site3.

56.2. Built-in Operator Classes

The core PostgreSQL distribution includes the GiST operator classes shown in Table 56-1. (Some of the optional modules described in Appendix F provide additional GiST operator classes.)

<table>
<thead>
<tr>
<th>Name</th>
<th>Indexed Data Type</th>
<th>Indexable Operators</th>
<th>Ordering Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td>box_ops</td>
<td>box</td>
<td>&amp;&amp; &amp;&gt; &amp;&lt;</td>
<td></td>
</tr>
<tr>
<td>circle_ops</td>
<td>circle</td>
<td>&amp;&amp; &amp;&gt; &amp;&lt;</td>
<td></td>
</tr>
<tr>
<td>inet_ops</td>
<td>inet,cidr</td>
<td>&amp;&amp; &gt;&gt; &gt;&gt;= &gt; &lt;= &lt;&lt;</td>
<td>&lt;&lt; &lt;&lt;= &lt;&lt;= =</td>
</tr>
<tr>
<td>point_ops</td>
<td>point</td>
<td>&gt;&gt; ^ &lt;&lt; &lt; @ &lt;0 &lt;</td>
<td>&lt;= =</td>
</tr>
<tr>
<td>poly_ops</td>
<td>polygon</td>
<td>&amp;&amp; &amp;&gt; &amp;&lt;</td>
<td></td>
</tr>
</tbody>
</table>

### 56.3. Extensibility

Traditionally, implementing a new index access method meant a lot of difficult work. It was necessary to understand the inner workings of the database, such as the lock manager and Write-Ahead Log. The GiST interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GiST layer itself takes care of concurrency, logging and searching the tree structure.

This extensibility should not be confused with the extensibility of the other standard search trees in terms of the data they can handle. For example, PostgreSQL supports extensible B-trees and hash indexes. That means that you can use PostgreSQL to build a B-tree or hash over any data type you want. But B-trees only support range predicates (\(<\), \(\leq\), \(\geq\)), and hash indexes only support equality queries.

So if you index, say, an image collection with a PostgreSQL B-tree, you can only issue queries such as “is imagex equal to imagey”, “is imagex less than imagey” and “is imagex greater than imagey”. Depending on how you define “equals”, “less than” and “greater than” in this context, this could be useful. However, by using a GiST based index, you could create ways to ask domain-specific questions, perhaps “find all images of horses” or “find all over-exposed images”.

All it takes to get a GiST access method up and running is to implement several user-defined methods, which define the behavior of keys in the tree. Of course these methods have to be pretty fancy to support fancy queries, but for all the standard queries (B-trees, R-trees, etc.) they’re relatively straightforward. In short, GiST combines extensibility along with generality, code reuse, and a clean interface.

There are seven methods that an index operator class for GiST must provide, and an eighth that is optional. Correctness of the index is ensured by proper implementation of the `same`, `consistent` and `union` methods, while efficiency (size and speed) of the index will depend on the `penalty` and `picksplit` methods. The remaining two basic methods are `compress` and `decompress`, which allow an index to have internal tree data of a different type than the data it indexes. The leaves are to be of the indexed data type, while the other tree nodes can be of any C struct (but you still have to follow PostgreSQL data type rules here, see about `varlena` for variable sized data). If the tree’s internal data type exists at the SQL level, the `STORAGE` option of the `CREATE OPERATOR CLASS` command can be used. The optional eighth method is `distance`, which is needed if the operator class wishes to support ordered scans (nearest-neighbor searches).
consistent

Given an index entry \( p \) and a query value \( q \), this function determines whether the index entry is "consistent" with the query; that is, could the predicate "indexed_column indexable_operator \( q \)" be true for any row represented by the index entry? For a leaf index entry this is equivalent to testing the indexable condition, while for an internal tree node this determines whether it is necessary to scan the subtree of the index represented by the tree node. When the result is true, a recheck flag must also be returned. This indicates whether the predicate is certainly true or only possibly true. If \( \text{recheck} = \text{false} \) then the index has tested the predicate condition exactly, whereas if \( \text{recheck} = \text{true} \) the row is only a candidate match. In that case the system will automatically evaluate the indexable_operator against the actual row value to see if it is really a match. This convention allows GiST to support both lossless and lossy index structures.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_consistent(internal, data_type, smallint, oid, internal)
RETURNS bool
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```c
Datum my_consistent(PG_FUNCTION_ARGS);
PG_FUNCTION_INFO_V1(my_consistent);
Datum
my_consistent(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
data_type *query = PG_GETARG_DATA_TYPE_P(1);
StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
/* Oid subtype = PG_GETARG_OID(3); */
bool *recheck = (bool *) PG_GETARG_POINTER(4);
data_type *key = DatumGetDataType(entry->key);
bool retval;

    /* determine return value as a function of strategy, key and query. */
    *recheck = true; /* or false if check is exact */
    PG_RETURN_BOOL(retval);
}
```

Here, \( \text{key} \) is an element in the index and \( \text{query} \) the value being looked up in the index. The \( \text{StrategyNumber} \) parameter indicates which operator of your operator class is being applied — it matches one of the operator numbers in the `CREATE OPERATOR CLASS` command. Depending on what operators you have included in the class, the data type of \( \text{query} \) could vary with the operator, but the above skeleton assumes it doesn’t.
This method consolidates information in the tree. Given a set of entries, this function generates a new index entry that represents all the given entries.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_union(internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```c
Datum my_union(PG_FUNCTION_ARGS);

Datum my_union(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
    GISTENTRY *ent = entryvec->vector;
    data_type *out,
        *tmp,
        *old;
    int numranges,
        i = 0;

    numranges = entryvec->n;
    tmp = DatumGetDataType(ent[0].key);
    out = tmp;

    if (numranges == 1)
    {
        out = data_type_deep_copy(tmp);
        PG_RETURN_DATA_TYPE_P(out);
    }

    for (i = 1; i < numranges; i++)
    {
        old = out;
        tmp = DatumGetDataType(ent[i].key);
        out = my_union_implementation(out, tmp);
    }

    PG_RETURN_DATA_TYPE_P(out);
}
```

As you can see, in this skeleton we’re dealing with a data type where \( \text{union}(X, Y, Z) = \text{union}(\text{union}(X, Y), Z) \). It’s easy enough to support data types where this is not the case, by implementing the proper union algorithm in this GiST support method.

The `union` implementation function should return a pointer to newly `palloc()`ed memory. You can’t just return whatever the input is.
compress

Converts the data item into a format suitable for physical storage in an index page.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_compress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```c
Datum my_compress(PG_FUNCTION_ARGS);
PG_FUNCTION_INFO_V1(my_compress);

Datum
my_compress(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *retval;

    if (entry->leafkey)
    {
        /* replace entry->key with a compressed version */
        compressed_data_type *compressed_data = palloc(sizeof(compressed_data_type));
        /* fill *compressed_data from entry->key ... */
        retval = palloc(sizeof(GISTENTRY));
        gistentryinit(*retval, PointerGetDatum(compressed_data),
                      entry->rel, entry->page, entry->offset, FALSE);
    }
    else
    {
        /* typically we needn’t do anything with non-leaf entries */
        retval = entry;
    }

    PG_RETURN_POINTER(retval);
}
```

You have to adapt `compressed_data_type` to the specific type you’re converting to in order to compress your leaf nodes, of course.

Depending on your needs, you could also need to care about compressing NULL values in there, storing for example `(Datum) 0` like `gist_circle_compress` does.

decompress

The reverse of the `compress` method. Converts the index representation of the data item into a format that can be manipulated by the database.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_decompress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
```
And the matching code in the C module could then follow this skeleton:

```c
Datum my_decompress(PG_FUNCTION_ARGS);
PG_FUNCTION_INFO_V1(my_decompress);

Datum
my_decompress(PG_FUNCTION_ARGS)
{
    PG_RETURN_POINTER(PG_GETARG_POINTER(0));
}

The above skeleton is suitable for the case where no decompression is needed.

penalty

Returns a value indicating the “cost” of inserting the new entry into a particular branch of the tree. Items will be inserted down the path of least penalty in the tree. Values returned by penalty should be non-negative. If a negative value is returned, it will be treated as zero.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_penalty(internal, internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT; -- in some cases penalty functions need not be strict
```

And the matching code in the C module could then follow this skeleton:

```c
Datum my_penalty(PG_FUNCTION_ARGS);
PG_FUNCTION_INFO_V1(my_penalty);

Datum
my_penalty(PG_FUNCTION_ARGS)
{
    GISTENTRY *origentry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *newentry = (GISTENTRY *) PG_GETARG_POINTER(1);
    float *penalty = (float *) PG_GETARG_POINTER(2);
    data_type *orig = DatumGetDataType(origentry->key);
    data_type *new = DatumGetDataType(newentry->key);

    *penalty = my_penalty_implementation(orig, new);
    PG_RETURN_POINTER(penalty);
}
```

The penalty function is crucial to good performance of the index. It’ll get used at insertion time to determine which branch to follow when choosing where to add the new entry in the tree. At query time, the more balanced the index, the quicker the lookup.

picksplit

When an index page split is necessary, this function decides which entries on the page are to stay on the old page, and which are to move to the new page.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_picksplit(internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```
And the matching code in the C module could then follow this skeleton:

```c
Datum my_picksplit(PG_FUNCTION_ARGS);
PG_FUNCTION_INFO_V1(my_picksplit);

Datum
my_picksplit(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
    OffsetNumber maxoff = entryvec->n - 1;
    GISTENTRY *ent = entryvec->vector;
    GIST_SPLITVEC *v = (GIST_SPLITVEC *) PG_GETARG_POINTER(1);
    int i,
        nbytes,
    OffsetNumber *left,
        *right;
    data_type *tmp_union;
    data_type *unionL;
    data_type *unionR;
    GISTENTRY **raw_entryvec;

    maxoff = entryvec->n - 1;
    nbytes = (maxoff + 1) * sizeof(OffsetNumber);

    v->spl_left = (OffsetNumber *) palloc(nbytes);
    left = v->spl_left;
    v->spl_nleft = 0;

    v->spl_right = (OffsetNumber *) palloc(nbytes);
    right = v->spl_right;
    v->spl_nright = 0;

    unionL = NULL;
    unionR = NULL;

    /* Initialize the raw entry vector. */
    raw_entryvec = (GISTENTRY **) malloc(entryvec->n * sizeof(void *));
    for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
        raw_entryvec[i] = &(entryvec->vector[i]);

    for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
    {
        int real_index = raw_entryvec[i] - entryvec->vector;

        tmp_union = DatumGetDataType(entryvec->vector[real_index].key);
        Assert(tmp_union != NULL);

        /*
         * Choose where to put the index entries and update unionL and unionR
         * accordingly. Append the entries to either v_spl_left or
         * v_spl_right, and care about the counters.
         */
        if (my_choice_is_left(unionL, curl, unionR, curr))
```

2085
if (unionL == NULL)
    unionL = tmp_union;
else
    unionL = my_union_implementation(unionL, tmp_union);

*left = real_index;
++left;
++(v->spl_nleft);
}
else
{
    /*
     * Same on the right
     */
}

v->spl_ldatum = DataTypeGetDatum(unionL);
v->spl_rdatum = DataTypeGetDatum(unionR);
PG_RETURN_POINTER(v);
}

Like penalty, the picksplit function is crucial to good performance of the index. Designing suitable penalty and picksplit implementations is where the challenge of implementing well-performing GiST indexes lies.

same

Returns true if two index entries are identical, false otherwise.

The SQL declaration of the function must look like this:

CREATE OR REPLACE FUNCTION my_same(internal, internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

And the matching code in the C module could then follow this skeleton:

Datum my_same(PG_FUNCTION_ARGS);
PG_FUNCTION_INFO_V1(my_same);

Datum
my_same(PG_FUNCTION_ARGS)
{
    prefix_range *v1 = PG_GETARG_PREFIX_RANGE_P(0);
    prefix_range *v2 = PG_GETARG_PREFIX_RANGE_P(1);
    bool *result = (bool *) PG_GETARG_POINTER(2);

    *result = my_eq(v1, v2);
    PG_RETURN_POINTER(result);
}

For historical reasons, the same function doesn’t just return a Boolean result; instead it has to store the flag at the location indicated by the third argument.
Given an index entry \( p \) and a query value \( q \), this function determines the index entry’s “distance” from the query value. This function must be supplied if the operator class contains any ordering operators. A query using the ordering operator will be implemented by returning index entries with the smallest “distance” values first, so the results must be consistent with the operator’s semantics. For a leaf index entry the result just represents the distance to the index entry; for an internal tree node, the result must be the smallest distance that any child entry could have.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_distance(internal, data_type, smallint, oid)
RETURNS float8
AS ’MODULE_PATHNAME’
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```c
Datum my_distance(PG_FUNCTION_ARGS);
PG_FUNCTION_INFO_V1(my_distance);
Datum my_distance(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    data_type *query = PG_GETARG_DATA_TYPE_P(1);
    StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
    data_type *key = DatumGetDataType(entry->key);
    double retval;
    /* determine return value as a function of strategy, key and query. */
    PG_RETURN_FLOAT8(retval);
}
```

The arguments to the `distance` function are identical to the arguments of the `consistent` function, except that no recheck flag is used. The distance to a leaf index entry must always be determined exactly, since there is no way to re-order the tuples once they are returned. Some approximation is allowed when determining the distance to an internal tree node, so long as the result is never greater than any child’s actual distance. Thus, for example, distance to a bounding box is usually sufficient in geometric applications. The result value can be any finite `float8` value. (Infinity and minus infinity are used internally to handle cases such as nulls, so it is not recommended that `distance` functions return these values.)

All the GiST support methods are normally called in short-lived memory contexts; that is, `CurrentMemoryContext` will get reset after each tuple is processed. It is therefore not very important to worry about `pfree`ing everything you `palloc`. However, in some cases it’s useful for a support method to cache data across repeated calls. To do that, allocate the longer-lived data in `fcinfo->flinfo->fn_mcxt`, and keep a pointer to it in `fcinfo->flinfo->fn_extra`. Such data will survive for the life of the index operation (e.g., a single GiST index scan, index build, or index tuple insertion). Be careful to `pfree` the previous value when replacing a `fn_extra` value, or the leak will accumulate for the duration of the operation.
56.4. Implementation

56.4.1. GiST buffering build

Building large GiST indexes by simply inserting all the tuples tends to be slow, because if the index tuples
are scattered across the index and the index is large enough to not fit in cache, the insertions need to
perform a lot of random I/O. Beginning in version 9.2, PostgreSQL supports a more efficient method to
build GiST indexes based on buffering, which can dramatically reduce the number of random I/Os needed
for non-ordered data sets. For well-ordered data sets the benefit is smaller or non-existent, because only a
small number of pages receive new tuples at a time, and those pages fit in cache even if the index as whole
does not.

However, buffering index build needs to call the penalty function more often, which consumes some
extra CPU resources. Also, the buffers used in the buffering build need temporary disk space, up to the
size of the resulting index. Buffering can also influence the quality of the resulting index, in both positive
and negative directions. That influence depends on various factors, like the distribution of the input data
and the operator class implementation.

By default, a GiST index build switches to the buffering method when the index size reaches effective_cache_size. It can be manually turned on or off by the BUFFERING parameter to the CREATE INDEX
command. The default behavior is good for most cases, but turning buffering off might speed up the build
somewhat if the input data is ordered.

56.5. Examples

The PostgreSQL source distribution includes several examples of index methods implemented
using GiST. The core system currently provides text search support (indexing for tsvector and
tquery) as well as R-Tree equivalent functionality for some of the built-in geometric data types (see
src/backend/access/gist/gistproc.c). The following contrib modules also contain GiST
operator classes:

btree_gist
  B-tree equivalent functionality for several data types
cube
  Indexing for multidimensional cubes
hstore
  Module for storing (key, value) pairs
intarray
  RD-Tree for one-dimensional array of int4 values
ltree
  Indexing for tree-like structures
pg_trgm
Text similarity using trigram matching

seg
Indexing for “float ranges”
Chapter 57. SP-GiST Indexes

57.1. Introduction

SP-GiST is an abbreviation for space-partitioned GiST. SP-GiST supports partitioned search trees, which facilitate development of a wide range of different non-balanced data structures, such as quad-trees, k-d trees, and radix trees (tries). The common feature of these structures is that they repeatedly divide the search space into partitions that need not be of equal size. Searches that are well matched to the partitioning rule can be very fast.

These popular data structures were originally developed for in-memory usage. In main memory, they are usually designed as a set of dynamically allocated nodes linked by pointers. This is not suitable for direct storing on disk, since these chains of pointers can be rather long which would require too many disk accesses. In contrast, disk-based data structures should have a high fanout to minimize I/O. The challenge addressed by SP-GiST is to map search tree nodes to disk pages in such a way that a search need access only a few disk pages, even if it traverses many nodes.

Like GiST, SP-GiST is meant to allow the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from Purdue University’s SP-GiST Indexing Project web site[1]. The SP-GiST implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their web site[2].

57.2. Built-in Operator Classes

The core PostgreSQL distribution includes the SP-GiST operator classes shown in Table 57-1.

<table>
<thead>
<tr>
<th>Name</th>
<th>Indexed Data Type</th>
<th>Indexable Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td>kd_point_ops</td>
<td>point</td>
<td>&lt;&lt; &lt;@ &lt;&lt; ^ &gt; ^ &gt; ^ &gt;= ^ =</td>
</tr>
<tr>
<td>quad_point_ops</td>
<td>point</td>
<td>&lt;&lt; &lt;@ &lt;&lt; ^ &gt; ^ &gt; ^ &gt;= ^ =</td>
</tr>
<tr>
<td>range_ops</td>
<td>any range type</td>
<td>&amp;&amp; &amp; &lt; &amp; &gt; -</td>
</tr>
<tr>
<td>text_ops</td>
<td>text</td>
<td>&lt; &lt;= = &gt; = = = = = = = = = =</td>
</tr>
</tbody>
</table>

Of the two operator classes for type point, quad_point_ops is the default. kd_point_ops supports the same operators but uses a different index data structure which may offer better performance in some

Applications.

57.3. Extensibility

SP-GiST offers an interface with a high level of abstraction, requiring the access method developer to implement only methods specific to a given data type. The SP-GiST core is responsible for efficient disk mapping and searching the tree structure. It also takes care of concurrency and logging considerations.

Leaf tuples of an SP-GiST tree contain values of the same data type as the indexed column. Leaf tuples at the root level will always contain the original indexed data value, but leaf tuples at lower levels might contain only a compressed representation, such as a suffix. In that case the operator class support functions must be able to reconstruct the original value using information accumulated from the inner tuples that are passed through to reach the leaf level.

Inner tuples are more complex, since they are branching points in the search tree. Each inner tuple contains a set of one or more nodes, which represent groups of similar leaf values. A node contains a downlink that leads to either another, lower-level inner tuple, or a short list of leaf tuples that all lie on the same index page. Each node has a label that describes it; for example, in a radix tree the node label could be the next character of the string value. Optionally, an inner tuple can have a prefix value that describes all its members. In a radix tree this could be the common prefix of the represented strings. The prefix value is not necessarily really a prefix, but can be any data needed by the operator class; for example, in a quad-tree it can store the central point that the four quadrants are measured with respect to. A quad-tree inner tuple would then also contain four nodes corresponding to the quadrants around this central point.

Some tree algorithms require knowledge of level (or depth) of the current tuple, so the SP-GiST core provides the possibility for operator classes to manage level counting while descending the tree. There is also support for incrementally reconstructing the represented value when that is needed.

Note: The SP-GiST core code takes care of null entries. Although SP-GiST indexes do store entries for nulls in indexed columns, this is hidden from the index operator class code: no null index entries or search conditions will ever be passed to the operator class methods. (It is assumed that SP-GiST operators are strict and so cannot succeed for null values.) Null values are therefore not discussed further here.

There are five user-defined methods that an index operator class for SP-GiST must provide. All five follow the convention of accepting two internal arguments, the first of which is a pointer to a C struct containing input values for the support method, while the second argument is a pointer to a C struct where output values must be placed. Four of the methods just return void, since all their results appear in the output struct; but leaf_consistent additionally returns a boolean result. The methods must not modify any fields of their input structs. In all cases, the output struct is initialized to zeroes before calling the user-defined method.

The five user-defined methods are:

config

Returns static information about the index implementation, including the data type OIDs of the prefix and node label data types.
The SQL declaration of the function must look like this:

```sql
CREATE FUNCTION my_config(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgConfigIn` struct, containing input data for the function. The second argument is a pointer to a `spgConfigOut` struct, which the function must fill with result data.

```c
typedef struct spgConfigIn {
    Oid attType; /* Data type to be indexed */
} spgConfigIn;

typedef struct spgConfigOut {
    Oid prefixType; /* Data type of inner-tuple prefixes */
    Oid labelType; /* Data type of inner-tuple node labels */
    bool canReturnData; /* Opclass can reconstruct original data */
    bool longValuesOK; /* Opclass can cope with values > 1 page */
} spgConfigOut;
```

`attType` is passed in order to support polymorphic index operator classes; for ordinary fixed-data-type operator classes, it will always have the same value and so can be ignored.

For operator classes that do not use prefixes, `prefixType` can be set to `VOIDOID`. Likewise, for operator classes that do not use node labels, `labelType` can be set to `VOIDOID`. `canReturnData` should be set true if the operator class is capable of reconstructing the originally-supplied index value. `longValuesOK` should be set true only when the `attType` is of variable length and the operator class is capable of segmenting long values by repeated suffixing (see Section 57.4.1).

`choose` chooses a method for inserting a new value into an inner tuple.

The SQL declaration of the function must look like this:

```sql
CREATE FUNCTION my_choose(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgChooseIn` struct, containing input data for the function. The second argument is a pointer to a `spgChooseOut` struct, which the function must fill with result data.

```c
typedef struct spgChooseIn {
    Datum datum; /* original datum to be indexed */
    Datum leafDatum; /* current datum to be stored at leaf */
    int level; /* current level (counting from zero) */

    /* Data from current inner tuple */
    bool allTheSame; /* tuple is marked all-the-same? */
    bool hasPrefix; /* tuple has a prefix? */
    Datum prefixDatum; /* if so, the prefix value */
    int nNodes; /* number of nodes in the inner tuple */
    Datum *nodeLabels; /* node label values (NULL if none) */
} spgChooseIn;

typedef enum spgChooseResultType {
    spgMatchNode = 1, /* descend into existing node */
Chapter 57. SP-GiST Indexes

spgAddNode, /* add a node to the inner tuple */
spgSplitTuple /* split inner tuple (change its prefix) */
} spgChooseResultType;

typedef struct spgChooseOut
{
    spgChooseResultType resultType; /* action code, see above */
    union
    {
        struct /* results for spgMatchNode */
        {
            int nodeN; /* descend to this node (index from 0) */
            int levelAdd; /* increment level by this much */
            Datum restDatum; /* new leaf datum */
        } matchNode;
        struct /* results for spgAddNode */
        {
            Datum nodeLabel; /* new node’s label */
            int nodeN; /* where to insert it (index from 0) */
        } addNode;
        struct /* results for spgSplitTuple */
        {
            /* Info to form new inner tuple with one node */
            bool prefixHasPrefix; /* tuple should have a prefix? */
            Datum prefixPrefixDatum; /* if so, its value */
            Datum nodeLabel; /* node’s label */

            /* Info to form new lower-level inner tuple with all old nodes */
            bool postfixHasPrefix; /* tuple should have a prefix? */
            Datum postfixPrefixDatum; /* if so, its value */
        } splitTuple;
    } result;
} spgChooseOut;

datum is the original datum that was to be inserted into the index. leafDatum is initially the same as datum, but can change at lower levels of the tree if the choose or picksplit methods change it. When the insertion search reaches a leaf page, the current value of leafDatum is what will be stored in the newly created leaf tuple. level is the current inner tuple’s level, starting at zero for the root level. allTheSame is true if the current inner tuple is marked as containing multiple equivalent nodes (see Section 57.4.3). hasPrefix is true if the current inner tuple contains a prefix; if so, prefixDatum is its value. nNodes is the number of child nodes contained in the inner tuple, and nodeLabels is an array of their label values, or NULL if there are no labels.

The choose function can determine either that the new value matches one of the existing child nodes, or that a new child node must be added, or that the new value is inconsistent with the tuple prefix and so the inner tuple must be split to create a less restrictive prefix.

If the new value matches one of the existing child nodes, set resultType to spgMatchNode. Set nodeN to the index (from zero) of that node in the node array. Set levelAdd to the increment in level caused by descending through that node, or leave it as zero if the operator class does not use levels. Set restDatum to equal datum if the operator class does not modify datums from one level to the next, or otherwise set it to the modified value to be used as leafDatum at the next level.
If a new child node must be added, set \texttt{resultType} to \texttt{spgAddNode}. Set \texttt{nodeLabel} to the label to be used for the new node, and set \texttt{nodeN} to the index (from zero) at which to insert the node in the node array. After the node has been added, the \texttt{choose} function will be called again with the modified inner tuple; that call should result in an \texttt{spgMatchNode} result.

If the new value is inconsistent with the tuple prefix, set \texttt{resultType} to \texttt{spgSplitTuple}. This action moves all the existing nodes into a new lower-level inner tuple, and replaces the existing inner tuple with a tuple having a single node that links to the new lower-level inner tuple. Set \texttt{prefixHasPrefix} to indicate whether the new upper tuple should have a prefix, and if so set \texttt{prefixPrefixDatum} to the prefix value. This new prefix value must be sufficiently less restrictive than the original to accept the new value to be indexed, and it should be no longer than the original prefix. Set \texttt{nodeLabel} to the label to be used for the node that will point to the new lower-level inner tuple. Set \texttt{postfixHasPrefix} to indicate whether the new lower-level inner tuple should have a prefix, and if so set \texttt{postfixPrefixDatum} to the prefix value. The combination of these two prefixes and the additional label must have the same meaning as the original prefix, because there is no opportunity to alter the node labels that are moved to the new lower-level tuple, nor to change any child index entries. After the node has been split, the \texttt{choose} function will be called again with the replacement inner tuple. That call will usually result in an \texttt{spgAddNode} result, since presumably the node label added in the split step will not match the new value; so after that, there will be a third call that finally returns \texttt{spgMatchNode} and allows the insertion to descend to the leaf level.

\texttt{picksplit}

Decides how to create a new inner tuple over a set of leaf tuples.

The SQL declaration of the function must look like this:

\begin{verbatim}
CREATE FUNCTION my_picksplit(internal, internal) RETURNS void ...
\end{verbatim}

The first argument is a pointer to a \texttt{spgPickSplitIn C struct}, containing input data for the function. The second argument is a pointer to a \texttt{spgPickSplitOut C struct}, which the function must fill with result data.

\begin{verbatim}
typedef struct spgPickSplitIn
{
    int nTuples; /* number of leaf tuples */
    Datum *datums; /* their datums (array of length nTuples) */
    int level;    /* current level (counting from zero) */
} spgPickSplitIn;

typedef struct spgPickSplitOut
{
    bool hasPrefix; /* new inner tuple should have a prefix? */
    Datum prefixDatum; /* if so, its value */
    int nNodes; /* number of nodes for new inner tuple */
    Datum *nodeLabels; /* their labels (or NULL for no labels) */
    int *mapTuplesToNodes; /* node index for each leaf tuple */
    Datum *leafTupleDatums; /* datum to store in each new leaf tuple */
} spgPickSplitOut;
\end{verbatim}

\texttt{nTuples} is the number of leaf tuples provided. \texttt{datums} is an array of their datum values. \texttt{level} is the current level that all the leaf tuples share, which will become the level of the new inner tuple.
Set `hasPrefix` to indicate whether the new inner tuple should have a prefix, and if so set `prefixDatum` to the prefix value. Set `nNodes` to indicate the number of nodes that the new inner tuple will contain, and set `nodeLabels` to an array of their label values. (If the nodes do not require labels, set `nodeLabels` to NULL; see Section 57.4.2 for details.) Set `mapTuplesToNodes` to an array that gives the index (from zero) of the node that each leaf tuple should be assigned to. Set `leafTupleDatums` to an array of the values to be stored in the new leaf tuples (these will be the same as the input `datums` if the operator class does not modify datums from one level to the next). Note that the `picksplit` function is responsible for `palloc`'ing the `nodeLabels`, `mapTuplesToNodes` and `leafTupleDatums` arrays.

If more than one leaf tuple is supplied, it is expected that the `picksplit` function will classify them into more than one node; otherwise it is not possible to split the leaf tuples across multiple pages, which is the ultimate purpose of this operation. Therefore, if the `picksplit` function ends up placing all the leaf tuples in the same node, the core SP-GiST code will override that decision and generate an inner tuple in which the leaf tuples are assigned at random to several identically-labeled nodes. Such a tuple is marked `allTheSame` to signify that this has happened. The `choose` and `inner_consistent` functions must take suitable care with such inner tuples. See Section 57.4.3 for more information.

`picksplit` can be applied to a single leaf tuple only in the case that the `config` function set `longValuesOK` to true and a larger-than-a-page input value has been supplied. In this case the point of the operation is to strip off a prefix and produce a new, shorter leaf datum value. The call will be repeated until a leaf datum short enough to fit on a page has been produced. See Section 57.4.1 for more information.

`inner_consistent`

Returns set of nodes (branches) to follow during tree search.

The SQL declaration of the function must look like this:

```sql
CREATE FUNCTION my_inner_consistent(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgInnerConsistentIn` C struct, containing input data for the function. The second argument is a pointer to a `spgInnerConsistentOut` C struct, which the function must fill with result data.

```c
typedef struct spgInnerConsistentIn
{
    ScanKey    scankeys;     /* array of operators and comparison values */
    int        nkeys;        /* length of array */
    Datum      reconstructedValue;  /* value reconstructed at parent */
    int        level;        /* current level (counting from zero) */
    bool       returnData;   /* original data must be returned? */

    bool   allTheSame;      /* tuple is marked all-the-same? */
    bool   hasPrefix;       /* tuple has a prefix? */
    Datum  prefixDatum;    /* if so, the prefix value */
    int    nNodes;         /* number of nodes in the inner tuple */
    Datum  *nodeLabels;    /* node label values (NULL if none) */
} spgInnerConsistentIn;

typedef struct spgInnerConsistentOut
```
Chapter 57. SP-GiST Indexes

```c
{ int nNodes; /* number of child nodes to be visited */
  int *nodeNumbers; /* their indexes in the node array */
  int *levelAdds; /* increment level by this much for each */
  Datum *reconstructedValues; /* associated reconstructed values */
} spgInnerConsistentOut;
```

The array `scankeys`, of length `nkeys`, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them are interesting. (Note that `nkeys = 0` implies that all index entries satisfy the query.) Usually the consistent function only cares about the `sk_strategy` and `sk_argument` fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check `sk_flags` to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. `reconstructedValue` is the value reconstructed for the parent tuple; it is (Datum) 0 at the root level or if the `inner_consistent` function did not provide a value at the parent level. `level` is the current inner tuple’s level, starting at zero for the root level. `returnData` is true if reconstructed data is required for this query; this will only be so if the `config` function asserted `canReturnData`. `allTheSame` is true if the current inner tuple is marked “all-the-same”; in this case all the nodes have the same label (if any) and so either all or none of them match the query (see Section 57.4.3). `hasPrefix` is true if the current inner tuple contains a prefix; if so, `prefixDatum` is its value. `nNodes` is the number of child nodes contained in the inner tuple, and `nodeLabels` is an array of their label values, or NULL if the nodes do not have labels.

`nNodes` must be set to the number of child nodes that need to be visited by the search, and `nodeNumbers` must be set to an array of their indexes. If the operator class keeps track of levels, set `levelAdds` to an array of the level increments required when descending to each node to be visited. (Often these increments will be the same for all the nodes, but that’s not necessarily so, so an array is used.) If value reconstruction is needed, set `reconstructedValues` to an array of the values reconstructed for each child node to be visited; otherwise, leave `reconstructedValues` as NULL. Note that the `inner_consistent` function is responsible for `palloc’ing` the `nodeNumbers`, `levelAdds` and `reconstructedValues` arrays.

`leaf_consistent`

Returns true if a leaf tuple satisfies a query.

The SQL declaration of the function must look like this:

```sql
CREATE FUNCTION my_leaf_consistent(internal, internal) RETURNS bool ...
```

The first argument is a pointer to a `spgLeafConsistentIn` C struct, containing input data for the function. The second argument is a pointer to a `spgLeafConsistentOut` C struct, which the function must fill with result data.

```c
typedef struct spgLeafConsistentIn {
  ScanKey scankeys; /* array of operators and comparison values */
  int nkeys; /* length of array */
  Datum reconstructedValue; /* value reconstructed at parent */
  int level; /* current level (counting from zero) */
  bool returnData; /* original data must be returned? */
  Datum leafDatum; /* datum in leaf tuple */
} spgLeafConsistentIn;
```
Chapter 57. SP-GiST Indexes

typedef struct spgLeafConsistentOut {
    Datum leafValue;  /* reconstructed original data, if any */
    bool recheck;     /* set true if operator must be rechecked */
} spgLeafConsistentOut;

The array scankeys, of length nkeys, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them satisfy the query. (Note that nkeys = 0 implies that all index entries satisfy the query.) Usually the consistent function only cares about the sk_strategy and sk_argument fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check sk_flags to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. reconstructedValue is the value reconstructed for the parent tuple; it is (Datum) 0 at the root level or if the inner_consistent function did not provide a value at the parent level. level is the current leaf tuple’s level, starting at zero for the root level. returnData is true if reconstructed data is required for this query; this will only be so if the config function asserted canReturnData. leafDatum is the key value stored in the current leaf tuple.

The function must return true if the leaf tuple matches the query, or false if not. In the true case, if returnData is true then leafValue must be set to the value originally supplied to be indexed for this leaf tuple. Also, recheck may be set to true if the match is uncertain and so the operator(s) must be re-applied to the actual heap tuple to verify the match.

All the SP-GiST support methods are normally called in a short-lived memory context; that is, CurrentMemoryContext will be reset after processing of each tuple. It is therefore not very important to worry about pfree’ing everything you palloc. (The config method is an exception: it should try to avoid leaking memory. But usually the config method need do nothing but assign constants into the passed parameter struct.)

If the indexed column is of a collatable data type, the index collation will be passed to all the support methods, using the standard PG_GET_COLLATION() mechanism.

57.4. Implementation

This section covers implementation details and other tricks that are useful for implementers of SP-GiST operator classes to know.

57.4.1. SP-GiST Limits

Individual leaf tuples and inner tuples must fit on a single index page (8KB by default). Therefore, when indexing values of variable-length data types, long values can only be supported by methods such as radix trees, in which each level of the tree includes a prefix that is short enough to fit on a page, and the final leaf level includes a suffix also short enough to fit on a page. The operator class should set longValuesOK to TRUE only if it is prepared to arrange for this to happen. Otherwise, the SP-GiST core will reject any request to index a value that is too large to fit on an index page.

Likewise, it is the operator class’s responsibility that inner tuples do not grow too large to fit on an index page; this limits the number of child nodes that can be used in one inner tuple, as well as the maximum size of a prefix value.
Another limitation is that when an inner tuple’s node points to a set of leaf tuples, those tuples must all be in the same index page. (This is a design decision to reduce seeking and save space in the links that chain such tuples together.) If the set of leaf tuples grows too large for a page, a split is performed and an intermediate inner tuple is inserted. For this to fix the problem, the new inner tuple must divide the set of leaf values into more than one node group. If the operator class’s \( \text{picksplit} \) function fails to do that, the SP-GiST core resorts to extraordinary measures described in Section 57.4.3.

### 57.4.2. SP-GiST Without Node Labels

Some tree algorithms use a fixed set of nodes for each inner tuple; for example, in a quad-tree there are always exactly four nodes corresponding to the four quadrants around the inner tuple’s centroid point. In such a case the code typically works with the nodes by number, and there is no need for explicit node labels. To suppress node labels (and thereby save some space), the \( \text{picksplit} \) function can return NULL for the \( \text{nodeLabels} \) array. This will in turn result in \( \text{nodeLabels} \) being NULL during subsequent calls to \( \text{choose} \) and \( \text{inner_consistent} \). In principle, node labels could be used for some inner tuples and omitted for others in the same index.

When working with an inner tuple having unlabeled nodes, it is an error for \( \text{choose} \) to return \( \text{spgAddNode} \), since the set of nodes is supposed to be fixed in such cases. Also, there is no provision for generating an unlabeled node in \( \text{spgSplitTuple} \) actions, since it is expected that an \( \text{spgAddNode} \) action will be needed as well.

### 57.4.3. “All-the-same” Inner Tuples

The SP-GiST core can override the results of the operator class’s \( \text{picksplit} \) function when \( \text{picksplit} \) fails to divide the supplied leaf values into at least two node categories. When this happens, the new inner tuple is created with multiple nodes that each have the same label (if any) that \( \text{picksplit} \) gave to the one node it did use, and the leaf values are divided at random among these equivalent nodes. The \( \text{allTheSame} \) flag is set on the inner tuple to warn the \( \text{choose} \) and \( \text{inner_consistent} \) functions that the tuple does not have the node set that they might otherwise expect.

When dealing with an \( \text{allTheSame} \) tuple, a \( \text{choose} \) result of \( \text{spgMatchNode} \) is interpreted to mean that the new value can be assigned to any of the equivalent nodes; the core code will ignore the supplied \( \text{nodeN} \) value and descend into one of the nodes at random (so as to keep the tree balanced). It is an error for \( \text{choose} \) to return \( \text{spgAddNode} \), since that would make the nodes not all equivalent; the \( \text{spgSplitTuple} \) action must be used if the value to be inserted doesn’t match the existing nodes.

When dealing with an \( \text{allTheSame} \) tuple, the \( \text{inner_consistent} \) function should return either all or none of the nodes as targets for continuing the index search, since they are all equivalent. This may or may not require any special-case code, depending on how much the \( \text{inner_consistent} \) function normally assumes about the meaning of the nodes.

### 57.5. Examples

The PostgreSQL source distribution includes several examples of index operator classes for SP-GiST. The
core system currently provides radix trees over text columns and two types of trees over points: quad-tree and k-d tree. Look into src/backend/access/spgist/ to see the code.
Chapter 58. GIN Indexes

58.1. Introduction

GIN stands for Generalized Inverted Index. GIN is designed for handling cases where the items to be indexed are composite values, and the queries to be handled by the index need to search for element values that appear within the composite items. For example, the items could be documents, and the queries could be searches for documents containing specific words.

We use the word item to refer to a composite value that is to be indexed, and the word key to refer to an element value. GIN always stores and searches for keys, not item values per se.

A GIN index stores a set of (key, posting list) pairs, where a posting list is a set of row IDs in which the key occurs. The same row ID can appear in multiple posting lists, since an item can contain more than one key. Each key value is stored only once, so a GIN index is very compact for cases where the same key appears many times.

GIN is generalized in the sense that the GIN access method code does not need to know the specific operations that it accelerates. Instead, it uses custom strategies defined for particular data types. The strategy defines how keys are extracted from indexed items and query conditions, and how to determine whether a row that contains some of the key values in a query actually satisfies the query.

One advantage of GIN is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert. This is much the same advantage as using GiST.

The GIN implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov. There is more information about GIN on their website.

58.2. Built-in Operator Classes

The core PostgreSQL distribution includes the GIN operator classes shown in Table 58-1. (Some of the optional modules described in Appendix F provide additional GIN operator classes.)

Table 58-1. Built-in GIN Operator Classes

<table>
<thead>

<td>&gt;&gt;= &lt;= = @ &gt; ≤ ≥</td>
</tr>
<tr>
<td>_timestamp_ops</td>
<td>timestamp[]</td>
<td>&gt;&gt;= &lt;= = @ &gt; ≤ ≥</td>
</tr>
<tr>
<td>_timestamp_tz_ops</td>
<td>timestamp with time zone[]</td>
<td>&gt;&gt;= &lt;= = @ &gt; ≤ ≥</td>
</tr>
<tr>
<td>_timetz_ops</td>
<td>time with time zone[]</td>
<td>&gt;&gt;= &lt;= = @ &gt; ≤ ≥</td>
</tr>
<tr>
<td>_tinterval_ops</td>
<td>tinterval[]</td>
<td>&gt;&gt;= &lt;= = @ &gt; ≤ ≥</td>
</tr>
<tr>
<td>_varbit_ops</td>
<td>bit varying[]</td>
<td>&gt;&gt;= &lt;= = @ &gt; ≤ ≥</td>
</tr>
<tr>
<td>_varchar_ops</td>
<td>character varying[]</td>
<td>&gt;&gt;= &lt;= = @ &gt; ≤ ≥</td>
</tr>
<tr>
<td>jsonb_ops</td>
<td>jsonb</td>
<td>&gt;= &lt;= = @ &gt; ≤ ≥</td>
</tr>
<tr>
<td>jsonb_path_ops</td>
<td>jsonb</td>
<td>&gt;= &lt;= = @ &gt; ≤ ≥</td>
</tr>
<tr>
<td>tsvector_ops</td>
<td>tsvector</td>
<td>&gt;= &lt;= = @ &gt; ≤ ≥</td>
</tr>
</tbody>
</table>

Of the two operator classes for type `jsonb`, `jsonb_ops` is the default. `jsonb_path_ops` supports fewer operators but offers better performance for those operators. See Section 8.14.4 for details.

### 58.3. Extensibility

The GIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GIN layer itself takes care of concurrency, logging and searching the tree structure.

All it takes to get a GIN access method working is to implement a few user-defined methods, which define
the behavior of keys in the tree and the relationships between keys, indexed items, and indexable queries. In short, GIN combines extensibility with generality, code reuse, and a clean interface.

There are three methods that an operator class for GIN must provide:

```c
int compare(Datum a, Datum b)
```

Compares two keys (not indexed items!) and returns an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second. Null keys are never passed to this function.

```c
Datum *extractValue(Datum itemValue, int32 *nkeys, bool **nullFlags)
```

Returns a palloc’d array of keys given an item to be indexed. The number of returned keys must be stored into *nkeys. If any of the keys can be null, also alloc an array of *nkeys bool fields, store its address at *nullFlags, and set these null flags as needed. *nullFlags can be left NULL (its initial value) if all keys are non-null. The return value can be NULL if the item contains no keys.

```c
Datum *extractQuery(Datum query, int32 *nkeys, StrategyNumber n, bool **pmatch, Pointer **extra_data, bool **nullFlags, int32 *searchMode)
```

Returns a palloc’d array of keys given a value to be queried; that is, query is the value on the right-hand side of an indexable operator whose left-hand side is the indexed column. n is the strategy number of the operator within the operator class (see Section 35.14.2). Often, extractQuery will need to consult n to determine the data type of query and the method it should use to extract key values. The number of returned keys must be stored into *nkeys. If any of the keys can be null, also alloc an array of *nkeys bool fields, store its address at *nullFlags, and set these null flags as needed. *nullFlags can be left NULL (its initial value) if all keys are non-null. The return value can be NULL if the query contains no keys.

*searchMode is an output argument that allows extractQuery to specify details about how the search will be done. If *searchMode is set to GIN_SEARCH_MODE_DEFAULT (which is the value it is initialized to before call), only items that match at least one of the returned keys are considered candidate matches. If *searchMode is set to GIN_SEARCH_MODE_INCLUDE_EMPTY, then in addition to items containing at least one matching key, items that contain no keys at all are considered candidate matches. (This mode is useful for implementing is-subset-of operators, for example.) If *searchMode is set to GIN_SEARCH_MODE_ALL, then all non-null items in the index are considered candidate matches, whether they match any of the returned keys or not. (This mode is much slower than the other two choices, since it requires scanning essentially the entire index, but it may be necessary to implement corner cases correctly. An operator that needs this mode in most cases is probably not a good candidate for a GIN operator class.) The symbols to use for setting this mode are defined in access/gin.h.

*pmatch is an output argument for use when partial match is supported. To use it, extractQuery must allocate an array of *nkeys booleans and store its address at *pmatch. Each element of the array should be set to TRUE if the corresponding key requires partial match, FALSE if not. If *pmatch is set to NULL then GIN assumes partial match is not required. The variable is initialized to NULL before call, so this argument can simply be ignored by operator classes that do not support partial match.

*extra_data is an output argument that allows extractQuery to pass additional data to the consistent and comparePartial methods. To use it, extractQuery must allocate an array of *nkeys pointers and store its address at *extra_data, then store whatever it wants to into the individual pointers. The variable is initialized to NULL before call, so this argument can simply be
ignored by operator classes that do not require extra data. If *extra_data is set, the whole array is passed to the consistent method, and the appropriate element to the comparePartial method.

An operator class must also provide a function to check if an indexed item matches the query. It comes in two flavors, a boolean consistent function, and a ternary triConsistent function. triConsistent covers the functionality of both, so providing triConsistent alone is sufficient. However, if the boolean variant is significantly cheaper to calculate, it can be advantageous to provide both. If only the boolean variant is provided, some optimizations that depend on refuting index items before fetching all the keys are disabled.

```c
bool consistent(bool check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], bool *recheck, Datum queryKeys[], bool nullFlags[])
```

Returns TRUE if an indexed item satisfies the query operator with strategy number n (or might satisfy it, if the recheck indication is returned). This function does not have direct access to the indexed item’s value, since GIN does not store items explicitly. Rather, what is available is knowledge about which key values extracted from the query appear in a given indexed item. The check array has length nkeys, which is the same as the number of keys previously returned by extractQuery for this query datum. Each element of the check array is TRUE if the indexed item contains the corresponding query key, i.e., if (check[i] == TRUE) the i-th key of the extractQuery result array is present in the indexed item. The original query datum is passed in case the consistent method needs to consult it, and so are the queryKeys[] and nullFlags[] arrays previously returned by extractQuery. extra_data is the extra-data array returned by extractQuery, or NULL if none.

When extractQuery returns a null key in queryKeys[], the corresponding check[] element is TRUE if the indexed item contains a null key; that is, the semantics of check[] are like IS NOT DISTINCT FROM. The consistent function can examine the corresponding nullFlags[] element if it needs to tell the difference between a regular value match and a null match.

On success, *recheck should be set to TRUE if the heap tuple needs to be rechecked against the query operator, or FALSE if the index test is exact. That is, a FALSE return value guarantees that the heap tuple does not match the query; a TRUE return value with *recheck set to FALSE guarantees that the heap tuple does match the query; and a TRUE return value with *recheck set to TRUE means that the heap tuple might match the query, so it needs to be fetched and rechecked by evaluating the query operator directly against the originally indexed item.

```c
GinTernaryValue triConsistent(GinTernaryValue check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], Datum queryKeys[], bool nullFlags[])
```

triConsistent is similar to consistent, but instead of a boolean check[], there are three possible values for each key: GIN_TRUE, GIN_FALSE and GIN_MAYBE. GIN_FALSE and GIN_TRUE have the same meaning as regular boolean values. GIN_MAYBE means that the presence of that key is not known. When GIN_MAYBE values are present, the function should only return GIN_TRUE if the item matches whether or not the index item contains the corresponding query keys. Likewise, the function must return GIN_FALSE only if the item does not match, whether or not it contains the GIN_MAYBE keys. If the result depends on the GIN_MAYBE entries, i.e. the match cannot be confirmed or refuted based on the known query keys, the function must return GIN_MAYBE.

When there are no GIN_MAYBE values in the check vector, GIN_MAYBE return value is equivalent of setting recheck flag in the boolean consistent function.

Optionally, an operator class for GIN can supply the following method:
int comparePartial(Datum partial_key, Datum key, StrategyNumber n, Pointer extra_data)

Compare a partial-match query key to an index key. Returns an integer whose sign indicates the result: less than zero means the index key does not match the query, but the index scan should continue; zero means that the index key does match the query; greater than zero indicates that the index scan should stop because no more matches are possible. The strategy number n of the operator that generated the partial match query is provided, in case its semantics are needed to determine when to end the scan. Also, extra_data is the corresponding element of the extra-data array made by extractQuery, or NULL if none. Null keys are never passed to this function.

To support “partial match” queries, an operator class must provide the comparePartial method, and its extractQuery method must set the pmatch parameter when a partial-match query is encountered. See Section 58.4.2 for details.

The actual data types of the various Datum values mentioned above vary depending on the operator class. The item values passed to extractValue are always of the operator class’s input type, and all key values must be of the class’s STORAGE type. The type of the query argument passed to extractQuery, consistent and triConsistent is whatever is specified as the right-hand input type of the class member operator identified by the strategy number. This need not be the same as the item type, so long as key values of the correct type can be extracted from it.

58.4. Implementation

Internally, a GIN index contains a B-tree index constructed over keys, where each key is an element of one or more indexed items (a member of an array, for example) and where each tuple in a leaf page contains either a pointer to a B-tree of heap pointers (a “posting tree”), or a simple list of heap pointers (a “posting list”) when the list is small enough to fit into a single index tuple along with the key value.

As of PostgreSQL 9.1, null key values can be included in the index. Also, placeholder nulls are included in the index for indexed items that are null or contain no keys according to extractValue. This allows searches that should find empty items to do so.

Multicolumn GIN indexes are implemented by building a single B-tree over composite values (column number, key value). The key values for different columns can be of different types.

58.4.1. GIN Fast Update Technique

Updating a GIN index tends to be slow because of the intrinsic nature of inverted indexes: inserting or updating one heap row can cause many inserts into the index (one for each key extracted from the indexed item). As of PostgreSQL 8.4, GIN is capable of postponing much of this work by inserting new tuples into a temporary, unsorted list of pending entries. When the table is vacuumed, or if the pending list becomes too large (larger than work_mem), the entries are moved to the main GIN data structure using the same bulk insert techniques used during initial index creation. This greatly improves GIN index update speed, even counting the additional vacuum overhead. Moreover the overhead work can be done by a background process instead of in foreground query processing.
The main disadvantage of this approach is that searches must scan the list of pending entries in addition to searching the regular index, and so a large list of pending entries will slow searches significantly. Another disadvantage is that, while most updates are fast, an update that causes the pending list to become “too large” will incur an immediate cleanup cycle and thus be much slower than other updates. Proper use of autovacuum can minimize both of these problems.

If consistent response time is more important than update speed, use of pending entries can be disabled by turning off the `FASTUPDATE` storage parameter for a GIN index. See `CREATE INDEX` for details.

58.4.2. Partial Match Algorithm

GIN can support “partial match” queries, in which the query does not determine an exact match for one or more keys, but the possible matches fall within a reasonably narrow range of key values (within the key sorting order determined by the `compare` support method). The `extractQuery` method, instead of returning a key value to be matched exactly, returns a key value that is the lower bound of the range to be searched, and sets the `pmatch` flag true. The key range is then scanned using the `comparePartial` method. `comparePartial` must return zero for a matching index key, less than zero for a non-match that is still within the range to be searched, or greater than zero if the index key is past the range that could match.

58.5. GIN Tips and Tricks

Create vs. insert

Insertion into a GIN index can be slow due to the likelihood of many keys being inserted for each item. So, for bulk insertions into a table it is advisable to drop the GIN index and recreate it after finishing bulk insertion.

As of PostgreSQL 8.4, this advice is less necessary since delayed indexing is used (see Section 58.4.1 for details). But for very large updates it may still be best to drop and recreate the index.

`maintenance_work_mem`

Build time for a GIN index is very sensitive to the `maintenance_work_mem` setting; it doesn’t pay to skimp on work memory during index creation.

`work_mem`

During a series of insertions into an existing GIN index that has `FASTUPDATE` enabled, the system will clean up the pending-entry list whenever the list grows larger than `work_mem`. To avoid fluctuations in observed response time, it’s desirable to have pending-list cleanup occur in the background (i.e., via autovacuum). Foreground cleanup operations can be avoided by increasing `work_mem` or making autovacuum more aggressive. However, enlarging `work_mem` means that if a foreground cleanup does occur, it will take even longer.

`gin_fuzzy_search_limit`

The primary goal of developing GIN indexes was to create support for highly scalable full-text search in PostgreSQL, and there are often situations when a full-text search returns a very large set of results.
Moreover, this often happens when the query contains very frequent words, so that the large result set is not even useful. Since reading many tuples from the disk and sorting them could take a lot of time, this is unacceptable for production. (Note that the index search itself is very fast.)

To facilitate controlled execution of such queries, GIN has a configurable soft upper limit on the number of rows returned: the \texttt{gin\_fuzzy\_search\_limit} configuration parameter. It is set to 0 (meaning no limit) by default. If a non-zero limit is set, then the returned set is a subset of the whole result set, chosen at random.

“Soft” means that the actual number of returned results could differ somewhat from the specified limit, depending on the query and the quality of the system’s random number generator.

From experience, values in the thousands (e.g., 5000 — 20000) work well.

### 58.6. Limitations

GIN assumes that indexable operators are strict. This means that \texttt{extractValue} will not be called at all on a null item value (instead, a placeholder index entry is created automatically), and \texttt{extractQuery} will not be called on a null query value either (instead, the query is presumed to be unsatisfiable). Note however that null key values contained within a non-null composite item or query value are supported.

### 58.7. Examples

The PostgreSQL source distribution includes GIN operator classes for \texttt{tsvector} and for one-dimensional arrays of all internal types. Prefix searching in \texttt{tsvector} is implemented using the GIN partial match feature. The following \texttt{contrib} modules also contain GIN operator classes:

- \texttt{btree\_gin}
  
  B-tree equivalent functionality for several data types

- \texttt{hstore}
  
  Module for storing (key, value) pairs

- \texttt{intarray}
  
  Enhanced support for \texttt{int[]} 

- \texttt{pg\_trgm}
  
  Text similarity using trigram matching
Chapter 59. Database Physical Storage

This chapter provides an overview of the physical storage format used by PostgreSQL databases.

59.1. Database File Layout

This section describes the storage format at the level of files and directories.

Traditionally, the configuration and data files used by a database cluster are stored together within the cluster’s data directory, commonly referred to as PGDATA (after the name of the environment variable that can be used to define it). A common location for PGDATA is /var/lib/pgsql/data. Multiple clusters, managed by different server instances, can exist on the same machine.

The PGDATA directory contains several subdirectories and control files, as shown in Table 59-1. In addition to these required items, the cluster configuration files postgresql.conf, pg_hba.conf, and pg_ident.conf are traditionally stored in PGDATA, although it is possible to place them elsewhere.

Table 59-1. Contents of PGDATA

<table>
<thead>
<tr>

<tr>
<td>postmaster.pid</td>
<td>A lock file recording the current postmaster process ID (PID), cluster data directory path, postmaster start timestamp, port number, Unix-domain socket directory path (empty on Windows), first valid listen_address (IP address or *, or empty if not listening on TCP), and shared memory segment ID (this file is not present after server shutdown)</td>
</tr>
</tbody>
</table>

For each database in the cluster there is a subdirectory within PGDATA/base, named after the database’s OID in pg_database. This subdirectory is the default location for the database’s files; in particular, its system catalogs are stored there.

Each table and index is stored in a separate file. For ordinary relations, these files are named after the table or index’s filenode number, which can be found in pg_class.relfilenode. But for temporary relations, the file name is of the form t.BBB.FFF, where BBB is the backend ID of the backend which created the file, and FFF is the filenode number. In either case, in addition to the main file (a/k/a main fork), each table and index has a free space map (see Section 59.3), which stores information about free space available in the relation. The free space map is stored in a file named with the filenode number plus the suffix _fsm. Tables also have a visibility map, stored in a fork with the suffix _vm, to track which pages are known to have no dead tuples. The visibility map is described further in Section 59.4. Unlogged tables and indexes have a third fork, known as the initialization fork, which is stored in a fork with the suffix _init (see Section 59.5).

Caution

Note that while a table's filenode often matches its OID, this is not necessarily the case; some operations, like TRUNCATE, REINDEX, CLUSTER and some forms of ALTER TABLE, can change the filenode while preserving the OID. Avoid assuming that filenode and table OID are the same. Also, for certain system catalogs including pg_class itself, pg_class.relfilenode contains zero. The actual filenode number of these catalogs is stored in a lower-level data structure, and can be obtained using the pg_relation_filenode() function.
When a table or index exceeds 1 GB, it is divided into gigabyte-sized segments. The first segment’s file name is the same as the filenode; subsequent segments are named filenode.1, filenode.2, etc. This arrangement avoids problems on platforms that have file size limitations. (Actually, 1 GB is just the default segment size. The segment size can be adjusted using the configuration option --with-segsize when building PostgreSQL.) In principle, free space map and visibility map forks could require multiple segments as well, though this is unlikely to happen in practice.

A table that has columns with potentially large entries will have an associated TOAST table, which is used for out-of-line storage of field values that are too large to keep in the table rows proper. pg_class.reltoastrelid links from a table to its TOAST table, if any. See Section 59.2 for more information.

The contents of tables and indexes are discussed further in Section 59.6.

Tablespaces make the scenario more complicated. Each user-defined tablespace has a symbolic link inside the PGDATA/pg_tblspc directory, which points to the physical tablespace directory (i.e., the location specified in the tablespace’s CREATE TABLESPACE command). This symbolic link is named after the tablespace’s OID. Inside the physical tablespace directory there is a subdirectory with a name that depends on the PostgreSQL server version, such as PG_9.0_201008051. (The reason for using this subdirectory is so that successive versions of the database can use the same CREATE TABLESPACE location value without conflicts.) Within the version-specific subdirectory, there is a subdirectory for each database that has elements in the tablespace, named after the database’s OID. Tables and indexes are stored within that directory, using the filenode naming scheme. The pg_default tablespace is not accessed through pg_tblspc, but corresponds to PGDATA/base. Similarly, the pg_global tablespace is not accessed through pg_tblspc, but corresponds to PGDATA/global.

The pg_relation_filepath() function shows the entire path (relative to PGDATA) of any relation. It is often useful as a substitute for remembering many of the above rules. But keep in mind that this function just gives the name of the first segment of the main fork of the relation — you may need to append a segment number and/or _fsm, _vm, or _init to find all the files associated with the relation.

Temporary files (for operations such as sorting more data than can fit in memory) are created within PGDATA/base/pgsql_tmp, or within a pgsql_tmp subdirectory of a tablespace directory if a tablespace other than pg_default is specified for them. The name of a temporary file has the form pgsql_tmpPPP.NNN, where PPP is the PID of the owning backend and NNN distinguishes different temporary files of that backend.

59.2. TOAST

This section provides an overview of TOAST (The Oversized-Attribute Storage Technique).

PostgreSQL uses a fixed page size (commonly 8 kB), and does not allow tuples to span multiple pages. Therefore, it is not possible to store very large field values directly. To overcome this limitation, large field values are compressed and/or broken up into multiple physical rows. This happens transparently to the user, with only small impact on most of the backend code. The technique is affectionately known as TOAST (or “the best thing since sliced bread”).

Only certain data types support TOAST — there is no need to impose the overhead on data types that cannot produce large field values. To support TOAST, a data type must have a variable-length (varlena) representation, in which the first 32-bit word of any stored value contains the total length of the value in
bytes (including itself). TOAST does not constrain the rest of the representation. All the C-level functions supporting a TOAST-able data type must be careful to handle TOASTed input values. (This is normally done by invoking `PG_DETOAST_DATUM` before doing anything with an input value, but in some cases more efficient approaches are possible.)

TOAST usurps two bits of the varlena length word (the high-order bits on big-endian machines, the low-order bits on little-endian machines), thereby limiting the logical size of any value of a TOAST-able data type to 1 GB ($2^{30} - 1$ bytes). When both bits are zero, the value is an ordinary un-TOASTed value of the data type, and the remaining bits of the length word give the total datum size (including length word) in bytes. When the highest-order or lowest-order bit is set, the value has only a single-byte header instead of the normal four-byte header, and the remaining bits give the total datum size (including length byte) in bytes. As a special case, if the remaining bits are all zero (which would be impossible for a self-inclusive length), the value is a pointer to out-of-line data stored in a separate TOAST table. (The size of a TOAST pointer is given in the second byte of the datum.) Values with single-byte headers aren’t aligned on any particular boundary, either. Lastly, when the highest-order or lowest-order bit is set but the adjacent bit is set, the content of the datum has been compressed and must be decompressed before use. In this case the remaining bits of the length word give the total size of the compressed datum, not the original data. Note that compression is also possible for out-of-line data but the varlena header does not tell whether it has occurred — the content of the TOAST pointer tells that, instead.

If any of the columns of a table are TOAST-able, the table will have an associated TOAST table, whose OID is stored in the table’s `pg_class.reltoastrelid` entry. Out-of-line TOASTed values are kept in the TOAST table, as described in more detail below.

The compression technique used is a fairly simple and very fast member of the LZ family of compression techniques. See `src/backend/utils/adt/pg_lzcompress.c` for the details.

Out-of-line values are divided (after compression if used) into chunks of at most `TOAST_MAX_CHUNK_SIZE` bytes (by default this value is chosen so that four chunk rows will fit on a page, making it about 2000 bytes). Each chunk is stored as a separate row in the TOAST table for the owning table. Every TOAST table has the columns `chunk_id` (an OID identifying the particular TOASTed value), `chunk_seq` (a sequence number for the chunk within its value), and `chunk_data` (the actual data of the chunk). A unique index on `chunk_id` and `chunk_seq` provides fast retrieval of the values. A pointer datum representing an out-of-line TOASTed value therefore needs to store the OID of the TOAST table in which to look and the OID of the specific value (its `chunk_id`). For convenience, pointer datums also store the logical datum size (original uncompressed data length) and actual stored size (different if compression was applied). Allowing for the varlena header bytes, the total size of a TOAST pointer datum is therefore 18 bytes regardless of the actual size of the represented value.

The TOAST code is triggered only when a row value to be stored in a table is wider than `TOAST_TUPLE_THRESHOLD` bytes (normally 2 kB). The TOAST code will compress and/or move field values out-of-line until the row value is shorter than `TOAST_TUPLE_TARGET` bytes (also normally 2 kB) or no more gains can be had. During an UPDATE operation, values of unchanged fields are normally preserved as-is; so an UPDATE of a row with out-of-line values incurs no TOAST costs if none of the out-of-line values change.

The TOAST code recognizes four different strategies for storing TOAST-able columns:

* **PLAIN** prevents either compression or out-of-line storage; furthermore it disables use of single-byte headers for varlena types. This is the only possible strategy for columns of non-TOAST-able data types.
Chapter 59. Database Physical Storage

- **EXTENDED** allows both compression and out-of-line storage. This is the default for most TOAST-able data types. Compression will be attempted first, then out-of-line storage if the row is still too big.

- **EXTERNAL** allows out-of-line storage but not compression. Use of **EXTERNAL** will make substring operations on wide text and bytea columns faster (at the penalty of increased storage space) because these operations are optimized to fetch only the required parts of the out-of-line value when it is not compressed.

- **MAIN** allows compression but not out-of-line storage. (Actually, out-of-line storage will still be performed for such columns, but only as a last resort when there is no other way to make the row small enough to fit on a page.)

Each TOAST-able data type specifies a default strategy for columns of that data type, but the strategy for a given table column can be altered with **ALTER TABLE SET STORAGE**.

This scheme has a number of advantages compared to a more straightforward approach such as allowing row values to span pages. Assuming that queries are usually qualified by comparisons against relatively small key values, most of the work of the executor will be done using the main row entry. The big values of TOASTed attributes will only be pulled out (if selected at all) at the time the result set is sent to the client. Thus, the main table is much smaller and more of its rows fit in the shared buffer cache than would be the case without any out-of-line storage. Sort sets shrink also, and sorts will more often be done entirely in memory. A little test showed that a table containing typical HTML pages and their URLs was stored in about half of the raw data size including the TOAST table, and that the main table contained only about 10% of the entire data (the URLs and some small HTML pages). There was no run time difference compared to an un-TOASTed comparison table, in which all the HTML pages were cut down to 7 kB to fit.

59.3. Free Space Map

Each heap and index relation, except for hash indexes, has a Free Space Map (FSM) to keep track of available space in the relation. It’s stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a _fsm suffix. For example, if the filenode of a relation is 12345, the FSM is stored in a file called 12345_fsm, in the same directory as the main relation file.

The Free Space Map is organized as a tree of FSM pages. The bottom level FSM pages store the free space available on each heap (or index) page, using one byte to represent each such page. The upper levels aggregate information from the lower levels.

Within each FSM page is a binary tree, stored in an array with one byte per node. Each leaf node represents a heap page, or a lower level FSM page. In each non-leaf node, the higher of its children’s values is stored. The maximum value in the leaf nodes is therefore stored at the root.

See src/backend/storage/freespace/README for more details on how the FSM is structured, and how it’s updated and searched. The pg_freespacemap module can be used to examine the information stored in free space maps.
59.4. Visibility Map

Each heap relation has a Visibility Map (VM) to keep track of which pages contain only tuples that are
known to be visible to all active transactions. It’s stored alongside the main relation data in a separate
relation fork, named after the filenode number of the relation, plus a _vm suffix. For example, if the
filenode of a relation is 12345, the VM is stored in a file called 12345_vm, in the same directory as the
main relation file. Note that indexes do not have VMs.

The visibility map simply stores one bit per heap page. A set bit means that all tuples on the page are
known to be visible to all transactions. This means that the page does not contain any tuples that need
to be vacuumed. This information can also be used by *index-only scans* to answer queries using only the
index tuple.

The map is conservative in the sense that we make sure that whenever a bit is set, we know the condition
is true, but if a bit is not set, it might or might not be true. Visibility map bits are only set by vacuum, but
are cleared by any data-modifying operations on a page.

59.5. The Initialization Fork

Each unlogged table, and each index on an unlogged table, has an initialization fork. The initialization
fork is an empty table or index of the appropriate type. When an unlogged table must be reset to empty
due to a crash, the initialization fork is copied over the main fork, and any other forks are erased (they will
be recreated automatically as needed).

59.6. Database Page Layout

This section provides an overview of the page format used within PostgreSQL tables and indexes. Sequences and TOAST tables are formatted just like a regular table.

In the following explanation, a byte is assumed to contain 8 bits. In addition, the term *item* refers to an
individual data value that is stored on a page. In a table, an item is a row; in an index, an item is an index
entry.

Every table and index is stored as an array of pages of a fixed size (usually 8 kB, although a different
page size can be selected when compiling the server). In a table, all the pages are logically equivalent,
so a particular item (row) can be stored in any page. In indexes, the first page is generally reserved
as a *metapage* holding control information, and there can be different types of pages within the index,
depending on the index access method.

Table 59-2 shows the overall layout of a page. There are five parts to each page.

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
</table>

1. Actually, index access methods need not use this page format. All the existing index methods do use this basic format, but the data kept on index metapages usually doesn’t follow the item layout rules.
Chapter 59. Database Physical Storage

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PageHeaderData</td>
<td>24 bytes long. Contains general information about the page, including free space pointers.</td>
</tr>
<tr>
<td>ItemIdData</td>
<td>Array of (offset,length) pairs pointing to the actual items. 4 bytes per item.</td>
</tr>
<tr>
<td>Free space</td>
<td>The unallocated space. New item pointers are allocated from the start of this area, new items from the end.</td>
</tr>
<tr>
<td>Items</td>
<td>The actual items themselves.</td>
</tr>
<tr>
<td>Special space</td>
<td>Index access method specific data. Different methods store different data. Empty in ordinary tables.</td>
</tr>
</tbody>
</table>

The first 24 bytes of each page consists of a page header (PageHeaderData). Its format is detailed in Table 59-3. The first field tracks the most recent WAL entry related to this page. The second field contains the page checksum if data checksums are enabled. Next is a 2-byte field containing flag bits. This is followed by three 2-byte integer fields (pd_lower, pd_upper, and pd_special). These contain byte offsets from the page start to the start of unallocated space, to the end of unallocated space, and to the start of the special space. The next 2 bytes of the page header, pd_pagesize_version, store both the page size and a version indicator. Beginning with PostgreSQL 8.3 the version number is 4; PostgreSQL 8.1 and 8.2 used version number 3; PostgreSQL 8.0 used version number 2; PostgreSQL 7.3 and 7.4 used version number 1; prior releases used version number 0. (The basic page layout and header format has not changed in most of these versions, but the layout of heap row headers has.) The page size is basically only present as a cross-check; there is no support for having more than one page size in an installation. The last field is a hint that shows whether pruning the page is likely to be profitable: it tracks the oldest un-pruned XMAX on the page.

Table 59-3. PageHeaderData Layout

<table>
<thead>
<tr>

<td>4 bytes</td>
<td>Oldest unpruned XMAX on page, or zero if none</td>
</tr>
</tbody>
</table>

All the details can be found in src/include/storage/bufpage.h.

Following the page header are item identifiers (ItemIdData), each requiring four bytes. An item identifier contains a byte-offset to the start of an item, its length in bytes, and a few attribute bits which affect its interpretation. New item identifiers are allocated as needed from the beginning of the unallocated space. The number of item identifiers present can be determined by looking at pd_lower, which is increased to allocate a new identifier. Because an item identifier is never moved until it is freed, its index can be used on a long-term basis to reference an item, even when the item itself is moved around on the page to compact free space. In fact, every pointer to an item (ItemPointer, also known as CTID) created by PostgreSQL consists of a page number and the index of an item identifier.

The items themselves are stored in space allocated backwards from the end of unallocated space. The exact structure varies depending on what the table is to contain. Tables and sequences both use a structure named HeapTupleHeaderData, described below.

The final section is the “special section” which can contain anything the access method wishes to store. For example, b-tree indexes store links to the page’s left and right siblings, as well as some other data relevant to the index structure. Ordinary tables do not use a special section at all (indicated by setting pd_special to equal the page size).

All table rows are structured in the same way. There is a fixed-size header (occupying 23 bytes on most machines), followed by an optional null bitmap, an optional object ID field, and the user data. The header is detailed in Table 59-4. The actual user data (columns of the row) begins at the offset indicated by t_hoff, which must always be a multiple of the MAXALIGN distance for the platform. The null bitmap is only present if the HEAP_HASNULL bit is set in t_infomask. If it is present it begins just after the fixed header and occupies enough bytes to have one bit per data column (that is, t_natts bits altogether). In this list of bits, a 1 bit indicates not-null, a 0 bit is a null. When the bitmap is not present, all columns are assumed not-null. The object ID is only present if the HEAP_HASOID bit is set in t_infomask. If present, it appears just before the t_hoff boundary. Any padding needed to make t_hoff a MAXALIGN multiple will appear between the null bitmap and the object ID. (This in turn ensures that the object ID is suitably aligned.)

</tbody>
</table>

All the details can be found in `src/include/access/htup_details.h`.

Interpreting the actual data can only be done with information obtained from other tables, mostly `pg_attribute`. The key values needed to identify field locations are `attlen` and `attalign`. There is no way to directly get a particular attribute, except when there are only fixed width fields and no null values. All this trickery is wrapped up in the functions `heap_getattr`, `fastgetattr` and `heap_getsysattr`.

To read the data you need to examine each attribute in turn. First check whether the field is NULL according to the null bitmap. If it is, go to the next. Then make sure you have the right alignment. If the field is a fixed width field, then all the bytes are simply placed. If it’s a variable length field (`attlen = -1`) then it’s a bit more complicated. All variable-length data types share the common header structure `struct varlena`, which includes the total length of the stored value and some flag bits. Depending on the flags, the data can be either inline or in a TOAST table; it might be compressed, too (see Section 59.2).
Chapter 60. BKI Backend Interface

Backend Interface (BKI) files are scripts in a special language that is understood by the PostgreSQL backend when running in the “bootstrap” mode. The bootstrap mode allows system catalogs to be created and filled from scratch, whereas ordinary SQL commands require the catalogs to exist already. BKI files can therefore be used to create the database system in the first place. (And they are probably not useful for anything else.)

initdb uses a BKI file to do part of its job when creating a new database cluster. The input file used by initdb is created as part of building and installing PostgreSQL by a program named genbki.pl, which reads some specially formatted C header files in the src/include/catalog/ directory of the source tree. The created BKI file is called postgres.bki and is normally installed in the share subdirectory of the installation tree.

Related information can be found in the documentation for initdb.

60.1. BKI File Format

This section describes how the PostgreSQL backend interprets BKI files. This description will be easier to understand if the postgres.bki file is at hand as an example.

BKI input consists of a sequence of commands. Commands are made up of a number of tokens, depending on the syntax of the command. Tokens are usually separated by whitespace, but need not be if there is no ambiguity. There is no special command separator; the next token that syntactically cannot belong to the preceding command starts a new one. (Usually you would put a new command on a new line, for clarity.) Tokens can be certain key words, special characters (parentheses, commas, etc.), numbers, or double-quoted strings. Everything is case sensitive.

Lines starting with # are ignored.

60.2. BKI Commands

```
create tablename tableoid [bootstrap] [shared_relation] [without_oids] [rowtype_oid oid] (name1 = type1 [, name2 = type2, ...])
```

Create a table named `tablename`, and having the OID `tableoid`, with the columns given in parentheses.

The following column types are supported directly by bootstrap.c: `bool, bytea, char (1 byte),
name, int2, int4, regproc, regclass, regtype, text, oid, tid, xid, cid, int2vector, oidvector, _int4 (array), _text (array), _oid (array), _char (array), _aclitem (array). Although it is possible to create tables containing columns of other types, this cannot be done until after `pg_type` has been created and filled with appropriate entries. (That effectively means that only
these column types can be used in bootstrapped tables, but non-bootstrap catalogs can contain any
built-in type.)

When `bootstrap` is specified, the table will only be created on disk; nothing is entered into
`pg_class`, `pg_attribute`, etc, for it. Thus the table will not be accessible by ordinary SQL
operations until such entries are made the hard way (with `insert` commands). This option is used
for creating `pg_class` etc themselves.

The table is created as shared if `shared_relation` is specified. It will have OIDs unless
`without_oids` is specified. The table’s row type OID (`pg_type OID`) can optionally be specified
via the `rowtype_oid` clause; if not specified, an OID is automatically generated for it. (The
`rowtype_oid` clause is useless if `bootstrap` is specified, but it can be provided anyway for
documentation.)

`open tablename`

Open the table named `tablename` for insertion of data. Any currently open table is closed.

`close [tablename]`

Close the open table. The name of the table can be given as a cross-check, but this is not required.

`insert [OID = oid_value] ( value1 value2 ... )`

Insert a new row into the open table using `value1`, `value2`, etc., for its column values and
`oid_value` for its OID. If `oid_value` is zero (0) or the clause is omitted, and the table has OIDs,
then the next available OID is assigned.

NULL values can be specified using the special key word `_null_`. Values containing spaces must be
double quoted.

`declare [unique] index indexname indexoid on tablename using amname ( opclass1 name1 [ , ... ])`

Create an index named `indexname`, having OID `indexoid`, on the table named `tablename`, using
the `amname` access method. The fields to index are called `name1`, `name2` etc., and the operator classes
to use are `opclass1`, `opclass2` etc., respectively. The index file is created and appropriate catalog
entries are made for it, but the index contents are not initialized by this command.

`declare toast toasttableoid toastindexoid on tablename`

Create a TOAST table for the table named `tablename`. The TOAST table is assigned OID
`toasttableoid` and its index is assigned OID `toastindexoid`. As with `declare index`,
filling of the index is postponed.

`build indices`

Fill in the indices that have previously been declared.

### 60.3. Structure of the Bootstrap BKI File

The `open` command cannot be used until the tables it uses exist and have entries for the table that is to
be opened. (These minimum tables are `pg_class`, `pg_attribute`, `pg_proc`, and `pg_type`.) To allow
those tables themselves to be filled, `create with the bootstrap` option implicitly opens the created table
for data insertion.
Also, the `declare index` and `declare toast` commands cannot be used until the system catalogs they need have been created and filled in.

Thus, the structure of the `postgres.bki` file has to be:

1. `create bootstrap one of the critical tables`
2. `insert data describing at least the critical tables`
3. `close`
4. Repeat for the other critical tables.
5. `create (without bootstrap) a noncritical table`
6. `open`
7. `insert desired data`
8. `close`
9. Repeat for the other noncritical tables.
10. Define indexes and toast tables.
11. `build indices`

There are doubtless other, undocumented ordering dependencies.

### 60.4. Example

The following sequence of commands will create the table `test_table` with OID 420, having two columns `cola` and `colb` of type `int4` and `text`, respectively, and insert two rows into the table:

```sql
create test_table 420 (cola = int4, colb = text)
open test_table
insert OID=421 ( 1 "value1" )
insert OID=422 ( 2 _null_ )
close test_table
```
Chapter 61. How the Planner Uses Statistics

This chapter builds on the material covered in Section 14.1 and Section 14.2 to show some additional details about how the planner uses the system statistics to estimate the number of rows each part of a query might return. This is a significant part of the planning process, providing much of the raw material for cost calculation.

The intent of this chapter is not to document the code in detail, but to present an overview of how it works. This will perhaps ease the learning curve for someone who subsequently wishes to read the code.

61.1. Row Estimation Examples

The examples shown below use tables in the PostgreSQL regression test database. The outputs shown are taken from version 8.3. The behavior of earlier (or later) versions might vary. Note also that since ANALYZE uses random sampling while producing statistics, the results will change slightly after any new ANALYZE.

Let’s start with a very simple query:

```sql
EXPLAIN SELECT * FROM tenk1;
```

```sql
QUERY PLAN
-------------------------------------------------------------------------------
Seq Scan on tenk1 (cost=0.00..458.00 rows=10000 width=244)
```

How the planner determines the cardinality of tenk1 is covered in Section 14.2, but is repeated here for completeness. The number of pages and rows is looked up in pg_class:

```sql
SELECT relpages, reltuples FROM pg_class WHERE relname = 'tenk1';
```

<table>
<thead>
<tr>
<th>relpages</th>
<th>reltuples</th>
</tr>
</thead>
<tbody>
<tr>
<td>358</td>
<td>10000</td>
</tr>
</tbody>
</table>

These numbers are current as of the last VACUUM or ANALYZE on the table. The planner then fetches the actual current number of pages in the table (this is a cheap operation, not requiring a table scan). If that is different from relpages then reltuples is scaled accordingly to arrive at a current number-of-rows estimate. In the example above, the value of relpages is up-to-date so the rows estimate is the same as reltuples.

Let’s move on to an example with a range condition in its WHERE clause:

```sql
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000;
```

```sql
QUERY PLAN
---------------------------------------------------------------------
Bitmap Heap Scan on tenk1 (cost=24.06..394.64 rows=1007 width=244)
  Recheck Cond: (unique1 < 1000)
```
Chapter 61. How the Planner Uses Statistics

The planner examines the WHERE clause condition and looks up the selectivity function for the operator < in pg_operator. This is held in the column oprrest, and the entry in this case is scalarltssel. The scalarltssel function retrieves the histogram for uniquel from pg_statistics. For manual queries it is more convenient to look in the simpler pg_stats view:

```
SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='unique1';
```

```
+-----------------------+
<table>
<thead>
<tr>
<th>histogram_bounds</th>
</tr>
</thead>
<tbody>
<tr>
<td>{0,993,1997,3050,4040,5036,5957,7057,8029,9016,9995}</td>
</tr>
</tbody>
</table>
+-----------------------+
```

Next the fraction of the histogram occupied by “< 1000” is worked out. This is the selectivity. The histogram divides the range into equal frequency buckets, so all we have to do is locate the bucket that our value is in and count part of it and all of the ones before. The value 1000 is clearly in the second bucket (993-1997). Assuming a linear distribution of values inside each bucket, we can calculate the selectivity as:

```
selectivity = (1 + (1000 - bucket[2].min)/(bucket[2].max - bucket[2].min))/num_buckets
= (1 + (1000 - 993)/(1997 - 993))/10
= 0.100697
```

that is, one whole bucket plus a linear fraction of the second, divided by the number of buckets. The estimated number of rows can now be calculated as the product of the selectivity and the cardinality of tenk1:

```
rows = rel_cardinality * selectivity
= 10000 * 0.100697
= 1007 (rounding off)
```

Next let’s consider an example with an equality condition in its WHERE clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'CRAAAA';
```

```
QUERY PLAN

Seq Scan on tenk1  (cost=0.00..483.00 rows=30 width=244)
  Filter: (stringu1 = 'CRAAAA'::name)
```

Again the planner examines the WHERE clause condition and looks up the selectivity function for =, which is eqsel. For equality estimation the histogram is not useful; instead the list of most common values (MCVs) is used to determine the selectivity. Let’s have a look at the MCVs, with some additional columns that will be useful later:

```
SELECT null_frac, n_distinct, most_common_vals, most_common_freqs FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';
```

```
null_frac | 0
```
Since CRAAAA appears in the list of MCVs, the selectivity is merely the corresponding entry in the list of most common frequencies (MCFs):

\[
\text{selectivity} = \text{mcf}[3] = 0.003
\]

As before, the estimated number of rows is just the product of this with the cardinality of tenk1:

\[
\text{rows} = 10000 \times 0.003 = 30
\]

Now consider the same query, but with a constant that is not in the MCV list:

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'xxx';
```

```
QUERY PLAN
----------------------------------------------------------
Seq Scan on tenk1 (cost=0.00..483.00 rows=15 width=244)
  Filter: (stringu1 = 'xxx'::name)
```

This is quite a different problem: how to estimate the selectivity when the value is not in the MCV list. The approach is to use the fact that the value is not in the list, combined with the knowledge of the frequencies for all of the MCVs:

\[
\text{selectivity} = \frac{1 - \text{sum(mvf)}}{(\text{num_distinct} - \text{num_mcv})}
\]

\[
= \frac{1 - (0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003)}{(676 - 10)}
\]

\[
= 0.0014559
\]

That is, add up all the frequencies for the MCVs and subtract them from one, then divide by the number of other distinct values. This amounts to assuming that the fraction of the column that is not any of the MCVs is evenly distributed among all the other distinct values. Notice that there are no null values so we don’t have to worry about those (otherwise we’d subtract the null fraction from the numerator as well). The estimated number of rows is then calculated as usual:

\[
\text{rows} = 10000 \times 0.0014559 = 15 \text{ (rounding off)}
\]

The previous example with unique1 < 1000 was an oversimplification of what scalarltsel really does; now that we have seen an example of the use of MCVs, we can fill in some more detail. The example was correct as far as it went, because since unique1 is a unique column it has no MCVs (obviously, no value is any more common than any other value). For a non-unique column, there will normally be both a histogram and an MCV list, and the histogram does not include the portion of the column population represented by the MCVs. We do things this way because it allows more precise estimation. In this situation scalarltsel directly applies the condition (e.g., “< 1000”) to each value of the MCV list, and adds up
the frequencies of the MCVs for which the condition is true. This gives an exact estimate of the selectivity within the portion of the table that is MCVs. The histogram is then used in the same way as above to estimate the selectivity in the portion of the table that is not MCVs, and then the two numbers are combined to estimate the overall selectivity. For example, consider

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 < 'IAAAAA';
```

```
QUERY PLAN

Seq Scan on tenk1 (cost=0.00..483.00 rows=3077 width=244)
  Filter: (stringu1 < 'IAAAAA'::name)
```

We already saw the MCV information for `stringu1`, and here is its histogram:

```
SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';
```

```
histogram_bounds
--------------------------------------------------------------------------------
{AAAAAA,CQAAAA,FRAAAA,IBAAAA,KRAAAA,NFAAAA,PSAAAA,SGAAAA,VAAAAA,XLAAAA,ZZAAAA}
```

Checking the MCV list, we find that the condition `stringu1 < 'IAAAAA'` is satisfied by the first six entries and not the last four, so the selectivity within the MCV part of the population is

\[
selectivity = \sum \text{relevant mvfs} = 0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 = 0.01833333
\]

Summing all the MCFs also tells us that the total fraction of the population represented by MCVs is 0.03033333, and therefore the fraction represented by the histogram is 0.96966667 (again, there are no nulls, else we’d have to exclude them here). We can see that the value `IAAAAA` falls nearly at the end of the third histogram bucket. Using some rather cheesy assumptions about the frequency of different characters, the planner arrives at the estimate 0.298387 for the portion of the histogram population that is less than `IAAAAA`. We then combine the estimates for the MCV and non-MCV populations:

\[
selectivity = \text{mcv_selectivity} + \text{histogram_selectivity} \times \text{histogram_fraction}
= 0.01833333 + 0.298387 \times 0.96966667
= 0.307669
\]

\[
\text{rows} = 10000 \times 0.307669
= 3077 \text{ (rounding off)}
\]

In this particular example, the correction from the MCV list is fairly small, because the column distribution is actually quite flat (the statistics showing these particular values as being more common than others are mostly due to sampling error). In a more typical case where some values are significantly more common than others, this complicated process gives a useful improvement in accuracy because the selectivity for the most common values is found exactly.

Now let’s consider a case with more than one condition in the `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE uniquel < 1000 AND stringu1 = 'xxx';
```

```
QUERY PLAN

2122
```
Chapter 61. How the Planner Uses Statistics

Bitmap Heap Scan on tenk1 (cost=23.80..396.91 rows=1 width=244)
  Recheck Cond: (unique1 < 1000)
  Filter: (stringu1 = ‘xxx’::name)
  -> Bitmap Index Scan on tenk1_unique1 (cost=0.00..23.80 rows=1007 width=0)
    Index Cond: (unique1 < 1000)

The planner assumes that the two conditions are independent, so that the individual selectivities of the clauses can be multiplied together:

\[
\text{selectivity} = \text{selectivity}(\text{unique1} < 1000) \times \text{selectivity}(\text{stringu1} = ‘xxx’)
\]

\[
= 0.100697 \times 0.0014559
\]

\[
= 0.0001466
\]

\[
\text{rows} = 10000 \times 0.0001466
\]

\[
= 1 \text{ (rounding off)}
\]

Notice that the number of rows estimated to be returned from the bitmap index scan reflects only the condition used with the index; this is important since it affects the cost estimate for the subsequent heap fetches.

Finally we will examine a query that involves a join:

EXPLAIN SELECT * FROM tenk1 t1, tenk2 t2
WHERE t1.unique1 < 50 AND t1.unique2 = t2.unique2;

QUERY PLAN

Nested Loop (cost=4.64..456.23 rows=50 width=488)
  -> Bitmap Heap Scan on tenk1 t1 (cost=4.64..142.17 rows=50 width=244)
    Recheck Cond: (unique1 < 50)
    -> Bitmap Index Scan on tenk1_unique1 (cost=0.00..4.63 rows=50 width=0)
      Index Cond: (unique1 < 50)
  -> Index Scan using tenk2_unique2 on tenk2 t2 (cost=0.00..6.27 rows=1 width=244)
    Index Cond: (unique2 = t1.unique2)

The restriction on tenk1.unique1 < 50, is evaluated before the nested-loop join. This is handled analogously to the previous range example. This time the value 50 falls into the first bucket of the unique1 histogram:

\[
\text{selectivity} = (0 + (50 - \text{bucket}[1].\text{min})/(\text{bucket}[1].\text{max} - \text{bucket}[1].\text{min}))/\text{num_buckets}
\]

\[
= (0 + (50 - 0)/(993 - 0))/10
\]

\[
= 0.005035
\]

\[
\text{rows} = 10000 \times 0.005035
\]

\[
= 50 \text{ (rounding off)}
\]

The restriction for the join is t2.unique2 = t1.unique2. The operator is just our familiar =, however the selectivity function is obtained from the oprjoin column of pg_operator, and is eqjoinsel. eqjoinsel looks up the statistical information for both tenk2 and tenk1:

SELECT tablename, null_frac,n_distinct, most_common_vals FROM pg_stats
WHERE tablename IN (‘tenk1’, ‘tenk2’) AND attname=’unique2’;
Chapter 61. How the Planner Uses Statistics

<table>
<thead>
<tr>
<th>tablename</th>
<th>null_frac</th>
<th>n_distinct</th>
<th>most_common_vals</th>
</tr>
</thead>
<tbody>
<tr>
<td>tenk1</td>
<td>0</td>
<td>-1</td>
<td></td>
</tr>
<tr>
<td>tenk2</td>
<td>0</td>
<td>-1</td>
<td></td>
</tr>
</tbody>
</table>

In this case there is no MCV information for `unique2` because all the values appear to be unique, so we use an algorithm that relies only on the number of distinct values for both relations together with their null fractions:

$$\text{selectivity} = (1 - \text{null_frac}_1) \times (1 - \text{null_frac}_2) \times \min(1/\text{num_distinct}_1, 1/\text{num_distinct}_2)$$

$$= (1 - 0) \times (1 - 0) / \max(10000, 10000)$$

$$= 0.0001$$

This is, subtract the null fraction from one for each of the relations, and divide by the maximum of the numbers of distinct values. The number of rows that the join is likely to emit is calculated as the cardinality of the Cartesian product of the two inputs, multiplied by the selectivity:

$$\text{rows} = (\text{outer_cardinality} \times \text{inner_cardinality}) \times \text{selectivity}$$

$$= (50 \times 10000) \times 0.0001$$

$$= 50$$

Had there been MCV lists for the two columns, `eqjoinsel` would have used direct comparison of the MCV lists to determine the join selectivity within the part of the column populations represented by the MCVs. The estimate for the remainder of the populations follows the same approach shown here.

Notice that we showed `inner_cardinality` as 10000, that is, the unmodified size of `tenk2`. It might appear from inspection of the EXPLAIN output that the estimate of join rows comes from 50 * 1, that is, the number of outer rows times the estimated number of rows obtained by each inner index scan on `tenk2`. But this is not the case: the join relation size is estimated before any particular join plan has been considered. If everything is working well then the two ways of estimating the join size will produce about the same answer, but due to round-off error and other factors they sometimes diverge significantly.

For those interested in further details, estimation of the size of a table (before any `WHERE` clauses) is done in `src/backend/optimizer/util/plancat.c`. The generic logic for clause selectivities is in `src/backend/optimizer/path/clausesel.c`. The operator-specific selectivity functions are mostly found in `src/backend/utils/adt/selfuncs.c`.

**61.2. Planner Statistics and Security**

Access to the table `pg_statistic` is restricted to superusers, so that ordinary users cannot learn about the contents of the tables of other users from it. Some selectivity estimation functions will use a user-provided operator (either the operator appearing in the query or a related operator) to analyze the stored statistics. For example, in order to determine whether a stored most common value is applicable, the selectivity estimator will have to run the appropriate `=` operator to compare the constant in the query to the stored value. Thus the data in `pg_statistic` is potentially passed to user-defined operators. An appropriately crafted operator can intentionally leak the passed operands (for example, by logging them or writing them...
to a different table), or accidentally leak them by showing their values in error messages, in either case possibly exposing data from `pg_statistic` to a user who should not be able to see it.

In order to prevent this, the following applies to all built-in selectivity estimation functions. When planning a query, in order to be able to use stored statistics, the current user must either have `SELECT` privilege on the table or the involved columns, or the operator used must be `LEAKPROOF` (more accurately, the function that the operator is based on). If not, then the selectivity estimator will behave as if no statistics are available, and the planner will proceed with default or fall-back assumptions.

If a user does not have the required privilege on the table or columns, then in many cases the query will ultimately receive a permission-denied error, in which case this mechanism is invisible in practice. But if the user is reading from a security-barrier view, then the planner might wish to check the statistics of an underlying table that is otherwise inaccessible to the user. In that case, the operator should be leak-proof or the statistics will not be used. There is no direct feedback about that, except that the plan might be suboptimal. If one suspects that this is the case, one could try running the query as a more privileged user, to see if a different plan results.

This restriction applies only to cases where the planner would need to execute a user-defined operator on one or more values from `pg_statistic`. Thus the planner is permitted to use generic statistical information, such as the fraction of null values or the number of distinct values in a column, regardless of access privileges.

Selectivity estimation functions contained in third-party extensions that potentially operate on statistics with user-defined operators should follow the same security rules. Consult the PostgreSQL source code for guidance.
VIII. Appendixes
Appendix A. PostgreSQL Error Codes

All messages emitted by the PostgreSQL server are assigned five-character error codes that follow the SQL standard’s conventions for “SQLSTATE” codes. Applications that need to know which error condition has occurred should usually test the error code, rather than looking at the textual error message. The error codes are less likely to change across PostgreSQL releases, and also are not subject to change due to localization of error messages. Note that some, but not all, of the error codes produced by PostgreSQL are defined by the SQL standard; some additional error codes for conditions not defined by the standard have been invented or borrowed from other databases.

According to the standard, the first two characters of an error code denote a class of errors, while the last three characters indicate a specific condition within that class. Thus, an application that does not recognize the specific error code might still be able to infer what to do from the error class.

Table A-1 lists all the error codes defined in PostgreSQL 9.4.20. (Some are not actually used at present, but are defined by the SQL standard.) The error classes are also shown. For each error class there is a “standard” error code having the last three characters 000. This code is used only for error conditions that fall within the class but do not have any more-specific code assigned.

The symbol shown in the column “Condition Name” is the condition name to use in PL/pgSQL. Condition names can be written in either upper or lower case. (Note that PL/pgSQL does not recognize warning, as opposed to error, condition names; those are classes 00, 01, and 02.)

For some types of errors, the server reports the name of a database object (a table, table column, data type, or constraint) associated with the error; for example, the name of the unique constraint that caused a unique_violation error. Such names are supplied in separate fields of the error report message so that applications need not try to extract them from the possibly-localized human-readable text of the message.

As of PostgreSQL 9.3, complete coverage for this feature exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

Appendix B. Date/Time Support

PostgreSQL uses an internal heuristic parser for all date/time input support. Dates and times are input as strings, and are broken up into distinct fields with a preliminary determination of what kind of information can be in the field. Each field is interpreted and either assigned a numeric value, ignored, or rejected. The parser contains internal lookup tables for all textual fields, including months, days of the week, and time zones.

This appendix includes information on the content of these lookup tables and describes the steps used by the parser to decode dates and times.

B.1. Date/Time Input Interpretation

The date/time type inputs are all decoded using the following procedure.

1. Break the input string into tokens and categorize each token as a string, time, time zone, or number.
   a. If the numeric token contains a colon (""'), this is a time string. Include all subsequent digits and colons.
   b. If the numeric token contains a dash (""-""), slash (""/""), or two or more dots ("".""), this is a date string which might have a text month. If a date token has already been seen, it is instead interpreted as a time zone name (e.g., America/New_York).
   c. If the token is numeric only, then it is either a single field or an ISO 8601 concatenated date (e.g., 19990113 for January 13, 1999) or time (e.g., 141516 for 14:15:16).
   d. If the token starts with a plus (""+""') or minus (""-""), then it is either a numeric time zone or a special field.

2. If the token is a text string, match up with possible strings:
   a. Do a binary-search table lookup for the token as a time zone abbreviation.
   b. If not found, do a similar binary-search table lookup to match the token as either a special string (e.g., today), day (e.g., Thursday), month (e.g., January), or noise word (e.g., at, on).
   c. If still not found, throw an error.

3. When the token is a number or number field:
   a. If there are eight or six digits, and if no other date fields have been previously read, then interpret as a “concatenated date” (e.g., 19990118 or 990118). The interpretation is YYYYMMDD or YMMMD.
   b. If the token is three digits and a year has already been read, then interpret as day of year.
   c. If four or six digits and a year has already been read, then interpret as a time (HHMM or HHMMSS).
d. If three or more digits and no date fields have yet been found, interpret as a year (this forces yy-mm-dd ordering of the remaining date fields).

e. Otherwise the date field ordering is assumed to follow the `DateStyle` setting: mm-dd-yy, dd-mm-yy, or yy-mm-dd. Throw an error if a month or day field is found to be out of range.

4. If BC has been specified, negate the year and add one for internal storage. (There is no year zero in the Gregorian calendar, so numerically 1 BC becomes year zero.)

5. If BC was not specified, and if the year field was two digits in length, then adjust the year to four digits. If the field is less than 70, then add 2000, otherwise add 1900.

**Tip:** Gregorian years AD 1-99 can be entered by using 4 digits with leading zeros (e.g., 0099 is AD 99).

### B.2. Date/Time Key Words

Table B-1 shows the tokens that are recognized as names of months.

**Table B-1. Month Names**

### B.3. Date/Time Configuration Files

Since timezone abbreviations are not well standardized, PostgreSQL provides a means to customize the set of abbreviations accepted by the server. The timezone_abbreviations run-time parameter determines the active set of abbreviations. While this parameter can be altered by any database user, the possible values for it are under the control of the database administrator — they are in fact names of configuration files stored in 
`.../share/timezonesets/` of the installation directory. By adding or altering files in that directory, the administrator can set local policy for timezone abbreviations.

`timezone_abbreviations` can be set to any file name found in 
`.../share/timezonesets/`, if the file’s name is entirely alphabetic. (The prohibition against non-alphabetic characters in `timezone_abbreviations` prevents reading files outside the intended directory, as well as reading editor backup files and other extraneous files.)

A timezone abbreviation file can contain blank lines and comments beginning with 
`#`. Non-comment lines must have one of these formats:

```
zone_abbreviation offset
zone_abbreviation offset D
zone_abbreviation time_zone_name
@INCLUDE file_name
@OVERRIDE
```

A `zone_abbreviation` is just the abbreviation being defined. An `offset` is an integer giving the equivalent offset in seconds from UTC, positive being east from Greenwich and negative being west. For ex-
ample, -18000 would be five hours west of Greenwich, or North American east coast standard time. 0 indicates that the zone name represents local daylight-savings time rather than standard time.

Alternatively, a `time_zone_name` can be given, referencing a zone name defined in the IANA timezone database. The zone’s definition is consulted to see whether the abbreviation is or has been in use in that zone, and if so, the appropriate meaning is used — that is, the meaning that was currently in use at the timestamp whose value is being determined, or the meaning in use immediately before that if it wasn’t current at that time, or the oldest meaning if it was used only after that time. This behavior is essential for dealing with abbreviations whose meaning has historically varied. It is also allowed to define an abbreviation in terms of a zone name in which that abbreviation does not appear; then using the abbreviation is just equivalent to writing out the zone name.

**Tip:** Using a simple integer `offset` is preferred when defining an abbreviation whose offset from UTC has never changed, as such abbreviations are much cheaper to process than those that require consulting a time zone definition.

The `@INCLUDE` syntax allows inclusion of another file in the `.../share/timezonesets/` directory. Inclusion can be nested, to a limited depth.

The `@OVERRIDE` syntax indicates that subsequent entries in the file can override previous entries (typically, entries obtained from included files). Without this, conflicting definitions of the same timezone abbreviation are considered an error.

In an unmodified installation, the file `Default` contains all the non-conflicting time zone abbreviations for most of the world. Additional files `Australia` and `India` are provided for those regions: these files first include the `Default` file and then add or modify abbreviations as needed.

For reference purposes, a standard installation also contains files `Africa.txt`, `America.txt`, etc, containing information about every time zone abbreviation known to be in use according to the IANA timezone database. The zone name definitions found in these files can be copied and pasted into a custom configuration file as needed. Note that these files cannot be directly referenced as `timezone_abbreviations` settings, because of the dot embedded in their names.

**Note:** If an error occurs while reading the time zone abbreviation set, no new value is applied and the old set is kept. If the error occurs while starting the database, startup fails.

---

**Caution**

Time zone abbreviations defined in the configuration file override non-timezone meanings built into PostgreSQL. For example, the `Australia` configuration file defines `SAT` (for South Australian Standard Time). When this file is active, `SAT` will not be recognized as an abbreviation for Saturday.

---

**Caution**

If you modify files in `.../share/timezonesets/`, it is up to you to make backups — a normal database dump will not include this directory.
B.4. History of Units

The SQL standard states that “Within the definition of a ‘datetime literal’, the ‘datetime values’ are con-
strained by the natural rules for dates and times according to the Gregorian calendar”. PostgreSQL follows
the SQL standard’s lead by counting dates exclusively in the Gregorian calendar, even for years before
that calendar was in use. This rule is known as the proleptic Gregorian calendar.

The Julian calendar was introduced by Julius Caesar in 45 BC. It was in common use in the Western world
until the year 1582, when countries started changing to the Gregorian calendar. In the Julian calendar, the
tropical year is approximated as 365 1/4 days = 365.25 days. This gives an error of about 1 day in 128
years.

The accumulating calendar error prompted Pope Gregory XIII to reform the calendar in accordance with
instructions from the Council of Trent. In the Gregorian calendar, the tropical year is approximated as 365
+ 97 / 400 days = 365.2425 days. Thus it takes approximately 3300 years for the tropical year to shift one
day with respect to the Gregorian calendar.

The approximation 365+97/400 is achieved by having 97 leap years every 400 years, using the following
rules:

- Every year divisible by 4 is a leap year.
- However, every year divisible by 100 is not a leap year.
- However, every year divisible by 400 is a leap year after all.

So, 1700, 1800, 1900, 2100, and 2200 are not leap years. But 1600, 2000, and 2400 are leap years. By
contrast, in the older Julian calendar all years divisible by 4 are leap years.

The papal bull of February 1582 decreed that 10 days should be dropped from October 1582 so that
15 October should follow immediately after 4 October. This was observed in Italy, Poland, Portugal,
and Spain. Other Catholic countries followed shortly after, but Protestant countries were reluctant to
change, and the Greek Orthodox countries didn’t change until the start of the 20th century. The reform was
observed by Great Britain and its dominions (including what is now the USA) in 1752. Thus 2 September
1752 was followed by 14 September 1752. This is why Unix systems have the cal program produce the
following:

$ cal 9 1752
    September 1752
    S M Tu W Th F S
    1 2 14 15 16
    17 18 19 20 21 22 23
    24 25 26 27 28 29 30

But, of course, this calendar is only valid for Great Britain and dominions, not other places. Since it would
be difficult and confusing to try to track the actual calendars that were in use in various places at various
times, PostgreSQL does not try, but rather follows the Gregorian calendar rules for all dates, even though
this method is not historically accurate.

Different calendars have been developed in various parts of the world, many predating the Gregorian
system. For example, the beginnings of the Chinese calendar can be traced back to the 14th century
BC. Legend has it that the Emperor Huangdi invented that calendar in 2637 BC. The People’s Republic
of China uses the Gregorian calendar for civil purposes. The Chinese calendar is used for determining
festivals.
Appendix B. Date/Time Support

The *Julian Date* system is another type of calendar, unrelated to the Julian calendar though it is confusingly named similarly to that calendar. The Julian Date system was invented by the French scholar Joseph Justus Scaliger (1540-1609) and probably takes its name from Scaliger’s father, the Italian scholar Julius Caesar Scaliger (1484-1558). In the Julian Date system, each day has a sequential number, starting from JD 0 (which is sometimes called the Julian Date). JD 0 corresponds to 1 January 4713 BC in the Julian calendar, or 24 November 4714 BC in the Gregorian calendar. Julian Date counting is most often used by astronomers for labeling their nightly observations, and therefore a date runs from noon UTC to the next noon UTC, rather than from midnight to midnight: JD 0 designates the 24 hours from noon UTC on 24 November 4714 BC to noon UTC on 25 November 4714 BC.

Although PostgreSQL supports Julian Date notation for input and output of dates (and also uses Julian dates for some internal datetime calculations), it does not observe the nicety of having dates run from noon to noon. PostgreSQL treats a Julian Date as running from midnight to midnight.
Appendix C. SQL Key Words

Table C-1 lists all tokens that are key words in the SQL standard and in PostgreSQL 9.4.20. Background information can be found in Section 4.1.1. (For space reasons, only the latest two versions of the SQL standard, and SQL-92 for historical comparison, are included. The differences between those and the other intermediate standard versions are small.)

SQL distinguishes between reserved and non-reserved key words. According to the standard, reserved key words are the only real key words; they are never allowed as identifiers. Non-reserved key words only have a special meaning in particular contexts and can be used as identifiers in other contexts. Most non-reserved key words are actually the names of built-in tables and functions specified by SQL. The concept of non-reserved key words essentially only exists to declare that some predefined meaning is attached to a word in some contexts.

In the PostgreSQL parser life is a bit more complicated. There are several different classes of tokens ranging from those that can never be used as an identifier to those that have absolutely no special status in the parser as compared to an ordinary identifier. (The latter is usually the case for functions specified by SQL.) Even reserved key words are not completely reserved in PostgreSQL, but can be used as column labels (for example, `SELECT 55 AS CHECK`, even though `CHECK` is a reserved key word).

In Table C-1 in the column for PostgreSQL we classify as “non-reserved” those key words that are explicitly known to the parser but are allowed as column or table names. Some key words that are otherwise non-reserved cannot be used as function or data type names and are marked accordingly. (Most of these words represent built-in functions or data types with special syntax. The function or type is still available but it cannot be redefined by the user.) Labeled “reserved” are those tokens that are not allowed as column or table names. Some reserved key words are allowable as names for functions or data types; this is also shown in the table. If not so marked, a reserved key word is only allowed as an “AS” column label name.

As a general rule, if you get spurious parser errors for commands that contain any of the listed key words as an identifier you should try to quote the identifier to see if the problem goes away.

It is important to understand before studying Table C-1 that the fact that a key word is not reserved in PostgreSQL does not mean that the feature related to the word is not implemented. Conversely, the presence of a key word does not indicate the existence of a feature.

Appendix D. SQL Conformance

This section attempts to outline to what extent PostgreSQL conforms to the current SQL standard. The following information is not a full statement of conformance, but it presents the main topics in as much detail as is both reasonable and useful for users.

The formal name of the SQL standard is ISO/IEC 9075 “Database Language SQL”. A revised version of the standard is released from time to time; the most recent update appearing in 2011. The 2011 version is referred to as ISO/IEC 9075:2011, or simply as SQL:2011. The versions prior to that were SQL:2008, SQL:2003, SQL:1999, and SQL-92. Each version replaces the previous one, so claims of conformance to earlier versions have no official merit. PostgreSQL development aims for conformance with the latest official version of the standard where such conformance does not contradict traditional features or common sense. Many of the features required by the SQL standard are supported, though sometimes with slightly differing syntax or function. Further moves towards conformance can be expected over time.

SQL-92 defined three feature sets for conformance: Entry, Intermediate, and Full. Most database management systems claiming SQL standard conformance were conforming at only the Entry level, since the entire set of features in the Intermediate and Full levels was either too voluminous or in conflict with legacy behaviors.

Starting with SQL:1999, the SQL standard defines a large set of individual features rather than the ineffectively broad three levels found in SQL-92. A large subset of these features represents the “Core” features, which every conforming SQL implementation must supply. The rest of the features are purely optional. Some optional features are grouped together to form “packages”, which SQL implementations can claim conformance to, thus claiming conformance to particular groups of features.

The standard versions beginning with SQL:2003 are also split into a number of parts. Each is known by a shorthand name. Note that these parts are not consecutively numbered.

- ISO/IEC 9075-1 Framework (SQL/Framework)
- ISO/IEC 9075-2 Foundation (SQL/Foundation)
- ISO/IEC 9075-3 Call Level Interface (SQL/CLI)
- ISO/IEC 9075-4 Persistent Stored Modules (SQL/PSM)
- ISO/IEC 9075-9 Management of External Data (SQL/MED)
- ISO/IEC 9075-10 Object Language Bindings (SQL/OLB)
- ISO/IEC 9075-11 Information and Definition Schemas (SQL/Schemata)
- ISO/IEC 9075-13 Routines and Types using the Java Language (SQL/JRT)
- ISO/IEC 9075-14 XML-related specifications (SQL/XML)

The PostgreSQL core covers parts 1, 2, 9, 11, and 14. Part 3 is covered by the ODBC driver, and part 13 is covered by the PL/Java plug-in, but exact conformance is currently not being verified for these components. There are currently no implementations of parts 4 and 10 for PostgreSQL.
Appendix D. SQL Conformance

PostgreSQL supports most of the major features of SQL:2011. Out of 179 mandatory features required for full Core conformance, PostgreSQL conforms to at least 160. In addition, there is a long list of supported optional features. It might be worth noting that at the time of writing, no current version of any database management system claims full conformance to Core SQL:2011.

In the following two sections, we provide a list of those features that PostgreSQL supports, followed by a list of the features defined in SQL:2011 which are not yet supported in PostgreSQL. Both of these lists are approximate: There might be minor details that are nonconforming for a feature that is listed as supported, and large parts of an unsupported feature might in fact be implemented. The main body of the documentation always contains the most accurate information about what does and does not work.

**Note:** Feature codes containing a hyphen are subfeatures. Therefore, if a particular subfeature is not supported, the main feature is listed as unsupported even if some other subfeatures are supported.

**D.2. Unsupported Features**

The following features defined in SQL:2011 are not implemented in this release of PostgreSQL. In a few cases, equivalent functionality is available.
<table>

Appendix E. Release Notes

The release notes contain the significant changes in each PostgreSQL release, with major features and migration issues listed at the top. The release notes do not contain changes that affect only a few users or changes that are internal and therefore not user-visible. For example, the optimizer is improved in almost every release, but the improvements are usually observed by users as simply faster queries.

A complete list of changes for each release can be obtained by viewing the Git logs for each release. The `pgsql-committers` email list records all source code changes as well. There is also a web interface that shows changes to specific files.

The name appearing next to each item represents the major developer for that item. Of course all changes involve community discussion and patch review, so each item is truly a community effort.

E.1. Release 9.4.20

Release date: 2018-11-08

This release contains a variety of fixes from 9.4.19. For information about new features in the 9.4 major release, see Section E.21.

E.1.1. Migration to Version 9.4.20

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.18, see Section E.3.

E.1.2. Changes

- Fix corner-case failures in `has_foo_privilege()` family of functions (Tom Lane)
  Return NULL rather than throwing an error when an invalid object OID is provided. Some of these functions got that right already, but not all. `has_column_privilege()` was additionally capable of crashing on some platforms.
- Avoid O(N^2) slowdown in regular expression match/split functions on long strings (Andrew Gierth)
- Avoid O(N^3) slowdown in lexer for long strings of + or - characters (Andrew Gierth)
- Fix mis-execution of SubPlans when the outer query is being scanned backwards (Andrew Gierth)
- Fix failure of `UPDATE/DELETE ... WHERE CURRENT OF ...` after rewinding the referenced cursor (Tom Lane)

---

1. https://archives.postgresql.org/pgsql-committers/
A cursor that scans multiple relations (particularly an inheritance tree) could produce wrong behavior if rewound to an earlier relation.

- **Fix EvalPlanQual to handle conditionally-executed InitPlans properly** (Andrew Gierth, Tom Lane)
  
  This resulted in hard-to-reproduce crashes or wrong answers in concurrent updates, if they contained code such as an uncorrelated sub-SELECT inside a CASE construct.

- **Fix character-class checks to not fail on Windows for Unicode characters above U+FFFF** (Tom Lane, Kenji Uno)
  
  This bug affected full-text-search operations, as well as contrib/ltree and contrib/pg_trgm.

- **Ensure that sequences owned by a foreign table are processed by ALTER OWNER on the table** (Peter Eisentraut)
  
  The ownership change should propagate to such sequences as well, but this was missed for foreign tables.

- **Fix over-allocation of space for array_out()’s result string** (Keiichi Hirobe)

- **Fix memory leak in repeated SP-GiST index scans** (Tom Lane)
  
  This is only known to amount to anything significant in cases where an exclusion constraint using SP-GiST receives many new index entries in a single command.

- **Ensure that ApplyLogicalMappingFile() closes the mapping file when done with it** (Tomas Vondra)
  
  Previously, the file descriptor was leaked, eventually resulting in failures during logical decoding.

- **Fix logical decoding to handle cases where a mapped catalog table is repeatedly rewritten, e.g. by VACUUM FULL** (Andres Freund)

- **Prevent starting the server with wal_level set to too low a value to support an existing replication slot** (Andres Freund)

- **Avoid crash if a utility command causes infinite recursion** (Tom Lane)

- **When initializing a hot standby, cope with duplicate XIDs caused by two-phase transactions on the master** (Michael Paquier, Konstantin Knizhnik)

- **Randomize the random() seed in bootstrap and standalone backends, and in initdb** (Noah Misch)
  
  The main practical effect of this change is that it avoids a scenario where initdb might mistakenly conclude that POSIX shared memory is not available, due to name collisions caused by always using the same random seed.

- **Allow DSM allocation to be interrupted** (Chris Travers)

- **Avoid possible buffer overrun when replaying GIN page recompression from WAL** (Alexander Korotkov, Sivasubramanian Ramasubramanian)

- **Fix missed fsync of a replication slot’s directory** (Konstantin Knizhnik, Michael Paquier)

- **Fix unexpected timeouts when using wal_sender_timeout on a slow server** (Noah Misch)

- **Ensure that hot standby processes use the correct WAL consistency point** (Alexander Kukushkin, Michael Paquier)
  
  This prevents possible misbehavior just after a standby server has reached a consistent database state during WAL replay.

2201
Appleid E. Release Notes

- Don't run atexit callbacks when servicing SIGQUIT (Heikki Linnakangas)
- Don't record foreign-server user mappings as members of extensions (Tom Lane)
  If CREATE USER MAPPING is executed in an extension script, an extension dependency was created for the user mapping, which is unexpected. Roles can’t be extension members, so user mappings shouldn’t be either.
- Make syslogger more robust against failures in opening CSV log files (Tom Lane)
- Fix possible inconsistency in pg_dump's sorting of dissimilar object names (Jacob Champion)
- Ensure that pg_restore will schema-qualify the table name when emitting DISABLE/ENABLE TRIGGER commands (Tom Lane)
  This avoids failures due to the new policy of running restores with restrictive search path.
- Fix pg_upgrade to handle event triggers in extensions correctly (Haribabu Kommi)
  pg_upgrade failed to preserve an event trigger’s extension-membership status.
- Fix pg_upgrade’s cluster state check to work correctly on a standby server (Bruce Momjian)
- Enforce type cube’s dimension limit in all contrib/cube functions (Andrey Borodin)
  Previously, some cube-related functions could construct values that would be rejected by cube_in(), leading to dump/reload failures.
- Fix contrib/unaccent's unaccent() function to use the unaccent text search dictionary that is in the same schema as the function (Tom Lane)
  Previously it tried to look up the dictionary using the search path, which could fail if the search path has a restrictive value.
- Fix build problems on macOS 10.14 (Mojave) (Tom Lane)
  Adjust configure to add an -isysroot switch to CPPFLAGS; without this, PL/Perl and PL/Tcl fail to configure or build on macOS 10.14. The specific sysroot used can be overridden at configure time or build time by setting the PG_SYSROOT variable in the arguments of configure or make.
  It is now recommended that Perl-related extensions write $(perl_includespec) rather than -I$(perl_archlibexp)/CORE in their compiler flags. The latter continues to work on most platforms, but not recent macOS.
  Also, it should no longer be necessary to specify --with-tclconfig manually to get PL/Tcl to build on recent macOS releases.
- Fix MSVC build and regression-test scripts to work on recent Perl versions (Andrew Dunstan)
  Perl no longer includes the current directory in its search path by default; work around that.
- Support building on Windows with Visual Studio 2015 or Visual Studio 2017 (Michael Paquier, Haribabu Kommi)
- Allow btree comparison functions to return INT_MIN (Tom Lane)
  Up to now, we’ve forbidden datatype-specific comparison functions from returning INT_MIN, which allows callers to invert the sort order just by negating the comparison result. However, this was never safe for comparison functions that directly return the result of memcmp(), strcmp(), etc, as POSIX doesn’t place any such restriction on those functions. At least some recent versions of memcmp() can
return INT_MIN, causing incorrect sort ordering. Hence, we’ve removed this restriction. Callers must now use the INVERTCOMPARE_RESULT() macro if they wish to invert the sort order.

- Fix recursion hazard in shared-invalidation message processing (Tom Lane)

  This error could, for example, result in failure to access a system catalog or index that had just been processed by VACUUM FULL.

  This change adds a new result code for LockAcquire, which might possibly affect external callers of that function, though only very unusual usage patterns would have an issue with it. The API of LockAcquireExtended is also changed.

- Save and restore SPI’s global variables during SPI_connect() and SPI_finish() (Chapman Flack, Tom Lane)

  This prevents possible interference when one SPI-using function calls another.

- Provide ALLOCSET_DEFAULT_SIZES and sibling macros in back branches (Tom Lane)

  These macros have existed since 9.6, but there were requests to add them to older branches to allow extensions to rely on them without branch-specific coding.

- Avoid using potentially-under-aligned page buffers (Tom Lane)

  Invent new union types PGAlignedBlock and PGAlignedXLogBlock, and use these in place of plain char arrays, ensuring that the compiler can’t place the buffer at a misaligned start address. This fixes potential core dumps on alignment-picky platforms, and may improve performance even on platforms that allow misalignment.

- Make src/port/snprintf.c follow the C99 standard’s definition of snprintf()’s result value (Tom Lane)

  On platforms where this code is used (mostly Windows), its pre-C99 behavior could lead to failure to detect buffer overrun, if the calling code assumed C99 semantics.

- When building on i386 with the clang compiler, require -msse2 to be used (Andres Freund)

  This avoids problems with missed floating point overflow checks.

- Fix configure’s detection of the result type of strerror_r() (Tom Lane)

  The previous coding got the wrong answer when building with gcc on Linux (and perhaps in other cases), leading to libpq not returning useful error messages for system-reported errors.

- Update time zone data files to tzdata release 2018g for DST law changes in Chile, Fiji, Morocco, and Russia (Volgograd), plus historical corrections for China, Hawaii, Japan, Macau, and North Korea.

### E.2. Release 9.4.19

**Release date:** 2018-08-09

This release contains a variety of fixes from 9.4.18. For information about new features in the 9.4 major release, see Section E.21.
E.2.1. Migration to Version 9.4.19

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.18, see Section E.3.

E.2.2. Changes

• Fix failure to reset libpq’s state fully between connection attempts (Tom Lane)

  An unprivileged user of dblink or postgres_fdw could bypass the checks intended to prevent use of server-side credentials, such as a ~/.pgpass file owned by the operating-system user running the server. Servers allowing peer authentication on local connections are particularly vulnerable. Other attacks such as SQL injection into a postgres_fdw session are also possible. Attacking postgres_fdw in this way requires the ability to create a foreign server object with selected connection parameters, but any user with access to dblink could exploit the problem. In general, an attacker with the ability to select the connection parameters for a libpq-using application could cause mischief, though other plausible attack scenarios are harder to think of. Our thanks to Andrew Krasichkov for reporting this issue. (CVE-2018-10915)

• Ensure that updates to the relfrozenxid and relminxid values for “nailed” system catalogs are processed in a timely fashion (Andres Freund)

  Overoptimistic caching rules could prevent these updates from being seen by other sessions, leading to spurious errors and/or data corruption. The problem was significantly worse for shared catalogs, such as pg_authid, because the stale cache data could persist into new sessions as well as existing ones.

• Fix case where a freshly-promoted standby crashes before having completed its first post-recovery checkpoint (Michael Paquier, Kyotaro Horiguchi, Pavan Deolasee, Álvaro Herrera)

  This led to a situation where the server did not think it had reached a consistent database state during subsequent WAL replay, preventing restart.

• Avoid emitting a bogus WAL record when recycling an all-zero btree page (Amit Kapila)

  This mistake has been seen to cause assertion failures, and potentially it could result in unnecessary query cancellations on hot standby servers.

• Improve performance of WAL replay for transactions that drop many relations (Fujii Masao)

  This change reduces the number of times that shared buffers are scanned, so that it is of most benefit when that setting is large.

• Improve performance of lock releasing in standby server WAL replay (Thomas Munro)

• Make logical WAL senders report streaming state correctly (Simon Riggs, Sawada Masahiko)

  The code previously mis-detected whether or not it had caught up with the upstream server.

• Fix bugs in snapshot handling during logical decoding, allowing wrong decoding results in rare cases (Arseny Sher, Álvaro Herrera)

• Ensure a table’s cached index list is correctly rebuilt after an index creation fails partway through (Peter Geoghegan)

  Previously, the failed index’s OID could remain in the list, causing problems later in the same session.
Appendix E. Release Notes

• Fix mishandling of empty uncompressed posting list pages in GIN indexes (Sivasubramanian Ramasubramanian, Alexander Korotkov)
  This could result in an assertion failure after pg_upgrade of a pre-9.4 GIN index (9.4 and later will not create such pages).

• Ensure that VACUUM will respond to signals within btree page deletion loops (Andres Freund)
  Corrupted btree indexes could result in an infinite loop here, and that previously wasn’t interruptible without forcing a crash.

• Fix misoptimization of equivalence classes involving composite-type columns (Tom Lane)
  This resulted in failure to recognize that an index on a composite column could provide the sort order needed for a mergejoin on that column.

• Fix SQL-standard FETCH FIRST syntax to allow parameters ($n$), as the standard expects (Andrew Gierth)

• Fix failure to schema-qualify some object names in getObjectDescription output (Kyotaro Horiguchi, Tom Lane)
  Names of collations, conversions, and text search objects were not schema-qualified when they should be.

• Widen COPY FROM’s current-line-number counter from 32 to 64 bits (David Rowley)
  This avoids two problems with input exceeding 4G lines: COPY FROM WITH HEADER would drop a line every 4G lines, not only the first line, and error reports could show a wrong line number.

• Add a string freeing function to ecpg’s pgtypes library, so that cross-module memory management problems can be avoided on Windows (Takayuki Tsunakawa)
  On Windows, crashes can ensue if the free call for a given chunk of memory is not made from the same DLL that malloc’ed the memory. The pgtypes library sometimes returns strings that it expects the caller to free, making it impossible to follow this rule. Add a PGTYPESchar_free() function that just wraps free, allowing applications to follow this rule.

• Fix ecpg’s support for long long variables on Windows, as well as other platforms that declare strtoll/strtoull nonstandardly or not at all (Dang Minh Huong, Tom Lane)

• Fix misidentification of SQL statement type in PL/pgSQL, when a rule change causes a change in the semantics of a statement intra-session (Tom Lane)
  This error led to assertion failures, or in rare cases, failure to enforce the INTO STRICT option as expected.

• Fix password prompting in client programs so that echo is properly disabled on Windows when stdin is not the terminal (Matthew Stickney)

• Further fix mis-quoting of values for list-valued GUC variables in dumps (Tom Lane)
  The previous fix for quoting of search_path and other list-valued variables in pg_dump output turned out to misbehave for empty-string list elements, and it risked truncation of long file paths.

• Fix pg_dump’s failure to dump REPLICA IDENTITY properties for constraint indexes (Tom Lane)
  Manually created unique indexes were properly marked, but not those created by declaring UNIQUE or PRIMARY KEY constraints.

• Make pg_upgrade check that the old server was shut down cleanly (Bruce Momjian)
Appendix E. Release Notes

The previous check could be fooled by an immediate-mode shutdown.

- Fix crash in contrib/ltree's lca() function when the input array is empty (Pierre Ducroquet)
- Fix various error-handling code paths in which an incorrect error code might be reported (Michael Paquier, Tom Lane, Magnus Hagander)
- Rearrange makefiles to ensure that programs link to freshly-built libraries (such as libpq.so) rather than ones that might exist in the system library directories (Tom Lane)
  
  This avoids problems when building on platforms that supply old copies of PostgreSQL libraries.
- Update time zone data files to tzdata release 2018e for DST law changes in North Korea, plus historical corrections for Czechoslovakia.

  This update includes a redefinition of “daylight savings” in Ireland, as well as for some past years in Namibia and Czechoslovakia. In those jurisdictions, legally standard time is observed in summer, and daylight savings time in winter, so that the daylight savings offset is one hour behind standard time not one hour ahead. This does not affect either the actual UTC offset or the timezone abbreviations in use; the only known effect is that the is_dst column in the pg_timezone_names view will now be true in winter and false in summer in these cases.

E.3. Release 9.4.18

Release date: 2018-05-10

This release contains a variety of fixes from 9.4.17. For information about new features in the 9.4 major release, see Section E.21.

E.3.1. Migration to Version 9.4.18

A dump/restore is not required for those running 9.4.X.

However, if the function marking mistakes mentioned in the first changelog entry below affect you, you will want to take steps to correct your database catalogs.

Also, if you are upgrading from a version earlier than 9.4.17, see Section E.4.

E.3.2. Changes

- Fix incorrect volatility markings on a few built-in functions (Thomas Munro, Tom Lane)

  The functions query_to_xml, cursor_to_xml, cursor_to_xmlschema, query_to_xmlschema, and query_to_xml_and_xmlschema should be marked volatile because they execute user-supplied queries that might contain volatile operations. They were not, leading to a risk of incorrect query optimization. This has been repaired for new installations by correcting the initial catalog data, but existing installations will continue to contain the incorrect markings. Practical use of these functions seems to pose little hazard, but in case of trouble, it can be fixed by manually updating these functions’ pg_proc entries, for example ALTER FUNCTION pg_catalog.query_to_xml(text, boolean,
Another option is to pg_upgrade the database to a version containing the corrected initial data.

- Avoid re-using TOAST value OIDs that match dead-but-not-yet-vacuumed TOAST entries (Pavan Deolasee)

  Once the OID counter has wrapped around, it’s possible to assign a TOAST value whose OID matches a previously deleted entry in the same TOAST table. If that entry were not yet vacuumed away, this resulted in “unexpected chunk number 0 (expected 1) for toast value nnnnn” errors, which would persist until the dead entry was removed by VACUUM. Fix by not selecting such OIDs when creating a new TOAST entry.

- Change ANALYZE’s algorithm for updating pg_class.reltuples (David Gould)

  Previously, pages not actually scanned by ANALYZE were assumed to retain their old tuple density. In a large table where ANALYZE samples only a small fraction of the pages, this meant that the overall tuple density estimate could not change very much, so that reltuples would change nearly proportionally to changes in the table’s physical size (relpages) regardless of what was actually happening in the table. This has been observed to result in reltuples becoming so much larger than reality as to effectively shut off autovacuuming. To fix, assume that ANALYZE’s sample is a statistically unbiased sample of the table (as it should be), and just extrapolate the density observed within those pages to the whole table.

- Avoid deadlocks in concurrent CREATE INDEX CONCURRENTLY commands that are run under SERIALIZABLE or REPEATABLE READ transaction isolation (Tom Lane)

- Fix possible slow execution of REFRESH MATERIALIZED VIEW CONCURRENTLY (Thomas Munro)

- Fix UPDATE/DELETE ... WHERE CURRENT OF to not fail when the referenced cursor uses an index-only-scan plan (Yugo Nagata, Tom Lane)

- Fix incorrect planning of join clauses pushed into parameterized paths (Andrew Gierth, Tom Lane)

  This error could result in misclassifying a condition as a “join filter” for an outer join when it should be a plain “filter” condition, leading to incorrect join output.

- Fix misoptimization of CHECK constraints having provably-NULL subclauses of top-level AND/OR conditions (Tom Lane, Dean Rasheed)

  This could, for example, allow constraint exclusion to exclude a child table that should not be excluded from a query.

- Avoid failure if a query-cancel or session-termination interrupt occurs while committing a prepared transaction (Stas Kelvich)

- Fix query-lifespan memory leakage in repeatedly executed hash joins (Tom Lane)

- Fix overly strict sanity check in heap_prepare_freeze_tuple (Álvaro Herrera)

  This could result in incorrect “cannot freeze committed xmax” failures in databases that have been pg_upgrade’d from 9.2 or earlier.

- Prevent dangling-pointer dereference when a C-coded before-update row trigger returns the “old” tuple (Rushabh Lathia)

- Reduce locking during autovacuum worker scheduling (Jeff Janes)

  The previous behavior caused drastic loss of potential worker concurrency in databases with many tables.
Appendix E. Release Notes

• Ensure client hostname is copied while copying pg_stat_activity data to local memory (Edmund Horner)
  Previously the supposedly-local snapshot contained a pointer into shared memory, allowing the client hostname column to change unexpectedly if any existing session disconnected.

• Fix incorrect processing of multiple compound affixes in ispell dictionaries (Arthur Zakirov)

• Fix collation-aware searches (that is, indexscans using inequality operators) in SP-GiST indexes on text columns (Tom Lane)
  Such searches would return the wrong set of rows in most non-C locales.

• Count the number of index tuples correctly during initial build of an SP-GiST index (Tomas Vondra)
  Previously, the tuple count was reported to be the same as that of the underlying table, which is wrong if the index is partial.

• Count the number of index tuples correctly during vacuuming of a GiST index (Andrey Borodin)
  Previously it reported the estimated number of heap tuples, which might be inaccurate, and is certainly wrong if the index is partial.

• Fix a corner case where a streaming standby gets stuck at a WAL continuation record (Kyotaro Horiguchi)

• In logical decoding, avoid possible double processing of WAL data when a walsender restarts (Craig Ringer)

• Allow scalarltsel and scalargtsel to be used on non-core datatypes (Tomas Vondra)

• Reduce libpq’s memory consumption when a server error is reported after a large amount of query output has been collected (Tom Lane)
  Discard the previous output before, not after, processing the error message. On some platforms, notably Linux, this can make a difference in the application’s subsequent memory footprint.

• Fix double-free crashes in ecpg (Patrick Krecker, Jeevan Ladhe)

• Fix ecpg to handle long long int variables correctly in MSVC builds (Michael Meskes, Andrew Gierth)

• Fix mis-quoting of values for list-valued GUC variables in dumps (Michael Paquier, Tom Lane)
  The local_preload_libraries, session_preload_libraries, shared_preload_libraries, and temp_tablespaces variables were not correctly quoted in pg_dump output. This would cause problems if settings for these variables appeared in CREATE FUNCTION ... SET or ALTER DATABASE/ROLE ... SET clauses.

• Fix pg_recvlogical to not fail against pre-v10 PostgreSQL servers (Michael Paquier)
  A previous fix caused pg_recvlogical to issue a command regardless of server version, but it should only be issued to v10 and later servers.

• Fix overflow handling in PL/pgSQL integer FOR loops (Tom Lane)
  The previous coding failed to detect overflow of the loop variable on some non-gcc compilers, leading to an infinite loop.

• Adjust PL/Python regression tests to pass under Python 3.7 (Peter Eisentraut)
• Support testing PL/Python and related modules when building with Python 3 and MSVC (Andrew Dunstan)

• Rename internal `b64_encode` and `b64_decode` functions to avoid conflict with Solaris 11.4 built-in functions (Rainer Orth)

• Sync our copy of the timezone library with IANA tzcode release 2018e (Tom Lane)
  This fixes the zic timezone data compiler to cope with negative daylight-savings offsets. While the PostgreSQL project will not immediately ship such timezone data, zic might be used with timezone data obtained directly from IANA, so it seems prudent to update zic now.

• Update time zone data files to tzdata release 2018d for DST law changes in Palestine and Antarctica (Casey Station), plus historical corrections for Portugal and its colonies, as well as Enderbury, Jamaica, Turks & Caicos Islands, and Uruguay.

E.4. Release 9.4.17

Release date: 2018-03-01
This release contains a variety of fixes from 9.4.16. For information about new features in the 9.4 major release, see Section E.21.

E.4.1. Migration to Version 9.4.17
A dump/restore is not required for those running 9.4.X.
However, if you run an installation in which not all users are mutually trusting, or if you maintain an application or extension that is intended for use in arbitrary situations, it is strongly recommended that you read the documentation changes described in the first changelog entry below, and take suitable steps to ensure that your installation or code is secure.
Also, the changes described in the second changelog entry below may cause functions used in index expressions or materialized views to fail during auto-analyze, or when reloading from a dump. After upgrading, monitor the server logs for such problems, and fix affected functions.
Also, if you are upgrading from a version earlier than 9.4.13, see Section E.8.

E.4.2. Changes

• Document how to configure installations and applications to guard against search-path-dependent trojan-horse attacks from other users (Noah Misch)
  Using a `search_path` setting that includes any schemas writable by a hostile user enables that user to capture control of queries and then run arbitrary SQL code with the permissions of the attacked user.
  While it is possible to write queries that are proof against such hijacking, it is notationally tedious, and it’s very easy to overlook holes. Therefore, we now recommend configurations in which no untrusted schemas appear in one’s search path. Relevant documentation appears in Section 5.7.6 (for database ad-
ministrators and users), Section 31.1 (for application authors), Section 35.15.1 (for extension authors), and CREATE FUNCTION (for authors of SECURITY DEFINER functions). (CVE-2018-1058)

- Avoid use of insecure search_path settings in pg_dump and other client programs (Noah Misch, Tom Lane)

pg_dump, pg_upgrade, vacuumdb and other PostgreSQL-provided applications were themselves vulnerable to the type of hijacking described in the previous changelog entry; since these applications are commonly run by superusers, they present particularly attractive targets. To make them secure whether or not the installation as a whole has been secured, modify them to include only the pg_catalog schema in their search_path settings. Autovacuum worker processes now do the same, as well.

In cases where user-provided functions are indirectly executed by these programs — for example, user-provided functions in index expressions — the tighter search_path may result in errors, which will need to be corrected by adjusting those user-provided functions to not assume anything about what search path they are invoked under. That has always been good practice, but now it will be necessary for correct behavior. (CVE-2018-1058)

- Fix misbehavior of concurrent-update rechecks with CTE references appearing in subplans (Tom Lane)

If a CTE (WITH clause reference) is used in an InitPlan or SubPlan, and the query requires a recheck due to trying to update or lock a concurrently-updated row, incorrect results could be obtained.

- Fix planner failures with overlapping mergejoin clauses in an outer join (Tom Lane)

These mistakes led to “left and right pathkeys do not match in mergejoin” or “outer pathkeys do not match merge clauses” planner errors in corner cases.

- Repair pg_upgrade’s failure to preserve relfrozenxid for materialized views (Tom Lane, Andres Freund)

This oversight could lead to data corruption in materialized views after an upgrade, manifesting as “could not access status of transaction” or “found xmin from before relfrozenxid” errors. The problem would be more likely to occur in seldom-refreshed materialized views, or ones that were maintained only with REFRESH MATERIALIZED VIEW CONCURRENTLY.

If such corruption is observed, it can be repaired by refreshing the materialized view (without CONCURRENTLY).

- Fix incorrect reporting of PL/Python function names in error CONTEXT stacks (Tom Lane)

An error occurring within a nested PL/Python function call (that is, one reached via a SPI query from another PL/Python function) would result in a stack trace showing the inner function’s name twice, rather than the expected results. Also, an error in a nested PL/Python DO block could result in a null pointer dereference crash on some platforms.

- Allow contrib/auto_explain’s log_min_duration setting to range up to INT_MAX, or about 24 days instead of 35 minutes (Tom Lane)

**E.5. Release 9.4.16**

Release date: 2018-02-08
This release contains a variety of fixes from 9.4.15. For information about new features in the 9.4 major release, see Section E.21.

**E.5.1. Migration to Version 9.4.16**

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.13, see Section E.8.

**E.5.2. Changes**

- Ensure that all temporary files made by `pg_upgrade` are non-world-readable (Tom Lane, Noah Misch)
  - `pg_upgrade` normally restricts its temporary files to be readable and writable only by the calling user. But the temporary file containing `pg_dumpall -g` output would be group- or world-readable, or even writable, if the user’s `umask` setting allows. In typical usage on multi-user machines, the `umask` and/or the working directory’s permissions would be tight enough to prevent problems; but there may be people using `pg_upgrade` in scenarios where this oversight would permit disclosure of database passwords to unfriendly eyes. (CVE-2018-1053)

- Fix vacuuming of tuples that were updated while key-share locked (Andres Freund, Álvaro Herrera)
  - In some cases `VACUUM` would fail to remove such tuples even though they are now dead, leading to assorted data corruption scenarios.

- Fix inadequate buffer locking in some LSN fetches (Jacob Champion, Asim Praveen, Ashwin Agrawal)
  - These errors could result in misbehavior under concurrent load. The potential consequences have not been characterized fully.

- Avoid unnecessary failure in a query on an inheritance tree that occurs concurrently with some child table being removed from the tree by `ALTER TABLE NO INHERIT` (Tom Lane)

- Fix spurious deadlock failures when multiple sessions are running `CREATE INDEX CONCURRENTLY` (Jeff Janes)

- Repair failure with correlated sub-`SELECT` inside `VALUES` inside a `LATERAL` subquery (Tom Lane)

- Fix “could not devise a query plan for the given query” planner failure for some cases involving nested `UNION ALL` inside a lateral subquery (Tom Lane)

- Fix logical decoding to correctly clean up disk files for crashed transactions (Atsushi Torikoshi)
  - Logical decoding may spill WAL records to disk for transactions generating many WAL records. Normally these files are cleaned up after the transaction’s commit or abort record arrives; but if no such record is ever seen, the removal code misbehaved.

- Fix walsender timeout failure and failure to respond to interrupts when processing a large transaction (Petr Jelinek)

- Fix `has_sequence_privilege()` to support `WITH GRANT OPTION` tests, as other privilege-testing functions do (Joe Conway)
• In databases using UTF8 encoding, ignore any XML declaration that asserts a different encoding (Pavel Stehule, Noah Misch)

We always store XML strings in the database encoding, so allowing libxml to act on a declaration of another encoding gave wrong results. In encodings other than UTF8, we don’t promise to support non-ASCII XML data anyway, so retain the previous behavior for bug compatibility. This change affects only `xpath()` and related functions; other XML code paths already acted this way.

• Provide for forward compatibility with future minor protocol versions (Robert Haas, Badrul Chowdhury)

Up to now, PostgreSQL servers simply rejected requests to use protocol versions newer than 3.0, so that there was no functional difference between the major and minor parts of the protocol version number. Allow clients to request versions 3.x without failing, sending back a message showing that the server only understands 3.0. This makes no difference at the moment, but back-patching this change should allow speedier introduction of future minor protocol upgrades.

• Cope with failure to start a parallel worker process (Amit Kapila, Robert Haas)

Parallel query previously tended to hang indefinitely if a worker could not be started, as the result of `fork()` failure or other low-probability problems.

• Prevent stack-overflow crashes when planning extremely deeply nested set operations (`UNION/INTERSECT/EXCEPT`) (Tom Lane)

• Fix null-pointer crashes for some types of LDAP URLs appearing in `pg_hba.conf` (Thomas Munro)

• Fix sample `INSTR()` functions in the PL/pgSQL documentation (Yugo Nagata, Tom Lane)

These functions are stated to be Oracle® compatible, but they weren’t exactly. In particular, there was a discrepancy in the interpretation of a negative third parameter: Oracle thinks that a negative value indicates the last place where the target substring can begin, whereas our functions took it as the last place where the target can end. Also, Oracle throws an error for a zero or negative fourth parameter, whereas our functions returned zero.

The sample code has been adjusted to match Oracle’s behavior more precisely. Users who have copied this code into their applications may wish to update their copies.

• Fix `pg_dump` to make ACL (permissions), comment, and security label entries reliably identifiable in archive output formats (Tom Lane)

The “tag” portion of an ACL archive entry was usually just the name of the associated object. Make it start with the object type instead, bringing ACLs into line with the convention already used for comment and security label archive entries. Also, fix the comment and security label entries for the whole database, if present, to make their tags start with `DATABASE` so that they also follow this convention. This prevents false matches in code that tries to identify large-object-related entries by seeing if the tag starts with `LARGE OBJECT`. That could have resulted in misclassifying entries as data rather than schema, with undesirable results in a schema-only or data-only dump.

Note that this change has user-visible results in the output of `pg_restore --list`.

• In ecpg, detect indicator arrays that do not have the correct length and report an error (David Rader)

• Avoid triggering a libc assertion in `contrib/hstore`, due to use of `memcpy()` with equal source and destination pointers (Tomas Vondra)

• Provide modern examples of how to auto-start Postgres on macOS (Tom Lane)
The scripts in contrib/start-scripts/osx use infrastructure that’s been deprecated for over a decade, and which no longer works at all in macOS releases of the last couple of years. Add a new subdirectory contrib/start-scripts/macos containing scripts that use the newer launchd infrastructure.

- Fix incorrect selection of configuration-specific libraries for OpenSSL on Windows (Andrew Dunstan)
- Support linking to MinGW-built versions of libperl (Noah Misch)
  This allows building PL/Perl with some common Perl distributions for Windows.
- Fix MSVC build to test whether 32-bit libperl needs -D_USE_32BIT_TIME_T (Noah Misch)
  Available Perl distributions are inconsistent about what they expect, and lack any reliable means of reporting it, so resort to a build-time test on what the library being used actually does.
- On Windows, install the crash dump handler earlier in postmaster startup (Takayuki Tsunakawa)
  This may allow collection of a core dump for some early-startup failures that did not produce a dump before.
- On Windows, avoid encoding-conversion-related crashes when emitting messages very early in postmaster startup (Takayuki Tsunakawa)
- Use our existing Motorola 68K spinlock code on OpenBSD as well as NetBSD (David Carlier)
- Add support for spinlocks on Motorola 88K (David Carlier)
- Update time zone data files to tzdata release 2018c for DST law changes in Brazil, Sao Tome and Principe, plus historical corrections for Bolivia, Japan, and South Sudan. The US/Pacific-New zone has been removed (it was only an alias for America/Los_Angeles anyway).

E.6. Release 9.4.15

Release date: 2017-11-09
This release contains a variety of fixes from 9.4.14. For information about new features in the 9.4 major release, see Section E.21.

E.6.1. Migration to Version 9.4.15
A dump/restore is not required for those running 9.4.X.
However, if you are upgrading from a version earlier than 9.4.13, see Section E.8.

E.6.2. Changes

- Fix crash due to rowtype mismatch in json[b]_populate_recordset() (Michael Paquier, Tom Lane)
Appendix E. Release Notes

These functions used the result rowtype specified in the `FROM ... AS` clause without checking that it matched the actual rowtype of the supplied tuple value. If it didn’t, that would usually result in a crash, though disclosure of server memory contents seems possible as well. (CVE-2017-15098)

- Fix sample server-start scripts to become `$PGUSER` before opening `$PGLOG` (Noah Misch)
  
  Previously, the postmaster log file was opened while still running as root. The database owner could therefore mount an attack against another system user by making `$PGLOG` be a symbolic link to some other file, which would then become corrupted by appending log messages.

  By default, these scripts are not installed anywhere. Users who have made use of them will need to manually recopy them, or apply the same changes to their modified versions. If the existing `$PGLOG` file is root-owned, it will need to be removed or renamed out of the way before restarting the server with the corrected script. (CVE-2017-12172)

- Fix crash when logical decoding is invoked from a SPI-using function, in particular any function written in a PL language (Tom Lane)

- Fix `json_build_array()`, `json_build_object()`, and their `jsonb` equivalents to handle explicit `VARIADIC` arguments correctly (Michael Paquier)

- Properly reject attempts to convert infinite float values to type `numeric` (Tom Lane, KaiGai Kohei)
  
  Previously the behavior was platform-dependent.

- Fix corner-case crashes when columns have been added to the end of a view (Tom Lane)

- Record proper dependencies when a view or rule contains `FieldSelect` or `FieldStore` expression nodes (Tom Lane)
  
  Lack of these dependencies could allow a column or data type `DROP` to go through when it ought to fail, thereby causing later uses of the view or rule to get errors. This patch does not do anything to protect existing views/rules, only ones created in the future.

- Correctly detect hashability of range data types (Tom Lane)
  
  The planner mistakenly assumed that any range type could be hashed for use in hash joins or hash aggregation, but actually it must check whether the range’s subtype has hash support. This does not affect any of the built-in range types, since they’re all hashable anyway.

- Fix low-probability loss of `NOTIFY` messages due to XID wraparound (Marko Tiikkaja, Tom Lane)
  
  If a session executed no queries, but merely listened for notifications, for more than 2 billion transactions, it started to miss some notifications from concurrently-committing transactions.

- Avoid SIGBUS crash on Linux when a DSM memory request exceeds the space available in tmpfs (Thomas Munro)

- Prevent low-probability crash in processing of nested trigger firings (Tom Lane)

- Allow `COPY`’s `FREEZE` option to work when the transaction isolation level is `REPEATABLE READ` or higher (Noah Misch)
  
  This case was unintentionally broken by a previous bug fix.

- Correctly restore the umask setting when file creation fails in `COPY` or `lo_export()` (Peter Eisentraut)

- Give a better error message for duplicate column names in `ANALYZE` (Nathan Bossart)

- Fix mis-parsing of the last line in a non-newline-terminated `pg_hba.conf` file (Tom Lane)
Appendix E. Release Notes

• Fix libpq to not require user’s home directory to exist (Tom Lane)
  In v10, failure to find the home directory while trying to read ~/.pgpass was treated as a hard error, but it should just cause that file to not be found. Both v10 and previous release branches made the same mistake when reading ~/.pg_service.conf, though this was less obvious since that file is not sought unless a service name is specified.

• Fix libpq to guard against integer overflow in the row count of a PGresult (Michael Paquier)

• Fix ecpg’s handling of out-of-scope cursor declarations with pointer or array variables (Michael Meskes)

• In ecpglib, correctly handle backslashes in string literals depending on whether standard_conforming_strings is set (Tsunakawa Takayuki)

• Make ecpglib’s Informix-compatibility mode ignore fractional digits in integer input strings, as expected (Gao Zengqi, Michael Meskes)

• Sync our copy of the timezone library with IANA release tzcode2017c (Tom Lane)
  This fixes various issues; the only one likely to be user-visible is that the default DST rules for a POSIX-style zone name, if no posixrules file exists in the timezone data directory, now match current US law rather than what it was a dozen years ago.

• Update time zone data files to tzdata release 2017c for DST law changes in Fiji, Namibia, Northern Cyprus, Sudan, Tonga, and Turks & Caicos Islands, plus historical corrections for Alaska, Apia, Burma, Calcutta, Detroit, Ireland, Namibia, and Pago Pago.

E.7. Release 9.4.14

Release date: 2017-08-31

This release contains a small number of fixes from 9.4.13. For information about new features in the 9.4 major release, see Section E.21.

E.7.1. Migration to Version 9.4.14

A dump/restore is not required for those running 9.4.X.
However, if you are upgrading from a version earlier than 9.4.13, see Section E.8.

E.7.2. Changes

• Fix failure of walsender processes to respond to shutdown signals (Marco Nenciarini)
  A missed flag update resulted in walsenders continuing to run as long as they had a standby server connected, preventing primary-server shutdown unless immediate shutdown mode is used.

• Show foreign tables in information_schema.table_privileges view (Peter Eisentraut)
  All other relevant information_schema views include foreign tables, but this one ignored them.
Appendix E. Release Notes

Since this view definition is installed by initdb, merely upgrading will not fix the problem. If you need to fix this in an existing installation, you can, as a superuser, do this in psql:

```sql
SET search_path TO information_schema;
CREATE OR REPLACE VIEW table_privileges AS
SELECT CAST(u_grantor.rolname AS sql_identifier) AS grantor,
    CAST(grantee.rolname AS sql_identifier) AS grantee,
    CAST(current_database() AS sql_identifier) AS table_catalog,
    CAST(nc.nspname AS sql_identifier) AS table_schema,
    CAST(c.relname AS sql_identifier) AS table_name,
    CAST(c.prtype AS character_data) AS privilege_type,
    CAST(CASE WHEN
        -- object owner always has grant options
        pg_has_role(grantee.oid, c.relowner, 'USAGE')
        OR c.grantable
    THEN 'YES' ELSE 'NO' END AS yes_or_no) AS is_grantable,
    CASE WHEN c.prtype = 'SELECT' THEN 'YES' ELSE 'NO' END AS with_hierarchy
FROM (SELECT oid, relname, relnamespace, relkind, relowner, (aclexplode(coalesce(relacl, acldefault('r', relowner)))).* FROM pg_class
    AS c (oid, relname, relnamespace, relkind, relowner, grantor, grantee, prtype, grantable),
    pg_namespace nc,
    pg_authid u_grantor,
    (SELECT oid, rolname FROM pg_authid
     UNION ALL
     SELECT 0::oid, 'PUBLIC') AS grantee
WHERE c.relnamespace = nc.oid
    AND c.relkind IN ('r', 'v', 'f')
    AND c.grantee = grantee.oid
    AND c.grantor = u_grantor.oid
    AND c.prtype IN ('INSERT', 'SELECT', 'UPDATE', 'DELETE', 'TRUNCATE', 'REFERENCES', 'TRIGGER')
    AND (pg_has_role(u_grantor.oid, 'USAGE')
        OR pg_has_role(grantee.oid, 'USAGE'))
    OR grantee.rolname = 'PUBLIC');
```

This must be repeated in each database to be fixed, including `template0`.

- Clean up handling of a fatal exit (e.g., due to receipt of SIGTERM) that occurs while trying to execute a `ROLLBACK` of a failed transaction (Tom Lane)
  
  This situation could result in an assertion failure. In production builds, the exit would still occur, but it would log an unexpected message about “cannot drop active portal”.

- Remove assertion that could trigger during a fatal exit (Tom Lane)

- Correctly identify columns that are of a range type or domain type over a composite type or domain type being searched for (Tom Lane)

  Certain `ALTER` commands that change the definition of a composite type or domain type are supposed to fail if there are any stored values of that type in the database, because they lack the infrastructure needed to update or check such values. Previously, these checks could miss relevant values that are wrapped inside range types or sub-domains, possibly allowing the database to become inconsistent.
• Fix crash in pg_restore when using parallel mode and using a list file to select a subset of items to restore (Fabrízio de Royes Mello)

• Change ecpg’s parser to allow RETURNING clauses without attached C variables (Michael Meskes)
  This allows ecpg programs to contain SQL constructs that use RETURNING internally (for example, inside a CTE) rather than using it to define values to be returned to the client.

• Improve selection of compiler flags for PL/Perl on Windows (Tom Lane)
  This fix avoids possible crashes of PL/Perl due to inconsistent assumptions about the width of time_t values. A side-effect that may be visible to extension developers is that _USE_32BIT_TIME_T is no longer defined globally in PostgreSQL Windows builds. This is not expected to cause problems, because type time_t is not used in any PostgreSQL API definitions.

---

Release date: 2017-08-10

This release contains a variety of fixes from 9.4.12. For information about new features in the 9.4 major release, see Section E.21.

E.8.1. Migration to Version 9.4.13

A dump/restore is not required for those running 9.4.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.4.12, see Section E.9.

E.8.2. Changes

• Further restrict visibility of pg_user_mappings.umoptions, to protect passwords stored as user mapping options (Noah Misch)
  The fix for CVE-2017-7486 was incorrect: it allowed a user to see the options in her own user mapping, even if she did not have USAGE permission on the associated foreign server. Such options might include a password that had been provided by the server owner rather than the user herself. Since information_schema.user_mapping_options does not show the options in such cases, pg_user_mappings should not either. (CVE-2017-7547)
  By itself, this patch will only fix the behavior in newly initdb’d databases. If you wish to apply this change in an existing database, you will need to do the following:

1. Restart the postmaster after adding allow_system_table_mods = true to postgresql.conf. (In versions supporting ALTER SYSTEM, you can use that to make the configuration change, but you’ll still need a restart.)
2. **In each** database of the cluster, run the following commands as superuser:

```
SET search_path = pg_catalog;
CREATE OR REPLACE VIEW pg_user_mappings AS
SELECT
    U.oid  AS umid,
    S.oid  AS srvid,
    S.srvname AS srvname,
    U.umuser AS umuser,
CASE WHEN U.umuser = 0 THEN
    'public'
ELSE
    A.rolname
END AS usename,
CASE WHEN (U.umuser <> 0 AND A.rolname = current_user
        AND (pg_has_role(S.srvowner, 'USAGE')
             OR has_server_privilege(S.oid, 'USAGE'))) 
OR (U.umuser = 0 AND pg_has_role(S.srvowner, 'USAGE'))
OR (SELECT rolsuper FROM pg_authid WHERE rolname = current_user)
THEN U.umoptions
ELSE NULL END AS umoptions
FROM pg_user_mapping U
LEFT JOIN pg_authid A ON (A.oid = U.umuser) JOIN pg_foreign_server S ON (U.umserver = S.oid);
```

3. Do not forget to include the template0 and template1 databases, or the vulnerability will still exist in databases you create later. To fix template0, you’ll need to temporarily make it accept connections. In PostgreSQL 9.5 and later, you can use

```
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS true;
and then after fixing template0, undo that with
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS false;
```

In prior versions, instead use

```
UPDATE pg_database SET datallowconn = true WHERE datname = 'template0';
UPDATE pg_database SET datallowconn = false WHERE datname = 'template0';
```

4. Finally, remove the allow_system_table_mods configuration setting, and again restart the postmaster.

- Disallow empty passwords in all password-based authentication methods (Heikki Linnakangas)
  
  libpq ignores empty password specifications, and does not transmit them to the server. So, if a user’s password has been set to the empty string, it’s impossible to log in with that password via psql or other libpq-based clients. An administrator might therefore believe that setting the password to empty is equivalent to disabling password login. However, with a modified or non-libpq-based client, logging in could be possible, depending on which authentication method is configured. In particular the most common method, md5, accepted empty passwords. Change the server to reject empty passwords in all cases. (CVE-2017-7546)

- Make `lo_put()` check for UPDATE privilege on the target large object (Tom Lane, Michael Paquier)
  
  `lo_put()` should surely require the same permissions as `lowrite()`, but the check was missing, allowing any user to change the data in a large object. (CVE-2017-7548)
Appendix E. Release Notes

- Fix concurrent locking of tuple update chains (Álvaro Herrera)
  If several sessions concurrently lock a tuple update chain with nonconflicting lock modes using an old snapshot, and they all succeed, it was possible for some of them to nonetheless fail (and conclude there is no live tuple version) due to a race condition. This had consequences such as foreign-key checks failing to see a tuple that definitely exists but is being updated concurrently.

- Fix potential data corruption when freezing a tuple whose XMAX is a multixact with exactly one still-interesting member (Teodor Sigaev)

- Avoid integer overflow and ensuing crash when sorting more than one billion tuples in-memory (Sergey Koposov)

- On Windows, retry process creation if we fail to reserve the address range for our shared memory in the new process (Tom Lane, Amit Kapila)
  This is expected to fix infrequent child-process-launch failures that are probably due to interference from antivirus products.

- Fix low-probability corruption of shared predicate-lock hash table in Windows builds (Thomas Munro, Tom Lane)

- Avoid logging clean closure of an SSL connection as though it were a connection reset (Michael Paquier)

- Prevent sending SSL session tickets to clients (Tom Lane)
  This fix prevents reconnection failures with ticket-aware client-side SSL code.

- Fix code for setting tcp_keepalives_idle on Solaris (Tom Lane)

- Fix statistics collector to honor inquiry messages issued just after a postmaster shutdown and immediate restart (Tom Lane)
  Statistics inquiries issued within half a second of the previous postmaster shutdown were effectively ignored.

- Ensure that the statistics collector’s receive buffer size is at least 100KB (Tom Lane)
  This reduces the risk of dropped statistics data on older platforms whose default receive buffer size is less than that.

- Fix possible creation of an invalid WAL segment when a standby is promoted just after it processes an XLOG_SWITCH WAL record (Andres Freund)

- Fix walsender to exit promptly when client requests shutdown (Tom Lane)

- Fix SIGHUP and SIGUSR1 handling in walsender processes (Petr Jelinek, Andres Freund)

- Prevent walsender-triggered panics during shutdown checkpoints (Andres Freund, Michael Paquier)

- Fix unnecessarily slow restarts of walreceiver processes due to race condition in postmaster (Tom Lane)

- Fix logical decoding failure with very wide tuples (Andres Freund)
  Logical decoding crashed on tuples that are wider than 64KB (after compression, but with all data in-line). The case arises only when REPLICA IDENTITY FULL is enabled for a table containing such tuples.

- Fix leakage of small subtransactions spilled to disk during logical decoding (Andres Freund)
  This resulted in temporary files consuming excessive disk space.
• Reduce the work needed to build snapshots during creation of logical-decoding slots (Andres Freund, Petr Jelinek)

The previous algorithm was infeasibly expensive on a server with a lot of open transactions.

• Fix race condition that could indefinitely delay creation of logical-decoding slots (Andres Freund, Petr Jelinek)

• Reduce overhead in processing syscache invalidation events (Tom Lane)

  This is particularly helpful for logical decoding, which triggers frequent cache invalidation.

• Fix cases where an INSERT or UPDATE assigns to more than one element of a column that is of domain-over-array type (Tom Lane)

• Allow window functions to be used in sub-SELECTS that are within the arguments of an aggregate function (Tom Lane)

• Move autogenerated array types out of the way during ALTER ... RENAME (Vik Fearing)

  Previously, we would rename a conflicting autogenerated array type out of the way during CREATE; this fix extends that behavior to renaming operations.

• Ensure that ALTER USER ... SET accepts all the syntax variants that ALTER ROLE ... SET does (Peter Eisentraut)

• Properly update dependency info when changing a datatype I/O function’s argument or return type from opaque to the correct type (Heikki Linnakangas)

  CREATE TYPE updates I/O functions declared in this long-obsolete style, but it forgot to record a dependency on the type, allowing a subsequent DROP TYPE to leave broken function definitions behind.

• Reduce memory usage when ANALYZE processes a tsvector column (Heikki Linnakangas)

• Fix unnecessary precision loss and sloppy rounding when multiplying or dividing money values by integers or floats (Tom Lane)

• Tighten checks for whitespace in functions that parse identifiers, such as regprocedurein() (Tom Lane)

  Depending on the prevailing locale, these functions could misinterpret fragments of multibyte characters as whitespace.

• Use relevant #define symbols from Perl while compiling PL/Perl (Ashutosh Sharma, Tom Lane)

  This avoids portability problems, typically manifesting as a “handshake” mismatch during library load, when working with recent Perl versions.

• In libpq, reset GSS/SASL and SSPI authentication state properly after a failed connection attempt (Michael Paquier)

  Failure to do this meant that when falling back from SSL to non-SSL connections, a GSS/SASL failure in the SSL attempt would always cause the non-SSL attempt to fail. SSPI did not fail, but it leaked memory.

• In psql, fix failure when COPY FROM STDIN is ended with a keyboard EOF signal and then another COPY FROM STDIN is attempted (Thomas Munro)

  This misbehavior was observed on BSD-derived platforms (including macOS), but not on most others.

• Fix pg_dump and pg_restore to emit REFRESH MATERIALIZED VIEW commands last (Tom Lane)
Appendix E. Release Notes

This prevents errors during dump/restore when a materialized view refers to tables owned by a different user.

- Improve pg_dump/pg_restore’s reporting of error conditions originating in zlib (Vladimir Kunschikov, Álvaro Herrera)

- Fix pg_dump with the --clean option to drop event triggers as expected (Tom Lane)
  It also now correctly assigns ownership of event triggers; before, they were restored as being owned by the superuser running the restore script.

- Fix pg_dump to not emit invalid SQL for an empty operator class (Daniel Gustafsson)

- Fix pg_dump output to stdout on Windows (Kuntal Ghosh)
  A compressed plain-text dump written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

- Fix pg_get_ruledef() to print correct output for the ON SELECT rule of a view whose columns have been renamed (Tom Lane)
  In some corner cases, pg_dump relies on pg_get_ruledef() to dump views, so that this error could result in dump/reload failures.

- Fix dumping of outer joins with empty constraints, such as the result of a NATURAL LEFT JOIN with no common columns (Tom Lane)

- Fix dumping of function expressions in the FROM clause in cases where the expression does not deparse into something that looks like a function call (Tom Lane)

- Fix pg_basebackup output to stdout on Windows (Haribabu Kommi)
  A backup written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

- Fix pg_upgrade to ensure that the ending WAL record does not have wal_level = minimum (Bruce Momijian)
  This condition could prevent upgraded standby servers from reconnecting.

- In postgres_fdw, re-establish connections to remote servers after ALTER SERVER or ALTER USER MAPPING commands (Kyotaro Horiguchi)
  This ensures that option changes affecting connection parameters will be applied promptly.

- In postgres_fdw, allow cancellation of remote transaction control commands (Robert Haas, Rafia Sabih)
  This change allows us to quickly escape a wait for an unresponsive remote server in many more cases than previously.

- Increase MAX_SYSCACHE_CALLBACKS to provide more room for extensions (Tom Lane)

- Always use -fpIC, not -fpic, when building shared libraries with gcc (Tom Lane)
  This supports larger extension libraries on platforms where it makes a difference.

- Fix unescaped-braces issue in our build scripts for Microsoft MSVC, to avoid a warning or error from recent Perl versions (Andrew Dunstan)

- In MSVC builds, handle the case where the openssl library is not within a VC subdirectory (Andrew Dunstan)
• In MSVC builds, add proper include path for libxml2 header files (Andrew Dunstan)
  This fixes a former need to move things around in standard Windows installations of libxml2.
• In MSVC builds, recognize a Tcl library that is named tcl86.lib (Noah Misch)
• In MSVC builds, honor `PROVE_FLAGS` settings on `vcregress.pl`'s command line (Andrew Dunstan)

Release date: 2017-05-11
This release contains a variety of fixes from 9.4.11. For information about new features in the 9.4 major release, see Section E.21.

E.9.1. Migration to Version 9.4.12
A dump/restore is not required for those running 9.4.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are using third-party replication tools that depend on “logical decoding”, see the fourth changelog entry below.

Also, if you are upgrading from a version earlier than 9.4.11, see Section E.10.

E.9.2. Changes

• Restrict visibility of `pg_user_mappings.umoptions`, to protect passwords stored as user mapping options (Michael Paquier, Feike Steenbergen)
  The previous coding allowed the owner of a foreign server object, or anyone he has granted server `USAGE` permission to, to see the options for all user mappings associated with that server. This might well include passwords for other users. Adjust the view definition to match the behavior of `information_schema.user_mapping_options`, namely that these options are visible to the user being mapped, or if the mapping is for `PUBLIC` and the current user is the server owner, or if the current user is a superuser. (CVE-2017-7486)
  By itself, this patch will only fix the behavior in newly initdb’d databases. If you wish to apply this change in an existing database, follow the corrected procedure shown in the changelog entry for CVE-2017-7547, in Section E.8.

• Prevent exposure of statistical information via leaky operators (Peter Eisentraut)
  Some selectivity estimation functions in the planner will apply user-defined operators to values obtained from `pg_statistic`, such as most common values and histogram entries. This occurs before table permissions are checked, so a nefarious user could exploit the behavior to obtain these values for table columns he does not have permission to read. To fix, fall back to a default estimate if the operator's implementation function is not certified leak-proof and the calling user does not have permission to
read the table column whose statistics are needed. At least one of these criteria is satisfied in most cases in practice. (CVE-2017-7484)

- Restore libpq’s recognition of the PGREQUIRESSL environment variable (Daniel Gustafsson)

  Processing of this environment variable was unintentionally dropped in PostgreSQL 9.3, but its documentation remained. This creates a security hazard, since users might be relying on the environment variable to force SSL-encrypted connections, but that would no longer be guaranteed. Restore handling of the variable, but give it lower priority than PGSSLMODE, to avoid breaking configurations that work correctly with post-9.3 code. (CVE-2017-7485)

- Fix possibly-invalid initial snapshot during logical decoding (Petr Jelinek, Andres Freund)

  The initial snapshot created for a logical decoding replication slot was potentially incorrect. This could cause third-party tools that use logical decoding to copy incomplete/inconsistent initial data. This was more likely to happen if the source server was busy at the time of slot creation, or if another logical slot already existed.

  If you are using a replication tool that depends on logical decoding, and it should have copied a nonempty data set at the start of replication, it is advisable to recreate the replica after installing this update, or to verify its contents against the source server.

- Fix possible corruption of “init forks” of unlogged indexes (Robert Haas, Michael Paquier)

  This could result in an unlogged index being set to an invalid state after a crash and restart. Such a problem would persist until the index was dropped and rebuilt.

- Fix incorrect reconstruction of pg_subtrans entries when a standby server replays a prepared but uncommitted two-phase transaction (Tom Lane)

  In most cases this turned out to have no visible ill effects, but in corner cases it could result in circular references in pg_subtrans, potentially causing infinite loops in queries that examine rows modified by the two-phase transaction.

- Avoid possible crash in walsender due to failure to initialize a string buffer (Stas Kelvich, Fujii Masao)

- Fix postmaster’s handling of fork() failure for a background worker process (Tom Lane)

  Previously, the postmaster updated portions of its state as though the process had been launched successfully, resulting in subsequent confusion.

- Ensure parsing of queries in extension scripts sees the results of immediately-preceding DDL (Julien Rouhaud, Tom Lane)

  Due to lack of a cache flush step between commands in an extension script file, non-utility queries might not see the effects of an immediately preceding catalog change, such as ALTER TABLE ... RENAME.

- Skip tablespace privilege checks when ALTER TABLE ... ALTER COLUMN TYPE rebuilds an existing index (Noah Misch)

  The command failed if the calling user did not currently have CREATE privilege for the tablespace containing the index. That behavior seems unhelpful, so skip the check, allowing the index to be rebuilt where it is.

- Fix ALTER TABLE ... VALIDATE CONSTRAINT to not recurse to child tables when the constraint is marked NO INHERIT (Amit Langote)

  This fix prevents unwanted “constraint does not exist” failures when no matching constraint is present in the child tables.
• Fix VACUUM to account properly for pages that could not be scanned due to conflicting page pins (Andrew Gierth)
  This tended to lead to underestimation of the number of tuples in the table. In the worst case of a small heavily-contended table, VACUUM could incorrectly report that the table contained no tuples, leading to very bad planning choices.
• Ensure that bulk-tuple-transfer loops within a hash join are interruptible by query cancel requests (Tom Lane, Thomas Munro)
• Fix integer-overflow problems in interval comparison (Kyotaro Horiguchi, Tom Lane)
  The comparison operators for type interval could yield wrong answers for intervals larger than about 296000 years. Indexes on columns containing such large values should be reindexed, since they may be corrupt.
• Fix cursor_to_xml() to produce valid output with tableforest = false (Thomas Munro, Peter Eisentraut)
  Previously it failed to produce a wrapping <table> element.
• Fix roundoff problems in float8_timestamptz() and make_interval() (Tom Lane)
  These functions truncated, rather than rounded, when converting a floating-point value to integer microseconds; that could cause unexpectedly off-by-one results.
• Improve performance of pg_timezone_names view (Tom Lane, David Rowley)
• Reduce memory management overhead for contexts containing many large blocks (Tom Lane)
• Fix sloppy handling of corner-case errors from lseek() and close() (Tom Lane)
  Neither of these system calls are likely to fail in typical situations, but if they did, fd.c could get quite confused.
• Fix incorrect check for whether postmaster is running as a Windows service (Michael Paquier)
  This could result in attempting to write to the event log when that isn’t accessible, so that no logging happens at all.
• Fix ecpg to support COMMIT PREPARED and ROLLBACK PREPARED (Masahiko Sawada)
• Fix a double-free error when processing dollar-quoted string literals in ecpg (Michael Meskes)
• In pg_dump, fix incorrect schema and owner marking for comments and security labels of some types of database objects (Giuseppe Broccolo, Tom Lane)
  In simple cases this caused no ill effects; but for example, a schema-selective restore might omit comments it should include, because they were not marked as belonging to the schema of their associated object.
• Avoid emitting an invalid list file in pg_restore -l when SQL object names contain newlines (Tom Lane)
  Replace newlines by spaces, which is sufficient to make the output valid for pg_restore -L’s purposes.
• Fix pg_upgrade to transfer comments and security labels attached to “large objects” (blobs) (Stephen Frost)
Previously, blobs were correctly transferred to the new database, but any comments or security labels attached to them were lost.

- Improve error handling in contrib/adminpack’s pg_file_write() function (Noah Misch)

  Notably, it failed to detect errors reported by fclose().

- In contrib/dblink, avoid leaking the previous unnamed connection when establishing a new unnamed connection (Joe Conway)

- Fix contrib/pg_trgm’s extraction of trigrams from regular expressions (Tom Lane)

  In some cases it would produce a broken data structure that could never match anything, leading to GIN or GiST indexscans that use a trigram index not finding any matches to the regular expression.

- In contrib/postgres_fdw, transmit query cancellation requests to the remote server (Michael Paquier, Etsuro Fujita)

  Previously, a local query cancellation request did not cause an already-sent remote query to terminate early. This is a back-patch of work originally done for 9.6.

- Support OpenSSL 1.1.0 (Heikki Linnakangas, Andreas Karlsson, Tom Lane)

  This is a back-patch of work previously done in newer branches; it’s needed since many platforms are adopting newer OpenSSL versions.

- Support Tcl 8.6 in MSVC builds (Álvaro Herrera)

- Sync our copy of the timezone library with IANA release tzcode2017b (Tom Lane)

  This fixes a bug affecting some DST transitions in January 2038.

- Update time zone data files to tzdata release 2017b for DST law changes in Chile, Haiti, and Mongolia, plus historical corrections for Ecuador, Kazakhstan, Liberia, and Spain. Switch to numeric abbreviations for numerous time zones in South America, the Pacific and Indian oceans, and some Asian and Middle Eastern countries.

  The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the pg_timezone_names view nor used for output.

- Use correct daylight-savings rules for POSIX-style time zone names in MSVC builds (David Rowley)

  The Microsoft MSVC build scripts neglected to install the posixrules file in the timezone directory tree. This resulted in the timezone code falling back to its built-in rule about what DST behavior to assume for a POSIX-style time zone name. For historical reasons that still corresponds to the DST rules the USA was using before 2007 (i.e., change on first Sunday in April and last Sunday in October). With this fix, a POSIX-style zone name will use the current and historical DST transition dates of the US/Eastern zone. If you don’t want that, remove the posixrules file, or replace it with a copy of some other zone file (see Section 8.5.3). Note that due to caching, you may need to restart the server to get such changes to take effect.
E.10. Release 9.4.11

Release date: 2017-02-09

This release contains a variety of fixes from 9.4.10. For information about new features in the 9.4 major release, see Section E.21.

E.10.1. Migration to Version 9.4.11

A dump/restore is not required for those running 9.4.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted indexes.

Also, if you are upgrading from a version earlier than 9.4.10, see Section E.11.

E.10.2. Changes

- Fix a race condition that could cause indexes built with \texttt{CREATE INDEX CONCURRENTLY} to be corrupt (Pavan Deolasee, Tom Lane)
  
  If \texttt{CREATE INDEX CONCURRENTLY} was used to build an index that depends on a column not previously indexed, then rows updated by transactions that ran concurrently with the \texttt{CREATE INDEX} command could have received incorrect index entries. If you suspect this may have happened, the most reliable solution is to rebuild affected indexes after installing this update.

- Ensure that the special snapshot used for catalog scans is not invalidated by premature data pruning (Tom Lane)
  
  Backends failed to account for this snapshot when advertising their oldest xmin, potentially allowing concurrent vacuuming operations to remove data that was still needed. This led to transient failures along the lines of “cache lookup failed for relation 1255”.

- Unconditionally WAL-log creation of the “init fork” for an unlogged table (Michael Paquier)
  
  Previously, this was skipped when \texttt{wal_level} = \texttt{minimal}, but actually it’s necessary even in that case to ensure that the unlogged table is properly reset to empty after a crash.

- Reduce interlocking on standby servers during the replay of btree index vacuuming operations (Simon Riggs)
  
  This change avoids substantial replication delays that sometimes occurred while replaying such operations.

- If the stats collector dies during hot standby, restart it (Takayuki Tsunakawa)

- Ensure that hot standby feedback works correctly when it’s enabled at standby server start (Ants Aasma, Craig Ringer)

- Check for interrupts while hot standby is waiting for a conflicting query (Simon Riggs)

- Avoid constantly respawning the autovacuum launcher in a corner case (Amit Khandekar)
Appendix E. Release Notes

This fix avoids problems when autovacuum is nominally off and there are some tables that require freezing, but all such tables are already being processed by autovacuum workers.

- Fix check for when an extension member object can be dropped (Tom Lane)
  Extension upgrade scripts should be able to drop member objects, but this was disallowed for serial-column sequences, and possibly other cases.

- Make sure ALTER TABLE preserves index tablespace assignments when rebuilding indexes (Tom Lane, Michael Paquier)
  Previously, non-default settings of default_tablespace could result in broken indexes.

- Fix incorrect updating of trigger function properties when changing a foreign-key constraint’s deferrability properties with ALTER TABLE ... ALTER CONSTRAINT (Tom Lane)
  This led to odd failures during subsequent exercise of the foreign key, as the triggers were fired at the wrong times.

- Prevent dropping a foreign-key constraint if there are pending trigger events for the referenced relation (Tom Lane)
  This avoids “could not find trigger NNN” or “relation NNN has no triggers” errors.

- Fix processing of OID column when a table with OIDs is associated to a parent with OIDs via ALTER TABLE ... INHERIT (Amit Langote)
  The OID column should be treated the same as regular user columns in this case, but it wasn’t, leading to odd behavior in later inheritance changes.

- Fix CREATE OR REPLACE VIEW to update the view query before attempting to apply the new view options (Dean Rasheed)
  Previously the command would fail if the new options were inconsistent with the old view definition.

- Report correct object identity during ALTER TEXT SEARCH CONFIGURATION (Artur Zakirov)
  The wrong catalog OID was reported to extensions such as logical decoding.

- Check for serializability conflicts before reporting constraint-violation failures (Thomas Munro)
  When using serializable transaction isolation, it is desirable that any error due to concurrent transactions should manifest as a serialization failure, thereby cueing the application that a retry might succeed. Unfortunately, this does not reliably happen for duplicate-key failures caused by concurrent insertions. This change ensures that such an error will be reported as a serialization error if the application explicitly checked for the presence of a conflicting key (and did not find it) earlier in the transaction.

- Prevent multicolumn expansion of foo.* in an UPDATE source expression (Tom Lane)
  This led to “UPDATE target count mismatch --- internal error”. Now the syntax is understood as a whole-row variable, as it would be in other contexts.

- Ensure that column typmods are determined accurately for multi-row VALUES constructs (Tom Lane)
  This fixes problems occurring when the first value in a column has a determinable typmod (e.g., length for a varchar value) but later values don’t share the same limit.

- Throw error for an unfinished Unicode surrogate pair at the end of a Unicode string (Tom Lane)
Normally, a Unicode surrogate leading character must be followed by a Unicode surrogate trailing character, but the check for this was missed if the leading character was the last character in a Unicode string literal (U&'...') or Unicode identifier (U&"...").

• Ensure that a purely negative text search query, such as !foo, matches empty tsvectors (Tom Dunstan)

Such matches were found by GIN index searches, but not by sequential scans or GiST index searches.

• Prevent crash when ts_rewrite() replaces a non-top-level subtree with an empty query (Artur Zakirov)

• Fix performance problems in ts_rewrite() (Tom Lane)

• Fix ts_rewrite()’s handling of nested NOT operators (Tom Lane)

• Fix array_fill() to handle empty arrays properly (Tom Lane)

• Fix one-byte buffer overrun in quote_literal_cstr() (Heikki Linnakangas)

The overrun occurred only if the input consisted entirely of single quotes and/or backslashes.

• Prevent multiple calls of pg_start_backup() and pg_stop_backup() from running concurrently (Michael Paquier)

This avoids an assertion failure, and possibly worse things, if someone tries to run these functions in parallel.

• Avoid discarding interval-to-interval casts that aren’t really no-ops (Tom Lane)

In some cases, a cast that should result in zeroing out low-order interval fields was mistakenly deemed to be a no-op and discarded. An example is that casting from INTERVAL MONTH to INTERVAL YEAR failed to clear the months field.

• Ensure that cached plans are invalidated by changes in foreign-table options (Amit Langote, Etsuro Fujita, Ashutosh Bapat)

• Fix pg_dump to dump user-defined casts and transforms that use built-in functions (Stephen Frost)

• Fix pg_restore with --create --if-exists to behave more sanely if an archive contains unrecognized DROP commands (Tom Lane)

This doesn’t fix any live bug, but it may improve the behavior in future if pg_restore is used with an archive generated by a later pg_dump version.

• Fix pg_basebackup’s rate limiting in the presence of slow I/O (Antonin Houska)

If disk I/O was transiently much slower than the specified rate limit, the calculation overflowed, effectively disabling the rate limit for the rest of the run.

• Fix pg_basebackup’s handling of symlinked pg_stat_tmp and pg_replslot subdirectories (Magnus Hagander, Michael Paquier)

• Fix possible pg_basebackup failure on standby server when including WAL files (Amit Kapila, Robert Haas)

• Ensure that the Python exception objects we create for PL/Python are properly reference-counted (Rafa de la Torre, Tom Lane)

This avoids failures if the objects are used after a Python garbage collection cycle has occurred.

• Fix PL/Tcl to support triggers on tables that have .tupno as a column name (Tom Lane)
This matches the (previously undocumented) behavior of PL/Tcl’s `spi_exec` and `spi_execp` commands, namely that a magic `.tupno` column is inserted only if there isn’t a real column named that.

- Allow DOS-style line endings in `~/.pgpass` files, even on Unix (Vik Fearing)
  This change simplifies use of the same password file across Unix and Windows machines.
- Fix one-byte buffer overrun if ecpg is given a file name that ends with a dot (Takayuki Tsunakawa)
- Fix psql’s tab completion for `ALTER DEFAULT PRIVILEGES` (Gilles Darold, Stephen Frost)
- In psql, treat an empty or all-blank setting of the `PAGER` environment variable as meaning “no pager” (Tom Lane)
  Previously, such a setting caused output intended for the pager to vanish entirely.
- Improve contrib/dblink’s reporting of low-level libpq errors, such as out-of-memory (Joe Conway)
- Teach contrib/dblink to ignore irrelevant server options when it uses a contrib/postgres_fdw foreign server as the source of connection options (Corey Huinker)
  Previously, if the foreign server object had options that were not also libpq connection options, an error occurred.
- On Windows, ensure that environment variable changes are propagated to DLLs built with debug options (Christian Ullrich)
- Sync our copy of the timezone library with IANA release tzcode2016j (Tom Lane)
  This fixes various issues, most notably that timezone data installation failed if the target directory didn’t support hard links.
- Update time zone data files to tzdata release 2016j for DST law changes in northern Cyprus (adding a new zone Asia/Famagusta), Russia (adding a new zone Europe/Saratov), Tonga, and Antarctica/Casey. Historical corrections for Italy, Kazakhstan, Malta, and Palestine. Switch to preferring numeric zone abbreviations for Tonga.

### E.11. Release 9.4.10

**Release date:** 2016-10-27

This release contains a variety of fixes from 9.4.9. For information about new features in the 9.4 major release, see Section E.21.

#### E.11.1. Migration to Version 9.4.10

A dump/restore is not required for those running 9.4.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted free space maps.

Also, if you are upgrading from a version earlier than 9.4.6, see Section E.15.
E.11.2. Changes

- Fix WAL-logging of truncation of relation free space maps and visibility maps (Pavan Deolasee, Heikki Linnakangas)

  It was possible for these files to not be correctly restored during crash recovery, or to be written incorrectly on a standby server. Bogus entries in a free space map could lead to attempts to access pages that have been truncated away from the relation itself, typically producing errors like “could not read block xxx: read only 0 of 8192 bytes”. Checksum failures in the visibility map are also possible, if checksumming is enabled.

  Procedures for determining whether there is a problem and repairing it if so are discussed at https://wiki.postgresql.org/wiki/Free_Space_Map_Problems.

- Fix incorrect creation of GIN index WAL records on big-endian machines (Tom Lane)

  The typical symptom was “unexpected GIN leaf action” errors during WAL replay.

- Fix SELECT FOR UPDATE/SHARE to correctly lock tuples that have been updated by a subsequently-aborted transaction (Álvaro Herrera)

  In 9.5 and later, the SELECT would sometimes fail to return such tuples at all. A failure has not been proven to occur in earlier releases, but might be possible with concurrent updates.

- Fix EvalPlanQual rechecks involving CTE scans (Tom Lane)

  The recheck would always see the CTE as returning no rows, typically leading to failure to update rows that were recently updated.

- Fix improper repetition of previous results from hashed aggregation in a subquery (Andrew Gierth)

  The test to see if we can reuse a previously-computed hash table of the aggregate state values neglected the possibility of an outer query reference appearing in an aggregate argument expression. A change in the value of such a reference should lead to recalculating the hash table, but did not.

- Fix query-lifespan memory leak in a bulk UPDATE on a table with a PRIMARY KEY or REPLICA IDENTITY index (Tom Lane)

- Fix EXPLAIN to emit valid XML when track_io_timing is on (Markus Winand)

  Previously the XML output-format option produced syntactically invalid tags such as <I/O-Read-Time>. That is now rendered as <I-O-Read-Time>.

- Suppress printing of zeroes for unmeasured times in EXPLAIN (Maksim Milyutin)

  Certain option combinations resulted in printing zero values for times that actually aren’t ever measured in that combination. Our general policy in EXPLAIN is not to print such fields at all, so do that consistently in all cases.

- Fix timeout length when VACUUM is waiting for exclusive table lock so that it can truncate the table (Simon Riggs)

  The timeout was meant to be 50 milliseconds, but it was actually only 50 microseconds, causing VACUUM to give up on truncation much more easily than intended. Set it to the intended value.

- Fix bugs in merging inherited CHECK constraints while creating or altering a table (Tom Lane, Amit Langote)
Appendix E. Release Notes

Allow identical CHECK constraints to be added to a parent and child table in either order. Prevent merging of a valid constraint from the parent table with a NOT VALID constraint on the child. Likewise, prevent merging of a NO INHERIT child constraint with an inherited constraint.

• Remove artificial restrictions on the values accepted by numeric_in() and numeric_recv() (Tom Lane)

We allow numeric values up to the limit of the storage format (more than 1e10000), so it seems fairly pointless that numeric_in() rejected scientific-notation exponents above 1000. Likewise, it was silly for numeric_recv() to reject more than 1000 digits in an input value.

• Avoid very-low-probability data corruption due to testing tuple visibility without holding buffer lock (Thomas Munro, Peter Geoghegan, Tom Lane)
• Fix logical WAL decoding to work properly when a subtransaction’s WAL output is large enough to spill to disk (Andres Freund)

• Fix buffer overread in logical WAL decoding (Tom Lane)

Logical decoding of a tuple update record read 23 bytes too many, which was usually harmless but with very bad luck could result in a crash.
• Fix file descriptor leakage when truncating a temporary relation of more than 1GB (Andres Freund)
• Disallow starting a standalone backend with standby_mode turned on (Michael Paquier)

This can’t do anything useful, since there will be no WAL receiver process to fetch more WAL data; and it could result in misbehavior in code that wasn’t designed with this situation in mind.
• Properly initialize replication slot state when recycling a previously-used slot (Michael Paquier)

This failure to reset all of the fields of the slot could prevent VACUUM from removing dead tuples.
• Round shared-memory allocation request to a multiple of the actual huge page size when attempting to use huge pages on Linux (Tom Lane)

This avoids possible failures during munmap() on systems with atypical default huge page sizes. Except in crash-recovery cases, there were no ill effects other than a log message.
• Use a more random value for the dynamic shared memory control segment’s ID (Robert Haas, Tom Lane)

Previously, the same value would be chosen every time, because it was derived from random() but srandom() had not yet been called. While relatively harmless, this was not the intended behavior.
• On Windows, retry creation of the dynamic shared memory control segment after an access-denied error (Kyotaro Horiguchi, Amit Kapila)

Windows sometimes returns ERROR_ACCESS_DENIED rather than ERROR_ALREADY_EXISTS when there is an existing segment. This led to postmaster startup failure due to believing that the former was an unrecoverable error.
• Don’t try to share SSL contexts across multiple connections in libpq (Heikki Linnakangas)

This led to assorted corner-case bugs, particularly when trying to use different SSL parameters for different connections.
• Avoid corner-case memory leak in libpq (Tom Lane)

The reported problem involved leaking an error report during PQreset(), but there might be related cases.
• Make ecpg’s --help and --version options work consistently with our other executables (Haribabu Kommi)

• Fix pgbench’s calculation of average latency (Fabien Coelho)
  The calculation was incorrect when there were \sleep commands in the script, or when the test duration was specified in number of transactions rather than total time.

• In pg_dump, never dump range constructor functions (Tom Lane)
  This oversight led to pg_upgrade failures with extensions containing range types, due to duplicate creation of the constructor functions.

• In pg_xlogdump, retry opening new WAL segments when using --follow option (Magnus Hagander)
  This allows for a possible delay in the server's creation of the next segment.

• Fix pg_xlogdump to cope with a WAL file that begins with a continuation record spanning more than one page (Pavan Deolasee)

• Fix contrib/pg_buffercache to work when shared_buffers exceeds 256GB (KaiGai Kohei)

• Fix contrib/intarray/bench/bench.pl to print the results of the EXPLAIN it does when given the -e option (Daniel Gustafsson)

• Install TAP test infrastructure so that it’s available for extension testing (Craig Ringer)
  When PostgreSQL has been configured with --enable-tap-tests, “make install” will now install the Perl support files for TAP testing where PGXS can find them. This allows non-core extensions to use $(prove_check) without extra tests.

• In MSVC builds, include pg_recvlogical in a client-only installtion (MauMau)

• Update Windows time zone mapping to recognize some time zone names added in recent Windows versions (Michael Paquier)

• Prevent failure of obsolete dynamic time zone abbreviations (Tom Lane)
  If a dynamic time zone abbreviation does not match any entry in the referenced time zone, treat it as equivalent to the time zone name. This avoids unexpected failures when IANA removes abbreviations from their time zone database, as they did in tzdata release 2016f and seem likely to do again in the future. The consequences were not limited to not recognizing the individual abbreviation; any mismatch caused the pg_timezone_abbrevs view to fail altogether.

• Update time zone data files to tzdata release 2016h for DST law changes in Palestine and Turkey, plus historical corrections for Turkey and some regions of Russia. Switch to numeric abbreviations for some time zones in Antarctica, the former Soviet Union, and Sri Lanka.
  The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the pg_timezone_names view nor used for output.
  In this update, AMT is no longer shown as being in use to mean Armenia Time. Therefore, we have changed the Default abbreviation set to interpret it as Amazon Time, thus UTC-4 not UTC+4.
Appendix E. Release Notes

E.12. Release 9.4.9

Release date: 2016-08-11

This release contains a variety of fixes from 9.4.8. For information about new features in the 9.4 major release, see Section E.21.

E.12.1. Migration to Version 9.4.9

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.6, see Section E.15.

E.12.2. Changes

• Fix possible mis-evaluation of nested CASE-WHEN expressions (Heikki Linnakangas, Michael Paquier, Tom Lane)

    A CASE expression appearing within the test value subexpression of another CASE could become confused about whether its own test value was null or not. Also, inlining of a SQL function implementing the equality operator used by a CASE expression could result in passing the wrong test value to functions called within a CASE expression in the SQL function’s body. If the test values were of different data types, a crash might result; moreover such situations could be abused to allow disclosure of portions of server memory. (CVE-2016-5423)

• Fix client programs’ handling of special characters in database and role names (Noah Misch, Nathan Bossart, Michael Paquier)

    Numerous places in vacuumdb and other client programs could become confused by database and role names containing double quotes or backslashes. Tighten up quoting rules to make that safe. Also, ensure that when a conninfo string is used as a database name parameter to these programs, it is correctly treated as such throughout.

    Fix handling of paired double quotes in psql’s \connect and \password commands to match the documentation.

    Introduce a new -reuse-previos option in psql’s \connect command to allow explicit control of whether to re-use connection parameters from a previous connection. (Without this, the choice is based on whether the database name looks like a conninfo string, as before.) This allows secure handling of database names containing special characters in pg_dumpall scripts.

    pg_dumpall now refuses to deal with database and role names containing carriage returns or newlines, as it seems impractical to quote those characters safely on Windows. In future we may reject such names on the server side, but that step has not been taken yet.

    These are considered security fixes because crafted object names containing special characters could have been used to execute commands with superuser privileges the next time a superuser executes pg_dumpall or other routine maintenance operations. (CVE-2016-5424)

• Fix corner-case misbehaviors for IS NULL/IS NOT NULL applied to nested composite values (Andrew Gierth, Tom Lane)
Appendix E. Release Notes

The SQL standard specifies that `IS NULL` should return TRUE for a row of all null values (thus `ROW(NULL, NULL) IS NULL` yields TRUE), but this is not meant to apply recursively (thus `ROW(NULL, ROW(NULL, NULL)) IS NULL` yields FALSE). The core executor got this right, but certain planner optimizations treated the test as recursive (thus producing TRUE in both cases), and contrib/postgres_fdw could produce remote queries that misbehaved similarly.

- Make the `inet` and `cidr` data types properly reject IPv6 addresses with too many colon-separated fields (Tom Lane)
- Prevent crash in `close_ps()` (the point `## lseg` operator) for NaN input coordinates (Tom Lane)
  Make it return NULL instead of crashing.
- Avoid possible crash in `pg_get_expr()` when inconsistent values are passed to it (Michael Paquier, Thomas Munro)
- Fix several one-byte buffer over-reads in `to_number()` (Peter Eisentraut)
  In several cases the `to_number()` function would read one more character than it should from the input string. There is a small chance of a crash, if the input happens to be adjacent to the end of memory.
- Do not run the planner on the query contained in `CREATE MATERIALIZED VIEW` or `CREATE TABLE AS` when `WITH NO DATA` is specified (Michael Paquier, Tom Lane)
  This avoids some unnecessary failure conditions, for example if a stable function invoked by the materialized view depends on a table that doesn’t exist yet.
- Avoid unsafe intermediate state during expensive paths through `heap_update()` (Masahiko Sawada, Andres Freund)
  Previously, these cases locked the target tuple (by setting its XMAX) but did not WAL-log that action, thus risking data integrity problems if the page were spilled to disk and then a database crash occurred before the tuple update could be completed.
- Fix hint bit update during WAL replay of row locking operations (Andres Freund)
  The only known consequence of this problem is that row locks held by a prepared, but uncommitted, transaction might fail to be enforced after a crash and restart.
- Avoid unnecessary “could not serialize access” errors when acquiring `FOR KEY SHARE` row locks in serializable mode (Álvaro Herrera)
- Avoid crash in `postgres -C` when the specified variable has a null string value (Michael Paquier)
- Fix possible loss of large subtransactions in logical decoding (Petru-Florin Mihancea)
- Fix failure of logical decoding when a subtransaction contains no actual changes (Marko Tiikkaja, Andrew Gierth)
- Ensure that backends see up-to-date statistics for shared catalogs (Tom Lane)
  The statistics collector failed to update the statistics file for shared catalogs after a request from a regular backend. This problem was partially masked because the autovacuum launcher regularly makes requests that did cause such updates; however, it became obvious with autovacuum disabled.
- Avoid redundant writes of the statistics files when multiple backends request updates close together (Tom Lane, Tomas Vondra)
- Avoid consuming a transaction ID during `VACUUM` (Alexander Korotkov)
Some cases in VACUUM unnecessarily caused an XID to be assigned to the current transaction. Normally this is negligible, but if one is up against the XID wraparound limit, consuming more XIDs during anti-wraparound vacuums is a very bad thing.

- Avoid canceling hot-standby queries during VACUUM FREEZE (Simon Riggs, Álvaro Herrera)

VACUUM FREEZE on an otherwise-idle master server could result in unnecessary cancellations of queries on its standby servers.

- Prevent possible failure when vacuuming multixact IDs in an installation that has been pg_upgrade’d from pre-9.3 (Andrew Gierth, Álvaro Herrera)

The usual symptom of this bug is errors like “MultiXactId NNN has not been created yet -- apparent wraparound”.

- When a manual ANALYZE specifies a column list, don’t reset the table’s changes_since_analyze counter (Tom Lane)

If we’re only analyzing some columns, we should not prevent routine auto-analyze from happening for the other columns.

- Fix ANALYZE’s overestimation of n_distinct for a unique or nearly-unique column with many null entries (Tom Lane)

The nulls could get counted as though they were themselves distinct values, leading to serious planner misestimates in some types of queries.

- Prevent autovacuum from starting multiple workers for the same shared catalog (Álvaro Herrera)

Normally this isn’t much of a problem because the vacuum doesn’t take long anyway; but in the case of a severely bloated catalog, it could result in all but one worker uselessly waiting instead of doing useful work on other tables.

- Avoid duplicate buffer lock release when abandoning a b-tree index page deletion attempt (Tom Lane)

This mistake prevented VACUUM from completing in some cases involving corrupt b-tree indexes.

- Prevent infinite loop in GiST index build for geometric columns containing NaN component values (Tom Lane)

- Fix contrib/btree_gin to handle the smallest possible bigint value correctly (Peter Eisentraut)

- Teach libpq to correctly decode server version from future servers (Peter Eisentraut)

It’s planned to switch to two-part instead of three-part server version numbers for releases after 9.6. Make sure that PQserverVersion() returns the correct value for such cases.

- Fix ecpg’s code for unsigned long long array elements (Michael Meskes)

- In pg_dump with both -c and -C options, avoid emitting an unwanted CREATE SCHEMA public command (David Johnston, Tom Lane)

- Improve handling of SIGTERM/control-C in parallel pg_dump and pg_restore (Tom Lane)

Make sure that the worker processes will exit promptly, and also arrange to send query-cancel requests to the connected backends, in case they are doing something long-running such as a CREATE INDEX.

- Fix error reporting in parallel pg_dump and pg_restore (Tom Lane)

Previously, errors reported by pg_dump or pg_restore worker processes might never make it to the user’s console, because the messages went through the master process, and there were various deadlock
scenarios that would prevent the master process from passing on the messages. Instead, just print everything to stderr. In some cases this will result in duplicate messages (for instance, if all the workers report a server shutdown), but that seems better than no message.

- Ensure that parallel pg_dump or pg_restore on Windows will shut down properly after an error (Kyotaro Horiguchi)
  Previously, it would report the error, but then just sit until manually stopped by the user.

- Make pg_dump behave better when built without zlib support (Kyotaro Horiguchi)
  It didn’t work right for parallel dumps, and emitted some rather pointless warnings in other cases.

- Make pg_basebackup accept -Z 0 as specifying no compression (Fujii Masao)

- Fix makefiles’ rule for building AIX shared libraries to be safe for parallel make (Noah Misch)

- Fix TAP tests and MSVC scripts to work when build directory’s path name contains spaces (Michael Paquier, Kyotaro Horiguchi)

- Be more predictable about reporting “statement timeout” versus “lock timeout” (Tom Lane)
  On heavily loaded machines, the regression tests sometimes failed due to reporting “lock timeout” even though the statement timeout should have occurred first.

- Make regression tests safe for Danish and Welsh locales (Jeff Janes, Tom Lane)
  Change some test data that triggered the unusual sorting rules of these locales.

- Update our copy of the timezone code to match IANA’s tzcode release 2016c (Tom Lane)
  This is needed to cope with anticipated future changes in the time zone data files. It also fixes some corner-case bugs in coping with unusual time zones.

- Update time zone data files to tzdata release 2016f for DST law changes in Kemerovo and Novosibirsk, plus historical corrections for Azerbaijan, Belarus, and Morocco.

E.13. Release 9.4.8

Release date: 2016-05-12
This release contains a variety of fixes from 9.4.7. For information about new features in the 9.4 major release, see Section E.21.

E.13.1. Migration to Version 9.4.8

A dump/restore is not required for those running 9.4.X.
However, if you are upgrading from a version earlier than 9.4.6, see Section E.15.
E.13.2. Changes

- Clear the OpenSSL error queue before OpenSSL calls, rather than assuming it’s clear already; and make sure we leave it clear afterwards (Peter Geoghegan, Dave Vitek, Peter Eisentraut)

  This change prevents problems when there are multiple connections using OpenSSL within a single process and not all the code involved follows the same rules for when to clear the error queue. Failures have been reported specifically when a client application uses SSL connections in libpq concurrently with SSL connections using the PHP, Python, or Ruby wrappers for OpenSSL. It’s possible for similar problems to arise within the server as well, if an extension module establishes an outgoing SSL connection.

- Fix “failed to build any N-way joins” planner error with a full join enclosed in the right-hand side of a left join (Tom Lane)

- Fix incorrect handling of equivalence-class tests in multilevel nestloop plans (Tom Lane)

  Given a three-or-more-way equivalence class of variables, such as \( x.x = y.y = z.z \), it was possible for the planner to omit some of the tests needed to enforce that all the variables are actually equal, leading to join rows being output that didn’t satisfy the \( \text{WHERE} \) clauses. For various reasons, erroneous plans were seldom selected in practice, so that this bug has gone undetected for a long time.

- Fix query-lifespan memory leak in GIN index scans (Julien Rouhaud)

- Fix query-lifespan memory leak and potential index corruption hazard in GIN index insertion (Tom Lane)

  The memory leak would typically not amount to much in simple queries, but it could be very substantial during a large GIN index build with high \texttt{maintenance\_work\_mem}.

- Fix possible misbehavior of \( \text{TH, th, and Y, YYYY} \) format codes in \texttt{to\_timestamp()} (Tom Lane)

  These could advance off the end of the input string, causing subsequent format codes to read garbage.

- Fix dumping of rules and views in which the \texttt{array} argument of a \textit{value operator} \texttt{ANY (array)} construct is a sub-SELECT (Tom Lane)

-Disallow newlines in \texttt{ALTER SYSTEM} parameter values (Tom Lane)

  The configuration-file parser doesn’t support embedded newlines in string literals, so we mustn’t allow them in values to be inserted by \texttt{ALTER SYSTEM}.

- Fix \texttt{ALTER TABLE ... REPLICA IDENTITY USING INDEX} to work properly if an index on OID is selected (David Rowley)

- Fix crash in logical decoding on alignment-picky platforms (Tom Lane, Andres Freund)

  The failure occurred only with a transaction large enough to spill to disk and a primary-key change within that transaction.

- Avoid repeated requests for feedback from receiver while shutting down walsender (Nick Cleaton)

- Make \texttt{pg\_regress} use a startup timeout from the \texttt{PGCTLTIMEOUT} environment variable, if that’s set (Tom Lane)

  This is for consistency with a behavior recently added to \texttt{pg\_ctl}; it eases automated testing on slow machines.
• Fix pg_upgrade to correctly restore extension membership for operator families containing only one
  operator class (Tom Lane)

  In such a case, the operator family was restored into the new database, but it was no longer marked as
  part of the extension. This had no immediate ill effects, but would cause later pg_dump runs to emit
  output that would cause (harmless) errors on restore.

• Fix pg_upgrade to not fail when new-cluster TOAST rules differ from old (Tom Lane)

  pg_upgrade had special-case code to handle the situation where the new PostgreSQL version thinks
  that a table should have a TOAST table while the old version did not. That code was broken, so remove
  it, and instead do nothing in such cases; there seems no reason to believe that we can’t get along fine
  without a TOAST table if that was okay according to the old version’s rules.

• Reduce the number of SysV semaphores used by a build configured with --disable-spinlocks
  (Tom Lane)

• Rename internal function strtoi() to strtoint() to avoid conflict with a NetBSD library function
  (Thomas Munro)

• Fix reporting of errors from bind() and listen() system calls on Windows (Tom Lane)

• Reduce verbosity of compiler output when building with Microsoft Visual Studio (Christian Ullrich)

• Fix putenv() to work properly with Visual Studio 2013 (Michael Paquier)

• Avoid possibly-unsafe use of Windows’ FormatMessage() function (Christian Ullrich)

  Use the FORMAT_MESSAGE_IGNORE_INSERTS flag where appropriate. No live bug is known to exist
  here, but it seems like a good idea to be careful.

• Update time zone data files to tzdata release 2016d for DST law changes in Russia and Venezuela.
  There are new zone names Europe/Kirov and Asia/Tomsk to reflect the fact that these regions now
  have different time zone histories from adjacent regions.

Release date: 2016-03-31

This release contains a variety of fixes from 9.4.6. For information about new features in the 9.4 major
release, see Section E.21.

E.14.1. Migration to Version 9.4.7

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.6, see Section E.15.

E.14.2. Changes

• Fix incorrect handling of NULL index entries in indexed ROW() comparisons (Tom Lane)
Appendix E. Release Notes

An index search using a row comparison such as \texttt{ROW(a, b) > ROW(‘x’, ‘y’)} would stop upon reaching a NULL entry in the \texttt{b} column, ignoring the fact that there might be non-NULL \texttt{b} values associated with later values of \texttt{a}.

- Avoid unlikely data-loss scenarios due to renaming files without adequate \texttt{fsync()} calls before and after (Michael Paquier, Tomas Vondra, Andres Freund)
- Fix bug in \texttt{json_to_record()} when a field of its input object contains a sub-object with a field name matching one of the requested output column names (Tom Lane)
- Fix misformatting of negative time zone offsets by \texttt{to_char()}’s \texttt{OF} format code (Thomas Munro, Tom Lane)
- Ignore recovery\_min\_apply\_delay parameter until recovery has reached a consistent state (Michael Paquier)

Previously, standby servers would delay application of WAL records in response to \texttt{recovery\_min\_apply\_delay} even while replaying the initial portion of WAL needed to make their database state valid. Since the standby is useless until it’s reached a consistent database state, this was deemed unhelpful.

- Correctly handle cases where \texttt{pg\_subtrans} is close to XID wraparound during server startup (Jeff Janes)
- Fix assorted bugs in logical decoding (Andres Freund)
  Trouble cases included tuples larger than one page when replica identity is \texttt{FULL}, \texttt{UPDATES} that change a primary key within a transaction large enough to be spooled to disk, incorrect reports of “subxact logged without previous toplevel record”, and incorrect reporting of a transaction’s commit time.
- Fix planner error with nested security barrier views when the outer view has a \texttt{WHERE} clause containing a correlated subquery (Dean Rasheed)
- Fix corner-case crash due to trying to free \texttt{localeconv()} output strings more than once (Tom Lane)
- Fix parsing of affix files for \texttt{ispell} dictionaries (Tom Lane)
  The code could go wrong if the affix file contained any characters whose byte length changes during case-folding, for example \texttt{I} in Turkish UTF8 locales.
- Avoid use of \texttt{sscanf()} to parse \texttt{ispell} dictionary files (Artur Zakirov)
  This dodges a portability problem on FreeBSD-derived platforms (including macOS).
- Avoid a crash on old Windows versions (before 7SP1/2008R2SP1) with an AVX2-capable CPU and a Postgres build done with Visual Studio 2013 (Christian Ullrich)
  This is a workaround for a bug in Visual Studio 2013’s runtime library, which Microsoft have stated they will not fix in that version.
- Fix \texttt{psql}’s tab completion logic to handle multibyte characters properly (Kyotaro Horiguchi, Robert Haas)
- Fix \texttt{psql}’s tab completion for \texttt{SECURITY LABEL} (Tom Lane)
  Pressing \texttt{TAB} after \texttt{SECURITY LABEL} might cause a crash or offering of inappropriate keywords.
- Make \texttt{pg\_ctl} accept a wait timeout from the \texttt{PGCTLTIMEOUT} environment variable, if none is specified on the command line (Noah Misch)
This eases testing of slower buildfarm members by allowing them to globally specify a longer-than-normal timeout for postmaster startup and shutdown.

- Fix incorrect test for Windows service status in pg_ctl (Manuel Mathar)
  The previous set of minor releases attempted to fix pg_ctl to properly determine whether to send log messages to Window’s Event Log, but got the test backwards.

- Fix pgbench to correctly handle the combination of -C and -M prepared options (Tom Lane)
  
- In pg_upgrade, skip creating a deletion script when the new data directory is inside the old data directory (Bruce Momjian)
  Blind application of the script in such cases would result in loss of the new data directory.

- In PL/Perl, properly translate empty Postgres arrays into empty Perl arrays (Alex Hunsaker)

- In PL/Python cope with function names that aren’t valid Python identifiers (Jim Nasby)

- Fix multiple mistakes in the statistics returned by contrib/pgstattuple's pgstatindex() function (Tom Lane)

- Remove dependency on psed in MSVC builds, since it’s no longer provided by core Perl (Michael Paquier, Andrew Dunstan)

- Update time zone data files to tzdata release 2016c for DST law changes in Azerbaijan, Chile, Haiti, Palestine, and Russia (Altai, Astrakhan, Kirov, Sakhalin, Ulyanovsk regions), plus historical corrections for Lithuania, Moldova, and Russia (Kaliningrad, Samara, Volgograd).

E.15. Release 9.4.6

Release date: 2016-02-11

This release contains a variety of fixes from 9.4.5. For information about new features in the 9.4 major release, see Section E.21.

E.15.1. Migration to Version 9.4.6

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading an installation that contains any GIN indexes that use the (non-default) jsonb_path_ops operator class, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.4.4, see Section E.17.

E.15.2. Changes

- Fix inconsistent hash calculations in jsonb_path_ops GIN indexes (Tom Lane)
  When processing jsonb values that contain both scalars and sub-objects at the same nesting level, for example an array containing both scalars and sub-arrays, key hash values could be calculated differently
than they would be for the same key in a different context. This could result in queries not finding entries that they should find. Fixing this means that existing indexes may now be inconsistent with the new hash calculation code. Users should `REINDEX jsonb_path_ops GIN indexes` after installing this update to make sure that all searches work as expected.

- Fix infinite loops and buffer-overrun problems in regular expressions (Tom Lane)
  Very large character ranges in bracket expressions could cause infinite loops in some cases, and memory overwrites in other cases. (CVE-2016-0773)

- Perform an immediate shutdown if the `postmaster.pid` file is removed (Tom Lane)
  The postmaster now checks every minute or so that `postmaster.pid` is still there and still contains its own PID. If not, it performs an immediate shutdown, as though it had received SIGQUIT. The main motivation for this change is to ensure that failed buildfarm runs will get cleaned up without manual intervention; but it also serves to limit the bad effects if a DBA forcibly removes `postmaster.pid` and then starts a new postmaster.

- In `SERIALIZABLE` transaction isolation mode, serialization anomalies could be missed due to race conditions during insertions (Kevin Grittner, Thomas Munro)

- Fix failure to emit appropriate WAL records when doing `ALTER TABLE ... SET TABLESPACE` for unlogged relations (Michael Paquier, Andres Freund)
  Even though the relation’s data is unlogged, the move must be logged or the relation will be inaccessible after a standby is promoted to master.

- Fix possible misinitialization of unlogged relations at the end of crash recovery (Andres Freund, Michael Paquier)

- Ensure walsender slots are fully re-initialized when being re-used (Magnus Hagander)

- Fix `ALTER COLUMN TYPE` to reconstruct inherited check constraints properly (Tom Lane)

- Fix `REASSIGN OWNED` to change ownership of composite types properly (Álvaro Herrera)

- Fix `REASSIGN OWNED` and `ALTER OWNER` to correctly update granted-permissions lists when changing owners of data types, foreign data wrappers, or foreign servers (Bruce Momjian, Álvaro Herrera)

- Fix `REASSIGN OWNED` to ignore foreign user mappings, rather than fail (Álvaro Herrera)

- Fix possible crash after doing query rewrite for an updatable view (Stephen Frost)

- Fix planner’s handling of `LATERAL` references (Tom Lane)
  This fixes some corner cases that led to “failed to build any N-way joins” or “could not devise a query plan” planner failures.

- Add more defenses against bad planner cost estimates for GIN index scans when the index’s internal statistics are very out-of-date (Tom Lane)

- Make planner cope with hypothetical GIN indexes suggested by an index advisor plug-in (Julien Rouhaud)

- Speed up generation of unique table aliases in `EXPLAIN` and rule dumping, and ensure that generated aliases do not exceed `NAMEDATALEN` (Tom Lane)

- Fix dumping of whole-row Vars in `ROW()` and `VALUES()` lists (Tom Lane)

- Translation of minus-infinity dates and timestamps to `json` or `jsonb` incorrectly rendered them as plus-infinity (Tom Lane)
• Fix possible internal overflow in numeric division (Dean Rasheed)

• Fix enforcement of restrictions inside parentheses within regular expression lookahead constraints (Tom Lane)

  Lookahead constraints aren’t allowed to contain backrefs, and parentheses within them are always considered non-capturing, according to the manual. However, the code failed to handle these cases properly inside a parenthesized subexpression, and would give unexpected results.

• Conversion of regular expressions to indexscan bounds could produce incorrect bounds from regexps containing lookahead constraints (Tom Lane)

• Fix regular-expression compiler to handle loops of constraint arcs (Tom Lane)

  The code added for CVE-2007-4772 was both incomplete, in that it didn’t handle loops involving more than one state, and incorrect, in that it could cause assertion failures (though there seem to be no bad consequences of that in a non-assert build). Multi-state loops would cause the compiler to run until the query was canceled or it reached the too-many-states error condition.

• Improve memory-usage accounting in regular-expression compiler (Tom Lane)

  This causes the code to emit “regular expression is too complex” errors in some cases that previously used unreasonable amounts of time and memory.

• Improve performance of regular-expression compiler (Tom Lane)

• Make %h and %r escapes in log_line_prefix work for messages emitted due to log_connections (Tom Lane)

  Previously, %h/%r started to work just after a new session had emitted the “connection received” log message; now they work for that message too.

• On Windows, ensure the shared-memory mapping handle gets closed in child processes that don’t need it (Tom Lane, Amit Kapila)

  This oversight resulted in failure to recover from crashes whenever logging_collector is turned on.

• Fix possible failure to detect socket EOF in non-blocking mode on Windows (Tom Lane)

  It’s not entirely clear whether this problem can happen in pre-9.5 branches, but if it did, the symptom would be that a walsender process would wait indefinitely rather than noticing a loss of connection.

• Avoid leaking a token handle during SSPI authentication (Christian Ullrich)

• In psql, ensure that libreadline’s idea of the screen size is updated when the terminal window size changes (Merlin Moncure)

  Previously, libreadline did not notice if the window was resized during query output, leading to strange behavior during later input of multiline queries.

• Fix psql’s \det command to interpret its pattern argument the same way as other \d commands with potentially schema-qualified patterns do (Reece Hart)

• Avoid possible crash in psql’s \c command when previous connection was via Unix socket and command specifies a new hostname and same username (Tom Lane)

• In pg_ctl start -w, test child process status directly rather than relying on heuristics (Tom Lane, Michael Paquier)
Previously, `pg_ctl` relied on an assumption that the new postmaster would always create `postmaster.pid` within five seconds. But that can fail on heavily-loaded systems, causing `pg_ctl` to report incorrectly that the postmaster failed to start.

Except on Windows, this change also means that a `pg_ctl start -w` done immediately after another such command will now reliably fail, whereas previously it would report success if done within two seconds of the first command.

- In `pg_ctl start -w`, don’t attempt to use a wildcard listen address to connect to the postmaster (Kondo Yuta)

On Windows, `pg_ctl` would fail to detect postmaster startup if `listen_addresses` is set to `0.0.0.0` or `::`, because it would try to use that value verbatim as the address to connect to, which doesn’t work. Instead assume that `127.0.0.1` or `::1`, respectively, is the right thing to use.

- In `pg_ctl` on Windows, check service status to decide where to send output, rather than checking if standard output is a terminal (Michael Paquier)

- In `pg_dump` and `pg_basebackup`, adopt the GNU convention for handling tar-archive members exceeding 8GB (Tom Lane)

  The POSIX standard for `tar` file format does not allow archive member files to exceed 8GB, but most modern implementations of `tar` support an extension that fixes that. Adopt this extension so that `pg_dump` with `-Ft` no longer fails on tables with more than 8GB of data, and so that `pg_basebackup` can handle files larger than 8GB. In addition, fix some portability issues that could cause failures for members between 4GB and 8GB on some platforms. Potentially these problems could cause unrecoverable data loss due to unreadable backup files.

- Fix assorted corner-case bugs in `pg_dump`’s processing of extension member objects (Tom Lane)

- Make `pg_dump` mark a view’s triggers as needing to be processed after its rule, to prevent possible failure during parallel `pg_restore` (Tom Lane)

- Ensure that relation option values are properly quoted in `pg_dump` (Kouhei Sutou, Tom Lane)

  A reloption value that isn’t a simple identifier or number could lead to dump/reload failures due to syntax errors in `CREATE` statements issued by `pg_dump`. This is not an issue with any reloption currently supported by core PostgreSQL, but extensions could allow reloptions that cause the problem.

- Avoid repeated password prompts during parallel `pg_dump` (Zeus Kronion)

- Fix `pg_upgrade`’s file-copying code to handle errors properly on Windows (Bruce Momjian)

- Install guards in `pgbench` against corner-case overflow conditions during evaluation of script-specified division or modulo operators (Fabien Coelho, Michael Paquier)

- Fix failure to localize messages emitted by `pg_receivexlog` and `pg_recvlogical` (Ioseph Kim)

- Avoid dump/reload problems when using both plpython2 and plpython3 (Tom Lane)

  In principle, both versions of PL/Python can be used in the same database, though not in the same session (because the two versions of libpython cannot safely be used concurrently). However, `pg_restore` and `pg_upgrade` both do things that can fall foul of the same-session restriction. Work around that by changing the timing of the check.

- Fix PL/Python regression tests to pass with Python 3.5 (Peter Eisentraut)

- Fix premature clearing of libpq’s input buffer when socket EOF is seen (Tom Lane)
This mistake caused libpq to sometimes not report the backend’s final error message before reporting “server closed the connection unexpectedly”.

• Prevent certain PL/Java parameters from being set by non-superusers (Noah Misch)
  This change mitigates a PL/Java security bug (CVE-2016-0766), which was fixed in PL/Java by marking these parameters as superuser-only. To fix the security hazard for sites that update PostgreSQL more frequently than PL/Java, make the core code aware of them also.

• Improve libpq’s handling of out-of-memory situations (Michael Paquier, Amit Kapila, Heikki Linnakangas)

• Fix order of arguments in ecpg-generated typedef statements (Michael Meskes)
• Use %g not %f format in ecpg’s PGTYPESnumeric_from_double() (Tom Lane)
• Fix ecpg-supplied header files to not contain comments continued from a preprocessor directive line onto the next line (Michael Meskes)
  Such a comment is rejected by ecpg. It’s not yet clear whether ecpg itself should be changed.
• Fix hstore_to_json_loose()’s test for whether an hstore value can be converted to a JSON number (Tom Lane)
  Previously this function could be fooled by non-alphanumeric trailing characters, leading to emitting syntactically-invalid JSON.

• Ensure that contrib/pgcrypto’s crypt() function can be interrupted by query cancel (Andreas Karlsson)
• In contrib/postgres_fdw, fix bugs triggered by use of tableoid in data-modifying commands (Etsuro Fujita, Robert Haas)
• Accept flex versions later than 2.5.x (Tom Lane, Michael Paquier)
  Now that flex 2.6.0 has been released, the version checks in our build scripts needed to be adjusted.
• Improve reproducibility of build output by ensuring filenames are given to the linker in a fixed order (Christoph Berg)
  This avoids possible bitwise differences in the produced executable files from one build to the next.
• Install our missing script where PGXS builds can find it (Jim Nasby)
  This allows sane behavior in a PGXS build done on a machine where build tools such as bison are missing.
• Ensure that dynloader.h is included in the installed header files in MSVC builds (Bruce Momjian, Michael Paquier)
• Add variant regression test expected-output file to match behavior of current libxml2 (Tom Lane)
  The fix for libxml2’s CVE-2015-7499 causes it not to output error context reports in some cases where it used to do so. This seems to be a bug, but we’ll probably have to live with it for some time, so work around it.
• Update time zone data files to tzdata release 2016a for DST law changes in Cayman Islands, Metlakatla, and Trans-Baikal Territory (Zabaykalsky Krai), plus historical corrections for Pakistan.
E.16. Release 9.4.5

Release date: 2015-10-08

This release contains a variety of fixes from 9.4.4. For information about new features in the 9.4 major release, see Section E.21.

E.16.1. Migration to Version 9.4.5

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.4, see Section E.17.

E.16.2. Changes

- Guard against stack overflows in json parsing (Oskari Saarenmaa)
  
  If an application constructs PostgreSQL json or jsonb values from arbitrary user input, the application’s users can reliably crash the PostgreSQL server, causing momentary denial of service. (CVE-2015-5289)

- Fix contrib/pgcrypto to detect and report too-short crypt() salts (Josh Kupershmidt)
  
  Certain invalid salt arguments crashed the server or disclosed a few bytes of server memory. We have not ruled out the viability of attacks that arrange for presence of confidential information in the disclosed bytes, but they seem unlikely. (CVE-2015-5288)

- Fix subtransaction cleanup after a portal (cursor) belonging to an outer subtransaction fails (Tom Lane, Michael Paquier)
  
  A function executed in an outer-subtransaction cursor could cause an assertion failure or crash by referencing a relation created within an inner subtransaction.

- Fix possible deadlock during WAL insertion when commit_delay is set (Heikki Linnakangas)

- Ensure all relations referred to by an updatable view are properly locked during an update statement (Dean Rasheed)

- Fix insertion of relations into the relation cache “init file” (Tom Lane)
  
  An oversight in a patch in the most recent minor releases caused pg_trigger_tgrelid_tgname_index to be omitted from the init file. Subsequent sessions detected this, then deemed the init file to be broken and silently ignored it, resulting in a significant degradation in session startup time. In addition to fixing the bug, install some guards so that any similar future mistake will be more obvious.

- Avoid O(N^2) behavior when inserting many tuples into a SPI query result (Neil Conway)

- Improve LISTEN startup time when there are many unread notifications (Matt Newell)

- Fix performance problem when a session alters large numbers of foreign key constraints (Jan Wieck, Tom Lane)
  
  This was seen primarily when restoring pg_dump output for databases with many thousands of tables.
• Disable SSL renegotiation by default (Michael Paquier, Andres Freund)

While use of SSL renegotiation is a good idea in theory, we have seen too many bugs in practice, both in the underlying OpenSSL library and in our usage of it. Renegotiation will be removed entirely in 9.5 and later. In the older branches, just change the default value of `ssl_renegotiation_limit` to zero (disabled).

• Lower the minimum values of the *_freeze_max_age parameters (Andres Freund)

This is mainly to make tests of related behavior less time-consuming, but it may also be of value for installations with limited disk space.

• Limit the maximum value of `wal_buffers` to 2GB to avoid server crashes (Josh Berkus)

• Avoid logging complaints when a parameter that can only be set at server start appears multiple times in `postgresql.conf`, and fix counting of line numbers after an `include_dir` directive (Tom Lane)

• Fix rare internal overflow in multiplication of numeric values (Dean Rasheed)

• Guard against hard-to-reach stack overflows involving record types, range types, `json`, `jsonb`, `tsquery`, `ltxtquery` and `query_int` (Noah Misch)

• Fix handling of `DOW` and `DOY` in datetime input (Greg Stark)

These tokens aren’t meant to be used in datetime values, but previously they resulted in opaque internal error messages rather than “invalid input syntax”.

• Add more query-cancel checks to regular expression matching (Tom Lane)

• Add recursion depth protections to regular expression, `SIMILAR TO`, and `LIKE` matching (Tom Lane)

Suitable search patterns and a low stack depth limit could lead to stack-overrun crashes.

• Fix potential infinite loop in regular expression execution (Tom Lane)

A search pattern that can apparently match a zero-length string, but actually doesn’t match because of a back reference, could lead to an infinite loop.

• In regular expression execution, correctly record match data for capturing parentheses within a quantifier even when the match is zero-length (Tom Lane)

• Fix low-memory failures in regular expression compilation (Andreas Seltenreich)

• Fix low-probability memory leak during regular expression execution (Tom Lane)

• Fix rare low-memory failure in lock cleanup during transaction abort (Tom Lane)

• Fix “unexpected out-of-memory situation during sort” errors when using tuplestores with small `work_mem` settings (Tom Lane)

• Fix very-low-probability stack overrun in `qsort` (Tom Lane)

• Fix “invalid memory alloc request size” failure in hash joins with large `work_mem` settings (Tomas Vondra, Tom Lane)

• Fix assorted planner bugs (Tom Lane)

These mistakes could lead to incorrect query plans that would give wrong answers, or to assertion failures in assert-enabled builds, or to odd planner errors such as “could not devise a query plan for the given query”, “could not find pathkey item to sort”, “plan should not reference subplan’s variable”, or “failed to assign all NestLoopParams to plan nodes”. Thanks are due to Andreas Seltenreich and Piotr Stefaniak for fuzz testing that exposed these problems.
Appendix E. Release Notes

- Improve planner’s performance for UPDATE/DELETE on large inheritance sets (Tom Lane, Dean Rasheed)
- Ensure standby promotion trigger files are removed at postmaster startup (Michael Paquier, Fujii Masao)
  This prevents unwanted promotion from occurring if these files appear in a database backup that is used to initialize a new standby server.
- During postmaster shutdown, ensure that per-socket lock files are removed and listen sockets are closed before we remove the postmaster.pid file (Tom Lane)
  This avoids race-condition failures if an external script attempts to start a new postmaster as soon as pg_ctl stop returns.
- Ensure that the postmaster does not exit until all its child processes are gone, even in an immediate shutdown (Tom Lane)
  Like the previous item, this avoids possible race conditions against a subsequently-started postmaster.
- Fix postmaster’s handling of a startup-process crash during crash recovery (Tom Lane)
  If, during a crash recovery cycle, the startup process crashes without having restored database consistency, we’d try to launch a new startup process, which typically would just crash again, leading to an infinite loop.
- Make emergency autovacuuming for multixact wraparound more robust (Andres Freund)
- Do not print a WARNING when an autovacuum worker is already gone when we attempt to signal it, and reduce log verbosity for such signals (Tom Lane)
- Prevent autovacuum launcher from sleeping unduly long if the server clock is moved backwards a large amount (Álvaro Herrera)
- Ensure that cleanup of a GIN index’s pending-insertions list is interruptable by cancel requests (Jeff Janes)
- Allow all-zeroes pages in GIN indexes to be reused (Heikki Linnakangas)
  Such a page might be left behind after a crash.
- Fix handling of all-zeroes pages in SP-GiST indexes (Heikki Linnakangas)
  VACUUM attempted to recycle such pages, but did so in a way that wasn’t crash-safe.
- Fix off-by-one error that led to otherwise-harmless warnings about “apparent wraparound” in subtrans/multixact truncation (Thomas Munro)
- Fix misreporting of CONTINUE and MOVE statement types in PL/pgSQL’s error context messages (Pavel Stehule, Tom Lane)
- Fix PL/Perl to handle non-ASCII error message texts correctly (Alex Hunsaker)
- Fix PL/Python crash when returning the string representation of a record result (Tom Lane)
- Fix some places in PL/Tcl that neglected to check for failure of malloc() calls (Michael Paquier, Álvaro Herrera)
- In contrib/isn, fix output of ISBN-13 numbers that begin with 979 (Fabien Coelho)
  EANs beginning with 979 (but not 9790) are considered ISBNs, but they must be printed in the new 13-digit format, not the 10-digit format.
Appendix E. Release Notes

- Improve contrib/pg_stat_statements’ handling of query-text garbage collection (Peter Geoghegan)
  The external file containing query texts could bloat to very large sizes; once it got past 1GB attempts to trim it would fail, soon leading to situations where the file could not be read at all.
- Improve contrib/postgres_fdw’s handling of collation-related decisions (Tom Lane)
  The main user-visible effect is expected to be that comparisons involving varchar columns will be sent to the remote server for execution in more cases than before.
- Improve libpq’s handling of out-of-memory conditions (Michael Paquier, Heikki Linnakangas)
- Fix memory leaks and missing out-of-memory checks in ecpg (Michael Paquier)
- Fix psqil’s code for locale-aware formatting of numeric output (Tom Lane)
  The formatting code invoked by \set numericlocale on did the wrong thing for some uncommon cases such as numbers with an exponent but no decimal point. It could also mangle already-localized output from the money data type.
- Prevent crash in psqil’s \c command when there is no current connection (Noah Misch)
- Make pg_dumps handle inherited NOT VALID check constraints correctly (Tom Lane)
- Fix selection of default zlib compression level in pg_dump’s directory output format (Andrew Dunstan)
- Ensure that temporary files created during a pg_dump run with tar-format output are not world-readable (Michael Paquier)
- Fix pg_dump and pg_upgrade to support cases where the postgres or template1 database is in a non-default tablespace (Marti Raudsepp, Bruce Momjian)
- Fix pg_dump to handle object privileges sanely when dumping from a server too old to have a particular privilege type (Tom Lane)
  When dumping data types from pre-9.2 servers, and when dumping functions or procedural languages from pre-7.3 servers, pg_dump would produce GRANT/REVOKE commands that revoked the owner’s grantable privileges and instead granted all privileges to PUBLIC. Since the privileges involved are just USAGE and EXECUTE, this isn’t a security problem, but it’s certainly a surprising representation of the older systems’ behavior. Fix it to leave the default privilege state alone in these cases.
- Fix pg_dump to dump shell types (Tom Lane)
  Shell types (that is, not-yet-fully-defined types) aren’t useful for much, but nonetheless pg_dump should dump them.
- Fix assorted minor memory leaks in pg_dump and other client-side programs (Michael Paquier)
- Fix pgbench’s progress-report behavior when a query, or pgbench itself, gets stuck (Fabien Coelho)
- Fix spinlock assembly code for Alpha hardware (Tom Lane)
- Fix spinlock assembly code for PPC hardware to be compatible with AIX’s native assembler (Tom Lane)
  Building with gcc didn’t work if gcc had been configured to use the native assembler, which is becoming more common.
- On AIX, test the -qlonglong compiler option rather than just assuming it’s safe to use (Noah Misch)
- On AIX, use -Wl,-brtllib link option to allow symbols to be resolved at runtime (Noah Misch)
Perl relies on this ability in 5.8.0 and later.

- Avoid use of inline functions when compiling with 32-bit xlc, due to compiler bugs (Noah Misch)
- Use librt for sched_yield() when necessary, which it is on some Solaris versions (Oskari Saarenmaa)
- Translate encoding UHC as Windows code page 949 (Noah Misch)
  This fixes presentation of non-ASCII log messages from processes that are not attached to any particular database, such as the postmaster.
- On Windows, avoid failure when doing encoding conversion to UTF16 outside a transaction, such as for log messages (Noah Misch)
- Fix postmaster startup failure due to not copying setlocale()’s return value (Noah Misch)
  This has been reported on Windows systems with the ANSI code page set to CP936 (“Chinese (Simplified, PRC”), and may occur with other multibyte code pages.
- Fix Windows install.bat script to handle target directory names that contain spaces (Heikki Linnakangas)
- Make the numeric form of the PostgreSQL version number (e.g., 90405) readily available to extension Makefiles, as a variable named VERSION_NUM (Michael Paquier)
- Update time zone data files to tzdata release 2015g for DST law changes in Cayman Islands, Fiji, Moldova, Morocco, Norfolk Island, North Korea, Turkey, and Uruguay. There is a new zone name America/Fort_Nelson for the Canadian Northern Rockies.

E.17. Release 9.4.4

Release date: 2015-06-12

This release contains a small number of fixes from 9.4.3. For information about new features in the 9.4 major release, see Section E.21.

E.17.1. Migration to Version 9.4.4

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading an installation that was previously upgraded using a pg_upgrade version between 9.3.0 and 9.3.4 inclusive, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.4.2, see Section E.19.

E.17.2. Changes

- Fix possible failure to recover from an inconsistent database state (Robert Haas)
Recent PostgreSQL releases introduced mechanisms to protect against multixact wraparound, but some of that code did not account for the possibility that it would need to run during crash recovery, when the database may not be in a consistent state. This could result in failure to restart after a crash, or failure to start up a secondary server. The lingering effects of a previously-fixed bug in pg_upgrade could also cause such a failure, in installations that had used pg_upgrade versions between 9.3.0 and 9.3.4.

The pg_upgrade bug in question was that it would set `oldestMultiXid` to 1 in `pg_control` even if the true value should be higher. With the fixes introduced in this release, such a situation will result in immediate emergency autovacuuming until a correct `oldestMultiXid` value can be determined. If that would pose a hardship, users can avoid it by doing manual vacuuming before upgrading to this release. In detail:

1. Check whether `pg_controldata` reports “Latest checkpoint’s oldestMultiXid” to be 1. If not, there’s nothing to do.
2. Look in `PGDATA/pg_multixact/offsets` to see if there’s a file named `0000`. If there is, there’s nothing to do.
3. Otherwise, for each table that has `pg_class.relminmxid` equal to 1, VACUUM that table with both `vacuum_multixact_freeze_min_age` and `vacuum_multixact_freeze_table_age` set to zero. (You can use the vacuum cost delay parameters described in Section 18.4.4 to reduce the performance consequences for concurrent sessions.)

- Fix rare failure to invalidate relation cache init file (Tom Lane)

With just the wrong timing of concurrent activity, a VACUUM FULL on a system catalog might fail to update the “init file” that’s used to avoid cache-loading work for new sessions. This would result in later sessions being unable to access that catalog at all. This is a very ancient bug, but it’s so hard to trigger that no reproducible case had been seen until recently.

- Avoid deadlock between incoming sessions and CREATE/DROP DATABASE (Tom Lane)

A new session starting in a database that is the target of a DROP DATABASE command, or is the template for a CREATE DATABASE command, could cause the command to wait for five seconds and then fail, even if the new session would have exited before that.

- Improve planner’s cost estimates for semi-joins and anti-joins with inner indexscans (Tom Lane, Tomas Vondra)

This type of plan is quite cheap when all the join clauses are used as index scan conditions, even if the inner scan would nominally fetch many rows, because the executor will stop after obtaining one row. The planner only partially accounted for that effect, and would therefore overestimate the cost, leading it to possibly choose some other much less efficient plan type.

### E.18. Release 9.4.3

**Release date:** 2015-06-04

This release contains a small number of fixes from 9.4.2. For information about new features in the 9.4 major release, see Section E.21.
Appendix E. Release Notes

E.18.1. Migration to Version 9.4.3

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.2, see Section E.19.

E.18.2. Changes

• Avoid failures while fsync’ing data directory during crash restart (Abhijit Menon-Sen, Tom Lane)
  In the previous minor releases we added a patch to fsync everything in the data directory after a crash. Unfortunately its response to any error condition was to fail, thereby preventing the server from starting up, even when the problem was quite harmless. An example is that an unwritable file in the data directory would prevent restart on some platforms; but it is common to make SSL certificate files unwritable by the server. Revise this behavior so that permissions failures are ignored altogether, and other types of failures are logged but do not prevent continuing.
  Also apply the same rules in initdb --sync-only. This case is less critical but it should act similarly.
• Fix pg_get_functiondef() to show functions’ LEAKPROOF property, if set (Jeevan Chalke)
• Fix pushJsonbValue() to unpack jbvBinary objects (Andrew Dunstan)
  This change does not affect any behavior in the core code as of 9.4, but it avoids a corner case for possible third-party callers.
• Remove configure’s check prohibiting linking to a threaded libpython on OpenBSD (Tom Lane)
  The failure this restriction was meant to prevent seems to not be a problem anymore on current OpenBSD versions.

E.19. Release 9.4.2

Release date: 2015-05-22

This release contains a variety of fixes from 9.4.1. For information about new features in the 9.4 major release, see Section E.21.

E.19.1. Migration to Version 9.4.2

A dump/restore is not required for those running 9.4.X.

However, if you use contrib/citext’s regexp_matches() functions, see the changelog entry below about that.

Also, if you are upgrading from a version earlier than 9.4.1, see Section E.20.
E.19.2. Changes

• Avoid possible crash when client disconnects just before the authentication timeout expires (Benkocs Norbert Attila)

  If the timeout interrupt fired partway through the session shutdown sequence, SSL-related state would be freed twice, typically causing a crash and hence denial of service to other sessions. Experimentation shows that an unauthenticated remote attacker could trigger the bug somewhat consistently, hence treat as security issue. (CVE-2015-3165)

• Improve detection of system-call failures (Noah Misch)

  Our replacement implementation of `snprintf()` failed to check for errors reported by the underlying system library calls; the main case that might be missed is out-of-memory situations. In the worst case this might lead to information exposure, due to our code assuming that a buffer had been overwritten when it hadn’t been. Also, there were a few places in which security-relevant calls of other system library functions did not check for failure.

  It remains possible that some calls of the `printf()` family of functions are vulnerable to information disclosure if an out-of-memory error occurs at just the wrong time. We judge the risk to not be large, but will continue analysis in this area. (CVE-2015-3166)

• In `contrib/pgcrypto`, uniformly report decryption failures as “Wrong key or corrupt data” (Noah Misch)

  Previously, some cases of decryption with an incorrect key could report other error message texts. It has been shown that such variance in error reports can aid attackers in recovering keys from other systems. While it’s unknown whether `pgcrypto`’s specific behaviors are likewise exploitable, it seems better to avoid the risk by using a one-size-fits-all message. (CVE-2015-3167)

• Protect against wraparound of multixact member IDs (Álvaro Herrera, Robert Haas, Thomas Munro)

  Under certain usage patterns, the existing defenses against this might be insufficient, allowing `pg_multixact/members` files to be removed too early, resulting in data loss. The fix for this includes modifying the server to fail transactions that would result in overwriting old multixact member ID data, and improving autovacuum to ensure it will act proactively to prevent multixact member ID wraparound, as it does for transaction ID wraparound.

• Fix incorrect declaration of `contrib/citext`’s `regexp_matches()` functions (Tom Lane)

  These functions should return `setof text[]`, like the core functions they are wrappers for; but they were incorrectly declared as returning `just text[]`. This mistake had two results: first, if there was no match you got a scalar null result, whereas what you should get is an empty set (zero rows). Second, the `g` flag was effectively ignored, since you would get only one result array even if there were multiple matches.

  While the latter behavior is clearly a bug, there might be applications depending on the former behavior; therefore the function declarations will not be changed by default until PostgreSQL 9.5. In pre-9.5 branches, the old behavior exists in version 1.0 of the `citext` extension, while we have provided corrected declarations in version 1.1 (which is not installed by default). To adopt the fix in pre-9.5 branches, execute `ALTER EXTENSION citext UPDATE TO ‘1.1’` in each database in which `citext` is installed. (You can also “update” back to 1.0 if you need to undo that.) Be aware that either update direction will require dropping and recreating any views or rules that use `citext`’s `regexp_matches()` functions.
Appendix E. Release Notes

- Render infinite dates and timestamps as `infinity` when converting to `json`, rather than throwing an error (Andrew Dunstan)
- Fix `json/jsonb`’s `populate_record()` and `to_record()` functions to handle empty input properly (Andrew Dunstan)
- Fix incorrect checking of deferred exclusion constraints after a HOT update (Tom Lane)
  
  If a new row that potentially violates a deferred exclusion constraint is HOT-updated (that is, no indexed columns change and the row can be stored back onto the same table page) later in the same transaction, the exclusion constraint would be reported as violated when the check finally occurred, even if the row(s) the new row originally conflicted with had been deleted.
- Fix behavior when changing foreign key constraint deferrability status with `ALTER TABLE ... ALTER CONSTRAINT` (Tom Lane)
  
  Operations later in the same session or concurrent sessions might not honor the status change promptly.
- Fix planning of star-schema-style queries (Tom Lane)
  
  Sometimes, efficient scanning of a large table requires that index parameters be provided from more than one other table (commonly, dimension tables whose keys are needed to index a large fact table). The planner should be able to find such plans, but an overly restrictive search heuristic prevented it.
- Prevent improper reordering of antijoins (NOT EXISTS joins) versus other outer joins (Tom Lane)
  
  This oversight in the planner has been observed to cause “could not find RelOptInfo for given relids” errors, but it seems possible that sometimes an incorrect query plan might get past that consistency check and result in silently-wrong query output.
- Fix incorrect matching of subexpressions in outer-join plan nodes (Tom Lane)
  
  Previously, if textually identical non-strict subexpressions were used both above and below an outer join, the planner might try to re-use the value computed below the join, which would be incorrect because the executor would force the value to NULL in case of an unmatched outer row.
- Fix GEQO planner to cope with failure of its join order heuristic (Tom Lane)
  
  This oversight has been seen to lead to “failed to join all relations together” errors in queries involving `LATERAL`, and that might happen in other cases as well.
- Ensure that row locking occurs properly when the target of an `UPDATE` or `DELETE` is a security-barrier view (Stephen Frost)
- Use a file opened for read/write when syncing replication slot data during database startup (Andres Freund)
  
  On some platforms, the previous coding could result in errors like “could not fsync file "pg_replslot/...": Bad file descriptor”.
- Fix possible deadlock at startup when `max_prepared_transactions` is too small (Heikki Linnakan-gas)
- Don’t archive useless preallocated WAL files after a timeline switch (Heikki Linnakangas)
- Recursively `fsync()` the data directory after a crash (Abhijit Menon-Sen, Robert Haas)
  
  This ensures consistency if another crash occurs shortly later. (The second crash would have to be a system-level crash, not just a database crash, for there to be a problem.)
• Fix autovacuum launcher’s possible failure to shut down, if an error occurs after it receives SIGTERM (Álvaro Herrera)

• Fix failure to handle invalidation messages for system catalogs early in session startup (Tom Lane)
  This oversight could result in failures in sessions that start concurrently with a VACUUM FULL on a system catalog.

• Fix crash in BackendIdGetTransactionIds() when trying to get status for a backend process that just exited (Tom Lane)

• Cope with unexpected signals in LockBufferForCleanup() (Andres Freund)
  This oversight could result in spurious errors about “multiple backends attempting to wait for pincount 1”.

• Fix crash when doing COPY IN to a table with check constraints that contain whole-row references (Tom Lane)
  The known failure case only crashes in 9.4 and up, but there is very similar code in 9.3 and 9.2, so back-patch those branches as well.

• Avoid waiting for WAL flush or synchronous replication during commit of a transaction that was read-
  only so far as the user is concerned (Andres Freund)
  Previously, a delay could occur at commit in transactions that had written WAL due to HOT page prun-
  ing, leading to undesirable effects such as sessions getting stuck at startup if all synchronous replicas are down. Sessions have also been observed to get stuck in catchup interrupt processing when using synchronous replication; this will fix that problem as well.

• Avoid busy-waiting with short recovery_min_apply_delay values (Andres Freund)

• Fix crash when manipulating hash indexes on temporary tables (Heikki Linnakangas)

• Fix possible failure during hash index bucket split, if other processes are modifying the index concurrently (Tom Lane)

• Fix memory leaks in GIN index vacuum (Heikki Linnakangas)

• Check for interrupts while analyzing index expressions (Jeff Janes)
  ANALYZE executes index expressions many times; if there are slow functions in such an expression, it’s desirable to be able to cancel the ANALYZE before that loop finishes.

• Ensure tableoid of a foreign table is reported correctly when a READ COMMITTED recheck occurs after locking rows in SELECT FOR UPDATE, UPDATE, or DELETE (Etsuro Fujita)

• Add the name of the target server to object description strings for foreign-server user mappings (Álvaro Herrera)

• Include the schema name in object identity strings for conversions (Álvaro Herrera)

• Recommend setting include_realm to 1 when using Kerberos/GSSAPI/SSPI authentication (Stephen Frost)
  Without this, identically-named users from different realms cannot be distinguished. For the moment this is only a documentation change, but it will become the default setting in PostgreSQL 9.5.

• Remove code for matching IPv4 pg_hba.conf entries to IPv4-in-IPv6 addresses (Tom Lane)
This hack was added in 2003 in response to a report that some Linux kernels of the time would report IPv4 connections as having IPv4-in-IPv6 addresses. However, the logic was accidentally broken in 9.0. The lack of any field complaints since then shows that it’s not needed anymore. Now we have reports that the broken code causes crashes on some systems, so let’s just remove it rather than fix it. (Had we chosen to fix it, that would make for a subtle and potentially security-sensitive change in the effective meaning of IPv4 pg_hba.conf entries, which does not seem like a good thing to do in minor releases.)

- Fix status reporting for terminated background workers that were never actually started (Robert Haas)
- After a database crash, don’t restart background workers that are marked BGW_NEVER_RESTART (Amit Khandekar)
- Report WAL flush, not insert, position in IDENTIFY_SYSTEM replication command (Heikki Linnakangas)
  This avoids a possible startup failure in pg_receivexlog.
- While shutting down service on Windows, periodically send status updates to the Service Control Manager to prevent it from killing the service too soon; and ensure that pg_ctl will wait for shutdown (Krystian Bigaj)
- Reduce risk of network deadlock when using libpq’s non-blocking mode (Heikki Linnakangas)
  When sending large volumes of data, it’s important to drain the input buffer every so often, in case the server has sent enough response data to cause it to block on output. (A typical scenario is that the server is sending a stream of NOTICE messages during COPY FROM STDIN.) This worked properly in the normal blocking mode, but not so much in non-blocking mode. We’ve modified libpq to opportunistically drain input when it can, but a full defense against this problem requires application cooperation: the application should watch for socket read-ready as well as write-ready conditions, and be sure to call PQconsumeInput() upon read-ready.
- In libpq, fix misparsing of empty values in URI connection strings (Thomas Fanghaenel)
- Fix array handling in ecpg (Michael Meskes)
- Fix psql to sanely handle URIs and conninfo strings as the first parameter to \connect (David Fetter, Andrew Dunstan, Álvaro Herrera)
  This syntax has been accepted (but undocumented) for a long time, but previously some parameters might be taken from the old connection instead of the given string, which was agreed to be undesirable.
- Suppress incorrect complaints from psql on some platforms that it failed to write ~/.psql_history at exit (Tom Lane)
  This misbehavior was caused by a workaround for a bug in very old (pre-2006) versions of libedit. We fixed it by removing the workaround, which will cause a similar failure to appear for anyone still using such versions of libedit. Recommendation: upgrade that library, or use libreadline.
- Fix pg_dump’s rule for deciding which casts are system-provided casts that should not be dumped (Tom Lane)
- In pg_dump, fix failure to honor -- compression level option together with --format (Michael Paquier)
- Make pg_dump consider foreign key relationships between extension configuration tables while choosing dump order (Gilles Darold, Michael Paquier, Stephen Frost)
  This oversight could result in producing dumps that fail to reload because foreign key constraints are transiently violated.
Appendix E. Release Notes

• Avoid possible pg_dump failure when concurrent sessions are creating and dropping temporary functions (Tom Lane)

• Fix dumping of views that are just \texttt{VALUES(...)} but have column aliases (Tom Lane)

• Ensure that a view’s replication identity is correctly set to \texttt{nothing} during dump/restore (Marko Tiikkaja)
  
  Previously, if the view was involved in a circular dependency, it might wind up with an incorrect replication identity property.

• In \texttt{pg\_upgrade}, force timeline 1 in the new cluster (Bruce Momjian)
  
  This change prevents upgrade failures caused by bogus complaints about missing WAL history files.

• In \texttt{pg\_upgrade}, check for improperly non-connectable databases before proceeding (Bruce Momjian)

• In \texttt{pg\_upgrade}, quote directory paths properly in the generated \texttt{delete\_old\_cluster} script (Bruce Momjian)

• In \texttt{pg\_upgrade}, preserve database-level freezing info properly (Bruce Momjian)
  
  This oversight could cause missing-clog-file errors for tables within the \texttt{postgres} and \texttt{template1} databases.

• Run \texttt{pg\_upgrade} and \texttt{pg\_resetxlog} with restricted privileges on Windows, so that they don’t fail when run by an administrator (Muhammad Asif Naeem)

• Improve handling of \texttt{readdir()} failures when scanning directories in \texttt{initdb} and \texttt{pg\_basebackup} (Marco Nenciarini)

• Fix slow sorting algorithm in \texttt{contrib/intarray} (Tom Lane)

• Fix compile failure on Sparc V8 machines (Rob Rowan)

• Silence some build warnings on macOS (Tom Lane)

• Update time zone data files to \texttt{tzdata} release 2015d for DST law changes in Egypt, Mongolia, and Palestine, plus historical changes in Canada and Chile. Also adopt revised zone abbreviations for the America/Adak zone (HST/HDT not HAST/HADT).

E.20. Release 9.4.1

Release date: 2015-02-05

This release contains a variety of fixes from 9.4.0. For information about new features in the 9.4 major release, see Section E.21.

E.20.1. Migration to Version 9.4.1

A dump/restore is not required for those running 9.4.X.

However, if you are a Windows user and are using the “Norwegian (Bokmål)” locale, manual action is needed after the upgrade to replace any “Norwegian (Bokmål)_Norway” or “norwegian-bokmal” locale
names stored in PostgreSQL system catalogs with the plain-ASCII alias “Norwegian_Norway”. For details see http://wiki.postgresql.org/wiki/Changes_To_Norwegian_Locale

**E.20.2. Changes**

- **Fix buffer overruns in **to_char()** (Bruce Momjian)**

  When **to_char()** processes a numeric formatting template calling for a large number of digits, PostgreSQL would read past the end of a buffer. When processing a crafted timestamp formatting template, PostgreSQL would write past the end of a buffer. Either case could crash the server. We have not ruled out the possibility of attacks that lead to privilege escalation, though they seem unlikely. (CVE-2015-0241)

- **Fix buffer overrun in replacement **printf()** functions (Tom Lane)**

  PostgreSQL includes a replacement implementation of **printf** and related functions. This code will overrun a stack buffer when formatting a floating point number (conversion specifiers **e**, **E**, **f**, **F**, **g** or **G**) with requested precision greater than about 500. This will crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. A database user can trigger such a buffer overrun through the **to_char()** SQL function. While that is the only affected core PostgreSQL functionality, extension modules that use printf-family functions may be at risk as well.

  This issue primarily affects PostgreSQL on Windows. PostgreSQL uses the system implementation of these functions where adequate, which it is on other modern platforms. (CVE-2015-0242)

- **Fix buffer overruns in **contrib/pgcrypto** (Marko Tiikkaja, Noah Misch)**

  Errors in memory size tracking within the **pgcrypto** module permitted stack buffer overruns and improper dependence on the contents of uninitialized memory. The buffer overrun cases can crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. (CVE-2015-0243)

- **Fix possible loss of frontend/backend protocol synchronization after an error (Heikki Linnakangas)**

  If any error occurred while the server was in the middle of reading a protocol message from the client, it could lose synchronization and incorrectly try to interpret part of the message’s data as a new protocol message. An attacker able to submit crafted binary data within a command parameter might succeed in injecting his own SQL commands this way. Statement timeout and query cancellation are the most likely sources of errors triggering this scenario. Particularly vulnerable are applications that use a timeout and also submit arbitrary user-crafted data as binary query parameters. Disabling statement timeout will reduce, but not eliminate, the risk of exploit. Our thanks to Emil Lenngren for reporting this issue. (CVE-2015-0244)

- **Fix information leak via constraint-violation error messages (Stephen Frost)**

  Some server error messages show the values of columns that violate a constraint, such as a unique constraint. If the user does not have **SELECT** privilege on all columns of the table, this could mean exposing values that the user should not be able to see. Adjust the code so that values are displayed only when they came from the SQL command or could be selected by the user. (CVE-2014-8161)

- **Lock down regression testing’s temporary installations on Windows (Noah Misch)**
Use SSPI authentication to allow connections only from the OS user who launched the test suite. This closes on Windows the same vulnerability previously closed on other platforms, namely that other users might be able to connect to the test postmaster. (CVE-2014-0067)

- Cope with the Windows locale named “Norwegian (Bokmål)” (Heikki Linnakangas)
  Non-ASCII locale names are problematic since it’s not clear what encoding they should be represented in. Map the troublesome locale name to a plain-ASCII alias, “Norwegian_Norway”.
  9.4.0 mapped the troublesome name to “norwegian-bokmål”, but that turns out not to work on all Windows configurations. “Norwegian_Norway” is now recommended instead.

- Fix use-of-already-freed-memory problem in EvalPlanQual processing (Tom Lane)
  In READ COMMITTED mode, queries that lock or update recently-updated rows could crash as a result of this bug.

- Avoid possible deadlock while trying to acquire tuple locks in EvalPlanQual processing (Álvaro Herrera, Mark Kirkwood)

- Fix failure to wait when a transaction tries to acquire a FOR NO KEY EXCLUSIVE tuple lock, while multiple other transactions currently hold FOR SHARE locks (Álvaro Herrera)

- Improve performance of EXPLAIN with large range tables (Tom Lane)

- Fix jsonb Unicode escape processing, and in consequence disallow \u0000 (Tom Lane)
  Previously, the JSON Unicode escape \u0000 was accepted and was stored as those six characters; but that is indistinguishable from what is stored for the input \u0000, resulting in ambiguity. Moreover, in cases where de-escaped textual output is expected, such as the \->> operator, the sequence was printed as \u0000, which does not meet the expectation that JSON escaping would be removed. (Consistent behavior would require emitting a zero byte, but PostgreSQL does not support zero bytes embedded in text strings.) 9.4.0 included an ill-advised attempt to improve this situation by adjusting JSON output conversion rules; but of course that could not fix the fundamental ambiguity, and it turned out to break other usages of Unicode escape sequences. Revert that, and to avoid the core problem, reject \u0000 in jsonb input.

  If a jsonb column contains a \u0000 value stored with 9.4.0, it will henceforth read out as though it were \\u0000, which is the other valid interpretation of the data stored by 9.4.0 for this case.

  The json type did not have the storage-ambiguity problem, but it did have the problem of inconsistent de-escaped textual output. Therefore \u0000 will now also be rejected in json values when conversion to de-escaped form is required. This change does not break the ability to store \u0000 in json columns so long as no processing is done on the values. This is exactly parallel to the cases in which non-ASCII Unicode escapes are allowed when the database encoding is not UTF8.

- Fix namespace handling in xpath() (Ali Akbar)
  Previously, the xml value resulting from an xpath() call would not have namespace declarations if the namespace declarations were attached to an ancestor element in the input xml value, rather than to the specific element being returned. Propagate the ancestral declaration so that the result is correct when considered in isolation.

- Fix assorted oversights in range-operator selectivity estimation (Emre Hasegeli)
  This patch fixes corner-case “unexpected operator NNNN” planner errors, and improves the selectivity estimates for some other cases.
• Revert unintended reduction in maximum size of a GIN index item (Heikki Linnakangas)

9.4.0 could fail with “index row size exceeds maximum” errors for data that previous versions would accept.

• Fix query-duration memory leak during repeated GIN index rescans (Heikki Linnakangas)

• Fix possible crash when using nonzero $\text{gin\_fuzzy\_search\_limit}$ (Heikki Linnakangas)

• Assorted fixes for logical decoding (Andres Freund)

• Fix incorrect replay of WAL parameter change records that report changes in the $\text{wal\_log\_hints}$ setting (Petr Jelinek)

• Change “pgstat wait timeout” warning message to be LOG level, and rephrase it to be more understandable (Tom Lane)

  This message was originally thought to be essentially a can’t-happen case, but it occurs often enough on our slower buildfarm members to be a nuisance. Reduce it to LOG level, and expend a bit more effort on the wording: it now reads “using stale statistics instead of current ones because stats collector is not responding”.

• Warn if macOS’s $\text{setlocale()}$ starts an unwanted extra thread inside the postmaster (Noah Misch)

• Fix libpq’s behavior when $\text{/etc/passwd}$ isn’t readable (Tom Lane)

  While doing $\text{PQsetdbLogin()}$, libpq attempts to ascertain the user’s operating system name, which on most Unix platforms involves reading $\text{/etc/passwd}$. As of 9.4, failure to do that was treated as a hard error. Restore the previous behavior, which was to fail only if the application does not provide a database role name to connect as. This supports operation in chroot environments that lack an $\text{/etc/passwd}$ file.

• Improve consistency of parsing of $\text{psql}$’s special variables (Tom Lane)

  Allow variant spellings of $\text{on}$ and $\text{off}$ (such as $1/0$) for $\text{ECHO\_HIDDEN}$ and $\text{ON\_ERROR\_ROLLBACK}$. Report a warning for unrecognized values for $\text{COMP\_KEYWORD\_CASE}$, $\text{ECHO}$, $\text{ECHO\_HIDDEN}$, $\text{HISTCONTROL}$, $\text{ON\_ERROR\_ROLLBACK}$, and $\text{VERBOSITY}$. Recognize all values for all these variables case-insensitively; previously there was a mishmash of case-sensitive and case-insensitive behaviors.

• Fix $\text{pg\_dump}$ to handle comments on event triggers without failing (Tom Lane)

• Allow parallel $\text{pg\_dump}$ to use $\text{--serializable-deferrable}$ (Kevin Grittner)

• Prevent WAL files created by $\text{pg\_basebackup}$ $\text{-x/-X}$ from being archived again when the standby is promoted (Andres Freund)

• Handle unexpected query results, especially NULLs, safely in contrib/tablefunc’s connectby() (Michael Paquier)

  connectby() previously crashed if it encountered a NULL key value. It now prints that row but doesn’t recurse further.

• Numerous cleanups of warnings from Coverity static code analyzer (Andres Freund, Tatsuo Ishii, Marko Kreen, Tom Lane, Michael Paquier)

  These changes are mostly cosmetic but in some cases fix corner-case bugs, for example a crash rather than a proper error report after an out-of-memory failure. None are believed to represent security issues.

• Allow $\text{CFLAGS}$ from configure’s environment to override automatically-supplied $\text{CFLAGS}$ (Tom Lane)

  Previously, configure would add any switches that it chose of its own accord to the end of the user-specified $\text{CFLAGS}$ string. Since most compilers process switches left-to-right, this meant that configure’s
choices would override the user-specified flags in case of conflicts. That should work the other way around, so adjust the logic to put the user’s string at the end not the beginning.

- Make pg_regress remove any temporary installation it created upon successful exit (Tom Lane)
  This results in a very substantial reduction in disk space usage during make check-world, since that sequence involves creation of numerous temporary installations.
- Add CST (China Standard Time) to our lists of timezone abbreviations (Tom Lane)
- Update time zone data files to tzdata release 2015a for DST law changes in Chile and Mexico, plus historical changes in Iceland.

E.21. Release 9.4

Release date: 2014-12-18

E.21.1. Overview

Major enhancements in PostgreSQL 9.4 include:

- Add jsonb, a more capable and efficient data type for storing JSON data
- Add new SQL command ALTER SYSTEM for changing postgresql.conf configuration file entries
- Reduce lock strength for some ALTER TABLE commands
- Allow materialized views to be refreshed without blocking concurrent reads
- Add support for logical decoding of WAL data, to allow database changes to be streamed out in a customizable format
- Allow background worker processes to be dynamically registered, started and terminated

The above items are explained in more detail in the sections below.

E.21.2. Migration to Version 9.4

A dump/restore using pg_dumpall, or use of pg_upgrade, is required for those wishing to migrate data from any previous release.

Version 9.4 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- Tighten checks for multidimensional array input (Bruce Momjian)
  Previously, an input array string that started with a single-element sub-array could later contain multi-element sub-arrays, e.g. ‘{{1}, {2,3}}’::int[] would be accepted.
- When converting values of type date, timestamp or timestamptz to JSON, render the values in a format compliant with ISO 8601 (Andrew Dunstan)
Previously such values were rendered according to the current DateStyle setting; but many JSON processors require timestamps to be in ISO 8601 format. If necessary, the previous behavior can be obtained by explicitly casting the datetime value to text before passing it to the JSON conversion function.

- The json #> text[] path extraction operator now returns its lefthand input, not NULL, if the array is empty (Tom Lane)

This is consistent with the notion that this represents zero applications of the simple field/element extraction operator ->. Similarly, json #>> text[] with an empty array merely coerces its lefthand input to text.

- Corner cases in the JSON field/element/path extraction operators now return NULL rather than raising an error (Tom Lane)

For example, applying field extraction to a JSON array now yields NULL not an error. This is more consistent (since some comparable cases such as no-such-field already returned NULL), and it makes it safe to create expression indexes that use these operators, since they will now not throw errors for any valid JSON input.

- Cause consecutive whitespace in to_timestamp() and to_date() format strings to consume a corresponding number of characters in the input string (whitespace or not), then conditionally consume adjacent whitespace, if not in FX mode (Jeevan Chalke)

Previously, consecutive whitespace characters in a non-FX format string behaved like a single whitespace character and consumed all adjacent whitespace in the input string. For example, previously a format string of three spaces would consume only the first space in ' 12', but it will now consume all three characters.

- Fix ts_rank_cd() to ignore stripped lexemes (Alex Hill)

Previously, stripped lexemes were treated as if they had a default location, producing a rank of dubious usefulness.

- For functions declared to take VARIADIC "any", an actual parameter marked as VARIADIC must be of a determinable array type (Pavel Stehule)

Such parameters can no longer be written as an undecorated string literal or NULL; a cast to an appropriate array data type will now be required. Note that this does not affect parameters not marked VARIADIC.

- Ensure that whole-row variables expose the expected column names to functions that pay attention to column names within composite arguments (Tom Lane)

Constructs like row_to_json(tab.*) now always emit column names that match the column aliases visible for table tab at the point of the call. In previous releases the emitted column names would sometimes be the table’s actual column names regardless of any aliases assigned in the query.

- DISCARD now also discards sequence-related state (Fabrízio de Royes Mello, Robert Haas)

- Rename EXPLAIN ANALYZE’s “total runtime” output to “execution time” (Tom Lane)

Now that planning time is also reported, the previous name was confusing.

- SHOW TIME ZONE now outputs simple numeric UTC offsets in POSIX timezone format (Tom Lane)

Previously, such timezone settings were displayed as interval values. The new output is properly interpreted by SET TIME ZONE when passed as a simple string, whereas the old output required special treatment to be re-parsed correctly.
• Foreign data wrappers that support updating foreign tables must consider the possible presence of
  AFTER ROW triggers (Noah Misch)
  When an AFTER ROW trigger is present, all columns of the table must be returned by updating actions,
  since the trigger might inspect any or all of them. Previously, foreign tables never had triggers, so the
  FDW might optimize away fetching columns not mentioned in the RETURNING clause (if any).
• Prevent CHECK constraints from referencing system columns, except tableoid (Amit Kapila)
  Previously such check constraints were allowed, but they would often cause errors during restores.
• Use the last specified recovery target parameter if multiple target parameters are specified (Heikki
  Linnakangas)
  Previously, there was an undocumented precedence order among the recovery_target_xxx parameters.
• On Windows, automatically preserve quotes in command strings supplied by the user (Heikki Lin-
  nakangas)
  User commands that did their own quote preservation might need adjustment. This is likely to be an
  issue for commands used in archive_command, restore_command, and COPY TO/FROM PROGRAM.
• Remove catalog column pg_class.reltoastidxid (Michael Paquier)
• Remove catalog column pg_rewrite.ev_attr (Kevin Grittner)
  Per-column rules have not been supported since PostgreSQL 7.3.
• Remove native support for Kerberos authentication (--with-krb5, etc) (Magnus Hagander)
  The supported way to use Kerberos authentication is with GSSAPI. The native code has been deprecated
  since PostgreSQL 8.3.
• In PL/Python, handle domains over arrays like the underlying array type (Rodolfo Campero)
  Previously such values were treated as strings.
• Make libpq’s PQconnectdbParams() and PQpingParams() functions process zero-length strings as
  defaults (Adrian Vondendriesch)
  Previously, these functions treated zero-length string values as selecting the default in only some cases.
• Change empty arrays returned by the intarray module to be zero-dimensional arrays (Bruce Momjian)
  Previously, empty arrays were returned as zero-length one-dimensional arrays, whose text representa-
  tion looked the same as zero-dimensional arrays ({}), but they acted differently in array operations.
  intarray’s behavior in this area now matches the built-in array operators.
• pg_upgrade now uses -U or --username to specify the user name (Bruce Momjian)
  Previously this option was spelled -u or --user, but that was inconsistent with other tools.

E.21.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 9.4 and the previous major
release.
Appendix E. Release Notes

E.21.3.1. Server

- Allow background worker processes to be dynamically registered, started and terminated (Robert Haas)
  The new worker_spi module shows an example of use of this feature.
- Allow dynamic allocation of shared memory segments (Robert Haas, Amit Kapila)
  This feature is illustrated in the test_shm_mq module.
- During crash recovery or immediate shutdown, send uncatchable termination signals (SIGKILL) to child processes that do not shut down promptly (MauMau, Álvaro Herrera)
  This reduces the likelihood of leaving orphaned child processes behind after postmaster shutdown, as well as ensuring that crash recovery can proceed if some child processes have become “stuck”.
- Improve randomness of the database system identifier (Tom Lane)
- Make VACUUM properly report dead but not-yet-removable rows to the statistics collector (Hari Babu)
  Previously these were reported as live rows.

E.21.3.1.1. Indexes

- Reduce GIN index size (Alexander Korotkov, Heikki Linnakangas)
  Indexes upgraded via pg_upgrade will work fine but will still be in the old, larger GIN format. Use REINDEX to recreate old GIN indexes in the new format.
- Improve speed of multi-key GIN lookups (Alexander Korotkov, Heikki Linnakangas)
- Add GiST index support for inet and cidr data types (Emre Hasegeli)
  Such indexes improve subnet and supernet lookups and ordering comparisons.
- Fix rare race condition in B-tree page deletion (Heikki Linnakangas)
- Make the handling of interrupted B-tree page splits more robust (Heikki Linnakangas)

E.21.3.1.2. General Performance

- Allow multiple backends to insert into WAL buffers concurrently (Heikki Linnakangas)
  This improves parallel write performance.
- Conditionally write only the modified portion of updated rows to WAL (Amit Kapila)
- Improve performance of aggregate functions used as window functions (David Rowley, Florian Pflug, Tom Lane)
- Improve speed of aggregates that use numeric state values (Hadi Moshayedi)
- Attempt to freeze tuples when tables are rewritten with CLUSTER or VACUUM FULL (Robert Haas, Andres Freund)
  This can avoid the need to freeze the tuples in the future.
- Improve speed of COPY with default nextval() columns (Simon Riggs)
Appendix E. Release Notes

- Improve speed of accessing many different sequences in the same session (David Rowley)
- Raise hard limit on the number of tuples held in memory during sorting and B-tree index builds (Noah Misch)
- Reduce memory allocated by PL/pgSQL DO blocks (Tom Lane)
- Make the planner more aggressive about extracting restriction clauses from mixed AND/OR clauses (Tom Lane)
- Disallow pushing volatile WHERE clauses down into DISTINCT subqueries (Tom Lane)

Pushing down a WHERE clause can produce a more efficient plan overall, but at the cost of evaluating the clause more often than is implied by the text of the query; so don’t do it if the clause contains any volatile functions.

- Auto-resize the catalog caches (Heikki Linnakangas)

This reduces memory consumption for sessions accessing only a few tables, and improves performance for sessions accessing many tables.

E.21.3.1.3. Monitoring

- Add pg_stat_archiver system view to report WAL archiver activity (Gabriele Bartolini)
- Add n_mod_since_analyze columns to pg_stat_all_tables and related system views (Mark Kirkwood)

These columns expose the system’s estimate of the number of changed tuples since the table’s last ANALYZE. This estimate drives decisions about when to auto-analyze.

- Add backend_xid and backend_xmin columns to the system view pg_stat_activity, and a backend_xmin column to pg_stat_replication (Christian Kruse)

E.21.3.1.4. SSL

- Add support for SSL ECDH key exchange (Marko Kreen)

This allows use of Elliptic Curve keys for server authentication. Such keys are faster and have better security than RSA keys. The new configuration parameter ssl_ecdh_curve controls which curve is used for ECDH.

- Improve the default ssl_ciphers setting (Marko Kreen)

By default, the server not the client now controls the preference order of SSL ciphers (Marko Kreen)

Previously, the order specified by ssl_ciphers was usually ignored in favor of client-side defaults, which are not configurable in most PostgreSQL clients. If desired, the old behavior can be restored via the new configuration parameter ssl_prefer_server_ciphers.

- Make log_connections show SSL encryption information (Andreas Kunert)

- Improve SSL renegotiation handling (Álvaro Herrera)
E.21.3.1.5. Server Settings

- Add new SQL command ALTER SYSTEM for changing postgresql.conf configuration file entries (Amit Kapila)
  Previously such settings could only be changed by manually editing postgresql.conf.
- Add autovacuum_work_mem configuration parameter to control the amount of memory used by autovacuum workers (Peter Geoghegan)
- Add huge_pages parameter to allow using huge memory pages on Linux (Christian Kruse, Richard Poole, Abhijit Menon-Sen)
  This can improve performance on large-memory systems.
- Add max_worker_processes parameter to limit the number of background workers (Robert Haas)
  This is helpful in configuring a standby server to have the required number of worker processes (the same as the primary).
- Add superuser-only session_preload_libraries parameter to load libraries at session start (Peter Eisentraut)
  In contrast to local_preload_libraries, this parameter can load any shared library, not just those in the $libdir/plugins directory.
- Add wal_log_hints parameter to enable WAL logging of hint-bit changes (Sawada Masahiko)
  Hint bit changes are not normally logged, except when checksums are enabled. This is useful for external tools like pg_rewind.
- Increase the default settings of work_mem and maintenance_work_mem by four times (Bruce Momjian)
  The new defaults are 4MB and 64MB respectively.
- Increase the default setting of effective_cache_size to 4GB (Bruce Momjian, Tom Lane)
- Allow printf-style space padding to be specified in log_line_prefix (David Rowley)
- Allow terabyte units (TB) to be used when specifying configuration variable values (Simon Riggs)
- Show PIDs of lock holders and waiters and improve information about relations in log_lock_waits log messages (Christian Kruse)
- Reduce server logging level when loading shared libraries (Peter Geoghegan)
  The previous level was LOG, which was too verbose for libraries loaded per-session.
- On Windows, make SQL_ASCII-encoded databases and server processes (e.g., postmaster) emit messages in the character encoding of the server’s Windows user locale (Alexander Law, Noah Misch)
  Previously these messages were output in the Windows ANSI code page.

E.21.3.2. Replication and Recovery

- Add replication slots to coordinate activity on streaming standbys with the node they are streaming from (Andres Freund, Robert Haas)
Replication slots allow preservation of resources like WAL files on the primary until they are no longer needed by standby servers.

- Add recovery parameter `recovery_min_apply_delay` to delay replication (Robert Haas, Fabrízio de Royes Mello, Simon Riggs)
  
  Delaying replay on standby servers can be useful for recovering from user errors.

- Add recovery_target option `immediate` to stop WAL recovery as soon as a consistent state is reached (MauMau, Heikki Linnakangas)

- Improve recovery target processing (Heikki Linnakangas)
  
  The timestamp reported by `pg_last_xact_replay_timestamp()` now reflects already-committed records, not transactions about to be committed. Recovering to a restore point now replays the restore point, rather than stopping just before the restore point.

- `pg_switch_xlog()` now clears any unused trailing space in the old WAL file (Heikki Linnakangas)
  
  This improves the compression ratio for WAL files.

- Report failure return codes from external recovery commands (Peter Eisentraut)

- Reduce spinlock contention during WAL replay (Heikki Linnakangas)

- Write WAL records of running transactions more frequently (Andres Freund)

  This allows standby servers to start faster and clean up resources more aggressively.

### E.21.3.2.1. Logical Decoding

Logical decoding allows database changes to be streamed in a configurable format. The data is read from the WAL and transformed into the desired target format. To implement this feature, the following changes were made:

- Add support for logical decoding of WAL data, to allow database changes to be streamed out in a customizable format (Andres Freund)

- Add new wal_level setting `logical` to enable logical change-set encoding in WAL (Andres Freund)

- Add table-level parameter `REPLICA IDENTITY` to control logical replication (Andres Freund)

- Add relation option `user_catalog_table` to identify user-created tables involved in logical change-set encoding (Andres Freund)

- Add `pg_recvlogical` application to receive logical-decoding data (Andres Freund)

- Add `test_decoding` module to illustrate logical decoding at the SQL level (Andres Freund)

### E.21.3.3. Queries

- Add `WITH ORDINALITY` syntax to number the rows returned from a set-returning function in the `FROM` clause (Andrew Gierth, David Fetter)

  This is particularly useful for functions like `unnest()`.
• Add `ROWS FROM()` syntax to allow horizontal concatenation of set-returning functions in the `FROM` clause (Andrew Gierth)

• Allow SELECT to have an empty target list (Tom Lane)
  
  This was added so that views that select from a table with zero columns can be dumped and restored correctly.

• Ensure that `SELECT ... FOR UPDATE NOWAIT` does not wait in corner cases involving already-concurrently-updated tuples (Craig Ringer and Thomas Munro)

### E.21.3.4. Utility Commands

• Add `DISCARD SEQUENCES` command to discard cached sequence-related state (Fabrízio de Royes Mello, Robert Haas)
  
  `DISCARD ALL` will now also discard such information.

• Add `FORCE NULL` option to `COPY FROM`, which causes quoted strings matching the specified null string to be converted to NULLs in CSV mode (Iian Barwick, Michael Paquier)
  
  Without this option, only unquoted matching strings will be imported as null values.

• Issue warnings for commands used outside of transaction blocks when they can have no effect (Bruce Momjian)
  
  New warnings are issued for `SET LOCAL`, `SET CONSTRAINTS`, `SET TRANSACTION` and `ABORT` when used outside a transaction block.

#### E.21.3.4.1. EXPLAIN

• Make `EXPLAIN ANALYZE` show planning time (Andreas Karlsson)

• Make `EXPLAIN` show the grouping columns in Agg and Group nodes (Tom Lane)

• Make `EXPLAIN ANALYZE` show exact and lossy block counts in bitmap heap scans (Etsuro Fujita)

#### E.21.3.4.2. Views

• Allow a materialized view to be refreshed without blocking other sessions from reading the view meanwhile (Kevin Grittner)
  
  This is done with `REFRESH MATERIALIZED VIEW CONCURRENTLY`.

• Allow views to be automatically updated even if they contain some non-updatable columns (Dean Rasheed)
  
  Previously the presence of non-updatable output columns such as expressions, literals, and function calls prevented automatic updates. Now `INSERTS`, `UPDATES` and `DELETES` are supported, provided that they do not attempt to assign new values to any of the non-updatable columns.

• Allow control over whether `INSERTS` and `UPDATES` can add rows to an auto-updatable view that would not appear in the view (Dean Rasheed)
This is controlled with the new CREATE VIEW clause with CHECK OPTION.

- Allow security barrier views to be automatically updatable (Dean Rasheed)

### E.21.3.5. Object Manipulation

- Support triggers on foreign tables (Ronan Dunklau)
- Allow moving groups of objects from one tablespace to another using the `ALL IN TABLESPACE ... SET TABLESPACE` form of ALTER TABLE, ALTER INDEX, or ALTER MATERIALIZED VIEW (Stephen Frost)
- Allow changing foreign key constraint deferrability via ALTER TABLE ... ALTER CONSTRAINT (Simon Riggs)
- Reduce lock strength for some ALTER TABLE commands (Simon Riggs, Noah Misch, Robert Haas)

  Specifically, `VALIDATE CONSTRAINT`, `CLUSTER ON`, `SET WITHOUT CLUSTER`, `ALTER COLUMN SET STATISTICS`, `ALTER COLUMN SET (attribute_option)`, `ALTER COLUMN RESET (attribute_option)` no longer require `ACCESS EXCLUSIVE` locks.

- Allow tablespace options to be set in CREATE TABLESPACE (Vik Fearing)

  Formerly these options could only be set via ALTER TABLESPACE.

- Allow CREATE AGGREGATE to define the estimated size of the aggregate’s transition state data (Hadi Moshayedi)

  Proper use of this feature allows the planner to better estimate how much memory will be used by aggregates.

- Fix DROP IF EXISTS to avoid errors for non-existent objects in more cases (Pavel Stehule, Dean Rasheed)

- Improve how system relations are identified (Andres Freund, Robert Haas)

  Previously, relations once moved into the `pg_catalog` schema could no longer be modified or dropped.

### E.21.3.6. Data Types

- Fully implement the `line` data type (Peter Eisentraut)

  The `line` data type (lseg) has always been fully supported. The previous `line` data type (which was enabled only via a compile-time option) is not binary or dump-compatible with the new implementation.

- Add `pg_lsn` data type to represent a WAL log sequence number (LSN) (Robert Haas, Michael Paquier)

- Allow single-point polygons to be converted to circles (Bruce Momjian)

- Support time zone abbreviations that change UTC offset from time to time (Tom Lane)

  Previously, PostgreSQL assumed that the UTC offset associated with a time zone abbreviation (such as `EST`) never changes in the usage of any particular locale. However this assumption fails in the real
world, so introduce the ability for a zone abbreviation to represent a UTC offset that sometimes changes. Update the zone abbreviation definition files to make use of this feature in timezone locales that have changed the UTC offset of their abbreviations since 1970 (according to the IANA timezone database). In such timezones, PostgreSQL will now associate the correct UTC offset with the abbreviation depending on the given date.

- Allow 5+ digit years for non-ISO timestamp and date strings, where appropriate (Bruce Momjian)
- Add checks for overflow/underflow of interval values (Bruce Momjian)

**E.21.3.6.1. JSON**

- Add jsonb, a more capable and efficient data type for storing JSON data (Oleg Bartunov, Teodor Sigaev, Alexander Korotkov, Peter Geoghegan, Andrew Dunstan)

  This new type allows faster access to values within a JSON document, and faster and more useful indexing of JSON columns. Scalar values in jsonb documents are stored as appropriate scalar SQL types, and the JSON document structure is pre-parsed rather than being stored as text as in the original json data type.

- Add new JSON functions to allow for the construction of arbitrarily complex JSON trees (Andrew Dunstan, Laurence Rowe)
  New functions include `json_array_elements_text()`, `json_build_array()`, `json_object()`, `json_object_agg()`, `json_to_record()`, and `json_to_recordset()`.

- Add `json_typeof()` to return the data type of a json value (Andrew Tipton)

**E.21.3.7. Functions**

- Add `pg_sleep_for(interval)` and `pg_sleep_until(timestamp)` to specify delays more flexibly (Vik Fearing, Julien Rouhaud)

  The existing `pg_sleep()` function only supports delays specified in seconds.

- Add `cardinality()` function for arrays (Marko Tiikkaja)

  This returns the total number of elements in the array, or zero for an array with no elements.

- Add SQL functions to allow large object reads/writes at arbitrary offsets (Pavel Stehule)

- Allow `unnest()` to take multiple arguments, which are individually unnested then horizontally concatenated (Andrew Gierth)

- Add functions to construct `times`, `dates`, `timestamptz`s, `timestamptzs`, and `intervals` from individual values, rather than strings (Pavel Stehule)

  These functions’ names are prefixed with `make_`, e.g. `make_date()`.

- Make `to_char()`’s `Tz` format specifier return a useful value for simple numeric time zone offsets (Tom Lane)

  Previously, `to_char(CURRENT_TIMESTAMP, 'Tz')` returned an empty string if the timezone was set to a constant like -4.
Appendix E. Release Notes

- Add timezone offset format specifier OF to `to_char()` (Bruce Momjian)
- Improve the random seed used for `random()` (Honza Horak)
- Tighten validity checking for Unicode code points in `chr(int)` (Tom Lane)
  This function now only accepts values that are valid UTF8 characters according to RFC 3629.

**E.21.3.7.1. System Information Functions**

- Add functions for looking up objects in `pg_class`, `pg_proc`, `pg_type`, and `pg_operator` that do not generate errors for non-existent objects (Yugo Nagata, Nozomi Anzai, Robert Haas)
  For example, `to_regclass()` does a lookup in `pg_class` similarly to the `regclass` input function, but it returns NULL for a non-existent object instead of failing.
- Add function `pg_filenode_relation()` to allow for more efficient lookup of relation names from filenodes (Andres Freund)
- Add `parameter_default` column to `information_schema.parameters` view (Peter Eisentraut)
- Make `information_schema.schemata` show all accessible schemas (Peter Eisentraut)
  Previously it only showed schemas owned by the current user.

**E.21.3.7.2. Aggregates**

- Add control over which rows are passed into aggregate functions via the `FILTER` clause (David Fetter)
- Support ordered-set (`WITHIN GROUP`) aggregates (Atri Sharma, Andrew Gierth, Tom Lane)
- Add standard ordered-set aggregates `percentile_cont()`, `percentile_disc()`, `mode()`, `rank()`, `dense_rank()`, `percent_rank()`, and `cume_dist()` (Atri Sharma, Andrew Gierth)
- Support `VARIADIC` aggregate functions (Tom Lane)
- Allow polymorphic aggregates to have non-polymorphic state data types (Tom Lane)
  This allows proper declaration in SQL of aggregates like the built-in aggregate `array_agg()`.

**E.21.3.8. Server-Side Languages**

- Add event trigger support to PL/Perl and PL/Tcl (Dimitri Fontaine)
- Convert numeric values to decimal in PL/Python (Szymon Guz, Ronan Dunklau)
  Previously such values were converted to Python `float` values, risking loss of precision.

**E.21.3.8.1. PL/pgSQL Server-Side Language**

- Add ability to retrieve the current PL/pgSQL call stack using `GET DIAGNOSTICS` (Pavel Stehule, Stephen Frost)
• Add option `print_strict_params` to display the parameters passed to a query that violated a `STRICT` constraint (Marko Tiikkaja)

• Add variables `plpgsql.extra_warnings` and `plpgsql.extra_errors` to enable additional PL/pgSQL warnings and errors (Marko Tiikkaja, Petr Jelinek)
  Currently only warnings/errors about shadowed variables are available.

E.21.3.9. libpq

• Make libpq’s `PQconndefaults()` function ignore invalid service files (Steve Singer, Bruce Momjian)
  Previously it returned NULL if an incorrect service file was encountered.

• Accept TLS protocol versions beyond `TLSv1` in libpq (Marko Kreen)

E.21.3.10. Client Applications

• Add createuser option `-g` to specify role membership (Christopher Browne)

• Add vacuumdb option `--analyze-in-stages` to analyze in stages of increasing granularity (Peter Eisentraut)
  This allows minimal statistics to be created quickly.

• Make `pg_resetxlog` with option `-n` output current and potentially changed values (Rajeev Rastogi)

• Make `initdb` throw error for incorrect locale settings, rather than silently falling back to a default choice (Tom Lane)

• Make `pg_ctl` return exit code 4 for an inaccessible data directory (Amit Kapila, Bruce Momjian)
  This behavior more closely matches the Linux Standard Base (LSB) Core Specification.

• On Windows, ensure that a non-absolute `-D` path specification is interpreted relative to `pg_ctl`’s current directory (Kumar Rajeev Rastogi)
  Previously it would be interpreted relative to whichever directory the underlying Windows service was started in.

• Allow `sizeof()` in ECPG C array definitions (Michael Meskes)

• Make ECPG properly handle nesting of C-style comments in both C and SQL text (Michael Meskes)

E.21.3.10.1. psql

• Suppress “No rows” output in psql `expanded` mode when the footer is disabled (Bruce Momjian)

• Allow Control-C to abort `psql` when it’s hung at connection startup (Peter Eisentraut)
Appendix E. Release Notes

E.21.3.10.1.1. Backslash Commands

- Make psql’s \db+ show tablespace options (Magnus Hagander)
- Make \do+ display the functions that implement the operators (Marko Tiikkaja)
- Make \d+ output an OID line only if an oid column exists in the table (Bruce Momjian)
  Previously, the presence or absence of an oid column was always reported.
- Make \d show disabled system triggers (Bruce Momjian)
  Previously, if you disabled all triggers, only user triggers would show as disabled.
- Fix \copy to no longer require a space between stdin and a semicolon (Etsuro Fujita)
- Output the row count at the end of \copy, just like COPY already did (Kumar Rajeev Rastogi)
- Fix \conninfo to display the server’s IP address for connections using hostaddr (Fujii Masao)
  Previously \conninfo could not display the server’s IP address in such cases.
- Show the SSL protocol version in \conninfo (Marko Kreen)
- Add tab completion for \pset (Pavel Stehule)
- Allow \pset with no arguments to show all settings (Gilles Darold)
- Make \s display the name of the history file it wrote without converting it to an absolute path (Tom Lane)
  The code previously attempted to convert a relative file name to an absolute path for display, but frequently got it wrong.

E.21.3.10.2. pg_dump

- Allow pg_restore options -I, -P, -T and -n to be specified multiple times (Heikki Linnakangas)
  This allows multiple objects to be restored in one operation.
- Optionally add IF EXISTS clauses to the DROP commands emitted when removing old objects during a restore (Pavel Stehule)
  This change prevents unnecessary errors when removing old objects. The new --if-exists option for pg_dump, pg_dumpall, and pg_restore is only available when --clean is also specified.

E.21.3.10.3. pg_basebackup

- Add pg_basebackup option --xlogdir to specify the pg_xlog directory location (Haribabu Kommi)
- Allow pg_basebackup to relocate tablespaces in the backup copy (Steeve Lennmark)
  This is particularly useful for using pg_basebackup on the same machine as the primary.
- Allow network-stream base backups to be throttled (Antonin Houska)
  This can be controlled with the pg_basebackup --max-rate parameter.
E.21.3.11. Source Code

- Improve the way tuples are frozen to preserve forensic information (Robert Haas, Andres Freund)
  
  This change removes the main objection to freezing tuples as soon as possible. Code that inspects tuple flag bits will need to be modified.

- No longer require function prototypes for functions marked with the `PG_FUNCTION_INFO_V1` macro (Peter Eisentraut)
  
  This change eliminates the need to write boilerplate prototypes. Note that the `PG_FUNCTION_INFO_V1` macro must appear before the corresponding function definition to avoid compiler warnings.

- Remove `SnapshotNow` and `HeapTupleSatisfiesNow()` (Robert Haas)
  
  All existing uses have been switched to more appropriate snapshot types. Catalog scans now use MVCC snapshots.

- Add an API to allow memory allocations over one gigabyte (Noah Misch)

- Add `psprintf()` to simplify memory allocation during string composition (Peter Eisentraut, Tom Lane)

- Support `printf()` size modifier `z` to print `size_t` values (Andres Freund)

- Change API of `appendStringInfoVA()` to better use `vsnprintf()` (David Rowley, Tom Lane)

- Allow new types of external toast datums to be created (Andres Freund)

- Add single-reader, single-writer, lightweight shared message queue (Robert Haas)

- Improve spinlock speed on x86_64 CPUs (Heikki Linnakangas)

- Remove spinlock support for unsupported platforms SINIX, Sun3, and NS32K (Robert Haas)

- Remove IRIX port (Robert Haas)

- Reduce the number of semaphores required by `--disable-spinlocks` builds (Robert Haas)

- Rewrite `duplicate_oids` Unix shell script in Perl (Andrew Dunstan)

- Add Test Anything Protocol (TAP) tests for client programs (Peter Eisentraut)
  
  Currently, these tests are run by `make check-world` only if the `--enable-tap-tests` option was given to configure. This might become the default behavior in some future release.

- Add `make` targets `check-tests` and `installcheck-tests`, which allow selection of individual tests to be run (Andrew Dunstan)

- Remove `maintainer-check` makefile rule (Peter Eisentraut)
  
  The default build rules now include all the formerly-optional tests.

- Improve support for `VPATH` builds of PGXS modules (Cédric Villemain, Andrew Dunstan, Peter Eisentraut)

- Upgrade to Autoconf 2.69 (Peter Eisentraut)

- Add a configure flag that appends custom text to the `PG_VERSION` string (Oskari Saarenmaa)
  
  This is useful for packagers building custom binaries.

- Improve DocBook XML validity (Peter Eisentraut)
Appendix E. Release Notes

- Fix various minor security and sanity issues reported by the Coverity scanner (Stephen Frost)
- Improve detection of invalid memory usage when testing PostgreSQL with Valgrind (Noah Misch)
- Improve sample Emacs configuration file `emacs.samples` (Peter Eisentraut)
  Also add `.dir-locals.el` to the top of the source tree.
- Allow pgindent to accept a command-line list of typedefs (Bruce Momjian)
- Make pgindent smarter about blank lines around preprocessor conditionals (Bruce Momjian)
- Avoid most uses of `dlltool` in Cygwin and Mingw builds (Marco Atzeri, Hiroshi Inoue)
- Support client-only installs in MSVC (Windows) builds (MauMau)

E.21.3.12. Additional Modules

- Add pg_prewarm extension to preload relation data into the shared buffer cache at server start (Robert Haas)
  This allows reaching full operating performance more quickly.
- Add UUID random number generator `gen_random_uuid()` to `pgcrypto` (Oskari Saarenmaa)
  This allows creation of version 4 UUIDs without requiring installation of uuid-ossp.
- Allow uuid-ossp to work with the BSD or e2fsprogs UUID libraries, not only the OSSP UUID library
  (Matteo Beccati)
  This improves the uuid-ossp module’s portability since it no longer has to have the increasingly-obsolete
  OSSP library. The module’s name is now rather a misnomer, but we won’t change it.
- Add option to `auto_explain` to include trigger execution time (Horiguchi Kyotaro)
- Fix `pgstattuple` to not report rows from uncommitted transactions as dead (Robert Haas)
- Make `pgstattuple` functions use `regclass-type` arguments (Satoshi Nagayasu)
  While `text-type` arguments are still supported, they may be removed in a future major release.
- Improve consistency of `pgrowlocks` output to honor snapshot rules more consistently (Robert Haas)
- Improve `pg_trgm`’s choice of trigrams for indexed regular expression searches (Alexander Korotkov)
  This change discourages use of trigrams containing whitespace, which are usually less selective.
- Allow `pg_xlogdump` to report a live log stream with `--follow` (Heikki Linnakangas)
- Store cube data more compactly (Stas Kelvich)
  Existing data must be dumped/restored to use the new format. The old format can still be read.
- Reduce vacuumlo client-side memory usage by using a cursor (Andrew Dunstan)
- Dramatically reduce memory consumption in `pg_upgrade` (Bruce Momjian)
- Pass `pg_upgrade`’s user name (`-U`) option to generated analyze scripts (Bruce Momjian)
Appendix E. Release Notes

E.21.3.12.1. pgbench

• Remove line length limit for pgbench scripts (Sawada Masahiko)
  The previous line limit was BUFSIZ.
• Add long option names to pgbench (Fabien Coelho)
• Add pgbench option --rate to control the transaction rate (Fabien Coelho)
• Add pgbench option --progress to print periodic progress reports (Fabien Coelho)

E.21.3.12.2. pg_stat_statements

• Make pg_stat_statements use a file, rather than shared memory, for query text storage (Peter Geoghegan)
  This removes the previous limitation on query text length, and allows a higher number of unique statements to be tracked by default.
• Allow reporting of pg_stat_statements’s internal query hash identifier (Daniel Farina, Sameer Thakur, Peter Geoghegan)
• Add the ability to retrieve all pg_stat_statements information except the query text (Peter Geoghegan)
  This allows monitoring tools to fetch query text only for just-created entries, improving performance during repeated querying of the statistics.
• Make pg_stat_statements ignore DEALLOCATE commands (Fabien Coelho)
  It already ignored PREPARE, as well as planning time in general, so this seems more consistent.
• Save the statistics file into $PGDATA/pg_stat at server shutdown, rather than $PGDATA/global (Fujii Masao)

E.22. Release 9.3.25

Release date: 2018-11-08

This release contains a variety of fixes from 9.3.24. For information about new features in the 9.3 major release, see Section E.47.

This is expected to be the last PostgreSQL release in the 9.3.X series. Users are encouraged to update to a newer release branch soon.

E.22.1. Migration to Version 9.3.25

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.23, see Section E.24.
E.22.2. Changes

• Fix corner-case failures in `hasfoo_privilege()` family of functions (Tom Lane)
  Return NULL rather than throwing an error when an invalid object OID is provided. Some of these
  functions got that right already, but not all. `has_column_privilege()` was additionally capable of
  crashing on some platforms.
• Avoid O(N^2) slowdown in regular expression match/split functions on long strings (Andrew Gierth)
• Avoid O(N^3) slowdown in lexer for long strings of + or - characters (Andrew Gierth)
• Fix mis-execution of SubPlans when the outer query is being scanned backwards (Andrew Gierth)
• Fix failure of `UPDATE/DELETE ... WHERE CURRENT OF ...` after rewinding the referenced cursor
  (Tom Lane)
  A cursor that scans multiple relations (particularly an inheritance tree) could produce wrong behavior
  if rewound to an earlier relation.
• Fix `EvalPlanQual` to handle conditionally-executed InitPlans properly (Andrew Gierth, Tom Lane)
  This resulted in hard-to-reproduce crashes or wrong answers in concurrent updates, if they contained
  code such as an uncorrelated sub-`SELECT` inside a `CASE` construct.
• Fix character-class checks to not fail on Windows for Unicode characters above U+FFFF (Tom Lane,
  Kenji Uno)
  This bug affected full-text-search operations, as well as `contrib/ltree` and `contrib/pg_trgm`.
• Ensure that sequences owned by a foreign table are processed by `ALTER OWNER` on the table (Peter
  Eisentraut)
  The ownership change should propagate to such sequences as well, but this was missed for foreign
  tables.
• Fix over-allocation of space for `array_out()`’s result string (Keiichi Hirobe)
• Fix memory leak in repeated SP-GiST index scans (Tom Lane)
  This is only known to amount to anything significant in cases where an exclusion constraint using
  SP-GiST receives many new index entries in a single command.
• Avoid crash if a utility command causes infinite recursion (Tom Lane)
• When initializing a hot standby, cope with duplicate XIDs caused by two-phase transactions on the
  master (Michael Paquier, Konstantin Knizhnik)
• Randomize the `random()` seed in bootstrap and standalone backends, and in initdb (Noah Misch)
  The main practical effect of this change is that it avoids a scenario where initdb might mistakenly
  conclude that POSIX shared memory is not available, due to name collisions caused by always using
  the same random seed.
• Ensure that hot standby processes use the correct WAL consistency point (Alexander Kukushkin,
  Michael Paquier)
  This prevents possible misbehavior just after a standby server has reached a consistent database state
  during WAL replay.
• Don’t run atexit callbacks when servicing `SIGQUIT` (Heikki Linnakangas)
Appendix E. Release Notes

- Don’t record foreign-server user mappings as members of extensions (Tom Lane)
  
  If `CREATE USER MAPPING` is executed in an extension script, an extension dependency was created for the user mapping, which is unexpected. Roles can’t be extension members, so user mappings shouldn’t be either.

- Make syslogger more robust against failures in opening CSV log files (Tom Lane)

- Fix possible inconsistency in `pg_dump`’s sorting of dissimilar object names (Jacob Champion)

- Ensure that `pg_restore` will schema-qualify the table name when emitting `DISABLE/ENABLE TRIGGER` commands (Tom Lane)
  
  This avoids failures due to the new policy of running restores with restrictive search path.

- Fix `pg_upgrade` to handle event triggers in extensions correctly (Haribabu Kommi)
  
  `pg_upgrade` failed to preserve an event trigger’s extension-membership status.

- Fix `pg_upgrade`’s cluster state check to work correctly on a standby server (Bruce Momjian)

- Enforce type `cube`’s dimension limit in all `contrib/cube` functions (Andrey Borodin)
  
  Previously, some cube-related functions could construct values that would be rejected by `cube_in()`, leading to dump/reload failures.

- Fix `contrib/unaccent`’s `unaccent()` function to use the `unaccent` text search dictionary that is in the same schema as the function (Tom Lane)
  
  Previously it tried to look up the dictionary using the search path, which could fail if the search path has a restrictive value.

- Fix build problems on macOS 10.14 (Mojave) (Tom Lane)
  
  Adjust configure to add an `-isysroot` switch to `CPPFLAGS`; without this, PL/Perl and PL/Tcl fail to configure or build on macOS 10.14. The specific sysroot used can be overridden at configure time or build time by setting the `PG_SYSROOT` variable in the arguments of configure or make.
  
  It is now recommended that Perl-related extensions write `$(perl_includespec)` rather than `-I$(perl_archlibexp)/CORE` in their compiler flags. The latter continues to work on most platforms, but not recent macOS.
  
  Also, it should no longer be necessary to specify `--with-tclconfig` manually to get PL/Tcl to build on recent macOS releases.

- Fix MSVC build and regression-test scripts to work on recent Perl versions (Andrew Dunstan)
  
  Perl no longer includes the current directory in its search path by default; work around that.

- Support building on Windows with Visual Studio 2015 or Visual Studio 2017 (Michael Paquier, Haribabu Kommi)

- Allow btree comparison functions to return `INT_MIN` (Tom Lane)
  
  Up to now, we’ve forbidden datatype-specific comparison functions from returning `INT_MIN`, which allows callers to invert the sort order just by negating the comparison result. However, this was never safe for comparison functions that directly return the result of `memcmp()`, `strcmp()`, etc, as POSIX doesn’t place any such restriction on those functions. At least some recent versions of `memcmp()` can return `INT_MIN`, causing incorrect sort ordering. Hence, we’ve removed this restriction. Callers must now use the `INVERTCOMPARERESULT()` macro if they wish to invert the sort order.
• Fix recursion hazard in shared-invalidation message processing (Tom Lane)
  This error could, for example, result in failure to access a system catalog or index that had just been
  processed by VACUUM FULL.
  This change adds a new result code for LockAcquire, which might possibly affect external callers
  of that function, though only very unusual usage patterns would have an issue with it. The API of
  LockAcquireExtended is also changed.
• Save and restore SPI’s global variables during SPI_connect() and SPI_finish() (Chapman Flack,
  Tom Lane)
  This prevents possible interference when one SPI-using function calls another.
• Provide ALLOCSET_DEFAULT_SIZES and sibling macros in back branches (Tom Lane)
  These macros have existed since 9.6, but there were requests to add them to older branches to allow
  extensions to rely on them without branch-specific coding.
• Avoid using potentially-under-aligned page buffers (Tom Lane)
  Invent new union types PGAlignedBlock and PGAlignedXLogBlock, and use these in place of plain
  char arrays, ensuring that the compiler can’t place the buffer at a misaligned start address. This fixes
  potential core dumps on alignment-picky platforms, and may improve performance even on platforms
  that allow misalignment.
• Make src/port/snprintf.c follow the C99 standard’s definition of snprintf()’s result value
  (Tom Lane)
  On platforms where this code is used (mostly Windows), its pre-C99 behavior could lead to failure to
  detect buffer overrun, if the calling code assumed C99 semantics.
• When building on i386 with the clang compiler, require -msse2 to be used (Andres Freund)
  This avoids problems with missed floating point overflow checks.
• Fix configure’s detection of the result type of strerror_r() (Tom Lane)
  The previous coding got the wrong answer when building with icc on Linux (and perhaps in other
  cases), leading to libpq not returning useful error messages for system-reported errors.
• Update time zone data files to tzdata release 2018g for DST law changes in Chile, Fiji, Morocco, and
  Russia (Volgograd), plus historical corrections for China, Hawaii, Japan, Macau, and North Korea.

E.23. Release 9.3.24

Release date: 2018-08-09

This release contains a variety of fixes from 9.3.23. For information about new features in the 9.3 major
release, see Section E.47.

The PostgreSQL community will stop releasing updates for the 9.3.X release series shortly after Septem-
ber 2018. Users are encouraged to update to a newer release branch soon.
Appendix E. Release Notes

E.23.1. Migration to Version 9.3.24

A dump/restore is not required for those running 9.3.X.
However, if you are upgrading from a version earlier than 9.3.23, see Section E.24.

E.23.2. Changes

• Fix failure to reset libpq’s state fully between connection attempts (Tom Lane)

An unprivileged user of dblink or postgres_fdw could bypass the checks intended to prevent use of server-side credentials, such as a ~/.pgpass file owned by the operating-system user running the server. Servers allowing peer authentication on local connections are particularly vulnerable. Other attacks such as SQL injection into a postgres_fdw session are also possible. Attacking postgres_fdw in this way requires the ability to create a foreign server object with selected connection parameters, but any user with access to dblink could exploit the problem. In general, an attacker with the ability to select the connection parameters for a libpq-using application could cause mischief, though other plausible attack scenarios are harder to think of. Our thanks to Andrew Krasichkov for reporting this issue. (CVE-2018-10915)

• Ensure that updates to the relfrozenxid and relminmxid values for “nailed” system catalogs are processed in a timely fashion (Andres Freund)

Overoptimistic caching rules could prevent these updates from being seen by other sessions, leading to spurious errors and/or data corruption. The problem was significantly worse for shared catalogs, such as pg_authid, because the stale cache data could persist into new sessions as well as existing ones.

• Fix case where a freshly-promoted standby crashes before having completed its first post-recovery checkpoint (Michael Paquier, Kyotaro Horiguchi, Pavan Deolasee, Álvaro Herrera)

This led to a situation where the server did not think it had reached a consistent database state during subsequent WAL replay, preventing restart.

• Avoid emitting a bogus WAL record when recycling an all-zero btree page (Amit Kapila)

This mistake has been seen to cause assertion failures, and potentially it could result in unnecessary query cancellations on hot standby servers.

• Improve performance of WAL replay for transactions that drop many relations (Fujii Masao)

This change reduces the number of times that shared buffers are scanned, so that it is of most benefit when that setting is large.

• Improve performance of lock releasing in standby server WAL replay (Thomas Munro)

• Ensure a table’s cached index list is correctly rebuilt after an index creation fails partway through (Peter Geoghegan)

Previously, the failed index’s OID could remain in the list, causing problems later in the same session.

• Fix misoptimization of equivalence classes involving composite-type columns (Tom Lane)

This resulted in failure to recognize that an index on a composite column could provide the sort order needed for a mergejoin on that column.
• Fix SQL-standard `FETCH FIRST` syntax to allow parameters ($n$), as the standard expects (Andrew Gierth)

• Fix failure to schema-qualify some object names in `getObjectDescription` output (Kyotaro Horiguchi, Tom Lane)
   
   Names of collations, conversions, and text search objects were not schema-qualified when they should be.

• Widen `COPY FROM`'s current-line-number counter from 32 to 64 bits (David Rowley)
   
   This avoids two problems with input exceeding 4G lines: `COPY FROM WITH HEADER` would drop a line every 4G lines, not only the first line, and error reports could show a wrong line number.

• Add a string freeing function to ecpg’s `pgtypes` library, so that cross-module memory management problems can be avoided on Windows (Takayuki Tsunakawa)
   
   On Windows, crashes can ensue if the `free` call for a given chunk of memory is not made from the same DLL that `malloc`ed the memory. The `pgtypes` library sometimes returns strings that it expects the caller to free, making it impossible to follow this rule. Add a `PGTYPESchar_free()` function that just wraps `free`, allowing applications to follow this rule.

• Fix ecpg’s support for `long long` variables on Windows, as well as other platforms that declare `strtoll`/`strtoull` nonstandardly or not at all (Dang Minh Huong, Tom Lane)

• Fix misidentification of SQL statement type in PL/pgSQL, when a rule change causes a change in the semantics of a statement intra-session (Tom Lane)
   
   This error led to assertion failures, or in rare cases, failure to enforce the `INTO STRICT` option as expected.

• Fix password prompting in client programs so that echo is properly disabled on Windows when `stdin` is not the terminal (Matthew Stickney)

• Further fix mis-quoting of values for list-valued GUC variables in dumps (Tom Lane)
   
   The previous fix for quoting of `search_path` and other list-valued variables in `pg_dump` output turned out to misbehave for empty-string list elements, and it risked truncation of long file paths.

• Make `pg_upgrade` check that the old server was shut down cleanly (Bruce Momjian)
   
   The previous check could be fooled by an immediate-mode shutdown.

• Fix crash in `contrib/ltree`’s `lca()` function when the input array is empty (Pierre Ducroquet)

• Fix various error-handling code paths in which an incorrect error code might be reported (Michael Paquier, Tom Lane, Magnus Hagander)

• Rearrange makefiles to ensure that programs link to freshly-built libraries (such as `libpq.so`) rather than ones that might exist in the system library directories (Tom Lane)
   
   This avoids problems when building on platforms that supply old copies of PostgreSQL libraries.

• Update time zone data files to tzdata release 2018e for DST law changes in North Korea, plus historical corrections for Czechoslovakia.
   
   This update includes a redefinition of “daylight savings” in Ireland, as well as for some past years in Namibia and Czechoslovakia. In those jurisdictions, legally standard time is observed in summer, and daylight savings time in winter, so that the daylight savings offset is one hour behind standard time not one hour ahead. This does not affect either the actual UTC offset or the timezone abbreviations in use;
the only known effect is that the is_dst column in the pg_timezone_names view will now be true in winter and false in summer in these cases.

E.24. Release 9.3.23

Release date: 2018-05-10

This release contains a variety of fixes from 9.3.22. For information about new features in the 9.3 major release, see Section E.47.

E.24.1. Migration to Version 9.3.23

A dump/restore is not required for those running 9.3.X.

However, if the function marking mistakes mentioned in the first changelog entry below affect you, you will want to take steps to correct your database catalogs.

Also, if you are upgrading from a version earlier than 9.3.22, see Section E.25.

E.24.2. Changes

- Fix incorrect volatility markings on a few built-in functions (Thomas Munro, Tom Lane)

  The functions query_to_xml, cursor_to_xml, cursor_to_xmlschema, query_to_xmlschema, and query_to_xml_and_xmlschema should be marked volatile because they execute user-supplied queries that might contain volatile operations. They were not, leading to a risk of incorrect query optimization. This has been repaired for new installations by correcting the initial catalog data, but existing installations will continue to contain the incorrect markings. Practical use of these functions seems to pose little hazard, but in case of trouble, it can be fixed by manually updating these functions’ pg_proc entries, for example ALTER FUNCTION pg_catalog.query_to_xml(text, boolean, boolean, text) VOLATILE. (Note that that will need to be done in each database of the installation.) Another option is to pg_upgrade the database to a version containing the corrected initial data.

- Avoid re-using TOAST value OIDs that match dead-but-not-yet-vacuumed TOAST entries (Pavan Deolasee)

  Once the OID counter has wrapped around, it’s possible to assign a TOAST value whose OID matches a previously deleted entry in the same TOAST table. If that entry were not yet vacuumed away, this resulted in “unexpected chunk number 0 (expected 1) for toast value nnnnn” errors, which would persist until the dead entry was removed by VACUUM. Fix by not selecting such OIDs when creating a new TOAST entry.

- Change ANALYZE’s algorithm for updating pg_class.reltuples (David Gould)

  Previously, pages not actually scanned by ANALYZE were assumed to retain their old tuple density. In a large table where ANALYZE samples only a small fraction of the pages, this meant that the overall tuple density estimate could not change very much, so that reltuples would change nearly proportionally to changes in the table’s physical size (relpages) regardless of what was actually happening in the
table. This has been observed to result in reltuples becoming so much larger than reality as to effectively shut off autovacuuming. To fix, assume that ANALYZE’s sample is a statistically unbiased sample of the table (as it should be), and just extrapolate the density observed within those pages to the whole table.

- Fix UPDATE/DELETE ... WHERE CURRENT OF to not fail when the referenced cursor uses an index-only-scan plan (Yugo Nagata, Tom Lane)
- Fix incorrect planning of join clauses pushed into parameterized paths (Andrew Gierth, Tom Lane)
  This error could result in misclassifying a condition as a “join filter” for an outer join when it should be a plain “filter” condition, leading to incorrect join output.
- Fix misoptimization of CHECK constraints having provably-NULL subclauses of top-level AND/OR conditions (Tom Lane, Dean Rasheed)
  This could, for example, allow constraint exclusion to exclude a child table that should not be excluded from a query.
- Avoid failure if a query-cancel or session-termination interrupt occurs while committing a prepared transaction (Stas Kelvich)
- Fix query-lifespan memory leakage in repeatedly executed hash joins (Tom Lane)
- Fix overly strict sanity check in heap_prepare_freeze_tuple (Álvaro Herrera)
  This could result in incorrect “cannot freeze committed xmax” failures in databases that have been pg_upgrade’d from 9.2 or earlier.
- Prevent dangling-pointer dereference when a C-coded before-update row trigger returns the “old” tuple (Rushabh Lathia)
- Reduce locking during autovacuum worker scheduling (Jeff Janes)
  The previous behavior caused drastic loss of potential worker concurrency in databases with many tables.
- Ensure client hostname is copied while copying pg_stat_activity data to local memory (Edmund Horner)
  Previously the supposedly-local snapshot contained a pointer into shared memory, allowing the client hostname column to change unexpectedly if any existing session disconnected.
- Fix incorrect processing of multiple compound affixes in ispell dictionaries (Arthur Zakirov)
- Fix collation-aware searches (that is, indexscans using inequality operators) in SP-GiST indexes on text columns (Tom Lane)
  Such searches would return the wrong set of rows in most non-C locales.
- Count the number of index tuples correctly during initial build of an SP-GiST index (Tomas Vondra)
  Previously, the tuple count was reported to be the same as that of the underlying table, which is wrong if the index is partial.
- Count the number of index tuples correctly during vacuuming of a GiST index (Andrey Borodin)
  Previously it reported the estimated number of heap tuples, which might be inaccurate, and is certainly wrong if the index is partial.
- Allow scalarltsel and scalargtsel to be used on non-core datatypes (Tomas Vondra)
• Reduce libpq’s memory consumption when a server error is reported after a large amount of query output has been collected (Tom Lane)
  Discard the previous output before, not after, processing the error message. On some platforms, notably Linux, this can make a difference in the application’s subsequent memory footprint.
• Fix double-free crashes in ecpg (Patrick Krecker, Jeevan Ladhe)
• Fix ecpg to handle long long int variables correctly in MSVC builds (Michael Meskes, Andrew Gierth)
• Fix mis-quoting of values for list-valued GUC variables in dumps (Michael Paquier, Tom Lane)
  The local_preload_libraries, session_preload_libraries, shared_preload_libraries, and temp_tablespaces variables were not correctly quoted in pg_dump output. This would cause problems if settings for these variables appeared in CREATE FUNCTION ... SET or ALTER DATABASE/ROLE ... SET clauses.
• Fix overflow handling in PL/pgSQL integer FOR loops (Tom Lane)
  The previous coding failed to detect overflow of the loop variable on some non-gcc compilers, leading to an infinite loop.
• Adjust PL/Python regression tests to pass under Python 3.7 (Peter Eisentraut)
• Support testing PL/Python and related modules when building with Python 3 and MSVC (Andrew Dunstan)
• Rename internal b64_encode and b64_decode functions to avoid conflict with Solaris 11.4 built-in functions (Rainer Orth)
• Sync our copy of the timezone library with IANA tzcode release 2018e (Tom Lane)
  This fixes the zic timezone data compiler to cope with negative daylight-savings offsets. While the PostgreSQL project will not immediately ship such timezone data, zic might be used with timezone data obtained directly from IANA, so it seems prudent to update zic now.
• Update time zone data files to tzdata release 2018d for DST law changes in Palestine and Antarctica (Casey Station), plus historical corrections for Portugal and its colonies, as well as Enderbury, Jamaica, Turks & Caicos Islands, and Uruguay.

E.25. Release 9.3.22

Release date: 2018-03-01

This release contains a variety of fixes from 9.3.21. For information about new features in the 9.3 major release, see Section E.47.

E.25.1. Migration to Version 9.3.22

A dump/restore is not required for those running 9.3.X.

However, if you run an installation in which not all users are mutually trusting, or if you maintain an application or extension that is intended for use in arbitrary situations, it is strongly recommended that
you read the documentation changes described in the first changelog entry below, and take suitable steps to ensure that your installation or code is secure.

Also, the changes described in the second changelog entry below may cause functions used in index expressions or materialized views to fail during auto-analyze, or when reloading from a dump. After upgrading, monitor the server logs for such problems, and fix affected functions.

Also, if you are upgrading from a version earlier than 9.3.18, see Section E.29.

### E.25.2. Changes

- **Document how to configure installations and applications to guard against search-path-dependent trojan-horse attacks from other users (Noah Misch)**

  Using a `search_path` setting that includes any schemas writable by a hostile user enables that user to capture control of queries and then run arbitrary SQL code with the permissions of the attacked user. While it is possible to write queries that are proof against such hijacking, it is notationally tedious, and it’s very easy to overlook holes. Therefore, we now recommend configurations in which no untrusted schemas appear in one’s search path. Relevant documentation appears in Section 5.7.6 (for database administrators and users), Section 31.1 (for application authors), Section 35.15.1 (for extension authors), and CREATE FUNCTION (for authors of `SECURITY DEFINER` functions). (CVE-2018-1058)

- **Avoid use of insecure `search_path` settings in pg_dump and other client programs (Noah Misch, Tom Lane)**

  pg_dump, pg_upgrade, vacuumdb and other PostgreSQL-provided applications were themselves vulnerable to the type of hijacking described in the previous changelog entry; since these applications are commonly run by superusers, they present particularly attractive targets. To make them secure whether or not the installation as a whole has been secured, modify them to include only the `pg_catalog` schema in their `search_path` settings. Autovacuum worker processes now do the same, as well.

  In cases where user-provided functions are indirectly executed by these programs — for example, user-provided functions in index expressions — the tighter `search_path` may result in errors, which will need to be corrected by adjusting those user-provided functions to not assume anything about what search path they are invoked under. That has always been good practice, but now it will be necessary for correct behavior. (CVE-2018-1058)

- **Fix misbehavior of concurrent-update rechecks with CTE references appearing in subplans (Tom Lane)**

  If a CTE (`WITH` clause reference) is used in an InitPlan or SubPlan, and the query requires a recheck due to trying to update or lock a concurrently-updated row, incorrect results could be obtained.

- **Fix planner failures with overlapping mergejoin clauses in an outer join (Tom Lane)**

  These mistakes led to “left and right pathkeys do not match in mergejoin” or “outer pathkeys do not match mergeclauses” planner errors in corner cases.

- **Repair pg_upgrade’s failure to preserve `relfrozenxid` for materialized views (Tom Lane, Andres Freund)**

  This oversight could lead to data corruption in materialized views after an upgrade, manifesting as “could not access status of transaction” or “found xmin from before relfrozenxid” errors. The problem
would be more likely to occur in seldom-refreshed materialized views, or ones that were maintained only with `REFRESH MATERIALIZED VIEW CONCURRENTLY`.

If such corruption is observed, it can be repaired by refreshing the materialized view (without `CONCURRENTLY`).

- Fix incorrect reporting of PL/Python function names in error `CONTEXT` stacks (Tom Lane)

  An error occurring within a nested PL/Python function call (that is, one reached via a SPI query from another PL/Python function) would result in a stack trace showing the inner function’s name twice, rather than the expected results. Also, an error in a nested PL/Python `DO` block could result in a null pointer dereference crash on some platforms.

- Allow `contrib/auto_explain`'s `log_min_duration` setting to range up to `INT_MAX`, or about 24 days instead of 35 minutes (Tom Lane)

---

### E.26. Release 9.3.21

**Release date:** 2018-02-08

This release contains a variety of fixes from 9.3.20. For information about new features in the 9.3 major release, see Section E.47.

#### E.26.1. Migration to Version 9.3.21

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.18, see Section E.29.

#### E.26.2. Changes

- Ensure that all temporary files made by `pg_upgrade` are non-world-readable (Tom Lane, Noah Misch)

  `pg_upgrade` normally restricts its temporary files to be readable and writable only by the calling user. But the temporary file containing `pg_dumpall -g` output would be group- or world-readable, or even writable, if the user’s `umask` setting allows. In typical usage on multi-user machines, the `umask` and/or the working directory’s permissions would be tight enough to prevent problems; but there may be people using `pg_upgrade` in scenarios where this oversight would permit disclosure of database passwords to unfriendly eyes. (CVE-2018-1053)

- Fix vacuuming of tuples that were updated while key-share locked (Andres Freund, Álvaro Herrera)

  In some cases `VACUUM` would fail to remove such tuples even though they are now dead, leading to assorted data corruption scenarios.

- Fix inadequate buffer locking in some LSN fetches (Jacob Champion, Asim Praveen, Ashwin Agrawal)

  These errors could result in misbehavior under concurrent load. The potential consequences have not been characterized fully.
• Avoid unnecessary failure in a query on an inheritance tree that occurs concurrently with some child
table being removed from the tree by\texttt{ALTER TABLE NO INHERIT} (Tom Lane)
• Repair failure with correlated sub-select inside VALUES inside a LATERAL subquery (Tom Lane)
• Fix “could not devise a query plan for the given query” planner failure for some cases involving nested
UNION ALL inside a lateral subquery (Tom Lane)
• Fix \texttt{has_sequence_privilege()} to support \texttt{WITH GRANT OPTION} tests, as other privilege-testing
functions do (Joe Conway)
• In databases using UTF8 encoding, ignore any XML declaration that asserts a different encoding (Pavel
Stehule, Noah Misch)
  We always store XML strings in the database encoding, so allowing libxml to act on a declaration of
another encoding gave wrong results. In encodings other than UTF8, we don’t promise to support non-
ASCII XML data anyway, so retain the previous behavior for bug compatibility. This change affects
only \texttt{xpath()} and related functions; other XML code paths already acted this way.
• Provide for forward compatibility with future minor protocol versions (Robert Haas, Badrul Chowdhury)
  Up to now, PostgreSQL servers simply rejected requests to use protocol versions newer than 3.0, so that
there was no functional difference between the major and minor parts of the protocol version number.
Allow clients to request versions 3.x without failing, sending back a message showing that the server
only understands 3.0. This makes no difference at the moment, but back-patching this change should
allow speedier introduction of future minor protocol upgrades.
• Prevent stack-overflow crashes when planning extremely deeply nested set operations
(UNION/INTERSECT/EXCEPT) (Tom Lane)
• Fix null-pointer crashes for some types of LDAP URLs appearing in \texttt{pg_hba.conf} (Thomas Munro)
• Fix sample \texttt{INSTR()} functions in the PL/pgSQL documentation (Yugo Nagata, Tom Lane)
  These functions are stated to be Oracle® compatible, but they weren’t exactly. In particular, there was
a discrepancy in the interpretation of a negative third parameter: Oracle thinks that a negative value
indicates the last place where the target substring can begin, whereas our functions took it as the last
place where the target can end. Also, Oracle throws an error for a zero or negative fourth parameter,
whereas our functions returned zero.
  The sample code has been adjusted to match Oracle’s behavior more precisely. Users who have copied
this code into their applications may wish to update their copies.
• Fix \texttt{pg_dump} to make ACL (permissions), comment, and security label entries reliably identifiable in
archive output formats (Tom Lane)
  The “tag” portion of an ACL archive entry was usually just the name of the associated object. Make it
start with the object type instead, bringing ACLs into line with the convention already used for com-
ment and security label archive entries. Also, fix the comment and security label entries for the whole
database, if present, to make their tags start with \texttt{DATABASE} so that they also follow this convention.
This prevents false matches in code that tries to identify large-object-related entries by seeing if the
tag starts with \texttt{LARGE OBJECT}. That could have resulted in misclassifying entries as data rather than
schema, with undesirable results in a schema-only or data-only dump.
  Note that this change has user-visible results in the output of \texttt{pg_restore --list}.
• In ecpg, detect indicator arrays that do not have the correct length and report an error (David Rader)
Appendix E. Release Notes

- Avoid triggering a libc assertion in contrib/hstore, due to use of memcpy() with equal source and destination pointers (Tomas Vondra)
- Provide modern examples of how to auto-start Postgres on macOS (Tom Lane)
  The scripts in contrib/start-scripts/osx use infrastructure that's been deprecated for over a decade, and which no longer works at all in macOS releases of the last couple of years. Add a new subdirectory contrib/start-scripts/macos containing scripts that use the newer launchd infrastructure.
- Fix incorrect selection of configuration-specific libraries for OpenSSL on Windows (Andrew Dunstan)
- Support linking to MinGW-built versions of libperl (Noah Misch)
  This allows building PL/Perl with some common Perl distributions for Windows.
- Fix MSVC build to test whether 32-bit libperl needs -D_USE_32BIT_TIME_T (Noah Misch)
  Available Perl distributions are inconsistent about what they expect, and lack any reliable means of reporting it, so resort to a build-time test on what the library being used actually does.
- On Windows, install the crash dump handler earlier in postmaster startup (Takayuki Tsunakawa)
  This may allow collection of a core dump for some early-startup failures that did not produce a dump before.
- On Windows, avoid encoding-conversion-related crashes when emitting messages very early in postmaster startup (Takayuki Tsunakawa)
- Use our existing Motorola 68K spinlock code on OpenBSD as well as NetBSD (David Carlier)
- Add support for spinlocks on Motorola 88K (David Carlier)
- Update time zone data files to tzdata release 2018c for DST law changes in Brazil, Sao Tome and Principe, plus historical corrections for Bolivia, Japan, and South Sudan. The US/Pacific-New zone has been removed (it was only an alias for America/Los_Angeles anyway).

E.27. Release 9.3.20

Release date: 2017-11-09

This release contains a variety of fixes from 9.3.19. For information about new features in the 9.3 major release, see Section E.47.

E.27.1. Migration to Version 9.3.20

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.18, see Section E.29.
E.27.2. Changes

- Fix crash due to rowtype mismatch in `jsonb_populate_recordset()` (Michael Paquier, Tom Lane)

  These functions used the result rowtype specified in the FROM ... AS clause without checking that it matched the actual rowtype of the supplied tuple value. If it didn’t, that would usually result in a crash, though disclosure of server memory contents seems possible as well. (CVE-2017-15098)

- Fix sample server-start scripts to become `$PGUSER` before opening `$PGLOG` (Noah Misch)

  Previously, the postmaster log file was opened while still running as root. The database owner could therefore mount an attack against another system user by making `$PGLOG` be a symbolic link to some other file, which would then become corrupted by appending log messages.

  By default, these scripts are not installed anywhere. Users who have made use of them will need to manually recopy them, or apply the same changes to their modified versions. If the existing `$PGLOG` file is root-owned, it will need to be removed or renamed out of the way before restarting the server with the corrected script. (CVE-2017-12172)

- Properly reject attempts to convert infinite float values to type `numeric` (Tom Lane, KaiGai Kohei)

  Previously the behavior was platform-dependent.

- Fix corner-case crashes when columns have been added to the end of a view (Tom Lane)

- Record proper dependencies when a view or rule contains `FieldSelect` or `FieldStore` expression nodes (Tom Lane)

  Lack of these dependencies could allow a column or data type `DROP` to go through when it ought to fail, thereby causing later uses of the view or rule to get errors. This patch does not do anything to protect existing views/rules, only ones created in the future.

- Correctly detect hashability of range data types (Tom Lane)

  The planner mistakenly assumed that any range type could be hashed for use in hash joins or hash aggregation, but actually it must check whether the range’s subtype has hash support. This does not affect any of the built-in range types, since they’re all hashable anyway.

- Fix low-probability loss of NOTIFY messages due to XID wraparound (Marko Tiikkaja, Tom Lane)

  If a session executed no queries, but merely listened for notifications, for more than 2 billion transactions, it started to miss some notifications from concurrently-committing transactions.

- Prevent low-probability crash in processing of nested trigger firings (Tom Lane)

- Correctly restore the umask setting when file creation fails in `COPY` or `lo_export()` (Peter Eisentraut)

- Give a better error message for duplicate column names in `ANALYZE` (Nathan Bossart)

- Fix mis-parsing of the last line in a non-newline-terminated `pg_hba.conf` file (Tom Lane)

- Fix `libpq` to not require user’s home directory to exist (Tom Lane)

  In v10, failure to find the home directory while trying to read `~/.pgpass` was treated as a hard error, but it should just cause that file to not be found. Both v10 and previous release branches made the same mistake when reading `~/.pg_service.conf`, though this was less obvious since that file is not sought unless a service name is specified.
• Fix libpq to guard against integer overflow in the row count of a PGresult (Michael Paquier)
• Fix ecpg’s handling of out-of-scope cursor declarations with pointer or array variables (Michael Meskes)
• Make ecpglib’s Informix-compatibility mode ignore fractional digits in integer input strings, as ex-pected (Gao Zengqi, Michael Meskes)
• Sync our copy of the timezone library with IANA release tzcode2017c (Tom Lane)
  This fixes various issues; the only one likely to be user-visible is that the default DST rules for a POSIX-
  style zone name, if no posixrules file exists in the timezone data directory, now match current US
  law rather than what it was a dozen years ago.
• Update time zone data files to tzdata release 2017c for DST law changes in Fiji, Namibia, Northern
  Cyprus, Sudan, Tonga, and Turks & Caicos Islands, plus historical corrections for Alaska, Apia, Burma,
  Calcutta, Detroit, Ireland, Namibia, and Pago Pago.

E.28. Release 9.3.19

Release date: 2017-08-31

This release contains a small number of fixes from 9.3.18. For information about new features in the 9.3
major release, see Section E.47.

E.28.1. Migration to Version 9.3.19

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.18, see Section E.29.

E.28.2. Changes

• Show foreign tables in information_schema.table_privileges view (Peter Eisentraut)
  All other relevant information_schema views include foreign tables, but this one ignored them.

Since this view definition is installed by initdb, merely upgrading will not fix the problem. If you need
to fix this in an existing installation, you can, as a superuser, do this in psql:

```sql
SET search_path TO information_schema;
CREATE OR REPLACE VIEW table_privileges AS
  SELECT CAST(u_grantor.rolname AS sql_identifier) AS grantor,
         CAST(grantee.rolname AS sql_identifier) AS grantee,
         CAST(current_database() AS sql_identifier) AS table_catalog,
         CAST(nc.nspname AS sql_identifier) AS table_schema,
         CAST(c.relname AS sql_identifier) AS table_name,
         CAST(c.prtype AS character_data) AS privilege_type,
         CAST(
            CASE WHEN
```
Appendix E. Release Notes

-- object owner always has grant options
pg_has_role(grantee.oid, c.relowner, 'USAGE')
OR c.grantable
THEN 'YES' ELSE 'NO' END AS yes_or_no) AS is_grantable,
CAST(CASE WHEN c.prtype = 'SELECT' THEN 'YES' ELSE 'NO' END AS yes_or_no) AS with_hierarchy
FROM (SELECT oid, relname, relnamespace, relkind, relowner, (aclexplode(coalesce(relacl, acldefault('r', relowner)))).* FROM pg_class
AS c (oid, relname, relnamespace, relkind, relowner, grantor, grantee, prtype, grantable),
pg_namespace nc,
pg_authid u_grantor,
(SELECT oid, rolname FROM pg_authid
UNION ALL
SELECT 0::oid, 'PUBLIC'
) AS grantee (oid, rolname)
WHERE c.relnamespace = nc.oid
AND c.relkind IN ('r', 'v', 'f')
AND c.grantee = grantee.oid
AND c.grantor = u_grantor.oid
AND c.prtype IN ('INSERT', 'SELECT', 'UPDATE', 'DELETE', 'TRUNCATE', 'REFERENCES', 'TRIGGER')
AND (pg_has_role(u_grantor.oid, 'USAGE')
OR pg_has_role(grantee.oid, 'USAGE')
OR grantee.rolname = 'PUBLIC');

This must be repeated in each database to be fixed, including template0.

• Clean up handling of a fatal exit (e.g., due to receipt of SIGTERM) that occurs while trying to execute a ROLLBACK of a failed transaction (Tom Lane)
   This situation could result in an assertion failure. In production builds, the exit would still occur, but it would log an unexpected message about “cannot drop active portal”.

• Remove assertion that could trigger during a fatal exit (Tom Lane)

• Correctly identify columns that are of a range type or domain type over a composite type or domain type being searched for (Tom Lane)
   Certain ALTER commands that change the definition of a composite type or domain type are supposed to fail if there are any stored values of that type in the database, because they lack the infrastructure needed to update or check such values. Previously, these checks could miss relevant values that are wrapped inside range types or sub-domains, possibly allowing the database to become inconsistent.

• Fix crash in pg_restore when using parallel mode and using a list file to select a subset of items to restore (Fabrizio de Royes Mello)

• Change ecpg’s parser to allow RETURNING clauses without attached C variables (Michael Meskes)
   This allows ecpg programs to contain SQL constructs that use RETURNING internally (for example, inside a CTE) rather than using it to define values to be returned to the client.

• Improve selection of compiler flags for PL/Perl on Windows (Tom Lane)
   This fix avoids possible crashes of PL/Perl due to inconsistent assumptions about the width of time_t values. A side-effect that may be visible to extension developers is that _USE_32BIT_TIME_T is no
longer defined globally in PostgreSQL Windows builds. This is not expected to cause problems, because type time_t is not used in any PostgreSQL API definitions.

E.29. Release 9.3.18

Release date: 2017-08-10

This release contains a variety of fixes from 9.3.17. For information about new features in the 9.3 major release, see Section E.47.

E.29.1. Migration to Version 9.3.18

A dump/restore is not required for those running 9.3.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.3.16, see Section E.31.

E.29.2. Changes

• Further restrict visibility of pg_user_mappings.umoptions, to protect passwords stored as user mapping options (Noah Misch)

The fix for CVE-2017-7486 was incorrect: it allowed a user to see the options in her own user mapping, even if she did not have USAGE permission on the associated foreign server. Such options might include a password that had been provided by the server owner rather than the user herself. Since information_schema.user_mapping_options does not show the options in such cases, pg_user_mappings should not either. (CVE-2017-7547)

By itself, this patch will only fix the behavior in newly initdb’d databases. If you wish to apply this change in an existing database, you will need to do the following:

1. Restart the postmaster after adding allow_system_table_mods = true to postgresql.conf. (In versions supporting ALTER SYSTEM, you can use that to make the configuration change, but you’ll still need a restart.)

2. In each database of the cluster, run the following commands as superuser:

   SET search_path = pg_catalog;
   CREATE OR REPLACE VIEW pg_user_mappings AS
   SELECT
       U.oid AS umid,
       S.oid AS srvid,
       S.srvname AS srvname,
       U.umuser AS umuser,
       CASE WHEN U.umuser = 0 THEN 'public'
   END AS umoptions;
3. Do not forget to include the template0 and template1 databases, or the vulnerability will still exist in databases you create later. To fix template0, you’ll need to temporarily make it accept connections. In PostgreSQL 9.5 and later, you can use

```
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS true;
```

and then after fixing template0, undo that with

```
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS false;
```

In prior versions, instead use

```
UPDATE pg_database SET datallowconn = true WHERE datname = 'template0';
UPDATE pg_database SET datallowconn = false WHERE datname = 'template0';
```

4. Finally, remove the allow_system_table_mods configuration setting, and again restart the postmaster.

- Disallow empty passwords in all password-based authentication methods (Heikki Linnakangas)

libpq ignores empty password specifications, and does not transmit them to the server. So, if a user’s password has been set to the empty string, it’s impossible to log in with that password via psql or other libpq-based clients. An administrator might therefore believe that setting the password to empty is equivalent to disabling password login. However, with a modified or non-libpq-based client, logging in could be possible, depending on which authentication method is configured. In particular the most common method, md5, accepted empty passwords. Change the server to reject empty passwords in all cases. (CVE-2017-7546)

- Fix concurrent locking of tuple update chains (Álvaro Herrera)

If several sessions concurrently lock a tuple update chain with nonconflicting lock modes using an old snapshot, and they all succeed, it was possible for some of them to nonetheless fail (and conclude there is no live tuple version) due to a race condition. This had consequences such as foreign-key checks failing to see a tuple that definitely exists but is being updated concurrently.

- Fix potential data corruption when freezing a tuple whose XMAX is a multixact with exactly one still-interesting member (Teodor Sigaev)

- On Windows, retry process creation if we fail to reserve the address range for our shared memory in the new process (Tom Lane, Amit Kapila)

This is expected to fix infrequent child-process-launch failures that are probably due to interference from antivirus products.
• Fix low-probability corruption of shared predicate-lock hash table in Windows builds (Thomas Munro, Tom Lane)

• Avoid logging clean closure of an SSL connection as though it were a connection reset (Michael Paquier)

• Prevent sending SSL session tickets to clients (Tom Lane)
  This fix prevents reconnection failures with ticket-aware client-side SSL code.

• Fix code for setting tcp_keepalives_idle on Solaris (Tom Lane)

• Fix statistics collector to honor inquiry messages issued just after a postmaster shutdown and immediate restart (Tom Lane)
  Statistics inquiries issued within half a second of the previous postmaster shutdown were effectively ignored.

• Ensure that the statistics collector’s receive buffer size is at least 100KB (Tom Lane)
  This reduces the risk of dropped statistics data on older platforms whose default receive buffer size is less than that.

• Fix possible creation of an invalid WAL segment when a standby is promoted just after it processes an XLOG_SWITCH WAL record (Andres Freund)

• Fix SIGHUP and SIGUSR1 handling in walsender processes (Petr Jelinek, Andres Freund)

• Fix unnecessarily slow restarts of walreceiver processes due to race condition in postmaster (Tom Lane)

• Fix cases where an INSERT or UPDATE assigns to more than one element of a column that is of domain-over-array type (Tom Lane)

• Allow window functions to be used in sub-SELECTs that are within the arguments of an aggregate function (Tom Lane)

• Move autogenerated array types out of the way during ALTER ... RENAME (Vik Fearing)
  Previously, we would rename a conflicting autogenerated array type out of the way during CREATE; this fix extends that behavior to renaming operations.

• Ensure that ALTER USER ... SET accepts all the syntax variants that ALTER ROLE ... SET does (Peter Eisentraut)

• Properly update dependency info when changing a datatype I/O function’s argument or return type from opaque to the correct type (Heikki Linnakangas)
  CREATE TYPE updates I/O functions declared in this long-obsolete style, but it forgot to record a dependency on the type, allowing a subsequent DROP TYPE to leave broken function definitions behind.

• Reduce memory usage when ANALYZE processes a tsvector column (Heikki Linnakangas)

• Fix unnecessary precision loss and sloppy rounding when multiplying or dividing money values by integers or floats (Tom Lane)

• Tighten checks for whitespace in functions that parse identifiers, such as regprocedurein() (Tom Lane)
  Depending on the prevailing locale, these functions could misinterpret fragments of multibyte characters as whitespace.

• Use relevant #define symbols from Perl while compiling PL/Perl (Ashutosh Sharma, Tom Lane)
This avoids portability problems, typically manifesting as a “handshake” mismatch during library load, when working with recent Perl versions.

- In libpq, reset GSS/SASL and SSPI authentication state properly after a failed connection attempt (Michael Paquier)
  Failure to do this meant that when falling back from SSL to non-SSL connections, a GSS/SASL failure in the SSL attempt would always cause the non-SSL attempt to fail. SSPI did not fail, but it leaked memory.

- In psql, fix failure when COPY FROM STDIN is ended with a keyboard EOF signal and then another COPY FROM STDIN is attempted (Thomas Munro)
  This misbehavior was observed on BSD-derived platforms (including macOS), but not on most others.

- Fix pg_dump and pg_restore to emit REFRESH MATERIALIZED VIEW commands last (Tom Lane)
  This prevents errors during dump/restore when a materialized view refers to tables owned by a different user.

- Fix pg_dump with the --clean option to drop event triggers as expected (Tom Lane)
  It also now correctly assigns ownership of event triggers; before, they were restored as being owned by the superuser running the restore script.

- Fix pg_dump to not emit invalid SQL for an empty operator class (Daniel Gustafsson)

- Fix pg_dump output to stdout on Windows (Kuntal Ghosh)
  A compressed plain-text dump written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

- Fix pg_get_ruledef() to print correct output for the ON SELECT rule of a view whose columns have been renamed (Tom Lane)
  In some corner cases, pg_dump relies on pg_get_ruledef() to dump views, so that this error could result in dump/reload failures.

- Fix dumping of outer joins with empty constraints, such as the result of a NATURAL LEFT JOIN with no common columns (Tom Lane)

- Fix dumping of function expressions in the FROM clause in cases where the expression does not deparse into something that looks like a function call (Tom Lane)

- Fix pg_basebackup output to stdout on Windows (Haribabu Kommi)
  A backup written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

- Fix pg_upgrade to ensure that the ending WAL record does not have wal_level = minimum (Bruce Momjian)
  This condition could prevent upgraded standby servers from reconnecting.

- In postgres_fdw, re-establish connections to remote servers after ALTER SERVER or ALTER USER MAPPING commands (Kyotaro Horiguchi)
  This ensures that option changes affecting connection parameters will be applied promptly.

- In postgres_fdw, allow cancellation of remote transaction control commands (Robert Haas, Rafia Sabih)
This change allows us to quickly escape a wait for an unresponsive remote server in many more cases than previously.

- Always use `-fPIC`, not `-fpic`, when building shared libraries with gcc (Tom Lane)
  This supports larger extension libraries on platforms where it makes a difference.
- Fix unescaped-braces issue in our build scripts for Microsoft MSVC, to avoid a warning or error from recent Perl versions (Andrew Dunstan)
- In MSVC builds, handle the case where the openssl library is not within a VC subdirectory (Andrew Dunstan)
- In MSVC builds, add proper include path for libxml2 header files (Andrew Dunstan)
  This fixes a former need to move things around in standard Windows installations of libxml2.
- In MSVC builds, recognize a Tcl library that is named `tcl86.lib` (Noah Misch)

---

**E.30. Release 9.3.17**

**Release date:** 2017-05-11

This release contains a variety of fixes from 9.3.16. For information about new features in the 9.3 major release, see Section E.47.

**E.30.1. Migration to Version 9.3.17**

A dump/restore is not required for those running 9.3.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.3.16, see Section E.31.

**E.30.2. Changes**

- Restrict visibility of `pg_user_mappings.umoptions`, to protect passwords stored as user mapping options (Michael Paquier, Feike Steenbergen)
  The previous coding allowed the owner of a foreign server object, or anyone he has granted server `USAGE` permission to, to see the options for all user mappings associated with that server. This might well include passwords for other users. Adjust the view definition to match the behavior of `information_schema.user_mapping_options`, namely that these options are visible to the user being mapped, or if the mapping is for `PUBLIC` and the current user is the server owner, or if the current user is a superuser. (CVE-2017-7486)
  By itself, this patch will only fix the behavior in newly initdb’d databases. If you wish to apply this change in an existing database, follow the corrected procedure shown in the changelog entry for CVE-2017-7547, in Section E.29.
• Prevent exposure of statistical information via leaky operators (Peter Eisentraut)

Some selectivity estimation functions in the planner will apply user-defined operators to values obtained from `pg_statistic`, such as most common values and histogram entries. This occurs before table permissions are checked, so a nefarious user could exploit the behavior to obtain these values for table columns he does not have permission to read. To fix, fall back to a default estimate if the operator’s implementation function is not certified leak-proof and the calling user does not have permission to read the table column whose statistics are needed. At least one of these criteria is satisfied in most cases in practice. (CVE-2017-7484)

• Restore libpq’s recognition of the `PGREQUIRESSL` environment variable (Daniel Gustafsson)

Processing of this environment variable was unintentionally dropped in PostgreSQL 9.3, but its documentation remained. This creates a security hazard, since users might be relying on the environment variable to force SSL-encrypted connections, but that would no longer be guaranteed. Restore handling of the variable, but give it lower priority than `PGSSLMODE`, to avoid breaking configurations that work correctly with post-9.3 code. (CVE-2017-7485)

• Fix possible corruption of “init forks” of unlogged indexes (Robert Haas, Michael Paquier)

This could result in an unlogged index being set to an invalid state after a crash and restart. Such a problem would persist until the index was dropped and rebuilt.

• Fix incorrect reconstruction of `pg_subtrans` entries when a standby server replays a prepared but uncommitted two-phase transaction (Tom Lane)

In most cases this turned out to have no visible ill effects, but in corner cases it could result in circular references in `pg_subtrans`, potentially causing infinite loops in queries that examine rows modified by the two-phase transaction.

• Ensure parsing of queries in extension scripts sees the results of immediately-preceding DDL (Julien Rouhaud, Tom Lane)

Due to lack of a cache flush step between commands in an extension script file, non-utility queries might not see the effects of an immediately preceding catalog change, such as `ALTER TABLE ... RENAME`.

• Skip tablespace privilege checks when `ALTER TABLE ... ALTER COLUMN TYPE` rebuilds an existing index (Noah Misch)

The command failed if the calling user did not currently have `CREATE` privilege for the tablespace containing the index. That behavior seems unhelpful, so skip the check, allowing the index to be rebuilt where it is.

• Fix `ALTER TABLE ... VALIDATE CONSTRAINT` to not recurse to child tables when the constraint is marked `NO INHERIT` (Amit Langote)

This fix prevents unwanted “constraint does not exist” failures when no matching constraint is present in the child tables.

• Fix `VACUUM` to account properly for pages that could not be scanned due to conflicting page pins (Andrew Gierth)

This tended to lead to underestimation of the number of tuples in the table. In the worst case of a small heavily-contended table, `VACUUM` could incorrectly report that the table contained no tuples, leading to very bad planning choices.

• Ensure that bulk-tuple-transfer loops within a hash join are interruptible by query cancel requests (Tom Lane, Thomas Munro)
Appendix E. Release Notes

- Fix cursor_to_xml() to produce valid output with tableforest = false (Thomas Munro, Peter Eisentraut)
  Previously it failed to produce a wrapping <table> element.

- Improve performance of pg_timezone_names view (Tom Lane, David Rowley)

- Fix sloppy handling of corner-case errors from lseek() and close() (Tom Lane)
  Neither of these system calls are likely to fail in typical situations, but if they did, fd.c could get quite confused.

- Fix incorrect check for whether postmaster is running as a Windows service (Michael Paquier)
  This could result in attempting to write to the event log when that isn’t accessible, so that no logging happens at all.

- Fix ecpg to support COMMIT PREPARED and ROLLBACK PREPARED (Masahiko Sawada)

- Fix a double-free error when processing dollar-quoted string literals in ecpg (Michael Meskes)

- In pg_dump, fix incorrect schema and owner marking for comments and security labels of some types of database objects (Giuseppe Broccolo, Tom Lane)
  In simple cases this caused no ill effects; but for example, a schema-selective restore might omit comments it should include, because they were not marked as belonging to the schema of their associated object.

- Avoid emitting an invalid list file in pg_restore -l when SQL object names contain newlines (Tom Lane)
  Replace newlines by spaces, which is sufficient to make the output valid for pg_restore -L’s purposes.

- Fix pg_upgrade to transfer comments and security labels attached to “large objects” (blobs) (Stephen Frost)
  Previously, blobs were correctly transferred to the new database, but any comments or security labels attached to them were lost.

- Improve error handling in contrib/adminpack’s pg_file_write() function (Noah Misch)
  Notably, it failed to detect errors reported by fclose().

- In contrib/dblink, avoid leaking the previous unnamed connection when establishing a new unnamed connection (Joe Conway)

- Fix contrib/pg_trgm’s extraction of trigrams from regular expressions (Tom Lane)
  In some cases it would produce a broken data structure that could never match anything, leading to GIN or GiST indexscans that use a trigram index not finding any matches to the regular expression.

- In contrib/postgres_fdw, transmit query cancellation requests to the remote server (Michael Paquier, Etsuro Fujita)
  Previously, a local query cancellation request did not cause an already-sent remote query to terminate early. This is a back-patch of work originally done for 9.6.

- Support OpenSSL 1.1.0 (Heikki Linnakangas, Andreas Karlsson, Tom Lane)
  This is a back-patch of work previously done in newer branches; it’s needed since many platforms are adopting newer OpenSSL versions.
• Support Tcl 8.6 in MSVC builds (Álvaro Herrera)

• Sync our copy of the timezone library with IANA release tzcode2017b (Tom Lane)
  This fixes a bug affecting some DST transitions in January 2038.

• Update time zone data files to tzdata release 2017b for DST law changes in Chile, Haiti, and Mongolia, plus historical corrections for Ecuador, Kazakhstan, Liberia, and Spain. Switch to numeric abbreviations for numerous time zones in South America, the Pacific and Indian oceans, and some Asian and Middle Eastern countries.

  The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the \texttt{pg\_timezone\_names} view nor used for output.

• Use correct daylight-savings rules for POSIX-style time zone names in MSVC builds (David Rowley)
  The Microsoft MSVC build scripts neglected to install the \texttt{posixrules} file in the timezone directory tree. This resulted in the timezone code falling back to its built-in rule about what DST behavior to assume for a POSIX-style time zone name. For historical reasons that still corresponds to the DST rules the USA was using before 2007 (i.e., change on first Sunday in April and last Sunday in October). With this fix, a POSIX-style zone name will use the current and historical DST transition dates of the \texttt{US/Eastern} zone. If you don’t want that, remove the \texttt{posixrules} file, or replace it with a copy of some other zone file (see Section 8.5.3). Note that due to caching, you may need to restart the server to get such changes to take effect.

\section*{E.31. Release 9.3.16}

Release date: 2017-02-09

This release contains a variety of fixes from 9.3.15. For information about new features in the 9.3 major release, see Section E.47.

\section*{E.31.1. Migration to Version 9.3.16}

A dump/restore is not required for those running 9.3.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted indexes.

Also, if you are upgrading from a version earlier than 9.3.15, see Section E.32.
Appendix E. Release Notes

E.31.2. Changes

• Fix a race condition that could cause indexes built with CREATE INDEX CONCURRENTLY to be corrupt
  (Pavan Deolasee, Tom Lane)

  If CREATE INDEX CONCURRENTLY was used to build an index that depends on a column not previously
  indexed, then rows updated by transactions that ran concurrently with the CREATE INDEX command
  could have received incorrect index entries. If you suspect this may have happened, the most reliable
  solution is to rebuild affected indexes after installing this update.

• Unconditionally WAL-log creation of the “init fork” for an unlogged table (Michael Paquier)

  Previously, this was skipped when wal_level = minimal, but actually it’s necessary even in that case to
  ensure that the unlogged table is properly reset to empty after a crash.

• If the stats collector dies during hot standby, restart it (Takayuki Tsunakawa)

• Ensure that hot standby feedback works correctly when it’s enabled at standby server start (Ants Aasma,
  Craig Ringer)

• Check for interrupts while hot standby is waiting for a conflicting query (Simon Riggs)

• Avoid constantly respawning the autovacuum launcher in a corner case (Amit Khandekar)

  This fix avoids problems when autovacuum is nominally off and there are some tables that require
  freezing, but all such tables are already being processed by autovacuum workers.

• Fix check for when an extension member object can be dropped (Tom Lane)

  Extension upgrade scripts should be able to drop member objects, but this was disallowed for serial-
  column sequences, and possibly other cases.

• Make sure ALTER TABLE preserves index tablespace assignments when rebuilding indexes (Tom Lane,
  Michael Paquier)

  Previously, non-default settings of default_tablespace could result in broken indexes.

• Prevent dropping a foreign-key constraint if there are pending trigger events for the referenced relation
  (Tom Lane)

  This avoids “could not find trigger NNN” or “relation NNN has no triggers” errors.

• Fix processing of OID column when a table with OIDs is associated to a parent with OIDs via ALTER
  TABLE ... INHERIT (Amit Langote)

  The OID column should be treated the same as regular user columns in this case, but it wasn’t, leading
  to odd behavior in later inheritance changes.

• Report correct object identity during ALTER TEXT SEARCH CONFIGURATION (Artur Zakirov)

  The wrong catalog OID was reported to extensions such as logical decoding.

• Check for serializability conflicts before reporting constraint-violation failures (Thomas Munro)

  When using serializable transaction isolation, it is desirable that any error due to concurrent transac-
  tions should manifest as a serialization failure, thereby cueing the application that a retry might succeed.
  Unfortunately, this does not reliably happen for duplicate-key failures caused by concurrent insertions.
  This change ensures that such an error will be reported as a serialization error if the application explicit-
  itly checked for the presence of a conflicting key (and did not find it) earlier in the transaction.
Appendix E. Release Notes

- Prevent multicolumn expansion of `foo.*` in an `UPDATE` source expression (Tom Lane)
  This led to “UPDATE target count mismatch --- internal error”. Now the syntax is understood as a whole-row variable, as it would be in other contexts.

- Ensure that column typmods are determined accurately for multi-row `VALUES` constructs (Tom Lane)
  This fixes problems occurring when the first value in a column has a determinable typmod (e.g., length for a `varchar` value) but later values don’t share the same limit.

- Throw error for an unfinished Unicode surrogate pair at the end of a Unicode string (Tom Lane)
  Normally, a Unicode surrogate leading character must be followed by a Unicode surrogate trailing character, but the check for this was missed if the leading character was the last character in a Unicode string literal (`U$'...'`) or Unicode identifier (`U$"...'`).

- Ensure that a purely negative text search query, such as `!foo`, matches empty `tsvector`s (Tom Dunstan)
  Such matches were found by GIN index searches, but not by sequential scans or GiST index searches.

- Prevent crash when `ts_rewrite()` replaces a non-top-level subtree with an empty query (Artur Zakirov)

- Fix performance problems in `ts_rewrite()` (Tom Lane)

- Fix `ts_rewrite()`’s handling of nested NOT operators (Tom Lane)

- Fix `array_fill()` to handle empty arrays properly (Tom Lane)

- Fix one-byte buffer overrun in `quote_literal_cstr()` (Heikki Linnakangas)
  The overrun occurred only if the input consisted entirely of single quotes and/or backslashes.

- Prevent multiple calls of `pg_start_backup()` and `pg_stop_backup()` from running concurrently (Michael Paquier)
  This avoids an assertion failure, and possibly worse things, if someone tries to run these functions in parallel.

- Avoid discarding `interval-to-interval` casts that aren’t really no-ops (Tom Lane)
  In some cases, a cast that should result in zeroing out low-order `interval` fields was mistakenly deemed to be a no-op and discarded. An example is that casting from `INTERVAL MONTH` to `INTERVAL YEAR` failed to clear the months field.

- Ensure that cached plans are invalidated by changes in foreign-table options (Amit Langote, Etsuro Fujita, Ashutosh Bapat)

- Fix `pg_dump` to dump user-defined casts and transforms that use built-in functions (Stephen Frost)

- Fix possible `pg_basebackup` failure on standby server when including WAL files (Amit Kapila, Robert Haas)

- Ensure that the Python exception objects we create for PL/Python are properly reference-counted (Rafa de la Torre, Tom Lane)
  This avoids failures if the objects are used after a Python garbage collection cycle has occurred.

- Fix PL/Tcl to support triggers on tables that have `.tupno` as a column name (Tom Lane)
  This matches the (previously undocumented) behavior of PL/Tcl’s `spi_exec` and `spi_execp` commands, namely that a magic `.tupno` column is inserted only if there isn’t a real column named that.
• Allow DOS-style line endings in ~/.pgpass files, even on Unix (Vik Fearing)
  This change simplifies use of the same password file across Unix and Windows machines.
• Fix one-byte buffer overrun if ecpg is given a file name that ends with a dot (Takayuki Tsunakawa)
• Fix psql’s tab completion for ALTER DEFAULT PRIVILEGES (Gilles Darold, Stephen Frost)
• In psql, treat an empty or all-blank setting of the PAGER environment variable as meaning “no pager” (Tom Lane)
  Previously, such a setting caused output intended for the pager to vanish entirely.
• Improve contrib/dblink’s reporting of low-level libpq errors, such as out-of-memory (Joe Conway)
• Teach contrib/dblink to ignore irrelevant server options when it uses a contrib/postgres_fdw foreign server as the source of connection options (Corey Huinker)
  Previously, if the foreign server object had options that were not also libpq connection options, an error occurred.
• On Windows, ensure that environment variable changes are propagated to DLLs built with debug options (Christian Ullrich)
• Sync our copy of the timezone library with IANA release tzcode2016j (Tom Lane)
  This fixes various issues, most notably that timezone data installation failed if the target directory didn’t support hard links.
• Update time zone data files to tzdata release 2016j for DST law changes in northern Cyprus (adding a new zone Asia/Famagusta), Russia (adding a new zone Europe/Saratov), Tonga, and Antarctica/Casey. Historical corrections for Italy, Kazakhstan, Malta, and Palestine. Switch to preferring numeric zone abbreviations for Tonga.

E.32. Release 9.3.15

Release date: 2016-10-27

This release contains a variety of fixes from 9.3.14. For information about new features in the 9.3 major release, see Section E.47.

E.32.1. Migration to Version 9.3.15

A dump/restore is not required for those running 9.3.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted free space maps.

Also, if you are upgrading from a version earlier than 9.3.9, see Section E.38.
E.32.2. Changes

• Fix WAL-logging of truncation of relation free space maps and visibility maps (Pavan Deolasee, Heikki Linnakangas)

It was possible for these files to not be correctly restored during crash recovery, or to be written incorrectly on a standby server. Bogus entries in a free space map could lead to attempts to access pages that have been truncated away from the relation itself, typically producing errors like “could not read block xxx: read only 0 of 8192 bytes”. Checksum failures in the visibility map are also possible, if checksumming is enabled.

Procedures for determining whether there is a problem and repairing it if so are discussed at https://wiki.postgresql.org/wiki/Free_Space_Map_Problems.

• Fix SELECT FOR UPDATE/SHARE to correctly lock tuples that have been updated by a subsequently-aborted transaction (Álvaro Herrera)

In 9.5 and later, the SELECT would sometimes fail to return such tuples at all. A failure has not been proven to occur in earlier releases, but might be possible with concurrent updates.

• Fix EvalPlanQual rechecks involving CTE scans (Tom Lane)

The recheck would always see the CTE as returning no rows, typically leading to failure to update rows that were recently updated.

• Fix improper repetition of previous results from hashed aggregation in a subquery (Andrew Gierth)

The test to see if we can reuse a previously-computed hash table of the aggregate state values neglected the possibility of an outer query reference appearing in an aggregate argument expression. A change in the value of such a reference should lead to recalculating the hash table, but did not.

• Fix EXPLAIN to emit valid XML when track_io_timing is on (Markus Winand)

Previously the XML output-format option produced syntactically invalid tags such as <I/O-Read-Time>. That is now rendered as <I-O-Read-Time>.

• Suppress printing of zeroes for unmeasured times in EXPLAIN (Maksim Milyutin)

Certain option combinations resulted in printing zero values for times that actually aren’t ever measured in that combination. Our general policy in EXPLAIN is not to print such fields at all, so do that consistently in all cases.

• Fix timeout length when VACUUM is waiting for exclusive table lock so that it can truncate the table (Simon Riggs)

The timeout was meant to be 50 milliseconds, but it was actually only 50 microseconds, causing VACUUM to give up on truncation much more easily than intended. Set it to the intended value.

• Fix bugs in merging inherited CHECK constraints while creating or altering a table (Tom Lane, Amit Langote)

Allow identical CHECK constraints to be added to a parent and child table in either order. Prevent merging of a valid constraint from the parent table with a NOT VALID constraint on the child. Likewise, prevent merging of a NO INHERIT child constraint with an inherited constraint.

• Remove artificial restrictions on the values accepted by numeric_in() and numeric_recv() (Tom Lane)
Appendix E. Release Notes

We allow numeric values up to the limit of the storage format (more than \(10^{100000}\)), so it seems fairly pointless that `numeric_in()` rejected scientific-notation exponents above 1000. Likewise, it was silly for `numeric_recv()` to reject more than 1000 digits in an input value.

- Avoid very-low-probability data corruption due to testing tuple visibility without holding buffer lock (Thomas Munro, Peter Geoghegan, Tom Lane)
- Fix file descriptor leakage when truncating a temporary relation of more than 1GB (Andres Freund)
- Disallow starting a standalone backend with `standby_mode` turned on (Michael Paquier)
  This can’t do anything useful, since there will be no WAL receiver process to fetch more WAL data; and it could result in misbehavior in code that wasn’t designed with this situation in mind.
- Don’t try to share SSL contexts across multiple connections in `libpq` (Heikki Linnakangas)
  This led to assorted corner-case bugs, particularly when trying to use different SSL parameters for different connections.
- Avoid corner-case memory leak in `libpq` (Tom Lane)
  The reported problem involved leaking an error report during `PQreset()`, but there might be related cases.
- Make `ecpg`’s `--help` and `--version` options work consistently with our other executables (Haribabu Kommi)
- In `pg_dump`, never dump range constructor functions (Tom Lane)
  This oversight led to `pg_upgrade` failures with extensions containing range types, due to duplicate creation of the constructor functions.
- In `pg_xlogdump`, retry opening new WAL segments when using `--follow` option (Magnus Hagander)
  This allows for a possible delay in the server’s creation of the next segment.
- Fix `pg_xlogdump` to cope with a WAL file that begins with a continuation record spanning more than one page (Pavan Deolasee)
- Fix `contrib/intarray/bench/bench.pl` to print the results of the `EXPLAIN` it does when given the `--e` option (Daniel Gustafsson)
- Update Windows time zone mapping to recognize some time zone names added in recent Windows versions (Michael Paquier)
- Prevent failure of obsolete dynamic time zone abbreviations (Tom Lane)
  If a dynamic time zone abbreviation does not match any entry in the referenced time zone, treat it as equivalent to the time zone name. This avoids unexpected failures when IANA removes abbreviations from their time zone database, as they did in tzdata release 2016f and seem likely to do again in the future. The consequences were not limited to not recognizing the individual abbreviation; any mismatch caused the `pg_timezone_abbrevs` view to fail altogether.
- Update time zone data files to tzdata release 2016h for DST law changes in Palestine and Turkey, plus historical corrections for Turkey and some regions of Russia. Switch to numeric abbreviations for some time zones in Antarctica, the former Soviet Union, and Sri Lanka.
  The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no
Appendix E. Release Notes

Evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the `pg_timezone_names` view nor used for output.

In this update, **AMT** is no longer shown as being in use to mean Armenia Time. Therefore, we have changed the Default abbreviation set to interpret it as Amazon Time, thus UTC-4 not UTC+4.

**E.33. Release 9.3.14**

**Release date:** 2016-08-11

This release contains a variety of fixes from 9.3.13. For information about new features in the 9.3 major release, see Section E.47.

**E.33.1. Migration to Version 9.3.14**

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.9, see Section E.38.

**E.33.2. Changes**

- Fix possible mis-evaluation of nested `CASE-WHEN` expressions (Heikki Linnakangas, Michael Paquier, Tom Lane)

  A `CASE` expression appearing within the test value subexpression of another `CASE` could become confused about whether its own test value was null or not. Also, inlining of a SQL function implementing the equality operator used by a `CASE` expression could result in passing the wrong test value to functions called within a `CASE` expression in the SQL function’s body. If the test values were of different data types, a crash might result; moreover such situations could be abused to allow disclosure of portions of server memory. (CVE-2016-5423)

- Fix client programs’ handling of special characters in database and role names (Noah Misch, Nathan Bossart, Michael Paquier)

  Numerous places in vacuumdb and other client programs could become confused by database and role names containing double quotes or backslashes. Tighten up quoting rules to make that safe. Also, ensure that when a conninfo string is used as a database name parameter to these programs, it is correctly treated as such throughout.

  Fix handling of paired double quotes in `psql`’s `\connect` and `\password` commands to match the documentation.

  Introduce a new `-reuse-previous` option in `psql`’s `\connect` command to allow explicit control of whether to re-use connection parameters from a previous connection. (Without this, the choice is based on whether the database name looks like a conninfo string, as before.) This allows secure handling of database names containing special characters in `pg_dumpall` scripts.
pg_dumpall now refuses to deal with database and role names containing carriage returns or newlines, as it seems impractical to quote those characters safely on Windows. In future we may reject such names on the server side, but that step has not been taken yet.

These are considered security fixes because crafted object names containing special characters could have been used to execute commands with superuser privileges the next time a superuser executes pg_dumpall or other routine maintenance operations. (CVE-2016-5424)

- Fix corner-case misbehaviors for `IS NULL/IS NOT NULL` applied to nested composite values (Andrew Gierth, Tom Lane)

  The SQL standard specifies that `IS NULL` should return TRUE for a row of all null values (thus `ROW(NULL,NULL) IS NULL` yields TRUE), but this is not meant to apply recursively (thus `ROW(NULL, ROW(NULL,NULL)) IS NULL` yields FALSE). The core executor got this right, but certain planner optimizations treated the test as recursive (thus producing TRUE in both cases), and contrib/postgres_fdw could produce remote queries that misbehaved similarly.

- Make the `inet` and `cidr` data types properly reject IPv6 addresses with too many colon-separated fields (Tom Lane)

- Prevent crash in `close_ps()` (the point ## lseg operator) for NaN input coordinates (Tom Lane)

  Make it return NULL instead of crashing.

- Avoid possible crash in `pg_get_expr()` when inconsistent values are passed to it (Michael Paquier, Thomas Munro)

- Fix several one-byte buffer over-reads in `to_number()` (Peter Eisentraut)

  In several cases the `to_number()` function would read one more character than it should from the input string. There is a small chance of a crash, if the input happens to be adjacent to the end of memory.

- Do not run the planner on the query contained in `CREATE MATERIALIZED VIEW` or `CREATE TABLE AS` when `WITH NO DATA` is specified (Michael Paquier, Tom Lane)

  This avoids some unnecessary failure conditions, for example if a stable function invoked by the materialized view depends on a table that doesn’t exist yet.

- Avoid unsafe intermediate state during expensive paths through `heap_update()` (Masahiko Sawada, Andres Freund)

  Previously, these cases locked the target tuple (by setting its XMAX) but did not WAL-log that action, thus risking data integrity problems if the page were spilled to disk and then a database crash occurred before the tuple update could be completed.

- Fix hint bit update during WAL replay of row locking operations (Andres Freund)

  The only known consequence of this problem is that row locks held by a prepared, but uncommitted, transaction might fail to be enforced after a crash and restart.

- Avoid unnecessary “could not serialize access” errors when acquiring `FOR KEY SHARE` row locks in serializable mode (Álvaro Herrera)

- Avoid crash in `postgres -C` when the specified variable has a null string value (Michael Paquier)

- Ensure that backends see up-to-date statistics for shared catalogs (Tom Lane)
Appendix E. Release Notes

The statistics collector failed to update the statistics file for shared catalogs after a request from a regular backend. This problem was partially masked because the autovacuum launcher regularly makes requests that did cause such updates; however, it became obvious with autovacuum disabled.

- Avoid redundant writes of the statistics files when multiple backends request updates close together (Tom Lane, Tomas Vondra)
- Avoid consuming a transaction ID during VACUUM (Alexander Korotkov)
  Some cases in VACUUM unnecessarily caused an XID to be assigned to the current transaction. Normally this is negligible, but if one is up against the XID wraparound limit, consuming more XIDs during anti-wraparound vacuums is a very bad thing.
- Avoid canceling hot-standby queries during VACUUM FREEZE (Simon Riggs, Álvaro Herrera)
  VACUUM FREEZE on an otherwise-idle master server could result in unnecessary cancellations of queries on its standby servers.
- Prevent possible failure when vacuuming multixact IDs in an installation that has been pg_upgrade’d from pre-9.3 (Andrew Gierth, Álvaro Herrera)
  The usual symptom of this bug is errors like “MultiXactId NNN has not been created yet -- apparent wraparound”.
- When a manual ANALYZE specifies a column list, don’t reset the table’s changes_since_analyze counter (Tom Lane)
  If we’re only analyzing some columns, we should not prevent routine auto-analyze from happening for the other columns.
- Fix ANALYZE’s overestimation of n_distinct for a unique or nearly-unique column with many null entries (Tom Lane)
  The nulls could get counted as though they were themselves distinct values, leading to serious planner misestimates in some types of queries.
- Prevent autovacuum from starting multiple workers for the same shared catalog (Álvaro Herrera)
  Normally this isn’t much of a problem because the vacuum doesn’t take long anyway; but in the case of a severely bloated catalog, it could result in all but one worker uselessly waiting instead of doing useful work on other tables.
- Prevent infinite loop in GiST index build for geometric columns containing NaN component values (Tom Lane)
- Fix contrib/btree_gin to handle the smallest possible bigint value correctly (Peter Eisentraut)
- Teach libpq to correctly decode server version from future servers (Peter Eisentraut)
  It’s planned to switch to two-part instead of three-part server version numbers for releases after 9.6. Make sure that PQserverVersion() returns the correct value for such cases.
- Fix ecpg’s code for unsigned long long array elements (Michael Meskes)
- In pg_dump with both -c and -C options, avoid emitting an unwanted CREATE SCHEMA public command (David Johnston, Tom Lane)
- Improve handling of SIGTERM/control-C in parallel pg_dump and pg_restore (Tom Lane)
  Make sure that the worker processes will exit promptly, and also arrange to send query-cancel requests to the connected backends, in case they are doing something long-running such as a CREATE INDEX.
• Fix error reporting in parallel pg_dump and pg_restore (Tom Lane)
  Previously, errors reported by pg_dump or pg_restore worker processes might never make it to the
  user’s console, because the messages went through the master process, and there were various deadlock
  scenarios that would prevent the master process from passing on the messages. Instead, just print ev-
  erything to stderr. In some cases this will result in duplicate messages (for instance, if all the workers
  report a server shutdown), but that seems better than no message.

• Ensure that parallel pg_dump or pg_restore on Windows will shut down properly after an error (Kyotaro
  Horiguchi)
  Previously, it would report the error, but then just sit until manually stopped by the user.

• Make pg_dump behave better when built without zlib support (Kyotaro Horiguchi)
  It didn’t work right for parallel dumps, and emitted some rather pointless warnings in other cases.

• Make pg_basebackup accept \-Z 0 as specifying no compression (Fujii Masao)

• Fix makefiles’ rule for building AIX shared libraries to be safe for parallel make (Noah Misch)

• Fix TAP tests and MSVC scripts to work when build directory’s path name contains spaces (Michael
  Paquier, Kyotaro Horiguchi)

• Be more predictable about reporting “statement timeout” versus “lock timeout” (Tom Lane)
  On heavily loaded machines, the regression tests sometimes failed due to reporting “lock timeout” even
  though the statement timeout should have occurred first.

• Make regression tests safe for Danish and Welsh locales (Jeff Janes, Tom Lane)
  Change some test data that triggered the unusual sorting rules of these locales.

• Update our copy of the timezone code to match IANA’s tzcode release 2016c (Tom Lane)
  This is needed to cope with anticipated future changes in the time zone data files. It also fixes some
  corner-case bugs in coping with unusual time zones.

• Update time zone data files to tzdata release 2016f for DST law changes in Kemerovo and Novosibirsk,
  plus historical corrections for Azerbaijan, Belarus, and Morocco.

E.34. Release 9.3.13

Release date: 2016-05-12

This release contains a variety of fixes from 9.3.12. For information about new features in the 9.3 major
release, see Section E.47.

E.34.1. Migration to Version 9.3.13

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.9, see Section E.38.

E.34.2. Changes

• Clear the OpenSSL error queue before OpenSSL calls, rather than assuming it’s clear already; and make sure we leave it clear afterwards (Peter Geoghegan, Dave Vitek, Peter Eisentraut)

This change prevents problems when there are multiple connections using OpenSSL within a single process and not all the code involved follows the same rules for when to clear the error queue. Failures have been reported specifically when a client application uses SSL connections in libpq concurrently with SSL connections using the PHP, Python, or Ruby wrappers for OpenSSL. It’s possible for similar problems to arise within the server as well, if an extension module establishes an outgoing SSL connection.

• Fix “failed to build any N-way joins” planner error with a full join enclosed in the right-hand side of a left join (Tom Lane)

• Fix incorrect handling of equivalence-class tests in multilevel nestloop plans (Tom Lane)

Given a three-or-more-way equivalence class of variables, such as $X.X = Y.Y = Z.Z$, it was possible for the planner to omit some of the tests needed to enforce that all the variables are actually equal, leading to join rows being output that didn’t satisfy the WHERE clauses. For various reasons, erroneous plans were seldom selected in practice, so that this bug has gone undetected for a long time.

• Fix possible misbehavior of $TH$, $th$, and $Y$, $YYY$ format codes in to_timestamp() (Tom Lane)

These could advance off the end of the input string, causing subsequent format codes to read garbage.

• Fix dumping of rules and views in which the array argument of a value operator ANY (array) construct is a sub-SELECT (Tom Lane)

• Make pg_regress use a startup timeout from the PGCTLTIMEOUT environment variable, if that’s set (Tom Lane)

This is for consistency with a behavior recently added to pg_ctl; it eases automated testing on slow machines.

• Fix pg_upgrade to correctly restore extension membership for operator families containing only one operator class (Tom Lane)

In such a case, the operator family was restored into the new database, but it was no longer marked as part of the extension. This had no immediate ill effects, but would cause later pg_dump runs to emit output that would cause (harmless) errors on restore.

• Fix pg_upgrade to not fail when new-cluster TOAST rules differ from old (Tom Lane)

pg_upgrade had special-case code to handle the situation where the new PostgreSQL version thinks that a table should have a TOAST table while the old version did not. That code was broken, so remove it, and instead do nothing in such cases; there seems no reason to believe that we can’t get along fine without a TOAST table if that was okay according to the old version’s rules.

• Back-port 9.4-era memory-barrier code changes into 9.2 and 9.3 (Tom Lane)

These changes were not originally needed in pre-9.4 branches, but we recently back-patched a fix that expected the barrier code to work properly. Only IA64 (when using icc), HPPA, and Alpha platforms are affected.

• Reduce the number of SysV semaphores used by a build configured with --disable-spinlocks (Tom Lane)
Appendix E. Release Notes

• Rename internal function `strtoi()` to `strtoint()` to avoid conflict with a NetBSD library function (Thomas Munro)
• Fix reporting of errors from `bind()` and `listen()` system calls on Windows (Tom Lane)
• Reduce verbosity of compiler output when building with Microsoft Visual Studio (Christian Ullrich)
• Fix `putenv()` to work properly with Visual Studio 2013 (Michael Paquier)
• Avoid possibly-unsafe use of Windows’ `FormatMessage()` function (Christian Ullrich)
  Use the `FORMAT_MESSAGE_IGNORE_INSERTS` flag where appropriate. No live bug is known to exist here, but it seems like a good idea to be careful.
• Update time zone data files to tzdata release 2016d for DST law changes in Russia and Venezuela. There are new zone names `Europe/Kirov` and `Asia/Tomsk` to reflect the fact that these regions now have different time zone histories from adjacent regions.

E.35. Release 9.3.12

Release date: 2016-03-31
This release contains a variety of fixes from 9.3.11. For information about new features in the 9.3 major release, see Section E.47.

E.35.1. Migration to Version 9.3.12
A dump/restore is not required for those running 9.3.X.
However, if you are upgrading from a version earlier than 9.3.9, see Section E.38.

E.35.2. Changes

• Fix incorrect handling of NULL index entries in indexed `ROW()` comparisons (Tom Lane)
  An index search using a row comparison such as `ROW(a, b) > ROW(’x’, ’y’)` would stop upon reaching a NULL entry in the `b` column, ignoring the fact that there might be non-NULL `b` values associated with later values of `a`.
• Avoid unlikely data-loss scenarios due to renaming files without adequate `fsync()` calls before and after (Michael Paquier, Tomas Vondra, Andres Freund)
• Correctly handle cases where `pg_subtrans` is close to XID wraparound during server startup (Jeff Janes)
• Fix corner-case crash due to trying to free `localeconv()` output strings more than once (Tom Lane)
• Fix parsing of affix files for `ispell` dictionaries (Tom Lane)
  The code could go wrong if the affix file contained any characters whose byte length changes during case-folding, for example I in Turkish UTF8 locales.
Appendix E. Release Notes

• Avoid use of `sscanf()` to parse `ispell` dictionary files (Artur Zakirov)
  This dodges a portability problem on FreeBSD-derived platforms (including macOS).

• Avoid a crash on old Windows versions (before 7SP1/2008R2SP1) with an AVX2-capable CPU and a
  Postgres build done with Visual Studio 2013 (Christian Ullrich)
  This is a workaround for a bug in Visual Studio 2013’s runtime library, which Microsoft have stated
  they will not fix in that version.

• Fix `psql`'s tab completion logic to handle multibyte characters properly (Kyotaro Horiguchi, Robert
  Haas)

• Fix `psql`'s tab completion for `SECURITY LABEL` (Tom Lane)
  Pressing TAB after `SECURITY LABEL` might cause a crash or offering of inappropriate keywords.

• Make `pg_ctl` accept a wait timeout from the `PGCTLTIMEOUT` environment variable, if none is specified
  on the command line (Noah Misch)
  This eases testing of slower buildfarm members by allowing them to globally specify a longer-than-
  normal timeout for postmaster startup and shutdown.

• Fix incorrect test for Windows service status in `pg_ctl` (Manuel Mathar)
  The previous set of minor releases attempted to fix `pg_ctl` to properly determine whether to send log
  messages to Window’s Event Log, but got the test backwards.

• Fix `pgbench` to correctly handle the combination of `-C` and `-M` prepared options (Tom Lane)

• In `pg_upgrade`, skip creating a deletion script when the new data directory is inside the old data directory
  (Bruce Momjian)
  Blind application of the script in such cases would result in loss of the new data directory.

• In PL/Perl, properly translate empty Postgres arrays into empty Perl arrays (Alex Hunsaker)

• Make PL/Python cope with function names that aren’t valid Python identifiers (Jim Nasby)

• Fix multiple mistakes in the statistics returned by `contrib/pgstattuple`'s `pgstatindex()` function
  (Tom Lane)

• Remove dependency on `psed` in MSVC builds, since it’s no longer provided by core Perl (Michael
  Paquier, Andrew Dunstan)

• Update time zone data files to `tzdata` release 2016c for DST law changes in Azerbaijan, Chile, Haiti,
  Palestine, and Russia (Altai, Astrakhan, Kirov, Sakhalin, Ulyanovsk regions), plus historical corrections
  for Lithuania, Moldova, and Russia (Kaliningrad, Samara, Volgograd).

E.36. Release 9.3.11

Release date: 2016-02-11

This release contains a variety of fixes from 9.3.10. For information about new features in the 9.3 major
release, see Section E.47.
E.36.1. Migration to Version 9.3.11

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.9, see Section E.38.

E.36.2. Changes

• Fix infinite loops and buffer-overrun problems in regular expressions (Tom Lane)
  
  Very large character ranges in bracket expressions could cause infinite loops in some cases, and memory overwrites in other cases. (CVE-2016-0773)

• Perform an immediate shutdown if the postmaster.pid file is removed (Tom Lane)
  
  The postmaster now checks every minute or so that postmaster.pid is still there and still contains its own PID. If not, it performs an immediate shutdown, as though it had received SIGQUIT. The main motivation for this change is to ensure that failed buildfarm runs will get cleaned up without manual intervention; but it also serves to limit the bad effects if a DBA forcibly removes postmaster.pid and then starts a new postmaster.

• In SERIALIZABLE transaction isolation mode, serialization anomalies could be missed due to race conditions during insertions (Kevin Grittner, Thomas Munro)

• Fix failure to emit appropriate WAL records when doing ALTER TABLE ... SET TABLESPACE for unlogged relations (Michael Paquier, Andres Freund)
  
  Even though the relation’s data is unlogged, the move must be logged or the relation will be inaccessible after a standby is promoted to master.

• Fix possible misinitialization of unlogged relations at the end of crash recovery (Andres Freund, Michael Paquier)

• Ensure walsender slots are fully re-initialized when being re-used (Magnus Hagander)

• Fix ALTER COLUMN TYPE to reconstruct inherited check constraints properly (Tom Lane)

• Fix REASSIGN OWNED to change ownership of composite types properly (Álvaro Herrera)

• Fix REASSIGN OWNED and ALTER OWNER to correctly update granted-permissions lists when changing owners of data types, foreign data wrappers, or foreign servers (Bruce Momjian, Álvaro Herrera)

• Fix REASSIGN OWNED to ignore foreign user mappings, rather than fail (Álvaro Herrera)

• Fix possible crash after doing query rewrite for an updatable view (Stephen Frost)

• Fix planner’s handling of LATERAL references (Tom Lane)
  
  This fixes some corner cases that led to “failed to build any N-way joins” or “could not devise a query plan” planner failures.

• Add more defenses against bad planner cost estimates for GIN index scans when the index’s internal statistics are very out-of-date (Tom Lane)

• Make planner cope with hypothetical GIN indexes suggested by an index advisor plug-in (Julien Rouhaud)
Appendix E. Release Notes

- Speed up generation of unique table aliases in `EXPLAIN` and rule dumping, and ensure that generated aliases do not exceed `NAMEDATALEN` (Tom Lane)

- Fix dumping of whole-row Vars in `ROW()` and `VALUES()` lists (Tom Lane)

- Fix possible internal overflow in numeric division (Dean Rasheed)

- Fix enforcement of restrictions inside parentheses within regular expression lookahead constraints (Tom Lane)

  Lookahead constraints aren’t allowed to contain backrefs, and parentheses within them are always considered non-capturing, according to the manual. However, the code failed to handle these cases properly inside a parenthesized subexpression, and would give unexpected results.

- Conversion of regular expressions to indexscan bounds could produce incorrect bounds from regexps containing lookahead constraints (Tom Lane)

- Fix regular-expression compiler to handle loops of constraint arcs (Tom Lane)

  The code added for CVE-2007-4772 was both incomplete, in that it didn’t handle loops involving more than one state, and incorrect, in that it could cause assertion failures (though there seem to be no bad consequences of that in a non-assert build). Multi-state loops would cause the compiler to run until the query was canceled or it reached the too-many-states error condition.

- Improve memory-usage accounting in regular-expression compiler (Tom Lane)

  This causes the code to emit “regular expression is too complex” errors in some cases that previously used unreasonable amounts of time and memory.

- Improve performance of regular-expression compiler (Tom Lane)

- Make `%h` and `%r` escapes in `log_line_prefix` work for messages emitted due to `log_connections` (Tom Lane)

  Previously, `%h/%r` started to work just after a new session had emitted the “connection received” log message; now they work for that message too.

- On Windows, ensure the shared-memory mapping handle gets closed in child processes that don’t need it (Tom Lane, Amit Kapila)

  This oversight resulted in failure to recover from crashes whenever `logging_collector` is turned on.

- Fix possible failure to detect socket EOF in non-blocking mode on Windows (Tom Lane)

  It’s not entirely clear whether this problem can happen in pre-9.5 branches, but if it did, the symptom would be that a walsender process would wait indefinitely rather than noticing a loss of connection.

- Avoid leaking a token handle during SSPI authentication (Christian Ullrich)

- In `psql`, ensure that `libreadline`’s idea of the screen size is updated when the terminal window size changes (Merlin Moncure)

  Previously, `libreadline` did not notice if the window was resized during query output, leading to strange behavior during later input of multiline queries.

- Fix `psql`’s `\det` command to interpret its pattern argument the same way as other `\d` commands with potentially schema-qualified patterns do (Reece Hart)

- Avoid possible crash in `psql`’s `\c` command when previous connection was via Unix socket and command specifies a new hostname and same username (Tom Lane)
• In `pg_ctl start -w`, test child process status directly rather than relying on heuristics (Tom Lane, Michael Paquier)

Previously, `pg_ctl` relied on an assumption that the new postmaster would always create `postmaster.pid` within five seconds. But that can fail on heavily-loaded systems, causing `pg_ctl` to report incorrectly that the postmaster failed to start.

Except on Windows, this change also means that a `pg_ctl start -w` done immediately after another such command will now reliably fail, whereas previously it would report success if done within two seconds of the first command.

• In `pg_ctl start -w`, don’t attempt to use a wildcard listen address to connect to the postmaster (Kondo Yuta)

On Windows, `pg_ctl` would fail to detect postmaster startup if `listen_addresses` is set to `0.0.0.0` or `::`, because it would try to use that value verbatim as the address to connect to, which doesn’t work. Instead assume that `127.0.0.1` or `::1`, respectively, is the right thing to use.

• In `pg_ctl` on Windows, check service status to decide where to send output, rather than checking if standard output is a terminal (Michael Paquier)

• In `pg_dump` and `pg_basebackup`, adopt the GNU convention for handling tar-archive members exceeding 8GB (Tom Lane)

The POSIX standard for `tar` file format does not allow archive member files to exceed 8GB, but most modern implementations of tar support an extension that fixes that. Adopt this extension so that `pg_dump` with `-Ft` no longer fails on tables with more than 8GB of data, and so that `pg_basebackup` can handle files larger than 8GB. In addition, fix some portability issues that could cause failures for members between 4GB and 8GB on some platforms. Potentially these problems could cause unrecoverable data loss due to unreadable backup files.

• Fix assorted corner-case bugs in `pg_dump`’s processing of extension member objects (Tom Lane)

• Make `pg_dump` mark a view’s triggers as needing to be processed after its rule, to prevent possible failure during parallel `pg_restore` (Tom Lane)

• Ensure that relation option values are properly quoted in `pg_dump` (Kouhei Sutou, Tom Lane)

A reloption value that isn’t a simple identifier or number could lead to dump/reload failures due to syntax errors in CREATE statements issued by `pg_dump`. This is not an issue with any reloption currently supported by core PostgreSQL, but extensions could allow reloptions that cause the problem.

• Avoid repeated password prompts during parallel `pg_dump` (Zeus Kronion)

• Fix `pg_upgrade`’s file-copying code to handle errors properly on Windows (Bruce Momjian)

• Install guards in `pgbench` against corner-case overflow conditions during evaluation of script-specified division or modulo operators (Fabien Coelho, Michael Paquier)

• Fix failure to localize messages emitted by `pg_receivexlog` and `pg_recvlogical` (Ioseph Kim)

• Avoid dump/reload problems when using both plpython2 and plpython3 (Tom Lane)

In principle, both versions of PL/Python can be used in the same database, though not in the same session (because the two versions of libpython cannot safely be used concurrently). However, `pg_restore` and `pg_upgrade` both do things that can fall foul of the same-session restriction. Work around that by changing the timing of the check.

• Fix PL/Python regression tests to pass with Python 3.5 (Peter Eisentraut)
Appendix E. Release Notes

• Fix premature clearing of libpq’s input buffer when socket EOF is seen (Tom Lane)
  This mistake caused libpq to sometimes not report the backend’s final error message before reporting
  “server closed the connection unexpectedly”.

• Prevent certain PL/Java parameters from being set by non-superusers (Noah Misch)
  This change mitigates a PL/Java security bug (CVE-2016-0766), which was fixed in PL/Java by mark-
  ing these parameters as superuser-only. To fix the security hazard for sites that update PostgreSQL more
  frequently than PL/Java, make the core code aware of them also.

• Improve libpq’s handling of out-of-memory situations (Michael Paquier, Amit Kapila, Heikki Lin-
  nakangas)

• Fix order of arguments in ecpg-generated typedef statements (Michael Meskes)

• Use %g not %f format in ecpg’s PGTYPEnumeric_from_double() (Tom Lane)

• Fix ecpg-supplied header files to not contain comments continued from a preprocessor directive line
  onto the next line (Michael Meskes)
  Such a comment is rejected by ecpg. It’s not yet clear whether ecpg itself should be changed.

• Fix hstore_to_json_loose()’s test for whether an hstore value can be converted to a JSON
  number (Tom Lane)
  Previously this function could be fooled by non-alphanumeric trailing characters, leading to emitting
  syntactically-invalid JSON.

• Ensure that contrib/pgcrypto’s crypt() function can be interrupted by query cancel (Andreas
  Karlsson)

• Accept flex versions later than 2.5.x (Tom Lane, Michael Paquier)
  Now that flex 2.6.0 has been released, the version checks in our build scripts needed to be adjusted.

• Improve reproducibility of build output by ensuring filenames are given to the linker in a fixed order
  (Christoph Berg)
  This avoids possible bitwise differences in the produced executable files from one build to the next.

• Install our missing script where PGXS builds can find it (Jim Nasby)
  This allows sane behavior in a PGXS build done on a machine where build tools such as bison are
  missing.

• Ensure that dynloader.h is included in the installed header files in MSVC builds (Bruce Momjian,
  Michael Paquier)

• Add variant regression test expected-output file to match behavior of current libxml2 (Tom Lane)
  The fix for libxml2’s CVE-2015-7499 causes it not to output error context reports in some cases where
  it used to do so. This seems to be a bug, but we’ll probably have to live with it for some time, so work
  around it.

• Update time zone data files to tzdata release 2016a for DST law changes in Cayman Islands, Metlakatla,
  and Trans-Baikal Territory (Zabaykalsky Krai), plus historical corrections for Pakistan.
E.37. Release 9.3.10

Release date: 2015-10-08

This release contains a variety of fixes from 9.3.9. For information about new features in the 9.3 major release, see Section E.47.

E.37.1. Migration to Version 9.3.10

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.9, see Section E.38.

E.37.2. Changes

- Guard against stack overflows in json parsing (Oskari Saarenmaa)
  If an application constructs PostgreSQL json or jsonb values from arbitrary user input, the application’s users can reliably crash the PostgreSQL server, causing momentary denial of service. (CVE-2015-5289)

- Fix contrib/pgcrypto to detect and report too-short crypt() salts (Josh Kupershmidt)
  Certain invalid salt arguments crashed the server or disclosed a few bytes of server memory. We have not ruled out the viability of attacks that arrange for presence of confidential information in the disclosed bytes, but they seem unlikely. (CVE-2015-5288)

- Fix subtransaction cleanup after a portal (cursor) belonging to an outer subtransaction fails (Tom Lane, Michael Paquier)
  A function executed in an outer-subtransaction cursor could cause an assertion failure or crash by referencing a relation created within an inner subtransaction.

- Ensure all relations referred to by an updatable view are properly locked during an update statement (Dean Rasheed)

- Fix insertion of relations into the relation cache “init file” (Tom Lane)
  An oversight in a patch in the most recent minor releases caused pg_trigger_tgrelid_tgname_index to be omitted from the init file. Subsequent sessions detected this, then deemed the init file to be broken and silently ignored it, resulting in a significant degradation in session startup time. In addition to fixing the bug, install some guards so that any similar future mistake will be more obvious.

- Avoid O(N^2) behavior when inserting many tuples into a SPI query result (Neil Conway)

- Improve LISTEN startup time when there are many unread notifications (Matt Newell)

- Fix performance problem when a session alters large numbers of foreign key constraints (Jan Wieck, Tom Lane)
  This was seen primarily when restoring pg_dump output for databases with many thousands of tables.

- Disable SSL renegotiation by default (Michael Paquier, Andres Freund)
While use of SSL renegotiation is a good idea in theory, we have seen too many bugs in practice, both in the underlying OpenSSL library and in our usage of it. Renegotiation will be removed entirely in 9.5 and later. In the older branches, just change the default value of `ssl_renegotiation_limit` to zero (disabled).

- Lower the minimum values of the `*_freeze_max_age` parameters (Andres Freund)
  This is mainly to make tests of related behavior less time-consuming, but it may also be of value for installations with limited disk space.
- Limit the maximum value of `wal_buffers` to 2GB to avoid server crashes (Josh Berkus)
- Avoid logging complaints when a parameter that can only be set at server start appears multiple times in `postgresql.conf`, and fix counting of line numbers after an `include_dir` directive (Tom Lane)
- Fix rare internal overflow in multiplication of numeric values (Dean Rasheed)
- Guard against hard-to-reach stack overflows involving record types, range types, `json`, `jsonb`, `tsquery`, `ltxtquery` and `query_int` (Noah Misch)
- Fix handling of `DOW` and `DOY` in datetime input (Greg Stark)
  These tokens aren’t meant to be used in datetime values, but previously they resulted in opaque internal error messages rather than “invalid input syntax”.
- Add more query-cancel checks to regular expression matching (Tom Lane)
- Add recursion depth protections to regular expression, `SIMILAR TO`, and `LIKE` matching (Tom Lane)
  Suitable search patterns and a low stack depth limit could lead to stack-overrun crashes.
- Fix potential infinite loop in regular expression execution (Tom Lane)
  A search pattern that can apparently match a zero-length string, but actually doesn’t match because of a back reference, could lead to an infinite loop.
- In regular expression execution, correctly record match data for capturing parentheses within a quantifier even when the match is zero-length (Tom Lane)
- Fix low-memory failures in regular expression compilation (Andreas Seltenreich)
- Fix low-probability memory leak during regular expression execution (Tom Lane)
- Fix rare low-memory failure in lock cleanup during transaction abort (Tom Lane)
- Fix “unexpected out-of-memory situation during sort” errors when using tuplestores with small `work_mem` settings (Tom Lane)
- Fix very-low-probability stack overrun in `qsort` (Tom Lane)
- Fix “invalid memory alloc request size” failure in hash joins with large `work_mem` settings (Tomas Vondra, Tom Lane)
- Fix assorted planner bugs (Tom Lane)
  These mistakes could lead to incorrect query plans that would give wrong answers, or to assertion failures in assert-enabled builds, or to odd planner errors such as “could not devise a query plan for the given query”, “could not find pathkey item to sort”, “plan should not reference subplan’s variable”, or “failed to assign all NestLoopParams to plan nodes”. Thanks are due to Andreas Seltenreich and Piotr Stefaniak for fuzz testing that exposed these problems.
Appendix E. Release Notes

- Improve planner’s performance for `UPDATE/DELETE` on large inheritance sets (Tom Lane, Dean Rasheed)

- Ensure standby promotion trigger files are removed at postmaster startup (Michael Paquier, Fujii Masao)

  This prevents unwanted promotion from occurring if these files appear in a database backup that is used to initialize a new standby server.

- During postmaster shutdown, ensure that per-socket lock files are removed and listen sockets are closed before we remove the `postmaster.pid` file (Tom Lane)

  This avoids race-condition failures if an external script attempts to start a new postmaster as soon as `pg_ctl stop` returns.

- Fix postmaster’s handling of a startup-process crash during crash recovery (Tom Lane)

  If, during a crash recovery cycle, the startup process crashes without having restored database consistency, we’d try to launch a new startup process, which typically would just crash again, leading to an infinite loop.

- Make emergency autovacuuming for multixact wraparound more robust (Andres Freund)

- Do not print a `WARNING` when an autovacuum worker is already gone when we attempt to signal it, and reduce log verbosity for such signals (Tom Lane)

- Prevent autovacuum launcher from sleeping unduly long if the server clock is moved backwards a large amount (Álvaro Herrera)

- Ensure that cleanup of a GIN index’s pending-insertions list is interruptable by cancel requests (Jeff Janes)

- Allow all-zeroes pages in GIN indexes to be reused (Heikki Linnakangas)

  Such a page might be left behind after a crash.

- Fix handling of all-zeroes pages in SP-GiST indexes (Heikki Linnakangas)

- `VACUUM` attempted to recycle such pages, but did so in a way that wasn’t crash-safe.

- Fix off-by-one error that led to otherwise-harmless warnings about “apparent wraparound” in subtrans/multixact truncation (Thomas Munro)

- Fix misreporting of `CONTINUE` and `MOVE` statement types in PL/pgSQL’s error context messages (Pavel Stehule, Tom Lane)

- Fix PL/Perl to handle non-ASCII error message texts correctly (Alex Hunsaker)

- Fix PL/Python crash when returning the string representation of a `record` result (Tom Lane)

- Fix some places in PL/Tcl that neglected to check for failure of `malloc()` calls (Michael Paquier, Álvaro Herrera)

- In `contrib/isn`, fix output of ISBN-13 numbers that begin with 979 (Fabien Coelho)

  EANs beginning with 979 (but not 9790) are considered ISBNs, but they must be printed in the new 13-digit format, not the 10-digit format.

- Improve `contrib/postgres_fdw`’s handling of collation-related decisions (Tom Lane)

  The main user-visible effect is expected to be that comparisons involving `varchar` columns will be sent to the remote server for execution in more cases than before.
• Improve libpq’s handling of out-of-memory conditions (Michael Paquier, Heikki Linnakangas)
• Fix memory leaks and missing out-of-memory checks in ecpg (Michael Paquier)
• Fix psql’s code for locale-aware formatting of numeric output (Tom Lane)
  The formatting code invoked by \pset numericlocale on did the wrong thing for some uncommon cases such as numbers with an exponent but no decimal point. It could also mangle already-localized output from the money data type.
• Prevent crash in psql’s \c command when there is no current connection (Noah Misch)
• Make pg_dump handle inherited NOT VALID check constraints correctly (Tom Lane)
• Fix selection of default zlib compression level in pg_dump’s directory output format (Andrew Dunstan)
• Ensure that temporary files created during a pg_dump run with tar-format output are not world-readable (Michael Paquier)
• Fix pg_dump and pg_upgrade to support cases where the postgres or template1 database is in a non-default tablespace (Marti Raudsepp, Bruce Momjian)
• Fix pg_dump to handle object privileges sanely when dumping from a server too old to have a particular privilege type (Tom Lane)
  When dumping data types from pre-9.2 servers, and when dumping functions or procedural languages from pre-7.3 servers, pg_dump would produce GRANT/REVOKE commands that revoked the owner’s grantable privileges and instead granted all privileges to PUBLIC. Since the privileges involved are just USAGE and EXECUTE, this isn’t a security problem, but it’s certainly a surprising representation of the older systems’ behavior. Fix it to leave the default privilege state alone in these cases.
• Fix pg_dump to dump shell types (Tom Lane)
  Shell types (that is, not-yet-fully-defined types) aren’t useful for much, but nonetheless pg_dump should dump them.
• Fix assorted minor memory leaks in pg_dump and other client-side programs (Michael Paquier)
• Fix spinlock assembly code for PPC hardware to be compatible with AIX’s native assembler (Tom Lane)
  Building with gcc didn’t work if gcc had been configured to use the native assembler, which is becoming more common.
• On AIX, test the -qlonglong compiler option rather than just assuming it’s safe to use (Noah Misch)
• On AIX, use -Wl,-brtllib link option to allow symbols to be resolved at runtime (Noah Misch)
  Perl relies on this ability in 5.8.0 and later.
• Avoid use of inline functions when compiling with 32-bit xlc, due to compiler bugs (Noah Misch)
• Use librt for sched_yield() when necessary, which it is on some Solaris versions (Oskari Saarenmaa)
• Fix Windows install.bat script to handle target directory names that contain spaces (Heikki Linnakangas)
• Make the numeric form of the PostgreSQL version number (e.g., 90405) readily available to extension Makefiles, as a variable named VERSION_NUM (Michael Paquier)
• Update time zone data files to tzdata release 2015g for DST law changes in Cayman Islands, Fiji, Moldova, Morocco, Norfolk Island, North Korea, Turkey, and Uruguay. There is a new zone name America/Fort_Nelson for the Canadian Northern Rockies.

E.38. Release 9.3.9

Release date: 2015-06-12

This release contains a small number of fixes from 9.3.8. For information about new features in the 9.3 major release, see Section E.47.

E.38.1. Migration to Version 9.3.9

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading an installation that was previously upgraded using a pg_upgrade version between 9.3.0 and 9.3.4 inclusive, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.3.7, see Section E.40.

E.38.2. Changes

• Fix possible failure to recover from an inconsistent database state (Robert Haas)

Recent PostgreSQL releases introduced mechanisms to protect against multixact wraparound, but some of that code did not account for the possibility that it would need to run during crash recovery, when the database may not be in a consistent state. This could result in failure to restart after a crash, or failure to start up a secondary server. The lingering effects of a previously-fixed bug in pg_upgrade could also cause such a failure, in installations that had used pg_upgrade versions between 9.3.0 and 9.3.4.

The pg_upgrade bug in question was that it would set oldestMultiXid to 1 in pg_control even if the true value should be higher. With the fixes introduced in this release, such a situation will result in immediate emergency autovacuuming until a correct oldestMultiXid value can be determined. If that would pose a hardship, users can avoid it by doing manual vacuuming before upgrading to this release. In detail:

1. Check whether pg_controldata reports “Latest checkpoint’s oldestMultiXid” to be 1. If not, there’s nothing to do.
2. Look in PGDATA/pg_multixact/offsets to see if there’s a file named 0000. If there is, there’s nothing to do.
3. Otherwise, for each table that has pg_class.relminmxid equal to 1, VACUUM that table with both vacuum_multixact_freeze_min_age and vacuum_multixact_freeze_table_age set to zero. (You can use the vacuum cost delay parameters described in Section 18.4.4 to reduce the performance consequences for concurrent sessions.) You must use PostgreSQL 9.3.5 or later to perform this step.
• Fix rare failure to invalidate relation cache init file (Tom Lane)

With just the wrong timing of concurrent activity, a `VACUUM FULL` on a system catalog might fail to update the “init file” that’s used to avoid cache-loading work for new sessions. This would result in later sessions being unable to access that catalog at all. This is a very ancient bug, but it’s so hard to trigger that no reproducible case had been seen until recently.

• Avoid deadlock between incoming sessions and `CREATE/DROP DATABASE` (Tom Lane)

A new session starting in a database that is the target of a `DROP DATABASE` command, or is the template for a `CREATE DATABASE` command, could cause the command to wait for five seconds and then fail, even if the new session would have exited before that.

• Improve planner’s cost estimates for semi-joins and anti-joins with inner indexscans (Tom Lane, Tomas Vondra)

This type of plan is quite cheap when all the join clauses are used as index scan conditions, even if the inner scan would nominally fetch many rows, because the executor will stop after obtaining one row. The planner only partially accounted for that effect, and would therefore overestimate the cost, leading it to possibly choose some other much less efficient plan type.

## E.39. Release 9.3.8

**Release date:** 2015-06-04

This release contains a small number of fixes from 9.3.7. For information about new features in the 9.3 major release, see Section E.47.

### E.39.1. Migration to Version 9.3.8

A dump/restore is not required for those running 9.3.X. However, if you are upgrading from a version earlier than 9.3.7, see Section E.40.

### E.39.2. Changes

• Avoid failures while `fsync`ing data directory during crash restart (Abhijit Menon-Sen, Tom Lane)

In the previous minor releases we added a patch to `fsync` everything in the data directory after a crash. Unfortunately its response to any error condition was to fail, thereby preventing the server from starting up, even when the problem was quite harmless. An example is that an unwritable file in the data directory would prevent restart on some platforms; but it is common to make SSL certificate files unwritable by the server. Revise this behavior so that permissions failures are ignored altogether, and other types of failures are logged but do not prevent continuing.

Also apply the same rules in `initdb --sync-only`. This case is less critical but it should act similarly.

• Fix `pg_get_functiondef()` to show functions’ `LEAKPROOF` property, if set (Jeevan Chalke)

• Remove configure’s check prohibiting linking to a threaded libpython on OpenBSD (Tom Lane)
The failure this restriction was meant to prevent seems to not be a problem anymore on current OpenBSD versions.

• Allow libpq to use TLS protocol versions beyond v1 (Noah Misch)

For a long time, libpq was coded so that the only SSL protocol it would allow was TLS v1. Now that newer TLS versions are becoming popular, allow it to negotiate the highest commonly-supported TLS version with the server. (PostgreSQL servers were already capable of such negotiation, so no change is needed on the server side.) This is a back-patch of a change already released in 9.4.0.

E.40. Release 9.3.7

Release date: 2015-05-22

This release contains a variety of fixes from 9.3.6. For information about new features in the 9.3 major release, see Section E.47.

E.40.1. Migration to Version 9.3.7

A dump/restore is not required for those running 9.3.X.

However, if you use contrib/citext’s regexp_matches() functions, see the changelog entry below about that.

Also, if you are upgrading from a version earlier than 9.3.6, see Section E.41.

E.40.2. Changes

• Avoid possible crash when client disconnects just before the authentication timeout expires (Benkocs Norbert Attila)

If the timeout interrupt fired partway through the session shutdown sequence, SSL-related state would be freed twice, typically causing a crash and hence denial of service to other sessions. Experimentation shows that an unauthenticated remote attacker could trigger the bug somewhat consistently, hence treat as security issue. (CVE-2015-3165)

• Improve detection of system-call failures (Noah Misch)

Our replacement implementation of snprintf() failed to check for errors reported by the underlying system library calls; the main case that might be missed is out-of-memory situations. In the worst case this might lead to information exposure, due to our code assuming that a buffer had been overwritten when it hadn’t been. Also, there were a few places in which security-relevant calls of other system library functions did not check for failure.

It remains possible that some calls of the *printf() family of functions are vulnerable to information disclosure if an out-of-memory error occurs at just the wrong time. We judge the risk to not be large, but will continue analysis in this area. (CVE-2015-3166)
• In contrib/pgcrypto, uniformly report decryption failures as “Wrong key or corrupt data” (Noah Misch)

Previously, some cases of decryption with an incorrect key could report other error message texts. It has been shown that such variance in error reports can aid attackers in recovering keys from other systems. While it’s unknown whether pgcrypto’s specific behaviors are likewise exploitable, it seems better to avoid the risk by using a one-size-fits-all message. (CVE-2015-3167)

• Protect against wraparound of multixact member IDs (Álvaro Herrera, Robert Haas, Thomas Munro)

Under certain usage patterns, the existing defenses against this might be insufficient, allowing pg_multixact/members files to be removed too early, resulting in data loss. The fix for this includes modifying the server to fail transactions that would result in overwriting old multixact member ID data, and improving autovacuum to ensure it will act proactively to prevent multixact member ID wraparound, as it does for transaction ID wraparound.

• Fix incorrect declaration of contrib/citext’s regexp_matches() functions (Tom Lane)

These functions should return setof text[], like the core functions they are wrappers for; but they were incorrectly declared as returning just text[]. This mistake had two results: first, if there was no match you got a scalar null result, whereas what you should get is an empty set (zero rows). Second, the g flag was effectively ignored, since you would get only one result array even if there were multiple matches.

While the latter behavior is clearly a bug, there might be applications depending on the former behavior; therefore the function declarations will not be changed by default until PostgreSQL 9.5. In pre-9.5 branches, the old behavior exists in version 1.0 of the citext extension, while we have provided corrected declarations in version 1.1 (which is not installed by default). To adopt the fix in pre-9.5 branches, execute ALTER EXTENSION citext UPDATE TO ‘1.1’ in each database in which citext is installed. (You can also “update” back to 1.0 if you need to undo that.) Be aware that either update direction will require dropping and recreating any views or rules that use citext’s regexp_matches() functions.

• Fix incorrect checking of deferred exclusion constraints after a HOT update (Tom Lane)

If a new row that potentially violates a deferred exclusion constraint is HOT-updated (that is, no indexed columns change and the row can be stored back onto the same table page) later in the same transaction, the exclusion constraint would be reported as violated when the check finally occurred, even if the row(s) the new row originally conflicted with had been deleted.

• Fix planning of star-schema-style queries (Tom Lane)

Sometimes, efficient scanning of a large table requires that index parameters be provided from more than one other table (commonly, dimension tables whose keys are needed to index a large fact table). The planner should be able to find such plans, but an overly restrictive search heuristic prevented it.

• Prevent improper reordering of antijoins (NOT EXISTS joins) versus other outer joins (Tom Lane)

This oversight in the planner has been observed to cause “could not find RelOptInfo for given relids” errors, but it seems possible that sometimes an incorrect query plan might get past that consistency check and result in silently-wrong query output.

• Fix incorrect matching of subexpressions in outer-join plan nodes (Tom Lane)

Previously, if textually identical non-strict subexpressions were used both above and below an outer join, the planner might try to re-use the value computed below the join, which would be incorrect
because the executor would force the value to NULL in case of an unmatched outer row.

- Fix GEQO planner to cope with failure of its join order heuristic (Tom Lane)
  This oversight has been seen to lead to “failed to join all relations together” errors in queries involving LATERAL, and that might happen in other cases as well.

- Fix possible deadlock at startup when max_prepared_transactions is too small (Heikki Linnakangas)

- Don’t archive useless preallocated WAL files after a timeline switch (Heikki Linnakangas)

- Recursively fsync() the data directory after a crash (Abhijit Menon-Sen, Robert Haas)
  This ensures consistency if another crash occurs shortly later. (The second crash would have to be a system-level crash, not just a database crash, for there to be a problem.)

- Fix autovacuum launcher’s possible failure to shut down, if an error occurs after it receives SIGTERM (Álvaro Herrera)

- Cope with unexpected signals in LockBufferForCleanup() (Andres Freund)
  This oversight could result in spurious errors about “multiple backends attempting to wait for pinct 1”.

- Fix crash when doing COPY IN to a table with check constraints that contain whole-row references (Tom Lane)
  The known failure case only crashes in 9.4 and up, but there is very similar code in 9.3 and 9.2, so back-patch those branches as well.

- Avoid waiting for WAL flush or synchronous replication during commit of a transaction that was read-only so far as the user is concerned (Andres Freund)
  Previously, a delay could occur at commit in transactions that had written WAL due to HOT page pruning, leading to undesirable effects such as sessions getting stuck at startup if all synchronous replicas are down. Sessions have also been observed to get stuck in catchup interrupt processing when using synchronous replication; this will fix that problem as well.

- Fix crash when manipulating hash indexes on temporary tables (Heikki Linnakangas)

- Fix possible failure during hash index bucket split, if other processes are modifying the index concurrently (Tom Lane)

- Check for interrupts while analyzing index expressions (Jeff Janes)
  ANALYZE executes index expressions many times; if there are slow functions in such an expression, it’s desirable to be able to cancel the ANALYZE before that loop finishes.

- Ensure tableoid of a foreign table is reported correctly when a READ COMMITTED recheck occurs after locking rows in SELECT FOR UPDATE, UPDATE, or DELETE (Etsuro Fujita)

- Add the name of the target server to object description strings for foreign-server user mappings (Álvaro Herrera)

- Include the schema name in object identity strings for conversions (Álvaro Herrera)

- Recommend setting include_realm to 1 when using Kerberos/GSSAPI/SSPI authentication (Stephen Frost)
Without this, identically-named users from different realms cannot be distinguished. For the moment this is only a documentation change, but it will become the default setting in PostgreSQL 9.5.

- **Remove code for matching IPv4 pg_hba.conf entries to IPv4-in-IPv6 addresses (Tom Lane)**

This hack was added in 2003 in response to a report that some Linux kernels of the time would report IPv4 connections as having IPv4-in-IPv6 addresses. However, the logic was accidentally broken in 9.0. The lack of any field complaints since then shows that it’s not needed anymore. Now we have reports that the broken code causes crashes on some systems, so let’s just remove it rather than fix it. (Had we chosen to fix it, that would make for a subtle and potentially security-sensitive change in the effective meaning of IPv4 pg_hba.conf entries, which does not seem like a good thing to do in minor releases.)

- **Report WAL flush, not insert, position in IDENTIFY_SYSTEM replication command (Heikki Linnakangas)**

This avoids a possible startup failure in pg_receivexlog.

- **While shutting down service on Windows, periodically send status updates to the Service Control Manager to prevent it from killing the service too soon; and ensure that pg_ctl will wait for shutdown (Krystian Bigaj)**

- **Reduce risk of network deadlock when using libpq’s non-blocking mode (Heikki Linnakangas)**

When sending large volumes of data, it’s important to drain the input buffer every so often, in case the server has sent enough response data to cause it to block on output. (A typical scenario is that the server is sending a stream of NOTICE messages during COPY FROM STDIN.) This worked properly in the normal blocking mode, but not so much in non-blocking mode. We’ve modified libpq to opportunistically drain input when it can, but a full defense against this problem requires application cooperation: the application should watch for socket read-ready as well as write-ready conditions, and be sure to call PQconsumeInput() upon read-ready.

- **In libpq, fix misparsing of empty values in URI connection strings (Thomas Fanghaenel)**

- **Fix array handling in ecpg (Michael Meskes)**

- **Fix psql to sanely handle URIs and conninfo strings as the first parameter to \connect (David Fetter, Andrew Dunstan, Álvaro Herrera)**

This syntax has been accepted (but undocumented) for a long time, but previously some parameters might be taken from the old connection instead of the given string, which was agreed to be undesirable.

- **Suppress incorrect complaints from psql on some platforms that it failed to write ~/.psql_history at exit (Tom Lane)**

This misbehavior was caused by a workaround for a bug in very old (pre-2006) versions of libedit. We fixed it by removing the workaround, which will cause a similar failure to appear for anyone still using such versions of libedit. Recommendation: upgrade that library, or use libreadline.

- **Fix pg_dump’s rule for deciding which casts are system-provided casts that should not be dumped (Tom Lane)**

- **In pg_dump, fix failure to honor -z compression level option together with -Fd (Michael Paquier)**

- **Make pg_dump consider foreign key relationships between extension configuration tables while choosing dump order (Gilles Darold, Michael Paquier, Stephen Frost)**

This oversight could result in producing dumps that fail to reload because foreign key constraints are transiently violated.
Appendix E. Release Notes

• Avoid possible pg_dump failure when concurrent sessions are creating and dropping temporary functions (Tom Lane)
• Fix dumping of views that are just \texttt{VALUES(...)} but have column aliases (Tom Lane)
• In \texttt{pg\_upgrade}, force timeline 1 in the new cluster (Bruce Momjian)
  This change prevents upgrade failures caused by bogus complaints about missing WAL history files.
• In \texttt{pg\_upgrade}, check for improperly non-connectable databases before proceeding (Bruce Momjian)
• In \texttt{pg\_upgrade}, quote directory paths properly in the generated \texttt{delete\_old\_cluster} script (Bruce Momjian)
• In \texttt{pg\_upgrade}, preserve database-level freezing info properly (Bruce Momjian)
  This oversight could cause missing-clog-file errors for tables within the \texttt{postgres} and \texttt{template1} databases.
• Run \texttt{pg\_upgrade} and \texttt{pg\_resetxlog} with restricted privileges on Windows, so that they don’t fail when run by an administrator (Muhammad Asif Naeem)
• Improve handling of \texttt{readdir()} failures when scanning directories in \texttt{initdb} and \texttt{pg\_basebackup} (Marco Nenciarini)
• Fix slow sorting algorithm in \texttt{contrib/intarray} (Tom Lane)
• Fix compile failure on Sparc V8 machines (Rob Rowan)
• Silence some build warnings on macOS (Tom Lane)
• Update time zone data files to tzdata release 2015d for DST law changes in Egypt, Mongolia, and Palestine, plus historical changes in Canada and Chile. Also adopt revised zone abbreviations for the America/Adak zone (HST/HDT not HAST/HADT).

E.41. Release 9.3.6

Release date: 2015-02-05
This release contains a variety of fixes from 9.3.5. For information about new features in the 9.3 major release, see Section E.47.

E.41.1. Migration to Version 9.3.6

A dump/restore is not required for those running 9.3.X.
However, if you are a Windows user and are using the “Norwegian (Bokmål)” locale, manual action is needed after the upgrade to replace any “Norwegian (Bokmål)_Norway” locale names stored in PostgreSQL system catalogs with the plain-ASCII alias “Norwegian_Norway”. For details see http://wiki.postgresql.org/wiki/Changes_To_Norwegian_Locale
Also, if you are upgrading from a version earlier than 9.3.5, see Section E.42.
E.41.2. Changes

- Fix buffer overruns in `to_char()` (Bruce Momjian)

When `to_char()` processes a numeric formatting template calling for a large number of digits, PostgreSQL would read past the end of a buffer. When processing a crafted timestamp formatting template, PostgreSQL would write past the end of a buffer. Either case could crash the server. We have not ruled out the possibility of attacks that lead to privilege escalation, though they seem unlikely. (CVE-2015-0241)

- Fix buffer overrun in replacement `*printf()` functions (Tom Lane)

PostgreSQL includes a replacement implementation of `printf` and related functions. This code will overrun a stack buffer when formatting a floating point number (conversion specifiers `e`, `E`, `f`, `F`, `g` or `G`) with requested precision greater than about 500. This will crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. A database user can trigger such a buffer overrun through the `to_char()` SQL function. While that is the only affected core PostgreSQL functionality, extension modules that use printf-family functions may be at risk as well.

This issue primarily affects PostgreSQL on Windows. PostgreSQL uses the system implementation of these functions where adequate, which it is on other modern platforms. (CVE-2015-0242)

- Fix buffer overruns in `contrib/pgcrypto` (Marko Tiikkaja, Noah Misch)

Errors in memory size tracking within the `pgcrypto` module permitted stack buffer overruns and improper dependence on the contents of uninitialized memory. The buffer overrun cases can crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. (CVE-2015-0243)

- Fix possible loss of frontend/backend protocol synchronization after an error (Heikki Linnakangas)

If any error occurred while the server was in the middle of reading a protocol message from the client, it could lose synchronization and incorrectly try to interpret part of the message’s data as a new protocol message. An attacker able to submit crafted binary data within a command parameter might succeed in injecting his own SQL commands this way. Statement timeout and query cancellation are the most likely sources of errors triggering this scenario. Particularly vulnerable are applications that use a timeout and also submit arbitrary user-crafted data as binary query parameters. Disabling statement timeout will reduce, but not eliminate, the risk of exploit. Our thanks to Emil Lenngren for reporting this issue. (CVE-2015-0244)

- Fix information leak via constraint-violation error messages (Stephen Frost)

Some server error messages show the values of columns that violate a constraint, such as a unique constraint. If the user does not have `SELECT` privilege on all columns of the table, this could mean exposing values that the user should not be able to see. Adjust the code so that values are displayed only when they came from the SQL command or could be selected by the user. (CVE-2014-8161)

- Lock down regression testing’s temporary installations on Windows (Noah Misch)

Use SSPI authentication to allow connections only from the OS user who launched the test suite. This closes on Windows the same vulnerability previously closed on other platforms, namely that other users might be able to connect to the test postmaster. (CVE-2014-0067)

- Cope with the Windows locale named “Norwegian (Bokmål)” (Heikki Linnakangas)
Non-ASCII locale names are problematic since it’s not clear what encoding they should be represented in. Map the troublesome locale name to a plain-ASCII alias, “Norwegian_Norway”.

- **Avoid possible data corruption if** `ALTER DATABASE SET TABLESPACE` **is used to move a database to a new tablespace and then shortly later move it back to its original tablespace** (Tom Lane)

- **Avoid corrupting tables when** `ANALYZE` **inside a transaction is rolled back** (Andres Freund, Tom Lane, Michael Paquier)

  If the failing transaction had earlier removed the last index, rule, or trigger from the table, the table would be left in a corrupted state with the relevant `pg_class` flags not set though they should be.

- **Ensure that unlogged tables are copied correctly during** `CREATE DATABASE` **or** `ALTER DATABASE SET TABLESPACE` **(Pavan Deolasee, Andres Freund)**

- **Fix incorrect processing of** `CreateEventTrigStmt.eventname` **(Petr Jelinek)**

  This could result in misbehavior if `CREATE EVENT TRIGGER` were executed as a prepared query, or via extended query protocol.

- **Fix** `DROP`’s dependency searching to correctly handle the case where a table column is recursively visited before its table (Petr Jelinek, Tom Lane)

  This case is only known to arise when an extension creates both a datatype and a table using that datatype. The faulty code might refuse a `DROP EXTENSION` unless `CASCADE` is specified, which should not be required.

- **Fix use-of-already-freed-memory problem in EvalPlanQual processing** (Tom Lane)

  In **READ COMMITTED** mode, queries that lock or update recently-updated rows could crash as a result of this bug.

- **Avoid possible deadlock while trying to acquire tuple locks in EvalPlanQual processing** (Álvaro Herrera, Mark Kirkwood)

- **Fix failure to wait when a transaction tries to acquire a** `FOR NO KEY EXCLUSIVE` **tuple lock, while multiple other transactions currently hold** `FOR SHARE` **locks** (Álvaro Herrera)

- **Fix planning of** `SELECT FOR UPDATE` **when using a partial index on a child table** (Kyotaro Horiguchi)

  In **READ COMMITTED** mode, `SELECT FOR UPDATE` must also recheck the partial index’s `WHERE` condition when rechecking a recently-updated row to see if it still satisfies the query’s `WHERE` condition. This requirement was missed if the index belonged to an inheritance child table, so that it was possible to incorrectly return rows that no longer satisfy the query condition.

- **Fix corner case wherein** `SELECT FOR UPDATE` **could return a row twice, and possibly miss returning other rows** (Tom Lane)

  In **READ COMMITTED** mode, a `SELECT FOR UPDATE` that is scanning an inheritance tree could incorrectly return a row from a prior child table instead of the one it should return from a later child table.

- **Improve performance of** `EXPLAIN` **with large range tables** (Tom Lane)

- **Reject duplicate column names in the referenced-columns list of a** `FOREIGN KEY` **declaration** (David Rowley)

  This restriction is per SQL standard. Previously we did not reject the case explicitly, but later on the code would fail with bizarre-looking errors.

- **Re-enable error for** `SELECT ... OFFSET -1` **(Tom Lane)**
Appendix E. Release Notes

A negative offset value has been an error since 8.4, but an optimization added in 9.3 accidentally turned the case into a no-op. Restore the expected behavior.

• Restore previous behavior of conversion of domains to JSON (Tom Lane)
  This change causes domains over numeric and boolean to be treated like their base types for purposes of conversion to JSON. It worked like that before 9.3.5 and 9.2.9, but was unintentionally changed while fixing a related problem.

• Fix json_agg() to not return extra trailing right brackets in its result (Tom Lane)

• Fix bugs in raising a numeric value to a large integral power (Tom Lane)
  The previous code could get a wrong answer, or consume excessive amounts of time and memory before realizing that the answer must overflow.

• In numeric_recv(), truncate away any fractional digits that would be hidden according to the value’s dscale field (Tom Lane)
  A numeric value’s display scale (dscale) should never be less than the number of nonzero fractional digits; but apparently there’s at least one broken client application that transmits binary numeric values in which that’s true. This leads to strange behavior since the extra digits are taken into account by arithmetic operations even though they aren’t printed. The least risky fix seems to be to truncate away such “hidden” digits on receipt, so that the value is indeed what it prints as.

• Fix incorrect search for shortest-first regular expression matches (Tom Lane)
  Matching would often fail when the number of allowed iterations is limited by a ? quantifier or a bound expression.

• Reject out-of-range numeric timezone specifications (Tom Lane)
  Simple numeric timezone specifications exceeding +/- 168 hours (one week) would be accepted, but could then cause null-pointer dereference crashes in certain operations. There’s no use-case for such large UTC offsets, so reject them.

• Fix bugs in tsquery @> tsquery operator (Heikki Linnakangas)
  Two different terms would be considered to match if they had the same CRC. Also, if the second operand had more terms than the first, it would be assumed not to be contained in the first; which is wrong since it might contain duplicate terms.

• Improve ispell dictionary’s defenses against bad affix files (Tom Lane)

• Allow more than 64K phrases in a thesaurus dictionary (David Boutin)
  The previous coding could crash on an oversize dictionary, so this was deemed a back-patchable bug fix rather than a feature addition.

• Fix namespace handling in xpath() (Ali Akbar)
  Previously, the xml value resulting from an xpath() call would not have namespace declarations if the namespace declarations were attached to an ancestor element in the input xml value, rather than to the specific element being returned. Propagate the ancestral declaration so that the result is correct when considered in isolation.

• Ensure that whole-row variables expose nonempty column names to functions that pay attention to column names within composite arguments (Tom Lane)
In some contexts, constructs like `row_to_json(tab.*)` may not produce the expected column names. This is fixed properly as of 9.4; in older branches, just ensure that we produce some nonempty name. (In some cases this will be the underlying table’s column name rather than the query-assigned alias that should theoretically be visible.)

- Fix mishandling of system columns, particularly `tableoid`, in FDW queries (Etsuro Fujita)
- Fix assorted oversights in range-operator selectivity estimation (Emre Hasegeli)
  
  This patch fixes corner-case “unexpected operator NNNN” planner errors, and improves the selectivity estimates for some other cases.

- Avoid doing `indexed_column = ANY (array)` as an index qualifier if that leads to an inferior plan (Andrew Gierth)
  
  In some cases, = ANY conditions applied to non-first index columns would be done as index conditions even though it would be better to use them as simple filter conditions.

- Fix “variable not found in subplan target list” planner failure when an inline-able SQL function taking a composite argument is used in a LATERAL subselect and the composite argument is a lateral reference (Tom Lane)
- Fix planner problems with nested append relations, such as inherited tables within UNION ALL sub-queries (Tom Lane)
- Fail cleanly when a GiST index tuple doesn’t fit on a page, rather than going into infinite recursion (Andrew Gierth)
- Exempt tables that have per-table `cost_limit` and/or `cost_delay` settings from autovacuum’s global cost balancing rules (Álvaro Herrera)
  
  The previous behavior resulted in basically ignoring these per-table settings, which was unintended. Now, a table having such settings will be vacuumed using those settings, independently of what is going on in other autovacuum workers. This may result in heavier total I/O load than before, so such settings should be re-examined for sanity.

- Avoid wholesale autovacuuming when autovacuum is nominally off (Tom Lane)
  
  Even when autovacuum is nominally off, we will still launch autovacuum worker processes to vacuum tables that are at risk of XID wraparound. However, such a worker process then proceeded to vacuum all tables in the target database, if they met the usual thresholds for autovacuuming. This is at best pretty unexpected; at worst it delays response to the wraparound threat. Fix it so that if autovacuum is turned off, workers only do anti-wraparound vacuums and not any other work.

- During crash recovery, ensure that unlogged relations are rewritten as empty and are synced to disk before recovery is considered complete (Abhijit Menon-Sen, Andres Freund)
  
  This prevents scenarios in which unlogged relations might contain garbage data following database crash recovery.

- Fix race condition between hot standby queries and replaying a full-page image (Heikki Linnakangas)
  
  This mistake could result in transient errors in queries being executed in hot standby.

- Fix several cases where recovery logic improperly ignored WAL records for COMMIT/ABORT PREPARED (Heikki Linnakangas)
  
  The most notable oversight was that `recovery_target_xid` could not be used to stop at a two-phase commit.
• Prevent latest WAL file from being archived a second time at completion of crash recovery (Fujii Masao)

• Avoid creating unnecessary .ready marker files for timeline history files (Fujii Masao)

• Fix possible null pointer dereference when an empty prepared statement is used and the log_statement setting is mod or ddl (Fujii Masao)

• Change “pgstat wait timeout” warning message to be LOG level, and rephrase it to be more understandable (Tom Lane)

This message was originally thought to be essentially a can’t-happen case, but it occurs often enough on our slower buildfarm members to be a nuisance. Reduce it to LOG level, and expend a bit more effort on the wording: it now reads “using stale statistics instead of current ones because stats collector is not responding”.

• Fix possible corruption of postmaster’s list of dynamic background workers (Andres Freund)

• Fix SPARC spinlock implementation to ensure correctness if the CPU is being run in a non-TSO coherence mode, as some non-Solaris kernels do (Andres Freund)

• Warn if macOS’s setlocale() starts an unwanted extra thread inside the postmaster (Noah Misch)

• Fix processing of repeated dbname parameters in PQconnectdbParams() (Alex Shulgin)

 Unexpected behavior ensued if the first occurrence of dbname contained a connection string or URI to be expanded.

• Ensure that libpq reports a suitable error message on unexpected socket EOF (Marko Tiikkaja, Tom Lane)

 Depending on kernel behavior, libpq might return an empty error string rather than something useful when the server unexpectedly closed the socket.

• Clear any old error message during PQreset() (Heikki Linnakangas)

 If PQreset() is called repeatedly, and the connection cannot be re-established, error messages from the failed connection attempts kept accumulating in the PGconn’s error string.

• Properly handle out-of-memory conditions while parsing connection options in libpq (Alex Shulgin, Heikki Linnakangas)

• Fix array overrun in ecpg’s version of ParseDateTime() (Michael Paquier)

• In initdb, give a clearer error message if a password file is specified but is empty (Mats Erik Andersson)

• Fix psql’s \s command to work nicely with libedit, and add pager support (Stepan Rutz, Tom Lane)

 When using libedit rather than readline, \s printed the command history in a fairly unreadable encoded format, and on recent libedit versions might fail altogether. Fix that by printing the history ourselves rather than having the library do it. A pleasant side-effect is that the pager is used if appropriate.

 This patch also fixes a bug that caused newline encoding to be applied inconsistently when saving the command history with libedit. Multiline history entries written by older psql versions will be read cleanly with this patch, but perhaps not vice versa, depending on the exact libedit versions involved.

• Improve consistency of parsing of psql’s special variables (Tom Lane)

 Allow variant spellings of on and off (such as 1/0) for ECHO_HIDDEN and ON_ERROR_ROLLBACK. Report a warning for unrecognized values for COMP_KEYWORD_CASE, ECHO, ECHO_HIDDEN,
HISTCONTROL, ON_ERROR_ROLLBACK, and VERBOSITY. Recognize all values for all these variables case-insensitively; previously there was a mishmash of case-sensitive and case-insensitive behaviors.

- Make psql's `\watch` command display nulls as specified by `\pset null` (Fujii Masao)
- Fix psql's expanded-mode display to work consistently when using `border = 3` and `linestyle = ascii` or `unicode` (Stephen Frost)
- Fix `pg_dump` to handle comments on event triggers without failing (Tom Lane)
- Allow parallel `pg_dump` to use `--serializable-deferrable` (Kevin Grittner)
- Improve performance of `pg_dump` when the database contains many instances of multiple dependency paths between the same two objects (Tom Lane)
- Fix `pg_dumpall` to restore its ability to dump from pre-8.1 servers (Gilles Darold)
- Fix possible deadlock during parallel restore of a schema-only dump (Robert Haas, Tom Lane)
- Fix core dump in `pg_dump` `--binary-upgrade` on zero-column composite type (Rushabh Lathia)
- Fix failure to fsync tables in nondefault tablespaces during `pg_upgrade` (Abhijit Menon-Sen, Andres Freund)

  With an operating system crash and some bad luck, this could result in data loss during an upgrade.

- In `pg_upgrade`, cope with cases where the new cluster creates a TOAST table for a table that didn’t previously have one (Bruce Momjian)

  Previously this could result in failures due to OID conflicts.

- In `pg_upgrade`, don’t try to set `autovacuum_multixact_freeze_max_age` for the old cluster (Bruce Momjian)

  This could result in failure because not all 9.3.X versions have that parameter. Fortunately, we don’t actually need to set it at all.

- In `pg_upgrade`, preserve the transaction ID epoch (Bruce Momjian)

  This oversight did not bother PostgreSQL proper, but could confuse some external replication tools.
- Prevent WAL files created by `pg_basebackup -x/-X` from being archived again when the standby is promoted (Andres Freund)
- Fix memory leak in `pg_receivexlog` (Fujii Masao)
- Fix unintended suppression of `pg_receivexlog` verbose messages (Fujii Masao)
- Fix failure of `contrib/auto_explain` to print per-node timing information when doing `EXPLAIN ANALYZE` (Tom Lane)
- Fix upgrade-from-unpackaged script for `contrib/citext` (Tom Lane)
- Avoid integer overflow and buffer overrun in `contrib/hstore`'s `hstore_to_json()` (Heikki Linnakangas)
- Fix recognition of numbers in `hstore_to_json_loose()`, so that JSON numbers and strings are correctly distinguished (Andrew Dunstan)
- Fix block number checking in `contrib/pageinspect`'s `get_raw_page()` (Tom Lane)

  The incorrect checking logic could prevent access to some pages in non-main relation forks.
Appendix E. Release Notes

- Fix contrib/pgcrypto’s pgp_sym_decrypt() to not fail on messages whose length is 6 less than a power of 2 (Marko Tiikkaja)
- Fix file descriptor leak in contrib/pg_test_fsync (Jeff Janes)
  This could cause failure to remove temporary files on Windows.
- Handle unexpected query results, especially NULLs, safely in contrib/tablefunc’s connectby() (Michael Paquier)
  connectby() previously crashed if it encountered a NULL key value. It now prints that row but doesn’t recurse further.
- Avoid a possible crash in contrib/xml2’s xslt_process() (Mark Simonetti)
  libxslt seems to have an undocumented dependency on the order in which resources are freed; reorder our calls to avoid a crash.
- Mark some contrib I/O functions with correct volatility properties (Tom Lane)
  The previous over-conservative marking was immaterial in normal use, but could cause optimization problems or rejection of valid index expression definitions. Since the consequences are not large, we’ve just adjusted the function definitions in the extension modules’ scripts, without changing version numbers.
- Numerous cleanups of warnings from Coverity static code analyzer (Andres Freund, Tatsuo Ishii, Marko Kreen, Tom Lane, Michael Paquier)
  These changes are mostly cosmetic but in some cases fix corner-case bugs, for example a crash rather than a proper error report after an out-of-memory failure. None are believed to represent security issues.
- Fix setup of background workers in EXEC_BACKEND builds, eg Windows (Robert Haas)
- Detect incompatible OpenLDAP versions during build (Noah Misch)
  With OpenLDAP versions 2.4.24 through 2.4.31, inclusive, PostgreSQL backends can crash at exit. Raise a warning during configure based on the compile-time OpenLDAP version number, and test the crashing scenario in the contrib/dblink regression test.
- In non-MSVC Windows builds, ensure libpq.dll is installed with execute permissions (Noah Misch)
- Make pg_regress remove any temporary installation it created upon successful exit (Tom Lane)
  This results in a very substantial reduction in disk space usage during make check-world, since that sequence involves creation of numerous temporary installations.
- Support time zone abbreviations that change UTC offset from time to time (Tom Lane)
  Previously, PostgreSQL assumed that the UTC offset associated with a time zone abbreviation (such as EST) never changes in the usage of any particular locale. However this assumption fails in the real world, so introduce the ability for a zone abbreviation to represent a UTC offset that sometimes changes. Update the zone abbreviation definition files to make use of this feature in timezone locales that have changed the UTC offset of their abbreviations since 1970 (according to the IANA timezone database). In such timezones, PostgreSQL will now associate the correct UTC offset with the abbreviation depending on the given date.
- Update time zone abbreviations lists (Tom Lane)
  Add CST (China Standard Time) to our lists. Remove references to ADT as “Arabia Daylight Time”, an abbreviation that’s been out of use since 2007; therefore, claiming there is a conflict with “Atlantic
Daylight Time” doesn’t seem especially helpful. Fix entirely incorrect GMT offsets for CKT (Cook Islands), FJT, and FJST (Fiji); we didn’t even have them on the proper side of the date line.

- Update time zone data files to tzdata release 2015a.

The IANA timezone database has adopted abbreviations of the form AxST/AxDT for all Australian time zones, reflecting what they believe to be current majority practice Down Under. These names do not conflict with usage elsewhere (other than ACST for Acre Summer Time, which has been in disuse since 1994). Accordingly, adopt these names into our “Default” timezone abbreviation set. The “Australia” abbreviation set now contains only CST, EAST, EST, SAST, SAT, and WST, all of which are thought to be mostly historical usage. Note that SAST has also been changed to be South Africa Standard Time in the “Default” abbreviation set.

Also, add zone abbreviations SRET (Asia/Srednekolymsk) and XJT (Asia/Urumqi), and use WSST/WSDT for western Samoa. Also, there were DST law changes in Chile, Mexico, the Turks & Caicos Islands (America/Grand_Turk), and Fiji. There is a new zone Pacific/Bougainville for portions of Papua New Guinea. Also, numerous corrections for historical (pre-1970) time zone data.

E.42. Release 9.3.5

Release date: 2014-07-24

This release contains a variety of fixes from 9.3.4. For information about new features in the 9.3 major release, see Section E.47.

E.42.1. Migration to Version 9.3.5

A dump/restore is not required for those running 9.3.X.

However, this release corrects a logic error in pg_upgrade, as well as an index corruption problem in some GiST indexes. See the first two changelog entries below to find out whether your installation has been affected and what steps you should take if so.

Also, if you are upgrading from a version earlier than 9.3.4, see Section E.43.

E.42.2. Changes

- In pg_upgrade, remove pg_multixact files left behind by initdb (Bruce Momjian)

If you used a pre-9.3.5 version of pg_upgrade to upgrade a database cluster to 9.3, it might have left behind a file $PGDATA/pg_multixact/offsets/0000 that should not be there and will eventually cause problems in VACUUM. However, in common cases this file is actually valid and must not be removed. To determine whether your installation has this problem, run this query as superuser, in any database of the cluster:

```sql
WITH list(file) AS (SELECT * FROM pg_ls_dir('pg_multixact/offsets'))
SELECT EXISTS (SELECT * FROM list WHERE file = '0000') AND
         NOT EXISTS (SELECT * FROM list WHERE file = '0001') AND
```
NOT EXISTS (SELECT * FROM list WHERE file = 'FFFF') AND
EXISTS (SELECT * FROM list WHERE file != '0000')
AS file_0000_removal_required;

If this query returns `t`, manually remove the file `$PGDATA/pg_multixact/offsets/0000`. Do nothing if the query returns `f`.

• Correctly initialize padding bytes in `contrib/btree_gist` indexes on `bit` columns (Heikki Linnakangas)

This error could result in incorrect query results due to values that should compare equal not being seen as equal. Users with GiST indexes on `bit` or `bit varying` columns should REINDEX those indexes after installing this update.

• Protect against torn pages when deleting GIN list pages (Heikki Linnakangas)

This fix prevents possible index corruption if a system crash occurs while the page update is being written to disk.

• Don’t clear the right-link of a GiST index page while replaying updates from WAL (Heikki Linnakangas)

This error could lead to transiently wrong answers from GiST index scans performed in Hot Standby.

• Fix corner-case infinite loop during insertion into an SP-GiST text index (Tom Lane)

• Fix incorrect answers from SP-GiST index searches with `|` (range adjacency) operator (Heikki Linnakangas)

• Fix wraparound handling for `pg_multixact/members` (Álvaro Herrera)

• Truncate `pg_multixact` during checkpoints, not during `VACUUM` (Álvaro Herrera)

This change ensures that `pg_multixact` segments can’t be removed if they’d still be needed during WAL replay after a crash.

• Fix possible inconsistency of all-visible flags after WAL recovery (Heikki Linnakangas)

• Fix possibly-incorrect cache invalidation during nested calls to `ReceiveSharedInvalidMessages` (Andres Freund)

• Fix race condition when updating a tuple concurrently locked by another process (Andres Freund, Álvaro Herrera)

• Fix “could not find pathkey item to sort” planner failures with `UNION ALL` over subqueries reading from tables with inheritance children (Tom Lane)

• Don’t assume a subquery’s output is unique if there’s a set-returning function in its targetlist (David Rowley)

This oversight could lead to misoptimization of constructs like `WHERE x IN (SELECT y, generate_series(1,10) FROM t GROUP BY y)`.

• Improve planner to drop constant-NULL inputs of `AND`/`OR` when possible (Tom Lane)

This change fixes some cases where the more aggressive parameter substitution done by 9.2 and later can lead to a worse plan than older versions produced.

• Ensure that the planner sees equivalent `VARIADIC` and non-`VARIADIC` function calls as equivalent (Tom Lane)
Appendix E. Release Notes

This bug could for example result in failure to use expression indexes involving variadic functions. It might be necessary to re-create such indexes, and/or re-create views including variadic function calls that should match the indexes, for the fix to be effective for existing 9.3 installations.

- Fix handling of nested JSON objects in `json_populate_recordset()` and friends (Michael Paquier, Tom Lane)
  A nested JSON object could result in previous fields of the parent object not being shown in the output.
- Fix identification of input type category in `to_json()` and friends (Tom Lane)
  This is known to have led to inadequate quoting of `money` fields in the JSON result, and there may have been wrong results for other data types as well.
- Fix failure to detoast fields in composite elements of structured types (Tom Lane)
  This corrects cases where TOAST pointers could be copied into other tables without being dereferenced. If the original data is later deleted, it would lead to errors like “missing chunk number 0 for toast value ...” when the now-dangling pointer is used.
- Fix “record type has not been registered” failures with whole-row references to the output of Append plan nodes (Tom Lane)
- Fix possible crash when invoking a user-defined function while rewinding a cursor (Tom Lane)
- Fix query-lifespan memory leak while evaluating the arguments for a function in `FROM` (Tom Lane)
- Fix session-lifespan memory leaks in regular-expression processing (Tom Lane, Arthur O’Dwyer, Greg Stark)
- Fix data encoding error in `hungarian.stop` (Tom Lane)
- Prevent foreign tables from being created with OIDS when `default_with_oids` is true (Etsuro Fujita)
- Fix liveness checks for rows that were inserted in the current transaction and then deleted by a now-rolled-back subtransaction (Andres Freund)
  This could cause problems (at least spurious warnings, and at worst an infinite loop) if `CREATE INDEX` or `CLUSTER` were done later in the same transaction.
- Clear `pg_stat_activity.xact_start` during `PREPARE TRANSACTION` (Andres Freund)
  After the `PREPARE`, the originating session is no longer in a transaction, so it should not continue to display a transaction start time.
- Fix `REASSIGN OWNED` to not fail for text search objects (Álvaro Herrera)
- Prevent `pg_class.relminmxid` values from going backwards during `VACUUM FULL` (Álvaro Herrera)
- Reduce indentation in rule/view dumps to improve readability and avoid excessive whitespace (Greg Stark, Tom Lane)
  This change reduces the amount of indentation applied to nested constructs, including some cases that the user probably doesn’t think of as nested, such as UNION lists. Previously, deeply nested constructs were printed with an amount of whitespace growing as $O(N^2)$, which created a performance problem and even risk of out-of-memory failures. Now the indentation is reduced modulo 40, which is initially odd to look at but seems to preserve readability better than simply limiting the indentation would do. Redundant parenthesization of UNION lists has been reduced as well.
- Fix dumping of rules/views when subsequent addition of a column has resulted in multiple input columns matching a `USING` specification (Tom Lane)
• Repair view printing for some cases involving functions in `FROM` that return a composite type containing dropped columns (Tom Lane)

• Block signals during postmaster startup (Tom Lane)
  
  This ensures that the postmaster will properly clean up after itself if, for example, it receives SIGINT while still starting up.

• Fix client host name lookup when processing `pg_hba.conf` entries that specify host names instead of IP addresses (Tom Lane)
  
  Ensure that reverse-DNS lookup failures are reported, instead of just silently not matching such entries. Also ensure that we make only one reverse-DNS lookup attempt per connection, not one per host name entry, which is what previously happened if the lookup attempts failed.

• Allow the root user to use `postgres -C variable` and `postgres --describe-config` (MauMau)
  
  The prohibition on starting the server as root does not need to extend to these operations, and relaxing it prevents failure of `pg_ctl` in some scenarios.

• Secure Unix-domain sockets of temporary postmasters started during `make check` (Noah Misch)
  
  Any local user able to access the socket file could connect as the server’s bootstrap superuser, then proceed to execute arbitrary code as the operating-system user running the test, as we previously noted in CVE-2014-0067. This change defends against that risk by placing the server’s socket in a temporary, mode 0700 subdirectory of `/tmp`. The hazard remains however on platforms where Unix sockets are not supported, notably Windows, because then the temporary postmaster must accept local TCP connections.
  
  A useful side effect of this change is to simplify `make check` testing in builds that override `DEFAULT_PGSOCKET_DIR`. Popular non-default values like `/var/run/postgresql` are often not writable by the build user, requiring workarounds that will no longer be necessary.

• Fix tablespace creation WAL replay to work on Windows (MauMau)

• Fix detection of socket creation failures on Windows (Bruce Momjian)

• On Windows, allow new sessions to absorb values of `PGC_BACKEND` parameters (such as `log_connections`) from the configuration file (Amit Kapila)
  
  Previously, if such a parameter were changed in the file post-startup, the change would have no effect.

• Properly quote executable path names on Windows (Nikhil Deshpande)
  
  This oversight could cause `initdb` and `pg_upgrade` to fail on Windows, if the installation path contained both spaces and `@` signs.

• Fix linking of `libpython` on macOS (Tom Lane)
  
  The method we previously used can fail with the Python library supplied by Xcode 5.0 and later.

• Avoid buffer bloat in `libpq` when the server consistently sends data faster than the client can absorb it (Shin-ichi Morita, Tom Lane)
  
  `libpq` could be coerced into enlarging its input buffer until it runs out of memory (which would be reported misleadingly as “lost synchronization with server”). Under ordinary circumstances it’s quite far-fetched that data could be continuously transmitted more quickly than the `recv()` loop can absorb it, but this has been observed when the client is artificially slowed by scheduler constraints.
Ensure that LDAP lookup attempts in libpq time out as intended (Laurenz Albe)

Fix ecpg to do the right thing when an array of char * is the target for a FETCH statement returning more than one row, as well as some other array-handling fixes (Ashutosh Bapat)

Fix pg_dump to cope with a materialized view that depends on a table’s primary key (Tom Lane)
This occurs if the view’s query relies on functional dependency to abbreviate a GROUP BY list. pg_dump got sufficiently confused that it dumped the materialized view as a regular view.

Fix parsing of pg_dumpall’s -i switch (Tom Lane)

Fix pg_restore’s processing of old-style large object comments (Tom Lane)
A direct-to-database restore from an archive file generated by a pre-9.0 version of pg_dump would usually fail if the archive contained more than a few comments for large objects.

Fix pg_upgrade for cases where the new server creates a TOAST table but the old version did not (Bruce Momjian)
This rare situation would manifest as “relation OID mismatch” errors.

In pg_upgrade, preserve pg_database.datminmxid and pg_class.relminmxid values from the old cluster, or insert reasonable values when upgrading from pre-9.3; also defend against unreasonable values in the core server (Bruce Momjian, Álvaro Herrera, Tom Lane)
These changes prevent scenarios in which autovacuum might insist on scanning the entire cluster’s contents immediately upon starting the new cluster, or in which tracking of unfrozen MXID values might be disabled completely.

Prevent contrib/auto_explain from changing the output of a user’s EXPLAIN (Tom Lane)
If auto_explain is active, it could cause an EXPLAIN (ANALYZE, TIMING OFF) command to nonetheless print timing information.

Fix query-lifespan memory leak in contrib/dblink (MauMau, Joe Conway)

In contrib/pgcrypto functions, ensure sensitive information is cleared from stack variables before returning (Marko Kreen)

Prevent use of already-freed memory in contrib/pgstattuple’s pgstat_heap() (Noah Misch)

In contrib/uuid-ossp, cache the state of the OSSP UUID library across calls (Tom Lane)
This improves the efficiency of UUID generation and reduces the amount of entropy drawn from /dev/urandom, on platforms that have that.

Update time zone data files to tzdata release 2014e for DST law changes in Crimea, Egypt, and Morocco.

---

E.43. Release 9.3.4

Release date: 2014-03-20

This release contains a variety of fixes from 9.3.3. For information about new features in the 9.3 major release, see Section E.47.
E.43.1. Migration to Version 9.3.4

A dump/restore is not required for those running 9.3.X.

However, the error fixed in the first changelog entry below could have resulted in corrupt data on standby servers. It may be prudent to reinitialize standby servers from fresh base backups after installing this update.

Also, if you are upgrading from a version earlier than 9.3.3, see Section E.44.

E.43.2. Changes

- Fix WAL replay of locking an already-updated tuple (Andres Freund, Álvaro Herrera)
  
  This error caused updated rows to not be found by index scans, resulting in inconsistent query results depending on whether an index scan was used. Subsequent processing could result in constraint violations, since the previously updated row would not be found by later index searches, thus possibly allowing conflicting rows to be inserted. Since this error is in WAL replay, it would only manifest during crash recovery or on standby servers. The improperly-replayed case most commonly arises when a table row that is referenced by a foreign-key constraint is updated concurrently with creation of a referencing row.

- Restore GIN metapages unconditionally to avoid torn-page risk (Heikki Linnakangas)
  
  Although this oversight could theoretically result in a corrupted index, it is unlikely to have caused any problems in practice, since the active part of a GIN metapage is smaller than a standard 512-byte disk sector.

- Avoid race condition in checking transaction commit status during receipt of a NOTIFY message (Marko Tiikkaja)
  
  This prevents a scenario wherein a sufficiently fast client might respond to a notification before database updates made by the notifier have become visible to the recipient.

- Allow materialized views to be referenced in UPDATE and DELETE commands (Michael Paquier)
  
  Previously such queries failed with a complaint about not being able to lock rows in the materialized view.

- Allow regular-expression operators to be terminated early by query cancel requests (Tom Lane)
  
  This prevents scenarios wherein a pathological regular expression could lock up a server process uninterruptibly for a long time.

- Remove incorrect code that tried to allow OVERLAPS with single-element row arguments (Joshua Yanovski)
  
  This code never worked correctly, and since the case is neither specified by the SQL standard nor documented, it seemed better to remove it than fix it.

- Avoid getting more than AccessShareLock when de-parsing a rule or view (Dean Rasheed)
  
  This oversight resulted in pg_dump unexpectedly acquiring RowExclusiveLock locks on tables mentioned as the targets of INSERT/UPDATE/DELETE commands in rules. While usually harmless, that could interfere with concurrent transactions that tried to acquire, for example, ShareLock on those tables.
• Improve performance of index endpoint probes during planning (Tom Lane)

  This change fixes a significant performance problem that occurred when there were many not-yet-committed rows at the end of the index, which is a common situation for indexes on sequentially-assigned values such as timestamps or sequence-generated identifiers.

• Use non-default selectivity estimates for \texttt{value IN (list)} and \texttt{value operator ANY (array)} expressions when the righthand side is a stable expression (Tom Lane)

• Remove the correct per-database statistics file during \texttt{DROP DATABASE} (Tomas Vondra)

  This fix prevents a permanent leak of statistics file space. Users who have done many \texttt{DROP DATABASE} commands since upgrading to PostgreSQL 9.3 may wish to check their statistics directory and delete statistics files that do not correspond to any existing database. Please note that \texttt{db_0.stat} should not be removed.

• Fix walsender ping logic to avoid inappropriate disconnects under continuous load (Andres Freund, Heikki Linnakangas)

  walsender failed to send ping messages to the client if it was constantly busy sending WAL data; but it expected to see ping responses despite that, and would therefore disconnect once wal_sender_timeout elapsed.

• Fix walsender’s failure to shut down cleanly when client is pg_receivexlog (Fujii Masao)

• Check WAL level and hot standby parameters correctly when doing crash recovery that will be followed by archive recovery (Heikki Linnakangas)

• Fix test to see if hot standby connections can be allowed immediately after a crash (Heikki Linnakangas)

• Add read-only data_checksums parameter to display whether page checksums are enabled (Heikki Linnakangas)

  Without this parameter, determining the state of checksum processing was difficult.

• Prevent interrupts while reporting non-\texttt{ERROR} messages (Tom Lane)

  This guards against rare server-process freezeups due to recursive entry to \texttt{syslog()}, and perhaps other related problems.

• Fix memory leak in PL/Perl when returning a composite result, including multiple-OUT-parameter cases (Alex Hunsaker)

• Fix tracking of \texttt{psql} script line numbers during \texttt{\copy} from out-of-line data (Kumar Rajeev Rastogi, Amit Khandekar)

  \texttt{\copy ... from} incremented the script file line number for each data line, even if the data was not coming from the script file. This mistake resulted in wrong line numbers being reported for any errors occurring later in the same script file.

• Fix contrib/postgres_fdw to handle multiple join conditions properly (Tom Lane)

  This oversight could result in sending \texttt{WHERE} clauses to the remote server for execution even though the clauses are not known to have the same semantics on the remote server (for example, clauses that use non-built-in operators). The query might succeed anyway, but it could also fail with errors from the remote server, or worse give silently wrong answers.

• Prevent intermittent “could not reserve shared memory region” failures on recent Windows versions (MauMau)
• Update time zone data files to tzdata release 2014a for DST law changes in Fiji and Turkey, plus historical changes in Israel and Ukraine.

E.44. Release 9.3.3

Release date: 2014-02-20

This release contains a variety of fixes from 9.3.2. For information about new features in the 9.3 major release, see Section E.47.

E.44.1. Migration to Version 9.3.3

A dump/restore is not required for those running 9.3.X.

However, several of the issues corrected in this release could have resulted in corruption of foreign-key constraints; that is, there might now be referencing rows for which there is no matching row in the referenced table. It may be worthwhile to recheck such constraints after installing this update. The simplest way to do that is to drop and recreate each suspect constraint; however, that will require taking an exclusive lock on both tables, so it is unlikely to be acceptable in production databases. Alternatively, you can do a manual join query between the two tables to look for unmatched rows.

Note also the requirement for replication standby servers to be upgraded before their master server is upgraded.

Also, if you are upgrading from a version earlier than 9.3.2, see Section E.45.

E.44.2. Changes

• Shore up `GRANT ... WITH ADMIN OPTION` restrictions (Noah Misch)

  Granting a role without `ADMIN OPTION` is supposed to prevent the grantee from adding or removing members from the granted role, but this restriction was easily bypassed by doing `SET ROLE` first. The security impact is mostly that a role member can revoke the access of others, contrary to the wishes of his grantor. Unapproved role member additions are a lesser concern, since an uncooperative role member could provide most of his rights to others anyway by creating views or `SECURITY DEFINER` functions. (CVE-2014-0060)

• Prevent privilege escalation via manual calls to PL validator functions (Andres Freund)

  The primary role of PL validator functions is to be called implicitly during `CREATE FUNCTION`, but they are also normal SQL functions that a user can call explicitly. Calling a validator on a function actually written in some other language was not checked for and could be exploited for privilege-escalation purposes. The fix involves adding a call to a privilege-checking function in each validator function. Non-core procedural languages will also need to make this change to their own validator functions, if any. (CVE-2014-0061)

• Avoid multiple name lookups during table and index DDL (Robert Haas, Andres Freund)
If the name lookups come to different conclusions due to concurrent activity, we might perform some parts of the DDL on a different table than other parts. At least in the case of CREATE INDEX, this can be used to cause the permissions checks to be performed against a different table than the index creation, allowing for a privilege escalation attack. (CVE-2014-0062)

• Prevent buffer overrun with long datetime strings (Noah Misch)

The MAXDATELEN constant was too small for the longest possible value of type interval, allowing a buffer overrun in interval_out(). Although the datetime input functions were more careful about avoiding buffer overrun, the limit was short enough to cause them to reject some valid inputs, such as input containing a very long timezone name. The ecpg library contained these vulnerabilities along with some of its own. (CVE-2014-0063)

• Prevent buffer overrun due to integer overflow in size calculations (Noah Misch, Heikki Linnakangas)

Several functions, mostly type input functions, calculated an allocation size without checking for overflow. If overflow did occur, a too-small buffer would be allocated and then written past. (CVE-2014-0064)

• Prevent overruns of fixed-size buffers (Peter Eisentraut, Jozef Mlíč)

Use strlcpy() and related functions to provide a clear guarantee that fixed-size buffers are not overrun. Unlike the preceding items, it is unclear whether these cases really represent live issues, since in most cases there appear to be previous constraints on the size of the input string. Nonetheless it seems prudent to silence all Coverity warnings of this type. (CVE-2014-0065)

• Avoid crashing if crypt() returns NULL (Honza Horák, Bruce Momjian)

There are relatively few scenarios in which crypt() could return NULL, but contrib/chkpass would crash if it did. One practical case in which this could be an issue is if libc is configured to refuse to execute unapproved hashing algorithms (e.g., “FIPS mode”). (CVE-2014-0066)

• Document risks of make check in the regression testing instructions (Noah Misch, Tom Lane)

Since the temporary server started by make check uses “trust” authentication, another user on the same machine could connect to it as database superuser, and then potentially exploit the privileges of the operating-system user who started the tests. A future release will probably incorporate changes in the testing procedure to prevent this risk, but some public discussion is needed first. So for the moment, just warn people against using make check when there are untrusted users on the same machine. (CVE-2014-0067)

• Rework tuple freezing protocol (Álvaro Herrera, Andres Freund)

The logic for tuple freezing was unable to handle some cases involving freezing of multixact IDs, with the practical effect that shared row-level locks might be forgotten once old enough.

Fixing this required changing the WAL record format for tuple freezing. While this is no issue for standalone servers, when using replication it means that standby servers must be upgraded to 9.3.3 or later before their masters are. An older standby will be unable to interpret freeze records generated by a newer master, and will fail with a PANIC message. (In such a case, upgrading the standby should be sufficient to let it resume execution.)

• Create separate GUC parameters to control multixact freezing (Álvaro Herrera)

9.3 requires multixact tuple labels to be frozen before they grow too old, in the same fashion as plain transaction ID labels have been frozen for some time. Previously, the transaction ID freezing parameters were used for multixact IDs too; but since the consumption rates of
transaction IDs and multixact IDs can be quite different, this did not work very well. Introduce new settings vacuum_multixact_freeze_min_age, vacuum_multixact_freeze_table_age, and autovacuum_multixact_freeze_max_age to control when to freeze multixacts.

- Account for remote row locks propagated by local updates (Álvaro Herrera)
  If a row was locked by transaction A, and transaction B updated it, the new version of the row created by B would be locked by A, yet visible only to B. If transaction B then again updated the row, A’s lock wouldn’t get checked, thus possibly allowing B to complete when it shouldn’t. This case is new in 9.3 since prior versions did not have any types of row locking that would permit another transaction to update the row at all.

  This oversight could allow referential integrity checks to give false positives (for instance, allow deletes that should have been rejected). Applications using the new commands SELECT FOR KEY SHARE and SELECT FOR NO KEY UPDATE might also have suffered locking failures of this kind.

- Prevent “forgetting” valid row locks when one of several holders of a row lock aborts (Álvaro Herrera)
  This was yet another mechanism by which a shared row lock could be lost, thus possibly allowing updates that should have been prevented by foreign-key constraints.

- Fix incorrect logic during update chain locking (Álvaro Herrera)
  This mistake could result in spurious “could not serialize access due to concurrent update” errors in REPEATABLE READ and SERIALIZABLE transaction isolation modes.

- Handle wraparound correctly during extension or truncation of pg_multixact/members (Andres Freund, Álvaro Herrera)

- Fix handling of 5-digit filenames in pg_multixact/members (Álvaro Herrera)
  As of 9.3, these names can be more than 4 digits, but the directory cleanup code ignored such files.

- Improve performance of multixact cache code (Álvaro Herrera)

- Optimize updating a row that’s already locked by the same transaction (Andres Freund, Álvaro Herrera)
  This fixes a performance regression from pre-9.3 versions when doing SELECT FOR UPDATE followed by UPDATE/DELETE.

- During archive recovery, prefer highest timeline number when WAL segments with the same ID are present in both the archive and pg_xlog/ (Kyotaro Horiguchi)
  Previously, not-yet-archived segments could get ignored during recovery. This reverts an undesirable behavioral change in 9.3.0 back to the way things worked pre-9.3.

- Fix possible mis-replay of WAL records when some segments of a relation aren’t full size (Greg Stark, Tom Lane)
  The WAL update could be applied to the wrong page, potentially many pages past where it should have been. Aside from corrupting data, this error has been observed to result in significant “bloat” of standby servers compared to their masters, due to updates being applied far beyond where the end-of-file should have been. This failure mode does not appear to be a significant risk during crash recovery, only when initially synchronizing a standby created from a base backup taken from a quickly-changing master.

- Fix bug in determining when recovery has reached consistency (Tomonari Katsumata, Heikki Linnakangas)
In some cases WAL replay would mistakenly conclude that the database was already consistent at the start of replay, thus possibly allowing hot-standby queries before the database was really consistent. Other symptoms such as “PANIC: WAL contains references to invalid pages” were also possible.

- Fix WAL logging of visibility map changes (Heikki Linnakangas)
- Fix improper locking of btree index pages while replaying a VACUUM operation in hot-standby mode (Andres Freund, Heikki Linnakangas, Tom Lane)

This error could result in “PANIC: WAL contains references to invalid pages” failures.

- Ensure that insertions into non-leaf GIN index pages write a full-page WAL record when appropriate (Heikki Linnakangas)

The previous coding risked index corruption in the event of a partial-page write during a system crash.

- When \texttt{pause\_at\_recovery\_target} and \texttt{recovery\_target\_inclusive} are both set, ensure the target record is applied before pausing, not after (Heikki Linnakangas)
- Ensure walreceiver sends hot-standby feedback messages on time even when there is a continuous stream of data (Andres Freund, Amit Kapila)
- Prevent timeout interrupts from taking control away from mainline code unless \texttt{ImmediateInterruptOK} is set (Andres Freund, Tom Lane)

This is a serious issue for any application making use of statement timeouts, as it could cause all manner of strange failures after a timeout occurred. We have seen reports of “stuck” spinlocks, ERRORs being unexpectedly promoted to PANICs, unkillable backends, and other misbehaviors.

- Fix race conditions during server process exit (Robert Haas)

Ensure that signal handlers don’t attempt to use the process’s \texttt{MyProc} pointer after it’s no longer valid.

- Fix race conditions in walsender shutdown logic and walreceiver SIGHUP signal handler (Tom Lane)
- Fix unsafe references to \texttt{errno} within error reporting logic (Christian Kruse)

This would typically lead to odd behaviors such as missing or inappropriate HINT fields.

- Fix possible crashes from using \texttt{ereport()} too early during server startup (Tom Lane)

The principal case we’ve seen in the field is a crash if the server is started in a directory it doesn’t have permission to read.

- Clear retry flags properly in OpenSSL socket write function (Alexander Kukushkin)

This omission could result in a server lockup after unexpected loss of an SSL-encrypted connection.

- Fix length checking for Unicode identifiers (\texttt{U"..."}) containing escapes (Tom Lane)

A spurious truncation warning would be printed for such identifiers if the escaped form of the identifier was too long, but the identifier actually didn’t need truncation after de-escaping.

- Fix parsing of Unicode literals and identifiers just before the end of a command string or function body (Tom Lane)

- Allow keywords that are type names to be used in lists of roles (Stephen Frost)

A previous patch allowed such keywords to be used without quoting in places such as role identifiers; but it missed cases where a list of role identifiers was permitted, such as \texttt{DROP ROLE}.

- Fix parser crash for \texttt{EXISTS(SELECT * FROM zero\_column\_table)} (Tom Lane)
Appendix E. Release Notes

- Fix possible crash due to invalid plan for nested sub-selects, such as `WHERE (... x IN (SELECT ...) ...) IN (SELECT ...)` (Tom Lane)
- Fix mishandling of `WHERE` conditions pulled up from a `LATERAL` subquery (Tom Lane)
  The typical symptom of this bug was a “JOIN qualification cannot refer to other relations” error, though subtle logic errors in created plans seem possible as well.
- Disallow `LATERAL` references to the target table of an `UPDATE/DELETE` (Tom Lane)
  While this might be allowed in some future release, it was unintentional in 9.3, and didn’t work quite right anyway.
- Fix `UPDATE/DELETE` of an inherited target table that has `UNION ALL` subqueries (Tom Lane)
  Without this fix, `UNION ALL` subqueries aren’t correctly inserted into the update plans for inheritance child tables after the first one, typically resulting in no update happening for those child table(s).
- Fix `ANALYZE` to not fail on a column that’s a domain over a range type (Tom Lane)
- Ensure that `ANALYZE` creates statistics for a table column even when all the values in it are “too wide” (Tom Lane)
  `ANALYZE` intentionally omits very wide values from its histogram and most-common-values calculations, but it neglected to do something sane in the case that all the sampled entries are too wide.
- In `ALTER TABLE ... SET TABLESPACE`, allow the database’s default tablespace to be used without a permissions check (Stephen Frost)
  `CREATE TABLE` has always allowed such usage, but `ALTER TABLE` didn’t get the memo.
- Fix support for extensions containing event triggers (Tom Lane)
- Fix “cannot accept a set” error when some arms of a `CASE` return a set and others don’t (Tom Lane)
- Fix memory leakage in JSON functions (Craig Ringer)
- Properly distinguish numbers from non-numbers when generating JSON output (Andrew Dunstan)
- Fix checks for all-zero client addresses in `pgstat` functions (Kevin Grittner)
- Fix possible misclassification of multibyte characters by the text search parser (Tom Lane)
  Non-ASCII characters could be misclassified when using C locale with a multibyte encoding. On Cygwin, non-C locales could fail as well.
- Fix possible misbehavior in ` plainto_tsquery()` (Heikki Linnakangas)
  Use `memmove()` not `memcpy()` for copying overlapping memory regions. There have been no field reports of this actually causing trouble, but it’s certainly risky.
- Fix placement of permissions checks in `pg_start_backup()` and `pg_stop_backup()` (Andres Freund, Magnus Hagander)
  The previous coding might attempt to do catalog access when it shouldn’t.
- Accept `SHIFT_JIS` as an encoding name for locale checking purposes (Tatsuo Ishii)
- Fix `*`-qualification of named parameters in SQL-language functions (Tom Lane)
  Given a composite-type parameter named `foo`, `$1.*` worked fine, but `foo.*` not so much.
- Fix misbehavior of `PQhost()` on Windows (Fujii Masao)
Appendix E. Release Notes

It should return localhost if no host has been specified.

- Improve error handling in libpq and psql for failures during `COPY TO STDOUT/FROM STDIN` (Tom Lane)
  In particular this fixes an infinite loop that could occur in 9.2 and up if the server connection was lost during `COPY FROM STDIN`. Variants of that scenario might be possible in older versions, or with other client applications.

- Fix incorrect translation handling in some psql `\d` commands (Peter Eisentraut, Tom Lane)

- Ensure pg_basebackup’s background process is killed when exiting its foreground process (Magnus Hagander)

- Fix possible incorrect printing of filenames in pg_basebackup’s verbose mode (Magnus Hagander)

- Avoid including tablespaces inside PGDATA twice in base backups (Dimitri Fontaine, Magnus Hagander)

- Fix misaligned descriptors in ecpg (MauMau)

- In ecpg, handle lack of a hostname in the connection parameters properly (Michael Meskes)

- Fix performance regression in contrib/dblink connection startup (Joe Conway)
  Avoid an unnecessary round trip when client and server encodings match.

- In contrib/isn, fix incorrect calculation of the check digit for ISMN values (Fabien Coelho)

- Fix contrib/pgbench’s progress logging to avoid overflow when the scale factor is large (Tatsuo Ishii)

- Fix contrib/pg_stat_statement’s handling of `CURRENT_DATE` and related constructs (Kyotaro Horiguchi)

- Improve lost-connection error handling in contrib/postgres_fdw (Tom Lane)

- Ensure client-code-only installation procedure works as documented (Peter Eisentraut)

- In Mingw and Cygwin builds, install the libpq DLL in the `bin` directory (Andrew Dunstan)
  This duplicates what the MSVC build has long done. It should fix problems with programs like psql failing to start because they can’t find the DLL.

- Avoid using the deprecated `dllwrap` tool in Cygwin builds (Marco Atzeri)

- Enable building with Visual Studio 2013 (Brar Piening)

- Don’t generate plain-text HISTORY and `src/test/regress/README` files anymore (Tom Lane)
  These text files duplicated the main HTML and PDF documentation formats. The trouble involved in maintaining them greatly outweighs the likely audience for plain-text format. Distribution tarballs will still contain files by these names, but they’ll just be stubs directing the reader to consult the main documentation. The plain-text `INSTALL` file will still be maintained, as there is arguably a use-case for that.

- Update time zone data files to tzdata release 2013i for DST law changes in Jordan and historical changes in Cuba.
  In addition, the zones Asia/Riyadh87, Asia/Riyadh88, and Asia/Riyadh89 have been removed, as they are no longer maintained by IANA, and never represented actual civil timekeeping practice.
E.45. Release 9.3.2

Release date: 2013-12-05

This release contains a variety of fixes from 9.3.1. For information about new features in the 9.3 major release, see Section E.47.

E.45.1. Migration to Version 9.3.2

A dump/restore is not required for those running 9.3.X.

However, this release corrects a number of potential data corruption issues. See the first three changelog entries below to find out whether your installation has been affected and what steps you can take if so.

Also, if you are upgrading from a version earlier than 9.3.1, see Section E.46.

E.45.2. Changes

• Fix VACUUM’s tests to see whether it can update relfrozenxid (Andres Freund)
  In some cases VACUUM (either manual or autovacuum) could incorrectly advance a table’s relfrozenxid value, allowing tuples to escape freezing, causing those rows to become invisible once 2^31 transactions have elapsed. The probability of data loss is fairly low since multiple incorrect advancements would need to happen before actual loss occurs, but it’s not zero. In 9.2.0 and later, the probability of loss is higher, and it’s also possible to get “could not access status of transaction” errors as a consequence of this bug. Users upgrading from releases 9.0.4 or 8.4.8 or earlier are not affected, but all later versions contain the bug.

  The issue can be ameliorated by, after upgrading, vacuuming all tables in all databases while having vacuum_freeze_table_age set to zero. This will fix any latent corruption but will not be able to fix all pre-existing data errors. However, an installation can be presumed safe after performing this vacuuming if it has executed fewer than 2^31 update transactions in its lifetime (check this with SELECT txid_current() < 2^31).

• Fix multiple bugs in MultiXactId freezing (Andres Freund, Álvaro Herrera)
  These bugs could lead to “could not access status of transaction” errors, or to duplicate or vanishing rows. Users upgrading from releases prior to 9.3.0 are not affected.

  The issue can be ameliorated by, after upgrading, vacuuming all tables in all databases while having vacuum_freeze_table_age set to zero. This will fix latent corruption but will not be able to fix all pre-existing data errors.

  As a separate issue, these bugs can also cause standby servers to get out of sync with the primary, thus exhibiting data errors that are not in the primary. Therefore, it’s recommended that 9.3.0 and 9.3.1 standby servers be re-cloned from the primary (e.g., with a new base backup) after upgrading.

• Fix initialization of pg_clog and pg_subtrans during hot standby startup (Andres Freund, Heikki Linnakangas)
  This bug can cause data loss on standby servers at the moment they start to accept hot-standby queries, by marking committed transactions as uncommitted. The likelihood of such corruption is small unless,
at the time of standby startup, the primary server has executed many updating transactions since its last
checkpoint. Symptoms include missing rows, rows that should have been deleted being still visible, and
obsolete versions of updated rows being still visible alongside their newer versions.

This bug was introduced in versions 9.3.0, 9.2.5, 9.1.10, and 9.0.14. Standby servers that have only
been running earlier releases are not at risk. It’s recommended that standby servers that have ever run
any of the buggy releases be re-cloned from the primary (e.g., with a new base backup) after upgrading.

- Fix multiple bugs in update chain traversal (Andres Freund, Álvaro Herrera)
  These bugs could result in incorrect behavior, such as locking or even updating the wrong row, in the
  presence of concurrent updates. Spurious “unable to fetch updated version of tuple” errors were also
  possible.
- Fix dangling-pointer problem in fast-path locking (Tom Lane)
  This could lead to corruption of the lock data structures in shared memory, causing “lock already held”
  and other odd errors.
- Fix assorted race conditions in timeout management (Tom Lane)
  These errors could result in a server process becoming unresponsive because it had blocked SIGALRM
  and/or SIGINT.
- Truncate pg_multixact contents during WAL replay (Andres Freund)
  This avoids ever-increasing disk space consumption in standby servers.
- Ensure an anti-wraparound VACUUM counts a page as scanned when it’s only verified that no tuples need
  freezing (Sergey Burladyan, Jeff Janes)
  This bug could result in failing to advance relfrozenxid, so that the table would still be thought to
  need another anti-wraparound vacuum. In the worst case the database might even shut down to prevent
  wraparound.
- Fix full-table-vacuum request mechanism for MultiXactIds (Andres Freund)
  This bug could result in large amounts of useless autovacuum activity.
- Fix race condition in GIN index posting tree page deletion (Heikki Linnakangas)
  This could lead to transient wrong answers or query failures.
- Fix “unexpected spgdoinsert() failure” error during SP-GiST index creation (Teodor Sigaev)
- Fix assorted bugs in materialized views (Kevin Grittner, Andres Freund)
- Re-allow duplicate table aliases if they’re within aliased JOINs (Tom Lane)
  Historically PostgreSQL has accepted queries like
  SELECT ... FROM tab1 x CROSS JOIN (tab2 x CROSS JOIN tab3 y) z
  although a strict reading of the SQL standard would forbid the duplicate usage of table alias x. A
  misguided change in 9.3.0 caused it to reject some such cases that were formerly accepted. Restore the
  previous behavior.
- Avoid flattening a subquery whose SELECT list contains a volatile function wrapped inside a sub-
  SELECT (Tom Lane)
  This avoids unexpected results due to extra evaluations of the volatile function.
- Fix planner’s processing of non-simple-variable subquery outputs nested within outer joins (Tom Lane)
Appendix E. Release Notes

This error could lead to incorrect plans for queries involving multiple levels of subqueries within JOIN syntax.

• Fix incorrect planning in cases where the same non-strict expression appears in multiple WHERE and outer JOIN equality clauses (Tom Lane)
• Fix planner crash with whole-row reference to a subquery (Tom Lane)
• Fix incorrect generation of optimized MIN()/MAX() plans for inheritance trees (Tom Lane)
  The planner could fail in cases where the MIN()/MAX() argument was an expression rather than a simple variable.
• Fix premature deletion of temporary files (Andres Freund)
• Prevent intra-transaction memory leak when printing range values (Tom Lane)
  This fix actually cures transient memory leaks in any datatype output function, but range types are the only ones known to have had a significant problem.
• Fix memory leaks when reloading configuration files (Heikki Linnakangas, Hari Babu)
• Prevent incorrect display of dropped columns in NOT NULL and CHECK constraint violation messages (Michael Paquier and Tom Lane)
• Allow default arguments and named-argument notation for window functions (Tom Lane)
  Previously, these cases were likely to crash.
• Suppress trailing whitespace on each line when pretty-printing rules and views (Tom Lane)
  9.3.0 generated such whitespace in many more cases than previous versions did. To reduce unexpected behavioral changes, suppress unnecessary whitespace in all cases.
• Fix possible read past end of memory in rule printing (Peter Eisentraut)
• Fix array slicing of int2vector and oidvector values (Tom Lane)
  Expressions of this kind are now implicitly promoted to regular int2 or oid arrays.
• Return a valid JSON value when converting an empty hstore value to json (Oskari Saarenmaa)
• Fix incorrect behaviors when using a SQL-standard, simple GMT offset timezone (Tom Lane)
  In some cases, the system would use the simple GMT offset value when it should have used the regular timezone setting that had prevailed before the simple offset was selected. This change also causes the timeofday function to honor the simple GMT offset zone.
• Prevent possible misbehavior when logging translations of Windows error codes (Tom Lane)
• Properly quote generated command lines in pg_ctl (Naoya Anzai and Tom Lane)
  This fix applies only to Windows.
• Fix pg_dumpall to work when a source database sets default_transaction_read_only via ALTER DATABASE SET (Kevin Grittner)
  Previously, the generated script would fail during restore.
• Fix pg_isready to handle its -d option properly (Fabrício de Royes Mello and Fujii Masao)
• Fix parsing of WAL file names in pg_receivexlog (Heikki Linnakangas)
This error made pg_receivexlog unable to restart streaming after stopping, once at least 4 GB of WAL had been written.

- Report out-of-disk-space failures properly in pg_upgrade (Peter Eisentraut)
- Make ecpg search for quoted cursor names case-sensitively (Zoltán Böszörményi)
- Fix ecpg’s processing of lists of variables declared `varchar` (Zoltán Böszörményi)
- Make `contrib/lo` defend against incorrect trigger definitions (Marc Cousin)
- Update time zone data files to tzdata release 2013h for DST law changes in Argentina, Brazil, Jordan, Libya, Liechtenstein, Morocco, and Palestine. Also, new timezone abbreviations WIB, WIT, WITA for Indonesia.

### E.46. Release 9.3.1

**Release date:** 2013-10-10

This release contains a variety of fixes from 9.3.0. For information about new features in the 9.3 major release, see Section E.47.

### E.46.1. Migration to Version 9.3.1

A dump/restore is not required for those running 9.3.X.

However, if you use the `hstore` extension, see the first changelog entry.

### E.46.2. Changes

- Ensure new-in-9.3 JSON functionality is added to the `hstore` extension during an update (Andrew Dunstan)
  
  Users who upgraded a pre-9.3 database containing `hstore` should execute
  ```sql
  ALTER EXTENSION hstore UPDATE;
  ```
  after installing 9.3.1, to add two new JSON functions and a cast. (If `hstore` is already up to date, this command does nothing.)

- Fix memory leak when creating B-tree indexes on range columns (Heikki Linnakangas)
- Fix memory leak caused by `lo_open()` failure (Heikki Linnakangas)
- Serializable snapshot fixes (Kevin Grittner, Heikki Linnakangas)
- Fix deadlock bug in `libpq` when using SSL (Stephen Frost)
- Fix timeline handling bugs in pg_receivexlog (Heikki Linnakangas, Andrew Gierth)
- Prevent `CREATE FUNCTION` from checking `SET` variables unless function body checking is enabled (Tom Lane)
- Remove rare inaccurate warning during vacuum of index-less tables (Heikki Linnakangas)
Appendix E. Release Notes

E.47. Release 9.3

Release date: 2013-09-09

E.47.1. Overview

Major enhancements in PostgreSQL 9.3 include:

- Add materialized views
- Make simple views auto-updatable
- Add many features for the JSON data type, including operators and functions to extract elements from JSON values
- Implement SQL-standard LATERAL option for FROM-clause subqueries and function calls
- Allow foreign data wrappers to support writes (inserts/updates/deletes) on foreign tables
- Add a Postgres foreign data wrapper to allow access to other Postgres servers
- Add support for event triggers
- Add optional ability to checksum data pages and report corruption
- Prevent non-key-field row updates from blocking foreign key checks
- Greatly reduce System V shared memory requirements

The above items are explained in more detail in the sections below.

E.47.2. Migration to Version 9.3

A dump/restore using pg_dumpall, or use of pg_upgrade, is required for those wishing to migrate data from any previous release.

Version 9.3 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

E.47.2.1. Server Settings

- Rename replication_timeout to wal_sender_timeout (Amit Kapila)
  This setting controls the WAL sender timeout.
- Require superuser privileges to set commit_delay because it can now potentially delay other sessions (Simon Riggs)
- Allow in-memory sorts to use their full memory allocation (Jeff Janes)

  Users who have set work_mem based on the previous behavior may need to revisit that setting.
Appendix E. Release Notes

E.47.2.2. Other

• Throw an error if a tuple to be updated or deleted has already been updated or deleted by a BEFORE trigger (Kevin Grittner)

Formerly, the originally-intended update was silently skipped, resulting in logical inconsistency since the trigger might have propagated data to other places based on the intended update. Now an error is thrown to prevent the inconsistent results from being committed. If this change affects your application, the best solution is usually to move the data-propagation actions to an AFTER trigger.

This error will also be thrown if a query invokes a volatile function that modifies rows that are later modified by the query itself. Such cases likewise previously resulted in silently skipping updates.

• Change multicol
   um
   on UPDATE SET NULL/SET DEFAULT foreign key actions to affect all columns of the constraint, not just those changed in the UPDATE (Tom Lane)

Previously, we would set only those referencing columns that correspond to referenced columns that were changed by the UPDATE. This was what was required by SQL-92, but more recent editions of the SQL standard specify the new behavior.

• Force cached plans to be replanned if the search_path changes (Tom Lane)

Previously, cached plans already generated in the current session were not redone if the query was re-executed with a new search_path setting, resulting in surprising behavior.

• Fix to_number() to properly handle a period used as a thousands separator (Tom Lane)

Previously, a period was considered to be a decimal point even when the locale says it isn’t and the D format code is used to specify use of the locale-specific decimal point. This resulted in wrong answers if FM format was also used.

• Fix STRICT non-set-returning functions that have set-returning functions in their arguments to properly return null rows (Tom Lane)

A null value passed to the strict function should result in a null output, but instead, that output row was suppressed entirely.

• Store WAL in a continuous stream, rather than skipping the last 16MB segment every 4GB (Heikki Linnakangas)

Previously, WAL files with names ending in FF were not used because of this skipping. If you have WAL backup or restore scripts that took this behavior into account, they will need to be adjusted.

• In pg_constraint.confmatchtype, store the default foreign key match type (non-FULL, non-PARTIAL) as s for “simple” (Tom Lane)

Previously this case was represented by u for “unspecified”.

E.47.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 9.3 and the previous major release.
E.47.3.1. Server

E.47.3.1.1. Locking

• Prevent non-key-field row updates from blocking foreign key checks (Álvaro Herrera, Noah Misch, Andres Freund, Alexander Shulgin, Marti Raudsepp, Alexander Shulgin)

This change improves concurrency and reduces the probability of deadlocks when updating tables involved in a foreign-key constraint. UPDATES that do not change any columns referenced in a foreign key now take the new NO KEY UPDATE lock mode on the row, while foreign key checks use the new KEY SHARE lock mode, which does not conflict with NO KEY UPDATE. So there is no blocking unless a foreign-key column is changed.

• Add configuration variable lock_timeout to allow limiting how long a session will wait to acquire any one lock (Zoltán Böszörményi)

E.47.3.1.2. Indexes

• Add SP-GiST support for range data types (Alexander Korotkov)

• Allow GiST indexes to be unlogged (Jeevan Chalke)

• Improve performance of GiST index insertion by randomizing the choice of which page to descend to when there are multiple equally good alternatives (Heikki Linnakangas)

• Improve concurrency of hash index operations (Robert Haas)

E.47.3.1.3. Optimizer

• Collect and use histograms of upper and lower bounds, as well as range lengths, for range types (Alexander Korotkov)

• Improve optimizer’s cost estimation for index access (Tom Lane)

• Improve optimizer’s hash table size estimate for doing DISTINCT via hash aggregation (Tom Lane)

• Suppress no-op Result and Limit plan nodes (Kyotaro Horiguchi, Amit Kapila, Tom Lane)

• Reduce optimizer overhead by not keeping plans on the basis of cheap startup cost when the optimizer only cares about total cost overall (Tom Lane)

E.47.3.1.4. General Performance

• Add COPY FREEZE option to avoid the overhead of marking tuples as frozen later (Simon Riggs, Jeff Davis)

• Improve performance of NUMERIC calculations (Kyotaro Horiguchi)

• Improve synchronization of sessions waiting for commit_delay (Peter Geoghegan)

This greatly improves the usefulness of commit_delay.
Appendix E. Release Notes

- Improve performance of the `CREATE TEMPORARY TABLE ... ON COMMIT DELETE ROWS` option by not truncating such temporary tables in transactions that haven’t touched any temporary tables (Heikki Linnakangas)

- Make vacuum recheck visibility after it has removed expired tuples (Pavan Deolasee)
  
  This increases the chance of a page being marked as all-visible.

- Add per-resource-owner lock caches (Jeff Janes)
  
  This speeds up lock bookkeeping at statement completion in multi-statement transactions that hold many locks; it is particularly useful for `pg_dump`.

- Avoid scanning the entire relation cache at commit of a transaction that creates a new relation (Jeff Janes)
  
  This speeds up sessions that create many tables in successive small transactions, such as a `pg_restore` run.

- Improve performance of transactions that drop many relations (Tomas Vondra)

E.47.3.1.5. Monitoring

- Add optional ability to checksum data pages and report corruption (Simon Riggs, Jeff Davis, Greg Smith, Ants Aasma)
  
  The checksum option can be set during `initdb`.

- Split the statistics collector’s data file into separate global and per-database files (Tomas Vondra)
  
  This reduces the I/O required for statistics tracking.

- Fix the statistics collector to operate properly in cases where the system clock goes backwards (Tom Lane)
  
  Previously, statistics collection would stop until the time again reached the latest time previously recorded.

- Emit an informative message to postmaster standard error when we are about to stop logging there (Tom Lane)
  
  This should help reduce user confusion about where to look for log output in common configurations that log to standard error only during postmaster startup.

E.47.3.1.6. Authentication

- When an authentication failure occurs, log the relevant `pg_hba.conf` line, to ease debugging of unintended failures (Magnus Hagander)

- Improve LDAP error reporting and documentation (Peter Eisentraut)

- Add support for specifying LDAP authentication parameters in URL format, per RFC 4516 (Peter Eisentraut)

- Change the `ssl_ciphers` parameter to start with `DEFAULT`, rather than `ALL`, then remove insecure ciphers (Magnus Hagander)
This should yield a more appropriate SSL cipher set.

- Parse and load `pg_ident.conf` once, not during each connection (Amit Kapila)
  This is similar to how `pg_hba.conf` is processed.

### E.47.3.1.7. Server Settings

- Greatly reduce System V shared memory requirements (Robert Haas)
  On Unix-like systems, `mmap()` is now used for most of PostgreSQL’s shared memory. For most users, this will eliminate any need to adjust kernel parameters for shared memory.

- Allow the postmaster to listen on multiple Unix-domain sockets (Honza Horák)
  The configuration parameter `unix_socket_directory` is replaced by `unix_socket_directories`, which accepts a list of directories.

- Allow a directory of configuration files to be processed (Magnus Hagander, Greg Smith, Selena Deckelmann)
  Such a directory is specified with `include_dir` in the server configuration file.

- Increase the maximum initdb-configured value for `shared_buffers` to 128MB (Robert Haas)
  This is the maximum value that initdb will attempt to set in `postgresql.conf`; the previous maximum was 32MB.

- Remove the external PID file, if any, on postmaster exit (Peter Eisentraut)

### E.47.3.2. Replication and Recovery

- Allow a streaming replication standby to follow a timeline switch (Heikki Linnakangas)
  This allows streaming standby servers to receive WAL data from a slave newly promoted to master status. Previously, other standbys would require a resync to begin following the new master.

- Add SQL functions `pg_is_in_backup()` and `pg_backup_start_time()` (Gilles Darold)
  These functions report the status of base backups.

- Improve performance of streaming log shipping with `synchronous_commit` disabled (Andres Freund)

- Allow much faster promotion of a streaming standby to primary (Simon Riggs, Kyotaro Horiguchi)

- Add the last checkpoint’s redo location to `pg_controldata`’s output (Fujii Masao)
  This information is useful for determining which WAL files are needed for restore.

- Allow tools like `pg_receivexlog` to run on computers with different architectures (Heikki Linnakangas)
  WAL files can still only be replayed on servers with the same architecture as the primary; but they can now be transmitted to and stored on machines of any architecture, since the streaming replication protocol is now machine-independent.
• Make `pg_basebackup --write-recovery-conf` output a minimal `recovery.conf` file (Zoltán Bőszörményi, Magnus Hagander)
  This simplifies setting up a standby server.
• Allow `pg_receivexlog` and `pg_basebackup --xlog-method` to handle streaming timeline switches (Heikki Linnakangas)
• Add `wal_receiver_timeout` parameter to control the WAL receiver’s timeout (Amit Kapila)
  This allows more rapid detection of connection failure.
• Change the WAL record format to allow splitting the record header across pages (Heikki Linnakangas)
  The new format is slightly more compact, and is more efficient to write.

E.47.3.3. Queries

• Implement SQL-standard `LATERAL` option for `FROM`-clause subqueries and function calls (Tom Lane)
  This feature allows subqueries and functions in `FROM` to reference columns from other tables in the `FROM` clause. The `LATERAL` keyword is optional for functions.
• Add support for piping `COPY` and `psql \copy` data to/from an external program (Etsuro Fujita)
• Allow a multirow `VALUES` clause in a rule to reference `OLD/NEW` (Tom Lane)

E.47.3.4. Object Manipulation

• Add support for event triggers (Dimitri Fontaine, Robert Haas, Álvaro Herrera)
  This allows server-side functions written in event-enabled languages to be called when DDL commands are run.
• Allow foreign data wrappers to support writes (inserts/updates/deletes) on foreign tables (KaiGai Kohei)
• Add `CREATE SCHEMA ... IF NOT EXISTS` clause (Fabrízio de Royes Mello)
• Make `REASSIGN OWNED` also change ownership of shared objects (Álvaro Herrera)
• Make `CREATE AGGREGATE` complain if the given initial value string is not valid input for the transition datatype (Tom Lane)
• Suppress `CREATE TABLE`’s messages about implicit index and sequence creation (Robert Haas)
  These messages now appear at `DEBUG1` verbosity, so that they will not be shown by default.
• Allow `DROP TABLE IF EXISTS` to succeed when a non-existent schema is specified in the table name (Bruce Momjian)
  Previously, it threw an error if the schema did not exist.
• Provide clients with constraint violation details as separate fields (Pavel Stehule)
Appendix E. Release Notes

This allows clients to retrieve table, column, data type, or constraint name error details. Previously such information had to be extracted from error strings. Client library support is required to access these fields.

E.47.3.4.1. ALTER

- **Support IF NOT EXISTS option in ALTER TYPE ... ADD VALUE** (Andrew Dunstan)
  This is useful for conditionally adding values to enumerated types.
- **Add ALTER ROLE ALL SET to establish settings for all users** (Peter Eisentraut)
  This allows settings to apply to all users in all databases. ALTER DATABASE SET already allowed addition of settings for all users in a single database. postgresql.conf has a similar effect.
- **Add support for ALTER RULE ... RENAME** (Ali Dar)

E.47.3.4.2. VIEWS

- **Add materialized views** (Kevin Grittner)
  Unlike ordinary views, where the base tables are read on every access, materialized views create physical tables at creation or refresh time. Access to the materialized view then reads from its physical table. There is not yet any facility for incrementally refreshing materialized views or auto-accessing them via base table access.
- **Make simple views auto-updatable** (Dean Rasheed)
  Simple views that reference some or all columns from a single base table are now updatable by default. More complex views can be made updatable using INSTEAD OF triggers or INSTEAD rules.
- **Add CREATE RECURSIVE VIEW syntax** (Peter Eisentraut)
  Internally this is translated into CREATE VIEW ... WITH RECURSIVE ....
- **Improve view/rule printing code to handle cases where referenced tables are renamed, or columns are renamed, added, or dropped** (Tom Lane)
  Table and column renamings can produce cases where, if we merely substitute the new name into the original text of a rule or view, the result is ambiguous. This change fixes the rule-dumping code to insert manufactured table and column aliases when needed to preserve the original semantics.

E.47.3.5. Data Types

- **Increase the maximum size of large objects from 2GB to 4TB** (Nozomi Anzai, Yugo Nagata)
  This change includes adding 64-bit-capable large object access functions, both in the server and in libpq.
- **Allow text timezone designations, e.g. “America/Chicago”, in the “T” field of ISO-format timestamptz input** (Bruce Momjian)
Appendix E. Release Notes

E.47.3.5.1. JSON

• Add operators and functions to extract elements from JSON values (Andrew Dunstan)
• Allow JSON values to be converted into records (Andrew Dunstan)
• Add functions to convert scalars, records, and hstore values to JSON (Andrew Dunstan)

E.47.3.6. Functions

• Add array_remove() and array_replace() functions (Marco Nenciarini, Gabriele Bartolini)
• Allow concat() and format() to properly expand VARIADIC-labeled arguments (Pavel Stehule)
• Improve format() to provide field width and left/right alignment options (Pavel Stehule)
• Make to_char(), to_date(), and to_timestamp() handle negative (BC) century values properly (Bruce Momjian)
  Previously the behavior was either wrong or inconsistent with positive/AD handling, e.g. with the format mask “IYYY-IW-DY”.
• Make to_date() and to_timestamp() return proper results when mixing ISO and Gregorian week/day designations (Bruce Momjian)
• Cause pg_get_viewdef() to start a new line by default after each SELECT target list entry and FROM entry (Marko Tiikkaja)
  This reduces line length in view printing, for instance in pg_dump output.
• Fix map_sql_value_to_xml_value() to print values of domain types the same way their base type would be printed (Pavel Stehule)
  There are special formatting rules for certain built-in types such as boolean; these rules now also apply to domains over these types.

E.47.3.7. Server-Side Languages

E.47.3.7.1. PL/pgSQL Server-Side Language

• Allow PL/pgSQL to use RETURN with a composite-type expression (Asif Rehman)
  Previously, in a function returning a composite type, RETURN could only reference a variable of that type.
• Allow PL/pgSQL to access constraint violation details as separate fields (Pavel Stehule)
• Allow PL/pgSQL to access the number of rows processed by COPY (Pavel Stehule)
  A COPY executed in a PL/pgSQL function now updates the value retrieved by GET DIAGNOSTICS x = ROW_COUNT.
• Allow unreserved keywords to be used as identifiers everywhere in PL/pgSQL (Tom Lane)
In certain places in the PL/pgSQL grammar, keywords had to be quoted to be used as identifiers, even if they were nominally unreserved.

E.47.3.7.2. PL/Python Server-Side Language

- Add PL/Python result object string handler (Peter Eisentraut)
  This allows \texttt{plpy.debug(rv)} to output something reasonable.
- Make PL/Python convert OID values to a proper Python numeric type (Peter Eisentraut)
- Handle SPI errors raised explicitly (with PL/Python’s \texttt{RAISE}) the same as internal SPI errors (Oskari Saarenmaa and Jan Urbanski)

E.47.3.8. Server Programming Interface (SPI)

- Prevent leakage of SPI tuple tables during subtransaction abort (Tom Lane)
  At the end of any failed subtransaction, the core SPI code now releases any SPI tuple tables that were created during that subtransaction. This avoids the need for SPI-using code to keep track of such tuple tables and release them manually in error-recovery code. Failure to do so caused a number of transaction-lifespan memory leakage issues in PL/pgSQL and perhaps other SPI clients. \texttt{SPI_freetuptable()} now protects itself against multiple freeing requests, so any existing code that did take care to clean up shouldn’t be broken by this change.
- Allow SPI functions to access the number of rows processed by \texttt{COPY} (Pavel Stehule)

E.47.3.9. Client Applications

- Add command-line utility \texttt{pg_isready} to check if the server is ready to accept connections (Phil Sorber)
- Support multiple \texttt{--table} arguments for \texttt{pg_restore}, \texttt{clusterdb}, \texttt{reindexdb}, and \texttt{vacuumdb} (Josh Kupershmidt)
  This is similar to the way \texttt{pg_dump’s} \texttt{--table} option works.
- Add \texttt{--dbname} option to \texttt{pg_dumpall}, \texttt{pg_basebackup}, and \texttt{pg_receivexlog} to allow specifying a connection string (Amit Kapila)
- Add \texttt{libpq} function \texttt{PQconninfo()} to return connection information (Zoltán Bőszörményi, Magnus Hagander)

E.47.3.9.1. \texttt{psql}

- Adjust function cost settings so \texttt{psql} tab completion and pattern searching are more efficient (Tom Lane)
- Improve \texttt{psql’s} tab completion coverage (Jeff Janes, Dean Rasheed, Peter Eisentraut, Magnus Hagander)
Appendix E. Release Notes

• Allow the psql `--single-transaction` mode to work when reading from standard input (Fabien Coelho, Robert Haas)
  Previously this option only worked when reading from a file.

• Remove psql warning when connecting to an older server (Peter Eisentraut)
  A warning is still issued when connecting to a server of a newer major version than psql’s.

E.47.3.9.1.1. Backslash Commands

• Add psql command `\watch` to repeatedly execute a SQL command (Will Leinweber)
• Add psql command `\gset` to store query results in psql variables (Pavel Stehule)
• Add SSL information to psql’s `\conninfo` command (Alastair Turner)
• Add “Security” column to psql’s `\df+` output (Jon Erdman)
• Allow psql command `\1` to accept a database name pattern (Peter Eisentraut)
• In psql, do not allow `\connect` to use defaults if there is no active connection (Bruce Momjian)
  This might be the case if the server had crashed.
• Properly reset state after failure of a SQL command executed with psql’s `\g file` (Tom Lane)
  Previously, the output from subsequent SQL commands would unexpectedly continue to go to the same file.

E.47.3.9.1.2. Output

• Add a `latex-longtable` output format to psql (Bruce Momjian)
  This format allows tables to span multiple pages.
• Add a `border=3` output mode to the psql `latex` format (Bruce Momjian)
• In psql’s tuples-only and expanded output modes, no longer emit “(No rows)” for zero rows (Peter Eisentraut)
• In psql’s unaligned, expanded output mode, no longer print an empty line for zero rows (Peter Eisentraut)

E.47.3.9.2. pg_dump

• Add `pg_dump --jobs` option to dump tables in parallel (Joachim Wieland)
• Make `pg_dump` output functions in a more predictable order (Joel Jacobson)
• Fix tar files emitted by `pg_dump` to be POSIX conformant (Brian Weaver, Tom Lane)
• Add `--dbname` option to `pg_dump`, for consistency with other client commands (Heikki Linnakangas)
  The database name could already be supplied last without a flag.
Appendix E. Release Notes

E.47.3.9.3. initdb

- Make initdb fsync the newly created data directory (Jeff Davis)
  This insures data integrity in event of a system crash shortly after initdb. This can be disabled by using
  \(--nosync\).
- Add initdb \(--sync-only\) option to sync the data directory to durable storage (Bruce Momjian)
  This is used by pg_upgrade.
- Make initdb issue a warning about placing the data directory at the top of a file system mount point
  (Bruce Momjian)

E.47.3.10. Source Code

- Add infrastructure to allow plug-in background worker processes (Álvaro Herrera)
- Create a centralized timeout API (Zoltán Böszörményi)
- Create libpgcommon and move \texttt{pg_malloc()} and other functions there (Álvaro Herrera, Andres Freund)
  This allows libpgport to be used solely for portability-related code.
- Add support for list links embedded in larger structs (Andres Freund)
- Use \texttt{SA_RESTART} for all signals, including \texttt{SIGALRM} (Tom Lane)
- Ensure that the correct text domain is used when translating \texttt{errcontext()} messages (Heikki Linnakangas)
- Standardize naming of client-side memory allocation functions (Tom Lane)
- Provide support for “static assertions” that will fail at compile time if some compile-time-constant
  condition is not met (Andres Freund, Tom Lane)
- Support \texttt{Assert()} in client-side code (Andrew Dunstan)
- Add decoration to inform the C compiler that some \texttt{ereport()} and \texttt{elog()} calls do not return (Peter
  Eisentraut, Andres Freund, Tom Lane, Heikki Linnakangas)
- Allow options to be passed to the regression test output comparison utility via
  \texttt{PG_REGRESS_DIFF_OPTS} (Peter Eisentraut)
- Add isolation tests for \texttt{CREATE INDEX CONCURRENTLY} (Abhijit Menon-Sen)
- Remove typedefs for \texttt{int2/int4} as they are better represented as \texttt{int16/int32} (Peter Eisentraut)
- Fix install-strip on Mac OS X (Peter Eisentraut)
- Remove configure flag \texttt{--disable-shared}, as it is no longer supported (Bruce Momjian)
- Rewrite pgindent in Perl (Andrew Dunstan)
- Provide Emacs macro to set Perl formatting to match PostgreSQL’s perltidy settings (Peter Eisentraut)
- Run tool to check the keyword list whenever the backend grammar is changed (Tom Lane)
• Change the way `UESCAPE` is lexed, to significantly reduce the size of the lexer tables (Heikki Linnakangas)

• Centralize flex and bison make rules (Peter Eisentraut)
  This is useful for pgxs authors.

• Change many internal backend functions to return object OIDs rather than void (Dimitri Fontaine)
  This is useful for event triggers.

• Invent pre-commit/pre-prepare/pre-subcommit events for transaction callbacks (Tom Lane)
  Loadable modules that use transaction callbacks might need modification to handle these new event types.

• Add function `pg_identify_object()` to produce a machine-readable description of a database object (Álvaro Herrera)

• Add post-ALTER-object server hooks (KaiGai Kohei)

• Implement a generic binary heap and use it for Merge-Append operations (Abhijit Menon-Sen)

• Provide a tool to help detect timezone abbreviation changes when updating the `src/timezone/data` files (Tom Lane)

• Add pkg-config support for libpq and ecpg libraries (Peter Eisentraut)

• Remove `src/tools/backend`, now that the content is on the PostgreSQL wiki (Bruce Momjian)

• Split out WAL reading as an independent facility (Heikki Linnakangas, Andres Freund)

• Use a 64-bit integer to represent WAL positions (`XLogRecPtr`) instead of two 32-bit integers (Heikki Linnakangas)
  Generally, tools that need to read the WAL format will need to be adjusted.

• Allow PL/Python to support platform-specific include directories (Peter Eisentraut)

• Allow PL/Python on OS X to build against custom versions of Python (Peter Eisentraut)

### E.47.3.11. Additional Modules

• Add a Postgres foreign data wrapper contrib module to allow access to other Postgres servers (Shigeru Hanada)
  This foreign data wrapper supports writes.

• Add `pg_xlogdump` contrib program (Andres Freund)

• Add support for indexing of regular-expression searches in `pg_trgm` (Alexander Korotkov)

• Improve `pg_trgm`’s handling of multibyte characters (Tom Lane)
  On a platform that does not have the `wcstombs()` or `towlower()` library functions, this could result in an incompatible change in the contents of `pg_trgm` indexes for non-ASCII data. In such cases, `REINDEX` those indexes to ensure correct search results.

• Add a `pgstattuple` function to report the size of the pending-insertions list of a GIN index (Fujii Masao)

• Make `oid2name`, `pgbench`, and `vacuumlo` set `fallback_application_name` (Amit Kapila)
Appendix E. Release Notes

• Improve output of pg_test_timing (Bruce Momjian)

• Improve output of pg_test_fsync (Peter Geoghegan)

• Create a dedicated foreign data wrapper, with its own option validator function, for dblink (Shigeru Hanada)

  When using this FDW to define the target of a dblink connection, instead of using a hard-wired list of connection options, the underlying libpq library is consulted to see what connection options it supports.

E.47.3.11.1. pg_upgrade

• Allow pg_upgrade to do dumps and restores in parallel (Bruce Momjian, Andrew Dunstan)

  This allows parallel schema dump/restore of databases, as well as parallel copy/link of data files per tablespace. Use the --jobs option to specify the level of parallelism.

• Make pg_upgrade create Unix-domain sockets in the current directory (Bruce Momjian, Tom Lane)

  This reduces the possibility that someone will accidentally connect during the upgrade.

• Make pg_upgrade --check mode properly detect the location of non-default socket directories (Bruce Momjian, Tom Lane)

• Improve performance of pg_upgrade for databases with many tables (Bruce Momjian)

• Improve pg_upgrade’s logs by showing executed commands (Álvaro Herrera)

• Improve pg_upgrade’s status display during copy/link (Bruce Momjian)

E.47.3.11.2. pgbench

• Add --foreign-keys option to pgbench (Jeff Janes)

  This adds foreign key constraints to the standard tables created by pgbench, for use in foreign key performance testing.

• Allow pgbench to aggregate performance statistics and produce output every --aggregate-interval seconds (Tomas Vondra)

• Add pgbench --sampling-rate option to control the percentage of transactions logged (Tomas Vondra)

• Reduce and improve the status message output of pgbench’s initialization mode (Robert Haas, Peter Eisentraut)

• Add pgbench -q mode to print one output line every five seconds (Tomas Vondra)

• Output pgbench elapsed and estimated remaining time during initialization (Tomas Vondra)

• Allow pgbench to use much larger scale factors, by changing relevant columns from integer to bigint when the requested scale factor exceeds 20000 (Greg Smith)
E.47.3.12. Documentation

- Allow EPUB-format documentation to be created (Peter Eisentraut)
- Update FreeBSD kernel configuration documentation (Brad Davis)
- Improve `WINDOW` function documentation (Bruce Momjian, Florian Pflug)
- Add instructions for setting up the documentation tool chain on macOS (Peter Eisentraut)
- Improve `commit_delay` documentation (Peter Geoghegan)

**Release date:** 2017-11-09

This release contains a variety of fixes from 9.2.23. For information about new features in the 9.2 major release, see Section E.72.

This is expected to be the last PostgreSQL release in the 9.2.X series. Users are encouraged to update to a newer release branch soon.

E.48.1. Migration to Version 9.2.24

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.22, see Section E.50.

E.48.2. Changes

- Fix sample server-start scripts to become `$PGUSER` before opening `$PGLOG` (Noah Misch)
  
  Previously, the postmaster log file was opened while still running as root. The database owner could therefore mount an attack against another system user by making `$PGLOG` be a symbolic link to some other file, which would then become corrupted by appending log messages.

  By default, these scripts are not installed anywhere. Users who have made use of them will need to manually recopy them, or apply the same changes to their modified versions. If the existing `$PGLOG` file is root-owned, it will need to be removed or renamed out of the way before restarting the server with the corrected script. (CVE-2017-12172)

- Properly reject attempts to convert infinite float values to type `numeric` (Tom Lane, KaiGai Kohei)
  
  Previously the behavior was platform-dependent.

- Fix corner-case crashes when columns have been added to the end of a view (Tom Lane)

- Record proper dependencies when a view or rule contains `FieldSelect` or `FieldStore` expression nodes (Tom Lane)
Lack of these dependencies could allow a column or data type `DROP` to go through when it ought to fail, thereby causing later uses of the view or rule to get errors. This patch does not do anything to protect existing views/rules, only ones created in the future.

- Correctly detect hashability of range data types (Tom Lane)
  The planner mistakenly assumed that any range type could be hashed for use in hash joins or hash aggregation, but actually it must check whether the range’s subtype has hash support. This does not affect any of the built-in range types, since they’re all hashable anyway.

- Fix low-probability loss of `NOTIFY` messages due to XID wraparound (Marko Tiikkaja, Tom Lane)
  If a session executed no queries, but merely listened for notifications, for more than 2 billion transactions, it started to miss some notifications from concurrently-committing transactions.

- Prevent low-probability crash in processing of nested trigger firings (Tom Lane)

- Correctly restore the umask setting when file creation fails in `COPY` or `lo_export()` (Peter Eisentraut)

- Give a better error message for duplicate column names in `ANALYZE` (Nathan Bossart)

- Fix `libpq` to not require user’s home directory to exist (Tom Lane)
  In v10, failure to find the home directory while trying to read `~/.pgpass` was treated as a hard error, but it should just cause that file to not be found. Both v10 and previous release branches made the same mistake when reading `~/.pg_service.conf`, though this was less obvious since that file is not sought unless a service name is specified.

- Fix `libpq` to guard against integer overflow in the row count of a `PGresult` (Michael Paquier)

- Sync our copy of the timezone library with IANA release tzcode2017c (Tom Lane)
  This fixes various issues; the only one likely to be user-visible is that the default DST rules for a POSIX-style zone name, if no `posixrules` file exists in the timezone data directory, now match current US law rather than what it was a dozen years ago.

- Update time zone data files to tzdata release 2017c for DST law changes in Fiji, Namibia, Northern Cyprus, Sudan, Tonga, and Turks & Caicos Islands, plus historical corrections for Alaska, Apia, Burma, Calcutta, Detroit, Ireland, Namibia, and Pago Pago.

### E.49. Release 9.2.23

**Release date:** 2017-08-31

This release contains a small number of fixes from 9.2.22. For information about new features in the 9.2 major release, see Section E.72.

The PostgreSQL community will stop releasing updates for the 9.2.X release series in September 2017. Users are encouraged to update to a newer release branch soon.

### E.49.1. Migration to Version 9.2.23

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.22, see Section E.50.
E.49.2. Changes

- Show foreign tables in `information_schema.table_privileges` view (Peter Eisentraut)

  All other relevant `information_schema` views include foreign tables, but this one ignored them.

  Since this view definition is installed by initdb, merely upgrading will not fix the problem. If you need to fix this in an existing installation, you can, as a superuser, do this in psql:

  ```sql
  SET search_path TO information_schema;
  CREATE OR REPLACE VIEW table_privileges AS
  SELECT CAST(u_grantor.rolname AS sql_identifier) AS grantor,
         CAST(grantee.rolname AS sql_identifier) AS grantee,
         CAST(current_database() AS sql_identifier) AS table_catalog,
         CAST(nc.nspname AS sql_identifier) AS table_schema,
         CAST(c.relname AS sql_identifier) AS table_name,
         CAST(c.prtype AS character_data) AS privilege_type,
         CAST(CASE WHEN
                  -- object owner always has grant options
                  pg_has_role(grantee.oid, c.relowner, 'USAGE')
                  OR c.grantable
                THEN 'YES' ELSE 'NO' END AS yes_or_no) AS is_grantable,
         CAST(CASE WHEN c.prtype = 'SELECT' THEN 'YES' ELSE 'NO' END AS yes_or_no) AS with_hierarchy
  FROM (SELECT oid, relname, relnamespace, relkind, relowner, (aclexplode(coalesce(relacl, acldefault('r', relowner)))).* FROM pg_class
        ) AS c (oid, relname, relnamespace, relkind, relowner, grantor, grantee, prtype, grantable)
  LEFT JOIN pg_namespace nc
  LEFT JOIN pg_authid u_grantor,
  (SELECT oid, rolname FROM pg_authid
   UNION ALL
   SELECT 0::oid, 'PUBLIC') AS grantee (oid, rolname)
  WHERE c.relnamespace = nc.oid
  AND c.relkind IN ('r', 'v', 'f')
  AND c.grantee = grantee.oid
  AND c.grantor = u_grantor.oid
  AND c.prtype IN ('INSERT', 'SELECT', 'UPDATE', 'DELETE', 'TRUNCATE', 'REFERENCES',
                   'TRIGGER')
  AND (pg_has_role(u_grantor.oid, 'USAGE')
       OR pg_has_role(grantee.oid, 'USAGE')
       OR grantee.rolname = 'PUBLIC');
  ```

  This must be repeated in each database to be fixed, including `template0`.

- Clean up handling of a fatal exit (e.g., due to receipt of SIGTERM) that occurs while trying to execute a `ROLLBACK` of a failed transaction (Tom Lane)

  This situation could result in an assertion failure. In production builds, the exit would still occur, but it would log an unexpected message about “cannot drop active portal”.

- Remove assertion that could trigger during a fatal exit (Tom Lane)
• Correctly identify columns that are of a range type or domain type over a composite type or domain type being searched for (Tom Lane)
  Certain ALTER commands that change the definition of a composite type or domain type are supposed to fail if there are any stored values of that type in the database, because they lack the infrastructure needed to update or check such values. Previously, these checks could miss relevant values that are wrapped inside range types or sub-domains, possibly allowing the database to become inconsistent.

• Change ecpg’s parser to allow RETURNING clauses without attached C variables (Michael Meskes)
  This allows ecpg programs to contain SQL constructs that use RETURNING internally (for example, inside a CTE) rather than using it to define values to be returned to the client.

• Improve selection of compiler flags for PL/Perl on Windows (Tom Lane)
  This fix avoids possible crashes of PL/Perl due to inconsistent assumptions about the width of time_t values. A side-effect that may be visible to extension developers is that _USE_32BIT_TIME_T is no longer defined globally in PostgreSQL Windows builds. This is not expected to cause problems, because type time_t is not used in any PostgreSQL API definitions.

E.50. Release 9.2.22

Release date: 2017-08-10

This release contains a variety of fixes from 9.2.21. For information about new features in the 9.2 major release, see Section E.72.

The PostgreSQL community will stop releasing updates for the 9.2.X release series in September 2017. Users are encouraged to update to a newer release branch soon.

E.50.1. Migration to Version 9.2.22

A dump/restore is not required for those running 9.2.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.2.20, see Section E.52.

E.50.2. Changes

• Further restrict visibility of pg_user_mappings.umoptions, to protect passwords stored as user mapping options (Noah Misch)
  The fix for CVE-2017-7486 was incorrect: it allowed a user to see the options in her own user mapping, even if she did not have USAGE permission on the associated foreign server. Such options might include a password that had been provided by the server owner rather than the user herself. Since information_schema.user_mapping_options does not show the options in such cases, pg_user_mappings should not either. (CVE-2017-7547)
Appendix E. Release Notes

By itself, this patch will only fix the behavior in newly initdb’d databases. If you wish to apply this change in an existing database, you will need to do the following:

1. **Restart the postmaster after adding** `allow_system_tableMods = true` **to** `postgresql.conf`. (In versions supporting `ALTER SYSTEM`, you can use that to make the configuration change, but you’ll still need a restart.)

2. **In each** database of the cluster, run the following commands as superuser:

   ```sql
   SET search_path = pg_catalog;
   CREATE OR REPLACE VIEW pg_user_mappings AS
     SELECT
       U.oid AS umid,
       S.oid AS srvid,
       S.srvname AS srvname,
       U.umuser AS umuser,
       CASE WHEN U.umuser = 0 THEN 'public' ELSE A.rolname END AS usename,
       CASE WHEN (U.umuser <> 0 AND A.rolname = current_user
       AND (pg_has_role(S.srvowner, 'USAGE')
       OR has_server_privilege(S.oid, 'USAGE'))) OR (U.umuser = 0 AND pg_has_role(S.srvowner, 'USAGE')) OR (SELECT rolsuper FROM pg_authid WHERE rolname = current_user)
       THEN U.umoptions
       ELSE NULL END AS umoptions
     FROM pg_user_mapping U
     LEFT JOIN pg_authid A ON (A.oid = U.umuser) JOIN
     pg_foreign_server S ON (U.umserver = S.oid);
   ```

3. **Do not forget to include the** `template0` **and** `template1` **databases, or the vulnerability will still exist in databases you create later. To fix** `template0`, **you’ll need to temporarily make it accept connections. In PostgreSQL 9.5 and later, you can use**

   ```sql
   ALTER DATABASE template0 WITH ALLOW_CONNECTIONS true;
   ```

   **and then after fixing** `template0`, **undo that with**

   ```sql
   ALTER DATABASE template0 WITH ALLOW_CONNECTIONS false;
   ```

   **In prior versions, instead use**

   ```sql
   UPDATE pg_database SET datallowconn = true WHERE datname = 'template0';
   UPDATE pg_database SET datallowconn = false WHERE datname = 'template0';
   ```

4. **Finally, remove the** `allow_system_tableMods` **configuration setting, and again restart the postmaster.**

   • Disallow empty passwords in all password-based authentication methods (Heikki Linnakangas)

   libpq ignores empty password specifications, and does not transmit them to the server. So, if a user’s password has been set to the empty string, it’s impossible to log in with that password via psql or other libpq-based clients. An administrator might therefore believe that setting the password to empty is equivalent to disabling password login. However, with a modified or non-libpq-based client, logging
Appendix E. Release Notes

in could be possible, depending on which authentication method is configured. In particular the most common method, md5, accepted empty passwords. Change the server to reject empty passwords in all cases. (CVE-2017-7546)

- On Windows, retry process creation if we fail to reserve the address range for our shared memory in the new process (Tom Lane, Amit Kapila)
  This is expected to fix infrequent child-process-launch failures that are probably due to interference from antivirus products.
- Fix low-probability corruption of shared predicate-lock hash table in Windows builds (Thomas Munro, Tom Lane)
- Avoid logging clean closure of an SSL connection as though it were a connection reset (Michael Paquier)
- Prevent sending SSL session tickets to clients (Tom Lane)
  This fix prevents reconnection failures with ticket-aware client-side SSL code.
- Fix code for setting tcp_keepalives_idle on Solaris (Tom Lane)
- Fix statistics collector to honor inquiry messages issued just after a postmaster shutdown and immediate restart (Tom Lane)
  Statistics inquiries issued within half a second of the previous postmaster shutdown were effectively ignored.
- Ensure that the statistics collector’s receive buffer size is at least 100KB (Tom Lane)
  This reduces the risk of dropped statistics data on older platforms whose default receive buffer size is less than that.
- Fix possible creation of an invalid WAL segment when a standby is promoted just after it processes an XLOG_SWITCH WAL record (Andres Freund)
- Fix SIGHUP and SIGUSR1 handling in walsender processes (Petr Jelinek, Andres Freund)
- Fix unnecessarily slow restarts of walreceiver processes due to race condition in postmaster (Tom Lane)
- Fix cases where an INSERT or UPDATE assigns to more than one element of a column that is of domain-over-array type (Tom Lane)
- Move autogenerated array types out of the way during ALTER ... RENAME (Vik Fearing)
  Previously, we would rename a conflicting autogenerated array type out of the way during CREATE; this fix extends that behavior to renaming operations.
- Ensure that ALTER USER ... SET accepts all the syntax variants that ALTER ROLE ... SET does (Peter Eisentraut)
- Properly update dependency info when changing a datatype I/O function’s argument or return type from opaque to the correct type (Heikki Linnakangas)
  CREATE TYPE updates I/O functions declared in this long-obsolete style, but it forgot to record a dependency on the type, allowing a subsequent DROP TYPE to leave broken function definitions behind.
- Reduce memory usage when ANALYZE processes a tsvector column (Heikki Linnakangas)
- Fix unnecessary precision loss and sloppy rounding when multiplying or dividing money values by integers or floats (Tom Lane)
Appendix E. Release Notes

• Tighten checks for whitespace in functions that parse identifiers, such as `regprocedurein()` (Tom Lane)

  Depending on the prevailing locale, these functions could misinterpret fragments of multibyte characters as whitespace.

• Use relevant `#define` symbols from Perl while compiling PL/Perl (Ashutosh Sharma, Tom Lane)

  This avoids portability problems, typically manifesting as a “handshake” mismatch during library load, when working with recent Perl versions.

• In `psql`, fix failure when `COPY FROM STDIN` is ended with a keyboard EOF signal and then another `COPY FROM STDIN` is attempted (Thomas Munro)

  This misbehavior was observed on BSD-derived platforms (including macOS), but not on most others.

• Fix `pg_dump` to not emit invalid SQL for an empty operator class (Daniel Gustafsson)

• Fix `pg_dump` output to `stdout` on Windows (Kuntal Ghosh)

  A compressed plain-text dump written to `stdout` would contain corrupt data due to failure to put the file descriptor into binary mode.

• Fix `pg_get_ruledef()` to print correct output for the `ON SELECT` rule of a view whose columns have been renamed (Tom Lane)

  In some corner cases, `pg_dump` relies on `pg_get_ruledef()` to dump views, so that this error could result in dump/reload failures.

• Fix dumping of function expressions in the `FROM` clause in cases where the expression does not deparse into something that looks like a function call (Tom Lane)

• Fix `pg_basebackup` output to `stdout` on Windows (Haribabu Kommi)

  A backup written to `stdout` would contain corrupt data due to failure to put the file descriptor into binary mode.

• Fix `pg_upgrade` to ensure that the ending WAL record does not have `wal_level = minimum` (Bruce Momjian)

  This condition could prevent upgraded standby servers from reconnecting.

• Always use `-fPIC`, not `-fpic`, when building shared libraries with gcc (Tom Lane)

  This supports larger extension libraries on platforms where it makes a difference.

• Fix unescaped-braces issue in our build scripts for Microsoft MSVC, to avoid a warning or error from recent Perl versions (Andrew Dunstan)

• In MSVC builds, handle the case where the openssl library is not within a `VC` subdirectory (Andrew Dunstan)

• In MSVC builds, add proper include path for libxml2 header files (Andrew Dunstan)

  This fixes a former need to move things around in standard Windows installations of libxml2.

• In MSVC builds, recognize a Tcl library that is named `tcl86.lib` (Noah Misch)
E.51. Release 9.2.21

Release date: 2017-05-11

This release contains a variety of fixes from 9.2.20. For information about new features in the 9.2 major release, see Section E.72.

The PostgreSQL community will stop releasing updates for the 9.2.X release series in September 2017. Users are encouraged to update to a newer release branch soon.

E.51.1. Migration to Version 9.2.21

A dump/restore is not required for those running 9.2.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.2.20, see Section E.52.

E.51.2. Changes

• Restrict visibility of pg_user_mappings.umoptions, to protect passwords stored as user mapping options (Michael Paquier, Feike Steenbergen)

The previous coding allowed the owner of a foreign server object, or anyone he has granted server USAGE permission to, to see the options for all user mappings associated with that server. This might well include passwords for other users. Adjust the view definition to match the behavior of information_schema.user_mapping_options, namely that these options are visible to the user being mapped, or if the mapping is for PUBLIC and the current user is the server owner, or if the current user is a superuser. (CVE-2017-7486)

By itself, this patch will only fix the behavior in newly initdb’d databases. If you wish to apply this change in an existing database, follow the corrected procedure shown in the changelog entry for CVE-2017-7547, in Section E.50.

• Prevent exposure of statistical information via leaky operators (Peter Eisentraut)

Some selectivity estimation functions in the planner will apply user-defined operators to values obtained from pg_statistic, such as most common values and histogram entries. This occurs before table permissions are checked, so a nefarious user could exploit the behavior to obtain these values for table columns he does not have permission to read. To fix, fall back to a default estimate if the operator’s implementation function is not certified leak-proof and the calling user does not have permission to read the table column whose statistics are needed. At least one of these criteria is satisfied in most cases in practice. (CVE-2017-7484)

• Fix possible corruption of “init forks” of unlogged indexes (Robert Haas, Michael Paquier)

This could result in an unlogged index being set to an invalid state after a crash and restart. Such a problem would persist until the index was dropped and rebuilt.

• Fix incorrect reconstruction of pg_subtrans entries when a standby server replays a prepared but uncommitted two-phase transaction (Tom Lane)
In most cases this turned out to have no visible ill effects, but in corner cases it could result in circular references in `pg_subtrans`, potentially causing infinite loops in queries that examine rows modified by the two-phase transaction.

- Ensure parsing of queries in extension scripts sees the results of immediately-preceding DDL (Julien Rouhaud, Tom Lane)

  Due to lack of a cache flush step between commands in an extension script file, non-utility queries might not see the effects of an immediately preceding catalog change, such as `ALTER TABLE ... RENAME`.

- Skip tablespace privilege checks when `ALTER TABLE ... ALTER COLUMN TYPE` rebuilds an existing index (Noah Misch)

  The command failed if the calling user did not currently have `CREATE` privilege for the tablespace containing the index. That behavior seems unhelpful, so skip the check, allowing the index to be rebuilt where it is.

- Fix `ALTER TABLE ... VALIDATE CONSTRAINT` to not recurse to child tables when the constraint is marked `NO INHERIT` (Amit Langote)

  This fix prevents unwanted “constraint does not exist” failures when no matching constraint is present in the child tables.

- Fix `VACUUM` to account properly for pages that could not be scanned due to conflicting page pins (Andrew Gierth)

  This tended to lead to underestimation of the number of tuples in the table. In the worst case of a small heavily-contended table, `VACUUM` could incorrectly report that the table contained no tuples, leading to very bad planning choices.

- Ensure that bulk-tuple-transfer loops within a hash join are interruptible by query cancel requests (Tom Lane, Thomas Munro)

- Fix `cursor_to_xml()` to produce valid output with `tableforest = false` (Thomas Munro, Peter Eisentraut)

  Previously it failed to produce a wrapping `<table>` element.

- Improve performance of `pg_timezone_names` view (Tom Lane, David Rowley)

- Fix sloppy handling of corner-case errors from `lseek()` and `close()` (Tom Lane)

  Neither of these system calls are likely to fail in typical situations, but if they did, `fd.c` could get quite confused.

- Fix incorrect check for whether postmaster is running as a Windows service (Michael Paquier)

  This could result in attempting to write to the event log when that isn’t accessible, so that no logging happens at all.

- Fix `ecpg` to support `COMMIT PREPARED` and `ROLLBACK PREPARED` (Masahiko Sawada)

- Fix a double-free error when processing dollar-quoted string literals in `ecpg` (Michael Meskes)

- In `pg_dump`, fix incorrect schema and owner marking for comments and security labels of some types of database objects (Giuseppe Broccolo, Tom Lane)

  In simple cases this caused no ill effects; but for example, a schema-selective restore might omit comments it should include, because they were not marked as belonging to the schema of their associated object.
• Avoid emitting an invalid list file in `pg_restore -l` when SQL object names contain newlines (Tom Lane)
  Replace newlines by spaces, which is sufficient to make the output valid for `pg_restore -L`’s purposes.

• Fix `pg_upgrade` to transfer comments and security labels attached to “large objects” (blobs) (Stephen Frost)
  Previously, blobs were correctly transferred to the new database, but any comments or security labels attached to them were lost.

• Improve error handling in `contrib/adminpack’s pg_file_write()` function (Noah Misch)
  Notably, it failed to detect errors reported by `fclose()`.

• In `contrib/dblink`, avoid leaking the previous unnamed connection when establishing a new unnamed connection (Joe Conway)

• Support OpenSSL 1.1.0 (Heikki Linnakangas, Andreas Karlsson, Tom Lane)
  This is a back-patch of work previously done in newer branches; it’s needed since many platforms are adopting newer OpenSSL versions.

• Support Tcl 8.6 in MSVC builds (Álvaro Herrera)

• Sync our copy of the timezone library with IANA release tzcode2017b (Tom Lane)
  This fixes a bug affecting some DST transitions in January 2038.

• Update time zone data files to tzdata release 2017b for DST law changes in Chile, Haiti, and Mongolia, plus historical corrections for Ecuador, Kazakhstan, Liberia, and Spain. Switch to numeric abbreviations for numerous time zones in South America, the Pacific and Indian oceans, and some Asian and Middle Eastern countries.
  The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the `pg_timezone_names` view nor used for output.

• Use correct daylight-savings rules for POSIX-style time zone names in MSVC builds (David Rowley)
  The Microsoft MSVC build scripts neglected to install the `posixrules` file in the timezone directory tree. This resulted in the timezone code falling back to its built-in rule about what DST behavior to assume for a POSIX-style time zone name. For historical reasons that still corresponds to the DST rules the USA was using before 2007 (i.e., change on first Sunday in April and last Sunday in October). With this fix, a POSIX-style zone name will use the current and historical DST transition dates of the US/Eastern zone. If you don’t want that, remove the `posixrules` file, or replace it with a copy of some other zone file (see Section 8.5.3). Note that due to caching, you may need to restart the server to get such changes to take effect.
E.52. Release 9.2.20

Release date: 2017-02-09

This release contains a variety of fixes from 9.2.19. For information about new features in the 9.2 major release, see Section E.72.

E.52.1. Migration to Version 9.2.20

A dump/restore is not required for those running 9.2.X. However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted indexes.

Also, if you are upgrading from a version earlier than 9.2.11, see Section E.61.

E.52.2. Changes

- Fix a race condition that could cause indexes built with `CREATE INDEX CONCURRENTLY` to be corrupt (Pavan Deolasee, Tom Lane)

  If `CREATE INDEX CONCURRENTLY` was used to build an index that depends on a column not previously indexed, then rows updated by transactions that ran concurrently with the `CREATE INDEX` command could have received incorrect index entries. If you suspect this may have happened, the most reliable solution is to rebuild affected indexes after installing this update.

- Unconditionally WAL-log creation of the “init fork” for an unlogged table (Michael Paquier)

  Previously, this was skipped when `wal_level = minimal`, but actually it’s necessary even in that case to ensure that the unlogged table is properly reset to empty after a crash.

- Fix WAL page header validation when re-reading segments (Takayuki Tsunakawa, Amit Kapila)

  In corner cases, a spurious “out-of-sequence TLI” error could be reported during recovery.

- If the stats collector dies during hot standby, restart it (Takayuki Tsunakawa)

- Check for interrupts while hot standby is waiting for a conflicting query (Simon Riggs)

- Avoid constantly respawning the autovacuum launcher in a corner case (Amit Khandekar)

  This fix avoids problems when autovacuum is nominally off and there are some tables that require freezing, but all such tables are already being processed by autovacuum workers.

- Fix check for when an extension member object can be dropped (Tom Lane)

  Extension upgrade scripts should be able to drop member objects, but this was disallowed for serial-column sequences, and possibly other cases.

- Make sure `ALTER TABLE` preserves index tablespace assignments when rebuilding indexes (Tom Lane, Michael Paquier)

  Previously, non-default settings of `default_tablespace` could result in broken indexes.

- Prevent dropping a foreign-key constraint if there are pending trigger events for the referenced relation (Tom Lane)
This avoids “could not find trigger NNN” or “relation NNN has no triggers” errors.

- Fix processing of OID column when a table with OIDs is associated to a parent with OIDs via \texttt{ALTER TABLE ... INHERIT} (Amit Langote)
  
  The OID column should be treated the same as regular user columns in this case, but it wasn’t, leading to odd behavior in later inheritance changes.

- Check for serializability conflicts before reporting constraint-violation failures (Thomas Munro)
  
  When using serializable transaction isolation, it is desirable that any error due to concurrent transactions should manifest as a serialization failure, thereby cueing the application that a retry might succeed. Unfortunately, this does not reliably happen for duplicate-key failures caused by concurrent insertions. This change ensures that such an error will be reported as a serialization error if the application explicitly checked for the presence of a conflicting key (and did not find it) earlier in the transaction.

- Ensure that column typmods are determined accurately for multi-row VALUES constructs (Tom Lane)
  
  This fixes problems occurring when the first value in a column has a determinable typmod (e.g., length for a \texttt{varchar} value) but later values don’t share the same limit.

- Throw error for an unfinished Unicode surrogate pair at the end of a Unicode string (Tom Lane)
  
  Normally, a Unicode surrogate leading character must be followed by a Unicode surrogate trailing character, but the check for this was missed if the leading character was the last character in a Unicode string literal (\texttt{U"..."}) or Unicode identifier (\texttt{U&"..."}).

- Ensure that a purely negative text search query, such as \texttt{!foo}, matches empty \texttt{tsvector}s (Tom Dunstan)
  
  Such matches were found by GIN index searches, but not by sequential scans or GiST index searches.

- Fix performance problems in \texttt{ts_rewrite()} (Tom Lane)

- Fix \texttt{ts_rewrite()}’s handling of nested NOT operators (Tom Lane)

- Fix \texttt{array\_fill()} to handle empty arrays properly (Tom Lane)

- Fix one-byte buffer overrun in \texttt{quote\_literal\_cstr()} (Heikki Linnakangas)
  
  The overrun occurred only if the input consisted entirely of single quotes and/or backslashes.

- Prevent multiple calls of \texttt{pg\_start\_backup()} and \texttt{pg\_stop\_backup()} from running concurrently (Michael Paquier)
  
  This avoids an assertion failure, and possibly worse things, if someone tries to run these functions in parallel.

- Avoid discarding \texttt{interval\_to\_interval} casts that aren’t really no-ops (Tom Lane)
  
  In some cases, a cast that should result in zeroing out low-order \texttt{interval} fields was mistakenly deemed to be a no-op and discarded. An example is that casting from \texttt{INTERVAL MONTH} to \texttt{INTERVAL YEAR} failed to clear the months field.

- Fix \texttt{pg\_dump} to dump user-defined casts and transforms that use built-in functions (Stephen Frost)

- Fix possible \texttt{pg\_basebackup} failure on standby server when including WAL files (Amit Kapila, Robert Haas)
• Ensure that the Python exception objects we create for PL/Python are properly reference-counted (Rafa de la Torre, Tom Lane)
  This avoids failures if the objects are used after a Python garbage collection cycle has occurred.
• Fix PL/Tcl to support triggers on tables that have .tupno as a column name (Tom Lane)
  This matches the (previously undocumented) behavior of PL/Tcl’s spi_exec and spi_execp commands, namely that a magic .tupno column is inserted only if there isn’t a real column named that.
• Allow DOS-style line endings in ~/.pgpass files, even on Unix (Vik Fearing)
  This change simplifies use of the same password file across Unix and Windows machines.
• Fix one-byte buffer overrun if ecpg is given a file name that ends with a dot (Takayuki Tsunakawa)
• Fix psql’s tab completion for ALTER DEFAULT PRIVILEGES (Gilles Darold, Stephen Frost)
• In psql, treat an empty or all-blank setting of the PAGER environment variable as meaning “no pager” (Tom Lane)
  Previously, such a setting caused output intended for the pager to vanish entirely.
• Improve contrib/dblink’s reporting of low-level libpq errors, such as out-of-memory (Joe Conway)
• On Windows, ensure that environment variable changes are propagated to DLLs built with debug options (Christian Ullrich)
• Sync our copy of the timezone library with IANA release tzcode2016j (Tom Lane)
  This fixes various issues, most notably that timezone data installation failed if the target directory didn’t support hard links.
• Update time zone data files to tzdata release 2016j for DST changes in northern Cyprus (adding a new zone Asia/Famagusta), Russia (adding a new zone Europe/Saratov), Tonga, and Antarctica/Casey. Historical corrections for Italy, Kazakhstan, Malta, and Palestine. Switch to preferring numeric zone abbreviations for Tonga.

E.53. Release 9.2.19

Release date: 2016-10-27

This release contains a variety of fixes from 9.2.18. For information about new features in the 9.2 major release, see Section E.72.

E.53.1. Migration to Version 9.2.19

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.61.
E.53.2. Changes

- Fix EvalPlanQual rechecks involving CTE scans (Tom Lane)

  The recheck would always see the CTE as returning no rows, typically leading to failure to update rows that were recently updated.

- Fix improper repetition of previous results from hashed aggregation in a subquery (Andrew Gierth)

  The test to see if we can reuse a previously-computed hash table of the aggregate state values neglected the possibility of an outer query reference appearing in an aggregate argument expression. A change in the value of such a reference should lead to recalculating the hash table, but did not.

- Fix EXPLAIN to emit valid XML when track_io_timing is on (Markus Winand)

  Previously the XML output-format option produced syntactically invalid tags such as &lt;I/O-Read-Time&gt;. That is now rendered as &lt;I-O-Read-Time&gt;.

- Suppress printing of zeroes for unmeasured times in EXPLAIN (Maksim Milyutin)

  Certain option combinations resulted in printing zero values for times that actually aren’t ever measured in that combination. Our general policy in EXPLAIN is not to print such fields at all, so do that consistently in all cases.

- Fix timeout length when VACUUM is waiting for exclusive table lock so that it can truncate the table (Simon Riggs)

  The timeout was meant to be 50 milliseconds, but it was actually only 50 microseconds, causing VACUUM to give up on truncation much more easily than intended. Set it to the intended value.

- Fix bugs in merging inherited CHECK constraints while creating or altering a table (Tom Lane, Amit Langote)

  Allow identical CHECK constraints to be added to a parent and child table in either order. Prevent merging of a valid constraint from the parent table with a NOT VALID constraint on the child. Likewise, prevent merging of a NO INHERIT child constraint with an inherited constraint.

- Remove artificial restrictions on the values accepted by numeric_in() and numeric_recv() (Tom Lane)

  We allow numeric values up to the limit of the storage format (more than 1e100000), so it seems fairly pointless that numeric_in() rejected scientific-notation exponents above 1000. Likewise, it was silly for numeric_recv() to reject more than 1000 digits in an input value.

- Avoid very-low-probability data corruption due to testing tuple visibility without holding buffer lock (Thomas Munro, Peter Geoghegan, Tom Lane)

- Fix file descriptor leakage when truncating a temporary relation of more than 1GB (Andres Freund)

- Disallow starting a standalone backend with standby_mode turned on (Michael Paquier)

  This can’t do anything useful, since there will be no WAL receiver process to fetch more WAL data; and it could result in misbehavior in code that wasn’t designed with this situation in mind.

- Don’t try to share SSL contexts across multiple connections in libpq (Heikki Linnakangas)

  This led to assorted corner-case bugs, particularly when trying to use different SSL parameters for different connections.
• Avoid corner-case memory leak in libpq (Tom Lane)
  The reported problem involved leaking an error report during PQreset(), but there might be related
cases.
• Make ecpg’s --help and --version options work consistently with our other executables (Haribabu
  Kommi)
• In pg_dump, never dump range constructor functions (Tom Lane)
  This oversight led to pg_upgrade failures with extensions containing range types, due to duplicate
creation of the constructor functions.
• Fix contrib/intarray/bench/bench.pl to print the results of the EXPLAIN it does when given
  the –e option (Daniel Gustafsson)
• Update Windows time zone mapping to recognize some time zone names added in recent Windows
  versions (Michael Paquier)
• Prevent failure of obsolete dynamic time zone abbreviations (Tom Lane)
  If a dynamic time zone abbreviation does not match any entry in the referenced time zone, treat it as
  equivalent to the time zone name. This avoids unexpected failures when IANA removes abbreviations
  from their time zone database, as they did in tzdata release 2016f and seem likely to do again in the
  future. The consequences were not limited to not recognizing the individual abbreviation; any mismatch
  caused the pg_timezone_abbrevs view to fail altogether.
• Update time zone data files to tzdata release 2016h for DST law changes in Palestine and Turkey, plus
  historical corrections for Turkey and some regions of Russia. Switch to numeric abbreviations for some
  time zones in Antarctica, the former Soviet Union, and Sri Lanka.

The IANA time zone database previously provided textual abbreviations for all time zones, some-
times making up abbreviations that have little or no currency among the local population. They are
in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no
evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will
continue to accept such removed abbreviations for timestamp input. But they will not be shown in the
pg_timezone_names view nor used for output.

In this update, AMT is no longer shown as being in use to mean Armenia Time. Therefore, we have
changed the Default abbreviation set to interpret it as Amazon Time, thus UTC-4 not UTC+4.

E.54. Release 9.2.18

Release date: 2016-08-11

This release contains a variety of fixes from 9.2.17. For information about new features in the 9.2 major
release, see Section E.72.

E.54.1. Migration to Version 9.2.18

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.61.
E.54.2. Changes

- Fix possible mis-evaluation of nested `CASE-WHEN` expressions (Heikki Linnakangas, Michael Paquier, Tom Lane)

A `CASE` expression appearing within the test value subexpression of another `CASE` could become confused about whether its own test value was null or not. Also, inlining of a SQL function implementing the equality operator used by a `CASE` expression could result in passing the wrong test value to functions called within a `CASE` expression in the SQL function’s body. If the test values were of different data types, a crash might result; moreover such situations could be abused to allow disclosure of portions of server memory. (CVE-2016-5423)

- Fix client programs’ handling of special characters in database and role names (Noah Misch, Nathan Bossart, Michael Paquier)

Numerous places in vacuumdb and other client programs could become confused by database and role names containing double quotes or backslashes. Tighten up quoting rules to make that safe. Also, ensure that when a conninfo string is used as a database name parameter to these programs, it is correctly treated as such throughout.

Fix handling of paired double quotes in psql’s `\connect` and `\password` commands to match the documentation.

Introduce a new `-reuse-previous` option in psql’s `\connect` command to allow explicit control of whether to re-use connection parameters from a previous connection. (Without this, the choice is based on whether the database name looks like a conninfo string, as before.) This allows secure handling of database names containing special characters in pg_dumpall scripts.

pg_dumpall now refuses to deal with database and role names containing carriage returns or newlines, as it seems impractical to quote those characters safely on Windows. In future we may reject such names on the server side, but that step has not been taken yet.

These are considered security fixes because crafted object names containing special characters could have been used to execute commands with superuser privileges the next time a superuser executes pg_dumpall or other routine maintenance operations. (CVE-2016-5424)

- Fix corner-case misbehaviors for `IS NULL/IS NOT NULL` applied to nested composite values (Andrew Gierth, Tom Lane)

The SQL standard specifies that `IS NULL` should return TRUE for a row of all null values (thus `ROW(NULL,NULL) IS NULL` yields TRUE), but this is not meant to apply recursively (thus `ROW(NULL, ROW(NULL,NULL)) IS NULL` yields FALSE). The core executor got this right, but certain planner optimizations treated the test as recursive (thus producing TRUE in both cases), and contrib/postgres_fdw could produce remote queries that misbehaved similarly.

- Make the inet and cidr data types properly reject IPv6 addresses with too many colon-separated fields (Tom Lane)

- Prevent crash in `close_ps()` (the point `## lseg` operator) for NaN input coordinates (Tom Lane)

Make it return NULL instead of crashing.

- Fix several one-byte buffer over-reads in `to_number()` (Peter Eisentraut)

In several cases the `to_number()` function would read one more character than it should from the input string. There is a small chance of a crash, if the input happens to be adjacent to the end of memory.
Appendix E. Release Notes

• Avoid unsafe intermediate state during expensive paths through `heap_update()` (Masahiko Sawada, Andres Freund)
  
  Previously, these cases locked the target tuple (by setting its XMAX) but did not WAL-log that action, thus risking data integrity problems if the page were spilled to disk and then a database crash occurred before the tuple update could be completed.

• Avoid crash in `postgres -C` when the specified variable has a null string value (Michael Paquier)

• Avoid consuming a transaction ID during `VACUUM` (Alexander Korotkov)
  
  Some cases in `VACUUM` unnecessarily caused an XID to be assigned to the current transaction. Normally this is negligible, but if one is up against the XID wraparound limit, consuming more XIDs during anti-wraparound vacuums is a very bad thing.

• Avoid canceling hot-standby queries during `VACUUM FREEZE` (Simon Riggs, Álvaro Herrera)
  
  `VACUUM FREEZE` on an otherwise-idle master server could result in unnecessary cancellations of queries on its standby servers.

• When a manual `ANALYZE` specifies a column list, don’t reset the table’s `changes_since_analyze` counter (Tom Lane)
  
  If we’re only analyzing some columns, we should not prevent routine auto-analyze from happening for the other columns.

• Fix `ANALYZE`’s overestimation of `n_distinct` for a unique or nearly-unique column with many null entries (Tom Lane)
  
  The nulls could get counted as though they were themselves distinct values, leading to serious planner misestimates in some types of queries.

• Prevent autovacuum from starting multiple workers for the same shared catalog (Álvaro Herrera)
  
  Normally this isn’t much of a problem because the vacuum doesn’t take long anyway; but in the case of a severely bloated catalog, it could result in all but one worker uselessly waiting instead of doing useful work on other tables.

• Prevent infinite loop in GiST index build for geometric columns containing NaN component values (Tom Lane)

• Fix `contrib/btree_gin` to handle the smallest possible `bigint` value correctly (Peter Eisentraut)

• Teach `libpq` to correctly decode server version from future servers (Peter Eisentraut)
  
  It’s planned to switch to two-part instead of three-part server version numbers for releases after 9.6. Make sure that `PQserverVersion()` returns the correct value for such cases.

• Fix `ecpg`’s code for unsigned long long array elements (Michael Meskes)

• In `pg_dump` with both `-c` and `-C` options, avoid emitting an unwanted `CREATE SCHEMA public` command (David Johnston, Tom Lane)

• Make `pg_basebackup` accept `-Z 0` as specifying no compression (Fujii Masao)

• Fix `makefiles`’ rule for building AIX shared libraries to be safe for parallel make (Noah Misch)

• Fix TAP tests and MSVC scripts to work when build directory’s path name contains spaces (Michael Paquier, Kyotaro Horiguchi)

• Make regression tests safe for Danish and Welsh locales (Jeff Janes, Tom Lane)
Appendix E. Release Notes

Change some test data that triggered the unusual sorting rules of these locales.

• Update our copy of the timezone code to match IANA’s tzcode release 2016c (Tom Lane)
  This is needed to cope with anticipated future changes in the time zone data files. It also fixes some
corner-case bugs in coping with unusual time zones.

• Update time zone data files to tzdata release 2016f for DST law changes in Kemerovo and Novosibirsk,
  plus historical corrections for Azerbaijan, Belarus, and Morocco.

E.55. Release 9.2.17

Release date: 2016-05-12

This release contains a variety of fixes from 9.2.16. For information about new features in the 9.2 major
release, see Section E.72.

E.55.1. Migration to Version 9.2.17

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.61.

E.55.2. Changes

• Clear the OpenSSL error queue before OpenSSL calls, rather than assuming it’s clear already; and make
  sure we leave it clear afterwards (Peter Geoghegan, Dave Vitek, Peter Eisentraut)
  This change prevents problems when there are multiple connections using OpenSSL within a single
  process and not all the code involved follows the same rules for when to clear the error queue. Failures
  have been reported specifically when a client application uses SSL connections in libpq concurrently
  with SSL connections using the PHP, Python, or Ruby wrappers for OpenSSL. It’s possible for sim-
  ilar problems to arise within the server as well, if an extension module establishes an outgoing SSL
  connection.

• Fix “failed to build any N-way joins” planner error with a full join enclosed in the right-hand side of a
  left join (Tom Lane)

• Fix incorrect handling of equivalence-class tests in multilevel nestloop plans (Tom Lane)
  Given a three-or-more-way equivalence class of variables, such as \( X.X = Y.Y = Z.Z \), it was possible
  for the planner to omit some of the tests needed to enforce that all the variables are actually equal,
  leading to join rows being output that didn't satisfy the WHERE clauses. For various reasons, erroneous
  plans were seldom selected in practice, so that this bug has gone undetected for a long time.

• Fix possible misbehavior of \( T H, th, \) and \( Y, YYYY \) format codes in to_timestamp() (Tom Lane)
  These could advance off the end of the input string, causing subsequent format codes to read garbage.
Appendix E. Release Notes

- Fix dumping of rules and views in which the array argument of a value operator ANY (array) construct is a sub-SELECT (Tom Lane)

- Make pg_regress use a startup timeout from the PGCTLTIMEOUT environment variable, if that’s set (Tom Lane)
  This is for consistency with a behavior recently added to pg_ctl; it eases automated testing on slow machines.

- Fix pg_upgrade to correctly restore extension membership for operator families containing only one operator class (Tom Lane)
  In such a case, the operator family was restored into the new database, but it was no longer marked as part of the extension. This had no immediate ill effects, but would cause later pg_dump runs to emit output that would cause (harmless) errors on restore.

- Back-port 9.4-era memory-barrier code changes into 9.2 and 9.3 (Tom Lane)
  These changes were not originally needed in pre-9.4 branches, but we recently back-patched a fix that expected the barrier code to work properly. Only IA64 (when using icc), HPPA, and Alpha platforms are affected.

- Reduce the number of SysV semaphores used by a build configured with --disable-spinlocks (Tom Lane)

- Rename internal function strtoi() to strtol() to avoid conflict with a NetBSD library function (Thomas Munro)

- Fix reporting of errors from bind() and listen() system calls on Windows (Tom Lane)

- Reduce verbosity of compiler output when building with Microsoft Visual Studio (Christian Ullrich)

- Avoid possibly-unsafe use of Windows’ FormatMessage() function (Christian Ullrich)
  Use the FORMAT_MESSAGE_IGNORE_INSERTS flag where appropriate. No live bug is known to exist here, but it seems like a good idea to be careful.

- Update time zone data files to tzdata release 2016d for DST law changes in Russia and Venezuela. There are new zone names Europe/Kirov and Asia/Tomsk to reflect the fact that these regions now have different time zone histories from adjacent regions.

E.56. Release 9.2.16

Release date: 2016-03-31

This release contains a variety of fixes from 9.2.15. For information about new features in the 9.2 major release, see Section E.72.

E.56.1. Migration to Version 9.2.16

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.61.
Appendix E. Release Notes

E.56.2. Changes

- Fix incorrect handling of NULL index entries in indexed \texttt{ROW()} comparisons (Tom Lane)
  
  An index search using a row comparison such as \texttt{ROW(a, b) > ROW('x', 'y')} would stop upon reaching a NULL entry in the b column, ignoring the fact that there might be non-NULl b values associated with later values of a.

- Avoid unlikely data-loss scenarios due to renaming files without adequate \texttt{fsync()} calls before and after (Michael Paquier, Tomas Vondra, Andres Freund)

- Correctly handle cases where \texttt{pg_subtrans} is close to XID wraparound during server startup (Jeff Janes)

- Fix corner-case crash due to trying to free \texttt{localeconv()} output strings more than once (Tom Lane)

- Fix parsing of affix files for \texttt{ispell} dictionaries (Tom Lane)
  
  The code could go wrong if the affix file contained any characters whose byte length changes during case-folding, for example 'I' in Turkish UTF8 locales.

- Avoid use of \texttt{sscanf()} to parse \texttt{ispell} dictionary files (Artur Zakirov)
  
  This dodges a portability problem on FreeBSD-derived platforms (including macOS).

- Avoid a crash on old Windows versions (before 7SP1/2008R2SP1) with an AVX2-capable CPU and a Postgres build done with Visual Studio 2013 (Christian Ullrich)
  
  This is a workaround for a bug in Visual Studio 2013’s runtime library, which Microsoft have stated they will not fix in that version.

- Fix \texttt{psql}'s tab completion logic to handle multibyte characters properly (Kyotaro Horiguchi, Robert Haas)

- Fix \texttt{psql}'s tab completion for \texttt{SECURITY LABEL} (Tom Lane)
  
  Pressing \texttt{TAB} after \texttt{SECURITY LABEL} might cause a crash or offering of inappropriate keywords.

- Make \texttt{pg_ctl} accept a wait timeout from the \texttt{PGCTLTIMEOUT} environment variable, if none is specified on the command line (Noah Misch)
  
  This eases testing of slower buildfarm members by allowing them to globally specify a longer-than-normal timeout for postmaster startup and shutdown.

- Fix incorrect test for Windows service status in \texttt{pg_ctl} (Manuel Mathar)
  
  The previous set of minor releases attempted to fix \texttt{pg_ctl} to properly determine whether to send log messages to Window’s Event Log, but got the test backwards.

- Fix pgbench to correctly handle the combination of \texttt{-C} and \texttt{-M} prepared options (Tom Lane)

- In PL/Perl, properly translate empty Postgres arrays into empty Perl arrays (Alex Hunsaker)

- Make PL/Python cope with function names that aren’t valid Python identifiers (Jim Nasby)

- Fix multiple mistakes in the statistics returned by \texttt{contrib/pgstatindex}'s \texttt{pgstatindex()} function (Tom Lane)

- Remove dependency on \texttt{psed} in MSVC builds, since it’s no longer provided by core Perl (Michael Paquier, Andrew Dunstan)
• Update time zone data files to tzdata release 2016c for DST law changes in Azerbaijan, Chile, Haiti, Palestine, and Russia (Altai, Astrakhan, Kirov, Sakhalin, Ulyanovsk regions), plus historical corrections for Lithuania, Moldova, and Russia (Kaliningrad, Samara, Volgograd).

---

**E.57. Release 9.2.15**

**Release date:** 2016-02-11

This release contains a variety of fixes from 9.2.14. For information about new features in the 9.2 major release, see Section E.72.

---

**E.57.1. Migration to Version 9.2.15**

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.61.

---

**E.57.2. Changes**

• Fix infinite loops and buffer-overrun problems in regular expressions (Tom Lane)
  
  Very large character ranges in bracket expressions could cause infinite loops in some cases, and memory overwrites in other cases. (CVE-2016-0773)

• Perform an immediate shutdown if the `postmaster.pid` file is removed (Tom Lane)
  
  The postmaster now checks every minute or so that `postmaster.pid` is still there and still contains its own PID. If not, it performs an immediate shutdown, as though it had received SIGQUIT. The main motivation for this change is to ensure that failed buildfarm runs will get cleaned up without manual intervention; but it also serves to limit the bad effects if a DBA forcibly removes `postmaster.pid` and then starts a new postmaster.

• In `SERIALIZABLE` transaction isolation mode, serialization anomalies could be missed due to race conditions during insertions (Kevin Grittner, Thomas Munro)

• Fix failure to emit appropriate WAL records when doing `ALTER TABLE ... SET TABLESPACE` for unlogged relations (Michael Paquier, Andres Freund)
  
  Even though the relation’s data is unlogged, the move must be logged or the relation will be inaccessible after a standby is promoted to master.

• Fix possible misinitialization of unlogged relations at the end of crash recovery (Andres Freund, Michael Paquier)

• Fix `ALTER COLUMN TYPE` to reconstruct inherited check constraints properly (Tom Lane)

• Fix `REASSIGN OWNED` to change ownership of composite types properly (Álvaro Herrera)

• Fix `REASSIGN OWNED` and `ALTER OWNER` to correctly update granted-permissions lists when changing owners of data types, foreign data wrappers, or foreign servers (Bruce Momjian, Álvaro Herrera)
• Fix `REASSIGN OWNED` to ignore foreign user mappings, rather than fail (Álvaro Herrera)

• Add more defenses against bad planner cost estimates for GIN index scans when the index’s internal statistics are very out-of-date (Tom Lane)

• Make planner cope with hypothetical GIN indexes suggested by an index advisor plug-in (Julien Rouhaud)

• Fix dumping of whole-row Vars in `ROW()` and `VALUES()` lists (Tom Lane)

• Fix possible internal overflow in `numeric` division (Dean Rasheed)

• Fix enforcement of restrictions inside parentheses within regular expression lookahead constraints (Tom Lane)

  Lookahead constraints aren’t allowed to contain backrefs, and parentheses within them are always considered non-capturing, according to the manual. However, the code failed to handle these cases properly inside a parenthesized subexpression, and would give unexpected results.

• Conversion of regular expressions to indexscan bounds could produce incorrect bounds from regexps containing lookahead constraints (Tom Lane)

• Fix regular-expression compiler to handle loops of constraint arcs (Tom Lane)

  The code added for CVE-2007-4772 was both incomplete, in that it didn’t handle loops involving more than one state, and incorrect, in that it could cause assertion failures (though there seem to be no bad consequences of that in a non-assert build). Multi-state loops would cause the compiler to run until the query was canceled or it reached the too-many-states error condition.

• Improve memory-usage accounting in regular-expression compiler (Tom Lane)

  This causes the code to emit “regular expression is too complex” errors in some cases that previously used unreasonable amounts of time and memory.

• Improve performance of regular-expression compiler (Tom Lane)

• Make `%h` and `%r` escapes in `log_line_prefix` work for messages emitted due to `log_connections` (Tom Lane)

  Previously, `%h/%r` started to work just after a new session had emitted the “connection received” log message; now they work for that message too.

• On Windows, ensure the shared-memory mapping handle gets closed in child processes that don’t need it (Tom Lane, Amit Kapila)

  This oversight resulted in failure to recover from crashes whenever `logging_collector` is turned on.

• Fix possible failure to detect socket EOF in non-blocking mode on Windows (Tom Lane)

  It’s not entirely clear whether this problem can happen in pre-9.5 branches, but if it did, the symptom would be that a walsender process would wait indefinitely rather than noticing a loss of connection.

• Avoid leaking a token handle during SSPI authentication (Christian Ullrich)

• In `psql`, ensure that libreadline’s idea of the screen size is updated when the terminal window size changes (Merlin Moncure)

  Previously, libreadline did not notice if the window was resized during query output, leading to strange behavior during later input of multiline queries.
Appendix E. Release Notes

- Fix psql’s \det command to interpret its pattern argument the same way as other \d commands with potentially schema-qualified patterns do (Reece Hart)
- Avoid possible crash in psql’s \c command when previous connection was via Unix socket and command specifies a new hostname and same username (Tom Lane)
- In pg_ctl start -w, test child process status directly rather than relying on heuristics (Tom Lane, Michael Paquier)

Previously, pg_ctl relied on an assumption that the new postmaster would always create postmaster.pid within five seconds. But that can fail on heavily-loaded systems, causing pg_ctl to report incorrectly that the postmaster failed to start.

Except on Windows, this change also means that a pg_ctl start -w done immediately after another such command will now reliably fail, whereas previously it would report success if done within two seconds of the first command.

- In pg_ctl start -w, don’t attempt to use a wildcard listen address to connect to the postmaster (Kondo Yuta)

On Windows, pg_ctl would fail to detect postmaster startup if listen_addresses is set to 0.0.0.0 or ::; because it would try to use that value verbatim as the address to connect to, which doesn’t work. Instead assume that 127.0.0.1 or ::1, respectively, is the right thing to use.

- In pg_ctl on Windows, check service status to decide where to send output, rather than checking if standard output is a terminal (Michael Paquier)

- In pg_dump and pg_basebackup, adopt the GNU convention for handling tar-archive members exceeding 8GB (Tom Lane)

The POSIX standard for tar file format does not allow archive member files to exceed 8GB, but most modern implementations of tar support an extension that fixes that. Adopt this extension so that pg_dump with -f t no longer fails on tables with more than 8GB of data, and so that pg_basebackup can handle files larger than 8GB. In addition, fix some portability issues that could cause failures for members between 4GB and 8GB on some platforms. Potentially these problems could cause unrecoverable data loss due to unreadable backup files.

- Fix assorted corner-case bugs in pg_dump’s processing of extension member objects (Tom Lane)

- Make pg_dump mark a view’s triggers as needing to be processed after its rule, to prevent possible failure during parallel pg_restore (Tom Lane)

- Ensure that relation option values are properly quoted in pg_dump (Kouhei Sutou, Tom Lane)

A reloption value that isn’t a simple identifier or number could lead to dump/reload failures due to syntax errors in CREATE statements issued by pg_dump. This is not an issue with any reloption currently supported by core PostgreSQL, but extensions could allow reloptions that cause the problem.

- Fix pg_upgrade’s file-copying code to handle errors properly on Windows (Bruce Momjian)

- Install guards in pgbench against corner-case overflow conditions during evaluation of script-specified division or modulo operators (Fabien Coelho, Michael Paquier)

- Fix failure to localize messages emitted by pg_receivexlog and pg_receivelogical (Ioseph Kim)

- Avoid dump/reload problems when using both plpython2 and plpython3 (Tom Lane)

In principle, both versions of PL/Python can be used in the same database, though not in the same session (because the two versions of libpython cannot safely be used concurrently). However, pg_restore
Appendix E. Release Notes

and pg_upgrade both do things that can fall foul of the same-session restriction. Work around that by changing the timing of the check.

- Fix PL/Python regression tests to pass with Python 3.5 (Peter Eisentraut)
- Prevent certain PL/Java parameters from being set by non-superusers (Noah Misch)
  This change mitigates a PL/Java security bug (CVE-2016-0766), which was fixed in PL/Java by marking these parameters as superuser-only. To fix the security hazard for sites that update PostgreSQL more frequently than PL/Java, make the core code aware of them also.
- Improve libpq’s handling of out-of-memory situations (Michael Paquier, Amit Kapila, Heikki Linnakangas)
- Fix order of arguments in ecpg-generated typedef statements (Michael Meskes)
- Use \%g not \%f format in ecpg’s PGTYPESnumeric_from_double() (Tom Lane)
- Fix ecpg-supplied header files to not contain comments continued from a preprocessor directive line onto the next line (Michael Meskes)
  Such a comment is rejected by ecpg. It’s not yet clear whether ecpg itself should be changed.
- Ensure that contrib/pgcrypto’s crypt() function can be interrupted by query cancel (Andreas Karlsson)
- Accept flex versions later than 2.5.x (Tom Lane, Michael Paquier)
  Now that flex 2.6.0 has been released, the version checks in our build scripts needed to be adjusted.
- Install our missing script where PGXS builds can find it (Jim Nasby)
  This allows sane behavior in a PGXS build done on a machine where build tools such as bison are missing.
- Ensure that dynloader.h is included in the installed header files in MSVC builds (Bruce Momjian, Michael Paquier)
- Add variant regression test expected-output file to match behavior of current libxml2 (Tom Lane)
  The fix for libxml2’s CVE-2015-7499 causes it not to output error context reports in some cases where it used to do so. This seems to be a bug, but we’ll probably have to live with it for some time, so work around it.
- Update time zone data files to tzdata release 2016a for DST law changes in Cayman Islands, Metlakatla, and Trans-Baikal Territory (Zabaykalsky Krai), plus historical corrections for Pakistan.

E.58. Release 9.2.14

Release date: 2015-10-08

This release contains a variety of fixes from 9.2.13. For information about new features in the 9.2 major release, see Section E.72.
E.58.1. Migration to Version 9.2.14

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.61.

E.58.2. Changes

- Fix contrib/pgcrypto to detect and report too-short crypt() salts (Josh Kupershmidt)
  Certain invalid salt arguments crashed the server or disclosed a few bytes of server memory. We have not ruled out the viability of attacks that arrange for presence of confidential information in the disclosed bytes, but they seem unlikely. (CVE-2015-5288)

- Fix subtransaction cleanup after a portal (cursor) belonging to an outer subtransaction fails (Tom Lane, Michael Paquier)
  A function executed in an outer-subtransaction cursor could cause an assertion failure or crash by referencing a relation created within an inner subtransaction.

- Fix insertion of relations into the relation cache “init file” (Tom Lane)
  An oversight in a patch in the most recent minor releases caused pg_trigger_tgrelid_tgname_index to be omitted from the init file. Subsequent sessions detected this, then deemed the init file to be broken and silently ignored it, resulting in a significant degradation in session startup time. In addition to fixing the bug, install some guards so that any similar future mistake will be more obvious.

- Avoid O(N^2) behavior when inserting many tuples into a SPI query result (Neil Conway)

- Improve LISTEN startup time when there are many unread notifications (Matt Newell)

- Back-patch 9.3-era addition of per-resource-owner lock caches (Jeff Janes)
  This substantially improves performance when pg_dump tries to dump a large number of tables.

- Disable SSL renegotiation by default (Michael Paquier, Andres Freund)
  While use of SSL renegotiation is a good idea in theory, we have seen too many bugs in practice, both in the underlying OpenSSL library and in our usage of it. Renegotiation will be removed entirely in 9.5 and later. In the older branches, just change the default value of ssl_renegotiation_limit to zero (disabled).

- Lower the minimum values of the *_freeze_max_age parameters (Andres Freund)
  This is mainly to make tests of related behavior less time-consuming, but it may also be of value for installations with limited disk space.

- Limit the maximum value of wal_buffers to 2GB to avoid server crashes (Josh Berkus)

- Fix rare internal overflow in multiplication of numeric values (Dean Rasheed)

- Guard against hard-to-reach stack overflows involving record types, range types, json, jsonb, tsquery, ltxtquery and query_int (Noah Misch)

- Fix handling of DOW and DOY in datetime input (Greg Stark)
Appendix E. Release Notes

These tokens aren’t meant to be used in datetime values, but previously they resulted in opaque internal error messages rather than “invalid input syntax”.

- Add more query-cancel checks to regular expression matching (Tom Lane)
- Add recursion depth protections to regular expression, SIMILAR TO, and LIKE matching (Tom Lane)
  Suitable search patterns and a low stack depth limit could lead to stack-overrun crashes.
- Fix potential infinite loop in regular expression execution (Tom Lane)
  A search pattern that can apparently match a zero-length string, but actually doesn’t match because of a back reference, could lead to an infinite loop.
- In regular expression execution, correctly record match data for capturing parentheses within a quantifier even when the match is zero-length (Tom Lane)
- Fix low-memory failures in regular expression compilation (Andreas Seltenreich)
- Fix low-probability memory leak during regular expression execution (Tom Lane)
- Fix rare low-memory failure in lock cleanup during transaction abort (Tom Lane)
- Fix “unexpected out-of-memory situation during sort” errors when using tuplestores with small \texttt{work\_mem} settings (Tom Lane)
- Fix very-low-probability stack overrun in \texttt{qsort} (Tom Lane)
- Fix “invalid memory alloc request size” failure in hash joins with large \texttt{work\_mem} settings (Tomas Vondra, Tom Lane)
- Fix assorted planner bugs (Tom Lane)
  These mistakes could lead to incorrect query plans that would give wrong answers, or to assertion failures in assert-enabled builds, or to odd planner errors such as “could not devise a query plan for the given query”, “could not find pathkey item to sort”, “plan should not reference subplan’s variable”, or “failed to assign all NestLoopParams to plan nodes”. Thanks are due to Andreas Seltenreich and Piotr Stefaniak for fuzz testing that exposed these problems.
- Improve planner’s performance for \texttt{UPDATE/DELETE} on large inheritance sets (Tom Lane, Dean Rasheed)
- Ensure standby promotion trigger files are removed at postmaster startup (Michael Paquier, Fujii Masao)
  This prevents unwanted promotion from occurring if these files appear in a database backup that is used to initialize a new standby server.
- During postmaster shutdown, ensure that per-socket lock files are removed and listen sockets are closed before we remove the \texttt{postmaster.pid} file (Tom Lane)
  This avoids race-condition failures if an external script attempts to start a new postmaster as soon as \texttt{pg\_ctl stop} returns.
- Fix postmaster’s handling of a startup-process crash during crash recovery (Tom Lane)
  If, during a crash recovery cycle, the startup process crashes without having restored database consistency, we’d try to launch a new startup process, which typically would just crash again, leading to an infinite loop.
Appendix E. Release Notes

- Do not print a WARNING when an autovacuum worker is already gone when we attempt to signal it, and reduce log verbosity for such signals (Tom Lane)
- Prevent autovacuum launcher from sleeping unduly long if the server clock is moved backwards a large amount (Álvaro Herrera)
- Ensure that cleanup of a GIN index’s pending-insertions list is interruptable by cancel requests (Jeff Janes)
- Allow all-zeroes pages in GIN indexes to be reused (Heikki Linnakangas)
  Such a page might be left behind after a crash.
- Fix handling of all-zeroes pages in SP-GiST indexes (Heikki Linnakangas)
  VACUUM attempted to recycle such pages, but did so in a way that wasn’t crash-safe.
- Fix off-by-one error that led to otherwise-harmless warnings about “apparent wraparound” in sub-trans/multixact truncation (Thomas Munro)
- Fix misreporting of CONTINUE and MOVE statement types in PL/pgSQL’s error context messages (Pavel Stehule, Tom Lane)
- Fix PL/Perl to handle non-ASCII error message texts correctly (Alex Hunsaker)
- Fix PL/Python crash when returning the string representation of a record result (Tom Lane)
- Fix some places in PL/Tcl that neglected to check for failure of malloc() calls (Michael Paquier, Álvaro Herrera)
- In contrib/isn, fix output of ISBN-13 numbers that begin with 979 (Fabien Coelho)
  EANs beginning with 979 (but not 9790) are considered ISBNs, but they must be printed in the new 13-digit format, not the 10-digit format.
- Fix contrib/sepgsql’s handling of SELECT INTO statements (Kohei KaiGai)
- Improve libpq’s handling of out-of-memory conditions (Michael Paquier, Heikki Linnakangas)
- Fix memory leaks and missing out-of-memory checks in ecpg (Michael Paquier)
- Fix psql’s code for locale-aware formatting of numeric output (Tom Lane)
  The formatting code invoked by \pset numericlocale on did the wrong thing for some uncommon cases such as numbers with an exponent but no decimal point. It could also mangle already-localized output from the money data type.
- Prevent crash in psql’s \c command when there is no current connection (Noah Misch)
- Make pg_dump handle inherited NOT VALID check constraints correctly (Tom Lane)
- Fix selection of default zlib compression level in pg_dump’s directory output format (Andrew Dunstan)
- Ensure that temporary files created during a pg_dump run with tar-format output are not world-readable (Michael Paquier)
- Fix pg_dump and pg_upgrade to support cases where the postgres or template1 database is in a non-default tablespace (Marti Raudsepp, Bruce Momjian)
- Fix pg_dump to handle object privileges sanely when dumping from a server too old to have a particular privilege type (Tom Lane)
When dumping data types from pre-9.2 servers, and when dumping functions or procedural languages
from pre-7.3 servers, pg_dump would produce `GRANT/REVOKE` commands that revoked the owner’s
grantable privileges and instead granted all privileges to `PUBLIC`. Since the privileges involved are just
`USAGE` and `EXECUTE`, this isn’t a security problem, but it’s certainly a surprising representation of the
older systems’ behavior. Fix it to leave the default privilege state alone in these cases.

- Fix `pg_dump` to dump shell types (Tom Lane)
  Shell types (that is, not-yet-fully-defined types) aren’t useful for much, but nonetheless `pg_dump` should
dump them.
- Fix assorted minor memory leaks in `pg_dump` and other client-side programs (Michael Paquier)
- Fix spinlock assembly code for PPC hardware to be compatible with AIX’s native assembler (Tom
  Lane)
  Building with gcc didn’t work if gcc had been configured to use the native assembler, which is becoming
  more common.
- On AIX, test the `-qlonglong` compiler option rather than just assuming it’s safe to use (Noah Misch)
- On AIX, use `-Wl,-brtllib` link option to allow symbols to be resolved at runtime (Noah Misch)
  Perl relies on this ability in 5.8.0 and later.
- Avoid use of inline functions when compiling with 32-bit xlc, due to compiler bugs (Noah Misch)
- Use `librt` for `sched_yield()` when necessary, which it is on some Solaris versions (Oskari Saaren-
  maa)
- Fix Windows `install.bat` script to handle target directory names that contain spaces (Heikki Lin-
  nankangas)
- Make the numeric form of the PostgreSQL version number (e.g., `90405`) readily available to extension
  Makefiles, as a variable named `VERSION_NUM` (Michael Paquier)
- Update time zone data files to `tzdata` release 2015g for DST law changes in Cayman Islands, Fiji,
  Moldova, Morocco, Norfolk Island, North Korea, Turkey, and Uruguay. There is a new zone name
  `America/Fort_Nelson` for the Canadian Northern Rockies.

**E.59. Release 9.2.13**

**Release date:** 2015-06-12

This release contains a small number of fixes from 9.2.12. For information about new features in the 9.2
major release, see Section E.72.

**E.59.1. Migration to Version 9.2.13**

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.61.
E.59.2. Changes

- Fix rare failure to invalidate relation cache init file (Tom Lane)
  
  With just the wrong timing of concurrent activity, a `VACUUM FULL` on a system catalog might fail to update the “init file” that’s used to avoid cache-loading work for new sessions. This would result in later sessions being unable to access that catalog at all. This is a very ancient bug, but it’s so hard to trigger that no reproducible case had been seen until recently.

- Avoid deadlock between incoming sessions and `CREATE/DROP DATABASE` (Tom Lane)
  
  A new session starting in a database that is the target of a `DROP DATABASE` command, or is the template for a `CREATE DATABASE` command, could cause the command to wait for five seconds and then fail, even if the new session would have exited before that.

E.60. Release 9.2.12

Release date: 2015-06-04

This release contains a small number of fixes from 9.2.11. For information about new features in the 9.2 major release, see Section E.72.

E.60.1. Migration to Version 9.2.12

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.61.

E.60.2. Changes

- Avoid failures while `fsync`ing data directory during crash restart (Abhijit Menon-Sen, Tom Lane)
  
  In the previous minor releases we added a patch to `fsync` everything in the data directory after a crash. Unfortunately its response to any error condition was to fail, thereby preventing the server from starting up, even when the problem was quite harmless. An example is that an unwritable file in the data directory would prevent restart on some platforms; but it is common to make SSL certificate files unwritable by the server. Revise this behavior so that permissions failures are ignored altogether, and other types of failures are logged but do not prevent continuing.

- Fix `pg_get_functiondef()` to show functions’ LEAKPROOF property, if set (Jeevan Chalke)

- Remove configure’s check prohibiting linking to a threaded libpython on OpenBSD (Tom Lane)
  
  The failure this restriction was meant to prevent seems to not be a problem anymore on current OpenBSD versions.

- Allow `libpq` to use TLS protocol versions beyond v1 (Noah Misch)
For a long time, libpq was coded so that the only SSL protocol it would allow was TLS v1. Now that newer TLS versions are becoming popular, allow it to negotiate the highest commonly-supported TLS version with the server. (PostgreSQL servers were already capable of such negotiation, so no change is needed on the server side.) This is a back-patch of a change already released in 9.4.0.

E.61. Release 9.2.11

Release date: 2015-05-22

This release contains a variety of fixes from 9.2.10. For information about new features in the 9.2 major release, see Section E.72.

E.61.1. Migration to Version 9.2.11

A dump/restore is not required for those running 9.2.X. However, if you use contrib/citext’s regexp_matches() functions, see the changelog entry below about that.

Also, if you are upgrading from a version earlier than 9.2.10, see Section E.62.

E.61.2. Changes

• Avoid possible crash when client disconnects just before the authentication timeout expires (Benkocs Norbert Attila)

  If the timeout interrupt fired partway through the session shutdown sequence, SSL-related state would be freed twice, typically causing a crash and hence denial of service to other sessions. Experimentation shows that an unauthenticated remote attacker could trigger the bug somewhat consistently, hence treat as security issue. (CVE-2015-3165)

• Improve detection of system-call failures (Noah Misch)

  Our replacement implementation of snprintf() failed to check for errors reported by the underlying system library calls; the main case that might be missed is out-of-memory situations. In the worst case this might lead to information exposure, due to our code assuming that a buffer had been overwritten when it hadn’t been. Also, there were a few places in which security-relevant calls of other system library functions did not check for failure.

  It remains possible that some calls of the *printf() family of functions are vulnerable to information disclosure if an out-of-memory error occurs at just the wrong time. We judge the risk to not be large, but will continue analysis in this area. (CVE-2015-3166)

• In contrib/pgcrypto, uniformly report decryption failures as “Wrong key or corrupt data” (Noah Misch)

  Previously, some cases of decryption with an incorrect key could report other error message texts. It has been shown that such variance in error reports can aid attackers in recovering keys from other systems.
Appendix E. Release Notes

While it’s unknown whether pgcrypto’s specific behaviors are likewise exploitable, it seems better to avoid the risk by using a one-size-fits-all message. (CVE-2015-3167)

• Fix incorrect declaration of contrib/citext’s regexp_matches() functions (Tom Lane)
  
  These functions should return setof text[], like the core functions they are wrappers for; but they were incorrectly declared as returning just text[]. This mistake had two results: first, if there was no match you got a scalar null result, whereas what you should get is an empty set (zero rows). Second, the g flag was effectively ignored, since you would get only one result array even if there were multiple matches.

  While the latter behavior is clearly a bug, there might be applications depending on the former behavior; therefore the function declarations will not be changed by default until PostgreSQL 9.5. In pre-9.5 branches, the old behavior exists in version 1.0 of the citext extension, while we have provided corrected declarations in version 1.1 (which is not installed by default). To adopt the fix in pre-9.5 branches, execute ALTER EXTENSION citext UPDATE TO ’1.1’ in each database in which citext is installed. (You can also “update” back to 1.0 if you need to undo that.) Be aware that either update direction will require dropping and recreating any views or rules that use citext’s regexp_matches() functions.

• Fix incorrect checking of deferred exclusion constraints after a HOT update (Tom Lane)
  
  If a new row that potentially violates a deferred exclusion constraint is HOT-updated (that is, no indexed columns change and the row can be stored back onto the same table page) later in the same transaction, the exclusion constraint would be reported as violated when the check finally occurred, even if the row(s) the new row originally conflicted with had been deleted.

• Fix planning of star-schema-style queries (Tom Lane)
  
  Sometimes, efficient scanning of a large table requires that index parameters be provided from more than one other table (commonly, dimension tables whose keys are needed to index a large fact table). The planner should be able to find such plans, but an overly restrictive search heuristic prevented it.

• Prevent improper reordering of antijoins (NOT EXISTS joins) versus other outer joins (Tom Lane)
  
  This oversight in the planner has been observed to cause “could not find RelOptInfo for given relids” errors, but it seems possible that sometimes an incorrect query plan might get past that consistency check and result in silently-wrong query output.

• Fix incorrect matching of subexpressions in outer-join plan nodes (Tom Lane)
  
  Previously, if textually identical non-strict subexpressions were used both above and below an outer join, the planner might try to re-use the value computed below the join, which would be incorrect because the executor would force the value to NULL in case of an unmatched outer row.

• Fix GEQO planner to cope with failure of its join order heuristic (Tom Lane)
  
  This oversight has been seen to lead to “failed to join all relations together” errors in queries involving LATERAL, and that might happen in other cases as well.

• Fix possible deadlock at startup when max_prepared_transactions is too small (Heikki Linnakan-
gas)

• Don’t archive useless preallocated WAL files after a timeline switch (Heikki Linnakangas)

• Avoid “cannot GetMultiXactIdMembers() during recovery” error (Álvaro Herrera)

• Recursively fsync() the data directory after a crash (Abhijit Menon-Sen, Robert Haas)
Appendix E. Release Notes

This ensures consistency if another crash occurs shortly later. (The second crash would have to be a system-level crash, not just a database crash, for there to be a problem.)

- Fix autovacuum launcher’s possible failure to shut down, if an error occurs after it receives SIGTERM (Álvaro Herrera)

- Cope with unexpected signals in LockBufferForCleanup() (Andres Freund)

  This oversight could result in spurious errors about “multiple backends attempting to wait for pincount 1”.

- Fix crash when doing COPY IN to a table with check constraints that contain whole-row references (Tom Lane)

  The known failure case only crashes in 9.4 and up, but there is very similar code in 9.3 and 9.2, so back-patch those branches as well.

- Avoid waiting for WAL flush or synchronous replication during commit of a transaction that was read-only so far as the user is concerned (Andres Freund)

  Previously, a delay could occur at commit in transactions that had written WAL due to HOT page pruning, leading to undesirable effects such as sessions getting stuck at startup if all synchronous replicas are down. Sessions have also been observed to get stuck in catchup interrupt processing when using synchronous replication; this will fix that problem as well.

- Fix crash when manipulating hash indexes on temporary tables (Heikki Linnakangas)

- Fix possible failure during hash index bucket split, if other processes are modifying the index concurrently (Tom Lane)

- Check for interrupts while analyzing index expressions (Jeff Janes)

  ANALYZE executes index expressions many times; if there are slow functions in such an expression, it’s desirable to be able to cancel the ANALYZE before that loop finishes.

- Ensure tableoid of a foreign table is reported correctly when a READ COMMITTED recheck occurs after locking rows in SELECT FOR UPDATE, UPDATE, or DELETE (Etsuro Fujita)

- Add the name of the target server to object description strings for foreign-server user mappings (Álvaro Herrera)

- Recommend setting include_realm to 1 when using Kerberos/GSSAPI/SSPI authentication (Stephen Frost)

  Without this, identically-named users from different realms cannot be distinguished. For the moment this is only a documentation change, but it will become the default setting in PostgreSQL 9.5.

- Remove code for matching IPv4 pg_hba.conf entries to IPv4-in-IPv6 addresses (Tom Lane)

  This hack was added in 2003 in response to a report that some Linux kernels of the time would report IPv4 connections as having IPv4-in-IPv6 addresses. However, the logic was accidentally broken in 9.0. The lack of any field complaints since then shows that it’s not needed anymore. Now we have reports that the broken code causes crashes on some systems, so let’s just remove it rather than fix it. (Had we chosen to fix it, that would make for a subtle and potentially security-sensitive change in the effective meaning of IPv4 pg_hba.conf entries, which does not seem like a good thing to do in minor releases.)

- Report WAL flush, not insert, position in IDENTIFY_SYSTEM replication command (Heikki Linnakangas)
This avoids a possible startup failure in pg_receivexlog.

- While shutting down service on Windows, periodically send status updates to the Service Control Manager to prevent it from killing the service too soon; and ensure that ps_ctl will wait for shutdown (Krystian Bigaj)

- Reduce risk of network deadlock when using libpq’s non-blocking mode (Heikki Linnakangas)

When sending large volumes of data, it’s important to drain the input buffer every so often, in case the server has sent enough response data to cause it to block on output. (A typical scenario is that the server is sending a stream of NOTICE messages during COPY FROM STDIN.) This worked properly in the normal blocking mode, but not so much in non-blocking mode. We’ve modified libpq to opportunistically drain input when it can, but a full defense against this problem requires application cooperation: the application should watch for socket read-ready as well as write-ready conditions, and be sure to call PQconsumeInput() upon read-ready.

- In libpq, fix misparsing of empty values in URI connection strings (Thomas Fanghaenel)

- Fix array handling in ecpg (Michael Meskes)

- Fix psql to sanely handle URIs and conninfo strings as the first parameter to \connect (David Fetter, Andrew Dunstan, Álvaro Herrera)

  This syntax has been accepted (but undocumented) for a long time, but previously some parameters might be taken from the old connection instead of the given string, which was agreed to be undesirable.

- Suppress incorrect complaints from psql on some platforms that it failed to write ~/psql_history at exit (Tom Lane)

  This misbehavior was caused by a workaround for a bug in very old (pre-2006) versions of libedit. We fixed it by removing the workaround, which will cause a similar failure to appear for anyone still using such versions of libedit. Recommendation: upgrade that library, or use libreadline.

- Fix pg_dump’s rule for deciding which casts are system-provided casts that should not be dumped (Tom Lane)

- In pg_dump, fix failure to honor -Z compression level option together with -Fd (Michael Paquier)

- Make pg_dump consider foreign key relationships between extension configuration tables while choosing dump order (Gilles Darold, Michael Paquier, Stephen Frost)

  This oversight could result in producing dumps that fail to reload because foreign key constraints are transiently violated.

- Fix dumping of views that are just VALUES(…) but have column aliases (Tom Lane)

- In pg_upgrade, force timeline 1 in the new cluster (Bruce Momjian)

  This change prevents upgrade failures caused by bogus complaints about missing WAL history files.

- In pg_upgrade, check for improperly non-connectable databases before proceeding (Bruce Momjian)

- In pg_upgrade, quote directory paths properly in the generated delete_old_cluster script (Bruce Momjian)

- In pg_upgrade, preserve database-level freezing info properly (Bruce Momjian)

  This oversight could cause missing-clog-file errors for tables within the postgres and template1 databases.
Appendix E. Release Notes

- Run pg_upgrade and pg_resetxlog with restricted privileges on Windows, so that they don’t fail when run by an administrator (Muhammad Asif Naeem)
- Improve handling of readdir() failures when scanning directories in initdb and pg_basebackup (Marco Nenciarini)
- Fix failure in pg_receivexlog (Andres Freund)
  A patch merge mistake in 9.2.10 led to “could not create archive status file” errors.
- Fix slow sorting algorithm in contrib/intarray (Tom Lane)
- Fix compile failure on Sparc V8 machines (Rob Rowan)
- Update time zone data files to tzdata release 2015d for DST law changes in Egypt, Mongolia, and Palestine, plus historical changes in Canada and Chile. Also adopt revised zone abbreviations for the America/Adak zone (HST/HDT not HAST/HADT).

E.62. Release 9.2.10

Release date: 2015-02-05

This release contains a variety of fixes from 9.2.9. For information about new features in the 9.2 major release, see Section E.72.

E.62.1. Migration to Version 9.2.10

A dump/restore is not required for those running 9.2.X.

However, if you are a Windows user and are using the “Norwegian (Bokmål)” locale, manual action is needed after the upgrade to replace any “Norwegian (Bokmål)_Norway” locale names stored in PostgreSQL system catalogs with the plain-ASCII alias “Norwegian_Norway”. For details see http://wiki.postgresql.org/wiki/Changes_To_Norwegian_Locale

Also, if you are upgrading from a version earlier than 9.2.9, see Section E.63.

E.62.2. Changes

- Fix buffer overruns in to_char() (Bruce Momjian)
  When to_char() processes a numeric formatting template calling for a large number of digits, PostgreSQL would read past the end of a buffer. When processing a crafted timestamp formatting template, PostgreSQL would write past the end of a buffer. Either case could crash the server. We have not ruled out the possibility of attacks that lead to privilege escalation, though they seem unlikely. (CVE-2015-0241)
- Fix buffer overrun in replacement *printf() functions (Tom Lane)
  PostgreSQL includes a replacement implementation of printf and related functions. This code will overrun a stack buffer when formatting a floating point number (conversion specifiers e, E, f, F, g or G)
with requested precision greater than about 500. This will crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. A database user can trigger such a buffer overrun through the `to_char()` SQL function. While that is the only affected core PostgreSQL functionality, extension modules that use printf-family functions may be at risk as well.

This issue primarily affects PostgreSQL on Windows. PostgreSQL uses the system implementation of these functions where adequate, which it is on other modern platforms. (CVE-2015-0242)

- Fix buffer overruns in `contrib/pgcrypto` (Marko Tiikkaja, Noah Misch)
  
  Errors in memory size tracking within the `pgcrypto` module permitted stack buffer overruns and improper dependence on the contents of uninitialized memory. The buffer overrun cases can crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. (CVE-2015-0243)

- Fix possible loss of frontend/backend protocol synchronization after an error (Heikki Linnakangas)
  
  If any error occurred while the server was in the middle of reading a protocol message from the client, it could lose synchronization and incorrectly try to interpret part of the message’s data as a new protocol message. An attacker able to submit crafted binary data within a command parameter might succeed in injecting his own SQL commands this way. Statement timeout and query cancellation are the most likely sources of errors triggering this scenario. Particularly vulnerable are applications that use a timeout and also submit arbitrary user-crafted data as binary query parameters. Disabling statement timeout will reduce, but not eliminate, the risk of exploit. Our thanks to Emil Lenngren for reporting this issue. (CVE-2015-0244)

- Fix information leak via constraint-violation error messages (Stephen Frost)
  
  Some server error messages show the values of columns that violate a constraint, such as a unique constraint. If the user does not have `SELECT` privilege on all columns of the table, this could mean exposing values that the user should not be able to see. Adjust the code so that values are displayed only when they came from the SQL command or could be selected by the user. (CVE-2014-8161)

- Lock down regression testing’s temporary installations on Windows (Noah Misch)
  
  Use SSPI authentication to allow connections only from the OS user who launched the test suite. This closes on Windows the same vulnerability previously closed on other platforms, namely that other users might be able to connect to the test postmaster. (CVE-2014-0067)

- Cope with the Windows locale named “Norwegian (Bokmål)” (Heikki Linnakangas)
  
  Non-ASCII locale names are problematic since it’s not clear what encoding they should be represented in. Map the troublesome locale name to a plain-ASCII alias, “Norwegian_Norway”.

- Avoid possible data corruption if `ALTER DATABASE SET TABLESPACE` is used to move a database to a new tablespace and then shortly later move it back to its original tablespace (Tom Lane)

- Avoid corrupting tables when `ANALYZE` inside a transaction is rolled back (Andres Freund, Tom Lane, Michael Paquier)
  
  If the failing transaction had earlier removed the last index, rule, or trigger from the table, the table would be left in a corrupted state with the relevant `pg_class` flags not set though they should be.

- Ensure that unlogged tables are copied correctly during `CREATE DATABASE` or `ALTER DATABASE SET TABLESPACE` (Pavan Deolasee, Andres Freund)

- Fix `DROP`’s dependency searching to correctly handle the case where a table column is recursively visited before its table (Petr Jelinek, Tom Lane)
This case is only known to arise when an extension creates both a datatype and a table using that datatype. The faulty code might refuse a `DROP EXTENSION` unless `CASCADE` is specified, which should not be required.

- Fix use-of-already-freed-memory problem in EvalPlanQual processing (Tom Lane)
  
  In `READ COMMITTED` mode, queries that lock or update recently-updated rows could crash as a result of this bug.

- Fix planning of `SELECT FOR UPDATE` when using a partial index on a child table (Kyotaro Horiguchi)
  
  In `READ COMMITTED` mode, `SELECT FOR UPDATE` must also recheck the partial index’s `WHERE` condition when rechecking a recently-updated row to see if it still satisfies the query’s `WHERE` condition. This requirement was missed if the index belonged to an inheritance child table, so that it was possible to incorrectly return rows that no longer satisfy the query condition.

- Fix corner case wherein `SELECT FOR UPDATE` could return a row twice, and possibly miss returning other rows (Tom Lane)
  
  In `READ COMMITTED` mode, a `SELECT FOR UPDATE` that is scanning an inheritance tree could incorrectly return a row from a prior child table instead of the one it should return from a later child table.

- Reject duplicate column names in the referenced-columns list of a `FOREIGN KEY` declaration (David Rowley)
  
  This restriction is per SQL standard. Previously we did not reject the case explicitly, but later on the code would fail with bizarre-looking errors.

- Restore previous behavior of conversion of domains to JSON (Tom Lane)
  
  This change causes domains over numeric and boolean to be treated like their base types for purposes of conversion to JSON. It worked like that before 9.3.5 and 9.2.9, but was unintentionally changed while fixing a related problem.

- Fix bugs in raising a numeric value to a large integral power (Tom Lane)
  
  The previous code could get a wrong answer, or consume excessive amounts of time and memory before realizing that the answer must overflow.

- In `numeric_recv()`, truncate away any fractional digits that would be hidden according to the value’s `dscale` field (Tom Lane)
  
  A numeric value’s display scale (`dscale`) should never be less than the number of nonzero fractional digits; but apparently there’s at least one broken client application that transmits binary numeric values in which that’s true. This leads to strange behavior since the extra digits are taken into account by arithmetic operations even though they aren’t printed. The least risky fix seems to be to truncate away such “hidden” digits on receipt, so that the value is indeed what it prints as.

- Fix incorrect search for shortest-first regular expression matches (Tom Lane)
  
  Matching would often fail when the number of allowed iterations is limited by a `?` quantifier or a bound expression.

- Reject out-of-range numeric timezone specifications (Tom Lane)
  
  Simple numeric timezone specifications exceeding +/- 168 hours (one week) would be accepted, but could then cause null-pointer dereference crashes in certain operations. There’s no use-case for such large UTC offsets, so reject them.
• Fix bugs in `tsquery @@ tsquery` operator (Heikki Linnakangas)

Two different terms would be considered to match if they had the same CRC. Also, if the second operand had more terms than the first, it would be assumed not to be contained in the first; which is wrong since it might contain duplicate terms.

• Improve ispell dictionary’s defenses against bad affix files (Tom Lane)

• Allow more than 64K phrases in a thesaurus dictionary (David Boutin)

The previous coding could crash on an oversize dictionary, so this was deemed a back-patchable bug fix rather than a feature addition.

• Fix namespace handling in `xpath()` (Ali Akbar)

Previously, the `xml` value resulting from an `xpath()` call would not have namespace declarations if the namespace declarations were attached to an ancestor element in the input `xml` value, rather than to the specific element being returned. Propagate the ancestral declaration so that the result is correct when considered in isolation.

• Ensure that whole-row variables expose nonempty column names to functions that pay attention to column names within composite arguments (Tom Lane)

In some contexts, constructs like `row_to_json(tab.*)` may not produce the expected column names. This is fixed properly as of 9.4; in older branches, just ensure that we produce some nonempty name. (In some cases this will be the underlying table’s column name rather than the query-assigned alias that should theoretically be visible.)

• Fix mishandling of system columns, particularly `tableoid`, in FDW queries (Etsuro Fujita)

• Avoid doing `indexed_column = ANY (array)` as an index qualifier if that leads to an inferior plan (Andrew Gierth)

In some cases, = ANY conditions applied to non-first index columns would be done as index conditions even though it would be better to use them as simple filter conditions.

• Fix planner problems with nested append relations, such as inherited tables within `UNION ALL` sub-queries (Tom Lane)

• Fail cleanly when a GiST index tuple doesn’t fit on a page, rather than going into infinite recursion (Andrew Gierth)

• Exempt tables that have per-table `cost_limit` and/or `cost_delay` settings from autovacuum’s global cost balancing rules (Álvaro Herrera)

The previous behavior resulted in basically ignoring these per-table settings, which was unintended. Now, a table having such settings will be vacuumed using those settings, independently of what is going on in other autovacuum workers. This may result in heavier total I/O load than before, so such settings should be re-examined for sanity.

• Avoid wholesale autovacuuming when autovacuum is nominally off (Tom Lane)

Even when autovacuum is nominally off, we will still launch autovacuum worker processes to vacuum tables that are at risk of XID wraparound. However, such a worker process then proceeded to vacuum all tables in the target database, if they met the usual thresholds for autovacuuming. This is at best pretty unexpected; at worst it delays response to the wraparound threat. Fix it so that if autovacuum is turned off, workers only do anti-wraparound vacuums and not any other work.
• During crash recovery, ensure that unlogged relations are rewritten as empty and are synced to disk before recovery is considered complete (Abhijit Menon-Sen, Andres Freund)

This prevents scenarios in which unlogged relations might contain garbage data following database crash recovery.

• Fix race condition between hot standby queries and replaying a full-page image (Heikki Linnakangas)

This mistake could result in transient errors in queries being executed in hot standby.

• Fix several cases where recovery logic improperly ignored WAL records for COMMIT/ABORT PREPARED (Heikki Linnakangas)

The most notable oversight was that recovery_target_xid could not be used to stop at a two-phase commit.

• Prevent latest WAL file from being archived a second time at completion of crash recovery (Fujii Masao)

• Avoid creating unnecessary .ready marker files for timeline history files (Fujii Masao)

• Fix possible null pointer dereference when an empty prepared statement is used and the log_statement setting is mod or ddl (Fujii Masao)

• Change “pgstat wait timeout” warning message to be LOG level, and rephrase it to be more understandable (Tom Lane)

This message was originally thought to be essentially a can’t-happen case, but it occurs often enough on our slower buildfarm members to be a nuisance. Reduce it to LOG level, and expend a bit more effort on the wording: it now reads “using stale statistics instead of current ones because stats collector is not responding”.

• Fix SPARC spinlock implementation to ensure correctness if the CPU is being run in a non-TSO coherence mode, as some non-Solaris kernels do (Andres Freund)

• Warn if macOS’s setlocale() starts an unwanted extra thread inside the postmaster (Noah Misch)

• Fix processing of repeated dbname parameters in PQconnectdbParams() (Alex Shulgin)

Unexpected behavior ensued if the first occurrence of dbname contained a connection string or URI to be expanded.

• Ensure that libpq reports a suitable error message on unexpected socket EOF (Marko Tiikkaja, Tom Lane)

Depending on kernel behavior, libpq might return an empty error string rather than something useful when the server unexpectedly closed the socket.

• Clear any old error message during PQreset() (Heikki Linnakangas)

If PQreset() is called repeatedly, and the connection cannot be re-established, error messages from the failed connection attempts kept accumulating in the PGconn’s error string.

• Properly handle out-of-memory conditions while parsing connection options in libpq (Alex Shulgin, Heikki Linnakangas)

• Fix array overrun in ecpg’s version of ParseDateTime() (Michael Paquier)

• In initdb, give a clearer error message if a password file is specified but is empty (Mats Erik Andersson)

• Fix psql’s \s command to work nicely with libedit, and add pager support (Stepan Rutz, Tom Lane)
When using libedit rather than readline, \s printed the command history in a fairly unreadable encoded format, and on recent libedit versions might fail altogether. Fix that by printing the history ourselves rather than having the library do it. A pleasant side-effect is that the pager is used if appropriate.

This patch also fixes a bug that caused newline encoding to be applied inconsistently when saving the command history with libedit. Multiline history entries written by older psql versions will be read cleanly with this patch, but perhaps not vice versa, depending on the exact libedit versions involved.

- Improve consistency of parsing of psql’s special variables (Tom Lane)
  Allow variant spellings of on and off (such as 1/o) for ECHO_HIDDEN and ON_ERROR_ROLLBACK. Report a warning for unrecognized values for COMP_KEYWORD_CASE, ECHO, ECHO_HIDDEN, HISTCONTROL, ON_ERROR_ROLLBACK, and VERBOSITY. Recognize all values for all these variables case-insensitively; previously there was a mishmash of case-sensitive and case-insensitive behaviors.
- Fix psql’s expanded-mode display to work consistently when using border = 3 and linestyle = ascii or unicode (Stephen Frost)
- Improve performance of pg_dump when the database contains many instances of multiple dependency paths between the same two objects (Tom Lane)
- Fix pg_dumpall to restore its ability to dump from pre-8.1 servers (Gilles Darold)
- Fix possible deadlock during parallel restore of a schema-only dump (Robert Haas, Tom Lane)
- Fix core dump in pg_dump --binary-upgrade on zero-column composite type (Rushabh Lathia)
- Prevent WAL files created by pg_basebackup -x/-X from being archived again when the standby is promoted (Andres Freund)
- Fix failure of contrib/auto_explain to print per-node timing information when doing EXPLAIN ANALYZE (Tom Lane)
- Fix upgrade-from-unpackaged script for contrib/citext (Tom Lane)
- Fix block number checking in contrib/pageinspect’s get_raw_page() (Tom Lane)
  The incorrect checking logic could prevent access to some pages in non-main relation forks.
- Fix contrib/pgcrypto’s pgp_sym_decrypt() to not fail on messages whose length is 6 less than a power of 2 (Marko Tiikkaja)
- Fix file descriptor leak in contrib/pg_test_fsync (Jeff Janes)
  This could cause failure to remove temporary files on Windows.
- Handle unexpected query results, especially NULLs, safely in contrib/tablefunc’s connectby() (Michael Paquier)
  connectby() previously crashed if it encountered a NULL key value. It now prints that row but doesn’t recurse further.
- Avoid a possible crash in contrib/xml2’s xslt_process() (Mark Simonetti)
  libxslt seems to have an undocumented dependency on the order in which resources are freed; reorder our calls to avoid a crash.
- Mark some contrib I/O functions with correct volatility properties (Tom Lane)
  The previous over-conservative marking was immaterial in normal use, but could cause optimization problems or rejection of valid index expression definitions. Since the consequences are not large, we’ve
just adjusted the function definitions in the extension modules’ scripts, without changing version numbers.

- Numerous cleanups of warnings from Coverity static code analyzer (Andres Freund, Tatsuo Ishii, Marko Kreen, Tom Lane, Michael Paquier)

  These changes are mostly cosmetic but in some cases fix corner-case bugs, for example a crash rather than a proper error report after an out-of-memory failure. None are believed to represent security issues.

- Detect incompatible OpenLDAP versions during build (Noah Misch)

  With OpenLDAP versions 2.4.24 through 2.4.31, inclusive, PostgreSQL backends can crash at exit. Raise a warning during configure based on the compile-time OpenLDAP version number, and test the crashing scenario in the contrib/dblink regression test.

- In non-MSVC Windows builds, ensure libpq.dll is installed with execute permissions (Noah Misch)

- Make pg_regress remove any temporary installation it created upon successful exit (Tom Lane)

  This results in a very substantial reduction in disk space usage during make check-world, since that sequence involves creation of numerous temporary installations.

- Support time zone abbreviations that change UTC offset from time to time (Tom Lane)

  Previously, PostgreSQL assumed that the UTC offset associated with a time zone abbreviation (such as EST) never changes in the usage of any particular locale. However this assumption fails in the real world, so introduce the ability for a zone abbreviation to represent a UTC offset that sometimes changes. Update the zone abbreviation definition files to make use of this feature in timezone locales that have changed the UTC offset of their abbreviations since 1970 (according to the IANA timezone database). In such timezones, PostgreSQL will now associate the correct UTC offset with the abbreviation depending on the given date.

- Update time zone abbreviations lists (Tom Lane)

  Add CST (China Standard Time) to our lists. Remove references to ADT as “Arabia Daylight Time”, an abbreviation that’s been out of use since 2007; therefore, claiming there is a conflict with “Atlantic Daylight Time” doesn’t seem especially helpful. Fix entirely incorrect GMT offsets for CKT (Cook Islands), FJT, and FIST (Fiji); we didn’t even have them on the proper side of the date line.

- Update time zone data files to tzdata release 2015a.

  The IANA timezone database has adopted abbreviations of the form AxsT/AxsDT for all Australian time zones, reflecting what they believe to be current majority practice Down Under. These names do not conflict with usage elsewhere (other than ACST for Acre Summer Time, which has been in disuse since 1994). Accordingly, adopt these names into our “Default” timezone abbreviation set. The “Australia” abbreviation set now contains only CST, EAST, EST, SAST, SAT, and WST, all of which are thought to be mostly historical usage. Note that SAST has also been changed to be South Africa Standard Time in the “Default” abbreviation set.

  Also, add zone abbreviations SRET (Asia/Srednekolymsk) and XJT (Asia/Urumqi), and use WSST/WSDT for western Samoa. Also, there were DST law changes in Chile, Mexico, the Turks & Caicos Islands (America/Grand_Turk), and Fiji. There is a new zone Pacific/Bougainville for portions of Papua New Guinea. Also, numerous corrections for historical (pre-1970) time zone data.
E.63. Release 9.2.9

Release date: 2014-07-24

This release contains a variety of fixes from 9.2.8. For information about new features in the 9.2 major release, see Section E.72.

E.63.1. Migration to Version 9.2.9

A dump/restore is not required for those running 9.2.X.

However, this release corrects an index corruption problem in some GiST indexes. See the first changelog entry below to find out whether your installation has been affected and what steps you should take if so.

Also, if you are upgrading from a version earlier than 9.2.6, see Section E.66.

E.63.2. Changes

- Correctly initialize padding bytes in contrib/btree_gist indexes on bit columns (Heikki Linnakangas)
  This error could result in incorrect query results due to values that should compare equal not being seen as equal. Users with GiST indexes on bit or bit varying columns should REINDEX those indexes after installing this update.
- Protect against torn pages when deleting GIN list pages (Heikki Linnakangas)
  This fix prevents possible index corruption if a system crash occurs while the page update is being written to disk.
- Don’t clear the right-link of a GiST index page while replaying updates from WAL (Heikki Linnakangas)
  This error could lead to transiently wrong answers from GiST index scans performed in Hot Standby.
- Fix corner-case infinite loop during insertion into an SP-GiST text index (Tom Lane)
- Fix feedback status when hot_standby_feedback is turned off on-the-fly (Simon Riggs)
- Fix possibly-incorrect cache invalidation during nested calls to ReceiveSharedInvalidMessages (Andres Freund)
- Fix planner’s mishandling of nested PlaceHolderVars generated in nested-nestloop plans (Tom Lane)
  This oversight could result in “variable not found in subplan target lists” errors, or in silently wrong query results.
- Fix “could not find pathkey item to sort” planner failures with UNION ALL over subqueries reading from tables with inheritance children (Tom Lane)
- Don’t assume a subquery’s output is unique if there’s a set-returning function in its targetlist (David Rowley)
  This oversight could lead to misoptimization of constructs like WHERE x IN (SELECT y, generate_series(1,10) FROM t GROUP BY y).
• Improve planner to drop constant-NULL inputs of AND/OR when possible (Tom Lane)
  This change fixes some cases where the more aggressive parameter substitution done by 9.2 and later can lead to a worse plan than older versions produced.

• Fix identification of input type category in to_json() and friends (Tom Lane)
  This is known to have led to inadequate quoting of money fields in the JSON result, and there may have been wrong results for other data types as well.

• Fix failure to detoast fields in composite elements of structured types (Tom Lane)
  This corrects cases where TOAST pointers could be copied into other tables without being dereferenced. If the original data is later deleted, it would lead to errors like “missing chunk number 0 for toast value ...” when the now-dangling pointer is used.

• Fix “record type has not been registered” failures with whole-row references to the output of Append plan nodes (Tom Lane)

• Fix possible crash when invoking a user-defined function while rewinding a cursor (Tom Lane)

• Fix query-lifespan memory leak while evaluating the arguments for a function in FROM (Tom Lane)

• Fix session-lifespan memory leaks in regular-expression processing (Tom Lane, Arthur O’Dwyer, Greg Stark)

• Fix data encoding error in hungarian.stop (Tom Lane)

• Prevent foreign tables from being created with OIDS when default_with_oids is true (Etsuro Fujita)

• Fix liveness checks for rows that were inserted in the current transaction and then deleted by a now-rolled-back subtransaction (Andres Freund)
  This could cause problems (at least spurious warnings, and at worst an infinite loop) if CREATE INDEX or CLUSTER were done later in the same transaction.

• Clear pg_stat_activity.xact_start during PREPARE TRANSACTION (Andres Freund)
  After the PREPARE, the originating session is no longer in a transaction, so it should not continue to display a transaction start time.

• Fix REASSIGN OWNED to not fail for text search objects (Álvaro Herrera)

• Block signals during postmaster startup (Tom Lane)
  This ensures that the postmaster will properly clean up after itself if, for example, it receives SIGINT while still starting up.

• Fix client host name lookup when processing pg_hba.conf entries that specify host names instead of IP addresses (Tom Lane)
  Ensure that reverse-DNS lookup failures are reported, instead of just silently not matching such entries. Also ensure that we make only one reverse-DNS lookup attempt per connection, not one per host name entry, which is what previously happened if the lookup attempts failed.

• Allow the root user to use postgres -C variable and postgres --describe-config (Mau-Mau)
  The prohibition on starting the server as root does not need to extend to these operations, and relaxing it prevents failure of pg_ctl in some scenarios.

• Secure Unix-domain sockets of temporary postmasters started during make check (Noah Misch)
Any local user able to access the socket file could connect as the server’s bootstrap superuser, then proceed to execute arbitrary code as the operating-system user running the test, as we previously noted in CVE-2014-0067. This change defends against that risk by placing the server’s socket in a temporary, mode 0700 subdirectory of /tmp. The hazard remains however on platforms where Unix sockets are not supported, notably Windows, because then the temporary postmaster must accept local TCP connections.

A useful side effect of this change is to simplify make check testing in builds that override DEFAULT_PGSOCKET_DIR. Popular non-default values like /var/run/postgresql are often not writable by the build user, requiring workarounds that will no longer be necessary.

- Fix tablespace creation WAL replay to work on Windows (MauMau)
- Fix detection of socket creation failures on Windows (Bruce Momjian)
- On Windows, allow new sessions to absorb values of PGC_BACKEND parameters (such as log_connections) from the configuration file (Amit Kapila)
  Previously, if such a parameter were changed in the file post-startup, the change would have no effect.
- Properly quote executable path names on Windows (Nikhil Deshpande)
  This oversight could cause initdb and pg_upgrade to fail on Windows, if the installation path contained both spaces and @ signs.
- Fix linking of libpython on macOS (Tom Lane)
  The method we previously used can fail with the Python library supplied by Xcode 5.0 and later.
- Avoid buffer bloat in libpq when the server consistently sends data faster than the client can absorb it (Shin-ichi Morita, Tom Lane)
  libpq could be coerced into enlarging its input buffer until it runs out of memory (which would be reported misleadingly as “lost synchronization with server”). Under ordinary circumstances it’s quite far-fetched that data could be continuously transmitted more quickly than the recv() loop can absorb it, but this has been observed when the client is artificially slowed by scheduler constraints.
- Ensure that LDAP lookup attempts in libpq time out as intended (Laurenz Albe)
- Fix ecpg to do the right thing when an array of char * is the target for a FETCH statement returning more than one row, as well as some other array-handling fixes (Ashutosh Bapat)
- Fix pg_restore’s processing of old-style large object comments (Tom Lane)
  A direct-to-database restore from an archive file generated by a pre-9.0 version of pg_dump would usually fail if the archive contained more than a few comments for large objects.
- Fix pg_upgrade for cases where the new server creates a TOAST table but the old version did not (Bruce Momjian)
  This rare situation would manifest as “relation OID mismatch” errors.
- Prevent contrib/auto_explain from changing the output of a user’s EXPLAIN (Tom Lane)
  If auto_explain is active, it could cause an EXPLAIN (ANALYZE, TIMING OFF) command to nonetheless print timing information.
- Fix query-lifespan memory leak in contrib/dblink (MauMau, Joe Conway)
- In contrib/pgcrypto functions, ensure sensitive information is cleared from stack variables before returning (Marko Kreen)
• Prevent use of already-freed memory in contrib/pgstattuple’s pgstat_heap() (Noah Misch)

• In contrib/uuid-ossp, cache the state of the OSSP UUID library across calls (Tom Lane)
  This improves the efficiency of UUID generation and reduces the amount of entropy drawn from
  /dev/urandom, on platforms that have that.

• Update time zone data files to tzdata release 2014e for DST law changes in Crimea, Egypt, and Mo-
  rocco.

E.64. Release 9.2.8

Release date: 2014-03-20
This release contains a variety of fixes from 9.2.7. For information about new features in the 9.2 major
release, see Section E.72.

E.64.1. Migration to Version 9.2.8
A dump/restore is not required for those running 9.2.X.
However, if you are upgrading from a version earlier than 9.2.6, see Section E.66.

E.64.2. Changes

• Restore GIN metapages unconditionally to avoid torn-page risk (Heikki Linnakangas)
  Although this oversight could theoretically result in a corrupted index, it is unlikely to have caused any
  problems in practice, since the active part of a GIN metapage is smaller than a standard 512-byte disk
  sector.

• Avoid race condition in checking transaction commit status during receipt of a NOTIFY message (Marko
  Tiikkaja)
  This prevents a scenario wherein a sufficiently fast client might respond to a notification before database
  updates made by the notifier have become visible to the recipient.

• Allow regular-expression operators to be terminated early by query cancel requests (Tom Lane)
  This prevents scenarios wherein a pathological regular expression could lock up a server process unin-
  terruptibly for a long time.

• Remove incorrect code that tried to allow OVERLAPS with single-element row arguments (Joshua
  Yanovski)
  This code never worked correctly, and since the case is neither specified by the SQL standard nor
  documented, it seemed better to remove it than fix it.

• Avoid getting more than AccessShareLock when de-parsing a rule or view (Dean Rasheed)
This oversight resulted in pg_dump unexpectedly acquiring RowExclusiveLock locks on tables mentioned as the targets of INSERT/UPDATE/DELETE commands in rules. While usually harmless, that could interfere with concurrent transactions that tried to acquire, for example, ShareLock on those tables.

- Improve performance of index endpoint probes during planning (Tom Lane)
  This change fixes a significant performance problem that occurred when there were many not-yet-committed rows at the end of the index, which is a common situation for indexes on sequentially-assigned values such as timestamps or sequence-generated identifiers.

- Fix walsender’s failure to shut down cleanly when client is pg_receivexlog (Fujii Masao)

- Check WAL level and hot standby parameters correctly when doing crash recovery that will be followed by archive recovery (Heikki Linnakangas)

- Fix test to see if hot standby connections can be allowed immediately after a crash (Heikki Linnakangas)

- Prevent interrupts while reporting non-ERROR messages (Tom Lane)
  This guards against rare server-process freezeups due to recursive entry to syslog(), and perhaps other related problems.

- Fix memory leak in PL/Perl when returning a composite result, including multiple-OUT-parameter cases (Alex Hunsaker)

- Fix tracking of psql script line numbers during \copy from out-of-line data (Kumar Rajeev Rastogi, Amit Khandekar)
  \copy ... from incremented the script file line number for each data line, even if the data was not coming from the script file. This mistake resulted in wrong line numbers being reported for any errors occurring later in the same script file.

- Prevent intermittent “could not reserve shared memory region” failures on recent Windows versions (MauMau)

- Update time zone data files to tzdata release 2014a for DST law changes in Fiji and Turkey, plus historical changes in Israel and Ukraine.

E.65. Release 9.2.7

Release date: 2014-02-20

This release contains a variety of fixes from 9.2.6. For information about new features in the 9.2 major release, see Section E.72.

E.65.1. Migration to Version 9.2.7

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.6, see Section E.66.
E.65.2. Changes

- Shore up GRANT ... WITH ADMIN OPTION restrictions (Noah Misch)
  Granting a role without ADMIN OPTION is supposed to prevent the grantee from adding or removing members from the granted role, but this restriction was easily bypassed by doing SET ROLE first. The security impact is mostly that a role member can revoke the access of others, contrary to the wishes of his grantor. Unapproved role member additions are a lesser concern, since an uncooperative role member could provide most of his rights to others anyway by creating views or SECURITY DEFINER functions. (CVE-2014-0060)

- Prevent privilege escalation via manual calls to PL validator functions (Andres Freund)
  The primary role of PL validator functions is to be called implicitly during CREATE FUNCTION, but they are also normal SQL functions that a user can call explicitly. Calling a validator on a function actually written in some other language was not checked for and could be exploited for privilege-escalation purposes. The fix involves adding a call to a privilege-checking function in each validator function. Non-core procedural languages will also need to make this change to their own validator functions, if any. (CVE-2014-0061)

- Avoid multiple name lookups during table and index DDL (Robert Haas, Andres Freund)
  If the name lookups come to different conclusions due to concurrent activity, we might perform some parts of the DDL on a different table than other parts. At least in the case of CREATE INDEX, this can be used to cause the permissions checks to be performed against a different table than the index creation, allowing for a privilege escalation attack. (CVE-2014-0062)

- Prevent buffer overrun with long datetime strings (Noah Misch)
  The MAXDATELEN constant was too small for the longest possible value of type interval, allowing a buffer overrun in interval_out(). Although the datetime input functions were more careful about avoiding buffer overrun, the limit was short enough to cause them to reject some valid inputs, such as input containing a very long timezone name. The ecpg library contained these vulnerabilities along with some of its own. (CVE-2014-0063)

- Prevent buffer overrun due to integer overflow in size calculations (Noah Misch, Heikki Linnakangas)
  Several functions, mostly type input functions, calculated an allocation size without checking for overflow. If overflow did occur, a too-small buffer would be allocated and then written past. (CVE-2014-0064)

- Prevent overruns of fixed-size buffers (Peter Eisentraut, Jozef Mlich)
  Use strlcpy() and related functions to provide a clear guarantee that fixed-size buffers are not overrun. Unlike the preceding items, it is unclear whether these cases really represent live issues, since in most cases there appear to be previous constraints on the size of the input string. Nonetheless it seems prudent to silence all Coverity warnings of this type. (CVE-2014-0065)

- Avoid crashing if crypt() returns NULL (Honza Horak, Bruce Momjian)
  There are relatively few scenarios in which crypt() could return NULL, but contrib/chkpass would crash if it did. One practical case in which this could be an issue is if libc is configured to refuse to execute unapproved hashing algorithms (e.g., “FIPS mode”). (CVE-2014-0066)

- Document risks of make check in the regression testing instructions (Noah Misch, Tom Lane)
Appendix E. Release Notes

Since the temporary server started by `make check` uses “trust” authentication, another user on the same machine could connect to it as database superuser, and then potentially exploit the privileges of the operating-system user who started the tests. A future release will probably incorporate changes in the testing procedure to prevent this risk, but some public discussion is needed first. So for the moment, just warn people against using `make check` when there are untrusted users on the same machine. (CVE-2014-0067)

- Fix possible mis-replay of WAL records when some segments of a relation aren’t full size (Greg Stark, Tom Lane)

  The WAL update could be applied to the wrong page, potentially many pages past where it should have been. Aside from corrupting data, this error has been observed to result in significant “bloat” of standby servers compared to their masters, due to updates being applied far beyond where the end-of-file should have been. This failure mode does not appear to be a significant risk during crash recovery, only when initially synchronizing a standby created from a base backup taken from a quickly-changing master.

- Fix bug in determining when recovery has reached consistency (Tomonari Katsumata, Heikki Linnakangas)

  In some cases WAL replay would mistakenly conclude that the database was already consistent at the start of replay, thus possibly allowing hot-standby queries before the database was really consistent. Other symptoms such as “PANIC: WAL contains references to invalid pages” were also possible.

- Fix improper locking of btree index pages while replaying a `VACUUM` operation in hot-standby mode (Andres Freund, Heikki Linnakangas, Tom Lane)

  This error could result in “PANIC: WAL contains references to invalid pages” failures.

- Ensure that insertions into non-leaf GIN index pages write a full-page WAL record when appropriate (Heikki Linnakangas)

  The previous coding risked index corruption in the event of a partial-page write during a system crash.

- When `pause_at_recovery_target` and `recovery_target_inclusive` are both set, ensure the target record is applied before pausing, not after (Heikki Linnakangas)

- Fix race conditions during server process exit (Robert Haas)

  Ensure that signal handlers don’t attempt to use the process’s `MyProc` pointer after it’s no longer valid.

- Fix race conditions in walsender shutdown logic and walreceiver SIGHUP signal handler (Tom Lane)

- Fix unsafe references to `errno` within error reporting logic (Christian Kruse)

  This would typically lead to odd behaviors such as missing or inappropriate `HINT` fields.

- Fix possible crashes from using `ereport()` too early during server startup (Tom Lane)

  The principal case we’ve seen in the field is a crash if the server is started in a directory it doesn’t have permission to read.

- Clear retry flags properly in OpenSSL socket write function (Alexander Kukushkin)

  This omission could result in a server lockup after unexpected loss of an SSL-encrypted connection.

- Fix length checking for Unicode identifiers (Us "..." syntax) containing escapes (Tom Lane)

  A spurious truncation warning would be printed for such identifiers if the escaped form of the identifier was too long, but the identifier actually didn’t need truncation after de-escaping.

- Allow keywords that are type names to be used in lists of roles (Stephen Frost)
Appendix E. Release Notes

A previous patch allowed such keywords to be used without quoting in places such as role identifiers; but it missed cases where a list of role identifiers was permitted, such as `DROP ROLE`.

- Fix parser crash for `EXISTS(SELECT * FROM zero_column_table)` (Tom Lane)
- Fix possible crash due to invalid plan for nested sub-selects, such as `WHERE (... x IN (SELECT ...)) ...)` in `IN (SELECT ...)` (Tom Lane)
- Fix `UPDATE/DELETE` of an inherited target table that has `UNION ALL` subqueries (Tom Lane)

Without this fix, `UNION ALL` subqueries aren’t correctly inserted into the update plans for inheritance child tables after the first one, typically resulting in no update happening for those child table(s).

- Ensure that `ANALYZE` creates statistics for a table column even when all the values in it are “too wide” (Tom Lane)

`ANALYZE` intentionally omits very wide values from its histogram and most-common-values calculations, but it neglected to do something sane in the case that all the sampled entries are too wide.

- In `ALTER TABLE ... SET TABLESPACE`, allow the database’s default tablespace to be used without a permissions check (Stephen Frost)

`CREATE TABLE` has always allowed such usage, but `ALTER TABLE` didn’t get the memo.

- Fix “cannot accept a set” error when some arms of a `CASE` return a set and others don’t (Tom Lane)

- Properly distinguish numbers from non-numbers when generating JSON output (Andrew Dunstan)

- Fix checks for all-zero client addresses in `pgstat` functions (Kevin Grittner)

- Fix possible misclassification of multibyte characters by the text search parser (Tom Lane)

Non-ASCII characters could be misclassified when using C locale with a multibyte encoding. On Cygwin, non-C locales could fail as well.

- Fix possible misbehavior in `plainto_tsquery()` (Heikki Linnakangas)

Use `memmove()` not `memcpy()` for copying overlapping memory regions. There have been no field reports of this actually causing trouble, but it’s certainly risky.

- Fix placement of permissions checks in `pg_start_backup()` and `pg_stop_backup()` (Andres Freund, Magnus Hagander)

The previous coding might attempt to do catalog access when it shouldn’t.

- Accept `SHIFT_JIS` as an encoding name for locale checking purposes (Tatsuo Ishii)

- Fix `*`-qualification of named parameters in SQL-language functions (Tom Lane)

  Given a composite-type parameter named `foo`, `$1.*` worked fine, but `foo.*` not so much.

- Fix misbehavior of `PQhost()` on Windows (Fujii Masao)

  It should return `localhost` if no host has been specified.

- Improve error handling in `libpq` and `psql` for failures during `COPY TO STDOUT/FROM STDIN` (Tom Lane)

  In particular this fixes an infinite loop that could occur in 9.2 and up if the server connection was lost during `COPY FROM STDIN`. Variants of that scenario might be possible in older versions, or with other client applications.

- Fix incorrect translation handling in some `psql` `\d` commands (Peter Eisentraut, Tom Lane)
Appendix E. Release Notes

- Ensure pg_basebackup’s background process is killed when exiting its foreground process (Magnus Hagander)
- Fix possible incorrect printing of filenames in pg_basebackup’s verbose mode (Magnus Hagander)
- Avoid including tablespaces inside PGDATA twice in base backups (Dimitri Fontaine, Magnus Hagander)
- Fix misaligned descriptors in ecpg (MauMau)
- In ecpg, handle lack of a hostname in the connection parameters properly (Michael Meskes)
- Fix performance regression in contrib/dblink connection startup (Joe Conway)
  Avoid an unnecessary round trip when client and server encodings match.
- In contrib/ism, fix incorrect calculation of the check digit for ISMN values (Fabien Coelho)
- Fix contrib/pg_stat_statement’s handling of CURRENT_DATE and related constructs (Kyotaro Horiguchi)
- Ensure client-code-only installation procedure works as documented (Peter Eisentraut)
- In Mingw and Cygwin builds, install the libpq DLL in the bin directory (Andrew Dunstan)
  This duplicates what the MSVC build has long done. It should fix problems with programs like psql failing to start because they can’t find the DLL.
- Avoid using the deprecated dllwrap tool in Cygwin builds (Marco Atzeri)
- Don’t generate plain-text HISTORY and src/test/regress/README files anymore (Tom Lane)
  These text files duplicated the main HTML and PDF documentation formats. The trouble involved in maintaining them greatly outweighs the likely audience for plain-text format. Distribution tarballs will still contain files by these names, but they’ll just be stubs directing the reader to consult the main documentation. The plain-text INSTALL file will still be maintained, as there is arguably a use-case for that.
- Update time zone data files to tzdata release 2013i for DST law changes in Jordan and historical changes in Cuba.
  In addition, the zones Asia/Riyadh87, Asia/Riyadh88, and Asia/Riyadh89 have been removed, as they are no longer maintained by IANA, and never represented actual civil timekeeping practice.

E.66. Release 9.2.6

Release date: 2013-12-05

This release contains a variety of fixes from 9.2.5. For information about new features in the 9.2 major release, see Section E.72.

E.66.1. Migration to Version 9.2.6

A dump/restore is not required for those running 9.2.X.
However, this release corrects a number of potential data corruption issues. See the first two changelog entries below to find out whether your installation has been affected and what steps you can take if so. Also, if you are upgrading from a version earlier than 9.2.4, see Section E.68.

E.66.2. Changes

- **Fix VACUUM's tests to see whether it can update relfrozenxid** (Andres Freund)

  In some cases VACUUM (either manual or autovacuum) could incorrectly advance a table’s relfrozenxid value, allowing tuples to escape freezing, causing those rows to become invisible once $2^{31}$ transactions have elapsed. The probability of data loss is fairly low since multiple incorrect advancements would need to happen before actual loss occurs, but it’s not zero. In 9.2.0 and later, the probability of loss is higher, and it’s also possible to get “could not access status of transaction” errors as a consequence of this bug. Users upgrading from releases 9.0.4 or 8.4.8 or earlier are not affected, but all later versions contain the bug.

  The issue can be ameliorated by, after upgrading, vacuuming all tables in all databases while having vacuum_freeze_table_age set to zero. This will fix any latent corruption but will not be able to fix all pre-existing data errors. However, an installation can be presumed safe after performing this vacuuming if it has executed fewer than $2^{31}$ update transactions in its lifetime (check this with SELECT txid_current() < $2^{31}$).

- **Fix initialization of pg_clog and pg_subtrans during hot standby startup** (Andres Freund, Heikki Linnakangas)

  This bug can cause data loss on standby servers at the moment they start to accept hot-standby queries, by marking committed transactions as uncommitted. The likelihood of such corruption is small unless, at the time of standby startup, the primary server has executed many updating transactions since its last checkpoint. Symptoms include missing rows, rows that should have been deleted being still visible, and obsolete versions of updated rows being still visible alongside their newer versions.

  This bug was introduced in versions 9.3.0, 9.2.5, 9.1.10, and 9.0.14. Standby servers that have only been running earlier releases are not at risk. It’s recommended that standby servers that have ever run any of the buggy releases be re-cloned from the primary (e.g., with a new base backup) after upgrading.

- **Fix dangling-pointer problem in fast-path locking** (Tom Lane)

  This could lead to corruption of the lock data structures in shared memory, causing “lock already held” and other odd errors.

- **Truncate pg_multixact contents during WAL replay** (Andres Freund)

  This avoids ever-increasing disk space consumption in standby servers.

- **Ensure an anti-wraparound VACUUM counts a page as scanned when it’s only verified that no tuples need freezing** (Sergey Burladyan, Jeff Janes)

  This bug could result in failing to advance relfrozenxid, so that the table would still be thought to need another anti-wraparound vacuum. In the worst case the database might even shut down to prevent wraparound.

- **Fix race condition in GIN index posting tree page deletion** (Heikki Linnakangas)
This could lead to transient wrong answers or query failures.

- Fix “unexpected spgdoinst() failure” error during SP-GiST index creation (Teodor Sigaev)
- Avoid flattening a subquery whose `SELECT` list contains a volatile function wrapped inside a sub-
  `SELECT` (Tom Lane)

  This avoids unexpected results due to extra evaluations of the volatile function.

- Fix planner’s processing of non-simple-variable subquery outputs nested within outer joins (Tom Lane)

  This error could lead to incorrect plans for queries involving multiple levels of subqueries within `JOIN`
  syntax.

- Fix incorrect planning in cases where the same non-strict expression appears in multiple `WHERE` and
  outer `JOIN` equality clauses (Tom Lane)
- Fix planner crash with whole-row reference to a subquery (Tom Lane)
- Fix incorrect generation of optimized `MIN()`/`MAX()` plans for inheritance trees (Tom Lane)

  The planner could fail in cases where the `MIN()`/`MAX()` argument was an expression rather than a
  simple variable.

- Fix premature deletion of temporary files (Andres Freund)
- Prevent intra-transaction memory leak when printing range values (Tom Lane)

  This fix actually cures transient memory leaks in any datatype output function, but range types are the
  only ones known to have had a significant problem.

- Prevent incorrect display of dropped columns in NOT NULL and CHECK constraint violation messages
  (Michael Paquier and Tom Lane)

- Allow default arguments and named-argument notation for window functions (Tom Lane)

  Previously, these cases were likely to crash.

- Fix possible read past end of memory in rule printing (Peter Eisentraut)
- Fix array slicing of `int2vector` and `oidvector` values (Tom Lane)

  Expressions of this kind are now implicitly promoted to regular `int2` or `oid` arrays.

- Fix incorrect behaviors when using a SQL-standard, simple GMT offset timezone (Tom Lane)

  In some cases, the system would use the simple GMT offset value when it should have used the regular
  timezone setting that had prevailed before the simple offset was selected. This change also causes the
  `timeofday` function to honor the simple GMT offset zone.

- Prevent possible misbehavior when logging translations of Windows error codes (Tom Lane)
- Properly quote generated command lines in `pg_ctl` (Naoya Anzai and Tom Lane)

  This fix applies only to Windows.

- Fix `pg_dumpall` to work when a source database sets `default_transaction_read_only` via `ALTER`
  `DATABASE SET` (Kevin Grittner)

  Previously, the generated script would fail during restore.

- Make `ecpg` search for quoted cursor names case-sensitively (Zoltán Böszörményi)
- Fix `ecpg`’s processing of lists of variables declared `varchar` (Zoltán Böszörményi)
Appendix E. Release Notes

• Make contrib/lo defend against incorrect trigger definitions (Marc Cousin)

• Update time zone data files to tzdata release 2013h for DST law changes in Argentina, Brazil, Jordan, Libya, Liechtenstein, Morocco, and Palestine. Also, new timezone abbreviations WIB, WIT, WITA for Indonesia.

E.67. Release 9.2.5

Release date: 2013-10-10

This release contains a variety of fixes from 9.2.4. For information about new features in the 9.2 major release, see Section E.72.

E.67.1. Migration to Version 9.2.5

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.4, see Section E.68.

E.67.2. Changes

• Prevent corruption of multi-byte characters when attempting to case-fold identifiers (Andrew Dunstan)

  PostgreSQL case-folds non-ASCII characters only when using a single-byte server encoding.

• Fix memory leak when creating B-tree indexes on range columns (Heikki Linnakangas)

• Fix checkpoint memory leak in background writer when wal_level = hot_standby (Naoya Anzai)

• Fix memory leak caused by lo_open() failure (Heikki Linnakangas)

• Fix memory overcommit bug when work_mem is using more than 24GB of memory (Stephen Frost)

• Serializable snapshot fixes (Kevin Grittner, Heikki Linnakangas)

• Fix deadlock bug in libpq when using SSL (Stephen Frost)

• Fix possible SSL state corruption in threaded libpq applications (Nick Phillips, Stephen Frost)

• Improve estimate of planner cost when choosing between generic and custom plans (Tom Lane)

  This change will favor generic plans when planning cost is high.

• Properly compute row estimates for boolean columns containing many NULL values (Andrew Gierth)

  Previously tests like col IS NOT TRUE and col IS NOT FALSE did not properly factor in NULL values when estimating plan costs.

• Fix accounting for qualifier evaluation costs in UNION ALL and inheritance queries (Tom Lane)

  This fixes cases where suboptimal query plans could be chosen if some WHERE clauses are expensive to calculate.

• Prevent pushing down WHERE clauses into unsafe UNION/INTERSECT subqueries (Tom Lane)
Subqueries of a UNION or INTERSECT that contain set-returning functions or volatile functions in their SELECT lists could be improperly optimized, leading to run-time errors or incorrect query results.

- Fix rare case of "failed to locate grouping columns" planner failure (Tom Lane)
- Fix pg_dump of foreign tables with dropped columns (Andrew Dunstan)
  Previously such cases could cause a pg_upgrade error.
- Reorder pg_dump processing of extension-related rules and event triggers (Joe Conway)
- Force dumping of extension tables if specified by pg_dump -t or -n (Joe Conway)
- Improve view dumping code’s handling of dropped columns in referenced tables (Tom Lane)
- Fix pg_restore -l with the directory archive to display the correct format name (Fujii Masao)
- Properly record index comments created using UNIQUE and PRIMARY KEY syntax (Andres Freund)
  This fixes a parallel pg_restore failure.
- Cause pg_basebackup -x with an empty xlog directory to throw an error rather than crashing (Magnus Hagander, Haruka Takatsuka)
- Properly guarantee transmission of WAL files before clean switchover (Fujii Masao)
  Previously, the streaming replication connection might close before all WAL files had been replayed on the standby.
- Fix WAL segment timeline handling during recovery (Mitsumasa Kondo, Heikki Linnakangas)
  WAL file recycling during standby recovery could lead to premature recovery completion, resulting in data loss.
- Prevent errors in WAL replay due to references to uninitialized empty pages (Andres Freund)
- Fix REINDEX TABLE and REINDEX DATABASE to properly revalidate constraints and mark invalidated indexes as valid (Noah Misch)
  REINDEX INDEX has always worked properly.
- Avoid deadlocks during insertion into SP-GiST indexes (Teodor Sigaev)
- Fix possible deadlock during concurrent CREATE INDEX CONCURRENTLY operations (Tom Lane)
- Fix GiST index lookup crash (Tom Lane)
- Fix regexp_matches() handling of zero-length matches (Jeevan Chalke)
  Previously, zero-length matches like '^' could return too many matches.
- Fix crash for overly-complex regular expressions (Heikki Linnakangas)
- Fix regular expression match failures for back references combined with non-greedy quantifiers (Jeevan Chalke)
- Prevent CREATE FUNCTION from checking SET variables unless function body checking is enabled (Tom Lane)
- Allow ALTER DEFAULT PRIVILEGES to operate on schemas without requiring CREATE permission (Tom Lane)
- Loosen restriction on keywords used in queries (Tom Lane)
Specifically, lessen keyword restrictions for role names, language names, EXPLAIN and COPY options, and SET values. This allows COPY ... (FORMAT BINARY) to work as expected; previously BINARY needed to be quoted.

- Print proper line number during COPY failure (Heikki Linnakangas)
- Fix pgp_pub_decrypt() so it works for secret keys with passwords (Marko Kreen)
- Make pg_upgrade use pg_dump --quote-all-identifiers to avoid problems with keyword changes between releases (Tom Lane)
- Remove rare inaccurate warning during vacuum of index-less tables (Heikki Linnakangas)
- Ensure that VACUUM ANALYZE still runs the ANALYZE phase if its attempt to truncate the file is cancelled due to lock conflicts (Kevin Grittner)
- Avoid possible failure when performing transaction control commands (e.g ROLLBACK) in prepared queries (Tom Lane)
- Ensure that floating-point data input accepts standard spellings of “infinity” on all platforms (Tom Lane)
  The C99 standard says that allowable spellings are inf, +inf, -inf, infinity, +infinity, and -infinity. Make sure we recognize these even if the platform’s strtod function doesn’t.
- Avoid unnecessary reporting when track_activities is off (Tom Lane)
- Expand ability to compare rows to records and arrays (Rafal Rzepecki, Tom Lane)
- Prevent crash when psql’s PSQLRC variable contains a tilde (Bruce Momjian)
- Add spinlock support for ARM64 (Mark Salter)
- Update time zone data files to tzdata release 2013d for DST law changes in Israel, Morocco, Palestine, and Paraguay. Also, historical zone data corrections for Macquarie Island.

E.68. Release 9.2.4

Release date: 2013-04-04

This release contains a variety of fixes from 9.2.3. For information about new features in the 9.2 major release, see Section E.72.

E.68.1. Migration to Version 9.2.4

A dump/restore is not required for those running 9.2.X.

However, this release corrects several errors in management of GiST indexes. After installing this update, it is advisable to REINDEX any GiST indexes that meet one or more of the conditions described below.

Also, if you are upgrading from a version earlier than 9.2.2, see Section E.70.
E.68.2. Changes

- Fix insecure parsing of server command-line switches (Mitsumasa Kondo, Kyotaro Horiguchi)
  A connection request containing a database name that begins with "-" could be crafted to damage or destroy files within the server’s data directory, even if the request is eventually rejected. (CVE-2013-1899)

- Reset OpenSSL randomness state in each postmaster child process (Marko Kreen)
  This avoids a scenario wherein random numbers generated by contrib/pgcrypto functions might be relatively easy for another database user to guess. The risk is only significant when the postmaster is configured with ssl = on but most connections don’t use SSL encryption. (CVE-2013-1900)

- Make REPLICATION privilege checks test current user not authenticated user (Noah Misch)
  An unprivileged database user could exploit this mistake to call pg_start_backup() or pg_stop_backup(), thus possibly interfering with creation of routine backups. (CVE-2013-1901)

- Fix GiST indexes to not use “fuzzy” geometric comparisons when it’s not appropriate to do so (Alexander Korotkov)
  The core geometric types perform comparisons using “fuzzy” equality, but gist_box_same must do exact comparisons, else GiST indexes using it might become inconsistent. After installing this update, users should REINDEX any GiST indexes on box, polygon, circle, or point columns, since all of these use gist_box_same.

- Fix erroneous range-union and penalty logic in GiST indexes that use contrib/btree_gist for variable-width data types, that is text, bytea, bit, and numeric columns (Tom Lane)
  These errors could result in inconsistent indexes in which some keys that are present would not be found by searches, and also in useless index bloat. Users are advised to REINDEX such indexes after installing this update.

- Fix bugs in GiST page splitting code for multi-column indexes (Tom Lane)
  These errors could result in inconsistent indexes in which some keys that are present would not be found by searches, and also in indexes that are unnecessarily inefficient to search. Users are advised to REINDEX multi-column GiST indexes after installing this update.

- Fix gist_point_consistent to handle fuzziness consistently (Alexander Korotkov)
  Index scans on GiST indexes on point columns would sometimes yield results different from a sequential scan, because gist_point_consistent disagreed with the underlying operator code about whether to do comparisons exactly or fuzzily.

- Fix buffer leak in WAL replay (Heikki Linnakangas)
  This bug could result in “incorrect local pin count” errors during replay, making recovery impossible.

- Ensure we do crash recovery before entering archive recovery, if the database was not stopped cleanly and a recovery.conf file is present (Heikki Linnakangas, Kyotaro Horiguchi, Mitsumasa Kondo)
  This is needed to ensure that the database is consistent in certain scenarios, such as initializing a standby server with a filesystem snapshot from a running server.

- Avoid deleting not-yet-archived WAL files during crash recovery (Heikki Linnakangas, Fujii Masao)

- Fix race condition in DELETE RETURNING (Tom Lane)
Under the right circumstances, `DELETE RETURNING` could attempt to fetch data from a shared buffer that the current process no longer has any pin on. If some other process changed the buffer meanwhile, this would lead to garbage `RETURNING` output, or even a crash.

- Fix infinite-loop risk in regular expression compilation (Tom Lane, Don Porter)
- Fix potential null-pointer dereference in regular expression compilation (Tom Lane)
- Fix `to_char()` to use ASCII-only case-folding rules where appropriate (Tom Lane)
  This fixes misbehavior of some template patterns that should be locale-independent, but mishandled “ı” and “ş” in Turkish locales.
- Fix unwanted rejection of timestamp `1999-12-31 24:00:00` (Tom Lane)
- Fix SQL-language functions to be safely usable as support functions for range types (Tom Lane)
- Fix logic error when a single transaction does `UNLISTEN` then `LISTEN` (Tom Lane)
  The session wound up not listening for notify events at all, though it surely should listen in this case.
- Fix possible planner crash after columns have been added to a view that’s depended on by another view (Tom Lane)
- Fix performance issue in `EXPLAIN` (ANALYZE, TIMING OFF) (Pavel Stehule)
- Remove useless “picksplit doesn’t support secondary split” log messages (Josh Hansen, Tom Lane)
  This message seems to have been added in expectation of code that was never written, and probably never will be, since GiST’s default handling of secondary splits is actually pretty good. So stop nagging end users about it.
- Remove vestigial secondary-split support in `gist_box_picksplit()` (Tom Lane)
  Not only was this implementation of secondary-split not better than the default implementation, it’s actually worse. So remove it and let the default code path handle the case.
- Fix possible failure to send a session’s last few transaction commit/abort counts to the statistics collector (Tom Lane)
- Eliminate memory leaks in PL/Perl’s `spi_prepare()` function (Alex Hunsaker, Tom Lane)
- Fix `pg_dumpall` to handle database names containing “=” correctly (Heikki Linnakangas)
- Avoid crash in `pg_dump` when an incorrect connection string is given (Heikki Linnakangas)
- Ignore invalid indexes in `pg_dump` and `pg_upgrade` (Michael Paquier, Bruce Momjijn)
  Dumping invalid indexes can cause problems at restore time, for example if the reason the index creation failed was because it tried to enforce a uniqueness condition not satisfied by the table’s data. Also, if the index creation is in fact still in progress, it seems reasonable to consider it to be an uncommitted DDL change, which `pg_dump` wouldn’t be expected to dump anyway. `pg_upgrade` now also skips invalid indexes rather than failing.
- In `pg_basebackup`, include only the current server version’s subdirectory when backing up a tablespace (Heikki Linnakangas)
- Add a server version check in `pg_basebackup` and `pg_receivexlog`, so they fail cleanly with version combinations that won’t work (Heikki Linnakangas)
- Fix `contrib/dblink` to handle inconsistent settings of `DateStyle` or `IntervalStyle` safely (Daniel Farina, Tom Lane)

2418
Previously, if the remote server had different settings of these parameters, ambiguous dates might be read incorrectly. This fix ensures that datetime and interval columns fetched by a `dblink` query will be interpreted correctly. Note however that inconsistent settings are still risky, since literal values appearing in SQL commands sent to the remote server might be interpreted differently than they would be locally.

- Fix `contrib/pg_trgm`'s `similarity()` function to return zero for trigram-less strings (Tom Lane)
  Previously it returned `NaN` due to internal division by zero.

- Enable building PostgreSQL with Microsoft Visual Studio 2012 (Brar Piening, Noah Misch)

- Update time zone data files to tzdata release 2013b for DST law changes in Chile, Haiti, Morocco, Paraguay, and some Russian areas. Also, historical zone data corrections for numerous places.
  Also, update the time zone abbreviation files for recent changes in Russia and elsewhere: CHOT, GET, IRKT, KGT, KRAT, MAGT, MAWT, MSK, NOVT, TKT, VLAT, WST, YAKT, YEKT now follow their current meanings, and VOLT (Europe/Volgograd) and MIST (Antarctica/Macquarie) are added to the default abbreviations list.

### E.69. Release 9.2.3

**Release date:** 2013-02-07

This release contains a variety of fixes from 9.2.2. For information about new features in the 9.2 major release, see Section E.72.

### E.69.1. Migration to Version 9.2.3

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.2, see Section E.70.

### E.69.2. Changes

- Prevent execution of `enum_recv` from SQL (Tom Lane)
  The function was misdeclared, allowing a simple SQL command to crash the server. In principle an attacker might be able to use it to examine the contents of server memory. Our thanks to Sumit Soni (via Secunia SVCRP) for reporting this issue. (CVE-2013-0255)

- Fix multiple problems in detection of when a consistent database state has been reached during WAL replay (Fujii Masao, Heikki Linnakangas, Simon Riggs, Andres Freund)

- Fix detection of end-of-backup point when no actual redo work is required (Heikki Linnakangas)
  This mistake could result in incorrect “WAL ends before end of online backup” errors.

- Update minimum recovery point when truncating a relation file (Heikki Linnakangas)
  Once data has been discarded, it’s no longer safe to stop recovery at an earlier point in the timeline.
• Fix recycling of WAL segments after changing recovery target timeline (Heikki Linnakangas)
• Properly restore timeline history files from archive on cascading standby servers (Heikki Linnakangas)
• Fix lock conflict detection on hot-standby servers (Andres Freund, Robert Haas)
• Fix missing cancellations in hot standby mode (Noah Misch, Simon Riggs)
  The need to cancel conflicting hot-standby queries would sometimes be missed, allowing those
  queries to see inconsistent data.
• Prevent recovery pause feature from pausing before users can connect (Tom Lane)
• Fix SQL grammar to allow subscripting or field selection from a sub-SELECT result (Tom Lane)
• Fix performance problems with autovacuum truncation in busy workloads (Jan Wieck)
  Truncation of empty pages at the end of a table requires exclusive lock, but autovacuum was coded to
  fail (and release the table lock) when there are conflicting lock requests. Under load, it is easily possi-
  ble that truncation would never occur, resulting in table bloat. Fix by performing a partial truncation,
  releasing the lock, then attempting to re-acquire the lock and continue. This fix also greatly reduces the
  average time before autovacuum releases the lock after a conflicting request arrives.
• Improve performance of SPI_execute and related functions, thereby improving PL/pgSQL’s
  EXECUTE (Heikki Linnakangas, Tom Lane)
  Remove some data-copying overhead that was added in 9.2 as a consequence of revisions in the plan
  caching mechanism. This eliminates a performance regression compared to 9.1, and also saves memory,
  especially when the query string to be executed contains many SQL statements.
  A side benefit is that multi-statement query strings are now processed fully serially, that is we complete
  execution of earlier statements before running parse analysis and planning on the following ones. This
  eliminates a long-standing issue, in that DDL that should affect the behavior of a later statement will
  now behave as expected.
• Restore pre-9.2 cost estimates for index usage (Tom Lane)
  An ill-considered change of a fudge factor led to undesirably high cost estimates for use of very large
  indexes.
• Fix intermittent crash in DROP INDEX CONCURRENTLY (Tom Lane)
• Fix potential corruption of shared-memory lock table during CREATE/DROP INDEX CONCURRENTLY
  (Tom Lane)
• Fix COPY’s multiple-tuple-insertion code for the case of a tuple larger than page size minus fillfactor
  (Heikki Linnakangas)
  The previous coding could get into an infinite loop.
• Protect against race conditions when scanning pg_tablespace (Stephen Frost, Tom Lane)
  CREATE DATABASE and DROP DATABASE could misbehave if there were concurrent updates of
  pg_tablespace entries.
• Prevent DROP OWNED from trying to drop whole databases or tablespaces (Álvaro Herrera)
  For safety, ownership of these objects must be reassigned, not dropped.
• Fix error in vacuum_freeze_table_age implementation (Andres Freund)
In installations that have existed for more than `vacuum_freeze_min_age` transactions, this mistake prevented autovacuum from using partial-table scans, so that a full-table scan would always happen instead.

- Prevent misbehavior when a RowExpr or XmlExpr is parse-analyzed twice (Andres Freund, Tom Lane)
  This mistake could be user-visible in contexts such as `CREATE TABLE LIKE INCLUDING INDEXES`.
- Improve defenses against integer overflow in hashtable sizing calculations (Jeff Davis)
- Fix some bugs associated with privileges on datatypes (Tom Lane)
  There were some issues with default privileges for types, and pg_dump failed to dump such privileges at all.
- Fix failure to ignore leftover temporary tables after a server crash (Tom Lane)
- Fix failure to rotate postmaster log files for size reasons on Windows (Jeff Janes, Heikki Linnakangas)
- Reject out-of-range dates in `to_date()` (Hitoshi Harada)
- Fix `pq_extension_config_dump()` to handle extension-update cases properly (Tom Lane)
  This function will now replace any existing entry for the target table, making it usable in extension update scripts.
- Fix PL/pgSQL’s reporting of plan-time errors in possibly-simple expressions (Tom Lane)
  The previous coding resulted in sometimes omitting the first line in the `CONTEXT` traceback for the error.
- Fix PL/Python’s handling of functions used as triggers on multiple tables (Andres Freund)
- Ensure that non-ASCII prompt strings are translated to the correct code page on Windows (Alexander Law, Noah Misch)
  This bug affected psql and some other client programs.
- Fix possible crash in psql’s `\?` command when not connected to a database (Meng Qingzhong)
- Fix possible error if a relation file is removed while `pg_basebackup` is running (Heikki Linnakangas)
- Tolerate timeline switches while `pg_basebackup -X fetch` is backing up a standby server (Heikki Linnakangas)
- Make `pg_dump` exclude data of unlogged tables when running on a hot-standby server (Magnus Hagander)
  This would fail anyway because the data is not available on the standby server, so it seems most convenient to assume `--no-unlogged-table-data` automatically.
- Fix `pg_upgrade` to deal with invalid indexes safely (Bruce Momjian)
- Fix `pg_upgrade`’s `-O/-o` options (Marti Raudsepp)
- Fix one-byte buffer overrun in libpq’s `PQprintTuples` (Xi Wang)
  This ancient function is not used anywhere by PostgreSQL itself, but it might still be used by some client code.
- Make ecpglib use translated messages properly (Chen Huajun)
- Properly install ecpg_compat and pgtypes libraries on MSVC (Jiang Guiqing)
Appendix E. Release Notes

- Include our version of isinf() in libecpg if it’s not provided by the system (Jiang Guiqing)
- Rearrange configure’s tests for supplied functions so it is not fooled by bogus exports from libedit/libreadline (Christoph Berg)
- Ensure Windows build number increases over time (Magnus Hagander)
- Make pgxs build executables with the right .exe suffix when cross-compiling for Windows (Zoltan Boszormenyi)
- Add new timezone abbreviation FET (Tom Lane)
  This is now used in some eastern-European time zones.

E.70. Release 9.2.2

Release date: 2012-12-06

This release contains a variety of fixes from 9.2.1. For information about new features in the 9.2 major release, see Section E.72.

E.70.1. Migration to Version 9.2.2

A dump/restore is not required for those running 9.2.X.

However, you may need to perform REINDEX operations to correct problems in concurrently-built indexes, as described in the first changelog item below.

Also, if you are upgrading from version 9.2.0, see Section E.71.

E.70.2. Changes

- Fix multiple bugs associated with CREATE/DROP INDEX CONCURRENTLY (Andres Freund, Tom Lane, Simon Riggs, Pavan Deolasee)

  An error introduced while adding DROP INDEX CONCURRENTLY allowed incorrect indexing decisions to be made during the initial phase of CREATE INDEX CONCURRENTLY; so that indexes built by that command could be corrupt. It is recommended that indexes built in 9.2.X with CREATE INDEX CONCURRENTLY be rebuilt after applying this update.

  In addition, fix CREATE/DROP INDEX CONCURRENTLY to use in-place updates when changing the state of an index’s pg_index row. This prevents race conditions that could cause concurrent sessions to miss updating the target index, thus again resulting in corrupt concurrently-created indexes.

  Also, fix various other operations to ensure that they ignore invalid indexes resulting from a failed CREATE INDEX CONCURRENTLY command. The most important of these is VACUUM, because an auto-vacuum could easily be launched on the table before corrective action can be taken to fix or remove the invalid index.
Also fix \texttt{DROP INDEX CONCURRENTLY} to not disable insertions into the target index until all queries using it are done.

Also fix misbehavior if \texttt{DROP INDEX CONCURRENTLY} is canceled: the previous coding could leave an un-droppable index behind.

- Correct predicate locking for \texttt{DROP INDEX CONCURRENTLY} (Kevin Grittner)
  
  Previously, SSI predicate locks were processed at the wrong time, possibly leading to incorrect behavior of serializable transactions executing in parallel with the \texttt{DROP}.

- Fix buffer locking during WAL replay (Tom Lane)
  
  The WAL replay code was insufficiently careful about locking buffers when replaying WAL records that affect more than one page. This could result in hot standby queries transiently seeing inconsistent states, resulting in wrong answers or unexpected failures.

- Fix an error in WAL generation logic for GIN indexes (Tom Lane)
  
  This could result in index corruption, if a torn-page failure occurred.

- Fix an error in WAL replay logic for SP-GiST indexes (Tom Lane)
  
  This could result in index corruption after a crash, or on a standby server.

- Fix incorrect detection of end-of-base-backup location during WAL recovery (Heikki Linnakangas)
  
  This mistake allowed hot standby mode to start up before the database reaches a consistent state.

- Properly remove startup process’s virtual XID lock when promoting a hot standby server to normal running (Simon Riggs)
  
  This oversight could prevent subsequent execution of certain operations such as \texttt{CREATE INDEX CONCURRENTLY}.

- Avoid bogus “out-of-sequence timeline ID” errors in standby mode (Heikki Linnakangas)

- Prevent the postmaster from launching new child processes after it’s received a shutdown signal (Tom Lane)
  
  This mistake could result in shutdown taking longer than it should, or even never completing at all without additional user action.

- Fix the syslogger process to not fail when \texttt{log\_rotation\_age} exceeds $2^{31}$ milliseconds (about 25 days) (Tom Lane)

- Fix \texttt{WaitLatch()} to return promptly when the requested timeout expires (Jeff Janes, Tom Lane)
  
  With the previous coding, a steady stream of non-wait-terminating interrupts could delay return from \texttt{WaitLatch()} indefinitely. This has been shown to be a problem for the autovacuum launcher process, and might cause trouble elsewhere as well.

- Avoid corruption of internal hash tables when out of memory (Hitoshi Harada)

- Prevent file descriptors for dropped tables from being held open past transaction end (Tom Lane)
  
  This should reduce problems with long-since-dropped tables continuing to occupy disk space.

- Prevent database-wide crash and restart when a new child process is unable to create a pipe for its latch (Tom Lane)
  
  Although the new process must fail, there is no good reason to force a database-wide restart, so avoid that. This improves robustness when the kernel is nearly out of file descriptors.
• Avoid planner crash with joins to unflattened subqueries (Tom Lane)
• Fix planning of non-strict equivalence clauses above outer joins (Tom Lane)
   The planner could derive incorrect constraints from a clause equating a non-strict construct to something else, for example WHERE COALESCE(foo, 0) = 0 when foo is coming from the nullable side of an outer join. 9.2 showed this type of error in more cases than previous releases, but the basic bug has been there for a long time.
• Fix SELECT DISTINCT with index-optimized MIN/MAX on an inheritance tree (Tom Lane)
   The planner would fail with “failed to re-find MinMaxAggInfo record” given this combination of factors.
• Make sure the planner sees implicit and explicit casts as equivalent for all purposes, except in the minority of cases where there’s actually a semantic difference (Tom Lane)
• Include join clauses when considering whether partial indexes can be used for a query (Tom Lane)
   A strict join clause can be sufficient to establish an x IS NOT NULL predicate, for example. This fixes a planner regression in 9.2, since previous versions could make comparable deductions.
• Limit growth of planning time when there are many indexable join clauses for the same index (Tom Lane)
• Improve planner’s ability to prove exclusion constraints from equivalence classes (Tom Lane)
• Fix partial-row matching in hashed subplans to handle cross-type cases correctly (Tom Lane)
   This affects multicolumn NOT IN subplans, such as WHERE (a, b) NOT IN (SELECT x, y FROM ... ) when for instance b and y are int4 and int8 respectively. This mistake led to wrong answers or crashes depending on the specific datatypes involved.
• Fix btree mark/restore functions to handle array keys (Tom Lane)
   This oversight could result in wrong answers from merge joins whose inner side is an index scan using an indexed_column = ANY(array) condition.
• Revert patch for taking fewer snapshots (Tom Lane)
   The 9.2 change to reduce the number of snapshots taken during query execution led to some anomalous behaviors not seen in previous releases, because execution would proceed with a snapshot acquired before locking the tables used by the query. Thus, for example, a query would not be guaranteed to see updates committed by a preceding transaction even if that transaction had exclusive lock. We’ll probably revisit this in future releases, but meanwhile put it back the way it was before 9.2.
• Acquire buffer lock when re-fetching the old tuple for an AFTER ROW UPDATE/DELETE trigger (Andres Freund)
   In very unusual circumstances, this oversight could result in passing incorrect data to a trigger WHEN condition, or to the precheck logic for a foreign-key enforcement trigger. That could result in a crash, or in an incorrect decision about whether to fire the trigger.
• Fix ALTER COLUMN TYPE to handle inherited check constraints properly (Pavan Deolasee)
   This worked correctly in pre-8.4 releases, and now works correctly in 8.4 and later.
• Fix ALTER EXTENSION SET SCHEMA’s failure to move some subsidiary objects into the new schema (Álvaro Herrera, Dimitri Fontaine)
• Handle CREATE TABLE AS EXECUTE correctly in extended query protocol (Tom Lane)
Appendix E. Release Notes

- Don’t modify the input parse tree in `DROP RULE IF NOT EXISTS` and `DROP TRIGGER IF NOT EXISTS` (Tom Lane)
  
  This mistake would cause errors if a cached statement of one of these types was re-executed.

- Fix `REASSIGN OWNED` to handle grants on tablespaces (Álvaro Herrera)

- Ignore incorrect `pg_attribute` entries for system columns for views (Tom Lane)
  
  Views do not have any system columns. However, we forgot to remove such entries when converting a table to a view. That’s fixed properly for 9.3 and later, but in previous branches we need to defend against existing mis-converted views.

- Fix rule printing to dump `INSERT INTO table DEFAULT VALUES` correctly (Tom Lane)

- Guard against stack overflow when there are too many `UNION/INTERSECT/EXCEPT` clauses in a query (Tom Lane)

- Prevent platform-dependent failures when dividing the minimum possible integer value by -1 (Xi Wang, Tom Lane)

- Fix possible access past end of string in date parsing (Hitoshi Harada)

- Fix possible crash in `pg_terminate_backend()` and `pg_cancel_backend()` to not throw error for a non-existent target process (Josh Kupershmidt)
  
  This case already worked as intended when called by a superuser, but not so much when called by ordinary users.

- Fix display of `pg_stat_replication.sync_state` at a page boundary (Kyotaro Horiguchi)

- Produce an understandable error message if the length of the path name for a Unix-domain socket exceeds the platform-specific limit (Tom Lane, Andrew Dunstan)
  
  Formerly, this would result in something quite unhelpful, such as “Non-recoverable failure in name resolution”.

- Fix memory leaks when sending composite column values to the client (Tom Lane)

- Save some cycles by not searching for subtransaction locks at commit (Simon Riggs)
  
  In a transaction holding many exclusive locks, this useless activity could be quite costly.

- Make `pg_ctl` more robust about reading the `postmaster.pid` file (Heikki Linnakangas)
  
  This fixes race conditions and possible file descriptor leakage.

- Fix possible crash in `psql` if incorrectly-encoded data is presented and the `client_encoding` setting is a client-only encoding, such as SJIS (Jiang Guiqing)

- Make `pg_dump` dump `SEQUENCE SET` items in the data not pre-data section of the archive (Tom Lane)
  
  This fixes an undesirable inconsistency between the meanings of `--data-only` and `--section=data`, and also fixes dumping of sequences that are marked as extension configuration tables.

- Fix `pg_dump`’s handling of `DROP DATABASE` commands in `--clean` mode (Guillaume Lelarge)
### Appendix E. Release Notes

Beginning in 9.2.0, `pg_dump --clean` would issue a `DROP DATABASE` command, which was either useless or dangerous depending on the usage scenario. It no longer does that. This change also fixes the combination of `--clean` and `--create` to work sensibly, i.e., emit `DROP DATABASE` then `CREATE DATABASE` before reconnecting to the target database.

- Fix `pg_dump` for views with circular dependencies and no relation options (Tom Lane)

  The previous fix to dump relation options when a view is involved in a circular dependency didn’t work right for the case that the view has no options; it emitted `ALTER VIEW foo SET ()` which is invalid syntax.

- Fix bugs in the `restore.sql` script emitted by `pg_dump` in `tar` output format (Tom Lane)

  The script would fail outright on tables whose names include upper-case characters. Also, make the script capable of restoring data in `--inserts` mode as well as the regular `COPY` mode.

- Fix `pg_restore` to accept POSIX-conformant `tar` files (Brian Weaver, Tom Lane)

  The original coding of `pg_dump`'s `tar` output mode produced files that are not fully conformant with the POSIX standard. This has been corrected for version 9.3. This patch updates previous branches so that they will accept both the incorrect and the corrected formats, in hopes of avoiding compatibility problems when 9.3 comes out.

- Fix `tar` files emitted by `pg_basebackup` to be POSIX conformant (Brian Weaver, Tom Lane)

- Fix `pg_resetxlog` to locate `postmaster.pid` correctly when given a relative path to the data directory (Tom Lane)

  This mistake could lead to `pg_resetxlog` not noticing that there is an active postmaster using the data directory.

- Fix `libpq`'s `lo_import()` and `lo_export()` functions to report file I/O errors properly (Tom Lane)

- Fix `ecpg`'s processing of nested structure pointer variables (Muhammad Usama)

- Fix `ecpg`'s `ecpg_get_data` function to handle arrays properly (Michael Meskes)

- Prevent `pg_upgrade` from trying to process TOAST tables for system catalogs (Bruce Momjian)

  This fixes an error seen when the `information_schema` has been dropped and recreated. Other failures were also possible.

- Improve `pg_upgrade` performance by setting `synchronous_commit` to `off` in the new cluster (Bruce Momjian)

- Make `contrib/pageinspect`'s btree page inspection functions take buffer locks while examining pages (Tom Lane)

- Work around unportable behavior of `malloc(0)` and `realloc(NULL, 0)` (Tom Lane)

  On platforms where these calls return `NULL`, some code mistakenly thought that meant out-of-memory. This is known to have broken `pg_dump` for databases containing no user-defined aggregates. There might be other cases as well.

- Ensure that `make install` for an extension creates the extension installation directory (Cédric Villemain)

  Previously, this step was missed if `MODULEDIR` was set in the extension’s Makefile.

- Fix `pgxs` support for building loadable modules on AIX (Tom Lane)
Building modules outside the original source tree didn’t work on AIX.

- Update time zone data files to tzdata release 2012j for DST law changes in Cuba, Israel, Jordan, Libya, Palestine, Western Samoa, and portions of Brazil.

## E.71. Release 9.2.1

**Release date:** 2012-09-24

This release contains a variety of fixes from 9.2.0. For information about new features in the 9.2 major release, see Section E.72.

### E.71.1. Migration to Version 9.2.1

A dump/restore is not required for those running 9.2.X. However, you may need to perform `REINDEX` and/or `VACUUM` operations to recover from the effects of the data corruption bug described in the first changelog item below.

### E.71.2. Changes

- Fix persistence marking of shared buffers during WAL replay (Jeff Davis)
  
  This mistake can result in buffers not being written out during checkpoints, resulting in data corruption if the server later crashes without ever having written those buffers. Corruption can occur on any server following crash recovery, but it is significantly more likely to occur on standby slave servers since those perform much more WAL replay. There is a low probability of corruption of btree and GIN indexes. There is a much higher probability of corruption of table "visibility maps", which might lead to wrong answers from index-only scans. Table data proper cannot be corrupted by this bug.
  
  While no index corruption due to this bug is known to have occurred in the field, as a precautionary measure it is recommended that production installations `REINDEX` all btree and GIN indexes at a convenient time after upgrading to 9.2.1.
  
  Also, it is recommended to perform a `VACUUM` of all tables while having `vacuum_freeze_table_age` set to zero. This will fix any incorrect visibility map data. `vacuum_cost_delay` can be adjusted to reduce the performance impact of vacuuming, while causing it to take longer to finish.

- Fix possible incorrect sorting of output from queries involving `WHERE indexed_column IN (list_of_values)` (Tom Lane)

- Fix planner failure for queries involving `GROUP BY` expressions along with window functions and aggregates (Tom Lane)

- Fix planner’s assignment of executor parameters (Tom Lane)
  
  This error could result in wrong answers from queries that scan the same `WITH` subquery multiple times.

- Improve planner’s handling of join conditions in index scans (Tom Lane)
Appendix E. Release Notes

- Improve selectivity estimation for text search queries involving prefixes, i.e. \texttt{word:*} patterns (Tom Lane)
- Fix delayed recognition of permissions changes (Tom Lane)
  
  A command that needed no locks other than ones its transaction already had might fail to notice a concurrent \texttt{GRANT} or \texttt{REVOKE} that committed since the start of its transaction.
- Fix \texttt{ANALYZE} to not fail when a column is a domain over an array type (Tom Lane)
- Prevent \texttt{PL/Perl} from crashing if a recursive \texttt{PL/Perl} function is redefined while being executed (Tom Lane)
- Work around possible misoptimization in \texttt{PL/Perl} (Tom Lane)
  
  Some Linux distributions contain an incorrect version of \texttt{pthread.h} that results in incorrect compiled code in \texttt{PL/Perl}, leading to crashes if a \texttt{PL/Perl} function calls another one that throws an error.
- Remove unnecessary dependency on \texttt{pg_config} from \texttt{pg_upgrade} (Peter Eisentraut)
- Update time zone data files to \texttt{tzdata} release 2012f for DST law changes in Fiji

E.72. Release 9.2

Release date: 2012-09-10

E.72.1. Overview

This release has been largely focused on performance improvements, though new SQL features are not lacking. Work also continues in the area of replication support. Major enhancements include:

- Allow queries to retrieve data only from indexes, avoiding heap access (\textit{index-only scans})
- Allow the planner to generate custom plans for specific parameter values even when using prepared statements
- Improve the planner’s ability to use nested loops with inner index scans
- Allow streaming replication slaves to forward data to other slaves (\textit{cascading replication})
- Allow \texttt{pg_basebackup} to make base backups from standby servers
- Add a \texttt{pg_receivexlog} tool to archive WAL file changes as they are written
- Add the SP-GiST (Space-Partitioned GiST) index access method
- Add support for range data types
- Add a \texttt{JSON} data type
- Add a \texttt{security_barrier} option for views
- Allow \texttt{libpq} connection strings to have the format of a URI
- Add a single-row processing mode to \texttt{libpq} for better handling of large result sets

The above items are explained in more detail in the sections below.
E.72.2. Migration to Version 9.2

A dump/restore using pg_dump, or use of pg_upgrade, is required for those wishing to migrate data from any previous release.

Version 9.2 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

E.72.2.1. System Catalogs

- Remove the `spclocation` field from `pg_tablespace` (Magnus Hagander)
  
  This field was duplicative of the symbolic links that actually define tablespace locations, and thus risked errors of omission when moving a tablespace. This change allows tablespace directories to be moved while the server is down, by manually adjusting the symbolic links. To replace this field, we have added `pg_tablespace_location()` to allow querying of the symbolic links.

- Move `tsvector` most-common-element statistics to new `pg_stats` columns (Alexander Korotkov)
  
  Consult `most_common_elems` and `most_common_elem_freqs` for the data formerly available in `most_common_vals` and `most_common_freqs` for a `tsvector` column.

E.72.2.2. Functions

- Remove `hstore`’s `=>` operator (Robert Haas)
  
  Users should now use `hstore(text, text)`. Since PostgreSQL 9.0, a warning message has been emitted when an operator named `=>` is created because the SQL standard reserves that token for another use.

- Ensure that `xpath()` escapes special characters in string values (Florian Pflug)
  
  Without this it is possible for the result not to be valid XML.

- Make `pg_relation_size()` and friends return NULL if the object does not exist (Phil Sorber)
  
  This prevents queries that call these functions from returning errors immediately after a concurrent `DROP`.

- Make `EXTRACT(EPOCH FROM timestamp without time zone)` measure the epoch from local midnight, not UTC midnight (Tom Lane)
  
  This change reverts an ill-considered change made in release 7.3. Measuring from UTC midnight was inconsistent because it made the result dependent on the `timezone` setting, which computations for `timestamp without time zone` should not be. The previous behavior remains available by casting the input value to `timestamp with time zone`.

- Properly parse time strings with trailing `yesterday`, `today`, and `tomorrow` (Dean Rasheed)
  
  Previously, `SELECT '04:00:00 yesterday'::timestamp` returned yesterday’s date at midnight.

- Fix `to_date()` and `to_timestamp()` to wrap incomplete dates toward 2020 (Bruce Momjian)
  
  Previously, supplied years and year masks of less than four digits wrapped inconsistently.
E.72.2.3. Object Modification

- Prevent ALTER DOMAIN from working on non-domain types (Peter Eisentraut)
  Owner and schema changes were previously possible on non-domain types.
- No longer forcibly lowercase procedural language names in CREATE FUNCTION (Robert Haas)
  While unquoted language identifiers are still lowercased, strings and quoted identifiers are no longer forcibly down-cased. Thus for example CREATE FUNCTION ... LANGUAGE 'C' will no longer work; it must be spelled 'c', or better omit the quotes.
- Change system-generated names of foreign key enforcement triggers (Tom Lane)
  This change ensures that the triggers fire in the correct order in some corner cases involving self-referential foreign key constraints.

E.72.2.4. Command-Line Tools

- Provide consistent backquote, variable expansion, and quoted substring behavior in psql meta-command arguments (Tom Lane)
  Previously, such references were treated oddly when not separated by whitespace from adjacent text. For example 'FOO'BAR was output as FOO BAR (unexpected insertion of a space) and FOO'BAR'BAZ was output unchanged (not removing the quotes as most would expect).
- No longer treat clusterdb table names as double-quoted; no longer treat reindexdb table and index names as double-quoted (Bruce Momjian)
  Users must now include double-quotes in the command arguments if quoting is wanted.
- createuser no longer prompts for option settings by default (Peter Eisentraut)
  Use --interactive to obtain the old behavior.
- Disable prompting for the user name in dropuser unless --interactive is specified (Peter Eisentraut)

E.72.2.5. Server Settings

- Add server parameters for specifying the locations of server-side SSL files (Peter Eisentraut)
  This allows changing the names and locations of the files that were previously hard-coded as server.crt, server.key, root.crt, and root.crl in the data directory. The server will no longer examine root.crt or root.crl by default; to load these files, the associated parameters must be set to non-default values.
- Remove the silent_mode parameter (Heikki Linnakangas)
  Similar behavior can be obtained with pg_ctl start -l postmaster.log.
- Remove the wal_sender_delay parameter, as it is no longer needed (Tom Lane)
- Remove the custom_variable_classes parameter (Tom Lane)
  The checking provided by this setting was dubious. Now any setting can be prefixed by any class name.
E.72.2.6. Monitoring

- Rename `pg_stat_activity.procpid` to `pid`, to match other system tables (Magnus Hagander)
- Create a separate `pg_stat_activity` column to report process state (Scott Mead, Magnus Hagander)
  The previous `query` and `query_start` values now remain available for an idle session, allowing enhanced analysis.
- Rename `pg_stat_activity.current_query` to `query` because it is not cleared when the query completes (Magnus Hagander)
- Change all SQL-level statistics timing values to be `float8` columns measured in milliseconds (Tom Lane)
  This change eliminates the designed-in assumption that the values are accurate to microseconds and no more (since the `float8` values can be fractional).
  The columns affected are `pg_stat_user_functions.total_time`, `pg_stat_user_functions.self_time`, `pg_stat_xact_user_functions.total_time`, and `pg_stat_xact_user_functions.self_time`. The statistics functions underlying these columns now also return `float8` milliseconds, rather than `bigint` microseconds. `contrib/pg_stat_statements` total_time column is now also measured in milliseconds.

E.72.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 9.2 and the previous major release.

E.72.3.1. Server

E.72.3.1.1. Performance

- Allow queries to retrieve data only from indexes, avoiding heap access (Robert Haas, Ibrar Ahmed, Heikki Linnakangas, Tom Lane)
  This feature is often called `index-only scans`. Heap access can be skipped for heap pages containing only tuples that are visible to all sessions, as reported by the visibility map; so the benefit applies mainly to mostly-static data. The visibility map was made crash-safe as a necessary part of implementing this feature.
- Add the SP-GiST (Space-Partitioned GiST) index access method (Teodor Sigaev, Oleg Bartunov, Tom Lane)
  SP-GiST is comparable to GiST in flexibility, but supports unbalanced partitioned search structures rather than balanced trees. For suitable problems, SP-GiST can be faster than GiST in both index build time and search time.
- Allow group commit to work effectively under heavy load (Peter Geoghegan, Simon Riggs, Heikki Linnakangas)
Appendix E. Release Notes

Previously, batching of commits became ineffective as the write workload increased, because of internal lock contention.

- Allow uncontended locks to be managed using a new fast-path lock mechanism (Robert Haas)
- Reduce overhead of creating virtual transaction ID locks (Robert Haas)
- Reduce the overhead of serializable isolation level locks (Dan Ports)
- Improve PowerPC and Itanium spinlock performance (Manabu Ori, Robert Haas, Tom Lane)
- Reduce overhead for shared invalidation cache messages (Robert Haas)
- Move the frequently accessed members of the \texttt{PGPROC} shared memory array to a separate array (Pavan Deolasee, Heikki Linnakangas, Robert Haas)
- Improve \texttt{COPY} performance by adding tuples to the heap in batches (Heikki Linnakangas)
- Improve GiST index performance for geometric data types by producing better trees with less memory allocation overhead (Alexander Korotkov)
- Improve GiST index build times (Alexander Korotkov, Heikki Linnakangas)
- Allow hint bits to be set sooner for temporary and unlogged tables (Robert Haas)
- Allow sorting to be performed by inlined, non-SQL-callable comparison functions (Peter Geoghegan, Robert Haas, Tom Lane)
- Make the number of CLOG buffers scale based on \texttt{shared_buffers} (Robert Haas, Simon Riggs, Tom Lane)
- Improve performance of buffer pool scans that occur when tables or databases are dropped (Jeff Janes, Simon Riggs)
- Improve performance of checkpointer’s fsync-request queue when many tables are being dropped or truncated (Tom Lane)
- Pass the safe number of file descriptors to child processes on Windows (Heikki Linnakangas)
  This allows Windows sessions to use more open file descriptors than before.

\textit{E.72.3.1.2. Process Management}

- Create a dedicated background process to perform checkpoints (Simon Riggs)
  Formerly the background writer did both dirty-page writing and checkpointing. Separating this into two processes allows each goal to be accomplished more predictably.
- Improve asynchronous commit behavior by waking the walwriter sooner (Simon Riggs)
  Previously, only \texttt{wal_writer_delay} triggered WAL flushing to disk; now filling a WAL buffer also triggers WAL writes.
- Allow the bgwriter, walwriter, checkpointer, statistics collector, log collector, and archiver background processes to sleep more efficiently during periods of inactivity (Peter Geoghegan, Tom Lane)
  This series of changes reduces the frequency of process wake-ups when there is nothing to do, dramatically reducing power consumption on idle servers.
E.72.3.1.3. Optimizer

- Allow the planner to generate custom plans for specific parameter values even when using prepared statements (Tom Lane)
  In the past, a prepared statement always had a single “generic” plan that was used for all parameter values, which was frequently much inferior to the plans used for non-prepared statements containing explicit constant values. Now, the planner attempts to generate custom plans for specific parameter values. A generic plan will only be used after custom plans have repeatedly proven to provide no benefit. This change should eliminate the performance penalties formerly seen from use of prepared statements (including non-dynamic statements in PL/pgSQL).
- Improve the planner’s ability to use nested loops with inner index scans (Tom Lane)
  The new “parameterized path” mechanism allows inner index scans to use values from relations that are more than one join level up from the scan. This can greatly improve performance in situations where semantic restrictions (such as outer joins) limit the allowed join orderings.
- Improve the planning API for foreign data wrappers (Etsuro Fujita, Shigeru Hanada, Tom Lane)
  Wrappers can now provide multiple access “paths” for their tables, allowing more flexibility in join planning.
- Recognize self-contradictory restriction clauses for non-table relations (Tom Lane)
  This check is only performed when constraint_exclusion is on.
- Allow indexed_col op ANY(ARRAY[...]) conditions to be used in plain index scans and index-only scans (Tom Lane)
  Formerly such conditions could only be used in bitmap index scans.
- Support MIN/MAX index optimizations on boolean columns (Marti Raudsepp)
- Account for set-returning functions in SELECT target lists when setting row count estimates (Tom Lane)
- Fix planner to handle indexes with duplicated columns more reliably (Tom Lane)
- Collect and use element-frequency statistics for arrays (Alexander Korotkov, Tom Lane)
  This change improves selectivity estimation for the array <@, &&, and @> operators (array containment and overlaps).
- Allow statistics to be collected for foreign tables (Etsuro Fujita)
- Improve cost estimates for use of partial indexes (Tom Lane)
- Improve the planner’s ability to use statistics for columns referenced in subqueries (Tom Lane)
- Improve statistical estimates for subqueries using DISTINCT (Tom Lane)

E.72.3.1.4. Authentication

- Do not treat role names and samerole specified in pg_hba.conf as automatically including superusers (Andrew Dunstan)
  This makes it easier to use reject lines with group roles.
Appendix E. Release Notes

- Adjust `pg_hba.conf` processing to handle token parsing more consistently (Brendan Jurd, Álvaro Herrera)
- Disallow empty `pg_hba.conf` files (Tom Lane)
  This was done to more quickly detect misconfiguration.
- Make superuser privilege imply replication privilege (Noah Misch)
  This avoids the need to explicitly assign such privileges.

**E.72.3.1.5. Monitoring**

- Attempt to log the current query string during a backend crash (Marti Raudsepp)
- Make logging of autovacuum I/O activity more verbose (Greg Smith, Noah Misch)
  This logging is triggered by `log_autovacuum_min_duration`.
- Make WAL replay report failures sooner (Fujii Masao)
  There were some cases where failures were only reported once the server went into master mode.
- Add `pg_xlog_location_diff()` to simplify WAL location comparisons (Euler Taveira de Oliveira)
  This is useful for computing replication lag.
- Support configurable event log application names on Windows (MauMau, Magnus Hagander)
  This allows different instances to use the event log with different identifiers, by setting the `event_source` server parameter, which is similar to how `syslog_ident` works.
- Change “unexpected EOF” messages to `DEBUG1` level, except when there is an open transaction (Magnus Hagander)
  This change reduces log chatter caused by applications that close database connections ungracefully.

**E.72.3.1.6. Statistical Views**

- Track temporary file sizes and file counts in the `pg_stat_database` system view (Tomas Vondra)
- Add a deadlock counter to the `pg_stat_database` system view (Magnus Hagander)
- Add a server parameter `track_io_timing` to track I/O timings (Ants Aasma, Robert Haas)
- Report checkpoint timing information in `pg_stat_bgwriter` (Greg Smith, Peter Geoghegan)

**E.72.3.1.7. Server Settings**

- Silently ignore nonexistent schemas specified in `search_path` (Tom Lane)
  This makes it more convenient to use generic path settings, which might include some schemas that don’t exist in all databases.
- Allow superusers to set `deadlock_timeout` per-session, not just per-cluster (Noah Misch)
This allows `deadlock_timeout` to be reduced for transactions that are likely to be involved in a deadlock, thus detecting the failure more quickly. Alternatively, increasing the value can be used to reduce the chances of a session being chosen for cancellation due to a deadlock.

• Add a server parameter `temp_file_limit` to constrain temporary file space usage per session (Mark Kirkwood)

• Allow a superuser to `SET` an extension’s superuser-only custom variable before loading the associated extension (Tom Lane)

  The system now remembers whether a `SET` was performed by a superuser, so that proper privilege checking can be done when the extension is loaded.

• Add postmaster `-C` option to query configuration parameters (Bruce Momjian)

  This allows `pg_ctl` to better handle cases where `PGDATA` or `-D` points to a configuration-only directory.

• Replace an empty locale name with the implied value in `CREATE DATABASE` (Tom Lane)

  This prevents cases where `pg_database.datcollate` or `datctype` could be interpreted differently after a server restart.

### E.72.3.1.7.1. `postgresql.conf`

• Allow multiple errors in `postgresql.conf` to be reported, rather than just the first one (Alexey Klyukin, Tom Lane)

• Allow a reload of `postgresql.conf` to be processed by all sessions, even if there are some settings that are invalid for particular sessions (Alexey Klyukin)

  Previously, such not-valid-within-session values would cause all setting changes to be ignored by that session.

• Add an `include_if_exists` facility for configuration files (Greg Smith)

  This works the same as `include`, except that an error is not thrown if the file is missing.

• Identify the server time zone during `initdb`, and set `postgresql.conf` entries `timezone` and `log_timezone` accordingly (Tom Lane)

  This avoids expensive time zone probes during server start.

• Fix `pg_settings` to report `postgresql.conf` line numbers on Windows (Tom Lane)

### E.72.3.2. Replication and Recovery

• Allow streaming replication slaves to forward data to other slaves (`cascading replication`) (Fujii Masao)

  Previously, only the master server could supply streaming replication log files to standby servers.

• Add new `synchronous_commit` mode `remote_write` (Fujii Masao, Simon Riggs)

  This mode waits for the standby server to write transaction data to its own operating system, but does not wait for the data to be flushed to the standby’s disk.
• Add a `pg_receivexlog` tool to archive WAL file changes as they are written, rather than waiting for completed WAL files (Magnus Hagander)

• Allow `pg_basebackup` to make base backups from standby servers (Jun Ishizuka, Fujii Masao)
  This feature lets the work of making new base backups be off-loaded from the primary server.

• Allow streaming of WAL files while `pg_basebackup` is performing a backup (Magnus Hagander)
  This allows passing of WAL files to the standby before they are discarded on the primary.

### E.72.3.3. Queries

• Cancel the running query if the client gets disconnected (Florian Pflug)
  If the backend detects loss of client connection during a query, it will now cancel the query rather than attempting to finish it.

• Retain column names at run time for row expressions (Andrew Dunstan, Tom Lane)
  This change allows better results when a row value is converted to `hstore` or `json` type: the fields of the resulting value will now have the expected names.

• Improve column labels used for sub-`SELECT` results (Marti Raudsepp)
  Previously, the generic label `?column?` was used.

• Improve heuristics for determining the types of unknown values (Tom Lane)
  The longstanding rule that an unknown constant might have the same type as the value on the other side of the operator using it is now applied when considering polymorphic operators, not only for simple operator matches.

• Warn about creating casts to or from domain types (Robert Haas)
  Such casts have no effect.

• When a row fails a `CHECK` or `NOT NULL` constraint, show the row’s contents as error detail (Jan Kundrát)
  This should make it easier to identify which row is problematic when an insert or update is processing many rows.

### E.72.3.4. Object Manipulation

• Provide more reliable operation during concurrent DDL (Robert Haas, Noah Misch)
  This change adds locking that should eliminate “cache lookup failed” errors in many scenarios. Also, it is no longer possible to add relations to a schema that is being concurrently dropped, a scenario that formerly led to inconsistent system catalog contents.

• Add `CONCURRENTLY` option to `DROP INDEX` (Simon Riggs)
  This allows index removal without blocking other sessions.

• Allow foreign data wrappers to have per-column options (Shigeru Hanada)

• Improve pretty-printing of view definitions (Andrew Dunstan)
Appendix E. Release Notes

E.72.3.4.1. Constraints

- Allow CHECK constraints to be declared NOT VALID (Álvaro Herrera)

  Adding a NOT VALID constraint does not cause the table to be scanned to verify that existing rows meet the constraint. Subsequently, newly added or updated rows are checked. Such constraints are ignored by the planner when considering constraint_exclusion, since it is not certain that all rows meet the constraint.

  The new ALTER TABLE VALIDATE command allows NOT VALID constraints to be checked for existing rows, after which they are converted into ordinary constraints.

- Allow CHECK constraints to be declared NO INHERIT (Nikhil Sontakke, Alex Hunsaker, Álvaro Herrera)

  This makes them enforceable only on the parent table, not on child tables.

- Add the ability to rename constraints (Peter Eisentraut)

E.72.3.4.2. ALTER

- Reduce need to rebuild tables and indexes for certain ALTER TABLE ... ALTER COLUMN TYPE operations (Noah Misch)

  Increasing the length limit for a varchar or varbit column, or removing the limit altogether, no longer requires a table rewrite. Similarly, increasing the allowable precision of a numeric column, or changing a column from constrained numeric to unconstrained numeric, no longer requires a table rewrite. Table rewrites are also avoided in similar cases involving the interval, timestamp, and timestamptz types.

- Avoid having ALTER TABLE revalidate foreign key constraints in some cases where it is not necessary (Noah Misch)

- Add IF EXISTS options to some ALTER commands (Pavel Stehule)

  For example, ALTER FOREIGN TABLE IF EXISTS foo RENAME TO bar.

- Add ALTER FOREIGN DATA WRAPPER ... RENAME and ALTER SERVER ... RENAME (Peter Eisentraut)

- Add ALTER DOMAIN ... RENAME (Peter Eisentraut)

  You could already rename domains using ALTER TYPE.

- Throw an error for ALTER DOMAIN ... DROP CONSTRAINT on a nonexistent constraint (Peter Eisentraut)

  An IF EXISTS option has been added to provide the previous behavior.

E.72.3.4.3. CREATE TABLE

- Allow CREATE TABLE (LIKE ...) from foreign tables, views, and composite types (Peter Eisentraut)

  For example, this allows a table to be created whose schema matches a view.
• Fix `CREATE TABLE (LIKE ...)` to avoid index name conflicts when copying index comments (Tom Lane)

• Fix `CREATE TABLE ... AS EXECUTE` to handle `WITH NO DATA` and column name specifications (Tom Lane)

E.72.3.4.4. Object Permissions

• Add a `security_barrier` option for views (KaiGai Kohei, Robert Haas)
  This option prevents optimizations that might allow view-protected data to be exposed to users, for example pushing a clause involving an insecure function into the `WHERE` clause of the view. Such views can be expected to perform more poorly than ordinary views.

• Add a new `LEAKPROOF` function attribute to mark functions that can safely be pushed down into `security_barrier` views (KaiGai Kohei)

• Add support for privileges on data types (Peter Eisentraut)
  This adds support for the SQL-conforming `USAGE` privilege on types and domains. The intent is to be able to restrict which users can create dependencies on types, since such dependencies limit the owner’s ability to alter the type.

• Check for `INSERT` privileges in `SELECT INTO / CREATE TABLE AS` (KaiGai Kohei)
  Because the object is being created by `SELECT INTO` or `CREATE TABLE AS`, the creator would ordinarily have insert permissions; but there are corner cases where this is not true, such as when `ALTER DEFAULT PRIVILEGES` has removed such permissions.

E.72.3.5. Utility Operations

• Allow `VACUUM` to more easily skip pages that cannot be locked (Simon Riggs, Robert Haas)
  This change should greatly reduce the incidence of `VACUUM` getting “stuck” waiting for other sessions.

• Make `EXPLAIN (BUFFERS)` count blocks dirtied and written (Robert Haas)

• Make `EXPLAIN ANALYZE` report the number of rows rejected by filter steps (Marko Tiikkaja)

• Allow `EXPLAIN ANALYZE` to avoid timing overhead when time values are not wanted (Tomas Vondra)
  This is accomplished by setting the new `TIMING` option to `FALSE`.

E.72.3.6. Data Types

• Add support for range data types (Jeff Davis, Tom Lane, Alexander Korotkov)
  A range data type stores a lower and upper bound belonging to its base data type. It supports operations like contains, overlaps, and intersection.

• Add a `JSON` data type (Robert Haas)
This type stores JSON (JavaScript Object Notation) data with proper validation.

- Add `array_to_json()` and `row_to_json()` (Andrew Dunstan)
- Add a `SMALLSERIAL` data type (Mike Pultz)
  
  This is like `SERIAL`, except it stores the sequence in a two-byte integer column (`int2`).
- Allow domains to be declared `NOT VALID` (Álvaro Herrera)
  
  This option can be set at domain creation time, or via `ALTER DOMAIN ... ADD CONSTRAINT ... NOT VALID`. `ALTER DOMAIN ... VALIDATE CONSTRAINT` fully validates the constraint.
- Support more locale-specific formatting options for the `money` data type (Tom Lane)
  
  Specifically, honor all the POSIX options for ordering of the value, sign, and currency symbol in monetary output. Also, make sure that the thousands separator is only inserted to the left of the decimal point, as required by POSIX.
- Add bitwise “and”, “or”, and “not” operators for the `macaddr` data type (Brendan Jurd)
- Allow `xpath()` to return a single-element XML array when supplied a scalar value (Florian Pflug)
  
  Previously, it returned an empty array. This change will also cause `xpath_exists()` to return true, not false, for such expressions.
- Improve XML error handling to be more robust (Florian Pflug)

### E.72.3.7. Functions

- Allow non-superusers to use `pg_cancel_backend()` and `pg_terminate_backend()` on other sessions belonging to the same user (Magnus Hagander, Josh Kupershmidt, Dan Farina)
  
  Previously only superusers were allowed to use these functions.
- Allow importing and exporting of transaction snapshots (Joachim Wieland, Tom Lane)
  
  This allows multiple transactions to share identical views of the database state. Snapshots are exported via `pg_export_snapshot()` and imported via `SET TRANSACTION SNAPSHOT`. Only snapshots from currently-running transactions can be imported.
- Support `COLLATION FOR` on expressions (Peter Eisentraut)
  
  This returns a string representing the collation of the expression.
- Add `pg_opfamily_is_visible()` (Josh Kupershmidt)
- Add a numeric variant of `pg_size_pretty()` for use with `pg_xlog_location_diff()` (Fujii Masao)
- Add a `pg_trigger_depth()` function (Kevin Grittner)
  
  This reports the current trigger call depth.
- Allow `string_agg()` to process `bytea` values (Pavel Stehule)
- Fix regular expressions in which a back-reference occurs within a larger quantified subexpression (Tom Lane)
Appendix E. Release Notes

For example, ^\(\w+)(\ \1)\+$. Previous releases did not check that the back-reference actually matched the first occurrence.

E.72.3.8. Information Schema

- Add information schema views `role_udt_grants`, `udt_privileges`, and `user_defined_types` (Peter Eisentraut)
- Add composite-type attributes to the information schema `element_types` view (Peter Eisentraut)
- Implement `interval_type` columns in the information schema (Peter Eisentraut)
- Formerly these columns read as nulls.
- Implement collation-related columns in the information schema `attributes`, `columns`, `domains`, and `element_types` views (Peter Eisentraut)
- Implement the `with_hierarchy` column in the information schema `table_privileges` view (Peter Eisentraut)
- Add display of sequence `USAGE` privileges to information schema (Peter Eisentraut)
- Make the information schema show default privileges (Peter Eisentraut)
  Previously, non-empty default permissions were not represented in the views.

E.72.3.9. Server-Side Languages

E.72.3.9.1. PL/pgSQL Server-Side Language

- Allow the PL/pgSQL `OPEN` cursor command to supply parameters by name (Yeb Havinga)
- Add a `GET STACKED DIAGNOSTICS` PL/pgSQL command to retrieve exception info (Pavel Stehule)
- Speed up PL/pgSQL array assignment by caching type information (Pavel Stehule)
- Improve performance and memory consumption for long chains of `ELSIF` clauses (Tom Lane)
- Output the function signature, not just the name, in PL/pgSQL error messages (Pavel Stehule)

E.72.3.9.2. PL/Python Server-Side Language

- Add PL/Python SPI cursor support (Jan Urbanski)
  This allows PL/Python to read partial result sets.
- Add result metadata functions to PL/Python (Peter Eisentraut)
  Specifically, this adds result object functions `.colnames`, `.coltypes`, and `.coltypmods`.
- Remove support for Python 2.2 (Peter Eisentraut)
E.72.3.9.3. SQL Server-Side Language

- Allow SQL-language functions to reference parameters by name (Matthew Draper)
  To use this, simply name the function arguments and then reference the argument names in the SQL function body.

E.72.3.10. Client Applications

- Add initdb options --auth-local and --auth-host (Peter Eisentraut)
  This allows separate control of local and host pg_hba.conf authentication settings. --auth still controls both.
- Add --replication/--no-replication flags to createuser to control replication permission (Fujii Masao)
- Add the --if-exists option to dropdb and dropuser (Josh Kupershmidt)
- Give command-line tools the ability to specify the name of the database to connect to, and fall back to template1 if a postgres database connection fails (Robert Haas)

E.72.3.10.1. psql

- Add a display mode to auto-expand output based on the display width (Peter Eisentraut)
  This adds the auto option to the \x command, which switches to the expanded mode when the normal output would be wider than the screen.
- Allow inclusion of a script file that is named relative to the directory of the file from which it was invoked (Gurjeet Singh)
  This is done with a new command \ir.
- Add support for non-ASCII characters in psql variable names (Tom Lane)
- Add support for major-version-specific .psqlrc files (Bruce Momjian)
  psql already supported minor-version-specific .psqlrc files.
- Provide environment variable overrides for psql history and startup file locations (Andrew Dunstan)
  PSQL_HISTORY and PSQLRC now determine these file names if set.
- Add a \setenv command to modify the environment variables passed to child processes (Andrew Dunstan)
- Name psql's temporary editor files with a .sql extension (Peter Eisentraut)
  This allows extension-sensitive editors to select the right mode.
- Allow psql to use zero-byte field and record separators (Peter Eisentraut)
  Various shell tools use zero-byte (NUL) separators, e.g. find.
- Make the \timing option report times for failed queries (Magnus Hagander)
Previously times were reported only for successful queries.

- Unify and tighten psql’s treatment of `\copy` and SQL `COPY` (Noah Misch)
  This fix makes failure behavior more predictable and honors `\set ON_ERROR_ROLLBACK`.

### E.72.3.10.2. Informational Commands

- Make `\d` on a sequence show the table/column name owning it (Magnus Hagander)
- Show statistics target for columns in `\d+` (Magnus Hagander)
- Show role password expiration dates in `\du` (Fabrízio de Royes Mello)
- Display comments for casts, conversions, domains, and languages (Josh Kupershmidt)
  These are included in the output of `\dC+`, `\dc+`, `\dD+`, and `\dL` respectively.
- Display comments for SQL/MED objects (Josh Kupershmidt)
  These are included in the output of `\des+`, `\det+`, and `\dew+` for foreign servers, foreign tables, and foreign data wrappers respectively.
- Change `\dd` to display comments only for object types without their own backslash command (Josh Kupershmidt)

### E.72.3.10.3. Tab Completion

- In psql tab completion, complete SQL keywords in either upper or lower case according to the new `COMP_KEYWORD_CASE` setting (Peter Eisentraut)
- Add tab completion support for `EXECUTE` (Andreas Karlsson)
- Allow tab completion of role references in `GRANT/REVOKE` (Peter Eisentraut)
- Allow tab completion of file names to supply quotes, when necessary (Noah Misch)
- Change tab completion support for `TABLE` to also include views (Magnus Hagander)

### E.72.3.10.4. pg_dump

- Add an `--exclude-table-data` option to pg_dump (Andrew Dunstan)
  This allows dumping of a table’s definition but not its data, on a per-table basis.
- Add a `--section` option to pg_dump and pg_restore (Andrew Dunstan)
  Valid values are `pre-data`, `data`, and `post-data`. The option can be given more than once to select two or more sections.
- Make pg_dumpall dump all roles first, then all configuration settings on roles (Phil Sorber)
  This allows a role’s configuration settings to mention other roles without generating an error.
- Allow pg_dumpall to avoid errors if the `postgres` database is missing in the new cluster (Robert Haas)
- Dump foreign server user mappings in user name order (Peter Eisentraut)
This helps produce deterministic dump files.

- Dump operators in a predictable order (Peter Eisentraut)
- Tighten rules for when extension configuration tables are dumped by pg_dump (Tom Lane)
- Make pg_dump emit more useful dependency information (Tom Lane)

The dependency links included in archive-format dumps were formerly of very limited use, because they frequently referenced objects that appeared nowhere in the dump. Now they represent actual dependencies (possibly indirect) among the dumped objects.

- Improve pg_dump’s performance when dumping many database objects (Tom Lane)

**E.72.3.11. libpq**

- Allow libpq connection strings to have the format of a URI (Alexander Shulgin)
  The syntax begins with `postgres://`. This can allow applications to avoid implementing their own parser for URIs representing database connections.
- Add a connection option to disable SSL compression (Laurenz Albe)
  This can be used to remove the overhead of SSL compression on fast networks.
- Add a single-row processing mode for better handling of large result sets (Kyotaro Horiguchi, Marko Kreen)
  Previously, libpq always collected the entire query result in memory before passing it back to the application.
- Add `const` qualifiers to the declarations of the functions `PQconnectdbParams`, `PQconnectStartParams`, and `PQpingParams` (Lionel Elie Mamane)
- Allow the `.pgpass` file to include escaped characters in the password field (Robert Haas)
- Make library functions use `abort()` instead of `exit()` when it is necessary to terminate the process (Peter Eisentraut)
  This choice does not interfere with the normal exit codes used by the program, and generates a signal that can be caught by the caller.

**E.72.3.12. Source Code**

- Remove dead ports (Peter Eisentraut)
  The following platforms are no longer supported: dgux, nextstep, sunos4, svr4, ultrix4, univel, bsd.
- Add support for building with MS Visual Studio 2010 (Brar Piening)
- Enable compiling with the MinGW-w64 32-bit compiler (Lars Kanis)
- Install `plpgsql.h` into `include/server` during installation (Heikki Linnakangas)
- Improve the latch facility to include detection of postmaster death (Peter Geoghegan, Heikki Linnakangas, Tom Lane)
This eliminates one of the main reasons that background processes formerly had to wake up to poll for events.

- Use C flexible array members, where supported (Peter Eisentraut)
- Improve the concurrent transaction regression tests (isolationtester) (Noah Misch)
- Modify thread_test to create its test files in the current directory, rather than /tmp (Bruce Momjian)
- Improve flex and bison warning and error reporting (Tom Lane)
- Add memory barrier support (Robert Haas)
  This is currently unused.
- Modify pgindent to use a typedef file (Bruce Momjian)
- Add a hook for processing messages due to be sent to the server log (Martin Pihlak)
- Add object access hooks for DROP commands (KaiGai Kohei)
- Centralize DROP handling for some object types (KaiGai Kohei)
- Add a pg_upgrade test suite (Peter Eisentraut)
- Sync regular expression code with TCL 8.5.11 and improve internal processing (Tom Lane)
- Move CRC tables to libpqport, and provide them in a separate include file (Daniel Farina)
- Add options to git_changelog for use in major release note creation (Bruce Momjian)
- Support Linux’s /proc/self/oom_score_adj API (Tom Lane)

### E.72.3.13. Additional Modules

- Improve efficiency of dblink by using libpq’s new single-row processing mode (Kyotaro Horiguchi, Marko Kreen)
  This improvement does not apply to dblink_send_query() / dblink_get_result().
- Support force_not_null option in file_fdw (Shigeru Hanada)
- Implement dry-run mode for pg_archivecleanup (Gabriele Bartolini)
  This only outputs the names of files to be deleted.
- Add new pgbench switches --unlogged-tables, --tablespace, and --index-tablespace (Robert Haas)
- Change pg_test_fsync to test for a fixed amount of time, rather than a fixed number of cycles (Bruce Momjian)
  The -c/cycles option was removed, and -s/seconds added.
- Add a pg_test_timing utility to measure clock monotonicity and timing overhead (Ants Aasma, Greg Smith)
- Add a tcn (triggered change notification) module to generate NOTIFY events on table changes (Kevin Grittner)
E.72.3.13.1. pg_upgrade

- Adjust pg_upgrade environment variables (Bruce Momjian)
  Rename data, bin, and port environment variables to begin with `PG`, and support `PGPORTOLD/PGPORTNEW`, to replace `PGPORT`.

- Overhaul pg_upgrade logging and failure reporting (Bruce Momjian)
  Create four append-only log files, and delete them on success. Add `-r/--retain` option to unconditionally retain these files. Also remove pg_upgrade options `-g/-G/-l` options as unnecessary, and tighten log file permissions.

- Make pg_upgrade create a script to incrementally generate more accurate optimizer statistics (Bruce Momjian)
  This reduces the time needed to generate minimal cluster statistics after an upgrade.

- Allow pg_upgrade to upgrade an old cluster that does not have a `postgres` database (Bruce Momjian)

- Allow pg_upgrade to handle cases where some old or new databases are missing, as long as they are empty (Bruce Momjian)

- Allow pg_upgrade to handle configuration-only directory installations (Bruce Momjian)

- In pg_upgrade, add `-o/-O` options to pass parameters to the servers (Bruce Momjian)
  This is useful for configuration-only directory installs.

- Change pg_upgrade to use port 50432 by default (Bruce Momjian)
  This helps avoid unintended client connections during the upgrade.

- Reduce cluster locking in pg_upgrade (Bruce Momjian)
  Specifically, only lock the old cluster if link mode is used, and do it right after the schema is restored.

E.72.3.13.2. pg_stat_statements

- Allow pg_stat_statements to aggregate similar queries via SQL text normalization (Peter Geoghegan, Tom Lane)
  Users with applications that use non-parameterized SQL will now be able to monitor query performance without detailed log analysis.

- Add dirtied and written block counts and read/write times to pg_stat_statements (Robert Haas, Ants Aasma)

- Prevent pg_stat_statements from double-counting `PREPARE` and `EXECUTE` commands (Tom Lane)

E.72.3.13.3. sepgsql

- Support `SECURITY LABEL` on global objects (KaiGai Kohei, Robert Haas)
  Specifically, add security labels to databases, tablespaces, and roles.

- Allow sepgsql to honor database labels (KaiGai Kohei)
Appendix E. Release Notes

• Perform sepgsql permission checks during the creation of various objects (KaiGai Kohei)
• Add sepgsql_setcon() and related functions to control the sepgsql security domain (KaiGai Kohei)
• Add a user space access cache to sepgsql to improve performance (KaiGai Kohei)

E.72.3.14. Documentation

• Add a rule to optionally build HTML documentation using the stylesheet from the website (Magnus Hagander)
  Use gmake STYLE=website draft.
• Improve EXPLAIN documentation (Tom Lane)
• Document that user/database names are preserved with double-quoting by command-line tools like vacuumdb (Bruce Momjian)
• Document the actual string returned by the client for MD5 authentication (Cyan Ogilvie)
• Deprecate use of GLOBAL and LOCAL in CREATE TEMP TABLE (Noah Misch)
  PostgreSQL has long treated these keyword as no-ops, and continues to do so; but in future they might mean what the SQL standard says they mean, so applications should avoid using them.

E.73. Release 9.1.24

Release date: 2016-10-27

This release contains a variety of fixes from 9.1.23. For information about new features in the 9.1 major release, see Section E.97.

This is expected to be the last PostgreSQL release in the 9.1.X series. Users are encouraged to update to a newer release branch soon.

E.73.1. Migration to Version 9.1.24

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.16, see Section E.81.

E.73.2. Changes

• Fix EvalPlanQual rechecks involving CTE scans (Tom Lane)
  The recheck would always see the CTE as returning no rows, typically leading to failure to update rows that were recently updated.
Appendix E. Release Notes

• Fix improper repetition of previous results from hashed aggregation in a subquery (Andrew Gierth)

The test to see if we can reuse a previously-computed hash table of the aggregate state values neglected the possibility of an outer query reference appearing in an aggregate argument expression. A change in the value of such a reference should lead to recalculating the hash table, but did not.

• Fix timeout length when VACUUM is waiting for exclusive table lock so that it can truncate the table (Simon Riggs)

The timeout was meant to be 50 milliseconds, but it was actually only 50 microseconds, causing VACUUM to give up on truncation much more easily than intended. Set it to the intended value.

• Remove artificial restrictions on the values accepted by numeric_in() and numeric_recv() (Tom Lane)

We allow numeric values up to the limit of the storage format (more than $10^{100000}$), so it seems fairly pointless that numeric_in() rejected scientific-notation exponents above 1000. Likewise, it was silly for numeric_recv() to reject more than 1000 digits in an input value.

• Avoid very-low-probability data corruption due to testing tuple visibility without holding buffer lock (Thomas Munro, Peter Geoghegan, Tom Lane)

• Fix file descriptor leakage when truncating a temporary relation of more than 1GB (Andres Freund)

•Disallow starting a standalone backend with standby_mode turned on (Michael Paquier)

This can’t do anything useful, since there will be no WAL receiver process to fetch more WAL data; and it could result in misbehavior in code that wasn’t designed with this situation in mind.

• Don’t try to share SSL contexts across multiple connections in libpq (Heikki Linnakangas)

This led to assorted corner-case bugs, particularly when trying to use different SSL parameters for different connections.

• Avoid corner-case memory leak in libpq (Tom Lane)

The reported problem involved leaking an error report during PQreset(), but there might be related cases.

• Make ecpg’s --help and --version options work consistently with our other executables (Haribabu Kommi)

• Fix contrib/intarray/bench/bench.pl to print the results of the EXPLAIN it does when given the -e option (Daniel Gustafsson)

• Prevent failure of obsolete dynamic time zone abbreviations (Tom Lane)

If a dynamic time zone abbreviation does not match any entry in the referenced time zone, treat it as equivalent to the time zone name. This avoids unexpected failures when IANA removes abbreviations from their time zone database, as they did in tzdata release 2016f and seem likely to do again in the future. The consequences were not limited to not recognizing the individual abbreviation; any mismatch caused the pg_timezone_abbrevs view to fail altogether.

• Update time zone data files to tzdata release 2016h for DST law changes in Palestine and Turkey, plus historical corrections for Turkey and some regions of Russia. Switch to numeric abbreviations for some time zones in Antarctica, the former Soviet Union, and Sri Lanka.

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are
in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no
evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will
continue to accept such removed abbreviations for timestamp input. But they will not be shown in the
pg_timezone_names view nor used for output.

In this update, AMT is no longer shown as being in use to mean Armenia Time. Therefore, we have
changed the Default abbreviation set to interpret it as Amazon Time, thus UTC-4 not UTC+4.

E.74. Release 9.1.23

Release date: 2016-08-11

This release contains a variety of fixes from 9.1.22. For information about new features in the 9.1 major
release, see Section E.97.

The PostgreSQL community will stop releasing updates for the 9.1.X release series in September 2016.
Users are encouraged to update to a newer release branch soon.

E.74.1. Migration to Version 9.1.23

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.16, see Section E.81.

E.74.2. Changes

• Fix possible mis-evaluation of nested CASE-WHEN expressions (Heikki Linnakangas, Michael Paquier,
  Tom Lane)

  A CASE expression appearing within the test value subexpression of another CASE could become con-
  fused about whether its own test value was null or not. Also, inlining of a SQL function implementing
  the equality operator used by a CASE expression could result in passing the wrong test value to functions
called within a CASE expression in the SQL function’s body. If the test values were of different data
types, a crash might result; moreover such situations could be abused to allow disclosure of portions of
server memory. (CVE-2016-5423)

• Fix client programs’ handling of special characters in database and role names (Noah Misch, Nathan
  Bossart, Michael Paquier)

  Numerous places in vacuumdb and other client programs could become confused by database and role
  names containing double quotes or backslashes. Tighten up quoting rules to make that safe. Also, ensure
  that when a conninfo string is used as a database name parameter to these programs, it is correctly
treated as such throughout.

  Fix handling of paired double quotes in psql’s \connect and \password commands to match the
documentation.
Appendix E. Release Notes

Introduce a new `-reuse-previous` option in psql's `\connect` command to allow explicit control of whether to re-use connection parameters from a previous connection. (Without this, the choice is based on whether the database name looks like a conninfo string, as before.) This allows secure handling of database names containing special characters in `pg_dumpall` scripts.

`pg_dumpall` now refuses to deal with database and role names containing carriage returns or newlines, as it seems impractical to quote those characters safely on Windows. In future we may reject such names on the server side, but that step has not been taken yet.

These are considered security fixes because crafted object names containing special characters could have been used to execute commands with superuser privileges the next time a superuser executes `pg_dumpall` or other routine maintenance operations. (CVE-2016-5424)

- **Fix corner-case misbehaviors for `IS NULL`/* NOT NULL** applied to nested composite values (Andrew Gierth, Tom Lane)

  The SQL standard specifies that `IS NULL` should return TRUE for a row of all null values (thus `ROW(NULL,NULL) IS NULL` yields TRUE), but this is not meant to apply recursively (thus `ROW(NULL, ROW(NULL,NULL)) IS NULL` yields FALSE). The core executor got this right, but certain planner optimizations treated the test as recursive (thus producing TRUE in both cases), and contrib/postgres_fdw could produce remote queries that misbehaved similarly.

- **Make the inet and cidr data types properly reject IPv6 addresses with too many colon-separated fields** (Tom Lane)

- **Prevent crash in `close_ps()` (the `point ## lseg` operator) for NaN input coordinates** (Tom Lane)

  Make it return NULL instead of crashing.

- **Fix several one-byte buffer over-reads in `to_number()`** (Peter Eisentraut)

  In several cases the `to_number()` function would read one more character than it should from the input string. There is a small chance of a crash, if the input happens to be adjacent to the end of memory.

- **Avoid unsafe intermediate state during expensive paths through `heap_update()`** (Masahiko Sawada, Andres Freund)

  Previously, these cases locked the target tuple (by setting its XMAX) but did not WAL-log that action, thus risking data integrity problems if the page were spilled to disk and then a database crash occurred before the tuple update could be completed.

- **Avoid consuming a transaction ID during VACUUM** (Alexander Korotkov)

  Some cases in VACUUM unnecessarily caused an XID to be assigned to the current transaction. Normally this is negligible, but if one is up against the XID wraparound limit, consuming more XIDs during anti-wraparound vacuums is a very bad thing.

- **Avoid canceling hot-standby queries during VACUUM FREEZE** (Simon Riggs, Álvaro Herrera)

  VACUUM FREEZE on an otherwise-idle master server could result in unnecessary cancellations of queries on its standby servers.

- **When a manual ANALYZE specifies a column list, don’t reset the table’s `changes_since_analyze` counter** (Tom Lane)

  If we’re only analyzing some columns, we should not prevent routine auto-analyze from happening for the other columns.

2449
• Fix ANALYZE’s overestimation of n_distinct for a unique or nearly-unique column with many null entries (Tom Lane)

  The nulls could get counted as though they were themselves distinct values, leading to serious planner misestimates in some types of queries.

• Prevent autovacuum from starting multiple workers for the same shared catalog (Álvaro Herrera)

  Normally this isn’t much of a problem because the vacuum doesn’t take long anyway; but in the case of a severely bloated catalog, it could result in all but one worker uselessly waiting instead of doing useful work on other tables.

• Fix contrib/btree_gin to handle the smallest possible bigint value correctly (Peter Eisentraut)

• Teach libpq to correctly decode server version from future servers (Peter Eisentraut)

  It’s planned to switch to two-part instead of three-part server version numbers for releases after 9.6. Make sure that PQserverVersion() returns the correct value for such cases.

• Fix ecpg’s code for unsigned long long array elements (Michael Meskes)

• Make pg_basebackup accept -Z 0 as specifying no compression (Fujii Masao)

• Revert to the old heuristic timeout for pg_ctl start -w (Tom Lane)

  The new method adopted as of release 9.1.20 does not work when silent_mode is enabled, so go back to the old way.

• Fix makefiles’ rule for building AIX shared libraries to be safe for parallel make (Noah Misch)

• Fix TAP tests and MSVC scripts to work when build directory’s path name contains spaces (Michael Paquier, Kyotaro Horiguchi)

• Make regression tests safe for Danish and Welsh locales (Jeff Janes, Tom Lane)

  Change some test data that triggered the unusual sorting rules of these locales.

• Update our copy of the timezone code to match IANA’s tzcode release 2016c (Tom Lane)

  This is needed to cope with anticipated future changes in the time zone data files. It also fixes some corner-case bugs in coping with unusual time zones.

• Update time zone data files to tzdata release 2016f for DST law changes in Kemerovo and Novosibirsk, plus historical corrections for Azerbaijan, Belarus, and Morocco.

**E.75. Release 9.1.22**

**Release date:** 2016-05-12

This release contains a variety of fixes from 9.1.21. For information about new features in the 9.1 major release, see Section E.97.

The PostgreSQL community will stop releasing updates for the 9.1.X release series in September 2016. Users are encouraged to update to a newer release branch soon.
Appendix E. Release Notes

E.75.1. Migration to Version 9.1.22

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.16, see Section E.81.

E.75.2. Changes

• Clear the OpenSSL error queue before OpenSSL calls, rather than assuming it’s clear already; and make sure we leave it clear afterwards (Peter Geoghegan, Dave Vitik, Peter Eisentraut)

This change prevents problems when there are multiple connections using OpenSSL within a single process and not all the code involved follows the same rules for when to clear the error queue. Failures have been reported specifically when a client application uses SSL connections in libpq concurrently with SSL connections using the PHP, Python, or Ruby wrappers for OpenSSL. It’s possible for similar problems to arise within the server as well, if an extension module establishes an outgoing SSL connection.

• Fix “failed to build any N-way joins” planner error with a full join enclosed in the right-hand side of a left join (Tom Lane)

• Fix possible misbehavior of TH, th, and Y, YYY format codes in to_timestamp() (Tom Lane)

These could advance off the end of the input string, causing subsequent format codes to read garbage.

• Fix dumping of rules and views in which the array argument of a value operator ANY (array) construct is a sub-SELECT (Tom Lane)

• Make pg_regress use a startup timeout from the PGCTLTIMEOUT environment variable, if that’s set (Tom Lane)

This is for consistency with a behavior recently added to pg_ctl; it eases automated testing on slow machines.

• Fix pg_upgrade to correctly restore extension membership for operator families containing only one operator class (Tom Lane)

In such a case, the operator family was restored into the new database, but it was no longer marked as part of the extension. This had no immediate ill effects, but would cause later pg_dump runs to emit output that would cause (harmless) errors on restore.

• Rename internal function strtoi() to strtoint() to avoid conflict with a NetBSD library function (Thomas Munro)

• Fix reporting of errors from bind() and listen() system calls on Windows (Tom Lane)

• Reduce verbosity of compiler output when building with Microsoft Visual Studio (Christian Ullrich)

• Avoid possibly-unsafe use of Windows’ FormatMessage() function (Christian Ullrich)

Use the FORMAT_MESSAGE_IGNORE_INSERTS flag where appropriate. No live bug is known to exist here, but it seems like a good idea to be careful.

• Update time zone data files to tzdata release 2016d for DST law changes in Russia and Venezuela. There are new zone names Europe/Kirov and Asia/Tomsk to reflect the fact that these regions now have different time zone histories from adjacent regions.
E.76. Release 9.1.21

Release date: 2016-03-31

This release contains a variety of fixes from 9.1.20. For information about new features in the 9.1 major release, see Section E.97.

E.76.1. Migration to Version 9.1.21

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.16, see Section E.81.

E.76.2. Changes

- Fix incorrect handling of NULL index entries in indexed \texttt{ROW()} comparisons (Tom Lane)

  An index search using a row comparison such as \texttt{ROW(a, b) > ROW(’x’, ’y’)} would stop upon reaching a NULL entry in the \texttt{b} column, ignoring the fact that there might be non-NULL \texttt{b} values associated with later values of \texttt{a}.

- Avoid unlikely data-loss scenarios due to renaming files without adequate \texttt{fsync()} calls before and after (Michael Paquier, Tomas Vondra, Andres Freund)

- Correctly handle cases where \texttt{pg_subtrans} is close to XID wraparound during server startup (Jeff Janes)

- Fix corner-case crash due to trying to free \texttt{localeconv()} output strings more than once (Tom Lane)

- Fix parsing of affix files for \texttt{ispell} dictionaries (Tom Lane)

  The code could go wrong if the affix file contained any characters whose byte length changes during case-folding, for example \texttt{I} in Turkish UTF8 locales.

- Avoid use of \texttt{sscanf()} to parse \texttt{ispell} dictionary files (Artur Zakirov)

  This dodges a portability problem on FreeBSD-derived platforms (including macOS).

- Avoid a crash on old Windows versions (before 7SP1/2008R2SP1) with an AVX2-capable CPU and a Postgres build done with Visual Studio 2013 (Christian Ullrich)

  This is a workaround for a bug in Visual Studio 2013’s runtime library, which Microsoft have stated they will not fix in that version.

- Fix \texttt{psql}’s tab completion logic to handle multibyte characters properly (Kyotaro Horiguchi, Robert Haas)

- Fix \texttt{psql}’s tab completion for \texttt{SECURITY LABEL} (Tom Lane)

  Pressing \texttt{TAB} after \texttt{SECURITY LABEL} might cause a crash or offering of inappropriate keywords.

- Make \texttt{pg_ctl} accept a wait timeout from the \texttt{PGCTLTIMEOUT} environment variable, if none is specified on the command line (Noah Misch)

  This eases testing of slower buildfarm members by allowing them to globally specify a longer-than-normal timeout for postmaster startup and shutdown.
• Fix incorrect test for Windows service status in pg_ctl (Manuel Mathar)
  The previous set of minor releases attempted to fix pg_ctl to properly determine whether to send log
  messages to Window’s Event Log, but got the test backwards.
• Fix pgbench to correctly handle the combination of \(-C\) and \(-M\) prepared options (Tom Lane)
• In PL/Perl, properly translate empty Postgres arrays into empty Perl arrays (Alex Hunsaker)
• Make PL/Python cope with function names that aren’t valid Python identifiers (Jim Nasby)
• Fix multiple mistakes in the statistics returned by contrib/pgstattuple’s \texttt{pgstatindex()} function (Tom Lane)
• Remove dependency on \texttt{psed} in MSVC builds, since it’s no longer provided by core Perl (Michael
  Paquier, Andrew Dunstan)
• Update time zone data files to tzdata release 2016c for DST law changes in Azerbaijan, Chile, Haiti,
  Palestine, and Russia (Altai, Astrakhan, Kirov, Sakhalin, Ulyanovsk regions), plus historical corrections
  for Lithuania, Moldova, and Russia (Kaliningrad, Samara, Volgograd).

**E.77. Release 9.1.20**

**Release date:** 2016-02-11

This release contains a variety of fixes from 9.1.19. For information about new features in the 9.1 major
release, see Section E.97.

**E.77.1. Migration to Version 9.1.20**

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.16, see Section E.81.

**E.77.2. Changes**

• Fix infinite loops and buffer-overrun problems in regular expressions (Tom Lane)
  Very large character ranges in bracket expressions could cause infinite loops in some cases, and memory
  overwrites in other cases. (CVE-2016-0773)
• Perform an immediate shutdown if the \texttt{postmaster.pid} file is removed (Tom Lane)
  The postmaster now checks every minute or so that \texttt{postmaster.pid} is still there and still contains
  its own PID. If not, it performs an immediate shutdown, as though it had received SIGQUIT. The main
  motivation for this change is to ensure that failed buildfarm runs will get cleaned up without manual
  intervention; but it also serves to limit the bad effects if a DBA forcibly removes \texttt{postmaster.pid}
  and then starts a new postmaster.
• In \texttt{SERIALIZABLE} transaction isolation mode, serialization anomalies could be missed due to race
  conditions during insertions (Kevin Grittner, Thomas Munro)
Appendix E. Release Notes

- Fix failure to emit appropriate WAL records when doing `ALTER TABLE ... SET TABLESPACE` for unlogged relations (Michael Paquier, Andres Freund)
  Even though the relation’s data is unlogged, the move must be logged or the relation will be inaccessible after a standby is promoted to master.
- Fix possible misinitialization of unlogged relations at the end of crash recovery (Andres Freund, Michael Paquier)
- Fix `ALTER COLUMN TYPE` to reconstruct inherited check constraints properly (Tom Lane)
- Fix `REASSIGN OWNED` to change ownership of composite types properly (Álvaro Herrera)
- Fix `REASSIGN OWNED` and `ALTER OWNER` to correctly update granted-permissions lists when changing owners of data types, foreign data wrappers, or foreign servers (Bruce Momjian, Álvaro Herrera)
- Fix `REASSIGN OWNED` to ignore foreign user mappings, rather than fail (Álvaro Herrera)
- Add more defenses against bad planner cost estimates for GIN index scans when the index’s internal statistics are very out-of-date (Tom Lane)
- Make planner cope with hypothetical GIN indexes suggested by an index advisor plug-in (Julien Rouhaud)
- Fix dumping of whole-row Vars in `ROW()` and `VALUES()` lists (Tom Lane)
- Fix possible internal overflow in `numeric` division (Dean Rasheed)
- Fix enforcement of restrictions inside parentheses within regular expression lookahead constraints (Tom Lane)
  Lookahead constraints aren’t allowed to contain backrefs, and parentheses within them are always considered non-capturing, according to the manual. However, the code failed to handle these cases properly inside a parenthesized subexpression, and would give unexpected results.
- Conversion of regular expressions to indexscan bounds could produce incorrect bounds from regexps containing lookahead constraints (Tom Lane)
- Fix regular-expression compiler to handle loops of constraint arcs (Tom Lane)
  The code added for CVE-2007-4772 was both incomplete, in that it didn’t handle loops involving more than one state, and incorrect, in that it could cause assertion failures (though there seem to be no bad consequences of that in a non-assert build). Multi-state loops would cause the compiler to run until the query was canceled or it reached the too-many-states error condition.
- Improve memory-usage accounting in regular-expression compiler (Tom Lane)
  This causes the code to emit “regular expression is too complex” errors in some cases that previously used unreasonable amounts of time and memory.
- Improve performance of regular-expression compiler (Tom Lane)
- Make `%h` and `%r` escapes in `log_line_prefix` work for messages emitted due to `log_connections` (Tom Lane)
  Previously, `%h/r` started to work just after a new session had emitted the “connection received” log message; now they work for that message too.
- On Windows, ensure the shared-memory mapping handle gets closed in child processes that don’t need it (Tom Lane, Amit Kapila)
This oversight resulted in failure to recover from crashes whenever `logging_collector` is turned on.

- Fix possible failure to detect socket EOF in non-blocking mode on Windows (Tom Lane)
  It’s not entirely clear whether this problem can happen in pre-9.5 branches, but if it did, the symptom would be that a walsender process would wait indefinitely rather than noticing a loss of connection.

- Avoid leaking a token handle during SSPI authentication (Christian Ullrich)

- In `psql`, ensure that libreadline’s idea of the screen size is updated when the terminal window size changes (Merlin Moncure)
  Previously, libreadline did not notice if the window was resized during query output, leading to strange behavior during later input of multiline queries.

- Fix `psql`’s `\det` command to interpret its pattern argument the same way as other `\d` commands with potentially schema-qualified patterns do (Reece Hart)

- Avoid possible crash in `psql`’s `\c` command when previous connection was via Unix socket and command specifies a new hostname and same username (Tom Lane)

- In `pg_ctl start` `-w`, test child process status directly rather than relying on heuristics (Tom Lane, Michael Paquier)
  Previously, `pg_ctl` relied on an assumption that the new postmaster would always create `postmaster.pid` within five seconds. But that can fail on heavily-loaded systems, causing `pg_ctl` to report incorrectly that the postmaster failed to start.
  Except on Windows, this change also means that `pg_ctl start` `-w` done immediately after another such command will now reliably fail, whereas previously it would report success if done within two seconds of the first command.

- In `pg_ctl start` `-w`, don’t attempt to use a wildcard listen address to connect to the postmaster (Kondo Yuta)
  On Windows, `pg_ctl` would fail to detect postmaster startup if `listen_addresses` is set to `0.0.0.0` or `::`, because it would try to use that value verbatim as the address to connect to, which doesn’t work. Instead assume that `127.0.0.1` or `::1`, respectively, is the right thing to use.

- In `pg_ctl` on Windows, check service status to decide where to send output, rather than checking if `standard output` is a terminal (Michael Paquier)

- In `pg_dump` and `pg_basebackup`, adopt the GNU convention for handling tar-archive members exceeding 8GB (Tom Lane)
  The POSIX standard for `tar` file format does not allow archive member files to exceed 8GB, but most modern implementations of tar support an extension that fixes that. Adopt this extension so that `pg_dump` with `-Ft` no longer fails on tables with more than 8GB of data, and so that `pg_basebackup` can handle files larger than 8GB. In addition, fix some portability issues that could cause failures for members between 4GB and 8GB on some platforms. Potentially these problems could cause unrecoverable data loss due to unreadable backup files.

- Fix assorted corner-case bugs in `pg_dump`’s processing of extension member objects (Tom Lane)

- Make `pg_dump` mark a view’s triggers as needing to be processed after its rule, to prevent possible failure during parallel `pg_restore` (Tom Lane)

- Ensure that relation option values are properly quoted in `pg_dump` (Kouhei Sutou, Tom Lane)
A reloption value that isn’t a simple identifier or number could lead to dump/reload failures due to syntax errors in CREATE statements issued by pg_dump. This is not an issue with any reloption currently supported by core PostgreSQL, but extensions could allow reloptions that cause the problem.

- Fix pg_upgrade’s file-copying code to handle errors properly on Windows (Bruce Momjian)
- Install guards in pgbench against corner-case overflow conditions during evaluation of script-specified division or modulo operators (Fabien Coelho, Michael Paquier)
- Prevent certain PL/Java parameters from being set by non-superusers (Noah Misch)
  
  This change mitigates a PL/Java security bug (CVE-2016-0766), which was fixed in PL/Java by marking these parameters as superuser-only. To fix the security hazard for sites that update PostgreSQL more frequently than PL/Java, make the core code aware of them also.
- Improve libpq’s handling of out-of-memory situations (Michael Paquier, Amit Kapila, Heikki Linnakangas)
- Fix order of arguments in ecpg-generated typedef statements (Michael Meskes)
- Use %g not %f format in ecpg’s PGTYPEsnumeric_from_double() (Tom Lane)
- Fix ecpg-supplied header files to not contain comments continued from a preprocessor directive line onto the next line (Michael Meskes)
  
  Such a comment is rejected by ecpg. It’s not yet clear whether ecpg itself should be changed.
- Ensure that contrib/pgcrypto’s crypt() function can be interrupted by query cancel (Andreas Karlsson)
- Accept flex versions later than 2.5.x (Tom Lane, Michael Paquier)
  
  Now that flex 2.6.0 has been released, the version checks in our build scripts needed to be adjusted.
- Install our missing script where PGXS builds can find it (Jim Nasby)
  
  This allows sane behavior in a PGXS build done on a machine where build tools such as bison are missing.
- Ensure that dynloader.h is included in the installed header files in MSVC builds (Bruce Momjian, Michael Paquier)
- Add variant regression test expected-output file to match behavior of current libxml2 (Tom Lane)
  
  The fix for libxml2’s CVE-2015-7499 causes it not to output error context reports in some cases where it used to do so. This seems to be a bug, but we’ll probably have to live with it for some time, so work around it.
- Update time zone data files to tzdata release 2016a for DST law changes in Cayman Islands, Metlakatla, and Trans-Baikal Territory (Zabaykalsky Krai), plus historical corrections for Pakistan.

**E.78. Release 9.1.19**

Release date: 2015-10-08

This release contains a variety of fixes from 9.1.18. For information about new features in the 9.1 major release, see Section E.97.
E.78.1. Migration to Version 9.1.19

A dump/restore is not required for those running 9.1.X.
However, if you are upgrading from a version earlier than 9.1.16, see Section E.81.

E.78.2. Changes

- Fix contrib/pgcrypto to detect and report too-short crypt() salts (Josh Kupershmidt)
  Certain invalid salt arguments crashed the server or disclosed a few bytes of server memory. We have not ruled out the viability of attacks that arrange for presence of confidential information in the disclosed bytes, but they seem unlikely. (CVE-2015-5288)

- Fix subtransaction cleanup after a portal (cursor) belonging to an outer subtransaction fails (Tom Lane, Michael Paquier)
  A function executed in an outer-subtransaction cursor could cause an assertion failure or crash by referencing a relation created within an inner subtransaction.

- Fix insertion of relations into the relation cache “init file” (Tom Lane)
  An oversight in a patch in the most recent minor releases caused pg_trigger_tgrelid_tgname_index to be omitted from the init file. Subsequent sessions detected this, then deemed the init file to be broken and silently ignored it, resulting in a significant degradation in session startup time. In addition to fixing the bug, install some guards so that any similar future mistake will be more obvious.

- Avoid $O(N^2)$ behavior when inserting many tuples into a SPI query result (Neil Conway)

- Improve LISTEN startup time when there are many unread notifications (Matt Newell)

- Back-patch 9.3-era addition of per-resource-owner lock caches (Jeff Janes)
  This substantially improves performance when pg_dump tries to dump a large number of tables.

- Disable SSL renegotiation by default (Michael Paquier, Andres Freund)
  While use of SSL renegotiation is a good idea in theory, we have seen too many bugs in practice, both in the underlying OpenSSL library and in our usage of it. Renegotiation will be removed entirely in 9.5 and later. In the older branches, just change the default value of ssl_renegotiation_limit to zero (disabled).

- Lower the minimum values of the *_freeze_max_age parameters (Andres Freund)
  This is mainly to make tests of related behavior less time-consuming, but it may also be of value for installations with limited disk space.

- Limit the maximum value of wal_buffers to 2GB to avoid server crashes (Josh Berkus)

- Fix rare internal overflow in multiplication of numeric values (Dean Rasheed)

- Guard against hard-to-reach stack overflows involving record types, range types, json, jsonb, tsquery, ltxtquery and query_int (Noah Misch)

- Fix handling of DOW and DOY in datetime input (Greg Stark)
These tokens aren’t meant to be used in datetime values, but previously they resulted in opaque internal error messages rather than “invalid input syntax”.

- Add more query-cancel checks to regular expression matching (Tom Lane)
- Add recursion depth protections to regular expression, **SIMILAR TO**, and **LIKE** matching (Tom Lane)
  Suitable search patterns and a low stack depth limit could lead to stack-overflow crashes.
- Fix potential infinite loop in regular expression execution (Tom Lane)
  A search pattern that can apparently match a zero-length string, but actually doesn’t match because of a back reference, could lead to an infinite loop.
- Fix low-memory failures in regular expression compilation (Andreas Seltenreich)
- Fix low-probability memory leak during regular expression execution (Tom Lane)
- Fix rare low-memory failure in lock cleanup during transaction abort (Tom Lane)
- Fix “unexpected out-of-memory situation during sort” errors when using tuplestores with small `work_mem` settings (Tom Lane)
- Fix very-low-probability stack overrun in `qsort` (Tom Lane)
- Fix “invalid memory alloc request size” failure in hash joins with large `work_mem` settings (Tomas Vondra, Tom Lane)
- Fix assorted planner bugs (Tom Lane)
  These mistakes could lead to incorrect query plans that would give wrong answers, or to assertion failures in assert-enabled builds, or to odd planner errors such as “could not devise a query plan for the given query”, “could not find pathkey item to sort”, “plan should not reference subplan’s variable”, or “failed to assign all NestLoopParams to plan nodes”. Thanks are due to Andreas Seltenreich and Piotr Stefaniak for fuzz testing that exposed these problems.
- Use fuzzy path cost tiebreaking rule in all supported branches (Tom Lane)
  This change is meant to avoid platform-specific behavior when alternative plan choices have effectively-identical estimated costs.
- Ensure standby promotion trigger files are removed at postmaster startup (Michael Paquier, Fujii Masao)
  This prevents unwanted promotion from occurring if these files appear in a database backup that is used to initialize a new standby server.
- During postmaster shutdown, ensure that per-socket lock files are removed and listen sockets are closed before we remove the `postmaster.pid` file (Tom Lane)
  This avoids race-condition failures if an external script attempts to start a new postmaster as soon as `pg_ctl stop` returns.
- Fix postmaster’s handling of a startup-process crash during crash recovery (Tom Lane)
  If, during a crash recovery cycle, the startup process crashes without having restored database consistency, we’d try to launch a new startup process, which typically would just crash again, leading to an infinite loop.
- Do not print a **WARNING** when an autovacuum worker is already gone when we attempt to signal it, and reduce log verbosity for such signals (Tom Lane)
• Prevent autovacuum launcher from sleeping unduly long if the server clock is moved backwards a large amount (Álvaro Herrera)

• Ensure that cleanup of a GIN index’s pending-insertions list is interruptable by cancel requests (Jeff Janes)

• Allow all-zeroes pages in GIN indexes to be reused (Heikki Linnakangas)
  Such a page might be left behind after a crash.

• Fix off-by-one error that led to otherwise-harmless warnings about “apparent wraparound” in subtrans/multixact truncation (Thomas Munro)

• Fix misreporting of CONTINUE and MOVE statement types in PL/pgSQL’s error context messages (Pavel Stehule, Tom Lane)

• Fix PL/Perl to handle non-ASCII error message texts correctly (Alex Hunsaker)

• Fix PL/Python crash when returning the string representation of a record result (Tom Lane)

• Fix some places in PL/Tcl that neglected to check for failure of malloc() calls (Michael Paquier, Álvaro Herrera)

• In contrib/isn, fix output of ISBN-13 numbers that begin with 979 (Fabien Coelho)
  EANs beginning with 979 (but not 9790) are considered ISBNs, but they must be printed in the new 13-digit format, not the 10-digit format.

• Improve libpq’s handling of out-of-memory conditions (Michael Paquier, Heikki Linnakangas)

• Fix memory leaks and missing out-of-memory checks in ecpg (Michael Paquier)

• Fix psql’s code for locale-aware formatting of numeric output (Tom Lane)
  The formatting code invoked by \pset numericlocale on did the wrong thing for some uncommon cases such as numbers with an exponent but no decimal point. It could also mangle already-localized output from the money data type.

• Prevent crash in psql’s \c command when there is no current connection (Noah Misch)

• Fix selection of default zlib compression level in pg_dump’s directory output format (Andrew Dunstan)

• Ensure that temporary files created during a pg_dump run with tar-format output are not world-readable (Michael Paquier)

• Fix pg_dump and pg_upgrade to support cases where the postgres or template1 database is in a non-default tablespace (Marti Raudsepp, Bruce Momjian)

• Fix pg_dump to handle object privileges sanely when dumping from a server too old to have a particular privilege type (Tom Lane)
  When dumping functions or procedural languages from pre-7.3 servers, pg_dump would produce GRANT/REVOKE commands that revoked the owner’s grantable privileges and instead granted all privileges to PUBLIC. Since the privileges involved are just USAGE and EXECUTE, this isn’t a security problem, but it’s certainly a surprising representation of the older systems’ behavior. Fix it to leave the default privilege state alone in these cases.

• Fix pg_dump to dump shell types (Tom Lane)
  Shell types (that is, not-yet-fully-defined types) aren’t useful for much, but nonetheless pg_dump should dump them.
• Fix assorted minor memory leaks in pg_dump and other client-side programs (Michael Paquier)
• Fix spinlock assembly code for PPC hardware to be compatible with AIX’s native assembler (Tom Lane)
  Building with gcc didn’t work if gcc had been configured to use the native assembler, which is becoming more common.
• On AIX, test the -qlonglong compiler option rather than just assuming it’s safe to use (Noah Misch)
• On AIX, use -Wl,-brtlilib link option to allow symbols to be resolved at runtime (Noah Misch)
  Perl relies on this ability in 5.8.0 and later.
• Avoid use of inline functions when compiling with 32-bit xlc, due to compiler bugs (Noah Misch)
• Use libcrt for sched_yield() when necessary, which it is on some Solaris versions (Oskari Saarenmaa)
• Fix Windows install.bat script to handle target directory names that contain spaces (Heikki Linnakangas)
• Make the numeric form of the PostgreSQL version number (e.g., 90405) readily available to extension Makefiles, as a variable named VERSION_NUM (Michael Paquier)
• Update time zone data files to tzdata release 2015g for DST law changes in Cayman Islands, Fiji, Moldova, Morocco, Norfolk Island, North Korea, Turkey, and Uruguay. There is a new zone name America/Fort_Nelson for the Canadian Northern Rockies.

E.79. Release 9.1.18

Release date: 2015-06-12
This release contains a small number of fixes from 9.1.17. For information about new features in the 9.1 major release, see Section E.97.

E.79.1. Migration to Version 9.1.18
A dump/restore is not required for those running 9.1.X.
However, if you are upgrading from a version earlier than 9.1.16, see Section E.81.

E.79.2. Changes
• Fix rare failure to invalidate relation cache init file (Tom Lane)
  With just the wrong timing of concurrent activity, a VACUUM FULL on a system catalog might fail to update the “init file” that’s used to avoid cache-loading work for new sessions. This would result in later sessions being unable to access that catalog at all. This is a very ancient bug, but it’s so hard to trigger that no reproducible case had been seen until recently.
• Avoid deadlock between incoming sessions and `CREATE/DROP DATABASE` (Tom Lane)

A new session starting in a database that is the target of a `DROP DATABASE` command, or is the template for a `CREATE DATABASE` command, could cause the command to wait for five seconds and then fail, even if the new session would have exited before that.

E.80. Release 9.1.17

Release date: 2015-06-04

This release contains a small number of fixes from 9.1.16. For information about new features in the 9.1 major release, see Section E.97.

E.80.1. Migration to Version 9.1.17

A dump/restore is not required for those running 9.1.X. However, if you are upgrading from a version earlier than 9.1.16, see Section E.81.

E.80.2. Changes

• Avoid failures while `fsync`ing data directory during crash restart (Abhijit Menon-Sen, Tom Lane)

In the previous minor releases we added a patch to `fsync` everything in the data directory after a crash. Unfortunately its response to any error condition was to fail, thereby preventing the server from starting up, even when the problem was quite harmless. An example is that an unwritable file in the data directory would prevent restart on some platforms; but it is common to make SSL certificate files unwritable by the server. Revise this behavior so that permissions failures are ignored altogether, and other types of failures are logged but do not prevent continuing.

• Remove configure’s check prohibiting linking to a threaded libpython on OpenBSD (Tom Lane)

The failure this restriction was meant to prevent seems to not be a problem anymore on current OpenBSD versions.

• Allow `libpq` to use TLS protocol versions beyond v1 (Noah Misch)

For a long time, `libpq` was coded so that the only SSL protocol it would allow was TLS v1. Now that newer TLS versions are becoming popular, allow it to negotiate the highest commonly-supported TLS version with the server. (PostgreSQL servers were already capable of such negotiation, so no change is needed on the server side.) This is a back-patch of a change already released in 9.4.0.

E.81. Release 9.1.16

Release date: 2015-05-22
This release contains a variety of fixes from 9.1.15. For information about new features in the 9.1 major release, see Section E.97.

**E.81.1. Migration to Version 9.1.16**

A dump/restore is not required for those running 9.1.X.

However, if you use contrib/citext’s `regexp_matches()` functions, see the changelog entry below about that.

Also, if you are upgrading from a version earlier than 9.1.14, see Section E.83.

**E.81.2. Changes**

- Avoid possible crash when client disconnects just before the authentication timeout expires (Benkocs Norbert Attila)

  If the timeout interrupt fired partway through the session shutdown sequence, SSL-related state would be freed twice, typically causing a crash and hence denial of service to other sessions. Experimentation shows that an unauthenticated remote attacker could trigger the bug somewhat consistently, hence treat as security issue. (CVE-2015-3165)

- Improve detection of system-call failures (Noah Misch)

  Our replacement implementation of `snprintf()` failed to check for errors reported by the underlying system library calls; the main case that might be missed is out-of-memory situations. In the worst case this might lead to information exposure, due to our code assuming that a buffer had been overwritten when it hadn’t been. Also, there were a few places in which security-relevant calls of other system library functions did not check for failure.

  It remains possible that some calls of the `printf()` family of functions are vulnerable to information disclosure if an out-of-memory error occurs at just the wrong time. We judge the risk to not be large, but will continue analysis in this area. (CVE-2015-3166)

- In contrib/pgcrypto, uniformly report decryption failures as “Wrong key or corrupt data” (Noah Misch)

  Previously, some cases of decryption with an incorrect key could report other error message texts. It has been shown that such variance in error reports can aid attackers in recovering keys from other systems. While it’s unknown whether pgcrypto’s specific behaviors are likewise exploitable, it seems better to avoid the risk by using a one-size-fits-all message. (CVE-2015-3167)

- Fix incorrect declaration of contrib/citext’s `regexp_matches()` functions (Tom Lane)

  These functions should return `setof text[]`, like the core functions they are wrappers for; but they were incorrectly declared as returning just `text[]`. This mistake had two results: first, if there was no match you got a scalar null result, whereas what you should get is an empty set (zero rows). Second, the `g` flag was effectively ignored, since you would get only one result array even if there were multiple matches.

  While the latter behavior is clearly a bug, there might be applications depending on the former behavior; therefore the function declarations will not be changed by default until PostgreSQL 9.5. In pre-9.5
branches, the old behavior exists in version 1.0 of the citext extension, while we have provided corrected declarations in version 1.1 (which is not installed by default). To adopt the fix in pre-9.5 branches, execute ALTER EXTENSION citext UPDATE TO '1.1' in each database in which citext is installed. (You can also “update” back to 1.0 if you need to undo that.) Be aware that either update direction will require dropping and recreating any views or rules that use citext's regexp_matches() functions.

- Fix incorrect checking of deferred exclusion constraints after a HOT update (Tom Lane)
  
  If a new row that potentially violates a deferred exclusion constraint is HOT-updated (that is, no indexed columns change and the row can be stored back onto the same table page) later in the same transaction, the exclusion constraint would be reported as violated when the check finally occurred, even if the row(s) the new row originally conflicted with had been deleted.

- Prevent improper reordering of antijoins (NOT EXISTS joins) versus other outer joins (Tom Lane)
  
  This oversight in the planner has been observed to cause “could not find RelOptInfo for given relids” errors, but it seems possible that sometimes an incorrect query plan might get past that consistency check and result in silently-wrong query output.

- Fix incorrect matching of subexpressions in outer-join plan nodes (Tom Lane)
  
  Previously, if textually identical non-strict subexpressions were used both above and below an outer join, the planner might try to re-use the value computed below the join, which would be incorrect because the executor would force the value to NULL in case of an unmatched outer row.

- Fix GEQO planner to cope with failure of its join order heuristic (Tom Lane)
  
  This oversight has been seen to lead to “failed to join all relations together” errors in queries involving LATERAL, and that might happen in other cases as well.

- Fix possible deadlock at startup when max_prepared_transactions is too small (Heikki Linnakangas)
  
- Don’t archive useless preallocated WAL files after a timeline switch (Heikki Linnakangas)

- Avoid “cannot GetMultiXactIdMembers() during recovery” error (Álvaro Herrera)

- Recursively fsync() the data directory after a crash (Abhijit Menon-Sen, Robert Haas)
  
  This ensures consistency if another crash occurs shortly later. (The second crash would have to be a system-level crash, not just a database crash, for there to be a problem.)

- Fix autovacuum launcher’s possible failure to shut down, if an error occurs after it receives SIGTERM (Álvaro Herrera)

- Cope with unexpected signals in LockBufferForCleanup() (Andres Freund)
  
  This oversight could result in spurious errors about “multiple backends attempting to wait for pincount 1”.

- Avoid waiting for WAL flush or synchronous replication during commit of a transaction that was read-only so far as the user is concerned (Andres Freund)
  
  Previously, a delay could occur at commit in transactions that had written WAL due to HOT page pruning, leading to undesirable effects such as sessions getting stuck at startup if all synchronous replicas are down. Sessions have also been observed to get stuck in catchup interrupt processing when using synchronous replication; this will fix that problem as well.
Appendix E. Release Notes

- Fix crash when manipulating hash indexes on temporary tables (Heikki Linnakangas)
- Fix possible failure during hash index bucket split, if other processes are modifying the index concurrently (Tom Lane)
- Check for interrupts while analyzing index expressions (Jeff Janes)

`ANALYZE` executes index expressions many times; if there are slow functions in such an expression, it’s desirable to be able to cancel the `ANALYZE` before that loop finishes.

- Ensure `tableoid` of a foreign table is reported correctly when a `READ COMMITTED` recheck occurs after locking rows in `SELECT FOR UPDATE`, `UPDATE`, or `DELETE` (Etsuro Fujita)
- Add the name of the target server to object description strings for foreign-server user mappings (Álvaro Herrera)
- Recommend setting `include_realm` to 1 when using Kerberos/GSSAPI/SSPI authentication (Stephen Frost)

Without this, identically-named users from different realms cannot be distinguished. For the moment this is only a documentation change, but it will become the default setting in PostgreSQL 9.5.

- Remove code for matching IPv4 `pg_hba.conf` entries to IPv4-in-IPv6 addresses (Tom Lane)

This hack was added in 2003 in response to a report that some Linux kernels of the time would report IPv4 connections as having IPv4-in-IPv6 addresses. However, the logic was accidentally broken in 9.0. The lack of any field complaints since then shows that it’s not needed anymore. Now we have reports that the broken code causes crashes on some systems, so let’s just remove it rather than fix it. (Had we chosen to fix it, that would make for a subtle and potentially security-sensitive change in the effective meaning of IPv4 `pg_hba.conf` entries, which does not seem like a good thing to do in minor releases.)

- Report WAL flush, not insert, position in `IDENTIFY_SYSTEM` replication command (Heikki Linnakangas)

This avoids a possible startup failure in `pg_receivexlog`.

- While shutting down service on Windows, periodically send status updates to the Service Control Manager to prevent it from killing the service too soon; and ensure that `pg_ctl` will wait for shutdown (Krystian Bigaj)

- Reduce risk of network deadlock when using `libpq`’s non-blocking mode (Heikki Linnakangas)

When sending large volumes of data, it’s important to drain the input buffer every so often, in case the server has sent enough response data to cause it to block on output. (A typical scenario is that the server is sending a stream of NOTICE messages during `COPY FROM STDIN`.) This worked properly in the normal blocking mode, but not so much in non-blocking mode. We’ve modified `libpq` to opportunistically drain input when it can, but a full defense against this problem requires application cooperation: the application should watch for socket read-ready as well as write-ready conditions, and be sure to call `PQconsumeInput()` upon read-ready.

- Fix array handling in `ecpg` (Michael Meskes)

- Fix `psql` to sanely handle URIs and `conninfo` strings as the first parameter to `\connect` (David Fetter, Andrew Dunstan, Álvaro Herrera)

This syntax has been accepted (but undocumented) for a long time, but previously some parameters might be taken from the old connection instead of the given string, which was agreed to be undesirable.
• Suppress incorrect complaints from psql on some platforms that it failed to write ~/.psql_history at exit (Tom Lane)

This misbehavior was caused by a workaround for a bug in very old (pre-2006) versions of libedit. We fixed it by removing the workaround, which will cause a similar failure to appear for anyone still using such versions of libedit. Recommendation: upgrade that library, or use libreadline.

• Fix pg_dump’s rule for deciding which casts are system-provided casts that should not be dumped (Tom Lane)

• In pg_dump, fix failure to honor -Z compression level option together with -Fd (Michael Paquier)

• Make pg_dump consider foreign key relationships between extension configuration tables while choosing dump order (Gilles Darold, Michael Paquier, Stephen Frost)

This oversight could result in producing dumps that fail to reload because foreign key constraints are transiently violated.

• Fix dumping of views that are just VALUES(...) but have column aliases (Tom Lane)

• In pg_upgrade, force timeline 1 in the new cluster (Bruce Momjian)

This change prevents upgrade failures caused by bogus complaints about missing WAL history files.

• In pg_upgrade, check for improperly non-connectable databases before proceeding (Bruce Momjian)

• In pg_upgrade, quote directory paths properly in the generated delete_old_cluster script (Bruce Momjian)

• In pg_upgrade, preserve database-level freezing info properly (Bruce Momjian)

This oversight could cause missing-clog-file errors for tables within the postgres and template1 databases.

• Run pg_upgrade and pg_resetxlog with restricted privileges on Windows, so that they don’t fail when run by an administrator (Muhammad Asif Naeem)

• Improve handling of readdir() failures when scanning directories in initdb and pg_basebackup (Marco Nenciarini)

• Fix slow sorting algorithm in contrib/intarray (Tom Lane)

• Fix compile failure on Sparc V8 machines (Rob Rowan)

• Update time zone data files to tzdata release 2015d for DST law changes in Egypt, Mongolia, and Palestine, plus historical changes in Canada and Chile. Also adopt revised zone abbreviations for the America/Adak zone (HST/HDT not HAST/HADT).

E.82. Release 9.1.15

Release date: 2015-02-05

This release contains a variety of fixes from 9.1.14. For information about new features in the 9.1 major release, see Section E.97.
Appendix E. Release Notes

E.82.1. Migration to Version 9.1.15

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.14, see Section E.83.

E.82.2. Changes

- Fix buffer overruns in `to_char()` (Bruce Momjian)

  When `to_char()` processes a numeric formatting template calling for a large number of digits, PostgreSQL would read past the end of a buffer. When processing a crafted timestamp formatting template, PostgreSQL would write past the end of a buffer. Either case could crash the server. We have not ruled out the possibility of attacks that lead to privilege escalation, though they seem unlikely. (CVE-2015-0241)

- Fix buffer overrun in replacement `*printf()` functions (Tom Lane)

  PostgreSQL includes a replacement implementation of `printf` and related functions. This code will overrun a stack buffer when formatting a floating point number (conversion specifiers `e`, `E`, `f`, `F`, `g` or `G`) with requested precision greater than about 500. This will crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. A database user can trigger such a buffer overrun through the `to_char()` SQL function. While that is the only affected core PostgreSQL functionality, extension modules that use printf-family functions may be at risk as well.

  This issue primarily affects PostgreSQL on Windows. PostgreSQL uses the system implementation of these functions where adequate, which it is on other modern platforms. (CVE-2015-0242)

- Fix buffer overruns in `contrib/pgcrypto` (Marko Tiikkaja, Noah Misch)

  Errors in memory size tracking within the `pgcrypto` module permitted stack buffer overruns and improper dependence on the contents of uninitialized memory. The buffer overrun cases can crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. (CVE-2015-0243)

- Fix possible loss of frontend/backend protocol synchronization after an error (Heikki Linnakangas)

  If any error occurred while the server was in the middle of reading a protocol message from the client, it could lose synchronization and incorrectly try to interpret part of the message’s data as a new protocol message. An attacker able to submit crafted binary data within a command parameter might succeed in injecting his own SQL commands this way. Statement timeout and query cancellation are the most likely sources of errors triggering this scenario. Particularly vulnerable are applications that use a timeout and also submit arbitrary user-crafted data as binary query parameters. Disabling statement timeout will reduce, but not eliminate, the risk of exploit. Our thanks to Emil Lenngren for reporting this issue. (CVE-2015-0244)

- Fix information leak via constraint-violation error messages (Stephen Frost)

  Some server error messages show the values of columns that violate a constraint, such as a unique constraint. If the user does not have `SELECT` privilege on all columns of the table, this could mean exposing values that the user should not be able to see. Adjust the code so that values are displayed only when they came from the SQL command or could be selected by the user. (CVE-2014-8161)
Appendix E. Release Notes

• Lock down regression testing’s temporary installations on Windows (Noah Misch)
  Use SSPI authentication to allow connections only from the OS user who launched the test suite. This
closes on Windows the same vulnerability previously closed on other platforms, namely that other users
might be able to connect to the test postmaster. (CVE-2014-0067)

• Avoid possible data corruption if \texttt{ALTER DATABASE SET TABLESPACE} is used to move a database to
  a new tablespace and then shortly later move it back to its original tablespace (Tom Lane)

• Avoid corrupting tables when \texttt{ANALYZE} inside a transaction is rolled back (Andres Freund, Tom Lane,
  Michael Paquier)
  If the failing transaction had earlier removed the last index, rule, or trigger from the table, the table
  would be left in a corrupted state with the relevant \texttt{pg_class} flags not set though they should be.

• Ensure that unlogged tables are copied correctly during \texttt{CREATE DATABASE} or \texttt{ALTER DATABASE SET}
  TABLESPACE (Pavan Deolasee, Andres Freund)

• Fix \texttt{DROP}’s dependency searching to correctly handle the case where a table column is recursively
  visited before its table (Petr Jelinek, Tom Lane)
  This case is only known to arise when an extension creates both a datatype and a table using that
datatype. The faulty code might refuse a \texttt{DROP EXTENSION} unless \texttt{CASCADE} is specified, which should
  not be required.

• Fix use-of-already-freed-memory problem in EvalPlanQual processing (Tom Lane)
  In \texttt{READ COMMITTED} mode, queries that lock or update recently-updated rows could crash as a result
  of this bug.

• Fix planning of \texttt{SELECT FOR UPDATE} when using a partial index on a child table (Kyotaro Horiguchi)
  In \texttt{READ COMMITTED} mode, \texttt{SELECT FOR UPDATE} must also recheck the partial index’s \texttt{WHERE}
  condition when rechecking a recently-updated row to see if it still satisfies the query’s \texttt{WHERE} condition.
  This requirement was missed if the index belonged to an inheritance child table, so that it was possible
to incorrectly return rows that no longer satisfy the query condition.

• Fix corner case wherein \texttt{SELECT FOR UPDATE} could return a row twice, and possibly miss returning
  other rows (Tom Lane)
  In \texttt{READ COMMITTED} mode, a \texttt{SELECT FOR UPDATE} that is scanning an inheritance tree could incor-
  rectly return a row from a prior child table instead of the one it should return from a later child table.

• Reject duplicate column names in the referenced-columns list of a \texttt{FOREIGN KEY} declaration (David
  Rowley)
  This restriction is per SQL standard. Previously we did not reject the case explicitly, but later on the
code would fail with bizarre-looking errors.

• Fix bugs in raising a \texttt{numeric} value to a large integral power (Tom Lane)
  The previous code could get a wrong answer, or consume excessive amounts of time and memory
  before realizing that the answer must overflow.

• In \texttt{numeric_recv()}, truncate away any fractional digits that would be hidden according to the value’s
  \texttt{dscale} field (Tom Lane)
  A \texttt{numeric} value’s display scale (\texttt{dscale}) should never be less than the number of nonzero fractional
digits; but apparently there’s at least one broken client application that transmits binary \texttt{numeric} values
in which that’s true. This leads to strange behavior since the extra digits are taken into account by
arithmetic operations even though they aren’t printed. The least risky fix seems to be to truncate away
such “hidden” digits on receipt, so that the value is indeed what it prints as.

• Reject out-of-range numeric timezone specifications (Tom Lane)
  Simple numeric timezone specifications exceeding +/- 168 hours (one week) would be accepted, but
could then cause null-pointer dereference crashes in certain operations. There’s no use-case for such
large UTC offsets, so reject them.

• Fix bugs in tsquery @> tsquery operator (Heikki Linnakangas)
  Two different terms would be considered to match if they had the same CRC. Also, if the second
operand had more terms than the first, it would be assumed not to be contained in the first; which is
wrong since it might contain duplicate terms.

• Improve ispell dictionary’s defenses against bad affix files (Tom Lane)

• Allow more than 64K phrases in a thesaurus dictionary (David Boutin)
  The previous coding could crash on an oversize dictionary, so this was deemed a back-patchable bug
fix rather than a feature addition.

• Fix namespace handling in xpath() (Ali Akbar)
  Previously, the xml value resulting from an xpath() call would not have namespace declarations if the
namespace declarations were attached to an ancestor element in the input xml value, rather than to the
specific element being returned. Propagate the ancestral declaration so that the result is correct when
considered in isolation.

• Fix planner problems with nested append relations, such as inherited tables within UNION ALL sub-
queries (Tom Lane)

• Fail cleanly when a GiST index tuple doesn’t fit on a page, rather than going into infinite recursion
  (Andrew Gierth)

• Exempt tables that have per-table cost_limit and/or cost_delay settings from autovacuum’s global
cost balancing rules (Alvaro Herrera)
  The previous behavior resulted in basically ignoring these per-table settings, which was unintended.
  Now, a table having such settings will be vacuumed using those settings, independently of what is
  going on in other autovacuum workers. This may result in heavier total I/O load than before, so such
  settings should be re-examined for sanity.

• Avoid wholesale autovacuuming when autovacuum is nominally off (Tom Lane)
  Even when autovacuum is nominally off, we will still launch autovacuum worker processes to vacuum
tables that are at risk of XID wraparound. However, such a worker process then proceeded to vacuum
all tables in the target database, if they met the usual thresholds for autovacuuming. This is at best pretty
unexpected; at worst it delays response to the wraparound threat. Fix it so that if autovacuum is turned
off, workers only do anti-wraparound vacuums and not any other work.

• During crash recovery, ensure that unlogged relations are rewritten as empty and are synced to disk
  before recovery is considered complete (Abhijit Menon-Sen, Andres Freund)
  This prevents scenarios in which unlogged relations might contain garbage data following database
  crash recovery.

• Fix race condition between hot standby queries and replaying a full-page image (Heikki Linnakangas)
This mistake could result in transient errors in queries being executed in hot standby.

- Fix several cases where recovery logic improperly ignored WAL records for COMMIT/ABORT PREPARED (Heikki Linnakangas)

The most notable oversight was that recovery_target_xid could not be used to stop at a two-phase commit.

- Avoid creating unnecessary .ready marker files for timeline history files (Fujii Masao)

- Fix possible null pointer dereference when an empty prepared statement is used and the log_statement setting is mod or ddl (Fujii Masao)

- Change “pgstat wait timeout” warning message to be LOG level, and rephrase it to be more understandable (Tom Lane)

  This message was originally thought to be essentially a can’t-happen case, but it occurs often enough on our slower buildfarm members to be a nuisance. Reduce it to LOG level, and expend a bit more effort on the wording: it now reads “using stale statistics instead of current ones because stats collector is not responding”.

- Fix SPARC spinlock implementation to ensure correctness if the CPU is being run in a non-TSO coherency mode, as some non-Solaris kernels do (Andres Freund)

- Warn if macOS’s setlocale() starts an unwanted extra thread inside the postmaster (Noah Misch)

- Fix processing of repeated dbname parameters in PQconnectdbParams() (Alex Shulgin)

  Unexpected behavior ensued if the first occurrence of dbname contained a connection string or URI to be expanded.

- Ensure that libpq reports a suitable error message on unexpected socket EOF (Marko Tiikkaja, Tom Lane)

  Depending on kernel behavior, libpq might return an empty error string rather than something useful when the server unexpectedly closed the socket.

- Clear any old error message during PQreset() (Heikki Linnakangas)

  If PQreset() is called repeatedly, and the connection cannot be re-established, error messages from the failed connection attempts kept accumulating in the PGconn’s error string.

- Properly handle out-of-memory conditions while parsing connection options in libpq (Alex Shulgin, Heikki Linnakangas)

- Fix array overrun in ecpg’s version of ParseDateTime() (Michael Paquier)

- In initdb, give a clearer error message if a password file is specified but is empty (Mats Erik Andersson)

- Fix psql’s \s command to work nicely with libedit, and add pager support (Stepan Rutz, Tom Lane)

  When using libedit rather than readline, \s printed the command history in a fairly unreadable encoded format, and on recent libedit versions might fail altogether. Fix that by printing the history ourselves rather than having the library do it. A pleasant side-effect is that the pager is used if appropriate.

  This patch also fixes a bug that caused newline encoding to be applied inconsistently when saving the command history with libedit. Multiline history entries written by older psql versions will be read cleanly with this patch, but perhaps not vice versa, depending on the exact libedit versions involved.

- Improve consistency of parsing of psql’s special variables (Tom Lane)
Appendix E. Release Notes

Allow variant spellings of on and off (such as 1/0) for ECHO_HIDDEN and ON_ERROR_ROLLBACK. Report a warning for unrecognized values for COMP_KEYWORD_CASE, ECHO, ECHO_HIDDEN, HISTCONTROL, ON_ERROR_ROLLBACK, and VERBOSITY. Recognize all values for all these variables case-insensitively; previously there was a mishmash of case-sensitive and case-insensitive behaviors.

- Fix psql’s expanded-mode display to work consistently when using border = 3 and linestyle = ascii or unicode (Stephen Frost)
- Improve performance of pg_dump when the database contains many instances of multiple dependency paths between the same two objects (Tom Lane)
- Fix possible deadlock during parallel restore of a schema-only dump (Robert Haas, Tom Lane)
- Fix core dump in pg_dump --binary-upgrade on zero-column composite type (Rushabh Lathia)
- Prevent WAL files created by pg_basebackup -x/-X from being archived again when the standby is promoted (Andres Freund)
- Fix upgrade-from-unpackaged script for contrib/citext (Tom Lane)
- Fix block number checking in contrib/pageinspect’s get_raw_page() (Tom Lane)
  The incorrect checking logic could prevent access to some pages in non-main relation forks.
- Fix contrib/pgcrypto’s pgp_sym_decrypt() to not fail on messages whose length is 6 less than a power of 2 (Marko Tiikkaja)
- Fix file descriptor leak in contrib/pg_test_fsync (Jeff Janes)
  This could cause failure to remove temporary files on Windows.
- Handle unexpected query results, especially NULLs, safely in contrib/tablefunc’s connectby() (Michael Paquier)
  connectby() previously crashed if it encountered a NULL key value. It now prints that row but doesn’t recurse further.
- Avoid a possible crash in contrib/xml2’s xslt_process() (Mark Simonetti)
  libxslt seems to have an undocumented dependency on the order in which resources are freed; reorder our calls to avoid a crash.
- Mark some contrib I/O functions with correct volatility properties (Tom Lane)
  The previous over-conservative marking was immaterial in normal use, but could cause optimization problems or rejection of valid index expression definitions. Since the consequences are not large, we’ve just adjusted the function definitions in the extension modules’ scripts, without changing version numbers.
- Numerous cleanups of warnings from Coverity static code analyzer (Andres Freund, Tatsuo Ishii, Marko Kreen, Tom Lane, Michael Paquier)
  These changes are mostly cosmetic but in some cases fix corner-case bugs, for example a crash rather than a proper error report after an out-of-memory failure. None are believed to represent security issues.
- Detect incompatible OpenLDAP versions during build (Noah Misch)
  With OpenLDAP versions 2.4.24 through 2.4.31, inclusive, PostgreSQL backends can crash at exit. Raise a warning during configure based on the compile-time OpenLDAP version number, and test the crashing scenario in the contrib/dblink regression test.
Appendix E. Release Notes

- In non-MSVC Windows builds, ensure libpq.dll is installed with execute permissions (Noah Misch)
- Make pg_regress remove any temporary installation it created upon successful exit (Tom Lane)
  This results in a very substantial reduction in disk space usage during make check-world, since that
  sequence involves creation of numerous temporary installations.
- Support time zone abbreviations that change UTC offset from time to time (Tom Lane)
  Previously, PostgreSQL assumed that the UTC offset associated with a time zone abbreviation (such
  as EST) never changes in the usage of any particular locale. However this assumption fails in the real
  world, so introduce the ability for a zone abbreviation to represent a UTC offset that sometimes changes.
  Update the zone abbreviation definition files to make use of this feature in timezone locales that have
  changed the UTC offset of their abbreviations since 1970 (according to the IANA timezone database).
  In such timezones, PostgreSQL will now associate the correct UTC offset with the abbreviation de-
  pending on the given date.
- Update time zone abbreviations lists (Tom Lane)
  Add CST (China Standard Time) to our lists. Remove references to ADT as “Arabia Daylight Time”,
  an abbreviation that’s been out of use since 2007; therefore, claiming there is a conflict with “Atlantic
  Daylight Time” doesn’t seem especially helpful. Fix entirely incorrect GMT offsets for CKT (Cook
  Islands), FJT, and FJST (Fiji); we didn’t even have them on the proper side of the date line.
- Update time zone data files to tzdata release 2015a.
  The IANA timezone database has adopted abbreviations of the form AxST/AxDT for all Australian time
  zones, reflecting what they believe to be current majority practice Down Under. These names do not
  conflict with usage elsewhere (other than ACST for Acre Summer Time, which has been in disuse since
  1994). Accordingly, adopt these names into our “Default” timezone abbreviation set. The “Australia”
  abbreviation set now contains only CST, EAST, EST, SAST, SAT, and WST, all of which are thought
  to be mostly historical usage. Note that SAST has also been changed to be South Africa Standard Time
  in the “Default” abbreviation set.
  Also, add zone abbreviations SRET (Asia/Srednekolymsk) and XJT (Asia/Urumqi), and use
  WSST/WSDT for western Samoa. Also, there were DST law changes in Chile, Mexico, the Turks &
  Caicos Islands (America/Grand_Turk), and Fiji. There is a new zone Pacific/Bougainville for portions
  of Papua New Guinea. Also, numerous corrections for historical (pre-1970) time zone data.

E.83. Release 9.1.14

Release date: 2014-07-24
This release contains a variety of fixes from 9.1.13. For information about new features in the 9.1 major
release, see Section E.97.

E.83.1. Migration to Version 9.1.14

A dump/restore is not required for those running 9.1.X.

However, this release corrects an index corruption problem in some GiST indexes. See the first changelog
entry below to find out whether your installation has been affected and what steps you should take if so.
Appendix E. Release Notes

Also, if you are upgrading from a version earlier than 9.1.11, see Section E.86.

E.83.2. Changes

• Correctly initialize padding bytes in contrib/btree_gist indexes on bit columns (Heikki Linnakangas)
  This error could result in incorrect query results due to values that should compare equal not being seen as equal. Users with GiST indexes on bit or bit varying columns should REINDEX those indexes after installing this update.

• Protect against torn pages when deleting GIN list pages (Heikki Linnakangas)
  This fix prevents possible index corruption if a system crash occurs while the page update is being written to disk.

• Don’t clear the right-link of a GiST index page while replaying updates from WAL (Heikki Linnakangas)
  This error could lead to transiently wrong answers from GiST index scans performed in Hot Standby.

• Fix feedback status when hot_standby_feedback is turned off on-the-fly (Simon Riggs)

• Fix possibly-incorrect cache invalidation during nested calls to ReceiveSharedInvalidMessages (Andres Freund)

• Fix “could not find pathkey item to sort” planner failures with UNION ALL over subqueries reading from tables with inheritance children (Tom Lane)

• Don’t assume a subquery’s output is unique if there’s a set-returning function in its targetlist (David Rowley)
  This oversight could lead to misoptimization of constructs like WHERE x IN (SELECT y, generate_series(1,10) FROM t GROUP BY y).

• Fix failure to detoast fields in composite elements of structured types (Tom Lane)
  This corrects cases where TOAST pointers could be copied into other tables without being dereferenced. If the original data is later deleted, it would lead to errors like “missing chunk number 0 for toast value ...” when the now-dangling pointer is used.

• Fix “record type has not been registered” failures with whole-row references to the output of Append plan nodes (Tom Lane)

• Fix possible crash when invoking a user-defined function while rewinding a cursor (Tom Lane)

• Fix query-lifespan memory leak while evaluating the arguments for a function in FROM (Tom Lane)

• Fix session-lifespan memory leaks in regular-expression processing (Tom Lane, Arthur O’Dwyer, Greg Stark)

• Fix data encoding error in hungarian.stop (Tom Lane)

• Prevent foreign tables from being created with OIDS when default_with_oids is true (Etsuro Fujita)

• Fix liveness checks for rows that were inserted in the current transaction and then deleted by a now-rolled-back subtransaction (Andres Freund)

2472
Appendix E. Release Notes

This could cause problems (at least spurious warnings, and at worst an infinite loop) if CREATE INDEX or CLUSTER were done later in the same transaction.

- Clear pg_stat_activity.xact_start during PREPARE TRANSACTION (Andres Freund)

  After the PREPARE, the originating session is no longer in a transaction, so it should not continue to display a transaction start time.

- Fix REASSIGN OWNED to not fail for text search objects (Álvaro Herrera)

- Block signals during postmaster startup (Tom Lane)

  This ensures that the postmaster will properly clean up after itself if, for example, it receives SIGINT while still starting up.

- Fix client host name lookup when processing pg_hba.conf entries that specify host names instead of IP addresses (Tom Lane)

  Ensure that reverse-DNS lookup failures are reported, instead of just silently not matching such entries. Also ensure that we make only one reverse-DNS lookup attempt per connection, not one per host name entry, which is what previously happened if the lookup attempts failed.

- Secure Unix-domain sockets of temporary postmasters started during make check (Noah Misch)

  Any local user able to access the socket file could connect as the server’s bootstrap superuser, then proceed to execute arbitrary code as the operating-system user running the test, as we previously noted in CVE-2014-0067. This change defends against that risk by placing the server’s socket in a temporary, mode 0700 subdirectory of /tmp. The hazard remains however on platforms where Unix sockets are not supported, notably Windows, because then the temporary postmaster must accept local TCP connections.

  A useful side effect of this change is to simplify make check testing in builds that override DEFAULT_PGSOCKET_DIR. Popular non-default values like /var/run/postgresql are often not writable by the build user, requiring workarounds that will no longer be necessary.

- Fix tablespace creation WAL replay to work on Windows (MauMau)

- Fix detection of socket creation failures on Windows (Bruce Momjian)

- On Windows, allow new sessions to absorb values of PGC_BACKEND parameters (such as log_connections) from the configuration file (Amit Kapila)

  Previously, if such a parameter were changed in the file post-startup, the change would have no effect.

- Properly quote executable path names on Windows (Nikhil Deshpande)

  This oversight could cause initdb and pg_upgrade to fail on Windows, if the installation path contained both spaces and @ signs.

- Fix linking of libpython on macOS (Tom Lane)

  The method we previously used can fail with the Python library supplied by Xcode 5.0 and later.

- Avoid buffer bloat in libpq when the server consistently sends data faster than the client can absorb it (Shin-ichi Morita, Tom Lane)

  libpq could be coerced into enlarging its input buffer until it runs out of memory (which would be reported misleadingly as “lost synchronization with server”). Under ordinary circumstances it’s quite far-fetched that data could be continuously transmitted more quickly than the recv() loop can absorb it, but this has been observed when the client is artificially slowed by scheduler constraints.
Appendix E. Release Notes

- Ensure that LDAP lookup attempts in libpq time out as intended (Laurenz Albe)
- Fix ecpg to do the right thing when an array of char * is the target for a FETCH statement returning more than one row, as well as some other array-handling fixes (Ashutosh Bapat)
- Fix pg_restore’s processing of old-style large object comments (Tom Lane)
  A direct-to-database restore from an archive file generated by a pre-9.0 version of pg_dump would usually fail if the archive contained more than a few comments for large objects.
- In contrib/pgcrypto functions, ensure sensitive information is cleared from stack variables before returning (Marko Kreen)
- In contrib/uuid-ossp, cache the state of the OSSP UUID library across calls (Tom Lane)
  This improves the efficiency of UUID generation and reduces the amount of entropy drawn from /dev/urandom, on platforms that have that.
- Update time zone data files to tzdata release 2014e for DST law changes in Crimea, Egypt, and Morocco.

E.84. Release 9.1.13

Release date: 2014-03-20

This release contains a variety of fixes from 9.1.12. For information about new features in the 9.1 major release, see Section E.97.

E.84.1. Migration to Version 9.1.13

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.11, see Section E.86.

E.84.2. Changes

- Restore GIN metapages unconditionally to avoid torn-page risk (Heikki Linnakangas)
  Although this oversight could theoretically result in a corrupted index, it is unlikely to have caused any problems in practice, since the active part of a GIN metapage is smaller than a standard 512-byte disk sector.
- Avoid race condition in checking transaction commit status during receipt of a NOTIFY message (Marko Tiikkaja)
  This prevents a scenario wherein a sufficiently fast client might respond to a notification before database updates made by the notifier have become visible to the recipient.
- Allow regular-expression operators to be terminated early by query cancel requests (Tom Lane)
This prevents scenarios wherein a pathological regular expression could lock up a server process uninterruptibly for a long time.

- **Remove incorrect code that tried to allow OVERLAPS with single-element row arguments (Joshua Yanovski)**
  This code never worked correctly, and since the case is neither specified by the SQL standard nor documented, it seemed better to remove it than fix it.

- **Avoid getting more than AccessShareLock when de-parsing a rule or view (Dean Rasheed)**
  This oversight resulted in pg_dump unexpectedly acquiring RowExclusiveLock locks on tables mentioned as the targets of INSERT/UPDATE/DELETE commands in rules. While usually harmless, that could interfere with concurrent transactions that tried to acquire, for example, ShareLock on those tables.

- **Improve performance of index endpoint probes during planning (Tom Lane)**
  This change fixes a significant performance problem that occurred when there were many not-yet-committed rows at the end of the index, which is a common situation for indexes on sequentially-assigned values such as timestamps or sequence-generated identifiers.

- **Fix walsender’s failure to shut down cleanly when client is pg_receivexlog (Fujii Masao)**
- **Fix test to see if hot standby connections can be allowed immediately after a crash (Heikki Linnakangas)**
- **Prevent interrupts while reporting non-ERROR messages (Tom Lane)**
  This guards against rare server-process freezeups due to recursive entry to syslog(), and perhaps other related problems.

- **Fix memory leak in PL/Perl when returning a composite result, including multiple-OUT-parameter cases (Alex Hunsaker)**
- **Prevent intermittent “could not reserve shared memory region” failures on recent Windows versions (MauMau)**
- **Update time zone data files to tzdata release 2014a for DST law changes in Fiji and Turkey, plus historical changes in Israel and Ukraine.**

### E.85. Release 9.1.12

**Release date:** 2014-02-20

This release contains a variety of fixes from 9.1.11. For information about new features in the 9.1 major release, see Section E.97.

**E.85.1. Migration to Version 9.1.12**

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.11, see Section E.86.
E.85.2. Changes

• Shore up `GRANT ... WITH ADMIN OPTION` restrictions (Noah Misch)

  Granting a role without `ADMIN OPTION` is supposed to prevent the grantee from adding or removing members from the granted role, but this restriction was easily bypassed by doing `SET ROLE` first. The security impact is mostly that a role member can revoke the access of others, contrary to the wishes of his grantor. Unapproved role member additions are a lesser concern, since an uncooperative role member could provide most of his rights to others anyway by creating views or `SECURITY DEFINER` functions. (CVE-2014-0060)

• Prevent privilege escalation via manual calls to PL validator functions (Andres Freund)

  The primary role of PL validator functions is to be called implicitly during `CREATE FUNCTION`, but they are also normal SQL functions that a user can call explicitly. Calling a validator on a function actually written in some other language was not checked for and could be exploited for privilege-escalation purposes. The fix involves adding a call to a privilege-checking function in each validator function. Non-core procedural languages will also need to make this change to their own validator functions, if any. (CVE-2014-0061)

• Avoid multiple name lookups during table and index DDL (Robert Haas, Andres Freund)

  If the name lookups come to different conclusions due to concurrent activity, we might perform some parts of the DDL on a different table than other parts. At least in the case of `CREATE INDEX`, this can be used to cause the permissions checks to be performed against a different table than the index creation, allowing for a privilege escalation attack. (CVE-2014-0062)

• Prevent buffer overrun with long datetime strings (Noah Misch)

  The `MAXDATELEN` constant was too small for the longest possible value of type `interval`, allowing a buffer overrun in `interval_out()`. Although the datetime input functions were more careful about avoiding buffer overrun, the limit was short enough to cause them to reject some valid inputs, such as input containing a very long timezone name. The ecpg library contained these vulnerabilities along with some of its own. (CVE-2014-0063)

• Prevent buffer overrun due to integer overflow in size calculations (Noah Misch, Heikki Linnakangas)

  Several functions, mostly type input functions, calculated an allocation size without checking for overflow. If overflow did occur, a too-small buffer would be allocated and then written past. (CVE-2014-0064)

• Prevent overruns of fixed-size buffers (Peter Eisentraut, Jozef Mlich)

  Use `strlcpy()` and related functions to provide a clear guarantee that fixed-size buffers are not overrun. Unlike the preceding items, it is unclear whether these cases really represent live issues, since in most cases there appear to be previous constraints on the size of the input string. Nonetheless it seems prudent to silence all Coverity warnings of this type. (CVE-2014-0065)

• Avoid crashing if `crypt()` returns NULL (Honza Horak, Bruce Momjian)

  There are relatively few scenarios in which `crypt()` could return NULL, but `contrib/chkpass` would crash if it did. One practical case in which this could be an issue is if libc is configured to refuse to execute unapproved hashing algorithms (e.g., “FIPS mode”). (CVE-2014-0066)

• Document risks of `make check` in the regression testing instructions (Noah Misch, Tom Lane)
Since the temporary server started by \texttt{make check} uses “trust” authentication, another user on the same machine could connect to it as database superuser, and then potentially exploit the privileges of the operating-system user who started the tests. A future release will probably incorporate changes in the testing procedure to prevent this risk, but some public discussion is needed first. So for the moment, just warn people against using \texttt{make check} when there are untrusted users on the same machine. (CVE-2014-0067)

- Fix possible mis-replay of WAL records when some segments of a relation aren’t full size (Greg Stark, Tom Lane)

  The WAL update could be applied to the wrong page, potentially many pages past where it should have been. Aside from corrupting data, this error has been observed to result in significant “bloat” of standby servers compared to their masters, due to updates being applied far beyond where the end-of-file should have been. This failure mode does not appear to be a significant risk during crash recovery, only when initially synchronizing a standby created from a base backup taken from a quickly-changing master.

- Fix bug in determining when recovery has reached consistency (Tomonari Katsumata, Heikki Linnakangas)

  In some cases WAL replay would mistakenly conclude that the database was already consistent at the start of replay, thus possibly allowing hot-standby queries before the database was really consistent. Other symptoms such as “PANIC: WAL contains references to invalid pages” were also possible.

- Fix improper locking of btree index pages while replaying a \texttt{VACUUM} operation in hot-standby mode (Andres Freund, Heikki Linnakangas, Tom Lane)

  This error could result in “PANIC: WAL contains references to invalid pages” failures.

- Ensure that insertions into non-leaf GIN index pages write a full-page WAL record when appropriate (Heikki Linnakangas)

  The previous coding risked index corruption in the event of a partial-page write during a system crash.

- When \texttt{pause_at_recovery_target} and \texttt{recovery_target_inclusive} are both set, ensure the target record is applied before pausing, not after (Heikki Linnakangas)

- Fix race conditions during server process exit (Robert Haas)

  Ensure that signal handlers don’t attempt to use the process’s \texttt{MyProc} pointer after it’s no longer valid.

- Fix race conditions in walsender shutdown logic and walreceiver SIGHUP signal handler (Tom Lane)

- Fix unsafe references to \texttt{errno} within error reporting logic (Christian Kruse)

  This would typically lead to odd behaviors such as missing or inappropriate \texttt{HINT} fields.

- Fix possible crashes from using \texttt{ereport()} too early during server startup (Tom Lane)

  The principal case we’ve seen in the field is a crash if the server is started in a directory it doesn’t have permission to read.

- Clear retry flags properly in OpenSSL socket write function (Alexander Kukushkin)

  This omission could result in a server lockup after unexpected loss of an SSL-encrypted connection.

- Fix length checking for Unicode identifiers (\texttt{Us"..."} syntax) containing escapes (Tom Lane)

  A spurious truncation warning would be printed for such identifiers if the escaped form of the identifier was too long, but the identifier actually didn’t need truncation after de-escaping.

- Allow keywords that are type names to be used in lists of roles (Stephen Frost)
Appendix E. Release Notes

A previous patch allowed such keywords to be used without quoting in places such as role identifiers; but it missed cases where a list of role identifiers was permitted, such as \texttt{DROP ROLE}.

- Fix parser crash for \texttt{EXISTS(SELECT \* FROM zero_column_table)} (Tom Lane)
- Fix possible crash due to invalid plan for nested sub-selects, such as \texttt{WHERE (... \times \text{IN (SELECT ...)} ... \text{IN (SELECT ...))}} (Tom Lane)
- Ensure that \texttt{ANALYZE} creates statistics for a table column even when all the values in it are “too wide” (Tom Lane)

\texttt{ANALYZE} intentionally omits very wide values from its histogram and most-common-values calculations, but it neglected to do something sane in the case that all the sampled entries are too wide.

- In \texttt{ALTER TABLE ... SET TABLESPACE}, allow the database’s default tablespace to be used without a permissions check (Stephen Frost)

\texttt{CREATE TABLE} has always allowed such usage, but \texttt{ALTER TABLE} didn’t get the memo.

- Fix “cannot accept a set” error when some arms of a \texttt{CASE} return a set and others don’t (Tom Lane)
- Fix checks for all-zero client addresses in \texttt{pgstat} functions (Kevin Grittner)
- Fix possible misclassification of multibyte characters by the text search parser (Tom Lane)

Non-ASCII characters could be misclassified when using C locale with a multibyte encoding. On Cygwin, non-C locales could fail as well.

- Fix possible misbehavior in \texttt{plainto_tsquery()} (Heikki Linnakangas)

Use \texttt{memmove()} not \texttt{memcpy()} for copying overlapping memory regions. There have been no field reports of this actually causing trouble, but it’s certainly risky.

- Fix placement of permissions checks in \texttt{pg_start_backup()} and \texttt{pg_stop_backup()} (Andres Freund, Magnus Hagander)

The previous coding might attempt to do catalog access when it shouldn’t.

- Accept \texttt{SHIFT_JIS} as an encoding name for locale checking purposes (Tatsuo Ishii)
- Fix misbehavior of \texttt{PQhost()} on Windows (Fujii Masao)

It should return localhost if no host has been specified.

- Improve error handling in \texttt{libpq} and \texttt{psql} for failures during \texttt{COPY TO STDOUT/FROM STDIN} (Tom Lane)

In particular this fixes an infinite loop that could occur in 9.2 and up if the server connection was lost during \texttt{COPY FROM STDIN}. Variants of that scenario might be possible in older versions, or with other client applications.

- Fix possible incorrect printing of filenames in \texttt{pg_basebackup}’s verbose mode (Magnus Hagander)
- Avoid including tablespaces inside \texttt{PGDATA} twice in base backups (Dimitri Fontaine, Magnus Hagander)
- Fix misaligned descriptors in \texttt{ecpg} (MauMau)
- In \texttt{ecpg}, handle lack of a hostname in the connection parameters properly (Michael Meskes)
- Fix performance regression in \texttt{contrib/dblink} connection startup (Joe Conway)

Avoid an unnecessary round trip when client and server encodings match.
Appendix E. Release Notes

• In contrib/ismn, fix incorrect calculation of the check digit for ISMN values (Fabien Coelho)

• Ensure client-code-only installation procedure works as documented (Peter Eisentraut)

• In Mingw and Cygwin builds, install the libpq DLL in the bin directory (Andrew Dunstan)
  This duplicates what the MSVC build has long done. It should fix problems with programs like psql failing to start because they can’t find the DLL.

• Avoid using the deprecated dllwrap tool in Cygwin builds (Marco Atzeri)

• Don’t generate plain-text HISTORY and src/test/regress/README files anymore (Tom Lane)
  These text files duplicated the main HTML and PDF documentation formats. The trouble involved in maintaining them greatly outweighs the likely audience for plain-text format. Distribution tarballs will still contain files by these names, but they’ll just be stubs directing the reader to consult the main documentation. The plain-text INSTALL file will still be maintained, as there is arguably a use-case for that.

• Update time zone data files to tzdata release 2013i for DST law changes in Jordan and historical changes in Cuba.
  In addition, the zones Asia/Riyadh87, Asia/Riyadh88, and Asia/Riyadh89 have been removed, as they are no longer maintained by IANA, and never represented actual civil timekeeping practice.

E.86. Release 9.1.11

Release date: 2013-12-05

This release contains a variety of fixes from 9.1.10. For information about new features in the 9.1 major release, see Section E.97.

E.86.1. Migration to Version 9.1.11

A dump/restore is not required for those running 9.1.X.

However, this release corrects a number of potential data corruption issues. See the first two changelog entries below to find out whether your installation has been affected and what steps you can take if so.

Also, if you are upgrading from a version earlier than 9.1.9, see Section E.88.

E.86.2. Changes

• Fix VACUUM’s tests to see whether it can update relfrozenxid (Andres Freund)
  In some cases VACUUM (either manual or autovacuum) could incorrectly advance a table’s relfrozenxid value, allowing tuples to escape freezing, causing those rows to become invisible once \(2^{31}\) transactions have elapsed. The probability of data loss is fairly low since multiple incorrect advancements would need to happen before actual loss occurs, but it’s not zero. Users upgrading from releases 9.0.4 or 8.4.8 or earlier are not affected, but all later versions contain the bug.
Appendix E. Release Notes

The issue can be ameliorated by, after upgrading, vacuuming all tables in all databases while having vacuum_freeze_table_age set to zero. This will fix any latent corruption but will not be able to fix all pre-existing data errors. However, an installation can be presumed safe after performing this vacuuming if it has executed fewer than $2^{31}$ update transactions in its lifetime (check this with `SELECT txid_current() < 2^{31}`.

- Fix initialization of `pg_clog` and `pg_subtrans` during hot standby startup (Andres Freund, Heikki Linnakangas)

  This bug can cause data loss on standby servers at the moment they start to accept hot-standby queries, by marking committed transactions as uncommitted. The likelihood of such corruption is small unless, at the time of standby startup, the primary server has executed many updating transactions since its last checkpoint. Symptoms include missing rows, rows that should have been deleted being still visible, and obsolete versions of updated rows being still visible alongside their newer versions.

  This bug was introduced in versions 9.3.0, 9.2.5, 9.1.10, and 9.0.14. Standby servers that have only been running earlier releases are not at risk. It's recommended that standby servers that have ever run any of the buggy releases be re-cloned from the primary (e.g., with a new base backup) after upgrading.

- Truncate `pg_multixact` contents during WAL replay (Andres Freund)

  This avoids ever-increasing disk space consumption in standby servers.

- Fix race condition in GIN index posting tree page deletion (Heikki Linnakangas)

  This could lead to transient wrong answers or query failures.

- Avoid flattening a subquery whose `SELECT` list contains a volatile function wrapped inside a sub-`SELECT` (Tom Lane)

  This avoids unexpected results due to extra evaluations of the volatile function.

- Fix planner’s processing of non-simple-variable subquery outputs nested within outer joins (Tom Lane)

  This error could lead to incorrect plans for queries involving multiple levels of subqueries within `JOIN` syntax.

- Fix incorrect generation of optimized MIN()/MAX() plans for inheritance trees (Tom Lane)

  The planner could fail in cases where the MIN()/MAX() argument was an expression rather than a simple variable.

- Fix premature deletion of temporary files (Andres Freund)

- Fix possible read past end of memory in rule printing (Peter Eisentraut)

- Fix array slicing of `int2vector` and `oidvector` values (Tom Lane)

  Expressions of this kind are now implicitly promoted to regular `int2` or `oid` arrays.

- Fix incorrect behaviors when using a SQL-standard, simple GMT offset timezone (Tom Lane)

  In some cases, the system would use the simple GMT offset value when it should have used the regular timezone setting that had prevailed before the simple offset was selected. This change also causes the `timeofday` function to honor the simple GMT offset zone.

- Prevent possible misbehavior when logging translations of Windows error codes (Tom Lane)

- Properly quote generated command lines in `pg_ctl` (Naoya Anzai and Tom Lane)

  This fix applies only to Windows.
Appendix E. Release Notes

- Fix `pg_dumpall` to work when a source database sets `default_transaction_read_only` via `ALTER DATABASE SET` (Kevin Grittner)
  Previously, the generated script would fail during restore.
- Make `ecpg` search for quoted cursor names case-sensitively (Zoltán Böszörményi)
- Fix `ecpg`’s processing of lists of variables declared `varchar` (Zoltán Böszörményi)
- Make `contrib/lo` defend against incorrect trigger definitions (Marc Cousin)
- Update time zone data files to `tzdata` release 2013h for DST law changes in Argentina, Brazil, Jordan, Libya, Liechtenstein, Morocco, and Palestine. Also, new timezone abbreviations WIB, WIT, WITA for Indonesia.

E.87. Release 9.1.10

Release date: 2013-10-10
This release contains a variety of fixes from 9.1.9. For information about new features in the 9.1 major release, see Section E.97.

E.87.1. Migration to Version 9.1.10
A dump/restore is not required for those running 9.1.X.
However, if you are upgrading from a version earlier than 9.1.9, see Section E.88.

E.87.2. Changes

- Prevent corruption of multi-byte characters when attempting to case-fold identifiers (Andrew Dunstan)
  PostgreSQL case-folds non-ASCII characters only when using a single-byte server encoding.
- Fix checkpoint memory leak in background writer when `wal_level = hot_standby` (Naoya Anzai)
- Fix memory leak caused by `lo_open()` failure (Heikki Linnakangas)
- Fix memory overcommit bug when `work_mem` is using more than 24GB of memory (Stephen Frost)
- Serializable snapshot fixes (Kevin Grittner, Heikki Linnakangas)
- Fix deadlock bug in `libpq` when using SSL (Stephen Frost)
- Fix possible SSL state corruption in threaded `libpq` applications (Nick Phillips, Stephen Frost)
- Properly compute row estimates for boolean columns containing many NULL values (Andrew Gierth)
  Previously tests like `col IS NOT TRUE` and `col IS NOT FALSE` did not properly factor in NULL values when estimating plan costs.
- Prevent pushing down `WHERE` clauses into unsafe `UNION/INTERSECT` subqueries (Tom Lane)
Subqueries of a `UNION` or `INTERSECT` that contain set-returning functions or volatile functions in their `SELECT` lists could be improperly optimized, leading to run-time errors or incorrect query results.

- Fix rare case of “failed to locate grouping columns” planner failure (Tom Lane)
- Fix `pg_dump` of foreign tables with dropped columns (Andrew Dunstan)
  Previously such cases could cause a `pg_upgrade` error.
- Reorder `pg_dump` processing of extension-related rules and event triggers (Joe Conway)
- Force dumping of extension tables if specified by `pg_dump -t` or `-n` (Joe Conway)
- Improve view dumping code’s handling of dropped columns in referenced tables (Tom Lane)
- Fix `pg_restore -l` with the directory archive to display the correct format name (Fujii Masao)
- Properly record index comments created using `UNIQUE` and `PRIMARY KEY` syntax (Andres Freund)
  This fixes a parallel `pg_restore` failure.
- Properly guarantee transmission of WAL files before clean switchover (Fujii Masao)
  Previously, the streaming replication connection might close before all WAL files had been replayed on the standby.
- Fix WAL segment timeline handling during recovery (Mitsumasa Kondo, Heikki Linnakangas)
  WAL file recycling during standby recovery could lead to premature recovery completion, resulting in data loss.
- Fix `REINDEX TABLE` and `REINDEX DATABASE` to properly revalidate constraints and mark invalidated indexes as valid (Noah Misch)
  `REINDEX INDEX` has always worked properly.
- Fix possible deadlock during concurrent `CREATE INDEX CONCURRENTLY` operations (Tom Lane)
- Fix `regexp_matches()` handling of zero-length matches (Jeevan Chalke)
  Previously, zero-length matches like `'^'` could return too many matches.
- Fix crash for overly-complex regular expressions (Heikki Linnakangas)
- Fix regular expression match failures for back references combined with non-greedy quantifiers (Jeevan Chalke)
- Prevent `CREATE FUNCTION` from checking `SET` variables unless function body checking is enabled (Tom Lane)
- Allow `ALTER DEFAULT PRIVILEGES` to operate on schemas without requiring `CREATE` permission (Tom Lane)
- Loosen restriction on keywords used in queries (Tom Lane)
  Specifically, lessen keyword restrictions for role names, language names, `EXPLAIN` and `COPY` options, and `SET` values. This allows `COPY ... (FORMAT BINARY)` to work as expected; previously `BINARY` needed to be quoted.
- Fix `pgp_pub_decrypt()` so it works for secret keys with passwords (Marko Kreen)
- Make `pg_upgrade` use `pg_dump --quote-all-identifiers` to avoid problems with keyword changes between releases (Tom Lane)
• Remove rare inaccurate warning during vacuum of index-less tables (Heikki Linnakangas)
• Ensure that VACUUM ANALYZE still runs the ANALYZE phase if its attempt to truncate the file is cancelled due to lock conflicts (Kevin Grittner)
• Avoid possible failure when performing transaction control commands (e.g. ROLLBACK) in prepared queries (Tom Lane)
• Ensure that floating-point data input accepts standard spellings of "infinity" on all platforms (Tom Lane)
  The C99 standard says that allowable spellings are inf, +inf, -inf, infinity, +infinity, and -infinity. Make sure we recognize these even if the platform’s strtod function doesn’t.
• Expand ability to compare rows to records and arrays (Rafal Rzepecki, Tom Lane)
• Update time zone data files to tzdata release 2013d for DST law changes in Israel, Morocco, Palestine, and Paraguay. Also, historical zone data corrections for Macquarie Island.

E.88. Release 9.1.9

Release date: 2013-04-04
This release contains a variety of fixes from 9.1.8. For information about new features in the 9.1 major release, see Section E.97.

E.88.1. Migration to Version 9.1.9
A dump/restore is not required for those running 9.1.X.
However, this release corrects several errors in management of GiST indexes. After installing this update, it is advisable to REINDEX any GiST indexes that meet one or more of the conditions described below. Also, if you are upgrading from a version earlier than 9.1.6, see Section E.91.

E.88.2. Changes

• Fix insecure parsing of server command-line switches (Mitsumasa Kondo, Kyotaro Horiguchi)
  A connection request containing a database name that begins with "-" could be crafted to damage or destroy files within the server’s data directory, even if the request is eventually rejected. (CVE-2013-1899)
• Reset OpenSSL randomness state in each postmaster child process (Marko Kreen)
  This avoids a scenario wherein random numbers generated by contrib/pgcrypto functions might be relatively easy for another database user to guess. The risk is only significant when the postmaster is configured with ssl=on but most connections don’t use SSL encryption. (CVE-2013-1900)
• Make REPLICATION privilege checks test current user not authenticated user (Noah Misch)
Appendix E. Release Notes

An unprivileged database user could exploit this mistake to call `pg_start_backup()` or `pg_stop_backup()`, thus possibly interfering with creation of routine backups. (CVE-2013-1901)

- Fix GiST indexes to not use “fuzzy” geometric comparisons when it’s not appropriate to do so (Alexander Korotkov)

  The core geometric types perform comparisons using “fuzzy” equality, but `gist_box_same` must do exact comparisons, else GiST indexes using it might become inconsistent. After installing this update, users should `REINDEX` any GiST indexes on `box`, `polygon`, `circle`, or `point` columns, since all of these use `gist_box_same`.

- Fix erroneous range-union and penalty logic in GiST indexes that use `contrib/btree_gist` for variable-width data types, that is `text`, `bytea`, `bit`, and `numeric` columns (Tom Lane)

  These errors could result in inconsistent indexes in which some keys that are present would not be found by searches, and also in useless index bloat. Users are advised to `REINDEX` such indexes after installing this update.

- Fix bugs in GiST page splitting code for multi-column indexes (Tom Lane)

  These errors could result in inconsistent indexes in which some keys that are present would not be found by searches, and also in indexes that are unnecessarily inefficient to search. Users are advised to `REINDEX` multi-column GiST indexes after installing this update.

- Fix `gist_point_consistent` to handle fuzziness consistently (Alexander Korotkov)

  Index scans on GiST indexes on `point` columns would sometimes yield results different from a sequential scan, because `gist_point_consistent` disagreed with the underlying operator code about whether to do comparisons exactly or fuzzily.

- Fix buffer leak in WAL replay (Heikki Linnakangas)

  This bug could result in “incorrect local pin count” errors during replay, making recovery impossible.

- Fix race condition in `DELETE RETURNING` (Tom Lane)

  Under the right circumstances, `DELETE RETURNING` could attempt to fetch data from a shared buffer that the current process no longer has any pin on. If some other process changed the buffer meanwhile, this would lead to garbage `RETURNING` output, or even a crash.

- Fix infinite-loop risk in regular expression compilation (Tom Lane, Don Porter)

- Fix potential null-pointer dereference in regular expression compilation (Tom Lane)

- Fix `to_char()` to use ASCII-only case-folding rules where appropriate (Tom Lane)

  This fixes misbehavior of some template patterns that should be locale-independent, but mishandled “ı” and “i” in Turkish locales.

- Fix unwanted rejection of timestamp `1999-12-31 24:00:00` (Tom Lane)

- Fix logic error when a single transaction does `UNLISTEN` then `LISTEN` (Tom Lane)

  The session wound up not listening for notify events at all, though it surely should listen in this case.

- Fix possible planner crash after columns have been added to a view that’s depended on by another view (Tom Lane)

- Remove useless “`picksplit doesn’t support secondary split`” log messages (Josh Hansen, Tom Lane)
This message seems to have been added in expectation of code that was never written, and probably never will be, since GiST’s default handling of secondary splits is actually pretty good. So stop nagging end users about it.

- Fix possible failure to send a session’s last few transaction commit/abort counts to the statistics collector (Tom Lane)
- Eliminate memory leaks in PL/Perl’s `spi_prepare()` function (Alex Hunsaker, Tom Lane)
- Fix `pg_dumpall` to handle database names containing “=” correctly (Heikki Linnakangas)
- Avoid crash in `pg_dump` when an incorrect connection string is given (Heikki Linnakangas)
- Ignore invalid indexes in `pg_dump` and `pg_upgrade` (Michael Paquier, Bruce Momjian)
  Dumping invalid indexes can cause problems at restore time, for example if the reason the index creation failed was because it tried to enforce a uniqueness condition not satisfied by the table’s data. Also, if the index creation is in fact still in progress, it seems reasonable to consider it to be an uncommitted DDL change, which `pg_dump` wouldn’t be expected to dump anyway. `pg_upgrade` now also skips invalid indexes rather than failing.
- In `pg_basebackup`, include only the current server version’s subdirectory when backing up a tablespace (Heikki Linnakangas)
- Add a server version check in `pg_basebackup` and `pg_receivexlog`, so they fail cleanly with version combinations that won’t work (Heikki Linnakangas)
- Fix `contrib/pg_trgm`’s `similarity()` function to return zero for trigram-less strings (Tom Lane)
  Previously it returned NaN due to internal division by zero.
- Update time zone data files to tzdata release 2013b for DST law changes in Chile, Haiti, Morocco, Paraguay, and some Russian areas. Also, historical zone data corrections for numerous places.
  Also, update the time zone abbreviation files for recent changes in Russia and elsewhere: `CHOT`, `GET`, `IRKT`, `KGT`, `KRAT`, `MAGT`, `MAWT`, `MSK`, `NOVT`, `OMST`, `TKT`, `VLAT`, `WST`, `YAKT`, `YET` now follow their current meanings, and `VOLT` (Europe/Volgograd) and `MIST` (Antarctica/Macquarie) are added to the default abbreviations list.

### E.89. Release 9.1.8

**Release date:** 2013-02-07

This release contains a variety of fixes from 9.1.7. For information about new features in the 9.1 major release, see Section E.97.

### E.89.1. Migration to Version 9.1.8

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.6, see Section E.91.
E.89.2. Changes

- Prevent execution of `enum_recv` from SQL (Tom Lane)
  The function was misdeclared, allowing a simple SQL command to crash the server. In principle an attacker might be able to use it to examine the contents of server memory. Our thanks to Sumit Soni (via Secunia SVCRP) for reporting this issue. (CVE-2013-0255)

- Fix multiple problems in detection of when a consistent database state has been reached during WAL replay (Fujii Masao, Heikki Linnakangas, Simon Riggs, Andres Freund)

- Update minimum recovery point when truncating a relation file (Heikki Linnakangas)
  Once data has been discarded, it’s no longer safe to stop recovery at an earlier point in the timeline.

- Fix recycling of WAL segments after changing recovery target timeline (Heikki Linnakangas)

- Fix missing cancellations in hot standby mode (Noah Misch, Simon Riggs)
  The need to cancel conflicting hot-standby queries would sometimes be missed, allowing those queries to see inconsistent data.

- Prevent recovery pause feature from pausing before users can connect (Tom Lane)

- Fix SQL grammar to allow subscripting or field selection from a sub-SELECT result (Tom Lane)

- Fix performance problems with autovacuum truncation in busy workloads (Jan Wieck)
  Truncation of empty pages at the end of a table requires exclusive lock, but autovacuum was coded to fail (and release the table lock) when there are conflicting lock requests. Under load, it is easily possible that truncation would never occur, resulting in table bloat. Fix by performing a partial truncation, releasing the lock, then attempting to re-acquire the lock and continue. This fix also greatly reduces the average time before autovacuum releases the lock after a conflicting request arrives.

- Protect against race conditions when scanning `pg_tablespace` (Stephen Frost, Tom Lane)
  `CREATE DATABASE` and `DROP DATABASE` could misbehave if there were concurrent updates of `pg_tablespace` entries.

- Prevent `DROP OWNED` from trying to drop whole databases or tablespaces (Álvaro Herrera)
  For safety, ownership of these objects must be reassigned, not dropped.

- Fix error in `vacuum_freeze_table_age` implementation (Andres Freund)
  In installations that have existed for more than `vacuum_freeze_min_age` transactions, this mistake prevented autovacuum from using partial-table scans, so that a full-table scan would always happen instead.

- Prevent misbehavior when a `RowExpr` or `XmlExpr` is parse-analyzed twice (Andres Freund, Tom Lane)
  This mistake could be user-visible in contexts such as `CREATE TABLE LIKE INCLUDING INDEXES`.

- Improve defenses against integer overflow in hashtable sizing calculations (Jeff Davis)

- Fix failure to ignore leftover temporary tables after a server crash (Tom Lane)

- Reject out-of-range dates in `to_date()` (Hitoshi Harada)

- Fix `pg_extension_config_dump()` to handle extension-update cases properly (Tom Lane)
This function will now replace any existing entry for the target table, making it usable in extension update scripts.

- Fix PL/Python’s handling of functions used as triggers on multiple tables (Andres Freund)
- Ensure that non-ASCII prompt strings are translated to the correct code page on Windows (Alexander Law, Noah Misch)

This bug affected psql and some other client programs.

- Fix possible crash in psql's `\?` command when not connected to a database (Meng Qingzhong)
- Fix possible error if a relation file is removed while pg_basebackup is running (Heikki Linnakangas)
- Make pg_dump exclude data of unlogged tables when running on a hot-standby server (Magnus Hagander)

  This would fail anyway because the data is not available on the standby server, so it seems most convenient to assume `--no-unlogged-table-data` automatically.

- Fix pg_upgrade to deal with invalid indexes safely (Bruce Momjian)
- Fix one-byte buffer overrun in libpq’s `PQprintTuples` (Xi Wang)

  This ancient function is not used anywhere by PostgreSQL itself, but it might still be used by some client code.

- Make ecpglib use translated messages properly (Chen Huajun)
- Properly install ecpg_compat and pgtypes libraries on MSVC (Jiang Guiqing)
- Include our version of `isinf()` in libcpg if it’s not provided by the system (Jiang Guiqing)
- Rearrange configure’s tests for supplied functions so it is not fooled by bogus exports from libedit/libreadline (Christoph Berg)
- Ensure Windows build number increases over time (Magnus Hagander)
- Make pgxs build executables with the right `.exe` suffix when cross-compiling for Windows (Zoltan Boszormenyi)
- Add new timezone abbreviation `FET` (Tom Lane)

  This is now used in some eastern-European time zones.

---

**E.90. Release 9.1.7**

**Release date:** 2012-12-06

This release contains a variety of fixes from 9.1.6. For information about new features in the 9.1 major release, see Section E.97.

---

**E.90.1. Migration to Version 9.1.7**

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.6, see Section E.91.
E.90.2. Changes

- Fix multiple bugs associated with \texttt{CREATE INDEX CONCURRENTLY} (Andres Freund, Tom Lane)

  Fix \texttt{CREATE INDEX CONCURRENTLY} to use in-place updates when changing the state of an index’s \texttt{pg_index} row. This prevents race conditions that could cause concurrent sessions to miss updating the target index, thus resulting in corrupt concurrently-created indexes.

  Also, fix various other operations to ensure that they ignore invalid indexes resulting from a failed \texttt{CREATE INDEX CONCURRENTLY} command. The most important of these is \texttt{VACUUM}, because an auto-vacuum could easily be launched on the table before corrective action can be taken to fix or remove the invalid index.

- Fix buffer locking during WAL replay (Tom Lane)

  The WAL replay code was insufficiently careful about locking buffers when replaying WAL records that affect more than one page. This could result in hot standby queries transiently seeing inconsistent states, resulting in wrong answers or unexpected failures.

- Fix an error in WAL generation logic for GIN indexes (Tom Lane)

  This could result in index corruption, if a torn-page failure occurred.

- Properly remove startup process’s virtual XID lock when promoting a hot standby server to normal running (Simon Riggs)

  This oversight could prevent subsequent execution of certain operations such as \texttt{CREATE INDEX CONCURRENTLY}.

- Avoid bogus “out-of-sequence timeline ID” errors in standby mode (Heikki Linnakangas)

- Prevent the postmaster from launching new child processes after it’s received a shutdown signal (Tom Lane)

  This mistake could result in shutdown taking longer than it should, or even never completing at all without additional user action.

- Avoid corruption of internal hash tables when out of memory (Hitoshi Harada)

- Prevent file descriptors for dropped tables from being held open past transaction end (Tom Lane)

  This should reduce problems with long-since-dropped tables continuing to occupy disk space.

- Prevent database-wide crash and restart when a new child process is unable to create a pipe for its latch (Tom Lane)

  Although the new process must fail, there is no good reason to force a database-wide restart, so avoid that. This improves robustness when the kernel is nearly out of file descriptors.

- Fix planning of non-strict equivalence clauses above outer joins (Tom Lane)

  The planner could derive incorrect constraints from a clause equating a non-strict construct to something else, for example \texttt{WHERE COALESCE(foo, 0) = 0} when \texttt{foo} is coming from the nullable side of an outer join.

- Fix \texttt{SELECT DISTINCT} with index-optimized \texttt{MIN/MAX} on an inheritance tree (Tom Lane)

  The planner would fail with “failed to re-find MinMaxAggInfo record” given this combination of factors.
• Improve planner’s ability to prove exclusion constraints from equivalence classes (Tom Lane)

• Fix partial-row matching in hashed subplans to handle cross-type cases correctly (Tom Lane)
  This affects multicolumn NOT IN subplans, such as WHERE (a, b) NOT IN (SELECT x, y FROM ...)
  when for instance b and y are int4 and int8 respectively. This mistake led to wrong answers or
  crashes depending on the specific datatypes involved.

• Acquire buffer lock when re-fetching the old tuple for an AFTER ROW UPDATE/DELETE trigger (Andres Freund)
  In very unusual circumstances, this oversight could result in passing incorrect data to a trigger
  WHEN condition, or to the precheck logic for a foreign-key enforcement trigger. That could result in a crash,
  or in an incorrect decision about whether to fire the trigger.

• Fix ALTER COLUMN TYPE to handle inherited check constraints properly (Pavan Deolasee)
  This worked correctly in pre-8.4 releases, and now works correctly in 8.4 and later.

• Fix ALTER EXTENSION SET SCHEMA’s failure to move some subsidiary objects into the new schema
  (Álvaro Herrera, Dimitri Fontaine)

• Fix REASSIGN OWNED to handle grants on tablespaces (Álvaro Herrera)

• Ignore incorrect pg_attribute entries for system columns for views (Tom Lane)
  Views do not have any system columns. However, we forgot to remove such entries when converting
  a table to a view. That’s fixed properly for 9.3 and later, but in previous branches we need to defend
  against existing mis-converted views.

• Fix rule printing to dump INSERT INTO table DEFAULT VALUES correctly (Tom Lane)

• Guard against stack overflow when there are too many UNION/INTERSECT/EXCEPT clauses in a query
  (Tom Lane)

• Prevent platform-dependent failures when dividing the minimum possible integer value by -1 (Xi Wang,
  Tom Lane)

• Fix possible access past end of string in date parsing (Hitoshi Harada)

• Fix failure to advance XID epoch if XID wraparound happens during a checkpoint and wal_level is
  hot_standby (Tom Lane, Andres Freund)
  While this mistake had no particular impact on PostgreSQL itself, it was bad for applications that rely
  on txid_current() and related functions: the TXID value would appear to go backwards.

• Fix display of pg_stat_replication.sync_state at a page boundary (Kyotaro Horiguchi)

• Produce an understandable error message if the length of the path name for a Unix-domain socket
  exceeds the platform-specific limit (Tom Lane, Andrew Dunstan)
  Formerly, this would result in something quite unhelpful, such as “Non-recoverable failure in name
  resolution”.

• Fix memory leaks when sending composite column values to the client (Tom Lane)

• Make pg_ctl more robust about reading the postmaster.pid file (Heikki Linnakangas)
  Fix race conditions and possible file descriptor leakage.

• Fix possible crash in psql if incorrectly-encoded data is presented and the client_encoding setting
  is a client-only encoding, such as SJIS (Jiang Guiqing)
Appendix E. Release Notes

- Make pg_dump dump `SEQUENCE SET` items in the data not pre-data section of the archive (Tom Lane)
  This change fixes dumping of sequences that are marked as extension configuration tables.
- Fix bugs in the `restore.sql` script emitted by pg_dump in `tar` output format (Tom Lane)
  The script would fail outright on tables whose names include upper-case characters. Also, make the script capable of restoring data in --inserts mode as well as the regular COPY mode.
- Fix pg_restore to accept POSIX-conformant `tar` files (Brian Weaver, Tom Lane)
  The original coding of pg_dump's `tar` output mode produced files that are not fully conformant with the POSIX standard. This has been corrected for version 9.3. This patch updates previous branches so that they will accept both the incorrect and the corrected formats, in hopes of avoiding compatibility problems when 9.3 comes out.
- Fix `tar` files emitted by pg_basebackup to be POSIX conformant (Brian Weaver, Tom Lane)
- Fix pg_resetxlog to locate `postmaster.pid` correctly when given a relative path to the data directory (Tom Lane)
  This mistake could lead to pg_resetxlog not noticing that there is an active postmaster using the data directory.
- Fix libpq's `lo_import()` and `lo_export()` functions to report file I/O errors properly (Tom Lane)
- Fix ecpg's processing of nested structure pointer variables (Muhammad Usama)
- Fix ecpg's `ecpg_get_data` function to handle arrays properly (Michael Meskes)
- Make contrib/pageinspect's btree page inspection functions take buffer locks while examining pages (Tom Lane)
- Ensure that `make install` for an extension creates the extension installation directory (Cédric Villemain)
  Previously, this step was missed if `MODULEDIR` was set in the extension’s Makefile.
- Fix pgxs support for building loadable modules on AIX (Tom Lane)
  Building modules outside the original source tree didn’t work on AIX.
- Update time zone data files to tzdata release 2012j for DST law changes in Cuba, Israel, Jordan, Libya, Palestine, Western Samoa, and portions of Brazil.

E.91. Release 9.1.6

Release date: 2012-09-24

This release contains a variety of fixes from 9.1.5. For information about new features in the 9.1 major release, see Section E.97.

E.91.1. Migration to Version 9.1.6

A dump/restore is not required for those running 9.1.X.
However, you may need to perform \texttt{REINDEX} operations to recover from the effects of the data corruption bug described in the first changelog item below.

Also, if you are upgrading from a version earlier than 9.1.4, see Section E.93.

**E.91.2. Changes**

- Fix persistence marking of shared buffers during WAL replay (Jeff Davis)
  
  This mistake can result in buffers not being written out during checkpoints, resulting in data corruption if the server later crashes without ever having written those buffers. Corruption can occur on any server following crash recovery, but it is significantly more likely to occur on standby slave servers since those perform much more WAL replay. There is a low probability of corruption of btree and GIN indexes. There is a much higher probability of corruption of table “visibility maps”. Fortunately, visibility maps are non-critical data in 9.1, so the worst consequence of such corruption in 9.1 installations is transient inefficiency of vacuuming. Table data proper cannot be corrupted by this bug.

  While no index corruption due to this bug is known to have occurred in the field, as a precautionary measure it is recommended that production installations \texttt{REINDEX} all btree and GIN indexes at a convenient time after upgrading to 9.1.6.

  Also, if you intend to do an in-place upgrade to 9.2.X, before doing so it is recommended to perform a \texttt{VACUUM} of all tables while having \texttt{vacuum_freeze_table_age} set to zero. This will ensure that any lingering wrong data in the visibility maps is corrected before 9.2.X can depend on it. \texttt{vacuum_cost_delay} can be adjusted to reduce the performance impact of vacuuming, while causing it to take longer to finish.

- Fix planner’s assignment of executor parameters, and fix executor’s rescan logic for CTE plan nodes (Tom Lane)

  These errors could result in wrong answers from queries that scan the same \texttt{WITH} subquery multiple times.

- Fix misbehavior when \texttt{default_transaction_isolation} is set to \texttt{serializable} (Kevin Grittner, Tom Lane, Heikki Linnakangas)

  Symptoms include crashes at process start on Windows, and crashes in hot standby operation.

- Improve selectivity estimation for text search queries involving prefixes, i.e. \	exttt{word:*} patterns (Tom Lane)

- Improve page-splitting decisions in GiST indexes (Alexander Korotkov, Robert Haas, Tom Lane)

  Multi-column GiST indexes might suffer unexpected bloat due to this error.

- Fix cascading privilege revoke to stop if privileges are still held (Tom Lane)

  If we revoke a grant option from some role $X$, but $X$ still holds that option via a grant from someone else, we should not recursively revoke the corresponding privilege from role(s) $Y$ that $X$ had granted it to.

- Disallow extensions from containing the schema they are assigned to (Thom Brown)

  This situation creates circular dependencies that confuse \texttt{pg_dump} and probably other things. It’s confusing for humans too, so disallow it.
• Improve error messages for Hot Standby misconfiguration errors (Gurjeet Singh)
• Make configure probe for `mbstowcs_l` (Tom Lane)
  This fixes build failures on some versions of AIX.
• Fix handling of `SIGFPE` when PL/Perl is in use (Andres Freund)
  Perl resets the process’s `SIGFPE` handler to `SIG_IGN`, which could result in crashes later on. Restore
  the normal Postgres signal handler after initializing PL/Perl.
• Prevent PL/Perl from crashing if a recursive PL/Perl function is redefined while being executed (Tom
  Lane)
• Work around possible misoptimization in PL/Perl (Tom Lane)
  Some Linux distributions contain an incorrect version of `pthread.h` that results in incorrect compiled
  code in PL/Perl, leading to crashes if a PL/Perl function calls another one that throws an error.
• Fix bugs in `contrib/pg_trgm`’s `LIKE` pattern analysis code (Fujii Masao)
  `LIKE` queries using a trigram index could produce wrong results if the pattern contained `LIKE` escape
  characters.
• Fix `pg_upgrade`’s handling of line endings on Windows (Andrew Dunstan)
  Previously, `pg_upgrade` might add or remove carriage returns in places such as function bodies.
• On Windows, make `pg_upgrade` use backslash path separators in the scripts it emits (Andrew Dunstan)
• Remove unnecessary dependency on `pg_config` from `pg_upgrade` (Peter Eisentraut)
• Update time zone data files to `tzdata` release 2012f for DST law changes in Fiji

**E.92. Release 9.1.5**

**Release date:** 2012-08-17

This release contains a variety of fixes from 9.1.4. For information about new features in the 9.1 major
release, see Section E.97.

**E.92.1. Migration to Version 9.1.5**

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.4, see Section E.93.

**E.92.2. Changes**

• Prevent access to external files/URLs via XML entity references (Noah Misch, Tom Lane)
  `xml_parse()` would attempt to fetch external files or URLs as needed to resolve DTD and entity
  references in an XML value, thus allowing unprivileged database users to attempt to fetch data with
the privileges of the database server. While the external data wouldn’t get returned directly to the user, portions of it could be exposed in error messages if the data didn’t parse as valid XML; and in any case the mere ability to check existence of a file might be useful to an attacker. (CVE-2012-3489)

- Prevent access to external files/URLs via contrib/xml2’s xslt_process() (Peter Eisentraut)

libxmlt offers the ability to read and write both files and URLs through stylesheet commands, thus allowing unprivileged database users to both read and write data with the privileges of the database server. Disable that through proper use of libxmlt’s security options. (CVE-2012-3488)

Also, remove xslt_process()'s ability to fetch documents and stylesheets from external files/URLs. While this was a documented “feature”, it was long regarded as a bad idea. The fix for CVE-2012-3489 broke that capability, and rather than expend effort on trying to fix it, we’re just going to summarily remove it.

- Prevent too-early recycling of btree index pages (Noah Misch)

When we allowed read-only transactions to skip assigning XIDs, we introduced the possibility that a deleted btree page could be recycled while a read-only transaction was still in flight to it. This would result in incorrect index search results. The probability of such an error occurring in the field seems very low because of the timing requirements, but nonetheless it should be fixed.

- Fix crash-safety bug with newly-created-or-reset sequences (Tom Lane)

If ALTER SEQUENCE was executed on a freshly created or reset sequence, and then precisely one nextval() call was made on it, and then the server crashed, WAL replay would restore the sequence to a state in which it appeared that no nextval() had been done, thus allowing the first sequence value to be returned again by the next nextval() call. In particular this could manifest for serial columns, since creation of a serial column’s sequence includes an ALTER SEQUENCE OWNED BY step.

- Fix race condition in enum-type value comparisons (Robert Haas, Tom Lane)

Comparisons could fail when encountering an enum value added since the current query started.

- Fix txid_current() to report the correct epoch when not in hot standby (Heikki Linnakangas)

This fixes a regression introduced in the previous minor release.

- Prevent selection of unsuitable replication connections as the synchronous standby (Fujii Masao)

The master might improperly choose pseudo-servers such as pg_receivexlog or pg_basebackup as the synchronous standby, and then wait indefinitely for them.

- Fix bug in startup of Hot Standby when a master transaction has many subtransactions (Andres Freund)

This mistake led to failures reported as “out-of-order XID insertion in KnownAssignedXids”.

- Ensure the backup_label file is fsync’d after pg_start_backup() (Dave Kerr)

- Fix timeout handling in walsender processes (Tom Lane)

WAL sender background processes neglected to establish a SIGALRM handler, meaning they would wait forever in some corner cases where a timeout ought to happen.

- Wake walsenders after each background flush by walwriter (Andres Freund, Simon Riggs)

This greatly reduces replication delay when the workload contains only asynchronously-committed transactions.

- Fix LISTEN/NOTIFY to cope better with I/O problems, such as out of disk space (Tom Lane)
Appendix E. Release Notes

After a write failure, all subsequent attempts to send more NOTIFY messages would fail with messages like “Could not read from file "pg_notify/nnnn" at offset nnnnn: Success”.

- Only allow autovacuum to be auto-canceled by a directly blocked process (Tom Lane)
  
  The original coding could allow inconsistent behavior in some cases; in particular, an autovacuum could get canceled after less than deadlock_timeout grace period.

- Improve logging of autovacuum cancels (Robert Haas)

- Fix log collector so that log_truncate_on_rotation works during the very first log rotation after server start (Tom Lane)

- Fix WITH attached to a nested set operation (UNION/INTERSECT/EXCEPT) (Tom Lane)

- Ensure that a whole-row reference to a subquery doesn’t include any extra GROUP BY or ORDER BY columns (Tom Lane)

- Fix dependencies generated during ALTER TABLE ... ADD CONSTRAINT USING INDEX (Tom Lane)
  
  This command left behind a redundant pg_depend entry for the index, which could confuse later operations, notably ALTER TABLE ... ALTER COLUMN TYPE on one of the indexed columns.

- Fix REASSIGN OWNED to work on extensions (Alvaro Herrera)

- Disallow copying whole-row references in CHECK constraints and index definitions during CREATE TABLE (Tom Lane)
  
  This situation can arise in CREATE TABLE with LIKE or INHERITS. The copied whole-row variable was incorrectly labeled with the row type of the original table not the new one. Rejecting the case seems reasonable for LIKE, since the row types might well diverge later. For INHERITS we should ideally allow it, with an implicit coercion to the parent table’s row type; but that will require more work than seems safe to back-patch.

- Fix memory leak in ARRAY(SELECT . . . ) subqueries (Heikki Linnakangas, Tom Lane)

- Fix planner to pass correct collation to operator selectivity estimators (Tom Lane)
  
  This was not previously required by any core selectivity estimation function, but third-party code might need it.

- Fix extraction of common prefixes from regular expressions (Tom Lane)
  
  The code could get confused by quantified parenthesized subexpressions, such as ^{foo}?bar. This would lead to incorrect index optimization of searches for such patterns.

- Fix bugs with parsing signed hh:mm and hh:mm:ss fields in interval constants (Amit Kapila, Tom Lane)

- Fix pg_dump to better handle views containing partial GROUP BY lists (Tom Lane)
  
  A view that lists only a primary key column in GROUP BY, but uses other table columns as if they were grouped, gets marked as depending on the primary key. Improper handling of such primary key dependencies in pg_dump resulted in poorly-ordered dumps, which at best would be inefficient to restore and at worst could result in outright failure of a parallel pg_restore run.

- In PL/Perl, avoid setting UTF8 flag when in SQL_ASCII encoding (Alex Hunsaker, Kyotaro Horiguchi, Alvaro Herrera)
Appendix E. Release Notes

- Use Postgres’ encoding conversion functions, not Python’s, when converting a Python Unicode string to the server encoding in PL/Python (Jan Urbanski)
  This avoids some corner-case problems, notably that Python doesn’t support all the encodings Postgres does. A notable functional change is that if the server encoding is SQL_ASCII, you will get the UTF-8 representation of the string; formerly, any non-ASCII characters in the string would result in an error.
- Fix mapping of PostgreSQL encodings to Python encodings in PL/Python (Jan Urbanski)
- Report errors properly in contrib/xml2’s xslt_process() (Tom Lane)
- Update time zone data files to tzdata release 2012e for DST law changes in Morocco and Tokelau

E.93. Release 9.1.4

Release date: 2012-06-04
This release contains a variety of fixes from 9.1.3. For information about new features in the 9.1 major release, see Section E.97.

E.93.1. Migration to Version 9.1.4

A dump/restore is not required for those running 9.1.X.
However, if you use the citext data type, and you upgraded from a previous major release by running pg_upgrade, you should run CREATE EXTENSION citext FROM unpackaged to avoid collation-related failures in citext operations. The same is necessary if you restore a dump from a pre-9.1 database that contains an instance of the citext data type. If you’ve already run the CREATE EXTENSION command before upgrading to 9.1.4, you will instead need to do manual catalog updates as explained in the third changelog item below.
Also, if you are upgrading from a version earlier than 9.1.2, see Section E.95.

E.93.2. Changes

- Fix incorrect password transformation in contrib/pgcrypto’s DES crypt() function (Solar Designer)
  If a password string contained the byte value 0x80, the remainder of the password was ignored, causing the password to be much weaker than it appeared. With this fix, the rest of the string is properly included in the DES hash. Any stored password values that are affected by this bug will thus no longer match, so the stored values may need to be updated. (CVE-2012-2143)
- Ignore SECURITY DEFINER and SET attributes for a procedural language’s call handler (Tom Lane)
  Applying such attributes to a call handler could crash the server. (CVE-2012-2655)
- Make contrib/citext’s upgrade script fix collations of citext arrays and domains over citext (Tom Lane)
Appendix E. Release Notes

Release 9.1.2 provided a fix for collations of citext columns and indexes in databases upgraded or reloaded from pre-9.1 installations, but that fix was incomplete: it neglected to handle arrays and domains over citext. This release extends the module’s upgrade script to handle these cases. As before, if you have already run the upgrade script, you’ll need to run the collation update commands by hand instead. See the 9.1.2 release notes for more information about doing this.

- Allow numeric timezone offsets in timestamp input to be up to 16 hours away from UTC (Tom Lane)
  Some historical time zones have offsets larger than 15 hours, the previous limit. This could result in dumped data values being rejected during reload.

- Fix timestamp conversion to cope when the given time is exactly the last DST transition time for the current timezone (Tom Lane)
  This oversight has been there a long time, but was not noticed previously because most DST-using zones are presumed to have an indefinite sequence of future DST transitions.

- Fix text to name and char to name casts to perform string truncation correctly in multibyte encodings (Karl Schnaitter)

- Fix memory copying bug in to_tsquery() (Heikki Linnakangas)

- Ensure txid_current() reports the correct epoch when executed in hot standby (Simon Riggs)

- Fix planner’s handling of outer PlaceHolderVars within subqueries (Tom Lane)
  This bug concerns sub-SELECTs that reference variables coming from the nullable side of an outer join of the surrounding query. In 9.1, queries affected by this bug would fail with “ERROR: Upper-level PlaceHolderVar found where not expected”. But in 9.0 and 8.4, you’d silently get possibly-wrong answers, since the value transmitted into the subquery wouldn’t go to null when it should.

- Fix planning of UNION ALL subqueries with output columns that are not simple variables (Tom Lane)
  Planning of such cases got noticeably worse in 9.1 as a result of a misguided fix for “MergeAppend child’s targetlist doesn’t match MergeAppend” errors. Revert that fix and do it another way.

- Fix slow session startup when pg_attribute is very large (Tom Lane)
  If pg_attribute exceeds one-fourth of shared_buffers, cache rebuilding code that is sometimes needed during session start would trigger the synchronized-scan logic, causing it to take many times longer than normal. The problem was particularly acute if many new sessions were starting at once.

- Ensure sequential scans check for query cancel reasonably often (Merlin Moncure)
  A scan encountering many consecutive pages that contain no live tuples would not respond to interrupts meanwhile.

- Ensure the Windows implementation of PGSemaphoreLock() clears ImmediateInterruptOK before returning (Tom Lane)
  This oversight meant that a query-cancel interrupt received later in the same query could be accepted at an unsafe time, with unpredictable but not good consequences.

- Show whole-row variables safely when printing views or rules (Abbas Butt, Tom Lane)
  Corner cases involving ambiguous names (that is, the name could be either a table or column name of the query) were printed in an ambiguous way, risking that the view or rule would be interpreted differently after dump and reload. Avoid the ambiguous case by attaching a no-op cast.

- Fix COPY FROM to properly handle null marker strings that correspond to invalid encoding (Tom Lane)
Appendix E. Release Notes

A null marker string such as E’\0’ should work, and did work in the past, but the case got broken in 8.4.

• Fix EXPLAIN VERBOSE for writable CTEs containing RETURNING clauses (Tom Lane)

• Fix PREPARE TRANSACTION to work correctly in the presence of advisory locks (Tom Lane)
  Historically, PREPARE TRANSACTION has simply ignored any session-level advisory locks the session holds, but this case was accidentally broken in 9.1.

• Fix truncation of unlogged tables (Robert Haas)

• Ignore missing schemas during non-interactive assignments of search_path (Tom Lane)
  This re-aligns 9.1’s behavior with that of older branches. Previously 9.1 would throw an error for nonexistent schemas mentioned in search_path settings obtained from places such as ALTER DATABASE SET.

• Fix bugs with temporary or transient tables used in extension scripts (Tom Lane)
  This includes cases such as a rewriting ALTER TABLE within an extension update script, since that uses a transient table behind the scenes.

• Ensure autovacuum worker processes perform stack depth checking properly (Heikki Linnakangas)
  Previously, infinite recursion in a function invoked by auto-Analyze could crash worker processes.

• Fix logging collector to not lose log coherency under high load (Andrew Dunstan)
  The collector previously could fail to reassemble large messages if it got too busy.

• Fix logging collector to ensure it will restart file rotation after receiving SIGHUP (Tom Lane)

• Fix “too many LWLocks taken” failure in GiST indexes (Heikki Linnakangas)

• Fix WAL replay logic for GIN indexes to not fail if the index was subsequently dropped (Tom Lane)

• Correctly detect SSI conflicts of prepared transactions after a crash (Dan Ports)

• Avoid synchronous replication delay when committing a transaction that only modified temporary tables (Heikki Linnakangas)
  In such a case the transaction’s commit record need not be flushed to standby servers, but some of the code didn’t know that and waited for it to happen anyway.

• Fix error handling in pg_basebackup (Thomas Ogrisegg, Fujii Masao)

• Fix walsender to not go into a busy loop if connection is terminated (Fujii Masao)

• Fix memory leak in PL/pgSQL’s RETURN NEXT command (Joe Conway)

• Fix PL/pgSQL’s GET DIAGNOSTICS command when the target is the function’s first variable (Tom Lane)

• Ensure that PL/Perl package-qualifies the _TD variable (Alex Hunsaker)
  This bug caused trigger invocations to fail when they are nested within a function invocation that changes the current package.

• Fix PL/Python functions returning composite types to accept a string for their result value (Jan Urban-ski)
  This case was accidentally broken by the 9.1 additions to allow a composite result value to be supplied in other formats, such as dictionaries.
Appendix E. Release Notes

- Fix potential access off the end of memory in psql’s expanded display (\x) mode (Peter Eisentraut)
- Fix several performance problems in pg_dump when the database contains many objects (Jeff Janes, Tom Lane)
  pg_dump could get very slow if the database contained many schemas, or if many objects are in dependency loops, or if there are many owned sequences.
- Fix memory and file descriptor leaks in pg_restore when reading a directory-format archive (Peter Eisentraut)
- Fix pg_upgrade for the case that a database stored in a non-default tablespace contains a table in the cluster’s default tablespace (Bruce Momjian)
- In ecpg, fix rare memory leaks and possible overwrite of one byte after the sqlca_t structure (Peter Eisentraut)
- Fix contrib/dblink’s dblink_exec() to not leak temporary database connections upon error (Tom Lane)
- Fix contrib/dblink to report the correct connection name in error messages (Kyotaro Horiguchi)
- Fix contrib/vacuumlo to use multiple transactions when dropping many large objects (Tim Lewis, Robert Haas, Tom Lane)
  This change avoids exceeding max_locks_per_transaction when many objects need to be dropped. The behavior can be adjusted with the new -l (limit) option.
- Update time zone data files to tzdata release 2012c for DST law changes in Antarctica, Armenia, Chile, Cuba, Falkland Islands, Gaza, Haiti, Hebron, Morocco, Syria, and Tokelau Islands; also historical corrections for Canada.

E.94. Release 9.1.3

Release date: 2012-02-27

This release contains a variety of fixes from 9.1.2. For information about new features in the 9.1 major release, see Section E.97.

E.94.1. Migration to Version 9.1.3

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.2, see Section E.95.

E.94.2. Changes

- Require execute permission on the trigger function for CREATE TRIGGER (Robert Haas)
This missing check could allow another user to execute a trigger function with forged input data, by installing it on a table he owns. This is only of significance for trigger functions marked **SECURITY DEFINER**, since otherwise trigger functions run as the table owner anyway. (CVE-2012-0866)

- **Remove arbitrary limitation on length of common name in SSL certificates** (Heikki Linnakangas)

  Both libpq and the server truncated the common name extracted from an SSL certificate at 32 bytes. Normally this would cause nothing worse than an unexpected verification failure, but there are some rather-implausible scenarios in which it might allow one certificate holder to impersonate another. The victim would have to have a common name exactly 32 bytes long, and the attacker would have to persuade a trusted CA to issue a certificate in which the common name has that string as a prefix. Impersonating a server would also require some additional exploit to redirect client connections. (CVE-2012-0867)

- **Convert newlines to spaces in names written in pg_dump comments** (Robert Haas)

  pg_dump was incautious about sanitizing object names that are emitted within SQL comments in its output script. A name containing a newline would at least render the script syntactically incorrect. Maliciously crafted object names could present a SQL injection risk when the script is reloaded. (CVE-2012-0868)

- **Fix btree index corruption from insertions concurrent with vacuuming** (Tom Lane)

  An index page split caused by an insertion could sometimes cause a concurrently-running **VACUUM** to miss removing index entries that it should remove. After the corresponding table rows are removed, the dangling index entries would cause errors (such as “could not read block N in file ...”) or worse, silently wrong query results after unrelated rows are re-inserted at the now-free table locations. This bug has been present since release 8.2, but occurs so infrequently that it was not diagnosed until now. If you have reason to suspect that it has happened in your database, reindexing the affected index will fix things.

- **Fix transient zeroing of shared buffers during WAL replay** (Tom Lane)

  The replay logic would sometimes zero and refill a shared buffer, so that the contents were transiently invalid. In hot standby mode this can result in a query that’s executing in parallel seeing garbage data. Various symptoms could result from that, but the most common one seems to be “invalid memory alloc request size”.

- **Fix handling of data-modifying **WITH** subplans in **READ COMMITTED** rechecking** (Tom Lane)

  A **WITH** clause containing **INSERT/UPDATE/DELETE** would crash if the parent **UPDATE** or **DELETE** command needed to be re-evaluated at one or more rows due to concurrent updates in **READ COMMITTED** mode.

- **Fix corner case in SSI transaction cleanup** (Dan Ports)

  When finishing up a read-write serializable transaction, a crash could occur if all remaining active serializable transactions are read-only.

- **Fix postmaster to attempt restart after a hot-standby crash** (Tom Lane)

  A logic error caused the postmaster to terminate, rather than attempt to restart the cluster, if any backend process crashed while operating in hot standby mode.

- **Fix **CLUSTER/VACUUM FULL** handling of toast values owned by recently-updated rows** (Tom Lane)

  This oversight could lead to “duplicate key value violates unique constraint” errors being reported against the toast table’s index during one of these commands.
Appendix E. Release Notes

- Update per-column permissions, not only per-table permissions, when changing table owner (Tom Lane)
  Failure to do this meant that any previously granted column permissions were still shown as having been granted by the old owner. This meant that neither the new owner nor a superuser could revoke the now-untraceable-to-table-owner permissions.

- Support foreign data wrappers and foreign servers in `REASSIGN OWNED` (Alvaro Herrera)
  This command failed with "unexpected classid" errors if it needed to change the ownership of any such objects.

- Allow non-existent values for some settings in `ALTER USER/DATABASE SET` (Heikki Linnakangas)
  Allow `default_text_search_config`, `default_tablespace`, and `temp_tablespace` to be set to names that are not known. This is because they might be known in another database where the setting is intended to be used, or for the tablespace cases because the tablespace might not be created yet. The same issue was previously recognized for `search_path`, and these settings now act like that one.

- Fix “unsupported node type” error caused by `COLLATE` in an `INSERT` expression (Tom Lane)

- Avoid crashing when we have problems deleting table files post-commit (Tom Lane)
  Dropping a table should lead to deleting the underlying disk files only after the transaction commits. In event of failure then (for instance, because of wrong file permissions) the code is supposed to just emit a warning message and go on, since it’s too late to abort the transaction. This logic got broken as of release 8.4, causing such situations to result in a PANIC and an unrestartable database.

- Recover from errors occurring during WAL replay of `DROP TABLESPACE` (Tom Lane)
  Replay will attempt to remove the tablespace’s directories, but there are various reasons why this might fail (for example, incorrect ownership or permissions on those directories). Formerly the replay code would panic, rendering the database unrestartable without manual intervention. It seems better to log the problem and continue, since the only consequence of failure to remove the directories is some wasted disk space.

- Fix race condition in logging `AccessExclusiveLocks` for hot standby (Simon Riggs)
  Sometimes a lock would be logged as being held by “transaction zero”. This is at least known to produce assertion failures on slave servers, and might be the cause of more serious problems.

- Track the OID counter correctly during WAL replay, even when it wraps around (Tom Lane)
  Previously the OID counter would remain stuck at a high value until the system exited replay mode. The practical consequences of that are usually nil, but there are scenarios wherein a standby server that’s been promoted to master might take a long time to advance the OID counter to a reasonable value once values are needed.

- Prevent emitting misleading “consistent recovery state reached” log message at the beginning of crash recovery (Heikki Linnakangas)

- Fix initial value of `pg_stat_replication.replay_location` (Fujii Masao)
  Previously, the value shown would be wrong until at least one WAL record had been replayed.

- Fix regular expression back-references with `*` attached (Tom Lane)
  Rather than enforcing an exact string match, the code would effectively accept any string that satisfies the pattern sub-expression referenced by the back-reference symbol.
Appendix E. Release Notes

A similar problem still afflicts back-references that are embedded in a larger quantified expression, rather than being the immediate subject of the quantifier. This will be addressed in a future PostgreSQL release.

- Fix recently-introduced memory leak in processing of inet/cidr values (Heikki Linnakangas)
  A patch in the December 2011 releases of PostgreSQL caused memory leakage in these operations, which could be significant in scenarios such as building a btree index on such a column.
- Fix planner’s ability to push down index-expression restrictions through \texttt{UNION ALL} (Tom Lane)
  This type of optimization was inadvertently disabled by a fix for another problem in 9.1.2.
- Fix planning of \texttt{WITH} clauses referenced in \texttt{UPDATE/DELETE} on an inherited table (Tom Lane)
  This bug led to “could not find plan for CTE” failures.
- Fix GIN cost estimation to handle \texttt{column IN (...) index conditions} (Marti Raudsepp)
  This oversight would usually lead to crashes if such a condition could be used with a GIN index.
- Prevent assertion failure when exiting a session with an open, failed transaction (Tom Lane)
  This bug has no impact on normal builds with asserts not enabled.
- Fix dangling pointer after \texttt{CREATE TABLE AS/SELECT INTO} in a SQL-language function (Tom Lane)
  In most cases this only led to an assertion failure in assert-enabled builds, but worse consequences seem possible.
- Avoid double close of file handle in syslogger on Windows (MauMau)
  Ordinarily this error was invisible, but it would cause an exception when running on a debug version of Windows.
- Fix I/O-conversion-related memory leaks in plpgsql (Andres Freund, Jan Urbanski, Tom Lane)
  Certain operations would leak memory until the end of the current function.
- Work around bug in perl’s \texttt{SvPVutf8()} function (Andrew Dunstan)
  This function crashes when handed a typeglob or certain read-only objects such as $^{\texttt{^V}}$. Make plperl avoid passing those to it.
- In \texttt{pg_dump}, don’t dump contents of an extension’s configuration tables if the extension itself is not being dumped (Tom Lane)
- Improve \texttt{pg_dump}’s handling of inherited table columns (Tom Lane)
  \texttt{pg_dump} mishandled situations where a child column has a different default expression than its parent column. If the default is textually identical to the parent’s default, but not actually the same (for instance, because of schema search path differences) it would not be recognized as different, so that after dump and restore the child would be allowed to inherit the parent’s default. Child columns that are \texttt{NOT NULL} where their parent is not could also be restored subtly incorrectly.
- Fix \texttt{pg_restore}’s direct-to-database mode for \texttt{INSERT}-style table data (Tom Lane)
  Direct-to-database restores from archive files made with \texttt{--inserts} or \texttt{--column-inserts} options fail when using \texttt{pg_restore} from a release dated September or December 2011, as a result of an oversight in a fix for another problem. The archive file itself is not at fault, and text-mode output is okay.
- Teach \texttt{pg_upgrade} to handle renaming of plpython’s shared library (Bruce Momjian)
Appendix E. Release Notes

Upgrading a pre-9.1 database that included plpython would fail because of this oversight.

- Allow `pg_upgrade` to process tables containing `regclass` columns (Bruce Momjian)

  Since `pg_upgrade` now takes care to preserve `pg_class` OIDs, there was no longer any reason for this restriction.

- Make `libpq` ignore `ENOTDIR` errors when looking for an SSL client certificate file (Magnus Hagander)

  This allows SSL connections to be established, though without a certificate, even when the user’s home directory is set to something like `/dev/null`.

- Fix some more field alignment issues in `ecpg`’s SQLDA area (Zoltan Boszormenyi)

- Allow `AT` option in `ecpg DEALLOCATE` statements (Michael Meskes)

  The infrastructure to support this has been there for awhile, but through an oversight there was still an error check rejecting the case.

- Do not use the variable name when defining a varchar structure in `ecpg` (Michael Meskes)

- Fix `contrib/auto_explain`’s JSON output mode to produce valid JSON (Andrew Dunstan)

  The output used brackets at the top level, when it should have used braces.

- Fix error in `contrib/intarray`’s `int[] & int[]` operator (Guillaume Lelarge)

  If the smallest integer the two input arrays have in common is 1, and there are smaller values in either array, then 1 would be incorrectly omitted from the result.

- Fix error detection in `contrib/pgcrypto`’s `encrypt_iv()` and `decrypt_iv()` (Marko Kreen)

  These functions failed to report certain types of invalid-input errors, and would instead return random garbage values for incorrect input.

- Fix one-byte buffer overrun in `contrib/test_parser` (Paul Guyot)

  The code would try to read one more byte than it should, which would crash in corner cases. Since `contrib/test_parser` is only example code, this is not a security issue in itself, but bad example code is still bad.

- Use `__sync_lock_test_and_set()` for spinlocks on ARM, if available (Martin Pitt)

  This function replaces our previous use of the `SWPB` instruction, which is deprecated and not available on ARMv6 and later. Reports suggest that the old code doesn’t fail in an obvious way on recent ARM boards, but simply doesn’t interlock concurrent accesses, leading to bizarre failures in multiprocess operation.

- Use `-fexcess-precision=standard` option when building with gcc versions that accept it (Andrew Dunstan)

  This prevents assorted scenarios wherein recent versions of gcc will produce creative results.

- Allow use of threaded Python on FreeBSD (Chris Rees)

  Our configure script previously believed that this combination wouldn’t work; but FreeBSD fixed the problem, so remove that error check.

- Allow MinGW builds to use standardly-named OpenSSL libraries (Tomasz Ostrowski)
E.95. Release 9.1.2

Release date: 2011-12-05

This release contains a variety of fixes from 9.1.1. For information about new features in the 9.1 major release, see Section E.97.

E.95.1. Migration to Version 9.1.2

A dump/restore is not required for those running 9.1.X.

However, a longstanding error was discovered in the definition of the information_schema.referential_constraints view. If you rely on correct results from that view, you should replace its definition as explained in the first changelog item below.

Also, if you use the citext data type, and you upgraded from a previous major release by running pg_upgrade, you should run CREATE EXTENSION citext FROM unpackaged to avoid collation-related failures in citext operations. The same is necessary if you restore a dump from a pre-9.1 database that contains an instance of the citext data type. If you’ve already run the CREATE EXTENSION command before upgrading to 9.1.2, you will instead need to do manual catalog updates as explained in the second changelog item.

E.95.2. Changes

• Fix bugs in information_schema.referential_constraints view (Tom Lane)

This view was being insufficiently careful about matching the foreign-key constraint to the depended-on primary or unique key constraint. That could result in failure to show a foreign key constraint at all, or showing it multiple times, or claiming that it depends on a different constraint than the one it really does.

Since the view definition is installed by initdb, merely upgrading will not fix the problem. If you need to fix this in an existing installation, you can (as a superuser) drop the information_schema schema then re-create it by sourcing $SHAREDIR/information_schema.sql. (Run pg_config --sharedir if you’re uncertain where $SHAREDIR is.) This must be repeated in each database to be fixed.

• Make contrib/citext’s upgrade script fix collations of citext columns and indexes (Tom Lane)

Existing citext columns and indexes aren’t correctly marked as being of a collatable data type during pg_upgrade from a pre-9.1 server, or when a pre-9.1 dump containing the citext type is loaded into a 9.1 server. That leads to operations on these columns failing with errors such as “could not determine which collation to use for string comparison”. This change allows them to be fixed by the same script that upgrades the citext module into a proper 9.1 extension during CREATE EXTENSION citext FROM unpackaged.

If you have a previously-upgraded database that is suffering from this problem, and you already ran the CREATE EXTENSION command, you can manually run (as superuser) the UPDATE commands found at the end of $SHAREDIR/extension/citext--unpackaged--1.0.sql. (Run pg_config --sharedir if you’re uncertain where $SHAREDIR is.) There is no harm in doing this again if unsure.
Appendix E. Release Notes

- Fix possible crash during UPDATE or DELETE that joins to the output of a scalar-returning function (Tom Lane)
  A crash could only occur if the target row had been concurrently updated, so this problem surfaced only intermittently.

- Fix incorrect replay of WAL records for GIN index updates (Tom Lane)
  This could result in transiently failing to find index entries after a crash, or on a hot-standby server. The problem would be repaired by the next VACUUM of the index, however.

- Fix TOAST-related data corruption during CREATE TABLE dest AS SELECT * FROM src or INSERT INTO dest SELECT * FROM src (Tom Lane)
  If a table has been modified by ALTER TABLE ADD COLUMN, attempts to copy its data verbatim to another table could produce corrupt results in certain corner cases. The problem can only manifest in this precise form in 8.4 and later, but we patched earlier versions as well in case there are other code paths that could trigger the same bug.

- Fix possible failures during hot standby startup (Simon Riggs)

- Start hot standby faster when initial snapshot is incomplete (Simon Riggs)

- Fix race condition during toast table access from stale syscache entries (Tom Lane)
  The typical symptom was transient errors like “missing chunk number 0 for toast value NNNNN in pg_toast_2619”, where the cited toast table would always belong to a system catalog.

- Track dependencies of functions on items used in parameter default expressions (Tom Lane)
  Previously, a referenced object could be dropped without having dropped or modified the function, leading to misbehavior when the function was used. Note that merely installing this update will not fix the missing dependency entries; to do that, you’d need to CREATE OR REPLACE each such function afterwards. If you have functions whose defaults depend on non-built-in objects, doing so is recommended.

- Fix incorrect management of placeholder variables in nestloop joins (Tom Lane)
  This bug is known to lead to “variable not found in subplan target list” planner errors, and could possibly result in wrong query output when outer joins are involved.

- Fix window functions that sort by expressions involving aggregates (Tom Lane)
  Previously these could fail with “could not find pathkey item to sort” planner errors.

- Fix “MergeAppend child’s targetlist doesn’t match MergeAppend” planner errors (Tom Lane)

- Fix index matching for operators with both collatable and noncollatable inputs (Tom Lane)
  In 9.1.0, an indexable operator that has a non-collatable left-hand input type and a collatable right-hand input type would not be recognized as matching the left-hand column’s index. An example is the hstore ? text operator.

- Allow inlining of set-returning SQL functions with multiple OUT parameters (Tom Lane)

- Don’t trust deferred-unique indexes for join removal (Tom Lane and Marti Raudsepp)
  A deferred uniqueness constraint might not hold intra-transaction, so assuming that it does could give incorrect query results.
• Make DatumGetInetP() unpack inet datums that have a 1-byte header, and add a new macro, DatumGetInetPP(), that does not (Heikki Linnakangas)

This change affects no core code, but might prevent crashes in add-on code that expects DatumGetInetP() to produce an unpacked datum as per usual convention.

• Improve locale support in money type’s input and output (Tom Lane)

Aside from not supporting all standard lc_monetary formatting options, the input and output functions were inconsistent, meaning there were locales in which dumped money values could not be re-read.

• Don’t let transform_null_equals affect CASE foo WHEN NULL ... constructs (Heikki Linnakangas)

transform_null_equals is only supposed to affect foo = NULL expressions written directly by the user, not equality checks generated internally by this form of CASE.

• Change foreign-key trigger creation order to better support self-referential foreign keys (Tom Lane)

For a cascading foreign key that references its own table, a row update will fire both the ON UPDATE trigger and the CHECK trigger as one event. The ON UPDATE trigger must execute first, else the CHECK will check a non-final state of the row and possibly throw an inappropriate error. However, the firing order of these triggers is determined by their names, which generally sort in creation order since the triggers have auto-generated names following the convention “RI_ConstraintTrigger_NNNN”. A proper fix would require modifying that convention, which we will do in 9.2, but it seems risky to change it in existing releases. So this patch just changes the creation order of the triggers. Users encountering this type of error should drop and re-create the foreign key constraint to get its triggers into the right order.

• Fix IF EXISTS to work correctly in DROP OPERATOR FAMILY (Robert Haas)

• Disallow dropping of an extension from within its own script (Tom Lane)

This prevents odd behavior in case of incorrect management of extension dependencies.

• Don’t mark auto-generated types as extension members (Robert Haas)

Relation rowtypes and automatically-generated array types do not need to have their own extension membership entries in pg_depend, and creating such entries complicates matters for extension upgrades.

• Cope with invalid pre-existing search_path settings during CREATE EXTENSION (Tom Lane)

• Avoid floating-point underflow while tracking buffer allocation rate (Greg Matthews)

While harmless in itself, on certain platforms this would result in annoying kernel log messages.

• Prevent autovacuum transactions from running in serializable mode (Tom Lane)

Autovacuum formerly used the cluster-wide default transaction isolation level, but there is no need for it to use anything higher than READ COMMITTED, and using SERIALIZABLE could result in unnecessary delays for other processes.

• Ensure walsender processes respond promptly to SIGTERM (Magnus Hagander)

• Exclude postmaster.opts from base backups (Magnus Hagander)

• Preserve configuration file name and line number values when starting child processes under Windows (Tom Lane)
Appendix E. Release Notes

Formerly, these would not be displayed correctly in the `pg_settings` view.

- Fix incorrect field alignment in ecpg’s SQLDA area (Zoltan Boszormenyi)
- Preserve blank lines within commands in `psql`’s command history (Robert Haas)
  The former behavior could cause problems if an empty line was removed from within a string literal, for example.
- Avoid platform-specific infinite loop in `pg_dump` (Steve Singer)
- Fix compression of plain-text output format in `pg_dump` (Adrian Klaver and Tom Lane)
  `pg_dump` has historically understood `-Z` with no `-F` switch to mean that it should emit a gzip-compressed version of its plain text output. Restore that behavior.
- Fix `pg_dump` to dump user-defined casts between auto-generated types, such as table rowtypes (Tom Lane)
- Fix missed quoting of foreign server names in `pg_dump` (Tom Lane)
- Assorted fixes for `pg_upgrade` (Bruce Momjian)
  Handle exclusion constraints correctly, avoid failures on Windows, don’t complain about mismatched toast table names in 8.4 databases.
- In PL/pgSQL, allow foreign tables to define row types (Alexander Soudakov)
- Fix up conversions of PL/Perl functions’ results (Alex Hunsaker and Tom Lane)
  Restore the pre-9.1 behavior that PL/Perl functions returning `void` ignore the result value of their last Perl statement; 9.1.0 would throw an error if that statement returned a reference. Also, make sure it works to return a string value for a composite type, so long as the string meets the type’s input format. In addition, throw errors for attempts to return Perl arrays or hashes when the function’s declared result type is not an array or composite type, respectively. (Pre-9.1 versions rather uselessly returned strings like `ARRAY(0x221a9a0)` or `HASH(0x221aa90)` in such cases.)
- Ensure PL/Perl strings are always correctly UTF8-encoded (Amit Khandekar and Alex Hunsaker)
- Use the preferred version of xsubpp to build PL/Perl, not necessarily the operating system’s main copy (David Wheeler and Alex Hunsaker)
- Correctly propagate SQLSTATE in PL/Python exceptions (Mika Eloranta and Jan Urbanski)
- Do not install PL/Python extension files for Python major versions other than the one built against (Peter Eisentraut)
- Change all the `contrib` extension script files to report a useful error message if they are fed to `psql` (Andrew Dunstan and Tom Lane)
  This should help teach people about the new method of using `CREATE EXTENSION` to load these files. In most cases, sourcing the scripts directly would fail anyway, but with harder-to-interpret messages.
- Fix incorrect coding in `contrib/dict_int` and `contrib/dict_xsyn` (Tom Lane)
  Some functions incorrectly assumed that memory returned by `palloc()` is guaranteed zeroed.
- Remove `contrib/sepgsql` tests from the regular regression test mechanism (Tom Lane)
  Since these tests require root privileges for setup, they’re impractical to run automatically. Switch over to a manual approach instead, and provide a testing script to help with that.
- Fix assorted errors in `contrib/unaccent`’s configuration file parsing (Tom Lane)
Appendix E. Release Notes

- Honor query cancel interrupts promptly in `pgstatindex()` (Robert Haas)
- Fix incorrect quoting of log file name in macOS start script (Sidar Lopez)
- Revert unintentional enabling of `WAL_DEBUG` (Robert Haas)
  Fortunately, as debugging tools go, this one is pretty cheap; but it’s not intended to be enabled by default, so revert.
- Ensure VPATH builds properly install all server header files (Peter Eisentraut)
- Shorten file names reported in verbose error messages (Peter Eisentraut)
  Regular builds have always reported just the name of the C file containing the error message call, but VPATH builds formerly reported an absolute path name.
- Fix interpretation of Windows timezone names for Central America (Tom Lane)
  Map “Central America Standard Time” to `CST6`, not `CST6CDT`, because DST is generally not observed anywhere in Central America.
- Update time zone data files to `tzdata` release 2011n for DST law changes in Brazil, Cuba, Fiji, Palestine, Russia, and Samoa; also historical corrections for Alaska and British East Africa.

E.96. Release 9.1.1

Release date: 2011-09-26
This release contains a small number of fixes from 9.1.0. For information about new features in the 9.1 major release, see Section E.97.

E.96.1. Migration to Version 9.1.1
A dump/restore is not required for those running 9.1.X.

E.96.2. Changes

- Make `pg_options_to_table` return NULL for an option with no value (Tom Lane)
  Previously such cases would result in a server crash.
- Fix memory leak at end of a GiST index scan (Tom Lane)
  Commands that perform many separate GiST index scans, such as verification of a new GiST-based exclusion constraint on a table already containing many rows, could transiently require large amounts of memory due to this leak.
- Fix explicit reference to `pg_temp` schema in `CREATE TEMPORARY TABLE` (Robert Haas)
  This used to be allowed, but failed in 9.1.0.
E.97. Release 9.1

Release date: 2011-09-12

E.97.1. Overview

This release shows PostgreSQL moving beyond the traditional relational-database feature set with new, ground-breaking functionality that is unique to PostgreSQL. The streaming replication feature introduced in release 9.0 is significantly enhanced by adding a synchronous-replication option, streaming backups, and monitoring improvements. Major enhancements include:

- Allow synchronous replication
- Add support for foreign tables
- Add per-column collation support
- Add extensions which simplify packaging of additions to PostgreSQL
- Add a true serializable isolation level
- Support unlogged tables using the `UNLOGGED` option in `CREATE TABLE`
- Allow data-modification commands (INSERT/UPDATE/DELETE) in WITH clauses
- Add nearest-neighbor (order-by-operator) searching to GiST indexes
- Add a SECURITY LABEL command and support for SELinux permissions control
- Update the PL/Python server-side language

The above items are explained in more detail in the sections below.

E.97.2. Migration to Version 9.1

A dump/restore using pg_dump, or use of pg_upgrade, is required for those wishing to migrate data from any previous release.

Version 9.1 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

E.97.2.1. Strings

- Change the default value of `standard_conforming_strings` to on (Robert Haas)

  By default, backslashes are now ordinary characters in string literals, not escape characters. This change removes a long-standing incompatibility with the SQL standard. `escape_string_warning` has produced warnings about this usage for years. \"E\" strings are the proper way to embed backslash escapes in strings and are unaffected by this change.
Warning

This change can break applications that are not expecting it and do their own string escaping according to the old rules. The consequences could be as severe as introducing SQL-injection security holes. Be sure to test applications that are exposed to untrusted input, to ensure that they correctly handle single quotes and backslashes in text strings.

E.97.2.2. Casting

- Disallow function-style and attribute-style data type casts for composite types (Tom Lane)
  For example, disallow `composite_value.text` and `text(composite_value)`. Unintentional uses of this syntax have frequently resulted in bug reports; although it was not a bug, it seems better to go back to rejecting such expressions. The `CAST` and `::` syntaxes are still available for use when a cast of an entire composite value is actually intended.
- Tighten casting checks for domains based on arrays (Tom Lane)
  When a domain is based on an array type, it is allowed to “look through” the domain type to access the array elements, including subscripting the domain value to fetch or assign an element. Assignment to an element of such a domain value, for instance via `UPDATE ... SET domaincol[5] = ...`, will now result in rechecking the domain type’s constraints, whereas before the checks were skipped.

E.97.2.3. Arrays

- Change `string_to_array()` to return an empty array for a zero-length string (Pavel Stehule)
  Previously this returned a null value.
- Change `string_to_array()` so a `NULL` separator splits the string into characters (Pavel Stehule)
  Previously this returned a null value.

E.97.2.4. Object Modification

- Fix improper checks for before/after triggers (Tom Lane)
  Triggers can now be fired in three cases: BEFORE, AFTER, or INSTEAD OF some action. Trigger function authors should verify that their logic behaves sanely in all three cases.
- Require superuser or CREATEROLE permissions in order to set comments on roles (Tom Lane)
E.97.2.5. Server Settings

- Change `pg_last_xlog_receive_location()` so it never moves backwards (Fujii Masao)
  
  Previously, the value of `pg_last_xlog_receive_location()` could move backward when streaming replication is restarted.

- Have logging of replication connections honor `log_connections` (Magnus Hagander)
  
  Previously, replication connections were always logged.

E.97.2.6. PL/pgSQL Server-Side Language

- Change PL/pgSQL’s `RAISE` command without parameters to be catchable by the attached exception block (Piyush Newe)
  
  Previously `RAISE` in a code block was always scoped to an attached exception block, so it was uncatchable at the same scope.

- Adjust PL/pgSQL’s error line numbering code to be consistent with other PLs (Pavel Stehule)
  
  Previously, PL/pgSQL would ignore (not count) an empty line at the start of the function body. Since this was inconsistent with all other languages, the special case was removed.

- Make PL/pgSQL complain about conflicting IN and OUT parameter names (Tom Lane)
  
  Formerly, the collision was not detected, and the name would just silently refer to only the OUT parameter.

- Type modifiers of PL/pgSQL variables are now visible to the SQL parser (Tom Lane)
  
  A type modifier (such as a varchar length limit) attached to a PL/pgSQL variable was formerly enforced during assignments, but was ignored for all other purposes. Such variables will now behave more like table columns declared with the same modifier. This is not expected to make any visible difference in most cases, but it could result in subtle changes for some SQL commands issued by PL/pgSQL functions.

E.97.2.7. Contrib

- All contrib modules are now installed with `CREATE EXTENSION` rather than by manually invoking their SQL scripts (Dimitri Fontaine, Tom Lane)
  
  To update an existing database containing the 9.0 version of a contrib module, use `CREATE EXTENSION ... FROM unpackaged` to wrap the existing contrib module’s objects into an extension. When updating from a pre-9.0 version, drop the contrib module’s objects using its old uninstall script, then use `CREATE EXTENSION`.

E.97.2.8. Other Incompatibilities

- Make `pg_stat_reset()` reset all database-level statistics (Tomas Vondra)
Some `pg_stat_database` counters were not being reset.

- Fix some `information_schema.triggers` column names to match the new SQL-standard names (Dean Rasheed)
- Treat ECPG cursor names as case-insensitive (Zoltan Boszormenyi)

**E.97.3. Changes**

Below you will find a detailed account of the changes between PostgreSQL 9.1 and the previous major release.

**E.97.3.1. Server**

**E.97.3.1.1. Performance**

- Support unlogged tables using the `UNLOGGED` option in `CREATE TABLE` (Robert Haas)
  Such tables provide better update performance than regular tables, but are not crash-safe: their contents are automatically cleared in case of a server crash. Their contents do not propagate to replication slaves, either.
- Allow `FULL OUTER JOIN` to be implemented as a hash join, and allow either side of a `LEFT OUTER JOIN` or `RIGHT OUTER JOIN` to be hashed (Tom Lane)
  Previously `FULL OUTER JOIN` could only be implemented as a merge join, and `LEFT OUTER JOIN` and `RIGHT OUTER JOIN` could hash only the nullable side of the join. These changes provide additional query optimization possibilities.
- Merge duplicate fsync requests (Robert Haas, Greg Smith)
  This greatly improves performance under heavy write loads.
- Improve performance of `commit_siblings` (Greg Smith)
  This allows the use of `commit_siblings` with less overhead.
- Reduce the memory requirement for large ispell dictionaries (Pavel Stehule, Tom Lane)
- Avoid leaving data files open after “blind writes” (Alvaro Herrera)
  This fixes scenarios in which backends might hold files open long after they were deleted, preventing the kernel from reclaiming disk space.

**E.97.3.1.2. Optimizer**

- Allow inheritance table scans to return meaningfully-sorted results (Greg Stark, Hans-Jurgen Schonig, Robert Haas, Tom Lane)
  This allows better optimization of queries that use `ORDER BY`, `LIMIT`, or `MIN/MAX` with inherited tables.
- Improve GIN index scan cost estimation (Teodor Sigaev)
• Improve cost estimation for aggregates and window functions (Tom Lane)

**E.97.3.1.3. Authentication**

• Support host names and host suffixes (e.g. .example.com) in pg_hba.conf (Peter Eisentraut)
  Previously only host IP addresses and CIDR values were supported.
• Support the key word **all** in the host column of pg_hba.conf (Peter Eisentraut)
  Previously people used 0.0.0.0/0 or ::/0 for this.
• Reject local lines in pg_hba.conf on platforms that don’t support Unix-socket connections (Magnus Hagander)
  Formerly, such lines were silently ignored, which could be surprising. This makes the behavior more like other unsupported cases.
• Allow GSSAPI to be used to authenticate to servers via SSPI (Christian Ullrich)
  Specifically this allows Unix-based GSSAPI clients to do SSPI authentication with Windows servers.
• **ident** authentication over local sockets is now known as **peer** (Magnus Hagander)
  The old term is still accepted for backward compatibility, but since the two methods are fundamentally different, it seemed better to adopt different names for them.
• Rewrite peer authentication to avoid use of credential control messages (Tom Lane)
  This makes the peer authentication code simpler and better-performing. However, it requires the platform to provide the getpeereid function or an equivalent socket operation. So far as is known, the only platform for which peer authentication worked before and now will not is pre-5.0 NetBSD.

**E.97.3.1.4. Monitoring**

• Add details to the logging of restartpoints and checkpoints, which is controlled by log_checkpoints (Fujii Masao, Greg Smith)
  New details include WAL file and sync activity.
• Add log_file_mode which controls the permissions on log files created by the logging collector (Martin Pihlak)
• Reduce the default maximum line length for syslog logging to 900 bytes plus prefixes (Noah Misch)
  This avoids truncation of long log lines on syslog implementations that have a 1KB length limit, rather than the more common 2KB.

**E.97.3.1.5. Statistical Views**

• Add client_hostname column to pg_stat_activity (Peter Eisentraut)
  Previously only the client address was reported.
• Add pg_stat_xact_* statistics functions and views (Joel Jacobson)
Appendix E. Release Notes

These are like the database-wide statistics counter views, but reflect counts for only the current transaction.

- Add time of last reset in database-level and background writer statistics views (Tomas Vondra)
- Add columns showing the number of vacuum and analyze operations in `pg_stat_*_tables` views (Magnus Hagander)
- Add `buffers_backend_fsync` column to `pg_stat_bgwriter` (Greg Smith)
  This new column counts the number of times a backend fsyncs a buffer.

E.97.3.1.6. Server Settings

- Provide auto-tuning of `wal_buffers` (Greg Smith)
  By default, the value of `wal_buffers` is now chosen automatically based on the value of `shared_buffers`.
- Increase the maximum values for `deadlock_timeout`, `log_min_duration_statement`, and `log_autovacuum_min_duration` (Peter Eisentraut)
  The maximum value for each of these parameters was previously only about 35 minutes. Much larger values are now allowed.

E.97.3.2. Replication and Recovery

E.97.3.2.1. Streaming Replication and Continuous Archiving

- Allow synchronous replication (Simon Riggs, Fujii Masao)
  This allows the primary server to wait for a standby to write a transaction’s information to disk before acknowledging the commit. One standby at a time can take the role of the synchronous standby, as controlled by the `synchronous_standby_names` setting. Synchronous replication can be enabled or disabled on a per-transaction basis using the `synchronous_commit` setting.
- Add protocol support for sending file system backups to standby servers using the streaming replication network connection (Magnus Hagander, Heikki Linnakangas)
  This avoids the requirement of manually transferring a file system backup when setting up a standby server.
- Add `replication_timeout` setting (Fujii Masao, Heikki Linnakangas)
  Replication connections that are idle for more than the `replication_timeout` interval will be terminated automatically. Formerly, a failed connection was typically not detected until the TCP timeout elapsed, which is inconveniently long in many situations.
- Add command-line tool `pg_basebackup` for creating a new standby server or database backup (Magnus Hagander)
- Add a replication permission for roles (Magnus Hagander)
This is a read-only permission used for streaming replication. It allows a non-superuser role to be used for replication connections. Previously only superusers could initiate replication connections; superusers still have this permission by default.

**E.97.3.2.2. Replication Monitoring**

- **Add system view** `pg_stat_replication` which displays activity of WAL sender processes (Itagaki Takahiro, Simon Riggs)
  
  This reports the status of all connected standby servers.

- **Add monitoring function** `pg_last_xact_replay_timestamp()` (Fujii Masao)
  
  This returns the time at which the primary generated the most recent commit or abort record applied on the standby.

**E.97.3.2.3. Hot Standby**

- **Add configuration parameter** `hot_standby_feedback` to enable standbys to postpone cleanup of old row versions on the primary (Simon Riggs)
  
  This helps avoid canceling long-running queries on the standby.

- **Add the** `pg_stat_database_conflicts` system view to show queries that have been canceled and the reason (Magnus Hagander)
  
  Cancellations can occur because of dropped tablespaces, lock timeouts, old snapshots, pinned buffers, and deadlocks.

- **Add a** `conflicts` **count to** `pg_stat_database` (Magnus Hagander)
  
  This is the number of conflicts that occurred in the database.

- **Increase the maximum values for** `max_standby_archive_delay` and `max_standby_streaming_delay`
  
  The maximum value for each of these parameters was previously only about 35 minutes. Much larger values are now allowed.

- **Add** `ERRCODE_T_R_DATABASE_DROPPED` error code to report recovery conflicts due to dropped databases (Tatsuo Ishii)
  
  This is useful for connection pooling software.

**E.97.3.2.4. Recovery Control**

- **Add functions to control streaming replication replay** (Simon Riggs)
  
  The new functions are `pg_xlog_replay_pause()`, `pg_xlog_replay_resume()`, and the status function `pg_is_xlog_replay_paused()`.

- **Add** `recovery.conf` **setting** `pause_at_recovery_target` **to pause recovery at target** (Simon Riggs)
Appendix E. Release Notes

This allows a recovery server to be queried to check whether the recovery point is the one desired.

- Add the ability to create named restore points using `pg_create_restore_point()` (Jaime Casanova)

  These named restore points can be specified as recovery targets using the new `recovery.conf` setting `recovery_target_name`.

- Allow standby recovery to switch to a new timeline automatically (Heikki Linnakangas)

  Now standby servers scan the archive directory for new timelines periodically.

- Add `restart_after_crash` setting which disables automatic server restart after a backend crash (Robert Haas)

  This allows external cluster management software to control whether the database server restarts or not.

- Allow `recovery.conf` to use the same quoting behavior as `postgresql.conf` (Dimitri Fontaine)

  Previously all values had to be quoted.

E.97.3.3. Queries

- Add a true serializable isolation level (Kevin Grittner, Dan Ports)

  Previously, asking for serializable isolation guaranteed only that a single MVCC snapshot would be used for the entire transaction, which allowed certain documented anomalies. The old snapshot isolation behavior is still available by requesting the `REPEATABLE READ` isolation level.

- Allow data-modification commands (`INSERT/UPDATE/DELETE`) in `WITH` clauses (Marko Tiikkaja, Hitoshi Harada)

  These commands can use `RETURNING` to pass data up to the containing query.

- Allow `WITH` clauses to be attached to `INSERT, UPDATE, DELETE` statements (Marko Tiikkaja, Hitoshi Harada)

- Allow non-`GROUP BY` columns in the query target list when the primary key is specified in the `GROUP BY` clause (Peter Eisentraut)

  The SQL standard allows this behavior, and because of the primary key, the result is unambiguous.

- Allow use of the key word `DISTINCT` in `UNION/INTERSECT/EXCEPT` clauses (Tom Lane)

  `DISTINCT` is the default behavior so use of this key word is redundant, but the SQL standard allows it.

- Fix ordinary queries with rules to use the same snapshot behavior as `EXPLAIN ANALYZE` (Marko Tiikkaja)

  Previously `EXPLAIN ANALYZE` used slightly different snapshot timing for queries involving rules. The `EXPLAIN ANALYZE` behavior was judged to be more logical.

E.97.3.3.1. Strings

- Add per-column collation support (Peter Eisentraut, Tom Lane)
Previously collation (the sort ordering of text strings) could only be chosen at database creation. Collation can now be set per column, domain, index, or expression, via the SQL-standard \texttt{COLLATE} clause.

**E.97.3.4. Object Manipulation**

- Add extensions which simplify packaging of additions to PostgreSQL (Dimitri Fontaine, Tom Lane)
  Extensions are controlled by the new \texttt{CREATE/ALTER/DROP EXTENSION} commands. This replaces ad-hoc methods of grouping objects that are added to a PostgreSQL installation.
- Add support for foreign tables (Shigeru Hanada, Robert Haas, Jan Urbanski, Heikki Linnakangas)
  This allows data stored outside the database to be used like native PostgreSQL-stored data. Foreign tables are currently read-only, however.
- Allow new values to be added to an existing enum type via \texttt{ALTER TYPE} (Andrew Dunstan)
- Add \texttt{ALTER TYPE ... ADD/DROP/ALTER/RENAME ATTRIBUTE} (Peter Eisentraut)
  This allows modification of composite types.

**E.97.3.4.1. ALTER Object**

- Add \texttt{RESTRICT/CASCADE} to \texttt{ALTER TYPE} operations on typed tables (Peter Eisentraut)
  This controls \texttt{ADD/DROP/ALTER/RENAME ATTRIBUTE} cascading behavior.
- Support \texttt{ALTER TABLE name (OF | NOT OF) type} (Noah Misch)
  This syntax allows a standalone table to be made into a typed table, or a typed table to be made standalone.
- Add support for more object types in \texttt{ALTER ... SET SCHEMA} commands (Dimitri Fontaine)
  This command is now supported for conversions, operators, operator classes, operator families, text search configurations, text search dictionaries, text search parsers, and text search templates.

**E.97.3.4.2. CREATE/ALTER TABLE**

- Add \texttt{ALTER TABLE ... ADD UNIQUE/PRIMARY KEY USING INDEX} (Gurjeet Singh)
  This allows a primary key or unique constraint to be defined using an existing unique index, including a concurrently created unique index.
- Allow \texttt{ALTER TABLE} to add foreign keys without validation (Simon Riggs)
  The new option is called \texttt{NOT VALID}. The constraint’s state can later be modified to \texttt{VALIDATED} and validation checks performed. Together these allow you to add a foreign key with minimal impact on read and write operations.
- Allow \texttt{ALTER TABLE ... SET DATA TYPE} to avoid table rewrites in appropriate cases (Noah Misch, Robert Haas)
For example, converting a \texttt{varchar} column to \texttt{text} no longer requires a rewrite of the table. However, increasing the length constraint on a \texttt{varchar} column still requires a table rewrite.

- **Add** \texttt{CREATE TABLE IF NOT EXISTS} syntax (Robert Haas)
  This allows table creation without causing an error if the table already exists.

- **Fix** possible “tuple concurrently updated” error when two backends attempt to add an inheritance child to the same table at the same time (Robert Haas)
  \texttt{ALTER TABLE} now takes a stronger lock on the parent table, so that the sessions cannot try to update it simultaneously.

### E.97.3.4.3. Object Permissions

- **Add** a \texttt{SECURITY LABEL} command (KaiGai Kohei)
  This allows security labels to be assigned to objects.

### E.97.3.5. Utility Operations

- **Add** transaction-level advisory locks (Marko Tiikkaja)
  These are similar to the existing session-level advisory locks, but such locks are automatically released at transaction end.

- **Make** \texttt{TRUNCATE ... RESTART IDENTITY} restart sequences transactionally (Steve Singer)
  Previously the counter could have been left out of sync if a backend crashed between the on-commit truncation activity and commit completion.

#### E.97.3.5.1. \texttt{COPY}

- **Add** \texttt{ENCODING} option to \texttt{COPY TO/FROM} (Hitoshi Harada, Itagaki Takahiro)
  This allows the encoding of the \texttt{COPY} file to be specified separately from client encoding.

- **Add** bidirectional \texttt{COPY} protocol support (Fujii Masao)
  This is currently only used by streaming replication.

#### E.97.3.5.2. \texttt{EXPLAIN}

- **Make** \texttt{EXPLAIN VERBOSE} show the function call expression in a \texttt{FunctionScan} node (Tom Lane)
Appendix E. Release Notes

E.97.3.5.3. VACUUM

- Add additional details to the output of VACUUM FULL VERBOSE and CLUSTER VERBOSE (Itagaki Takahiro)
  
  New information includes the live and dead tuple count and whether CLUSTER is using an index to rebuild.

- Prevent autovacuum from waiting if it cannot acquire a table lock (Robert Haas)
  It will try to vacuum that table later.

E.97.3.5.4. CLUSTER

- Allow CLUSTER to sort the table rather than scanning the index when it seems likely to be cheaper (Leonardo Francalanci)

E.97.3.5.5. Indexes

- Add nearest-neighbor (order-by-operator) searching to GiST indexes (Teodor Sigaev, Tom Lane)
  
  This allows GiST indexes to quickly return the $N$ closest values in a query with LIMIT. For example
  
  \[
  \text{SELECT * FROM places ORDER BY location \ <-> \ point '}(101,456)\text{' LIMIT 10;}
  \]
  
  finds the ten places closest to a given target point.

- Allow GIN indexes to index null and empty values (Tom Lane)
  
  This allows full GIN index scans, and fixes various corner cases in which GIN scans would fail.

- Allow GIN indexes to better recognize duplicate search entries (Tom Lane)
  
  This reduces the cost of index scans, especially in cases where it avoids unnecessary full index scans.

- Fix GiST indexes to be fully crash-safe (Heikki Linnakangas)
  
  Previously there were rare cases where a REINDEX would be required (you would be informed).

E.97.3.6. Data Types

- Allow numeric to use a more compact, two-byte header in common cases (Robert Haas)
  
  Previously all numeric values had four-byte headers; this change saves on disk storage.

- Add support for dividing money by money (Andy Balholm)

- Allow binary I/O on type void (Radoslaw Smogura)

- Improve hypotenuse calculations for geometric operators (Paul Matthews)
  
  This avoids unnecessary overflows, and may also be more accurate.

- Support hashing array values (Tom Lane)
This provides additional query optimization possibilities.

- Don’t treat a composite type as sortable unless all its column types are sortable (Tom Lane)
  This avoids possible “could not identify a comparison function” failures at runtime, if it is possible to implement the query without sorting. Also, \texttt{ANALYZE} won’t try to use inappropriate statistics-gathering methods for columns of such composite types.

### E.97.3.6.1. Casting

- Add support for casting between \texttt{money} and \texttt{numeric} (Andy Balholm)
- Add support for casting from \texttt{int4} and \texttt{int8} to \texttt{money} (Joey Adams)
- Allow casting a table’s row type to the table’s supertype if it’s a typed table (Peter Eisentraut)
  This is analogous to the existing facility that allows casting a row type to a supertype’s row type.

### E.97.3.6.2. XML

- Add XML function \texttt{XMLEXISTS} and \texttt{xpath_exists()} functions (Mike Fowler)
  These are used for XPath matching.
- Add XML functions \texttt{xml_is_well_formed()}, \texttt{xml_is_well_formed_document()}, \texttt{xml_is_well_formed_content()} (Mike Fowler)
  These check whether the input is properly-formed XML. They provide functionality that was previously available only in the deprecated \texttt{contrib/xml2} module.

### E.97.3.7. Functions

- Add SQL function \texttt{format(text, \ldots)}, which behaves analogously to C’s \texttt{printf()} (Pavel Stehule, Robert Haas)
  It currently supports formats for strings, SQL literals, and SQL identifiers.
- Add string functions \texttt{concat()}, \texttt{concat_ws()}, \texttt{left()}, \texttt{right()}, and \texttt{reverse()} (Pavel Stehule)
  These improve compatibility with other database products.
- Add function \texttt{pg_read_binary_file()} to read binary files (Dimitri Fontaine, Itagaki Takahiro)
- Add a single-parameter version of function \texttt{pg_read_file()} to read an entire file (Dimitri Fontaine, Itagaki Takahiro)
- Add three-parameter forms of \texttt{array_to_string()} and \texttt{string_to_array()} for null value processing control (Pavel Stehule)

### E.97.3.7.1. Object Information Functions

- Add the \texttt{pg_describe_object()} function (Alvaro Herrera)
Appendix E. Release Notes

This function is used to obtain a human-readable string describing an object, based on the pg_class OID, object OID, and sub-object ID. It can be used to help interpret the contents of pg_depend.

- Update comments for built-in operators and their underlying functions (Tom Lane)
  Functions that are meant to be used via an associated operator are now commented as such.
- Add variable quote_all_identifiers to force the quoting of all identifiers in EXPLAIN and in system catalog functions like pg_get_viewdef() (Robert Haas)
  This makes exporting schemas to tools and other databases with different quoting rules easier.
- Add columns to the information_schema.sequences system view (Peter Eisentraut)
  Previously, though the view existed, the columns about the sequence parameters were unimplemented.
- Allow public as a pseudo-role name in has_table_privilege() and related functions (Alvaro Herrera)
  This allows checking for public permissions.

E.97.3.7.2. Function and Trigger Creation

- Support INSTEAD OF triggers on views (Dean Rasheed)
  This feature can be used to implement fully updatable views.

E.97.3.8. Server-Side Languages

E.97.3.8.1. PL/pgSQL Server-Side Language

- Add FOREACH IN ARRAY to PL/pgSQL (Pavel Stehule)
  This is more efficient and readable than previous methods of iterating through the elements of an array value.
- Allow RAISE without parameters to be caught in the same places that could catch a RAISE ERROR from the same location (Piyush Newe)
  The previous coding threw the error from the block containing the active exception handler. The new behavior is more consistent with other DBMS products.

E.97.3.8.2. PL/Perl Server-Side Language

- Allow generic record arguments to PL/Perl functions (Andrew Dunstan)
  PL/Perl functions can now be declared to accept type record. The behavior is the same as for any named composite type.
- Convert PL/Perl array arguments to Perl arrays (Alexey Klyukin, Alex Hunsaker)
  String representations are still available.
• Convert PL/Perl composite-type arguments to Perl hashes (Alexey Klyukin, Alex Hunsaker)
  String representations are still available.

**E.97.3.8.3. PL/Python Server-Side Language**

• Add table function support for PL/Python (Jan Urbanski)
  PL/Python can now return multiple OUT parameters and record sets.
• Add a validator to PL/Python (Jan Urbanski)
  This allows PL/Python functions to be syntax-checked at function creation time.
• Allow exceptions for SQL queries in PL/Python (Jan Urbanski)
  This allows access to SQL-generated exception error codes from PL/Python exception blocks.
• Add explicit subtransactions to PL/Python (Jan Urbanski)
• Add PL/Python functions for quoting strings (Jan Urbanski)
  These functions are `plpy.quote_ident`, `plpy.quote_literal`, and `plpy.quote_nullable`.
• Add traceback information to PL/Python errors (Jan Urbanski)
• Report PL/Python errors from iterators with `PLy_elog` (Jan Urbanski)
• Fix exception handling with Python 3 (Jan Urbanski)
  Exception classes were previously not available in `plpy` under Python 3.

**E.97.3.9. Client Applications**

• Mark createlang and droplang as deprecated now that they just invoke extension commands (Tom Lane)

**E.97.3.9.1. psql**

• Add psql command `\conninfo` to show current connection information (David Christensen)
• Add psql command `\sf` to show a function’s definition (Pavel Stehule)
• Add psql command `\dL` to list languages (Fernando Ike)
• Add the `$` (“system”) option to psql’s `\dn` (list schemas) command (Tom Lane)
  `\dn` without $ now suppresses system schemas.
• Allow psql’s `\e` and `\ef` commands to accept a line number to be used to position the cursor in the editor (Pavel Stehule)
  This is passed to the editor according to the `PSQL_EDITOR_LINENUMBER_ARG` environment variable.
• Have psql set the client encoding from the operating system locale by default (Heikki Linnakangas)
  This only happens if the `PGCLIENTENCODING` environment variable is not set.
• Make `\d` distinguish between unique indexes and unique constraints (Josh Kupershmidt)

• Make `\dt+` report `pg_table_size` instead of `pg_relation_size` when talking to 9.0 or later servers (Bernd Helmle)

  This is a more useful measure of table size, but note that it is not identical to what was previously reported in the same display.

• Additional tab completion support (Itagaki Takahiro, Pavel Stehule, Andrey Popp, Christoph Berg, David Fetter, Josh Kupershmidt)

_E.97.3.9.2. pg_dump_

• Add `pg_dump` and `pg_dumpall` option `--quote-all-identifiers` to force quoting of all identifiers (Robert Haas)

• Add `directory` format to `pg_dump` (Joachim Wieland, Heikki Linnakangas)

  This is internally similar to the `tar pg_dump` format.

_E.97.3.9.3. pg_ctl_

• Fix `pg_ctl` so it no longer incorrectly reports that the server is not running (Bruce Momjian)

  Previously this could happen if the server was running but `pg_ctl` could not authenticate.

• Improve `pg_ctl` start’s “wait” (`-w`) option (Bruce Momjian, Tom Lane)

  The wait mode is now significantly more robust. It will not get confused by non-default postmaster port numbers, non-default Unix-domain socket locations, permission problems, or stale postmaster lock files.

• Add `promote` option to `pg_ctl` to switch a standby server to primary (Fujii Masao)

_E.97.3.10. Development Tools_

_E.97.3.10.1. libpq_

• Add a `libpq` connection option `client_encoding` which behaves like the `PGCLIENTENCODING` environment variable (Heikki Linnakangas)

  The value `auto` sets the client encoding based on the operating system locale.

• Add `PQlibVersion()` function which returns the `libpq` library version (Magnus Hagander)

  `libpq` already had `PQserverVersion()` which returns the server version.

• Allow `libpq`-using clients to check the user name of the server process when connecting via Unix-domain sockets, with the new `requirepeer` connection option (Peter Eisentraut)

  PostgreSQL already allowed servers to check the client user name when connecting via Unix-domain sockets.
Appendix E. Release Notes

- Add PQping() and PQpingParams() to libpq (Bruce Momjian, Tom Lane)
  These functions allow detection of the server’s status without trying to open a new session.

**E.97.3.10.2. ECPG**

- Allow ECPG to accept dynamic cursor names even in WHERE CURRENT OF clauses (Zoltan Boszormenyi)
- Make ecpglib write double values with a precision of 15 digits, not 14 as formerly (Akira Kurosawa)

**E.97.3.11. Build Options**

- Use +Olibmerrno compile flag with HP-UX C compilers that accept it (Ibrar Ahmed)
  This avoids possible misbehavior of math library calls on recent HP platforms.

**E.97.3.11.1. Makefiles**

- Improved parallel make support (Peter Eisentraut)
  This allows for faster compiles. Also, make -k now works more consistently.
- Require GNU make 3.80 or newer (Peter Eisentraut)
  This is necessary because of the parallel-make improvements.
- Add make maintainer-check target (Peter Eisentraut)
  This target performs various source code checks that are not appropriate for either the build or the regression tests. Currently: duplicate_oids, SGML syntax and tabs check, NLS syntax check.
- Support make check in contrib (Peter Eisentraut)
  Formerly only make installcheck worked, but now there is support for testing in a temporary installation. The top-level make check-world target now includes testing contrib this way.

**E.97.3.11.2. Windows**

- On Windows, allow pg_ctl to register the service as auto-start or start-on-demand (Quan Zongliang)
- Add support for collecting crash dumps on Windows (Craig Ringer, Magnus Hagander)
  minidumps can now be generated by non-debug Windows binaries and analyzed by standard debugging tools.
- Enable building with the MinGW64 compiler (Andrew Dunstan)
  This allows building 64-bit Windows binaries even on non-Windows platforms via cross-compiling.
E.97.3.12. Source Code

- Revise the API for GUC variable assign hooks (Tom Lane)
  The previous functions of assign hooks are now split between check hooks and assign hooks, where
  the former can fail but the latter shouldn’t. This change will impact add-on modules that define custom
  GUC parameters.
- Add latches to the source code to support waiting for events (Heikki Linnakangas)
- Centralize data modification permissions-checking logic (KaiGai Kohei)
- Add missing \texttt{get\_object\_oid()} functions, for consistency (Robert Haas)
- Improve ability to use C++ compilers for compiling add-on modules by removing conflicting key words
  (Tom Lane)
- Add support for DragonFly BSD (Rumko)
- Expose \texttt{quote\_literal\_cstr()} for backend use (Robert Haas)
- Run regression tests in the default encoding (Peter Eisentraut)
  Regression tests were previously always run with \texttt{SQL\_ASCII} encoding.
- Add \texttt{src/tools/git\_changelog} to replace \texttt{cvs2cl} and \texttt{pgcvslog} (Robert Haas, Tom Lane)
- Add \texttt{git-external-diff} script to \texttt{src/tools} (Bruce Momjian)
  This is used to generate context diffs from git.
- Improve support for building with Clang (Peter Eisentraut)

E.97.3.12.1. Server Hooks

- Add source code hooks to check permissions (Robert Haas, Stephen Frost)
- Add post-object-creation function hooks for use by security frameworks (KaiGai Kohei)
- Add a client authentication hook (KaiGai Kohei)

E.97.3.13. Contrib

- Modify \texttt{contrib} modules and procedural languages to install via the new extension mechanism (Tom
  Lane, Dimitri Fontaine)
- Add \texttt{contrib/file\_fdw} foreign-data wrapper (Shigeru Hanada)
  Foreign tables using this foreign data wrapper can read flat files in a manner very similar to \texttt{COPY}.
- Add nearest-neighbor search support to \texttt{contrib/pg\_trgm} and \texttt{contrib/btree\_gist} (Teodor
  Sigaev)
- Add \texttt{contrib/btree\_gist} support for searching on not-equals (Jeff Davis)
- Fix \texttt{contrib/fuzzystrmatch}'s \texttt{levenshtein()} function to handle multibyte characters (Alexan-
  der Korotkov)
Appendix E. Release Notes

- Add `ssl_cipher()` and `ssl_version()` functions to `contrib/sslinfo` (Robert Haas)

- Fix `contrib/intarray` and `contrib/hstore` to give consistent results with indexed empty arrays (Tom Lane)
  Previously an empty-array query that used an index might return different results from one that used a sequential scan.

- Allow `contrib/intarray` to work properly on multidimensional arrays (Tom Lane)

- In `contrib/intarray`, avoid errors complaining about the presence of nulls in cases where no nulls are actually present (Tom Lane)

- In `contrib/intarray`, fix behavior of containment operators with respect to empty arrays (Tom Lane)
  Empty arrays are now correctly considered to be contained in any other array.

- Remove `contrib/xml2`’s arbitrary limit on the number of `parameter=value` pairs that can be handled by `xslt_process()` (Pavel Stehule)
  The previous limit was 10.

- In `contrib/pageinspect`, fix `heap_page_item` to return infomasks as 32-bit values (Alvaro Herrera)
  This avoids returning negative values, which was confusing. The underlying value is a 16-bit unsigned integer.

**E.97.3.13.1. Security**

- Add `contrib/sepgsql` to interface permission checks with SELinux (KaiGai Kohei)
  This uses the new `SECURITY LABEL` facility.

- Add contrib module `auth_delay` (KaiGai Kohei)
  This causes the server to pause before returning authentication failure; it is designed to make brute force password attacks more difficult.

- Add `dummy_seclabel` contrib module (KaiGai Kohei)
  This is used for permission regression testing.

**E.97.3.13.2. Performance**

- Add support for `LIKE` and `ILIKE` index searches to `contrib/pg_trgm` (Alexander Korotkov)

- Add `levenshtein_less_equal()` function to `contrib/fuzzystrmatch`, which is optimized for small distances (Alexander Korotkov)

- Improve performance of index lookups on `contrib/seg` columns (Alexander Korotkov)

- Improve performance of `pg_upgrade` for databases with many relations (Bruce Momjian)

- Add flag to `contrib/pgbench` to report per-statement latencies (Florian Pflug)
E.97.3.13.3. Fsync Testing

- Move src/tools/test_fsync to contrib/pg_test_fsync (Bruce Momjian, Tom Lane)
- Add O_DIRECT support to contrib/pg_test_fsync (Bruce Momjian)
  This matches the use of O_DIRECT by wal_sync_method.
- Add new tests to contrib/pg_test_fsync (Bruce Momjian)

E.97.3.14. Documentation

- Extensive ECPG documentation improvements (Satoshi Nagayasu)
- Extensive proofreading and documentation improvements (Thom Brown, Josh Kupershmidt, Susanne Ebrecht)
- Add documentation for exit_on_error (Robert Haas)
  This parameter causes sessions to exit on any error.
- Add documentation for pg_options_to_table() (Josh Berkus)
  This function shows table storage options in a readable form.
- Document that it is possible to access all composite type fields using (compositeval).* syntax (Peter Eisentraut)
- Document that translate() removes characters in from that don’t have a corresponding to character (Josh Kupershmidt)
- Merge documentation for CREATE CONSTRAINT TRIGGER and CREATE TRIGGER (Alvaro Herrera)
- Centralize permission and upgrade documentation (Bruce Momjian)
- Add kernel tuning documentation for Solaris 10 (Josh Berkus)
  Previously only Solaris 9 kernel tuning was documented.
- Handle non-ASCII characters consistently in HISTORY file (Peter Eisentraut)
  While the HISTORY file is in English, we do have to deal with non-ASCII letters in contributor names. These are now transliterated so that they are reasonably legible without assumptions about character set.

E.98. Release 9.0.23

Release date: 2015-10-08

This release contains a variety of fixes from 9.0.22. For information about new features in the 9.0 major release, see Section E.121.
Appendix E. Release Notes

This is expected to be the last PostgreSQL release in the 9.0.X series. Users are encouraged to update to a newer release branch soon.

E.98.1. Migration to Version 9.0.23

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.18, see Section E.103.

E.98.2. Changes

- Fix contrib/pgcrypto to detect and report too-short crypt() salts (Josh Kupershmidt)
  
  Certain invalid salt arguments crashed the server or disclosed a few bytes of server memory. We have not ruled out the viability of attacks that arrange for presence of confidential information in the disclosed bytes, but they seem unlikely. (CVE-2015-5288)

- Fix subtransaction cleanup after a portal (cursor) belonging to an outer subtransaction fails (Tom Lane, Michael Paquier)
  
  A function executed in an outer-subtransaction cursor could cause an assertion failure or crash by referencing a relation created within an inner subtransaction.

- Fix insertion of relations into the relation cache “init file” (Tom Lane)

  An oversight in a patch in the most recent minor releases caused pg_trigger_tgrelid_tgname_index to be omitted from the init file. Subsequent sessions detected this, then deemed the init file to be broken and silently ignored it, resulting in a significant degradation in session startup time. In addition to fixing the bug, install some guards so that any similar future mistake will be more obvious.

- Avoid O(N^2) behavior when inserting many tuples into a SPI query result (Neil Conway)

- Improve LISTEN startup time when there are many unread notifications (Matt Newell)

- Disable SSL renegotiation by default (Michael Paquier, Andres Freund)

  While use of SSL renegotiation is a good idea in theory, we have seen too many bugs in practice, both in the underlying OpenSSL library and in our usage of it. Renegotiation will be removed entirely in 9.5 and later. In the older branches, just change the default value of ssl_renegotiation_limit to zero (disabled).

- Lower the minimum values of the *_freeze_max_age parameters (Andres Freund)

  This is mainly to make tests of related behavior less time-consuming, but it may also be of value for installations with limited disk space.

- Limit the maximum value of wal_buffers to 2GB to avoid server crashes (Josh Berkus)

- Fix rare internal overflow in multiplication of numeric values (Dean Rasheed)

- Guard against hard-to-reach stack overflows involving record types, range types, json, jsonb, tsquery, ltxtquery and query_int (Noah Misch)

- Fix handling of DOW and DOY in datetime input (Greg Stark)
These tokens aren’t meant to be used in datetime values, but previously they resulted in opaque internal error messages rather than “invalid input syntax”.

- Add more query-cancel checks to regular expression matching (Tom Lane)
- Add recursion depth protections to regular expression, SIMILAR TO, and LIKE matching (Tom Lane)
  Suitable search patterns and a low stack depth limit could lead to stack-overrun crashes.
- Fix potential infinite loop in regular expression execution (Tom Lane)
  A search pattern that can apparently match a zero-length string, but actually doesn’t match because of a back reference, could lead to an infinite loop.
- Fix low-memory failures in regular expression compilation (Andreas Seltenreich)
- Fix low-probability memory leak during regular expression execution (Tom Lane)
- Fix rare low-memory failure in lock cleanup during transaction abort (Tom Lane)
- Fix “unexpected out-of-memory situation during sort” errors when using tuplestores with small work_mem settings (Tom Lane)
- Fix very-low-probability stack overrun in qsort (Tom Lane)
- Fix “invalid memory alloc request size” failure in hash joins with large work_mem settings (Tomas Vondra, Tom Lane)
- Fix assorted planner bugs (Tom Lane)
  These mistakes could lead to incorrect query plans that would give wrong answers, or to assertion failures in assert-enabled builds, or to odd planner errors such as “could not devise a query plan for the given query”, “could not find pathkey item to sort”, “plan should not reference subplan’s variable”, or “failed to assign all NestLoopParams to plan nodes”. Thanks are due to Andreas Seltenreich and Piotr Stefaniak for fuzz testing that exposed these problems.
- Use fuzzy path cost tiebreaking rule in all supported branches (Tom Lane)
  This change is meant to avoid platform-specific behavior when alternative plan choices have effectively-identical estimated costs.
- During postmaster shutdown, ensure that per-socket lock files are removed and listen sockets are closed before we remove the postmaster.pid file (Tom Lane)
  This avoids race-condition failures if an external script attempts to start a new postmaster as soon as pg_ctl stop returns.
- Fix postmaster’s handling of a startup-process crash during crash recovery (Tom Lane)
  If, during a crash recovery cycle, the startup process crashes without having restored database consistency, we’d try to launch a new startup process, which typically would just crash again, leading to an infinite loop.
- Do not print a WARNING when an autovacuum worker is already gone when we attempt to signal it, and reduce log verbosity for such signals (Tom Lane)
- Prevent autovacuum launcher from sleeping unduly long if the server clock is moved backwards a large amount (Álvaro Herrera)
- Ensure that cleanup of a GIN index’s pending-insertions list is interruptable by cancel requests (Jeff Janes)
Appendix E. Release Notes

- Allow all-zeroes pages in GIN indexes to be reused (Heikki Linnakangas)
  Such a page might be left behind after a crash.
- Fix off-by-one error that led to otherwise-harmless warnings about “apparent wraparound” in subtrans/multixact truncation (Thomas Munro)
- Fix misreporting of `CONTINUE` and `MOVE` statement types in PL/pgSQL’s error context messages (Pavel Stehule, Tom Lane)
- Fix some places in PL/Tcl that neglected to check for failure of `malloc()` calls (Michael Paquier, Álvaro Herrera)
- Improve libpq’s handling of out-of-memory conditions (Michael Paquier, Heikki Linnakangas)
- Fix memory leaks and missing out-of-memory checks in ecpg (Michael Paquier)
- Fix psq1’s code for locale-aware formatting of numeric output (Tom Lane)
  The formatting code invoked by \pset numericlocale on did the wrong thing for some uncommon cases such as numbers with an exponent but no decimal point. It could also mangle already-localized output from the `money` data type.
- Prevent crash in psq1’s \c command when there is no current connection (Noah Misch)
- Ensure that temporary files created during a pg_dump run with tar-format output are not world-readable (Michael Paquier)
- Fix pg_dump and pg_upgrade to support cases where the `postgres` or `template1` database is in a non-default tablespace (Marti Raudsepp, Bruce Momjian)
- Fix pg_dump to handle object privileges sanely when dumping from a server too old to have a particular privilege type (Tom Lane)
  When dumping functions or procedural languages from pre-7.3 servers, pg_dump would produce `GRANT/REVOKE` commands that revoked the owner’s grantable privileges and instead granted all privileges to `PUBLIC`. Since the privileges involved are just `USAGE` and `EXECUTE`, this isn’t a security problem, but it’s certainly a surprising representation of the older systems’ behavior. Fix it to leave the default privilege state alone in these cases.
- Fix pg_dump to dump shell types (Tom Lane)
  Shell types (that is, not-yet-fully-defined types) aren’t useful for much, but nonetheless pg_dump should dump them.
- Fix spinlock assembly code for PPC hardware to be compatible with AIX’s native assembler (Tom Lane)
  Building with gcc didn’t work if gcc had been configured to use the native assembler, which is becoming more common.
- On AIX, test the `-qlonglong` compiler option rather than just assuming it’s safe to use (Noah Misch)
- On AIX, use `-Wl,-brtllib` link option to allow symbols to be resolved at runtime (Noah Misch)
  Perl relies on this ability in 5.8.0 and later.
- Avoid use of inline functions when compiling with 32-bit xlc, due to compiler bugs (Noah Misch)
- Use `librt` for `sched_yield()` when necessary, which it is on some Solaris versions (Oskari Saarenmaa)
• Fix Windows install.bat script to handle target directory names that contain spaces (Heikki Linnakangas)

• Make the numeric form of the PostgreSQL version number (e.g., 90405) readily available to extension Makefiles, as a variable named VERSION_NUM (Michael Paquier)

• Update time zone data files to tzdata release 2015g for DST law changes in Cayman Islands, Fiji, Moldova, Morocco, Norfolk Island, North Korea, Turkey, and Uruguay. There is a new zone name America/Fort_Nelson for the Canadian Northern Rockies.

E.99. Release 9.0.22

Release date: 2015-06-12

This release contains a small number of fixes from 9.0.21. For information about new features in the 9.0 major release, see Section E.121.

The PostgreSQL community will stop releasing updates for the 9.0.X release series in September 2015. Users are encouraged to update to a newer release branch soon.

E.99.1. Migration to Version 9.0.22

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.18, see Section E.103.

E.99.2. Changes

• Fix rare failure to invalidate relation cache init file (Tom Lane)

With just the wrong timing of concurrent activity, a VACUUM FULL on a system catalog might fail to update the “init file” that’s used to avoid cache-loading work for new sessions. This would result in later sessions being unable to access that catalog at all. This is a very ancient bug, but it’s so hard to trigger that no reproducible case had been seen until recently.

• Avoid deadlock between incoming sessions and CREATE/DROP DATABASE (Tom Lane)

A new session starting in a database that is the target of a DROP DATABASE command, or is the template for a CREATE DATABASE command, could cause the command to wait for five seconds and then fail, even if the new session would have exited before that.

E.100. Release 9.0.21

Release date: 2015-06-04
This release contains a small number of fixes from 9.0.20. For information about new features in the 9.0 major release, see Section E.121.

The PostgreSQL community will stop releasing updates for the 9.0.X release series in September 2015. Users are encouraged to update to a newer release branch soon.

### E.100.1. Migration to Version 9.0.21

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.18, see Section E.103.

### E.100.2. Changes

- **Avoid failures while `fsync`'ing data directory during crash restart (Abhijit Menon-Sen, Tom Lane)**
  In the previous minor releases we added a patch to `fsync` everything in the data directory after a crash. Unfortunately its response to any error condition was to fail, thereby preventing the server from starting up, even when the problem was quite harmless. An example is that an unwritable file in the data directory would prevent restart on some platforms; but it is common to make SSL certificate files unwritable by the server. Revise this behavior so that permissions failures are ignored altogether, and other types of failures are logged but do not prevent continuing.

- **Remove configure’s check prohibiting linking to a threaded libpython on OpenBSD (Tom Lane)**
  The failure this restriction was meant to prevent seems to not be a problem anymore on current OpenBSD versions.

- **Allow libpq to use TLS protocol versions beyond v1 (Noah Misch)**
  For a long time, libpq was coded so that the only SSL protocol it would allow was TLS v1. Now that newer TLS versions are becoming popular, allow it to negotiate the highest commonly-supported TLS version with the server. (PostgreSQL servers were already capable of such negotiation, so no change is needed on the server side.) This is a back-patch of a change already released in 9.4.0.

### E.101. Release 9.0.20

**Release date:** 2015-05-22

This release contains a variety of fixes from 9.0.19. For information about new features in the 9.0 major release, see Section E.121.

The PostgreSQL community will stop releasing updates for the 9.0.X release series in September 2015. Users are encouraged to update to a newer release branch soon.

### E.101.1. Migration to Version 9.0.20

A dump/restore is not required for those running 9.0.X.
However, if you are upgrading from a version earlier than 9.0.18, see Section E.103.

## E.101.2. Changes

- **Avoid possible crash when client disconnects just before the authentication timeout expires** (Benkocs Norbert Attila)
  
  If the timeout interrupt fired partway through the session shutdown sequence, SSL-related state would be freed twice, typically causing a crash and hence denial of service to other sessions. Experimentation shows that an unauthenticated remote attacker could trigger the bug somewhat consistently, hence treat as security issue. (CVE-2015-3165)

- **Improve detection of system-call failures** (Noah Misch)
  
  Our replacement implementation of `snprintf()` failed to check for errors reported by the underlying system library calls; the main case that might be missed is out-of-memory situations. In the worst case this might lead to information exposure, due to our code assuming that a buffer had been overwritten when it hadn’t been. Also, there were a few places in which security-relevant calls of other system library functions did not check for failure.

  It remains possible that some calls of the `printf()` family of functions are vulnerable to information disclosure if an out-of-memory error occurs at just the wrong time. We judge the risk to not be large, but will continue analysis in this area. (CVE-2015-3166)

- **In contrib/pgcrypto, uniformly report decryption failures as “Wrong key or corrupt data”** (Noah Misch)
  
  Previously, some cases of decryption with an incorrect key could report other error message texts. It has been shown that such variance in error reports can aid attackers in recovering keys from other systems. While it’s unknown whether pgcrypto’s specific behaviors are likewise exploitable, it seems better to avoid the risk by using a one-size-fits-all message. (CVE-2015-3167)

- **Fix incorrect checking of deferred exclusion constraints after a HOT update** (Tom Lane)
  
  If a new row that potentially violates a deferred exclusion constraint is HOT-updated (that is, no indexed columns change and the row can be stored back onto the same table page) later in the same transaction, the exclusion constraint would be reported as violated when the check finally occurred, even if the row(s) the new row originally conflicted with had been deleted.

- **Prevent improper reordering of antijoins (NOT EXISTS joins) versus other outer joins** (Tom Lane)
  
  This oversight in the planner has been observed to cause “could not find RelOptInfo for given relids” errors, but it seems possible that sometimes an incorrect query plan might get past that consistency check and result in silently-wrong query output.

- **Fix incorrect matching of subexpressions in outer-join plan nodes** (Tom Lane)
  
  Previously, if textually identical non-strict subexpressions were used both above and below an outer join, the planner might try to re-use the value computed below the join, which would be incorrect because the executor would force the value to NULL in case of an unmatched outer row.

- **Fix GEQO planner to cope with failure of its join order heuristic** (Tom Lane)
This oversight has been seen to lead to “failed to join all relations together” errors in queries involving 
\texttt{LATERAL}, and that might happen in other cases as well.

- Fix possible deadlock at startup when \texttt{max\_prepared\_transactions} is too small (Heikki Linnakangas)
- Don’t archive useless preallocated WAL files after a timeline switch (Heikki Linnakangas)
- Avoid “cannot GetMultiXactIdMembers() during recovery” error (Álvaro Herrera)
- Recursively \texttt{fsync()} the data directory after a crash (Abhijit Menon-Sen, Robert Haas)
  This ensures consistency if another crash occurs shortly later. (The second crash would have to be a 
system-level crash, not just a database crash, for there to be a problem.)
- Fix autovacuum launcher’s possible failure to shut down, if an error occurs after it receives SIGTERM 
  (Álvaro Herrera)
- Cope with unexpected signals in \texttt{LockBufferForCleanup()} (Andres Freund)
  This oversight could result in spurious errors about “multiple backends attempting to wait for pincount 
  1”.
- Avoid waiting for WAL flush or synchronous replication during commit of a transaction that was read-
  only so far as the user is concerned (Andres Freund)
  Previously, a delay could occur at commit in transactions that had written WAL due to HOT page prun-
  ing, leading to undesirable effects such as sessions getting stuck at startup if all synchronous replicas 
  are down. Sessions have also been observed to get stuck in catchup interrupt processing when using 
synchronous replication; this will fix that problem as well.
- Fix crash when manipulating hash indexes on temporary tables (Heikki Linnakangas)
- Fix possible failure during hash index bucket split, if other processes are modifying the index concur-
  rently (Tom Lane)
- Check for interrupts while analyzing index expressions (Jeff Janes)
  \texttt{ANALYZE} executes index expressions many times; if there are slow functions in such an expression, it’s 
desirable to be able to cancel the \texttt{ANALYZE} before that loop finishes.
- Add the name of the target server to object description strings for foreign-server user mappings (Álvaro 
  Herrera)
- Recommend setting \texttt{include\_realm} to 1 when using Kerberos/GSSAPI/SSPI authentication (Stephen 
  Frost)
  Without this, identically-named users from different realms cannot be distinguished. For the moment 
  this is only a documentation change, but it will become the default setting in PostgreSQL 9.5.
- Remove code for matching IPv4 \texttt{pg\_hba\_conf} entries to IPv4-in-IPv6 addresses (Tom Lane)
  This hack was added in 2003 in response to a report that some Linux kernels of the time would report 
IPv4 connections as having IPv4-in-IPv6 addresses. However, the logic was accidentally broken in 9.0. 
The lack of any field complaints since then shows that it’s not needed anymore. Now we have reports 
that the broken code causes crashes on some systems, so let’s just remove it rather than fix it. (Had we 
chosen to fix it, that would make for a subtle and potentially security-sensitive change in the effective 
meaning of IPv4 \texttt{pg\_hba\_conf} entries, which does not seem like a good thing to do in minor releases.)
Appendix E. Release Notes

- While shutting down service on Windows, periodically send status updates to the Service Control Manager to prevent it from killing the service too soon; and ensure that pg_ctl will wait for shutdown (Krystian Bigaj)

- Reduce risk of network deadlock when using libpq’s non-blocking mode (Heikki Linnakangas)

  When sending large volumes of data, it’s important to drain the input buffer every so often, in case the server has sent enough response data to cause it to block on output. (A typical scenario is that the server is sending a stream of NOTICE messages during COPY FROM STDIN.) This worked properly in the normal blocking mode, but not so much in non-blocking mode. We’ve modified libpq to opportunistically drain input when it can, but a full defense against this problem requires application cooperation: the application should watch for socket read-ready as well as write-ready conditions, and be sure to call PQconsumeInput() upon read-ready.

- Fix array handling in ecpg (Michael Meskes)

- Fix psql to sanely handle URIs and conninfo strings as the first parameter to \connect (David Fetter, Andrew Dunstan, Álvaro Herrera)

  This syntax has been accepted (but undocumented) for a long time, but previously some parameters might be taken from the old connection instead of the given string, which was agreed to be undesirable.

- Suppress incorrect complaints from psql on some platforms that it failed to write ~/.psql_history at exit (Tom Lane)

  This misbehavior was caused by a workaround for a bug in very old (pre-2006) versions of libedit. We fixed it by removing the workaround, which will cause a similar failure to appear for anyone still using such versions of libedit. Recommendation: upgrade that library, or use libedit.

- Fix pg_dump’s rule for deciding which casts are system-provided casts that should not be dumped (Tom Lane)

- Fix dumping of views that are just VALUES(...) but have column aliases (Tom Lane)

- In pg_upgrade, force timeline 1 in the new cluster (Bruce Momjian)

  This change prevents upgrade failures caused by bogus complaints about missing WAL history files.

- In pg_upgrade, check for improperly non-connectable databases before proceeding (Bruce Momjian)

- In pg_upgrade, quote directory paths properly in the generated delete_old_cluster script (Bruce Momjian)

- In pg_upgrade, preserve database-level freezing info properly (Bruce Momjian)

  This oversight could cause missing-clog-file errors for tables within the postgres and template1 databases.

- Run pg_upgrade and pg_resetxlog with restricted privileges on Windows, so that they don’t fail when run by an administrator (Muhammad Asif Naeem)

- Fix slow sorting algorithm in contrib/intarray (Tom Lane)

- Fix compile failure on Sparc V8 machines (Rob Rowan)

- Update time zone data files to tzdata release 2015d for DST law changes in Egypt, Mongolia, and Palestine, plus historical changes in Canada and Chile. Also adopt revised zone abbreviations for the America/Adak zone (HST/HDT not HAST/HADT).
Appendix E. Release Notes

E.102. Release 9.0.19

Release date: 2015-02-05

This release contains a variety of fixes from 9.0.18. For information about new features in the 9.0 major release, see Section E.121.

E.102.1. Migration to Version 9.0.19

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.18, see Section E.103.

E.102.2. Changes

• Fix buffer overruns in to_char() (Bruce Momjian)

  When to_char() processes a numeric formatting template calling for a large number of digits, PostgreSQL would read past the end of a buffer. When processing a crafted timestamp formatting template, PostgreSQL would write past the end of a buffer. Either case could crash the server. We have not ruled out the possibility of attacks that lead to privilege escalation, though they seem unlikely. (CVE-2015-0241)

• Fix buffer overrun in replacement *printf() functions (Tom Lane)

  PostgreSQL includes a replacement implementation of printf and related functions. This code will overrun a stack buffer when formatting a floating point number (conversion specifiers e, E, f, F, g or G) with requested precision greater than about 500. This will crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. A database user can trigger such a buffer overrun through the to_char() SQL function. While that is the only affected core PostgreSQL functionality, extension modules that use printf-family functions may be at risk as well.

  This issue primarily affects PostgreSQL on Windows. PostgreSQL uses the system implementation of these functions where adequate, which it is on other modern platforms. (CVE-2015-0242)

• Fix buffer overruns in contrib/pgcrypto (Marko Tiikkaja, Noah Misch)

  Errors in memory size tracking within the pgcrypto module permitted stack buffer overruns and improper dependence on the contents of uninitialized memory. The buffer overrun cases can crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. (CVE-2015-0243)

• Fix possible loss of frontend/backend protocol synchronization after an error (Heikki Linnakangas)

  If any error occurred while the server was in the middle of reading a protocol message from the client, it could lose synchronization and incorrectly try to interpret part of the message’s data as a new protocol message. An attacker able to submit crafted binary data within a command parameter might succeed in injecting his own SQL commands this way. Statement timeout and query cancellation are the most likely sources of errors triggering this scenario. Particularly vulnerable are applications that use a timeout and also submit arbitrary user-crafted data as binary query parameters. Disabling statement timeout will
reduce, but not eliminate, the risk of exploit. Our thanks to Emil Lenngren for reporting this issue. (CVE-2015-0244)

- Fix information leak via constraint-violation error messages (Stephen Frost)
  Some server error messages show the values of columns that violate a constraint, such as a unique constraint. If the user does not have SELECT privilege on all columns of the table, this could mean exposing values that the user should not be able to see. Adjust the code so that values are displayed only when they came from the SQL command or could be selected by the user. (CVE-2014-8161)

- Lock down regression testing’s temporary installations on Windows (Noah Misch)
  Use SSPI authentication to allow connections only from the OS user who launched the test suite. This closes on Windows the same vulnerability previously closed on other platforms, namely that other users might be able to connect to the test postmaster. (CVE-2014-0067)

- Avoid possible data corruption if ALTER DATABASE SET TABLESPACE is used to move a database to a new tablesapce and then shortly later move it back to its original tablespace (Tom Lane)

- Avoid corrupting tables when ANALYZE inside a transaction is rolled back (Andres Freund, Tom Lane, Michael Paquier)
  If the failing transaction had earlier removed the last index, rule, or trigger from the table, the table would be left in a corrupted state with the relevant pg_class flags not set though they should be.

- Fix use-of-already-freed-memory problem in EvalPlanQual processing (Tom Lane)
  In READ COMMITTED mode, queries that lock or update recently-updated rows could crash as a result of this bug.

- Fix planning of SELECT FOR UPDATE when using a partial index on a child table (Kyotaro Horiguchi)
  In READ COMMITTED mode, SELECT FOR UPDATE must also recheck the partial index’s WHERE condition when rechecking a recently-updated row to see if it still satisfies the query’s WHERE condition. This requirement was missed if the index belonged to an inheritance child table, so that it was possible to incorrectly return rows that no longer satisfy the query condition.

- Fix corner case wherein SELECT FOR UPDATE could return a row twice, and possibly miss returning other rows (Tom Lane)
  In READ COMMITTED mode, a SELECT FOR UPDATE that is scanning an inheritance tree could incorrectly return a row from a prior child table instead of the one it should return from a later child table.

- Reject duplicate column names in the referenced-columns list of a FOREIGN KEY declaration (David Rowley)
  This restriction is per SQL standard. Previously we did not reject the case explicitly, but later on the code would fail with bizarre-looking errors.

- Fix bugs in raising a numeric value to a large integral power (Tom Lane)
  The previous code could get a wrong answer, or consume excessive amounts of time and memory before realizing that the answer must overflow.

- In numeric_recv(), truncate away any fractional digits that would be hidden according to the value’s dscale field (Tom Lane)
  A numeric value’s display scale (dscale) should never be less than the number of nonzero fractional digits; but apparently there’s at least one broken client application that transmits binary numeric values
Appendix E. Release Notes

in which that’s true. This leads to strange behavior since the extra digits are taken into account by
arithmetic operations even though they aren’t printed. The least risky fix seems to be to truncate away
such “hidden” digits on receipt, so that the value is indeed what it prints as.

• Reject out-of-range numeric timezone specifications (Tom Lane)
  Simple numeric timezone specifications exceeding +/- 168 hours (one week) would be accepted, but
could then cause null-pointer dereference crashes in certain operations. There’s no use-case for such
large UTC offsets, so reject them.

• Fix bugs in \texttt{tsquery @> tsquery} operator (Heikki Linnakangas)
  Two different terms would be considered to match if they had the same CRC. Also, if the second
operand had more terms than the first, it would be assumed not to be contained in the first; which is
wrong since it might contain duplicate terms.

• Improve ispell dictionary’s defenses against bad affix files (Tom Lane)

• Allow more than 64K phrases in a thesaurus dictionary (David Boutin)
  The previous coding could crash on an oversize dictionary, so this was deemed a back-patchable bug
fix rather than a feature addition.

• Fix namespace handling in \texttt{xpath()} (Ali Akbar)
  Previously, the \texttt{xml} value resulting from an \texttt{xpath()} call would not have namespace declarations if the
namespace declarations were attached to an ancestor element in the input \texttt{xml} value, rather than to the
specific element being returned. Propagate the ancestral declaration so that the result is correct when
considered in isolation.

• Fix planner problems with nested append relations, such as inherited tables within \texttt{UNION ALL}
  sub-queries (Tom Lane)

• Fail cleanly when a GiST index tuple doesn’t fit on a page, rather than going into infinite recursion
  (Andrew Gierth)

• Exempt tables that have per-table \texttt{cost_limit} and/or \texttt{cost_delay} settings from autovacuum’s global
cost balancing rules (Alvaro Herrera)
  The previous behavior resulted in basically ignoring these per-table settings, which was unintended.
Now, a table having such settings will be vacuumed using those settings, independently of what is
going on in other autovacuum workers. This may result in heavier total I/O load than before, so such
settings should be re-examined for sanity.

• Avoid wholesale autovacuuming when autovacuum is nominally off (Tom Lane)
  Even when autovacuum is nominally off, we will still launch autovacuum worker processes to vacuum
tables that are at risk of XID wraparound. However, such a worker process then proceeded to vacuum
all tables in the target database, if they met the usual thresholds for autovacuuming. This is at best pretty
unexpected; at worst it delays response to the wraparound threat. Fix it so that if autovacuum is turned
off, workers \textit{only} do anti-wraparound vacuums and not any other work.

• Fix race condition between hot standby queries and replaying a full-page image (Heikki Linnakangas)
  This mistake could result in transient errors in queries being executed in hot standby.

• Fix several cases where recovery logic improperly ignored WAL records for COMMIT/ABORT
  PREPARED (Heikki Linnakangas)
The most notable oversight was that recovery_target_xid could not be used to stop at a two-phase commit.

- Avoid creating unnecessary .ready marker files for timeline history files (Fujii Masao)
- Fix possible null pointer dereference when an empty prepared statement is used and the log_statement setting is mod or ddl (Fujii Masao)
- Change “pgstat wait timeout” warning message to be LOG level, and rephrase it to be more understandable (Tom Lane)
  This message was originally thought to be essentially a can’t-happen case, but it occurs often enough on our slower buildfarm members to be a nuisance. Reduce it to LOG level, and expend a bit more effort on the wording: it now reads “using stale statistics instead of current ones because stats collector is not responding”.
- Fix SPARC spinlock implementation to ensure correctness if the CPU is being run in a non-TSO coherency mode, as some non-Solaris kernels do (Andres Freund)
- Warn if OS X’s setlocale() starts an unwanted extra thread inside the postmaster (Noah Misch)
- Fix processing of repeated dbname parameters in PQconnectdbParams() (Alex Shulgin)
  Unexpected behavior ensued if the first occurrence of dbname contained a connection string or URI to be expanded.
- Ensure that libpq reports a suitable error message on unexpected socket EOF (Marko Tiikkaja, Tom Lane)
  Depending on kernel behavior, libpq might return an empty error string rather than something useful when the server unexpectedly closed the socket.
- Clear any old error message during PQreset() (Heikki Linnakangas)
  If PQreset() is called repeatedly, and the connection cannot be re-established, error messages from the failed connection attempts kept accumulating in the PGconn’s error string.
- Properly handle out-of-memory conditions while parsing connection options in libpq (Alex Shulgin, Heikki Linnakangas)
- Fix array overrun in ecpg’s version of ParseDateTime() (Michael Paquier)
- In initdb, give a clearer error message if a password file is specified but is empty (Mats Erik Andersson)
- Fix psql’s \s command to work nicely with libedit, and add pager support (Stepan Rutz, Tom Lane)
  When using libedit rather than readline, \s printed the command history in a fairly unreadable encoded format, and on recent libedit versions might fail altogether. Fix that by printing the history ourselves rather than having the library do it. A pleasant side-effect is that the pager is used if appropriate.
  This patch also fixes a bug that caused newline encoding to be applied inconsistently when saving the command history with libedit. Multiline history entries written by older psql versions will be read cleanly with this patch, but perhaps not vice versa, depending on the exact libedit versions involved.
- Improve consistency of parsing of psql’s special variables (Tom Lane)
  Allow variant spellings of on and off (such as 1/0) for ECHO_HIDDEN and ON_ERROR_ROLLBACK. Report a warning for unrecognized values for COMP_KEYWORD_CASE, ECHO, ECHO_HIDDEN, HISTCONTROL, ON_ERROR_ROLLBACK, and VERBOSITY. Recognize all values for all these variables case-insensitively; previously there was a mishmash of case-sensitive and case-insensitive behaviors.
Appendix E. Release Notes

- Fix psql’s expanded-mode display to work consistently when using `border = 3` and `linestyle` = `ascii` or `unicode` (Stephen Frost)
- Fix possible deadlock during parallel restore of a schema-only dump (Robert Haas, Tom Lane)
- Fix core dump in `pg_dump --binary-upgrade` on zero-column composite type (Rushabh Lathia)
- Fix block number checking in `contrib/pageinspect`’s `get_raw_page()` (Tom Lane)
  The incorrect checking logic could prevent access to some pages in non-main relation forks.
- Fix `contrib/pgcrypto`’s `pgp_sym_decrypt()` to not fail on messages whose length is 6 less than a power of 2 (Marko Tiikkaja)
- Handle unexpected query results, especially NULLs, safely in `contrib/tablefunc`’s `connectby()` (Michael Paquier)
  `connectby()` previously crashed if it encountered a NULL key value. It now prints that row but doesn’t recurse further.
- Avoid a possible crash in `contrib/xml2`’s `xslt_process()` (Mark Simonetti)
  libxslt seems to have an undocumented dependency on the order in which resources are freed; reorder our calls to avoid a crash.
- Numerous cleanups of warnings from Coverity static code analyzer (Andres Freund, Tatsuo Ishii, Marko Kreen, Tom Lane, Michael Paquier)
  These changes are mostly cosmetic but in some cases fix corner-case bugs, for example a crash rather than a proper error report after an out-of-memory failure. None are believed to represent security issues.
- Detect incompatible OpenLDAP versions during build (Noah Misch)
  With OpenLDAP versions 2.4.24 through 2.4.31, inclusive, PostgreSQL backends can crash at exit. Raise a warning during configure based on the compile-time OpenLDAP version number, and test the crashing scenario in the `contrib/dblink` regression test.
- In non-MSVC Windows builds, ensure `libpq.dll` is installed with execute permissions (Noah Misch)
- Make `pg_regress` remove any temporary installation it created upon successful exit (Tom Lane)
  This results in a very substantial reduction in disk space usage during `make check-world`, since that sequence involves creation of numerous temporary installations.
- Support time zone abbreviations that change UTC offset from time to time (Tom Lane)
  Previously, PostgreSQL assumed that the UTC offset associated with a time zone abbreviation (such as EST) never changes in the usage of any particular locale. However this assumption fails in the real world, so introduce the ability for a zone abbreviation to represent a UTC offset that sometimes changes. Update the zone abbreviation definition files to make use of this feature in timezone locales that have changed the UTC offset of their abbreviations since 1970 (according to the IANA timezone database). In such timezones, PostgreSQL will now associate the correct UTC offset with the abbreviation depending on the given date.
- Update time zone abbreviations lists (Tom Lane)
  Add CST (China Standard Time) to our lists. Remove references to ADT as “Arabia Daylight Time”, an abbreviation that’s been out of use since 2007; therefore, claiming there is a conflict with “Atlantic Daylight Time” doesn’t seem especially helpful. Fix entirely incorrect GMT offsets for CKT (Cook Islands), FJT, and FJST (Fiji); we didn’t even have them on the proper side of the date line.
Appendix E. Release Notes

- Update time zone data files to tzdata release 2015a.

  The IANA timezone database has adopted abbreviations of the form \texttt{AxST/AxDT} for all Australian time zones, reflecting what they believe to be current majority practice Down Under. These names do not conflict with usage elsewhere (other than ACST for Acre Summer Time, which has been in disuse since 1994). Accordingly, adopt these names into our “Default” timezone abbreviation set. The “Australia” abbreviation set now contains only CST, EAST, EST, SAST, SAT, and WST, all of which are thought to be mostly historical usage. Note that SAST has also been changed to be South Africa Standard Time in the “Default” abbreviation set.

  Also, add zone abbreviations SRET (Asia/Srednekolymsk) and XJT (Asia/Urumqi), and use WSST/WSDT for western Samoa. Also, there were DST law changes in Chile, Mexico, the Turks & Caicos Islands (America/Grand_Turk), and Fiji. There is a new zone Pacific/Bougainville for portions of Papua New Guinea. Also, numerous corrections for historical (pre-1970) time zone data.

E.103. Release 9.0.18

Release date: 2014-07-24

This release contains a variety of fixes from 9.0.17. For information about new features in the 9.0 major release, see Section E.121.

E.103.1. Migration to Version 9.0.18

A dump/restore is not required for those running 9.0.X.

However, this release corrects an index corruption problem in some GiST indexes. See the first changelog entry below to find out whether your installation has been affected and what steps you should take if so. Also, if you are upgrading from a version earlier than 9.0.15, see Section E.106.

E.103.2. Changes

- Correctly initialize padding bytes in \texttt{contrib/btree_gist} indexes on \texttt{bit} columns (Heikki Linnakangas)

  This error could result in incorrect query results due to values that should compare equal not being seen as equal. Users with GiST indexes on \texttt{bit} or \texttt{bit varying} columns should \texttt{REINDEX} those indexes after installing this update.

- Protect against torn pages when deleting GIN list pages (Heikki Linnakangas)

  This fix prevents possible index corruption if a system crash occurs while the page update is being written to disk.

- Don’t clear the right-link of a GiST index page while replaying updates from WAL (Heikki Linnakangas)

  This error could lead to transiently wrong answers from GiST index scans performed in Hot Standby.
Appendix E. Release Notes

- Fix possibly-incorrect cache invalidation during nested calls to ReceiveSharedInvalidMessages (Andres Freund)

- Don’t assume a subquery’s output is unique if there’s a set-returning function in its targetlist (David Rowley)

  This oversight could lead to misoptimization of constructs like WHERE x IN (SELECT y, generate_series(1,10) FROM t GROUP BY y).

- Fix failure to detoast fields in composite elements of structured types (Tom Lane)

  This corrects cases where TOAST pointers could be copied into other tables without being dereferenced. If the original data is later deleted, it would lead to errors like “missing chunk number 0 for toast value ...” when the now-dangling pointer is used.

- Fix “record type has not been registered” failures with whole-row references to the output of Append plan nodes (Tom Lane)

- Fix possible crash when invoking a user-defined function while rewinding a cursor (Tom Lane)

- Fix query-lifespan memory leak while evaluating the arguments for a function in FROM (Tom Lane)

- Fix session-lifespan memory leaks in regular-expression processing (Tom Lane, Arthur O’Dwyer, Greg Stark)

- Fix data encoding error in hungarian.stop (Tom Lane)

- Fix liveness checks for rows that were inserted in the current transaction and then deleted by a now-rolled-back subtransaction (Andres Freund)

  This could cause problems (at least spurious warnings, and at worst an infinite loop) if CREATE INDEX or CLUSTER were done later in the same transaction.

- Clear pg_stat_activity.xact_start during PREPARE TRANSACTION (Andres Freund)

  After the PREPARE, the originating session is no longer in a transaction, so it should not continue to display a transaction start time.

- Fix REASSIGN OWNED to not fail for text search objects (Álvaro Herrera)

- Block signals during postmaster startup (Tom Lane)

  This ensures that the postmaster will properly clean up after itself if, for example, it receives SIGINT while still starting up.

- Secure Unix-domain sockets of temporary postmasters started during make check (Noah Misch)

  Any local user able to access the socket file could connect as the server’s bootstrap superuser, then proceed to execute arbitrary code as the operating-system user running the test, as we previously noted in CVE-2014-0067. This change defends against that risk by placing the server’s socket in a temporary, mode 0700 subdirectory of /tmp. The hazard remains however on platforms where Unix sockets are not supported, notably Windows, because then the temporary postmaster must accept local TCP connections.

  A useful side effect of this change is to simplify make check testing in builds that override DEFAULT_PGSOCKET_DIR. Popular non-default values like /var/run/postgresql are often not writable by the build user, requiring workarounds that will no longer be necessary.

- Fix tablespace creation WAL replay to work on Windows (MauMau)

- Fix detection of socket creation failures on Windows (Bruce Momjian)
On Windows, allow new sessions to absorb values of PGC_BACKEND parameters (such as log_connections) from the configuration file (Amit Kapila)

Previously, if such a parameter were changed in the file post-startup, the change would have no effect.

Properly quote executable path names on Windows (Nikhil Deshpande)

This oversight could cause initdb and pg_upgrade to fail on Windows, if the installation path contained both spaces and @ signs.

Fix linking of libpython on OS X (Tom Lane)

The method we previously used can fail with the Python library supplied by Xcode 5.0 and later.

Avoid buffer bloat in libpq when the server consistently sends data faster than the client can absorb it (Shin-ichi Morita, Tom Lane)

libpq could be coerced into enlarging its input buffer until it runs out of memory (which would be reported misleadingly as “lost synchronization with server”). Under ordinary circumstances it’s quite far-fetched that data could be continuously transmitted more quickly than the recv() loop can absorb it, but this has been observed when the client is artificially slowed by scheduler constraints.

Ensure that LDAP lookup attempts in libpq time out as intended (Laurenz Albe)

Fix ecpg to do the right thing when an array of char * is the target for a FETCH statement returning more than one row, as well as some other array-handling fixes (Ashutosh Bapat)

Fix pg_restore’s processing of old-style large object comments (Tom Lane)

A direct-to-database restore from an archive file generated by a pre-9.0 version of pg_dump would usually fail if the archive contained more than a few comments for large objects.

In contrib/pgcrypto functions, ensure sensitive information is cleared from stack variables before returning (Marko Kreen)

In contrib/uuid-ossp, cache the state of the OSSP UUID library across calls (Tom Lane)

This improves the efficiency of UUID generation and reduces the amount of entropy drawn from /dev/urandom, on platforms that have that.

Update time zone data files to tzdata release 2014e for DST law changes in Crimea, Egypt, and Morocco.

---

**E.104. Release 9.0.17**

**Release date:** 2014-03-20

This release contains a variety of fixes from 9.0.16. For information about new features in the 9.0 major release, see Section E.121.

**E.104.1. Migration to Version 9.0.17**

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.15, see Section E.106.
E.104.2. Changes

- Restore GIN metapages unconditionally to avoid torn-page risk (Heikki Linnakangas)
  Although this oversight could theoretically result in a corrupted index, it is unlikely to have caused any problems in practice, since the active part of a GIN metapage is smaller than a standard 512-byte disk sector.

- Avoid race condition in checking transaction commit status during receipt of a NOTIFY message (Marko Tiikkaja)
  This prevents a scenario wherein a sufficiently fast client might respond to a notification before database updates made by the notifier have become visible to the recipient.

- Allow regular-expression operators to be terminated early by query cancel requests (Tom Lane)
  This prevents scenarios wherein a pathological regular expression could lock up a server process uninterruptibly for a long time.

- Remove incorrect code that tried to allow OVERLAPS with single-element row arguments (Joshua Yanovski)
  This code never worked correctly, and since the case is neither specified by the SQL standard nor documented, it seemed better to remove it than fix it.

- Avoid getting more than AccessShareLock when de-parsing a rule or view (Dean Rasheed)
  This oversight resulted in pg_dump unexpectedly acquiring RowExclusiveLock locks on tables mentioned as the targets of INSERT/UPDATE/DELETE commands in rules. While usually harmless, that could interfere with concurrent transactions that tried to acquire, for example, ShareLock on those tables.

- Improve performance of index endpoint probes during planning (Tom Lane)
  This change fixes a significant performance problem that occurred when there were many not-yet-committed rows at the end of the index, which is a common situation for indexes on sequentially-assigned values such as timestamps or sequence-generated identifiers.

- Fix test to see if hot standby connections can be allowed immediately after a crash (Heikki Linnakangas)

- Prevent interrupts while reporting non-ERROR messages (Tom Lane)
  This guards against rare server-process freezeups due to recursive entry to syslog(), and perhaps other related problems.

- Prevent intermittent “could not reserve shared memory region” failures on recent Windows versions (MauMau)

- Update time zone data files to tzdata release 2014a for DST law changes in Fiji and Turkey, plus historical changes in Israel and Ukraine.

E.105. Release 9.0.16

Release date: 2014-02-20
This release contains a variety of fixes from 9.0.15. For information about new features in the 9.0 major release, see Section E.121.

E.105.1. Migration to Version 9.0.16

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.15, see Section E.106.

E.105.2. Changes

- **Shore up `GRANT ... WITH ADMIN OPTION` restrictions (Noah Misch)**

  Granting a role without `ADMIN OPTION` is supposed to prevent the grantee from adding or removing members from the granted role, but this restriction was easily bypassed by doing `SET ROLE` first. The security impact is mostly that a role member can revoke the access of others, contrary to the wishes of his grantor. Unapproved role member additions are a lesser concern, since an uncooperative role member could provide most of his rights to others anyway by creating views or `SECURITY DEFINER` functions. (CVE-2014-0060)

- **Prevent privilege escalation via manual calls to PL validator functions (Andres Freund)**

  The primary role of PL validator functions is to be called implicitly during `CREATE FUNCTION`, but they are also normal SQL functions that a user can call explicitly. Calling a validator on a function actually written in some other language was not checked for and could be exploited for privilege-escalation purposes. The fix involves adding a call to a privilege-checking function in each validator function. Non-core procedural languages will also need to make this change to their own validator functions, if any. (CVE-2014-0061)

- **Avoid multiple name lookups during table and index DDL (Robert Haas, Andres Freund)**

  If the name lookups come to different conclusions due to concurrent activity, we might perform some parts of the DDL on a different table than other parts. At least in the case of `CREATE INDEX`, this can be used to cause the permissions checks to be performed against a different table than the index creation, allowing for a privilege escalation attack. (CVE-2014-0062)

- **Prevent buffer overrun with long datetime strings (Noah Misch)**

  The `MAXDATELEN` constant was too small for the longest possible value of type `interval`, allowing a buffer overrun in `interval_out()`. Although the datetime input functions were more careful about avoiding buffer overrun, the limit was short enough to cause them to reject some valid inputs, such as input containing a very long timezone name. The ecpg library contained these vulnerabilities along with some of its own. (CVE-2014-0063)

- **Prevent buffer overrun due to integer overflow in size calculations (Noah Misch, Heikki Linnakangas)**

  Several functions, mostly type input functions, calculated an allocation size without checking for overflow. If overflow did occur, a too-small buffer would be allocated and then written past. (CVE-2014-0064)

- **Prevent overruns of fixed-size buffers (Peter Eisentraut, Jozef Mlich)**
Appendix E. Release Notes

Use `strlcpy()` and related functions to provide a clear guarantee that fixed-size buffers are not overrun. Unlike the preceding items, it is unclear whether these cases really represent live issues, since in most cases there appear to be previous constraints on the size of the input string. Nonetheless it seems prudent to silence all Coverity warnings of this type. (CVE-2014-0065)

- Avoid crashing if `crypt()` returns NULL (Honza Horak, Bruce Momjian)

  There are relatively few scenarios in which `crypt()` could return NULL, but `contrib/chkpass` would crash if it did. One practical case in which this could be an issue is if libc is configured to refuse to execute unapproved hashing algorithms (e.g., “FIPS mode”). (CVE-2014-0066)

- Document risks of `make check` in the regression testing instructions (Noah Misch, Tom Lane)

  Since the temporary server started by `make check` uses “trust” authentication, another user on the same machine could connect to it as database superuser, and then potentially exploit the privileges of the operating-system user who started the tests. A future release will probably incorporate changes in the testing procedure to prevent this risk, but some public discussion is needed first. So for the moment, just warn people against using `make check` when there are untrusted users on the same machine. (CVE-2014-0067)

- Fix possible mis-replay of WAL records when some segments of a relation aren’t full size (Greg Stark, Tom Lane)

  The WAL update could be applied to the wrong page, potentially many pages past where it should have been. Aside from corrupting data, this error has been observed to result in significant “bloat” of standby servers compared to their masters, due to updates being applied far beyond where the end-of-file should have been. This failure mode does not appear to be a significant risk during crash recovery, only when initially synchronizing a standby created from a base backup taken from a quickly-changing master.

- Fix bug in determining when recovery has reached consistency (Tomonari Katsumata, Heikki Linnakangas)

  In some cases WAL replay would mistakenly conclude that the database was already consistent at the start of replay, thus possibly allowing hot-standby queries before the database was really consistent. Other symptoms such as “PANIC: WAL contains references to invalid pages” were also possible.

- Fix improper locking of btree index pages while replaying a `VACUUM` operation in hot-standby mode (Andres Freund, Heikki Linnakangas, Tom Lane)

  This error could result in “PANIC: WAL contains references to invalid pages” failures.

- Ensure that insertions into non-leaf GIN index pages write a full-page WAL record when appropriate (Heikki Linnakangas)

  The previous coding risked index corruption in the event of a partial-page write during a system crash.

- Fix race conditions during server process exit (Robert Haas)

  Ensure that signal handlers don’t attempt to use the process’s `MyProc` pointer after it’s no longer valid.

- Fix unsafe references to `errno` within error reporting logic (Christian Kruse)

  This would typically lead to odd behaviors such as missing or inappropriate `HINT` fields.

- Fix possible crashes from using `ereport()` too early during server startup (Tom Lane)

  The principal case we’ve seen in the field is a crash if the server is started in a directory it doesn’t have permission to read.
Appendix E. Release Notes

• Clear retry flags properly in OpenSSL socket write function (Alexander Kukushkin)
  This omission could result in a server lockup after unexpected loss of an SSL-encrypted connection.
• Fix length checking for Unicode identifiers (“...” syntax) containing escapes (Tom Lane)
  A spurious truncation warning would be printed for such identifiers if the escaped form of the identifier
  was too long, but the identifier actually didn’t need truncation after de-escaping.
• Allow keywords that are type names to be used in lists of roles (Stephen Frost)
  A previous patch allowed such keywords to be used without quoting in places such as role identifiers;
  but it missed cases where a list of role identifiers was permitted, such as **DROP ROLE**.
• Fix possible crash due to invalid plan for nested sub-selects, such as **WHERE (... x IN (SELECT ...
  ...) ...) IN (SELECT ...)** (Tom Lane)
• Ensure that **ANALYZE** creates statistics for a table column even when all the values in it are “too wide”
  (Tom Lane)
  **ANALYZE** intentionally omits very wide values from its histogram and most-common-values calculations,
  but it neglected to do something sane in the case that all the sampled entries are too wide.
• In **ALTER TABLE ... SET TABLESPACE**, allow the database’s default tablespace to be used without
  a permissions check (Stephen Frost)
  **CREATE TABLE** has always allowed such usage, but **ALTER TABLE** didn’t get the memo.
• Fix “cannot accept a set” error when some arms of a **CASE** return a set and others don’t (Tom Lane)
• Fix checks for all-zero client addresses in pgsas functions (Kevin Grittner)
• Fix possible misclassification of multibyte characters by the text search parser (Tom Lane)
  Non-ASCII characters could be misclassified when using C locale with a multibyte encoding. On Cygwin,
  non-C locales could fail as well.
• Fix possible misbehavior in **plainto_tsquery()** (Heikki Linnakangas)
  Use **memmove()** not **memcpy()** for copying overlapping memory regions. There have been no field
  reports of this actually causing trouble, but it’s certainly risky.
• Accept **SHIFT_JIS** as an encoding name for locale checking purposes (Tatsuo Ishii)
• Fix misbehavior of **PQhost()** on Windows (Fujii Masao)
  It should return **localhost** if no host has been specified.
• Improve error handling in **libpq** and **psql** for failures during **COPY TO STDOUT/FROM STDIN** (Tom Lane)
  In particular this fixes an infinite loop that could occur in 9.2 and up if the server connection was lost
  during **COPY FROM STDIN**. Variants of that scenario might be possible in older versions, or with other
  client applications.
• Fix misaligned descriptors in **ecpg** (MauMau)
• In **ecpg**, handle lack of a hostname in the connection parameters properly (Michael Meskes)
• Fix performance regression in **contrib/dblink** connection startup (Joe Conway)
  Avoid an unnecessary round trip when client and server encodings match.
• In **contrib/isn**, fix incorrect calculation of the check digit for ISMN values (Fabien Coelho)
• Ensure client-code-only installation procedure works as documented (Peter Eisentraut)

• In Mingw and Cygwin builds, install the libpq DLL in the bin directory (Andrew Dunstan)
  This duplicates what the MSVC build has long done. It should fix problems with programs like psql failing to start because they can’t find the DLL.

• Avoid using the deprecated dllwrap tool in Cygwin builds (Marco Atzeri)

• Don’t generate plain-text HISTORY and src/test/regress/README files anymore (Tom Lane)
  These text files duplicated the main HTML and PDF documentation formats. The trouble involved in maintaining them greatly outweighs the likely audience for plain-text format. Distribution tarballs will still contain files by these names, but they’ll just be stubs directing the reader to consult the main documentation. The plain-text INSTALL file will still be maintained, as there is arguably a use-case for that.

• Update time zone data files to tzdata release 2013i for DST law changes in Jordan and historical changes in Cuba.
  In addition, the zones Asia/Riyadh87, Asia/Riyadh88, and Asia/Riyadh89 have been removed, as they are no longer maintained by IANA, and never represented actual civil timekeeping practice.

E.106. Release 9.0.15

Release date: 2013-12-05
This release contains a variety of fixes from 9.0.14. For information about new features in the 9.0 major release, see Section E.121.

E.106.1. Migration to Version 9.0.15
A dump/restore is not required for those running 9.0.X.
However, this release corrects a number of potential data corruption issues. See the first two changelog entries below to find out whether your installation has been affected and what steps you can take if so.
Also, if you are upgrading from a version earlier than 9.0.13, see Section E.108.

E.106.2. Changes

• Fix VACUUM’s tests to see whether it can update relfrozenxid (Andres Freund)
  In some cases VACUUM (either manual or autovacuum) could incorrectly advance a table’s relfrozenxid value, allowing tuples to escape freezing, causing those rows to become invisible once $2^{31}$ transactions have elapsed. The probability of data loss is fairly low since multiple incorrect advancements would need to happen before actual loss occurs, but it’s not zero. Users upgrading from releases 9.0.4 or 8.4.8 or earlier are not affected, but all later versions contain the bug.
Appendix E. Release Notes

The issue can be ameliorated by, after upgrading, vacuuming all tables in all databases while having vacuum_freeze_table_age set to zero. This will fix any latent corruption but will not be able to fix all pre-existing data errors. However, an installation can be presumed safe after performing this vacuuming if it has executed fewer than $2^{31}$ update transactions in its lifetime (check this with `SELECT txid_current() < 2^{31}`).

• Fix initialization of `pg_clog` and `pg_subtrans` during hot standby startup (Andres Freund, Heikki Linnakangas)

  This bug can cause data loss on standby servers at the moment they start to accept hot-standby queries, by marking committed transactions as uncommitted. The likelihood of such corruption is small unless, at the time of standby startup, the primary server has executed many updating transactions since its last checkpoint. Symptoms include missing rows, rows that should have been deleted being still visible, and obsolete versions of updated rows being still visible alongside their newer versions.

  This bug was introduced in versions 9.3.0, 9.2.5, 9.1.10, and 9.0.14. Standby servers that have only been running earlier releases are not at risk. It’s recommended that standby servers that have ever run any of the buggy releases be re-cloned from the primary (e.g., with a new base backup) after upgrading.

• Truncate `pg_multixact` contents during WAL replay (Andres Freund)

  This avoids ever-increasing disk space consumption in standby servers.

• Fix race condition in GIN index posting tree page deletion (Heikki Linnakangas)

  This could lead to transient wrong answers or query failures.

• Avoid flattening a subquery whose `SELECT` list contains a volatile function wrapped inside a sub-
  `SELECT` (Tom Lane)

  This avoids unexpected results due to extra evaluations of the volatile function.

• Fix planner’s processing of non-simple-variable subquery outputs nested within outer joins (Tom Lane)

  This error could lead to incorrect plans for queries involving multiple levels of subqueries within `JOIN` syntax.

• Fix premature deletion of temporary files (Andres Freund)

• Fix possible read past end of memory in rule printing (Peter Eisentraut)

• Fix array slicing of `int2vector` and `oidvector` values (Tom Lane)

  Expressions of this kind are now implicitly promoted to regular `int2` or `oid` arrays.

• Fix incorrect behaviors when using a SQL-standard, simple GMT offset timezone (Tom Lane)

  In some cases, the system would use the simple GMT offset value when it should have used the regular timezone setting that had prevailed before the simple offset was selected. This change also causes the `timeofday` function to honor the simple GMT offset zone.

• Prevent possible misbehavior when logging translations of Windows error codes (Tom Lane)

• Properly quote generated command lines in `pg_ctl` (Naoya Anzai and Tom Lane)

  This fix applies only to Windows.

• Fix `pg_dumpall` to work when a source database sets `default_transaction_read_only` via `ALTER DATABASE SET` (Kevin Grittner)

  Previously, the generated script would fail during restore.
Appendix E. Release Notes

• Fix ecpg’s processing of lists of variables declared varchar (Zoltán Böszörményi)
• Make contrib/lo defend against incorrect trigger definitions (Marc Cousin)
• Update time zone data files to tzdata release 2013h for DST law changes in Argentina, Brazil, Jordan, Libya, Liechtenstein, Morocco, and Palestine. Also, new timezone abbreviations WIB, WIT, WITA for Indonesia.

E.107. Release 9.0.14

Release date: 2013-10-10

This release contains a variety of fixes from 9.0.13. For information about new features in the 9.0 major release, see Section E.121.

E.107.1. Migration to Version 9.0.14

A dump/restore is not required for those running 9.0.X. However, if you are upgrading from a version earlier than 9.0.13, see Section E.108.

E.107.2. Changes

• Prevent corruption of multi-byte characters when attempting to case-fold identifiers (Andrew Dunstan)
  PostgreSQL case-folds non-ASCII characters only when using a single-byte server encoding.
• Fix checkpoint memory leak in background writer when wal_level = hot_standby (Naoya Anzai)
• Fix memory leak caused by lo_open() failure (Heikki Linnakangas)
• Fix memory overcommit bug when work_mem is using more than 24GB of memory (Stephen Frost)
• Fix deadlock bug in libpq when using SSL (Stephen Frost)
• Fix possible SSL state corruption in threaded libpq applications (Nick Phillips, Stephen Frost)
• Properly compute row estimates for boolean columns containing many NULL values (Andrew Gierth)
  Previously tests like col IS NOT TRUE and col IS NOT FALSE did not properly factor in NULL values when estimating plan costs.
• Prevent pushing down WHERE clauses into unsafe UNION/INTERSECT subqueries (Tom Lane)
  Subqueries of a UNION or INTERSECT that contain set-returning functions or volatile functions in their SELECT lists could be improperly optimized, leading to run-time errors or incorrect query results.
• Fix rare case of “failed to locate grouping columns” planner failure (Tom Lane)
• Improve view dumping code’s handling of dropped columns in referenced tables (Tom Lane)
• Properly record index comments created using UNIQUE and PRIMARY KEY syntax (Andres Freund)
  This fixes a parallel pg_restore failure.
• Fix `REINDEX TABLE` and `REINDEX DATABASE` to properly revalidate constraints and mark invalidated indexes as valid (Noah Misch)
  
  `REINDEX INDEX` has always worked properly.

• Fix possible deadlock during concurrent `CREATE INDEX CONCURRENTLY` operations (Tom Lane)

• Fix `regexp_matches()` handling of zero-length matches (Jeevan Chalke)
  
  Previously, zero-length matches like `''` could return too many matches.

• Fix crash for overly-complex regular expressions (Heikki Linnakangas)

• Fix regular expression match failures for back references combined with non-greedy quantifiers (Jeevan Chalke)

• Prevent `CREATE FUNCTION` from checking `SET` variables unless function body checking is enabled (Tom Lane)

• Allow `ALTER DEFAULT PRIVILEGES` to operate on schemas without requiring `CREATE` permission (Tom Lane)

• Loosen restriction on keywords used in queries (Tom Lane)

  Specifically, lessen keyword restrictions for role names, language names, `EXPLAIN` and `COPY` options, and `SET` values. This allows `COPY ... (FORMAT BINARY)` to work as expected; previously `BINARY` needed to be quoted.

• Fix `pgp_pub_decrypt()` so it works for secret keys with passwords (Marko Kreen)

• Remove rare inaccurate warning during vacuum of index-less tables (Heikki Linnakangas)

• Ensure that `VACUUM ANALYZE` still runs the `ANALYZE` phase if its attempt to truncate the file is cancelled due to lock conflicts (Kevin Grittner)

• Avoid possible failure when performing transaction control commands (e.g ROLLBACK) in prepared queries (Tom Lane)

• Ensure that floating-point data input accepts standard spellings of “infinity” on all platforms (Tom Lane)

  The C99 standard says that allowable spellings are `inf`, `+inf`, `-inf`, `infinity`, `+infinity`, and `-infinity`. Make sure we recognize these even if the platform’s `strtod` function doesn’t.

• Expand ability to compare rows to records and arrays (Rafal Rzepecki, Tom Lane)

• Update time zone data files to `tzdata` release 2013d for DST law changes in Israel, Morocco, Palestine, and Paraguay. Also, historical zone data corrections for Macquarie Island.

---

E.108. Release 9.0.13

**Release date:** 2013-04-04

This release contains a variety of fixes from 9.0.12. For information about new features in the 9.0 major release, see Section E.121.
Appendix E. Release Notes

E.108.1. Migration to Version 9.0.13

A dump/restore is not required for those running 9.0.X.

However, this release corrects several errors in management of GiST indexes. After installing this update, it is advisable to **REINDEX** any GiST indexes that meet one or more of the conditions described below.

Also, if you are upgrading from a version earlier than 9.0.6, see Section E.115.

E.108.2. Changes

- Fix insecure parsing of server command-line switches (Mitsumasa Kondo, Kyotaro Horiguchi)
  A connection request containing a database name that begins with “-” could be crafted to damage or destroy files within the server’s data directory, even if the request is eventually rejected. (CVE-2013-1899)

- Reset OpenSSL randomness state in each postmaster child process (Marko Kreen)
  This avoids a scenario wherein random numbers generated by `contrib/pgcrypto` functions might be relatively easy for another database user to guess. The risk is only significant when the postmaster is configured with `ssl = on` but most connections don’t use SSL encryption. (CVE-2013-1900)

- Fix GiST indexes to not use “fuzzy” geometric comparisons when it’s not appropriate to do so (Alexander Korotkov)
  The core geometric types perform comparisons using “fuzzy” equality, but `gist_box_same` must do exact comparisons, else GiST indexes using it might become inconsistent. After installing this update, users should **REINDEX** any GiST indexes on `box`, `polygon`, `circle`, or `point` columns, since all of these use `gist_box_same`.

- Fix erroneous range-union and penalty logic in GiST indexes that use `contrib/btree_gist` for variable-width data types, that is `text`, `bytea`, `bit`, and `numeric` columns (Tom Lane)
  These errors could result in inconsistent indexes in which some keys that are present would not be found by searches, and also in useless index bloat. Users are advised to **REINDEX** such indexes after installing this update.

- Fix bugs in GiST page splitting code for multi-column indexes (Tom Lane)
  These errors could result in inconsistent indexes in which some keys that are present would not be found by searches, and also in indexes that are unnecessarily inefficient to search. Users are advised to **REINDEX** multi-column GiST indexes after installing this update.

- Fix `gist_point_consistent` to handle fuzziness consistently (Alexander Korotkov)
  Index scans on GiST indexes on `point` columns would sometimes yield results different from a sequential scan, because `gist_point_consistent` disagreed with the underlying operator code about whether to do comparisons exactly or fuzzily.

- Fix buffer leak in WAL replay (Heikki Linnakangas)
  This bug could result in “incorrect local pin count” errors during replay, making recovery impossible.

- Fix race condition in `DELETE RETURNING` (Tom Lane)
Under the right circumstances, `DELETE RETURNING` could attempt to fetch data from a shared buffer that the current process no longer has any pin on. If some other process changed the buffer meanwhile, this would lead to garbage `RETURNING` output, or even a crash.

- Fix infinite-loop risk in regular expression compilation (Tom Lane, Don Porter)
- Fix potential null-pointer dereference in regular expression compilation (Tom Lane)
- Fix `to_char()` to use ASCII-only case-folding rules where appropriate (Tom Lane)
  This fixes misbehavior of some template patterns that should be locale-independent, but mishandled “ı” and “ı” in Turkish locales.
- Fix unwanted rejection of timestamp `1999-12-31 24:00:00` (Tom Lane)
- Fix logic error when a single transaction does `UNLISTEN` then `LISTEN` (Tom Lane)
  The session wound up not listening for notify events at all, though it surely should listen in this case.
- Remove useless “picksplit doesn’t support secondary split” log messages (Josh Hansen, Tom Lane)
  This message seems to have been added in expectation of code that was never written, and probably never will be, since GiST’s default handling of secondary splits is actually pretty good. So stop nagging end users about it.
- Fix possible failure to send a session’s last few transaction commit/abort counts to the statistics collector (Tom Lane)
- Eliminate memory leaks in PL/Perl’s `spi_prepare()` function (Alex Hunsaker, Tom Lane)
- Fix `pg_dumpall` to handle database names containing “=” correctly (Heikki Linnakangas)
- Avoid crash in `pg_dump` when an incorrect connection string is given (Heikki Linnakangas)
- Ignore invalid indexes in `pg_dump` and `pg Upgrade` (Michael Paquier, Bruce Momjian)
  Dumping invalid indexes can cause problems at restore time, for example if the reason the index creation failed was because it tried to enforce a uniqueness condition not satisfied by the table’s data. Also, if the index creation is in fact still in progress, it seems reasonable to consider it to be an uncommitted DDL change, which `pg_dump` wouldn’t be expected to dump anyway. `pg_upgrade` now also skips invalid indexes rather than failing.
- Fix `contrib/pg_trgm’s similarity()` function to return zero for trigram-less strings (Tom Lane)
  Previously it returned `NaN` due to internal division by zero.
- Update time zone data files to `tzdata` release 2013b for DST law changes in Chile, Haiti, Morocco, Paraguay, and some Russian areas. Also, historical zone data corrections for numerous places.
  Also, update the time zone abbreviation files for recent changes in Russia and elsewhere: `CHOT`, `GET`, `IRKT`, `KGT`, `KRAT`, `MAGT`, `MAWT`, `MSK`, `NOVT`, `OMST`, `TKT`, `VLAT`, `WST`, `YAKT`, `YETK` now follow their current meanings, and `VOLT` (Europe/Volgograd) and `MIST` (Antarctica/Macquarie) are added to the default abbreviations list.

**E.109. Release 9.0.12**

**Release date:** 2013-02-07
This release contains a variety of fixes from 9.0.11. For information about new features in the 9.0 major release, see Section E.121.

**E.109.1. Migration to Version 9.0.12**

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.6, see Section E.115.

**E.109.2. Changes**

- Prevent execution of `enum_recv` from SQL (Tom Lane)
  The function was misdeclared, allowing a simple SQL command to crash the server. In principle an attacker might be able to use it to examine the contents of server memory. Our thanks to Sumit Soni (via Secunia SVCRP) for reporting this issue. (CVE-2013-0255)

- Fix multiple problems in detection of when a consistent database state has been reached during WAL replay (Fujii Masao, Heikki Linnakangas, Simon Riggs, Andres Freund)

- Update minimum recovery point when truncating a relation file (Heikki Linnakangas)
  Once data has been discarded, it’s no longer safe to stop recovery at an earlier point in the timeline.

- Fix missing cancellations in hot standby mode (Noah Misch, Simon Riggs)
  The need to cancel conflicting hot-standby queries would sometimes be missed, allowing those queries to see inconsistent data.

- Fix SQL grammar to allow subscripting or field selection from a sub-SELECT result (Tom Lane)

- Fix performance problems with autovacuum truncation in busy workloads (Jan Wieck)
  Truncation of empty pages at the end of a table requires exclusive lock, but autovacuum was coded to fail (and release the table lock) when there are conflicting lock requests. Under load, it is easily possible that truncation would never occur, resulting in table bloat. Fix by performing a partial truncation, releasing the lock, then attempting to re-acquire the lock and continue. This fix also greatly reduces the average time before autovacuum releases the lock after a conflicting request arrives.

- Protect against race conditions when scanning `pg_tablespace` (Stephen Frost, Tom Lane)
  `CREATE DATABASE` and `DROP DATABASE` could misbehave if there were concurrent updates of `pg_tablespace` entries.

- Prevent `DROP OWNED` from trying to drop whole databases or tablespaces (Álvaro Herrera)
  For safety, ownership of these objects must be reassigned, not dropped.

- Fix error in `vacuum_freeze_table_age` implementation (Andres Freund)
  In installations that have existed for more than `vacuum_freeze_min_age` transactions, this mistake prevented autovacuum from using partial-table scans, so that a full-table scan would always happen instead.

- Prevent misbehavior when a `RowExpr` or `XmlExpr` is parse-analyzed twice (Andres Freund, Tom Lane)
This mistake could be user-visible in contexts such as `CREATE TABLE LIKE INCLUDING INDEXES`.

- Improve defenses against integer overflow in hashtable sizing calculations (Jeff Davis)
- Reject out-of-range dates in `to_date()` (Hitoshi Harada)
- Ensure that non-ASCII prompt strings are translated to the correct code page on Windows (Alexander Law, Noah Misch)
  This bug affected psql and some other client programs.
- Fix possible crash in psql’s `\?` command when not connected to a database (Meng Qingzhong)
- Fix `pg_upgrade` to deal with invalid indexes safely (Bruce Momjian)
- Fix one-byte buffer overrun in libpq’s `PQprintTuples` (Xi Wang)
  This ancient function is not used anywhere by PostgreSQL itself, but it might still be used by some client code.
- Make ecpglib use translated messages properly (Chen Huajun)
- Properly install ecpg_compat and pgtypes libraries on MSVC (Jiang Guiqing)
- Include our version of `isinf()` in libecpg if it’s not provided by the system (Jiang Guiqing)
- Rearrange configure’s tests for supplied functions so it is not fooled by bogus exports from libedit/libreadline (Christoph Berg)
- Ensure Windows build number increases over time (Magnus Hagander)
- Make `pgxs` build executables with the right `.exe` suffix when cross-compiling for Windows (Zoltan Boszormenyi)
- Add new timezone abbreviation `FET` (Tom Lane)
  This is now used in some eastern-European time zones.

**E.110. Release 9.0.11**

*Release date:* 2012-12-06

This release contains a variety of fixes from 9.0.10. For information about new features in the 9.0 major release, see Section E.121.

**E.110.1. Migration to Version 9.0.11**

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.6, see Section E.115.

**E.110.2. Changes**

- Fix multiple bugs associated with `CREATE INDEX CONCURRENTLY` (Andres Freund, Tom Lane)
Fix `CREATE INDEX CONCURRENTLY` to use in-place updates when changing the state of an index’s `pg_index` row. This prevents race conditions that could cause concurrent sessions to miss updating the target index, thus resulting in corrupt concurrently-created indexes.

Also, fix various other operations to ensure that they ignore invalid indexes resulting from a failed `CREATE INDEX CONCURRENTLY` command. The most important of these is `VACUUM`, because an auto-vacuum could easily be launched on the table before corrective action can be taken to fix or remove the invalid index.

- Fix buffer locking during WAL replay (Tom Lane)
  The WAL replay code was insufficiently careful about locking buffers when replaying WAL records that affect more than one page. This could result in hot standby queries transiently seeing inconsistent states, resulting in wrong answers or unexpected failures.

- Fix an error in WAL generation logic for GIN indexes (Tom Lane)
  This could result in index corruption, if a torn-page failure occurred.

- Properly remove startup process’s virtual XID lock when promoting a hot standby server to normal running (Simon Riggs)
  This oversight could prevent subsequent execution of certain operations such as `CREATE INDEX CONCURRENTLY`.

- Avoid “out-of-sequence timeline ID” errors in standby mode (Heikki Linnakangas)

- Prevent the postmaster from launching new child processes after it’s received a shutdown signal (Tom Lane)
  This mistake could result in shutdown taking longer than it should, or even never completing at all without additional user action.

- Avoid corruption of internal hash tables when out of memory (Hitoshi Harada)

- Fix planning of non-strict equivalence clauses above outer joins (Tom Lane)
  The planner could derive incorrect constraints from a clause equating a non-strict construct to something else, for example `WHERE COALESCE(foo, 0) = 0` when `foo` is coming from the nullable side of an outer join.

- Improve planner’s ability to prove exclusion constraints from equivalence classes (Tom Lane)

- Fix partial-row matching in hashed subplans to handle cross-type cases correctly (Tom Lane)
  This affects multicolumn `NOT IN` subplans, such as `WHERE (a, b) NOT IN (SELECT x, y FROM . . .)` when for instance `b` and `y` are `int4` and `int8` respectively. This mistake led to wrong answers or crashes depending on the specific datatypes involved.

- Acquire buffer lock when re-fetching the old tuple for an `AFTER ROW UPDATE/DELETE` trigger (Andres Freund)
  In very unusual circumstances, this oversight could result in passing incorrect data to the precheck logic for a foreign-key enforcement trigger. That could result in a crash, or in an incorrect decision about whether to fire the trigger.

- Fix `ALTER COLUMN TYPE` to handle inherited check constraints properly (Pavan Deolasee)
  This worked correctly in pre-8.4 releases, and now works correctly in 8.4 and later.

- Fix `REASSIGN OWNED` to handle grants on tablespaces (Álvaro Herrera)
Appendix E. Release Notes

• Ignore incorrect pg_attribute entries for system columns for views (Tom Lane)
  Views do not have any system columns. However, we forgot to remove such entries when converting
  a table to a view. That’s fixed properly for 9.3 and later, but in previous branches we need to defend
  against existing mis-converted views.

• Fix rule printing to dump INSERT INTO table DEFAULT VALUES correctly (Tom Lane)

• Guard against stack overflow when there are too many UNION/INTERSECT/EXCEPT clauses in a query
  (Tom Lane)

• Prevent platform-dependent failures when dividing the minimum possible integer value by -1 (Xi Wang,
  Tom Lane)

• Fix possible access past end of string in date parsing (Hitoshi Harada)

• Fix failure to advance XID epoch if XID wraparound happens during a checkpoint and wal_level is
  hot_standby (Tom Lane, Andres Freund)
  While this mistake had no particular impact on PostgreSQL itself, it was bad for applications that rely
  on txid_current() and related functions: the TXID value would appear to go backwards.

• Produce an understandable error message if the length of the path name for a Unix-domain socket
  exceeds the platform-specific limit (Tom Lane, Andrew Dunstan)
  Formerly, this would result in something quite unhelpful, such as “Non-recoverable failure in name
  resolution”.

• Fix memory leaks when sending composite column values to the client (Tom Lane)

• Make pg_ctl more robust about reading the postmaster.pid file (Heikki Linnakangas)
  Fix race conditions and possible file descriptor leakage.

• Fix possible crash in psql if incorrectly-encoded data is presented and the client_encoding setting
  is a client-only encoding, such as SJIS (Jiang Guiqing)

• Fix bugs in the restore.sql script emitted by pg_dump in tar output format (Tom Lane)
  The script would fail outright on tables whose names include upper-case characters. Also, make the
  script capable of restoring data in --inserts mode as well as the regular COPY mode.

• Fix pg_restore to accept POSIX-conformant tar files (Brian Weaver, Tom Lane)
  The original coding of pg_dump’s tar output mode produced files that are not fully conformant with
  the POSIX standard. This has been corrected for version 9.3. This patch updates previous branches so
  that they will accept both the incorrect and the corrected formats, in hopes of avoiding compatibility
  problems when 9.3 comes out.

• Fix pg_resetxlog to locate postmaster.pid correctly when given a relative path to the data directory
  (Tom Lane)
  This mistake could lead to pg_resetxlog not noticing that there is an active postmaster using the data
  directory.

• Fix libpq’s lo_import() and lo_export() functions to report file I/O errors properly (Tom Lane)

• Fix ecpg’s processing of nested structure pointer variables (Muhammad Usama)

• Fix ecpg’s ecpg_get_data function to handle arrays properly (Michael Meskes)
• Make contrib/pageinspect’s btree page inspection functions take buffer locks while examining pages (Tom Lane)
• Fix pgxs support for building loadable modules on AIX (Tom Lane)
  Building modules outside the original source tree didn’t work on AIX.
• Update time zone data files to tzdata release 2012j for DST law changes in Cuba, Israel, Jordan, Libya, Palestine, Western Samoa, and portions of Brazil.

E.111. Release 9.0.10

Release date: 2012-09-24

This release contains a variety of fixes from 9.0.9. For information about new features in the 9.0 major release, see Section E.121.

E.111.1. Migration to Version 9.0.10

A dump/restore is not required for those running 9.0.X. However, if you are upgrading from a version earlier than 9.0.6, see Section E.115.

E.111.2. Changes

• Fix planner’s assignment of executor parameters, and fix executor’s rescan logic for CTE plan nodes (Tom Lane)
  These errors could result in wrong answers from queries that scan the same WITH subquery multiple times.
• Improve page-splitting decisions in GiST indexes (Alexander Korotkov, Robert Haas, Tom Lane)
  Multi-column GiST indexes might suffer unexpected bloat due to this error.
• Fix cascading privilege revoke to stop if privileges are still held (Tom Lane)
  If we revoke a grant option from some role \( x \), but \( x \) still holds that option via a grant from someone else, we should not recursively revoke the corresponding privilege from role(s) \( y \) that \( x \) had granted it to.
• Improve error messages for Hot Standby misconfiguration errors (Gurjeet Singh)
• Fix handling of SIGFPE when PL/Perl is in use (Andres Freund)
  Perl resets the process’s SIGFPE handler to SIG_IGN, which could result in crashes later on. Restore the normal PostgreSQL signal handler after initializing PL/Perl.
• Prevent PL/Perl from crashing if a recursive PL/Perl function is redefined while being executed (Tom Lane)
• Work around possible misoptimization in PL/Perl (Tom Lane)
Some Linux distributions contain an incorrect version of `pthread.h` that results in incorrect compiled code in PL/Perl, leading to crashes if a PL/Perl function calls another one that throws an error.

- Fix `pg_upgrade`’s handling of line endings on Windows (Andrew Dunstan)
  Previously, `pg_upgrade` might add or remove carriage returns in places such as function bodies.
- On Windows, make `pg_upgrade` use backslash path separators in the scripts it emits (Andrew Dunstan)
- Update time zone data files to tzdata release 2012f for DST law changes in Fiji

## E.112. Release 9.0.9

**Release date:** 2012-08-17

This release contains a variety of fixes from 9.0.8. For information about new features in the 9.0 major release, see Section E.121.

### E.112.1. Migration to Version 9.0.9

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.6, see Section E.115.

### E.112.2. Changes

- Prevent access to external files/URLs via XML entity references (Noah Misch, Tom Lane)
  `xml_parse()` would attempt to fetch external files or URLs as needed to resolve DTD and entity references in an XML value, thus allowing unprivileged database users to attempt to fetch data with the privileges of the database server. While the external data wouldn’t get returned directly to the user, portions of it could be exposed in error messages if the data didn’t parse as valid XML; and in any case the mere ability to check existence of a file might be useful to an attacker. (CVE-2012-3489)
- Prevent access to external files/URLs via `contrib/xml2`'s `xslt_process()` (Peter Eisentraut)
  `libxslt` offers the ability to read and write both files and URLs through stylesheet commands, thus allowing unprivileged database users to both read and write data with the privileges of the database server. Disable that through proper use of `libxslt`’s security options. (CVE-2012-3488)
  Also, remove `xslt_process()`’s ability to fetch documents and stylesheets from external files/URLs. While this was a documented “feature”, it was long regarded as a bad idea. The fix for CVE-2012-3489 broke that capability, and rather than expend effort on trying to fix it, we’re just going to summarily remove it.
- Prevent too-early recycling of btree index pages (Noah Misch)
  When we allowed read-only transactions to skip assigning XIDs, we introduced the possibility that a deleted btree page could be recycled while a read-only transaction was still in flight to it. This would
result in incorrect index search results. The probability of such an error occurring in the field seems very low because of the timing requirements, but nonetheless it should be fixed.

- Fix crash-safety bug with newly-created-or-reset sequences (Tom Lane)

  If `ALTER SEQUENCE` was executed on a freshly created or reset sequence, and then precisely one `nextval()` call was made on it, and then the server crashed, WAL replay would restore the sequence to a state in which it appeared that no `nextval()` had been done, thus allowing the first sequence value to be returned again by the next `nextval()` call. In particular this could manifest for serial columns, since creation of a serial column’s sequence includes an `ALTER SEQUENCE OWNED BY` step.

- Fix `txid_current()` to report the correct epoch when not in hot standby (Heikki Linnakangas)

  This fixes a regression introduced in the previous minor release.

- Fix bug in startup of Hot Standby when a master transaction has many subtransactions (Andres Freund)

  This mistake led to failures reported as “out-of-order XID insertion in KnownAssignedXids”.

- Ensure the `backup_label` file is fsync’d after `pg_start_backup()` (Dave Kerr)

- Fix timeout handling in walsender processes (Tom Lane)

  WAL sender background processes neglected to establish a SIGALRM handler, meaning they would wait forever in some corner cases where a timeout ought to happen.

- Back-patch 9.1 improvement to compress the fsync request queue (Robert Haas)

  This improves performance during checkpoints. The 9.1 change has now seen enough field testing to seem safe to back-patch.

- Fix `LISTEN/NOTIFY` to cope better with I/O problems, such as out of disk space (Tom Lane)

  After a write failure, all subsequent attempts to send more `NOTIFY` messages would fail with messages like “Could not read from file "pg_notify/nnnn" at offset nnnnn: Success”.

- Only allow autovacuum to be auto-canceled by a directly blocked process (Tom Lane)

  The original coding could allow inconsistent behavior in some cases; in particular, an autovacuum could get canceled after less than `deadlock_timeout` grace period.

- Improve logging of autovacuum cancels (Robert Haas)

- Fix log collector so that `log_truncate_on_rotation` works during the very first log rotation after server start (Tom Lane)

- Fix `WITH` attached to a nested set operation (`UNION/INTERSECT/EXCEPT`) (Tom Lane)

- Ensure that a whole-row reference to a subquery doesn’t include any extra `GROUP BY` or `ORDER BY` columns (Tom Lane)

- Disallow copying whole-row references in `CHECK` constraints and index definitions during `CREATE TABLE` (Tom Lane)

  This situation can arise in `CREATE TABLE with LIKE or INHERITS`. The copied whole-row variable was incorrectly labeled with the row type of the original table not the new one. Rejecting the case seems reasonable for `LIKE`, since the row types might well diverge later. For `INHERITS` we should ideally allow it, with an implicit coercion to the parent table’s row type; but that will require more work than seems safe to back-patch.

- Fix memory leak in `ARRAY(SELECT . . .)` subqueries (Heikki Linnakangas, Tom Lane)
- Fix extraction of common prefixes from regular expressions (Tom Lane)

  The code could get confused by quantified parenthesized subexpressions, such as ^{foo}?bar. This would lead to incorrect index optimization of searches for such patterns.

- Fix bugs with parsing signed \texttt{hh:mm} and \texttt{hh:mm:ss} fields in interval constants (Amit Kapila, Tom Lane)

- Use Postgres’ encoding conversion functions, not Python’s, when converting a Python Unicode string to the server encoding in PL/Python (Jan Urbanski)

  This avoids some corner-case problems, notably that Python doesn’t support all the encodings Postgres does. A notable functional change is that if the server encoding is SQL\_ASCII, you will get the UTF-8 representation of the string; formerly, any non-ASCII characters in the string would result in an error.

- Fix mapping of PostgreSQL encodings to Python encodings in PL/Python (Jan Urbanski)

- Report errors properly in \texttt{contrib/xml2}'s \texttt{xslt\_process()} (Tom Lane)

- Update time zone data files to tzdata release 2012e for DST law changes in Morocco and Tokelau

\textbf{E.113. Release 9.0.8}

\textbf{Release date: 2012-06-04}

This release contains a variety of fixes from 9.0.7. For information about new features in the 9.0 major release, see Section E.121.

\textbf{E.113.1. Migration to Version 9.0.8}

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.6, see Section E.115.

\textbf{E.113.2. Changes}

- Fix incorrect password transformation in \texttt{contrib/pgcrypto}'s \texttt{DES\_crypt()} function (Solar Designer)

  If a password string contained the byte value 0x80, the remainder of the password was ignored, causing the password to be much weaker than it appeared. With this fix, the rest of the string is properly included in the DES hash. Any stored password values that are affected by this bug will thus no longer match, so the stored values may need to be updated. (CVE-2012-2143)

- Ignore \texttt{SECURITY\_DEFINER} and \texttt{SET} attributes for a procedural language's call handler (Tom Lane)

  Applying such attributes to a call handler could crash the server. (CVE-2012-2655)

- Allow numeric timezone offsets in \texttt{timestamp} input to be up to 16 hours away from UTC (Tom Lane)
Appendix E. Release Notes

Some historical time zones have offsets larger than 15 hours, the previous limit. This could result in dumped data values being rejected during reload.

- **Fix timestamp conversion to cope when the given time is exactly the last DST transition time for the current timezone (Tom Lane)**
  
  This oversight has been there a long time, but was not noticed previously because most DST-using zones are presumed to have an indefinite sequence of future DST transitions.

- **Fix `text` to `name` and `char` to `name` casts to perform string truncation correctly in multibyte encodings (Karl Schnaitter)**

- **Fix memory copying bug in `to_tsquery()` (Heikki Linnakangas)**

- **Ensure `txid_current()` reports the correct epoch when executed in hot standby (Simon Riggs)**

- **Fix planner’s handling of outer PlaceholderVars within subqueries (Tom Lane)**
  
  This bug concerns sub-SELECTs that reference variables coming from the nullable side of an outer join of the surrounding query. In 9.1, queries affected by this bug would fail with “ERROR: Upper-level PlaceholderVar found where not expected”. But in 9.0 and 8.4, you’d silently get possibly-wrong answers, since the value transmitted into the subquery wouldn’t go to null when it should.

- **Fix slow session startup when `pg_attribute` is very large (Tom Lane)**
  
  If `pg_attribute` exceeds one-fourth of `shared_buffers`, cache rebuilding code that is sometimes needed during session start would trigger the synchronized-scan logic, causing it to take many times longer than normal. The problem was particularly acute if many new sessions were starting at once.

- **Ensure sequential scans check for query cancel reasonably often (Merlin Moncure)**
  
  A scan encountering many consecutive pages that contain no live tuples would not respond to interrupts meanwhile.

- **Ensure the Windows implementation of `PGSemaphoreLock()` clears `ImmediateInterruptOK` before returning (Tom Lane)**
  
  This oversight meant that a query-cancel interrupt received later in the same query could be accepted at an unsafe time, with unpredictable but not good consequences.

- **Show whole-row variables safely when printing views or rules (Abbas Butt, Tom Lane)**
  
  Corner cases involving ambiguous names (that is, the name could be either a table or column name of the query) were printed in an ambiguous way, risking that the view or rule would be interpreted differently after dump and reload. Avoid the ambiguous case by attaching a no-op cast.

- **Fix `COPY FROM` to properly handle null marker strings that correspond to invalid encoding (Tom Lane)**
  
  A null marker string such as `E'\0'` should work, and did work in the past, but the case got broken in 8.4.

- **Ensure autovacuum worker processes perform stack depth checking properly (Heikki Linnakangas)**
  
  Previously, infinite recursion in a function invoked by `auto-Analyze` could crash worker processes.

- **Fix logging collector to not lose log coherency under high load (Andrew Dunstan)**
  
  The collector previously could fail to reassemble large messages if it got too busy.

- **Fix logging collector to ensure it will restart file rotation after receiving SIGHUP (Tom Lane)**

- **Fix WAL replay logic for GIN indexes to not fail if the index was subsequently dropped (Tom Lane)**
Appendix E. Release Notes

- Fix memory leak in PL/pgSQL’s RETURN NEXT command (Joe Conway)
- Fix PL/pgSQL’s GET DIAGNOSTICS command when the target is the function’s first variable (Tom Lane)
- Fix potential access off the end of memory in psql’s expanded display (\x) mode (Peter Eisentraut)
- Fix several performance problems in pg_dump when the database contains many objects (Jeff Janes, Tom Lane)
  
  pg_dump could get very slow if the database contained many schemas, or if many objects are in dependency loops, or if there are many owned sequences.
- Fix pg_upgrade for the case that a database stored in a non-default tablespace contains a table in the cluster’s default tablespace (Bruce Momjian)
- In ecpg, fix rare memory leaks and possible overwrite of one byte after the sqlca_t structure (Peter Eisentraut)
- Fix contrib/dblink’s dblink_exec() to not leak temporary database connections upon error (Tom Lane)
- Fix contrib/dblink to report the correct connection name in error messages (Kyotaro Horiguchi)
- Fix contrib/vacuumlo to use multiple transactions when dropping many large objects (Tim Lewis, Robert Haas, Tom Lane)
  
  This change avoids exceeding max_locks_per_transaction when many objects need to be dropped. The behavior can be adjusted with the new \-l (limit) option.
- Update time zone data files to tzdata release 2012c for DST law changes in Antarctica, Armenia, Chile, Cuba, Falkland Islands, Gaza, Haiti, Hebron, Morocco, Syria, and Tokelau Islands; also historical corrections for Canada.

E.114. Release 9.0.7

Release date: 2012-02-27

This release contains a variety of fixes from 9.0.6. For information about new features in the 9.0 major release, see Section E.121.

E.114.1. Migration to Version 9.0.7

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.6, see Section E.115.

E.114.2. Changes

- Require execute permission on the trigger function for CREATE TRIGGER (Robert Haas)
This missing check could allow another user to execute a trigger function with forged input data, by installing it on a table he owns. This is only of significance for trigger functions marked `SECURITY DEFINER`, since otherwise trigger functions run as the table owner anyway. (CVE-2012-0866)

• Remove arbitrary limitation on length of common name in SSL certificates (Heikki Linnakangas)

Both libpq and the server truncated the common name extracted from an SSL certificate at 32 bytes. Normally this would cause nothing worse than an unexpected verification failure, but there are some rather-implausible scenarios in which it might allow one certificate holder to impersonate another. The victim would have to have a common name exactly 32 bytes long, and the attacker would have to persuade a trusted CA to issue a certificate in which the common name has that string as a prefix. Impersonating a server would also require some additional exploit to redirect client connections. (CVE-2012-0867)

• Convert newlines to spaces in names written in pg_dump comments (Robert Haas)

`pg_dump` was incautious about sanitizing object names that are emitted within SQL comments in its output script. A name containing a newline would at least render the script syntactically incorrect. Maliciously crafted object names could present a SQL injection risk when the script is reloaded. (CVE-2012-0868)

• Fix btree index corruption from insertions concurrent with vacuuming (Tom Lane)

An index page split caused by an insertion could sometimes cause a concurrently-running `VACUUM` to miss removing index entries that it should remove. After the corresponding table rows are removed, the dangling index entries would cause errors (such as “could not read block N in file ...”) or worse, silently wrong query results after unrelated rows are re-inserted at the now-free table locations. This bug has been present since release 8.2, but occurs so infrequently that it was not diagnosed until now. If you have reason to suspect that it has happened in your database, reindexing the affected index will fix things.

• Fix transient zeroing of shared buffers during WAL replay (Tom Lane)

The replay logic would sometimes zero and refill a shared buffer, so that the contents were transiently invalid. In hot standby mode this can result in a query that’s executing in parallel seeing garbage data. Various symptoms could result from that, but the most common one seems to be “invalid memory alloc request size”.

• Fix postmaster to attempt restart after a hot-standby crash (Tom Lane)

A logic error caused the postmaster to terminate, rather than attempt to restart the cluster, if any backend process crashed while operating in hot standby mode.

• Fix `CLUSTER/VACUUM FULL` handling of toast values owned by recently-updated rows (Tom Lane)

This oversight could lead to “duplicate key value violates unique constraint” errors being reported against the toast table’s index during one of these commands.

• Update per-column permissions, not only per-table permissions, when changing table owner (Tom Lane)

Failure to do this meant that any previously granted column permissions were still shown as having been granted by the old owner. This meant that neither the new owner nor a superuser could revoke the now-untraceable-to-table-owner permissions.

• Support foreign data wrappers and foreign servers in `REASSIGN OWNED` (Alvaro Herrera)
This command failed with “unexpected classid” errors if it needed to change the ownership of any such objects.

- Allow non-existent values for some settings in `ALTER USER/DATABASE SET` (Heikki Linnakangas)

  Allow `default_text_search_config`, `default_tablespace`, and `temp_tablespaces` to be set to names that are not known. This is because they might be known in another database where the setting is intended to be used, or for the tablespace cases because the tablespace might not be created yet. The same issue was previously recognized for `search_path`, and these settings now act like that one.

- Avoid crashing when we have problems deleting table files post-commit (Tom Lane)

  Dropping a table should lead to deleting the underlying disk files only after the transaction commits. In event of failure then (for instance, because of wrong file permissions) the code is supposed to just emit a warning message and go on, since it’s too late to abort the transaction. This logic got broken as of release 8.4, causing such situations to result in a PANIC and an unrestartable database.

- Recover from errors occurring during WAL replay of `DROP TABLESPACE` (Tom Lane)

  Replay will attempt to remove the tablespace’s directories, but there are various reasons why this might fail (for example, incorrect ownership or permissions on those directories). Formerly the replay code would panic, rendering the database unrestartable without manual intervention. It seems better to log the problem and continue, since the only consequence of failure to remove the directories is some wasted disk space.

- Fix race condition in logging `AccessExclusiveLocks` for hot standby (Simon Riggs)

  Sometimes a lock would be logged as being held by “transaction zero”. This is at least known to produce assertion failures on slave servers, and might be the cause of more serious problems.

- Track the OID counter correctly during WAL replay, even when it wraps around (Tom Lane)

  Previously the OID counter would remain stuck at a high value until the system exited replay mode. The practical consequences of that are usually nil, but there are scenarios wherein a standby server that’s been promoted to master might take a long time to advance the OID counter to a reasonable value once values are needed.

- Prevent emitting misleading “consistent recovery state reached” log message at the beginning of crash recovery (Heikki Linnakangas)

- Fix initial value of `pg_stat_replication.replay_location` (Fujii Masao)

  Previously, the value shown would be wrong until at least one WAL record had been replayed.

- Fix regular expression back-references with `*` attached (Tom Lane)

  Rather than enforcing an exact string match, the code would effectively accept any string that satisfies the pattern sub-expression referenced by the back-reference symbol.

  A similar problem still afflicts back-references that are embedded in a larger quantified expression, rather than being the immediate subject of the quantifier. This will be addressed in a future PostgreSQL release.

- Fix recently-introduced memory leak in processing of `inet/cidr` values (Heikki Linnakangas)

  A patch in the December 2011 releases of PostgreSQL caused memory leakage in these operations, which could be significant in scenarios such as building a btree index on such a column.

- Fix dangling pointer after `CREATE TABLE AS/SELECT INTO` in a SQL-language function (Tom Lane)
In most cases this only led to an assertion failure in assert-enabled builds, but worse consequences seem possible.

- Avoid double close of file handle in syslogger on Windows (MauMau)
  Ordinarily this error was invisible, but it would cause an exception when running on a debug version of Windows.
- Fix I/O-conversion-related memory leaks in plpgsql (Andres Freund, Jan Urbanski, Tom Lane)
  Certain operations would leak memory until the end of the current function.
- Improve pg_dump’s handling of inherited table columns (Tom Lane)
  pg_dump mishandled situations where a child column has a different default expression than its parent column. If the default is textually identical to the parent’s default, but not actually the same (for instance, because of schema search path differences) it would not be recognized as different, so that after dump and restore the child would be allowed to inherit the parent’s default. Child columns that are NOT NULL where their parent is not could also be restored subtly incorrectly.
- Fix pg_restore’s direct-to-database mode for INSERT-style table data (Tom Lane)
  Direct-to-database restores from archive files made with --inserts or --column-inserts options fail when using pg_restore from a release dated September or December 2011, as a result of an oversight in a fix for another problem. The archive file itself is not at fault, and text-mode output is okay.
- Allow pg_upgrade to process tables containing regclass columns (Bruce Momjian)
  Since pg_upgrade now takes care to preserve pg_class OIDs, there was no longer any reason for this restriction.
- Make libpq ignore ENOTDIR errors when looking for an SSL client certificate file (Magnus Hagander)
  This allows SSL connections to be established, though without a certificate, even when the user’s home directory is set to something like /dev/null.
- Fix some more field alignment issues in ecpg’s SQLDA area (Zoltan Boszormenyi)
- Allow AT option in ecpg DEALLOCATE statements (Michael Meskes)
  The infrastructure to support this has been there for awhile, but through an oversight there was still an error check rejecting the case.
- Do not use the variable name when defining a varchar structure in ecpg (Michael Meskes)
- Fix contrib/auto_explain’s JSON output mode to produce valid JSON (Andrew Dunstan)
  The output used brackets at the top level, when it should have used braces.
- Fix error in contrib/intarray’s int[] & int[] operator (Guillaume Lelarge)
  If the smallest integer the two input arrays have in common is 1, and there are smaller values in either array, then 1 would be incorrectly omitted from the result.
- Fix error detection in contrib/pgcrypto’s encrypt_iv() and decrypt_iv() (Marko Kreen)
  These functions failed to report certain types of invalid-input errors, and would instead return random garbage values for incorrect input.
- Fix one-byte buffer overrun in contrib/test_parser (Paul Guyot)
Appendix E. Release Notes

The code would try to read one more byte than it should, which would crash in corner cases. Since `contrib/test_parser` is only example code, this is not a security issue in itself, but bad example code is still bad.

- **Use `__sync_lock_test_and_set()`** for spinlocks on ARM, if available (Martin Pitt)
  
  This function replaces our previous use of the SWPB instruction, which is deprecated and not available on ARMv6 and later. Reports suggest that the old code doesn’t fail in an obvious way on recent ARM boards, but simply doesn’t interlock concurrent accesses, leading to bizarre failures in multiprocess operation.

- **Use `-fexcess-precision=standard` option** when building with gcc versions that accept it (Andrew Dunstan)
  
  This prevents assorted scenarios wherein recent versions of gcc will produce creative results.

- **Allow use of threaded Python on FreeBSD** (Chris Rees)
  
  Our configure script previously believed that this combination wouldn’t work; but FreeBSD fixed the problem, so remove that error check.

### E.115. Release 9.0.6

**Release date:** 2011-12-05

This release contains a variety of fixes from 9.0.5. For information about new features in the 9.0 major release, see Section E.121.

#### E.115.1. Migration to Version 9.0.6

A dump/restore is not required for those running 9.0.X.

However, a longstanding error was discovered in the definition of the `information_schema.referential_constraints` view. If you rely on correct results from that view, you should replace its definition as explained in the first changelog item below.

Also, if you are upgrading from a version earlier than 9.0.4, see Section E.117.

#### E.115.2. Changes

- **Fix bugs in `information_schema.referential_constraints` view** (Tom Lane)
  
  This view was being insufficiently careful about matching the foreign-key constraint to the depended-on primary or unique key constraint. That could result in failure to show a foreign key constraint at all, or showing it multiple times, or claiming that it depends on a different constraint than the one it really does.

  Since the view definition is installed by `initdb`, merely upgrading will not fix the problem. If you need to fix this in an existing installation, you can (as a superuser) drop the `information_schema` schema.
then re-create it by sourcing `SHAREDIR/information_schema.sql`. (Run `pg_config --sharedir` if you’re uncertain where `SHAREDIR` is.) This must be repeated in each database to be fixed.

- Fix possible crash during `UPDATE` or `DELETE` that joins to the output of a scalar-returning function (Tom Lane)
  
  A crash could only occur if the target row had been concurrently updated, so this problem surfaced only intermittently.

- Fix incorrect replay of WAL records for GIN index updates (Tom Lane)
  
  This could result in transiently failing to find index entries after a crash, or on a hot-standby server. The problem would be repaired by the next `VACUUM` of the index, however.

- Fix TOAST-related data corruption during `CREATE TABLE dest AS SELECT * FROM src` or `INSERT INTO dest SELECT * FROM src` (Tom Lane)
  
  If a table has been modified by `ALTER TABLE ADD COLUMN`, attempts to copy its data verbatim to another table could produce corrupt results in certain corner cases. The problem can only manifest in this precise form in 8.4 and later, but we patched earlier versions as well in case there are other code paths that could trigger the same bug.

- Fix possible failures during hot standby startup (Simon Riggs)

- Start hot standby faster when initial snapshot is incomplete (Simon Riggs)

- Fix race condition during toast table access from stale syscache entries (Tom Lane)
  
  The typical symptom was transient errors like “missing chunk number 0 for toast value NNNNN in `pg_toast_2619`”, where the cited toast table would always belong to a system catalog.

- Track dependencies of functions on items used in parameter default expressions (Tom Lane)
  
  Previously, a referenced object could be dropped without having dropped or modified the function, leading to misbehavior when the function was used. Note that merely installing this update will not fix the missing dependency entries; to do that, you’d need to `CREATE OR REPLACE` each such function afterwards. If you have functions whose defaults depend on non-built-in objects, doing so is recommended.

- Allow inlining of set-returning SQL functions with multiple OUT parameters (Tom Lane)

- Don’t trust deferred-unique indexes for join removal (Tom Lane and Marti Raudsepp)
  
  A deferred uniqueness constraint might not hold intra-transaction, so assuming that it does could give incorrect query results.

- Make `DatumGetInetP()` unpack inet datums that have a 1-byte header, and add a new macro, `DatumGetInetPP()`, that does not (Heikki Linnakangas)
  
  This change affects no core code, but might prevent crashes in add-on code that expects `DatumGetInetP()` to produce an unpacked datum as per usual convention.

- Improve locale support in `money` type’s input and output (Tom Lane)
  
  Aside from not supporting all standard `lc_monetary` formatting options, the input and output functions were inconsistent, meaning there were locales in which dumped `money` values could not be re-read.

- Don’t let `transform_null_equals` affect `CASE` `foo WHEN NULL ...` constructs (Heikki Linnakangas)
transform_null_equals is only supposed to affect foo = NULL expressions written directly by the user, not equality checks generated internally by this form of CASE.

- Change foreign-key trigger creation order to better support self-referential foreign keys (Tom Lane)

  For a cascading foreign key that references its own table, a row update will fire both the ON UPDATE trigger and the CHECK trigger as one event. The ON UPDATE trigger must execute first, else the CHECK will check a non-final state of the row and possibly throw an inappropriate error. However, the firing order of these triggers is determined by their names, which generally sort in creation order since the triggers have auto-generated names following the convention “RI_ConstraintTrigger_NNNN”. A proper fix would require modifying that convention, which we will do in 9.2, but it seems risky to change it in existing releases. So this patch just changes the creation order of the triggers. Users encountering this type of error should drop and re-create the foreign key constraint to get its triggers into the right order.

- Avoid floating-point underflow while tracking buffer allocation rate (Greg Matthews)

  While harmless in itself, on certain platforms this would result in annoying kernel log messages.

- Preserve configuration file name and line number values when starting child processes under Windows (Tom Lane)

  Formerly, these would not be displayed correctly in the pg_settings view.

- Fix incorrect field alignment in ecpg’s SQLDA area (Zoltan Boszormenyi)

- Preserve blank lines within commands in psql’s command history (Robert Haas)

  The former behavior could cause problems if an empty line was removed from within a string literal, for example.

- Fix pg_dump to dump user-defined casts between auto-generated types, such as table rowtypes (Tom Lane)

- Assorted fixes for pg_upgrade (Bruce Momjian)

  Handle exclusion constraints correctly, avoid failures on Windows, don’t complain about mismatched toast table names in 8.4 databases.

- Use the preferred version of xsubpp to build PL/Perl, not necessarily the operating system’s main copy (David Wheeler and Alex Hunsaker)

- Fix incorrect coding in contrib/dict_int and contrib/dict_xsyn (Tom Lane)

  Some functions incorrectly assumed that memory returned by palloc() is guaranteed zeroed.

- Fix assorted errors in contrib/unaccent’s configuration file parsing (Tom Lane)

- Honor query cancel interrupts promptly in pgstatindex() (Robert Haas)

- Fix incorrect quoting of log file name in Mac OS X start script (Sidar Lopez)

- Ensure VPATH builds properly install all server header files (Peter Eisentraut)

- Shorten file names reported in verbose error messages (Peter Eisentraut)

  Regular builds have always reported just the name of the C file containing the error message call, but VPATH builds formerly reported an absolute path name.

- Fix interpretation of Windows timezone names for Central America (Tom Lane)
Map “Central America Standard Time” to CST6, not CST6CDT, because DST is generally not observed anywhere in Central America.

• Update time zone data files to tzdata release 2011n for DST law changes in Brazil, Cuba, Fiji, Palestine, Russia, and Samoa; also historical corrections for Alaska and British East Africa.

E.116. Release 9.0.5

Release date: 2011-09-26

This release contains a variety of fixes from 9.0.4. For information about new features in the 9.0 major release, see Section E.121.

E.116.1. Migration to Version 9.0.5

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.4, see Section E.117.

E.116.2. Changes

• Fix catalog cache invalidation after a VACUUM FULL or CLUSTER on a system catalog (Tom Lane)
  
  In some cases the relocation of a system catalog row to another place would not be recognized by concurrent server processes, allowing catalog corruption to occur if they then tried to update that row. The worst-case outcome could be as bad as complete loss of a table.

• Fix incorrect order of operations during sINVAL reset processing, and ensure that TOAST OIDs are preserved in system catalogs (Tom Lane)
  
  These mistakes could lead to transient failures after a VACUUM FULL or CLUSTER on a system catalog.

• Fix bugs in indexing of in-doubt HOT-updated tuples (Tom Lane)
  
  These bugs could result in index corruption after reindexing a system catalog. They are not believed to affect user indexes.

• Fix multiple bugs in GiST index page split processing (Heikki Linnakangas)
  
  The probability of occurrence was low, but these could lead to index corruption.

• Fix possible buffer overrun in tsvector_concat() (Tom Lane)
  
  The function could underestimate the amount of memory needed for its result, leading to server crashes.

• Fix crash in xml_recv when processing a “standalone” parameter (Tom Lane)

• Make pg_options_to_table return NULL for an option with no value (Tom Lane)
  
  Previously such cases would result in a server crash.

• Avoid possibly accessing off the end of memory in ANALYZE and in SJIS-2004 encoding conversion (Noah Misch)
Appendix E. Release Notes

This fixes some very-low-probability server crash scenarios.

- Protect `pg_stat_reset_shared()` against NULL input (Magnus Hagander)
- Fix possible failure when a recovery conflict deadlock is detected within a sub-transaction (Tom Lane)
- Avoid spurious conflicts while recycling btree index pages during hot standby (Noah Misch, Simon Riggs)
- Shut down WAL receiver if it’s still running at end of recovery (Heikki Linnakangas)
  The postmaster formerly panicked in this situation, but it’s actually a legitimate case.
- Fix race condition in relcache init file invalidation (Tom Lane)
  There was a window wherein a new backend process could read a stale init file but miss the inval messages that would tell it the data is stale. The result would be bizarre failures in catalog accesses, typically “could not read block 0 in file ...” later during startup.
- Fix memory leak at end of a GiST index scan (Tom Lane)
  Commands that perform many separate GiST index scans, such as verification of a new GiST-based exclusion constraint on a table already containing many rows, could transiently require large amounts of memory due to this leak.
- Fix memory leak when encoding conversion has to be done on incoming command strings and LISTEN is active (Tom Lane)
- Fix incorrect memory accounting (leading to possible memory bloat) in tuplestores supporting holdable cursors and plpgsql’s `RETURN NEXT` command (Tom Lane)
- Fix trigger `WHEN` conditions when both `BEFORE` and `AFTER` triggers exist (Tom Lane)
  Evaluation of `WHEN` conditions for `AFTER ROW UPDATE` triggers could crash if there had been a `BEFORE ROW trigger fired for the same update.
- Fix performance problem when constructing a large, lossy bitmap (Tom Lane)
- Fix join selectivity estimation for unique columns (Tom Lane)
  This fixes an erroneous planner heuristic that could lead to poor estimates of the result size of a join.
- Fix nested `PlaceholderVar` expressions that appear only in sub-select target lists (Tom Lane)
  This mistake could result in outputs of an outer join incorrectly appearing as NULL.
- Allow the planner to assume that empty parent tables really are empty (Tom Lane)
  Normally an empty table is assumed to have a certain minimum size for planning purposes; but this heuristic seems to do more harm than good for the parent table of an inheritance hierarchy, which often is permanently empty.
- Allow nested `EXISTS` queries to be optimized properly (Tom Lane)
- Fix array- and path-creating functions to ensure padding bytes are zeroes (Tom Lane)
  This avoids some situations where the planner will think that semantically-equal constants are not equal, resulting in poor optimization.
- Fix `EXPLAIN` to handle gating Result nodes within inner-indexscan subplans (Tom Lane)
  The usual symptom of this oversight was “bogus varno” errors.
- Fix btree preprocessing of `indexedcol IS NULL` conditions (Dean Rasheed)
Such a condition is unsatisfiable if combined with any other type of btree-indexable condition on the same index column. The case was handled incorrectly in 9.0.0 and later, leading to query output where there should be none.

- Work around gcc 4.6.0 bug that breaks WAL replay (Tom Lane)
  This could lead to loss of committed transactions after a server crash.
- Fix dump bug for `VALUES` in a view (Tom Lane)
- Disallow `SELECT FOR UPDATE/SHARE` on sequences (Tom Lane)
  This operation doesn’t work as expected and can lead to failures.
- Fix `VACUUM` so that it always updates `pg_class.reltuples/relpages` (Tom Lane)
  This fixes some scenarios where autovacuum could make increasingly poor decisions about when to vacuum tables.
- Defend against integer overflow when computing size of a hash table (Tom Lane)
- Fix cases where `CLUSTER` might attempt to access already-removed TOAST data (Tom Lane)
- Fix premature timeout failures during initial authentication transaction (Tom Lane)
- Fix portability bugs in use of credentials control messages for “peer” authentication (Tom Lane)
- Fix SSPI login when multiple roundtrips are required (Ahmed Shinwari, Magnus Hagander)
  The typical symptom of this problem was “The function requested is not supported” errors during SSPI login.
- Fix failure when adding a new variable of a custom variable class to `postgresql.conf` (Tom Lane)
- Throw an error if `pg_hba.conf` contains `hostssl` but SSL is disabled (Tom Lane)
  This was concluded to be more user-friendly than the previous behavior of silently ignoring such lines.
- Fix failure when `DROP OWNED BY` attempts to remove default privileges on sequences (Shigeru Hanada)
- Fix typo in `pg_srand48` seed initialization (Andres Freund)
  This led to failure to use all bits of the provided seed. This function is not used on most platforms (only those without `srandom`), and the potential security exposure from a less-random-than-expected seed seems minimal in any case.
- Avoid integer overflow when the sum of `LIMIT` and `OFFSET` values exceeds 2^63 (Heikki Linnakangas)
- Add overflow checks to `int4` and `int8` versions of `generate_series()` (Robert Haas)
- Fix trailing-zero removal in `to_char()` (Marti Raudsepp)
  In a format with `FM` and no digit positions after the decimal point, zeroes to the left of the decimal point could be removed incorrectly.
- Fix `pg_size_pretty()` to avoid overflow for inputs close to 2^63 (Tom Lane)
- Weaken `plpgsql`’s check for typmod matching in record values (Tom Lane)
  An overly enthusiastic check could lead to discarding length modifiers that should have been kept.
- Correctly handle quotes in locale names during `initdb` (Heikki Linnakangas)
  The case can arise with some Windows locales, such as “People’s Republic of China”.

2571
Appendix E. Release Notes

• In pg_upgrade, avoid dumping orphaned temporary tables (Bruce Momjian)
  This prevents situations wherein table OID assignments could get out of sync between old and new
  installations.

• Fix pg_upgrade to preserve toast tables’ relfrozenxids during an upgrade from 8.3 (Bruce Momjian)
  Failure to do this could lead to pg_clog files being removed too soon after the upgrade.

• In pg_upgrade, fix the -l (log) option to work on Windows (Bruce Momjian)
• In pg_ctl, support silent mode for service registrations on Windows (MauMau)
• Fix psql’s counting of script file line numbers during COPY from a different file (Tom Lane)
• Fix pg_restore’s direct-to-database mode for standard_conforming_strings (Tom Lane)
  pg_restore could emit incorrect commands when restoring directly to a database server from an archive
  file that had been made with standard_conforming_strings set to on.

• Be more user-friendly about unsupported cases for parallel pg_restore (Tom Lane)
  This change ensures that such cases are detected and reported before any restore actions have been
  taken.
• Fix write-past-buffer-end and memory leak in libpq’s LDAP service lookup code (Albe Laurenz)
• In libpq, avoid failures when using nonblocking I/O and an SSL connection (Martin Pihlak, Tom Lane)
• Improve libpq’s handling of failures during connection startup (Tom Lane)
  In particular, the response to a server report of fork() failure during SSL connection startup is now
  saner.
• Improve libpq’s error reporting for SSL failures (Tom Lane)
• Fix PQsetValue() to avoid possible crash when adding a new tuple to a PGresult originally obtained
  from a server query (Andrew Chernow)
• Make ecpglib write double values with 15 digits precision (Akira Kurosawa)
• In ecpglib, be sure LC_NUMERIC setting is restored after an error (Michael Meskes)
• Apply upstream fix for blowfish signed-character bug (CVE-2011-2483) (Tom Lane)
  contrib/pg_crypto’s blowfish encryption code could give wrong results on platforms where char is
  signed (which is most), leading to encrypted passwords being weaker than they should be.
• Fix memory leak in contrib/seg (Heikki Linnakangas)
• Fix pgstatindex() to give consistent results for empty indexes (Tom Lane)
• Allow building with perl 5.14 (Alex Hunsaker)
• Fix assorted issues with build and install file paths containing spaces (Tom Lane)
• Update time zone data files to tzdata release 2011i for DST law changes in Canada, Egypt, Russia,
  Samoa, and South Sudan.
E.117. Release 9.0.4

Release date: 2011-04-18

This release contains a variety of fixes from 9.0.3. For information about new features in the 9.0 major release, see Section E.121.

E.117.1. Migration to Version 9.0.4

A dump/restore is not required for those running 9.0.X.

However, if your installation was upgraded from a previous major release by running pg_upgrade, you should take action to prevent possible data loss due to a now-fixed bug in pg_upgrade. The recommended solution is to run VACUUM FREEZE on all TOAST tables. More information is available at http://wiki.postgresql.org/wiki/20110408pg_upgrade_fix3.

E.117.2. Changes

- Fix pg_upgrade’s handling of TOAST tables (Bruce Momjian)
  The pg_class.relrofxenid value for TOAST tables was not correctly copied into the new installation during pg_upgrade. This could later result in pg_clog files being discarded while they were still needed to validate tuples in the TOAST tables, leading to “could not access status of transaction” failures.
  This error poses a significant risk of data loss for installations that have been upgraded with pg_upgrade. This patch corrects the problem for future uses of pg_upgrade, but does not in itself cure the issue in installations that have been processed with a buggy version of pg_upgrade.

- Suppress incorrect “PD_ALL_VISIBLE flag was incorrectly set” warning (Heikki Linnakangas)
  VACUUM would sometimes issue this warning in cases that are actually valid.

- Use better SQLSTATE error codes for hot standby conflict cases (Tatsuo Ishii and Simon Riggs)
  All retryable conflict errors now have an error code that indicates that a retry is possible. Also, session closure due to the database being dropped on the master is now reported as ERRCODE_DATABASE_DROPPED, rather than ERRCODE_ADMIN_SHUTDOWN, so that connection poolers can handle the situation correctly.

- Prevent intermittent hang in interactions of startup process with bgwriter process (Simon Riggs)
  This affected recovery in non-hot-standby cases.

- Disallow including a composite type in itself (Tom Lane)
  This prevents scenarios wherein the server could recurse infinitely while processing the composite type. While there are some possible uses for such a structure, they don’t seem compelling enough to justify the effort required to make sure it always works safely.

- Avoid potential deadlock during catalog cache initialization (Nikhil Sontakke)

In some cases the cache loading code would acquire share lock on a system index before locking the index’s catalog. This could deadlock against processes trying to acquire exclusive locks in the other, more standard order.

- Fix dangling-pointer problem in BEFORE ROW UPDATE trigger handling when there was a concurrent update to the target tuple (Tom Lane)
  This bug has been observed to result in intermittent “cannot extract system attribute from virtual tuple” failures while trying to do UPDATE RETURNING ctid. There is a very small probability of more serious errors, such as generating incorrect index entries for the updated tuple.

- Disallow DROP TABLE when there are pending deferred trigger events for the table (Tom Lane)
  Formerly the DROP would go through, leading to “could not open relation with OID nnn” errors when the triggers were eventually fired.

- Allow “replication” as a user name in pg_hba.conf (Andrew Dunstan)
  “replication” is special in the database name column, but it was mistakenly also treated as special in the user name column.

- Prevent crash triggered by constant-false WHERE conditions during GEQO optimization (Tom Lane)

- Improve planner’s handling of semi-join and anti-join cases (Tom Lane)

- Fix handling of SELECT FOR UPDATE in a sub-SELECT (Tom Lane)
  This bug typically led to “cannot extract system attribute from virtual tuple” errors.

- Fix selectivity estimation for text search to account for NULLs (Jesper Krogh)

- Fix get_actual_variable_range() to support hypothetical indexes injected by an index adviser plugin (Gurjeet Singh)

- Fix PL/Python memory leak involving array slices (Daniel Popowich)

- Allow libpq’s SSL initialization to succeed when user’s home directory is unavailable (Tom Lane)
  If the SSL mode is such that a root certificate file is not required, there is no need to fail. This change restores the behavior to what it was in pre-9.0 releases.

- Fix libpq to return a useful error message for errors detected in conninfo_array_parse (Joseph Adams)
  A typo caused the library to return NULL, rather than the PGconn structure containing the error message, to the application.

- Fix ecpg preprocessor’s handling of float constants (Heikki Linnakangas)

- Fix parallel pg_restore to handle comments on POST_DATA items correctly (Arnd Hannemann)

- Fix pg_restore to cope with long lines (over 1KB) in TOC files (Tom Lane)

- Put in more safeguards against crashing due to division-by-zero with overly enthusiastic compiler optimization (Aurelien Jarno)

- Support use of dlopen() in FreeBSD and OpenBSD on MIPS (Tom Lane)
  There was a hard-wired assumption that this system function was not available on MIPS hardware on these systems. Use a compile-time test instead, since more recent versions have it.

- Fix compilation failures on HP-UX (Heikki Linnakangas)
Appendix E. Release Notes

- Avoid crash when trying to write to the Windows console very early in process startup (Rushabh Lathia)
- Support building with MinGW 64 bit compiler for Windows (Andrew Dunstan)
- Fix version-incompatibility problem with libintl on Windows (Hiroshi Inoue)
- Fix usage of xcopy in Windows build scripts to work correctly under Windows 7 (Andrew Dunstan)
  This affects the build scripts only, not installation or usage.
- Fix path separator used by pg_regress on Cygwin (Andrew Dunstan)
- Update time zone data files to tzdata release 2011f for DST law changes in Chile, Cuba, Falkland Islands, Morocco, Samoa, and Turkey; also historical corrections for South Australia, Alaska, and Hawaii.

E.118. Release 9.0.3

Release date: 2011-01-31

This release contains a variety of fixes from 9.0.2. For information about new features in the 9.0 major release, see Section E.121.

E.118.1. Migration to Version 9.0.3

A dump/restore is not required for those running 9.0.X.

E.118.2. Changes

- Before exiting walreceiver, ensure all the received WAL is fsync’d to disk (Heikki Linnakangas)
  Otherwise the standby server could replay some un-synced WAL, conceivably leading to data corruption if the system crashes just at that point.
- Avoid excess fsync activity in walreceiver (Heikki Linnakangas)
- Make ALTER TABLE revalidate uniqueness and exclusion constraints when needed (Noah Misch)
  This was broken in 9.0 by a change that was intended to suppress revalidation during VACUUM FULL and CLUSTER, but unintentionally affected ALTER TABLE as well.
- Fix EvalPlanQual for UPDATE of an inheritance tree in which the tables are not all alike (Tom Lane)
  Any variation in the table row types (including dropped columns present in only some child tables) would confuse the EvalPlanQual code, leading to misbehavior or even crashes. Since EvalPlanQual is only executed during concurrent updates to the same row, the problem was only seen intermittently.
- Avoid failures when EXPLAIN tries to display a simple-form CASE expression (Tom Lane)
  If the CASE’s test expression was a constant, the planner could simplify the CASE into a form that confused the expression-display code, resulting in “unexpected CASE WHEN clause” errors.
- Fix assignment to an array slice that is before the existing range of subscripts (Tom Lane)
If there was a gap between the newly added subscripts and the first pre-existing subscript, the code miscalculated how many entries needed to be copied from the old array’s null bitmap, potentially leading to data corruption or crash.

- Avoid unexpected conversion overflow in planner for very distant date values (Tom Lane)
  The date type supports a wider range of dates than can be represented by the timestamp types, but the planner assumed it could always convert a date to timestamp with impunity.

- Fix PL/Python crash when an array contains null entries (Alex Hunsaker)

- Remove ecpg’s fixed length limit for constants defining an array dimension (Michael Meskes)

- Fix erroneous parsing of tsquery values containing ... & !(subexpression) | ... (Tom Lane)
  Queries containing this combination of operators were not executed correctly. The same error existed in contrib/intarray’s query_int type and contrib/ltree’s ltxtquery type.

- Fix buffer overrun in contrib/intarray’s input function for the query_int type (Apple)
  This bug is a security risk since the function’s return address could be overwritten. Thanks to Apple Inc’s security team for reporting this issue and supplying the fix. (CVE-2010-4015)

- Fix bug in contrib/seg’s GiST picksplit algorithm (Alexander Korotkov)
  This could result in considerable inefficiency, though not actually incorrect answers, in a GiST index on a seg column. If you have such an index, consider REINDEXing it after installing this update. (This is identical to the bug that was fixed in contrib/cube in the previous update.)

E.119. Release 9.0.2

Release date: 2010-12-16
This release contains a variety of fixes from 9.0.1. For information about new features in the 9.0 major release, see Section E.121.

E.119.1. Migration to Version 9.0.2
A dump/restore is not required for those running 9.0.X.

E.119.2. Changes

- Force the default wal_sync_method to be fdatasync on Linux (Tom Lane, Marti Raudsepp)
  The default on Linux has actually been fdatasync for many years, but recent kernel changes caused PostgreSQL to choose open_dataasync instead. This choice did not result in any performance improvement, and caused outright failures on certain filesystems, notably ext4 with the data=journal mount option.

- Fix “too many KnownAssignedXids” error during Hot Standby replay (Heikki Linnakangas)
• Fix race condition in lock acquisition during Hot Standby (Simon Riggs)
• Avoid unnecessary conflicts during Hot Standby (Simon Riggs)
  This fixes some cases where replay was considered to conflict with standby queries (causing delay of
  replay or possibly cancellation of the queries), but there was no real conflict.
• Fix assorted bugs in WAL replay logic for GIN indexes (Tom Lane)
  This could result in "bad buffer id: 0" failures or corruption of index contents during replication.
• Fix recovery from base backup when the starting checkpoint WAL record is not in the same WAL
  segment as its redo point (Jeff Davis)
• Fix corner-case bug when streaming replication is enabled immediately after creating the master
  database cluster (Heikki Linnakangas)
• Fix persistent slowdown of autovacuum workers when multiple workers remain active for a long time
  (Tom Lane)
  The effective vacuum_cost_limit for an autovacuum worker could drop to nearly zero if it processed
  enough tables, causing it to run extremely slowly.
• Fix long-term memory leak in autovacuum launcher (Alvaro Herrera)
• Avoid failure when trying to report an impending transaction wraparound condition from outside a
  transaction (Tom Lane)
  This oversight prevented recovery after transaction wraparound got too close, because database startup
  processing would fail.
• Add support for detecting register-stack overrun on IA64 (Tom Lane)
  The IA64 architecture has two hardware stacks. Full prevention of stack-overrun failures requires
  checking both.
• Add a check for stack overflow in copyObject() (Tom Lane)
  Certain code paths could crash due to stack overflow given a sufficiently complex query.
• Fix detection of page splits in temporary GiST indexes (Heikki Linnakangas)
  It is possible to have a "concurrent" page split in a temporary index, if for example there is an open
  cursor scanning the index when an insertion is done. GiST failed to detect this case and hence could
  deliver wrong results when execution of the cursor continued.
• Fix error checking during early connection processing (Tom Lane)
  The check for too many child processes was skipped in some cases, possibly leading to postmaster
  crash when attempting to add the new child process to fixed-size arrays.
• Improve efficiency of window functions (Tom Lane)
  Certain cases where a large number of tuples needed to be read in advance, but work_mem was large
  enough to allow them all to be held in memory, were unexpectedly slow. percent_rank(),
  cume_dist() and ntile() in particular were subject to this problem.
• Avoid memory leakage while ANALYZE'ing complex index expressions (Tom Lane)
• Ensure an index that uses a whole-row Var still depends on its table (Tom Lane)
  An index declared like create index i on t (foo(t.*) would not automatically get dropped
  when its table was dropped.
Appendix E. Release Notes

• Add missing support in DROP OWNED BY for removing foreign data wrapper/server privileges belonging to a user (Heikki Linnakangas)

• Do not “inline” a SQL function with multiple OUT parameters (Tom Lane)
  This avoids a possible crash due to loss of information about the expected result rowtype.

• Fix crash when inline-ing a set-returning function whose argument list contains a reference to an inlineable user function (Tom Lane)

• Behave correctly if ORDER BY, LIMIT, FOR UPDATE, or WITH is attached to the VALUES part of INSERT ... VALUES (Tom Lane)

• Make the OFF keyword unreserved (Heikki Linnakangas)
  This prevents problems with using off as a variable name in PL/pgSQL. That worked before 9.0, but was now broken because PL/pgSQL now treats all core reserved words as reserved.

• Fix constant-folding of COALESCE() expressions (Tom Lane)
  The planner would sometimes attempt to evaluate sub-expressions that in fact could never be reached, possibly leading to unexpected errors.

• Fix “could not find pathkey item to sort” planner failure with comparison of whole-row Vars (Tom Lane)

• Fix postmaster crash when connection acceptance (accept() or one of the calls made immediately after it) fails, and the postmaster was compiled with GSSAPI support (Alexander Chernikov)

• Retry after receiving an invalid response packet from a RADIUS authentication server (Magnus Hagander)
  This fixes a low-risk potential denial of service condition.

• Fix missed unlink of temporary files when log_temp_files is active (Tom Lane)
  If an error occurred while attempting to emit the log message, the unlink was not done, resulting in accumulation of temp files.

• Add print functionality for InhRelation nodes (Tom Lane)
  This avoids a failure when debug_print_parse is enabled and certain types of query are executed.

• Fix incorrect calculation of distance from a point to a horizontal line segment (Tom Lane)
  This bug affected several different geometric distance-measurement operators.

• Fix incorrect calculation of transaction status in ecpg (Itagaki Takahiro)

• Fix errors in psql’s Unicode-escape support (Tom Lane)

• Speed up parallel pg_restore when the archive contains many large objects (blobs) (Tom Lane)

• Fix PL/pgSQL’s handling of “simple” expressions to not fail in recursion or error-recovery cases (Tom Lane)

• Fix PL/pgSQL’s error reporting for no-such-column cases (Tom Lane)
  As of 9.0, it would sometimes report “missing FROM-clause entry for table foo” when “record foo has no field bar” would be more appropriate.

• Fix PL/Python to honor typmod (i.e., length or precision restrictions) when assigning to tuple fields (Tom Lane)
Appendix E. Release Notes

This fixes a regression from 8.4.

• Fix PL/Python’s handling of set-returning functions (Jan Urbanski)
  Attempts to call SPI functions within the iterator generating a set result would fail.

• Fix bug in contrib/cube’s GiST picksplit algorithm (Alexander Korotkov)
  This could result in considerable inefficiency, though not actually incorrect answers, in a GiST index
  on a cube column. If you have such an index, consider REINDEXing it after installing this update.

• Don’t emit “identifier will be truncated” notices in contrib/dblink except when creating new con-
  nections (Itagaki Takahiro)

• Fix potential coredump on missing public key in contrib/pgcrypto (Marti Raudsepp)

• Fix buffer overrun in contrib/pg_upgrade (Hernan Gonzalez)

• Fix memory leak in contrib/xml2’s XPath query functions (Tom Lane)

• Update time zone data files to tzdata release 2010o for DST law changes in Fiji and Samoa; also
  historical corrections for Hong Kong.

E.120. Release 9.0.1

Release date: 2010-10-04

This release contains a variety of fixes from 9.0.0. For information about new features in the 9.0 major
release, see Section E.121.

E.120.1. Migration to Version 9.0.1

A dump/restore is not required for those running 9.0.X.

E.120.2. Changes

• Use a separate interpreter for each calling SQL userid in PL/Perl and PL/Tcl (Tom Lane)
  This change prevents security problems that can be caused by subverting Perl or Tcl code that will be
  executed later in the same session under another SQL user identity (for example, within a SECURITY
  DEFINER function). Most scripting languages offer numerous ways that that might be done, such as
  redefining standard functions or operators called by the target function. Without this change, any SQL
  user with Perl or Tcl language usage rights can do essentially anything with the SQL privileges of the
  target function’s owner.

  The cost of this change is that intentional communication among Perl and Tcl functions becomes more
difficult. To provide an escape hatch, PL/PerlU and PL/TclU functions continue to use only one inter-
preter per session. This is not considered a security issue since all such functions execute at the trust
level of a database superuser already.
It is likely that third-party procedural languages that claim to offer trusted execution have similar security issues. We advise contacting the authors of any PL you are depending on for security-critical purposes.

Our thanks to Tim Bunce for pointing out this issue (CVE-2010-3433).

- Improve `pg_get_expr()` security fix so that the function can still be used on the output of a sub-select (Tom Lane)
- Fix incorrect placement of placeholder evaluation (Tom Lane)
  This bug could result in query outputs being non-null when they should be null, in cases where the inner side of an outer join is a sub-select with non-strict expressions in its output list.
- Fix join removal’s handling of placeholder expressions (Tom Lane)
- Fix possible duplicate scans of `UNION ALL` member relations (Tom Lane)
- Prevent infinite loop in `ProcessIncomingNotify()` after unlistening (Jeff Davis)
- Prevent `show_session_authorization()` from crashing within autovacuum processes (Tom Lane)
- Re-allow input of Julian dates prior to 0001-01-01 AD (Tom Lane)
  Input such as `'J100000'::date` worked before 8.4, but was unintentionally broken by added error-checking.
- Make `psql` recognize `DISCARD ALL` as a command that should not be encased in a transaction block in autocommit-off mode (Itagaki Takahiro)
- Update build infrastructure and documentation to reflect the source code repository’s move from CVS to Git (Magnus Hagander and others)

**E.121. Release 9.0**

**Release date:** 2010-09-20

**E.121.1. Overview**

This release of PostgreSQL adds features that have been requested for years, such as easy-to-use replication, a mass permission-changing facility, and anonymous code blocks. While past major releases have been conservative in their scope, this release shows a bold new desire to provide facilities that new and existing users of PostgreSQL will embrace. This has all been done with few incompatibilities. Major enhancements include:

- Built-in replication based on log shipping. This advance consists of two features: Streaming Replication, allowing continuous archive (WAL) files to be streamed over a network connection to a standby server, and Hot Standby, allowing continuous archive standby servers to execute read-only queries. The net effect is to support a single master with multiple read-only slave servers.
- Easier database object permissions management. `GRANT/REVOKE IN SCHEMA` supports mass permissions changes on existing objects, while `ALTER DEFAULT PRIVILEGES` allows control of privileges for objects created in the future. Large objects (BLOBs) now support permissions management as well.
• Broadly enhanced stored procedure support. The DO statement supports ad-hoc or “anonymous” code blocks. Functions can now be called using named parameters. PL/pgSQL is now installed by default, and PL/Perl and PL/Python have been enhanced in several ways, including support for Python3.

• Full support for 64-bit Windows.

• More advanced reporting queries, including additional windowing options (PRECEDING and FOLLOWING) and the ability to control the order in which values are fed to aggregate functions.

• New trigger features, including SQL-standard-compliant per-column triggers and conditional trigger execution.

• Deferrable unique constraints. Mass updates to unique keys are now possible without trickery.

• Exclusion constraints. These provide a generalized version of unique constraints, allowing enforcement of complex conditions.

• New and enhanced security features, including RADIUS authentication, LDAP authentication improvements, and a new contrib module passwordcheck for testing password strength.

• New high-performance implementation of the LISTEN/NOTIFY feature. Pending events are now stored in a memory-based queue rather than a table. Also, a “payload” string can be sent with each event, rather than transmitting just an event name as before.

• New implementation of VACUUM FULL. This command now rewrites the entire table and indexes, rather than moving individual rows to compact space. It is substantially faster in most cases, and no longer results in index bloat.

• New contrib module pg_upgrade to support in-place upgrades from 8.3 or 8.4 to 9.0.

• Multiple performance enhancements for specific types of queries, including elimination of unnecessary joins. This helps optimize some automatically-generated queries, such as those produced by object-relational mappers (ORMs).

• EXPLAIN enhancements. The output is now available in JSON, XML, or YAML format, and includes buffer utilization and other data not previously available.

• hstore improvements, including new functions and greater data capacity.

The above items are explained in more detail in the sections below.

E.121.2. Migration to Version 9.0

A dump/restore using pg_dump, or use of pg_upgrade, is required for those wishing to migrate data from any previous release.

Version 9.0 contains a number of changes that selectively break backwards compatibility in order to support new features and code quality improvements. In particular, users who make extensive use of PL/pgSQL, Point-In-Time Recovery (PITR), or Warm Standby should test their applications because of slight user-visible changes in those areas. Observe the following incompatibilities:

E.121.2.1. Server Settings

• Remove server parameter add_missing_from, which was defaulted to off for many years (Tom Lane)
Appendix E. Release Notes

- Remove server parameter `regex_flavor`, which was defaulted to `advanced` for many years (Tom Lane)
- `archive_mode` now only affects `archive_command`; a new setting, `wal_level`, affects the contents of the write-ahead log (Heikki Linnakangas)
- `log_temp_files` now uses default file size units of kilobytes (Robert Haas)

E.121.2.2. Queries

- When querying a parent table, do not do any separate permission checks on child tables scanned as part of the query (Peter Eisentraut)
  The SQL standard specifies this behavior, and it is also much more convenient in practice than the former behavior of checking permissions on each child as well as the parent.

E.121.2.3. Data Types

- `bytea` output now appears in hex format by default (Peter Eisentraut)
  The server parameter `bytea_output` can be used to select the traditional output format if needed for compatibility.
- Array input now considers only plain ASCII whitespace characters to be potentially ignorable; it will never ignore non-ASCII characters, even if they are whitespace according to some locales (Tom Lane)
  This avoids some corner cases where array values could be interpreted differently depending on the server’s locale settings.
- Improve standards compliance of `SIMILAR TO` patterns and SQL-style `substring()` patterns (Tom Lane)
  This includes treating `?` and `{...}` as pattern metacharacters, while they were simple literal characters before; that corresponds to new features added in SQL:2008. Also, `^` and `$` are now treated as simple literal characters; formerly they were treated as metacharacters, as if the pattern were following POSIX rather than SQL rules. Also, in SQL-standard `substring()`, use of parentheses for nesting no longer interferes with capturing of a substring. Also, processing of bracket expressions (character classes) is now more standards-compliant.
- Reject negative length values in 3-parameter `substring()` for bit strings, per the SQL standard (Tom Lane)
- Make `date_trunc` truncate rather than round when reducing precision of fractional seconds (Tom Lane)
  The code always acted this way for integer-based dates/times. Now float-based dates/times behave similarly.
E.121.2.4. Object Renaming

- Tighten enforcement of column name consistency during RENAME when a child table inherits the same column from multiple unrelated parents (KaiGai Kohei)
- No longer automatically rename indexes and index columns when the underlying table columns are renamed (Tom Lane)
  Administrators can still rename such indexes and columns manually. This change will require an update of the JDBC driver, and possibly other drivers, so that unique indexes are correctly recognized after a rename.
- CREATE OR REPLACE FUNCTION can no longer change the declared names of function parameters (Pavel Stehule)
  In order to avoid creating ambiguity in named-parameter calls, it is no longer allowed to change the aliases for input parameters in the declaration of an existing function (although names can still be assigned to previously unnamed parameters). You now have to DROP and recreate the function to do that.

E.121.2.5. PL/pgSQL

- PL/pgSQL now throws an error if a variable name conflicts with a column name used in a query (Tom Lane)
  The former behavior was to bind ambiguous names to PL/pgSQL variables in preference to query columns, which often resulted in surprising misbehavior. Throwing an error allows easy detection of ambiguous situations. Although it's recommended that functions encountering this type of error be modified to remove the conflict, the old behavior can be restored if necessary via the configuration parameter plpgsql.variable_conflict, or via the per-function option #variable_conflict.
- PL/pgSQL no longer allows variable names that match certain SQL reserved words (Tom Lane)
  This is a consequence of aligning the PL/pgSQL parser to match the core SQL parser more closely. If necessary, variable names can be double-quoted to avoid this restriction.
- PL/pgSQL now requires columns of composite results to match the expected type modifier as well as base type (Pavel Stehule, Tom Lane)
  For example, if a column of the result type is declared as NUMERIC(30,2), it is no longer acceptable to return a NUMERIC of some other precision in that column. Previous versions neglected to check the type modifier and would thus allow result rows that didn’t actually conform to the declared restrictions.
- PL/pgSQL now treats selection into composite fields more consistently (Tom Lane)
  Formerly, a statement like SELECT ... INTO rec.fld FROM ... was treated as a scalar assignment even if the record field fld was of composite type. Now it is treated as a record assignment, the same as when the INTO target is a regular variable of composite type. So the values to be assigned to the field’s subfields should be written as separate columns of the SELECT list, not as a ROW(...) construct as in previous versions.
  If you need to do this in a way that will work in both 9.0 and previous releases, you can write something like rec.fld := ROW(...) FROM ....
Appendix E. Release Notes

- Remove PL/pgSQL’s `RENAME` declaration (Tom Lane)
  Instead of `RENAME`, use `ALIAS`, which can now create an alias for any variable, not only dollar sign parameter names (such as `$1`) as before.

E.121.2.6. Other Incompatibilities

- Deprecate use of `=>` as an operator name (Robert Haas)
  Future versions of PostgreSQL will probably reject this operator name entirely, in order to support the SQL-standard notation for named function parameters. For the moment, it is still allowed, but a warning is emitted when such an operator is defined.
- Remove support for platforms that don't have a working 64-bit integer data type (Tom Lane)
  It is believed all still-supported platforms have working 64-bit integer data types.

E.121.3. Changes

Version 9.0 has an unprecedented number of new major features, and over 200 enhancements, improvements, new commands, new functions, and other changes.

E.121.3.1. Server

E.121.3.1.1. Continuous Archiving and Streaming Replication

PostgreSQL’s existing standby-server capability has been expanded both to support read-only queries on standby servers and to greatly reduce the lag between master and standby servers. For many users, this will be a useful and low-administration form of replication, either for high availability or for horizontal scalability.

- Allow a standby server to accept read-only queries (Simon Riggs, Heikki Linnakangas)
  This feature is called Hot Standby. There are new `postgresql.conf` and `recovery.conf` settings to control this feature, as well as extensive documentation.
- Allow write-ahead log (WAL) data to be streamed to a standby server (Fujii Masao, Heikki Linnakangas)
  This feature is called Streaming Replication. Previously WAL data could be sent to standby servers only in units of entire WAL files (normally 16 megabytes each). Streaming Replication eliminates this inefficiency and allows updates on the master to be propagated to standby servers with very little delay. There are new `postgresql.conf` and `recovery.conf` settings to control this feature, as well as extensive documentation.
- Add `pg_last_xlog_receive_location()` and `pg_last_xlog_replay_location()`, which can be used to monitor standby server WAL activity (Simon Riggs, Fujii Masao, Heikki Linnakangas)
Appendix E. Release Notes

E.121.3.1.2. Performance

- Allow per-tablespace values to be set for sequential and random page cost estimates (seq_page_cost/random_page_cost) via ALTER TABLESPACE ... SET/RESET (Robert Haas)
- Improve performance and reliability of EvalPlanQual rechecks in join queries (Tom Lane)
  UPDATE, DELETE, and SELECT FOR UPDATE/SHARE queries that involve joins will now behave much better when encountering freshly-updated rows.
- Improve performance of TRUNCATE when the table was created or truncated earlier in the same transaction (Tom Lane)
- Improve performance of finding inheritance child tables (Tom Lane)

E.121.3.1.3. Optimizer

- Remove unnecessary outer joins (Robert Haas)
  Outer joins where the inner side is unique and not referenced above the join are unnecessary and are therefore now removed. This will accelerate many automatically generated queries, such as those created by object-relational mappers (ORMs).
- Allow IS NOT NULL restrictions to use indexes (Tom Lane)
  This is particularly useful for finding MAX() / MIN() values in indexes that contain many null values.
- Improve the optimizer’s choices about when to use materialize nodes, and when to use sorting versus hashing for DISTINCT (Tom Lane)
- Improve the optimizer’s equivalence detection for expressions involving boolean <> operators (Tom Lane)

E.121.3.1.4. GEQO

- Use the same random seed every time GEQO plans a query (Andres Freund)
  While the Genetic Query Optimizer (GEQO) still selects random plans, it now always selects the same random plans for identical queries, thus giving more consistent performance. You can modify geqo_seed to experiment with alternative plans.
- Improve GEQO plan selection (Tom Lane)
  This avoids the rare error “failed to make a valid plan”, and should also improve planning speed.

E.121.3.1.5. Optimizer Statistics

- Improve ANALYZE to support inheritance-tree statistics (Tom Lane)
  This is particularly useful for partitioned tables. However, autovacuum does not yet automatically re-analyze parent tables when child tables change.
- Improve autovacuum’s detection of when re-analyze is necessary (Tom Lane)
Appendix E. Release Notes

- Improve optimizer’s estimation for greater/less-than comparisons (Tom Lane)
  When looking up statistics for greater/less-than comparisons, if the comparison value is in the first or last histogram bucket, use an index (if available) to fetch the current actual column minimum or maximum. This greatly improves the accuracy of estimates for comparison values near the ends of the data range, particularly if the range is constantly changing due to addition of new data.

- Allow setting of number-of-distinct-values statistics using ALTER TABLE (Robert Haas)
  This allows users to override the estimated number or percentage of distinct values for a column. This statistic is normally computed by ANALYZE, but the estimate can be poor, especially on tables with very large numbers of rows.

E.121.3.1.6. Authentication

- Add support for RADIUS (Remote Authentication Dial In User Service) authentication (Magnus Hagander)

- Allow LDAP (Lightweight Directory Access Protocol) authentication to operate in “search/bind” mode (Robert Fleming, Magnus Hagander)
  This allows the user to be looked up first, then the system uses the DN (Distinguished Name) returned for that user.

- Add samehost and samenet designations to pg_hba.conf (Stef Walter)
  These match the server’s IP address and subnet address respectively.

- Pass trusted SSL root certificate names to the client so the client can return an appropriate client certificate (Craig Ringer)

E.121.3.1.7. Monitoring

- Add the ability for clients to set an application name, which is displayed in pg_stat_activity (Dave Page)
  This allows administrators to characterize database traffic and troubleshoot problems by source application.

- Add a SQLSTATE option (%e) to log_line_prefix (Guillaume Smet)
  This allows users to compile statistics on errors and messages by error code number.

- Write to the Windows event log in UTF16 encoding (Itagaki Takahiro)
  Now there is true multilingual support for PostgreSQL log messages on Windows.

E.121.3.1.8. Statistics Counters

- Add pg_stat_reset_shared('bgwriter') to reset the cluster-wide shared statistics for the background writer (Greg Smith)
• Add `pg_stat_reset_single_table_counters()` and `pg_stat_reset_single_function_counters()` to allow resetting the statistics counters for individual tables and functions (Magnus Hagander)

E.121.3.1.9. Server Settings

• Allow setting of configuration parameters based on database/role combinations (Alvaro Herrera)
  
  Previously only per-database and per-role settings were possible, not combinations. All role and database settings are now stored in the new `pg_db_role_setting` system catalog. A new psql command `\drds` shows these settings. The legacy system views `pg_roles`, `pg_shadow`, and `pg_user` do not show combination settings, and therefore no longer completely represent the configuration for a user or database.

• Add server parameter `bonjour`, which controls whether a Bonjour-enabled server advertises itself via Bonjour (Tom Lane)
  
  The default is off, meaning it does not advertise. This allows packagers to distribute Bonjour-enabled builds without worrying that individual users might not want the feature.

• Add server parameter `enable_material`, which controls the use of materialize nodes in the optimizer (Robert Haas)
  
  The default is on. When off, the optimizer will not add materialize nodes purely for performance reasons, though they will still be used when necessary for correctness.

• Change server parameter `log_temp_files` to use default file size units of kilobytes (Robert Haas)
  
  Previously this setting was interpreted in bytes if no units were specified.

• Log changes of parameter values when `postgresql.conf` is reloaded (Peter Eisentraut)
  
  This lets administrators and security staff audit changes of database settings, and is also very convenient for checking the effects of `postgresql.conf` edits.

• Properly enforce superuser permissions for custom server parameters (Tom Lane)
  
  Non-superusers can no longer issue `ALTER ROLE/DATABASE SET` for parameters that are not currently known to the server. This allows the server to correctly check that superuser-only parameters are only set by superusers. Previously, the `SET` would be allowed and then ignored at session start, making superuser-only custom parameters much less useful than they should be.

E.121.3.2. Queries

• Perform `SELECT FOR UPDATE/SHARE` processing after applying `LIMIT`, so the number of rows returned is always predictable (Tom Lane)
  
  Previously, changes made by concurrent transactions could cause a `SELECT FOR UPDATE` to unexpectedly return fewer rows than specified by its `LIMIT`. For `UPDATE` in combination with `ORDER BY` can still produce surprising results, but that can be corrected by placing `FOR UPDATE` in a subquery.

• Allow mixing of traditional and SQL-standard `LIMIT/OFFSET` syntax (Tom Lane)
• Extend the supported frame options in window functions (Hitoshi Harada)
  Frames can now start with CURRENT ROW, and the ROWS n PRECEDING/FOLLOWING options are now supported.

• Make SELECT INTO and CREATE TABLE AS return row counts to the client in their command tags (Boszormenyi Zoltan)
  This can save an entire round-trip to the client, allowing result counts and pagination to be calculated without an additional COUNT query.

E.121.3.2.1. Unicode Strings

• Support Unicode surrogate pairs (dual 16-bit representation) in \u\ strings and identifiers (Peter Eisentraut)

• Support Unicode escapes in E'... strings (Marko Kreen)

E.121.3.3. Object Manipulation

• Speed up CREATE DATABASE by deferring flushes to disk (Andres Freund, Greg Stark)

• Allow comments on columns of tables, views, and composite types only, not other relation types such as indexes and TOAST tables (Tom Lane)

• Allow the creation of enumerated types containing no values (Bruce Momjian)

• Let values of columns having storage type MAIN remain on the main heap page unless the row cannot fit on a page (Kevin Grittner)
  Previously MAIN values were forced out to TOAST tables until the row size was less than one-quarter of the page size.

E.121.3.3.1. ALTER TABLE

• Implement IF EXISTS for ALTER TABLE DROP COLUMN and ALTER TABLE DROP CONSTRAINT (Andres Freund)

• Allow ALTER TABLE commands that rewrite tables to skip WAL logging (Itagaki Takahiro)
  Such operations either produce a new copy of the table or are rolled back, so WAL archiving can be skipped, unless running in continuous archiving mode. This reduces I/O overhead and improves performance.

• Fix failure of ALTER TABLE table ADD COLUMN col serial when done by non-owner of table (Tom Lane)
E.121.3.3.2. CREATE TABLE

- Add support for copying COMMENTS and STORAGE settings in CREATE TABLE ... LIKE commands (Itagaki Takahiro)
- Add a shortcut for copying all properties in CREATE TABLE ... LIKE commands (Itagaki Takahiro)
- Add the SQL-standard CREATE TABLE ... OF type command (Peter Eisentraut)
  This allows creation of a table that matches an existing composite type. Additional constraints and defaults can be specified in the command.

E.121.3.3.3. Constraints

- Add deferrable unique constraints (Dean Rasheed)
  This allows mass updates, such as UPDATE tab SET col = col + 1, to work reliably on columns that have unique indexes or are marked as primary keys. If the constraint is specified as DEFERRABLE it will be checked at the end of the statement, rather than after each row is updated. The constraint check can also be deferred until the end of the current transaction, allowing such updates to be spread over multiple SQL commands.
- Add exclusion constraints (Jeff Davis)
  Exclusion constraints generalize uniqueness constraints by allowing arbitrary comparison operators, not just equality. They are created with the CREATE TABLE CONSTRAINT ... EXCLUDE clause. The most common use of exclusion constraints is to specify that column entries must not overlap, rather than simply not be equal. This is useful for time periods and other ranges, as well as arrays. This feature enhances checking of data integrity for many calendaring, time-management, and scientific applications.
- Improve uniqueness-constraint violation error messages to report the values causing the failure (Itagaki Takahiro)
  For example, a uniqueness constraint violation might now report Key (x)=(2) already exists.

E.121.3.3.4. Object Permissions

- Add the ability to make mass permission changes across a whole schema using the new GRANT/REVOKE IN SCHEMA clause (Petr Jelinek)
  This simplifies management of object permissions and makes it easier to utilize database roles for application data security.
- Add ALTER DEFAULT PRIVILEGES command to control privileges of objects created later (Petr Jelinek)
  This greatly simplifies the assignment of object privileges in a complex database application. Default privileges can be set for tables, views, sequences, and functions. Defaults may be assigned on a per-schema basis, or database-wide.
- Add the ability to control large object (BLOB) permissions with GRANT/REVOKE (KaiGai Kohei)
Formerly, any database user could read or modify any large object. Read and write permissions can now be granted and revoked per large object, and the ownership of large objects is tracked.

E.121.3.4. Utility Operations

- Make `LISTEN/NOTIFY` store pending events in a memory queue, rather than in a system table (Joachim Wieland)
  This substantially improves performance, while retaining the existing features of transactional support and guaranteed delivery.
- Allow `NOTIFY` to pass an optional “payload” string to listeners (Joachim Wieland)
  This greatly improves the usefulness of `LISTEN/NOTIFY` as a general-purpose event queue system.
- Allow `CLUSTER` on all per-database system catalogs (Tom Lane)
  Shared catalogs still cannot be clustered.

E.121.3.4.1. COPY

- Accept `COPY ... CSV FORCE QUOTE *` (Itagaki Takahiro)
  Now `*` can be used as shorthand for “all columns” in the `FORCE QUOTE` clause.
- Add new `COPY` syntax that allows options to be specified inside parentheses (Robert Haas, Emmanuel Cecchet)
  This allows greater flexibility for future `COPY` options. The old syntax is still supported, but only for pre-existing options.

E.121.3.4.2. EXPLAIN

- Allow `EXPLAIN` to output in XML, JSON, or YAML format (Robert Haas, Greg Sabino Mullane)
  The new output formats are easily machine-readable, supporting the development of new tools for analysis of `EXPLAIN` output.
- Add new `BUFFERS` option to report query buffer usage during `EXPLAIN ANALYZE` (Itagaki Takahiro)
  This allows better query profiling for individual queries. Buffer usage is no longer reported in the output for `log_statement_stats` and related settings.
- Add hash usage information to `EXPLAIN` output (Robert Haas)
- Add new `EXPLAIN` syntax that allows options to be specified inside parentheses (Robert Haas)
  This allows greater flexibility for future `EXPLAIN` options. The old syntax is still supported, but only for pre-existing options.
E.121.3.4.3. VACUUM

- Change `VACUUM FULL` to rewrite the entire table and rebuild its indexes, rather than moving individual rows around to compact space (Itagaki Takahiro, Tom Lane)

  The previous method was usually slower and caused index bloat. Note that the new method will use more disk space transiently during `VACUUM FULL`; potentially as much as twice the space normally occupied by the table and its indexes.

- Add new `VACUUM` syntax that allows options to be specified inside parentheses (Itagaki Takahiro)

  This allows greater flexibility for future `VACUUM` options. The old syntax is still supported, but only for pre-existing options.

E.121.3.4.4. Indexes

- Allow an index to be named automatically by omitting the index name in `CREATE INDEX` (Tom Lane)

- By default, multicolumn indexes are now named after all their columns; and index expression columns are now named based on their expressions (Tom Lane)

- Reindexing shared system catalogs is now fully transactional and crash-safe (Tom Lane)

  Formerly, reindexing a shared index was only allowed in standalone mode, and a crash during the operation could leave the index in worse condition than it was before.

- Add `point_ops` operator class for GiST (Teodor Sigaev)

  This feature permits GiST indexing of `point` columns. The index can be used for several types of queries such as `point <@ polygon` (point is in polygon). This should make many PostGIS queries faster.

- Use red-black binary trees for GIN index creation (Teodor Sigaev)

  Red-black trees are self-balancing. This avoids slowdowns in cases where the input is in nonrandom order.

E.121.3.5. Data Types

- Allow `bytea` values to be written in hex notation (Peter Eisentraut)

  The server parameter `bytea_output` controls whether hex or traditional format is used for `bytea` output. Libpq's `PQescapeByteaConn()` function automatically uses the hex format when connected to PostgreSQL 9.0 or newer servers. However, pre-9.0 libpq versions will not correctly process hex format from newer servers.

  The new hex format will be directly compatible with more applications that use binary data, allowing them to store and retrieve it without extra conversion. It is also significantly faster to read and write than the traditional format.

- Allow server parameter `extra_float_digits` to be increased to 3 (Tom Lane)
Appendix E. Release Notes

The previous maximum `extra_float_digits` setting was 2. There are cases where 3 digits are needed to dump and restore `float4` values exactly. `pg_dump` will now use the setting of 3 when dumping from a server that allows it.

- Tighten input checking for `int2vector` values (Caleb Welton)

E.121.3.5.1. Full Text Search

- Add prefix support in synonym dictionaries (Teodor Sigaev)
- Add filtering dictionaries (Teodor Sigaev)
  Filtering dictionaries allow tokens to be modified then passed to subsequent dictionaries.
- Allow underscores in email-address tokens (Teodor Sigaev)
- Use more standards-compliant rules for parsing URL tokens (Tom Lane)

E.121.3.6. Functions

- Allow function calls to supply parameter names and match them to named parameters in the function definition (Pavel Stehule)
  For example, if a function is defined to take parameters `a` and `b`, it can be called with `func(a := 7, b := 12)` or `func(b := 12, a := 7)`.
- Support locale-specific regular expression processing with UTF-8 server encoding (Tom Lane)
  Locale-specific regular expression functionality includes case-insensitive matching and locale-specific character classes. Previously, these features worked correctly for non-ASCII characters only if the database used a single-byte server encoding (such as LATIN1). They will still misbehave in multi-byte encodings other than UTF-8.
- Add support for scientific notation in `to_char()` (EEEE specification) (Pavel Stehule, Brendan Jurd)
- Make `to_char()` honor `FM` (fill mode) in Y, YY, and YYYY specifications (Bruce Momjian, Tom Lane)
  It was already honored by YYYY.
- Fix `to_char()` to output localized numeric and monetary strings in the correct encoding on Windows (Hiroshi Inoue, Itagaki Takahiro, Bruce Momjian)
- Correct calculations of “overlaps” and “contains” operations for polygons (Teodor Sigaev)
  The polygon `&&` (overlaps) operator formerly just checked to see if the two polygons’ bounding boxes overlapped. It now does a more correct check. The polygon `@>` and `<@` (contains/contained by) operators formerly checked to see if one polygon’s vertexes were all contained in the other; this can wrongly report “true” for some non-convex polygons. Now they check that all line segments of one polygon are contained in the other.

E.121.3.6.1. Aggregates

- Allow aggregate functions to use `ORDER BY` (Andrew Gierth)
Appendix E. Release Notes

For example, this is now supported: array_agg(a ORDER BY b). This is useful with aggregates for which the order of input values is significant, and eliminates the need to use a nonstandard subquery to determine the ordering.

- Multi-argument aggregate functions can now use DISTINCT (Andrew Gierth)
- Add the string_agg() aggregate function to combine values into a single string (Pavel Stehule)
- Aggregate functions that are called with DISTINCT are now passed NULL values if the aggregate transition function is not marked as STRICT (Andrew Gierth)

  For example, agg(DISTINCT x) might pass a NULL x value to agg(). This is more consistent with the behavior in non-DISTINCT cases.

E.121.3.6.2. Bit Strings

- Add get_bit() and set_bit() functions for bit strings, mirroring those for bytea (Leonardo F)
- Implement OVERLAY() (replace) for bit strings and bytea (Leonardo F)

E.121.3.6.3. Object Information Functions

- Add pg_table_size() and pg_indexes_size() to provide a more user-friendly interface to the pg_relation_size() function (Bernd Helmle)
- Add has_sequence_privilege() for sequence permission checking (Abhijit Menon-Sen)
- Update the information_schema views to conform to SQL:2008 (Peter Eisentraut)
- Make the information_schema views correctly display maximum octet lengths for char and varchar columns (Peter Eisentraut)
- Speed up information_schema privilege views (Joachim Wieland)

E.121.3.6.4. Function and Trigger Creation

- Support execution of anonymous code blocks using the DO statement (Petr Jelinek, Joshua Tolley, Hannu Valtonen)

  This allows execution of server-side code without the need to create and delete a temporary function definition. Code can be executed in any language for which the user has permissions to define a function.

- Implement SQL-standard-compliant per-column triggers (Itagaki Takahiro)

  Such triggers are fired only when the specified column(s) are affected by the query, e.g. appear in an UPDATE’s SET list.

- Add the WHEN clause to CREATE TRIGGER to allow control over whether a trigger is fired (Itagaki Takahiro)

  While the same type of check can always be performed inside the trigger, doing it in an external WHEN clause can have performance benefits.
E.121.3.7. Server-Side Languages

- Add the **OR REPLACE** clause to **CREATE LANGUAGE** (Tom Lane)

  This is helpful to optionally install a language if it does not already exist, and is particularly helpful now that PL/pgSQL is installed by default.

E.121.3.7.1. PL/pgSQL Server-Side Language

- Install PL/pgSQL by default (Bruce Momjian)

  The language can still be removed from a particular database if the administrator has security or performance concerns about making it available.

- Improve handling of cases where PL/pgSQL variable names conflict with identifiers used in queries within a function (Tom Lane)

  The default behavior is now to throw an error when there is a conflict, so as to avoid surprising behaviors. This can be modified, via the configuration parameter `plpgsql.variable_conflict` or the per-function option `variable_conflict`, to allow either the variable or the query-supplied column to be used. In any case PL/pgSQL will no longer attempt to substitute variables in places where they would not be syntactically valid.

- Make PL/pgSQL use the main lexer, rather than its own version (Tom Lane)

  This ensures accurate tracking of the main system’s behavior for details such as string escaping. Some user-visible details, such as the set of keywords considered reserved in PL/pgSQL, have changed in consequence.

- Avoid throwing an unnecessary error for an invalid record reference (Tom Lane)

  An error is now thrown only if the reference is actually fetched, rather than whenever the enclosing expression is reached. For example, many people have tried to do this in triggers:

  ```sql
  if TG_OP = 'INSERT' and NEW.col1 = ... then
  ```

  This will now actually work as expected.

- Improve PL/pgSQL’s ability to handle row types with dropped columns (Pavel Stehule)

- Allow input parameters to be assigned values within PL/pgSQL functions (Steve Prentice)

  Formerly, input parameters were treated as being declared **CONST**, so the function’s code could not change their values. This restriction has been removed to simplify porting of functions from other DBMSes that do not impose the equivalent restriction. An input parameter now acts like a local variable initialized to the passed-in value.

- Improve error location reporting in PL/pgSQL (Tom Lane)

- Add **count** and **ALL** options to **MOVE FORWARD/BACKWARD** in PL/pgSQL (Pavel Stehule)

- Allow PL/pgSQL’s **WHERE CURRENT OF** to use a cursor variable (Tom Lane)

- Allow PL/pgSQL’s **OPEN cursor FOR EXECUTE** to use parameters (Pavel Stehule, Itagaki Takahiro)

  This is accomplished with a new **USING** clause.
E.121.3.7.2. PL/Perl Server-Side Language

- Add new PL/Perl functions:
  - `quote_literal()`, `quote_nullable()`, `quote_ident()`,
  - `encode_bytea()`, `decode_bytea()`, `looks_like_number()`, `encode_array_literal()`,
  - `encode_array_constructor()` (Tim Bunce)
- Add server parameter `plperl.on_init` to specify a PL/Perl initialization function (Tim Bunce)
  - `plperl.on_plperl_init` and `plperl.on_plperlu_init` are also available for initialization that is specific to the trusted or untrusted language respectively.
- Support `END` blocks in PL/Perl (Tim Bunce)
  - `END` blocks do not currently allow database access.
- Allow `use strict` in PL/Perl (Tim Bunce)
  - `Perl strict` checks can also be globally enabled with the new server parameter `plperl.use_strict`.
- Allow `require` in PL/Perl (Tim Bunce)
  - This basically tests to see if the module is loaded, and if not, generates an error. It will not allow loading of modules that the administrator has not preloaded via the initialization parameters.
- Allow `use feature` in PL/Perl if Perl version 5.10 or later is used (Tim Bunce)
- Verify that PL/Perl return values are valid in the server encoding (Andrew Dunstan)

E.121.3.7.3. PL/Python Server-Side Language

- Add Unicode support in PL/Python (Peter Eisentraut)
  - Strings are automatically converted from/to the server encoding as necessary.
- Improve `bytea` support in PL/Python (Caleb Welton)
  - `Bytea` values passed into PL/Python are now represented as binary, rather than the PostgreSQL `bytea` text format. `Bytea` values containing null bytes are now also output properly from PL/Python. Passing of boolean, integer, and float values was also improved.
- Support arrays as parameters and return values in PL/Python (Peter Eisentraut)
- Improve mapping of SQL domains to Python types (Peter Eisentraut)
- Add Python 3 support to PL/Python (Peter Eisentraut)
  - The new server-side language is called `plpython3u`. This cannot be used in the same session with the Python 2 server-side language.
- Improve error location and exception reporting in PL/Python (Peter Eisentraut)

E.121.3.8. Client Applications

- Add an `--analyze-only` option to `vacuumdb`, to analyze without vacuuming (Bruce Momjian)
Appendix E. Release Notes

E.121.3.8.1. psql

- Add support for quoting/escaping the values of psql variables as SQL strings or identifiers (Pavel Stehule, Robert Haas)
  For example, :’var’ will produce the value of var quoted and properly escaped as a literal string, while :"var" will produce its value quoted and escaped as an identifier.
- Ignore a leading UTF-8-encoded Unicode byte-order marker in script files read by psql (Itagaki Takahiro)
  This is enabled when the client encoding is UTF-8. It improves compatibility with certain editors, mostly on Windows, that insist on inserting such markers.
- Fix psql --file - to properly honor --single-transaction (Bruce Momjian)
- Avoid overwriting of psql’s command-line history when two psql sessions are run concurrently (Tom Lane)
- Improve psql’s tab completion support (Itagaki Takahiro)
- Show \timing output when it is enabled, regardless of “quiet” mode (Peter Eisentraut)

E.121.3.8.1.1. psql Display

- Improve display of wrapped columns in psql (Roger Leigh)
  This behavior is now the default. The previous formatting is available by using \pset linestyle old-ascii.
- Allow psql to use fancy Unicode line-drawing characters via \pset linestyle unicode (Roger Leigh)

E.121.3.8.1.2. psql \d Commands

- Make \d show child tables that inherit from the specified parent (Damien Clochard)
  \d shows only the number of child tables, while \d+ shows the names of all child tables.
- Show definitions of index columns in \d index_name (Khee Chin)
  The definition is useful for expression indexes.
- Show a view’s defining query only in \d+, not in \d (Peter Eisentraut)
  Always including the query was deemed overly verbose.

E.121.3.8.2. pg_dump

- Make pg_dump/pg_restore --clean also remove large objects (Itagaki Takahiro)
- Fix pg_dump to properly dump large objects when standard_conforming_strings is enabled (Tom Lane)
The previous coding could fail when dumping to an archive file and then generating script output from pg_restore.

- **pg_restore now emits large-object data in hex format when generating script output (Tom Lane)**
  
  This could cause compatibility problems if the script is then loaded into a pre-9.0 server. To work around that, restore directly to the server, instead.

- **Allow pg_dump to dump comments attached to columns of composite types (Taro Minowa (Higepon))**

- **Make pg_dump --verbose output the pg_dump and server versions in text output mode (Jim Cox, Tom Lane)**

  These were already provided in custom output mode.

- **pg_restore now complains if any command-line arguments remain after the switches and optional file name (Tom Lane)**

  Previously, it silently ignored any such arguments.

### E.121.3.8.3. pg_ctl

- **Allow pg_ctl to be used safely to start the postmaster during a system reboot (Tom Lane)**

  Previously, pg_ctl’s parent process could have been mistakenly identified as a running postmaster based on a stale postmaster lock file, resulting in a transient failure to start the database.

- **Give pg_ctl the ability to initialize the database (by invoking initdb) (Zdenek Kotala)**

### E.121.3.9. Development Tools

#### E.121.3.9.1. libpq

- **Add new libpq functions PQconnectdbParams() and PQconnectStartParams() (Guillaume Lelarge)**

  These functions are similar to PQconnectdb() and PQconnectStart() except that they accept a null-terminated array of connection options, rather than requiring all options to be provided in a single string.

- **Add libpq functions PQescapeLiteral() and PQescapeIdentifier() (Robert Haas)**

  These functions return appropriately quoted and escaped SQL string literals and identifiers. The caller is not required to pre-allocate the string result, as is required by PQescapeStringConn().

- **Add support for a per-user service file (.pg_service.conf), which is checked before the site-wide service file (Peter Eisentraut)**

- **Properly report an error if the specified libpq service cannot be found (Peter Eisentraut)**

- **Add TCP keepalive settings in libpq (Tollef Fog Heen, Fujii Masao, Robert Haas)**

  Keepalive settings were already supported on the server end of TCP connections.
Appendix E. Release Notes

- Avoid extra system calls to block and unblock SIGPIPE in libpq, on platforms that offer alternative methods (Jeremy Kerr)
- When a .pgpass-supplied password fails, mention where the password came from in the error message (Bruce Momjian)
- Load all SSL certificates given in the client certificate file (Tom Lane)
  This improves support for indirectly-signed SSL certificates.

E.121.3.9.2. ecpg

- Add SQLDA (SQL Descriptor Area) support to ecpg (Boszormenyi Zoltan)
- Add the DESCRIBE [OUTPUT] statement to ecpg (Boszormenyi Zoltan)
- Add an ECPGtransactionStatus function to return the current transaction status (Bernd Helmle)
- Add the string data type in ecpg Informix-compatibility mode (Boszormenyi Zoltan)
- Allow ecpg to use new and old variable names without restriction (Michael Meskes)
- Allow ecpg to use variable names in free() (Michael Meskes)
- Make ecpg_dynamic_type() return zero for non-SQL3 data types (Michael Meskes)
  Previously it returned the negative of the data type OID. This could be confused with valid type OIDs, however.
- Support long long types on platforms that already have 64-bit long (Michael Meskes)

E.121.3.9.2.1. ecpg Cursors

- Add out-of-scope cursor support in ecpg’s native mode (Boszormenyi Zoltan)
  This allows DECLARE to use variables that are not in scope when OPEN is called. This facility already existed in ecpg’s Informix-compatibility mode.
- Allow dynamic cursor names in ecpg (Boszormenyi Zoltan)
- Allow ecpg to use noise words FROM and IN in FETCH and MOVE (Boszormenyi Zoltan)

E.121.3.10. Build Options

- Enable client thread safety by default (Bruce Momjian)
  The thread-safety option can be disabled with configure --disable-thread-safety.
- Add support for controlling the Linux out-of-memory killer (Alex Hunsaker, Tom Lane)
  Now that /proc/self/oom_adj allows disabling of the Linux out-of-memory (OOM) killer, it’s recommendable to disable OOM kills for the postmaster. It may then be desirable to re-enable OOM kills for the postmaster’s child processes. The new compile-time option LINUX_OOM_ADJ allows the killer to be reactivated for child processes.
Appendix E. Release Notes

E.121.3.10.1. Makefiles

- New Makefile targets `world`, `install-world`, and `installcheck-world` (Andrew Dunstan)
  These are similar to the existing `all`, `install`, and `installcheck` targets, but they also build the HTML documentation, build and test `contrib`, and test server-side languages and `ecpg`.
- Add data and documentation installation location control to PGXS Makefiles (Mark Cave-Ayland)
- Add Makefile rules to build the PostgreSQL documentation as a single HTML file or as a single plaintext file (Peter Eisentraut, Bruce Momjian)

E.121.3.10.2. Windows

- Support compiling on 64-bit Windows and running in 64-bit mode (Tsutomu Yamada, Magnus Hagander)
  This allows for large shared memory sizes on Windows.
- Support server builds using Visual Studio 2008 (Magnus Hagander)

E.121.3.11. Source Code

- Distribute prebuilt documentation in a subdirectory tree, rather than as tar archive files inside the distribution tarball (Peter Eisentraut)
  For example, the prebuilt HTML documentation is now in `doc/src/sgml/html/`; the manual pages are packaged similarly.
- Make the server’s lexer reentrant (Tom Lane)
  This was needed for use of the lexer by PL/pgSQL.
- Improve speed of memory allocation (Tom Lane, Greg Stark)
- User-defined constraint triggers now have entries in `pg_constraint` as well as `pg_trigger` (Tom Lane)
  Because of this change, `pg_constraint.pgconstrname` is now redundant and has been removed.
- Add system catalog columns `pg_constraint.conindid` and `pg_trigger.tgconstrindid` to better document the use of indexes for constraint enforcement (Tom Lane)
- Allow multiple conditions to be communicated to backends using a single operating system signal (Fujii Masao)
  This allows new features to be added without a platform-specific constraint on the number of signal conditions.
- Improve source code test coverage, including `contrib`, PL/Python, and PL/Perl (Peter Eisentraut, Andrew Dunstan)
- Remove the use of flat files for system table bootstrapping (Tom Lane, Alvaro Herrera)
This improves performance when using many roles or databases, and eliminates some possible failure conditions.

- Automatically generate the initial contents of `pg_attribute` for “bootstrapped” catalogs (John Naylor)
  
  This greatly simplifies changes to these catalogs.

- Split the processing of `INSERT/UPDATE/DELETE` operations out of `execMain.c` (Marko Tiikkaja)
  
  Updates are now executed in a separate ModifyTable node. This change is necessary infrastructure for future improvements.

- Simplify translation of psql’s SQL help text (Peter Eisentraut)

- Reduce the lengths of some file names so that all file paths in the distribution tarball are less than 100 characters (Tom Lane)
  
  Some decompression programs have problems with longer file paths.

- Add a new `ERRCODE_INVALID_PASSWORD` SQLSTATE error code (Bruce Momjian)

- With authors’ permissions, remove the few remaining personal source code copyright notices (Bruce Momjian)
  
  The personal copyright notices were insignificant but the community occasionally had to answer questions about them.

- Add new documentation section about running PostgreSQL in non-durable mode to improve performance (Bruce Momjian)

- Restructure the HTML documentation `Makefile` rules to make their dependency checks work correctly, avoiding unnecessary rebuilds (Peter Eisentraut)

- Use DocBook XSL stylesheets for man page building, rather than Docbook2X (Peter Eisentraut)
  
  This changes the set of tools needed to build the man pages.

- Improve PL/Perl code structure (Tim Bunce)

- Improve error context reports in PL/Perl (Alexey Klyukin)

### E.121.3.11.1. New Build Requirements

Note that these requirements do not apply when building from a distribution tarball, since tarballs include the files that these programs are used to build.

- Require Autoconf 2.63 to build configure (Peter Eisentraut)

- Require Flex 2.5.31 or later to build from a CVS checkout (Tom Lane)

- Require Perl version 5.8 or later to build from a CVS checkout (John Naylor, Andrew Dunstan)

### E.121.3.11.2. Portability

- Use a more modern API for Bonjour (Tom Lane)
  
  Bonjour support now requires OS X 10.3 or later. The older API has been deprecated by Apple.
Appendix E. Release Notes

- Add spinlock support for the SuperH architecture (Nobuhiro Iwamatsu)
- Allow non-GCC compilers to use inline functions if they support them (Kurt Harriman)
- Remove support for platforms that don’t have a working 64-bit integer data type (Tom Lane)
- Restructure use of `LDFLAGS` to be more consistent across platforms (Tom Lane)

`LDFLAGS` is now used for linking both executables and shared libraries, and we add on `LDFLAGS_EX` when linking executables, or `LDFLAGS_SL` when linking shared libraries.

E.121.3.11.3. Server Programming

- Make backend header files safe to include in C++ (Kurt Harriman, Peter Eisentraut)

  These changes remove keyword conflicts that previously made C++ usage difficult in backend code. However, there are still other complexities when using C++ for backend functions. `extern "C" { }` is still necessary in appropriate places, and memory management and error handling are still problematic.

- Add `AggCheckCallContext()` for use in detecting if a C function is being called as an aggregate (Hitoshi Harada)

- Change calling convention for `SearchSysCache()` and related functions to avoid hard-wiring the maximum number of cache keys (Robert Haas)

  Existing calls will still work for the moment, but can be expected to break in 9.1 or later if not converted to the new style.

- Require calls of `fastgetattr()` and `heap_getattr()` backend macros to provide a non-NULL fourth argument (Robert Haas)

- Custom `typanalyze` functions should no longer rely on `VacAttrStats.attr` to determine the type of data they will be passed (Tom Lane)

  This was changed to allow collection of statistics on index columns for which the storage type is different from the underlying column data type. There are new fields that tell the actual datatype being analyzed.

E.121.3.11.4. Server Hooks

- Add parser hooks for processing `ColumnRef` and `ParamRef` nodes (Tom Lane)

- Add a `ProcessUtility` hook so loadable modules can control utility commands (Itagaki Takahiro)

E.121.3.11.5. Binary Upgrade Support

- Add `contrib/pg_upgrade` to support in-place upgrades (Bruce Momjian)

  This avoids the requirement of dumping/reloading the database when upgrading to a new major release of PostgreSQL, thus reducing downtime by orders of magnitude. It supports upgrades to 9.0 from PostgreSQL 8.3 and 8.4.

- Add support for preserving relation `relfilenode` values during binary upgrades (Bruce Momjian)
Appendix E. Release Notes

- Add support for preserving `pg_type` and `pg_enum` OIDs during binary upgrades (Bruce Momjian)
- Move data files within tablespaces into PostgreSQL-version-specific subdirectories (Bruce Momjian)
  This simplifies binary upgrades.

E.121.3.12. Contrib

- Add multithreading option (`-j`) to `contrib/pgbench` (Itagaki Takahiro)
  This allows multiple CPUs to be used by pgbench, reducing the risk of pgbench itself becoming the test bottleneck.
- Add `\shell` and `\setshell` meta commands to `contrib/pgbench` (Michael Paquier)
- New features for `contrib/dict_xsyn` (Sergey Karpov)
  The new options are `matchorig`, `matchsynonyms`, and `keepsynonyms`.
- Add full text dictionary `contrib/unaccent` (Teodor Sigaev)
  This filtering dictionary removes accents from letters, which makes full-text searches over multiple languages much easier.
- Add `dblink_get_notify()` to `contrib/dblink` (Marcus Kempe)
  This allows asynchronous notifications in dblink.
- Improve `contrib/dblink`’s handling of dropped columns (Tom Lane)
  This affects `dblink_build_sql_insert()` and related functions. These functions now number columns according to logical not physical column numbers.
- Greatly increase `contrib/hstore`’s data length limit, and add B-tree and hash support so `GROUP BY` and `DISTINCT` operations are possible on `hstore` columns (Andrew Gierth)
  New functions and operators were also added. These improvements make `hstore` a full-function key-value store embedded in PostgreSQL.
- Add `contrib/passwordcheck` to support site-specific password strength policies (Laurenz Albe)
  The source code of this module should be modified to implement site-specific password policies.
- Add `contrib/pg_archivecleanup` tool (Simon Riggs)
  This is designed to be used in the `archive_cleanup_command` server parameter, to remove no-longer-needed archive files.
- Add query text to `contrib/auto_explain` output (Andrew Dunstan)
- Add buffer access counters to `contrib/pg_stat_statements` (Itagaki Takahiro)
- Update `contrib/start-scripts/linux` to use `/proc/self/oom_adj` to disable the Linux out-of-memory (OOM) killer (Alex Hunsaker, Tom Lane)
E.122. Release 8.4.22

Release date: 2014-07-24

This release contains a variety of fixes from 8.4.21. For information about new features in the 8.4 major release, see Section E.144.

This is expected to be the last PostgreSQL release in the 8.4.X series. Users are encouraged to update to a newer release branch soon.

E.122.1. Migration to Version 8.4.22

A dump/restore is not required for those running 8.4.X.

However, this release corrects an index corruption problem in some GiST indexes. See the first changelog entry below to find out whether your installation has been affected and what steps you should take if so.

Also, if you are upgrading from a version earlier than 8.4.19, see Section E.125.

E.122.2. Changes

- Correctly initialize padding bytes in contrib/btree_gist indexes on bit columns (Heikki Linnakangas)
  
  This error could result in incorrect query results due to values that should compare equal not being seen as equal. Users with GiST indexes on bit or bit varying columns should REINDEX those indexes after installing this update.

- Protect against torn pages when deleting GIN list pages (Heikki Linnakangas)
  
  This fix prevents possible index corruption if a system crash occurs while the page update is being written to disk.

- Fix possibly-incorrect cache invalidation during nested calls to ReceiveSharedInvalidMessages (Andres Freund)

- Don’t assume a subquery’s output is unique if there’s a set-returning function in its targetlist (David Rowley)
  
  This oversight could lead to misoptimization of constructs like WHERE x IN (SELECT y, generate_series(1,10) FROM t GROUP BY y).

- Fix failure to detoast fields in composite elements of structured types (Tom Lane)
  
  This corrects cases where TOAST pointers could be copied into other tables without being dereferenced. If the original data is later deleted, it would lead to errors like “missing chunk number 0 for toast value ...” when the now-dangling pointer is used.

- Fix “record type has not been registered” failures with whole-row references to the output of Append plan nodes (Tom Lane)

- Fix possible crash when invoking a user-defined function while rewinding a cursor (Tom Lane)

- Fix query-lifespan memory leak while evaluating the arguments for a function in FROM (Tom Lane)
• Fix session-lifespan memory leaks in regular-expression processing (Tom Lane, Arthur O’Dwyer, Greg Stark)

• Fix data encoding error in hungarian_stop (Tom Lane)

• Fix liveness checks for rows that were inserted in the current transaction and then deleted by a now-rolled-back subtransaction (Andres Freund)

  This could cause problems (at least spurious warnings, and at worst an infinite loop) if CREATE INDEX or CLUSTER were done later in the same transaction.

• Clear pg_stat_activity.xact_start during PREPARE TRANSACTION (Andres Freund)

  After the PREPARE, the originating session is no longer in a transaction, so it should not continue to display a transaction start time.

• Fix REASSIGN OWNED to not fail for text search objects (Álvaro Herrera)

• Block signals during postmaster startup (Tom Lane)

  This ensures that the postmaster will properly clean up after itself if, for example, it receives SIGINT while still starting up.

• Secure Unix-domain sockets of temporary postmasters started during make check (Noah Misch)

  Any local user able to access the socket file could connect as the server’s bootstrap superuser, then proceed to execute arbitrary code as the operating-system user running the test, as we previously noted in CVE-2014-0067. This change defends against that risk by placing the server’s socket in a temporary, mode 0700 subdirectory of /tmp. The hazard remains however on platforms where Unix sockets are not supported, notably Windows, because then the temporary postmaster must accept local TCP connections.

  A useful side effect of this change is to simplify make check testing in builds that override DEFAULT_PGSOCKET_DIR. Popular non-default values like /var/run/postgresql are often not writable by the build user, requiring workarounds that will no longer be necessary.

• On Windows, allow new sessions to absorb values of PGC_BACKEND parameters (such as log_connections) from the configuration file (Amit Kapila)

  Previously, if such a parameter were changed in the file post-startup, the change would have no effect.

• Properly quote executable path names on Windows (Nikhil Deshpande)

  This oversight could cause initdb and pg_upgrade to fail on Windows, if the installation path contained both spaces and @ signs.

• Fix linking of libpython on OS X (Tom Lane)

  The method we previously used can fail with the Python library supplied by Xcode 5.0 and later.

• Avoid buffer bloat in libpq when the server consistently sends data faster than the client can absorb it (Shin-ichi Morita, Tom Lane)

  libpq could be coerced into enlarging its input buffer until it runs out of memory (which would be reported misleadingly as “lost synchronization with server”). Under ordinary circumstances it’s quite far-fetched that data could be continuously transmitted more quickly than the recv() loop can absorb it, but this has been observed when the client is artificially slowed by scheduler constraints.

• Ensure that LDAP lookup attempts in libpq time out as intended (Laurenz Albe)

• Fix pg_restore’s processing of old-style large object comments (Tom Lane)
A direct-to-database restore from an archive file generated by a pre-9.0 version of pg_dump would usually fail if the archive contained more than a few comments for large objects.

• In contrib/pgcrypto functions, ensure sensitive information is cleared from stack variables before returning (Marko Kreen)

• In contrib/uuid-ossp, cache the state of the OSSP UUID library across calls (Tom Lane)

  This improves the efficiency of UUID generation and reduces the amount of entropy drawn from /dev/urandom, on platforms that have that.

• Update time zone data files to tzdata release 2014e for DST law changes in Crimea, Egypt, and Morocco.

E.123. Release 8.4.21

Release date: 2014-03-20

This release contains a variety of fixes from 8.4.20. For information about new features in the 8.4 major release, see Section E.144.

The PostgreSQL community will stop releasing updates for the 8.4.X release series in July 2014. Users are encouraged to update to a newer release branch soon.

E.123.1. Migration to Version 8.4.21

A dump/restore is not required for those running 8.4.X.

However, if you are upgrading from a version earlier than 8.4.19, see Section E.125.

E.123.2. Changes

• Restore GIN metapages unconditionally to avoid torn-page risk (Heikki Linnakangas)

  Although this oversight could theoretically result in a corrupted index, it is unlikely to have caused any problems in practice, since the active part of a GIN metapage is smaller than a standard 512-byte disk sector.

• Allow regular-expression operators to be terminated early by query cancel requests (Tom Lane)

  This prevents scenarios wherein a pathological regular expression could lock up a server process uninterruptibly for a long time.

• Remove incorrect code that tried to allow OVERLAPS with single-element row arguments (Joshua Yanovski)

  This code never worked correctly, and since the case is neither specified by the SQL standard nor documented, it seemed better to remove it than fix it.

• Avoid getting more than AccessShareLock when de-parsing a rule or view (Dean Rasheed)
This oversight resulted in `pg_dump` unexpectedly acquiring `RowExclusiveLock` locks on tables mentioned as the targets of `INSERT/UPDATE/DELETE` commands in rules. While usually harmless, that could interfere with concurrent transactions that tried to acquire, for example, `ShareLock` on those tables.

- Prevent interrupts while reporting non-ERROR messages (Tom Lane)
  This guards against rare server-process freezeups due to recursive entry to `syslog()`, and perhaps other related problems.
- Update time zone data files to `tzdata` release 2014a for DST law changes in Fiji and Turkey, plus historical changes in Israel and Ukraine.

### E.124. Release 8.4.20

**Release date:** 2014-02-20

This release contains a variety of fixes from 8.4.19. For information about new features in the 8.4 major release, see Section E.144.

The PostgreSQL community will stop releasing updates for the 8.4.X release series in July 2014. Users are encouraged to update to a newer release branch soon.

### E.124.1. Migration to Version 8.4.20

A dump/restore is not required for those running 8.4.X.

However, if you are upgrading from a version earlier than 8.4.19, see Section E.125.

### E.124.2. Changes

- Shore up `GRANT ... WITH ADMIN OPTION` restrictions (Noah Misch)
  Granting a role without `ADMIN OPTION` is supposed to prevent the grantee from adding or removing members from the granted role, but this restriction was easily bypassed by doing `SET ROLE` first. The security impact is mostly that a role member can revoke the access of others, contrary to the wishes of his grantor. Unapproved role member additions are a lesser concern, since an uncooperative role member could provide most of his rights to others anyway by creating views or `SECURITY DEFINER` functions. (CVE-2014-0060)
- Prevent privilege escalation via manual calls to PL validator functions (Andres Freund)
  The primary role of PL validator functions is to be called implicitly during `CREATE FUNCTION`, but they are also normal SQL functions that a user can call explicitly. Calling a validator on a function actually written in some other language was not checked for and could be exploited for privilege-escalation purposes. The fix involves adding a call to a privilege-checking function in each validator function. Non-core procedural languages will also need to make this change to their own validator functions, if any. (CVE-2014-0061)
- Avoid multiple name lookups during table and index DDL (Robert Haas, Andres Freund)
Appendix E. Release Notes

If the name lookups come to different conclusions due to concurrent activity, we might perform some parts of the DDL on a different table than other parts. At least in the case of `CREATE INDEX`, this can be used to cause the permissions checks to be performed against a different table than the index creation, allowing for a privilege escalation attack. (CVE-2014-0062)

- Prevent buffer overrun with long datetime strings (Noah Misch)

  The `MAXDATELEN` constant was too small for the longest possible value of type `interval`, allowing a buffer overrun in `interval_out()`. Although the datetime input functions were more careful about avoiding buffer overrun, the limit was short enough to cause them to reject some valid inputs, such as input containing a very long timezone name. The ecpg library contained these vulnerabilities along with some of its own. (CVE-2014-0063)

- Prevent buffer overrun due to integer overflow in size calculations (Noah Misch, Heikki Linnakangas)

  Several functions, mostly type input functions, calculated an allocation size without checking for over-flow. If overflow did occur, a too-small buffer would be allocated and then written past. (CVE-2014-0064)

- Prevent overruns of fixed-size buffers (Peter Eisentraut, Jozef Mlich)

  Use `strlcpy()` and related functions to provide a clear guarantee that fixed-size buffers are not overrun. Unlike the preceding items, it is unclear whether these cases really represent live issues, since in most cases there appear to be previous constraints on the size of the input string. Nonetheless it seems prudent to silence all Coverity warnings of this type. (CVE-2014-0065)

- Avoid crashing if `crypt()` returns NULL (Honza Horak, Bruce Momjian)

  There are relatively few scenarios in which `crypt()` could return NULL, but `contrib/chkpass` would crash if it did. One practical case in which this could be an issue is if libc is configured to refuse to execute unapproved hashing algorithms (e.g., “FIPS mode”). (CVE-2014-0066)

- Document risks of `make check` in the regression testing instructions (Noah Misch, Tom Lane)

  Since the temporary server started by `make check` uses “trust” authentication, another user on the same machine could connect to it as database superuser, and then potentially exploit the privileges of the operating-system user who started the tests. A future release will probably incorporate changes in the testing procedure to prevent this risk, but some public discussion is needed first. So for the moment, just warn people against using `make check` when there are untrusted users on the same machine. (CVE-2014-0067)

- Fix possible mis-replay of WAL records when some segments of a relation aren’t full size (Greg Stark, Tom Lane)

  The WAL update could be applied to the wrong page, potentially many pages past where it should have been. Aside from corrupting data, this error has been observed to result in significant “bloat” of standby servers compared to their masters, due to updates being applied far beyond where the end-of-file should have been. This failure mode does not appear to be a significant risk during crash recovery, only when initially synchronizing a standby created from a base backup taken from a quickly-changing master.

- Ensure that insertions into non-leaf GIN index pages write a full-page WAL record when appropriate (Heikki Linnakangas)

  The previous coding risked index corruption in the event of a partial-page write during a system crash.

- Fix race conditions during server process exit (Robert Haas)

  Ensure that signal handlers don’t attempt to use the process’s `MyProc` pointer after it’s no longer valid.
• Fix unsafe references to $\texttt{errno}$ within error reporting logic (Christian Kruse)

   This would typically lead to odd behaviors such as missing or inappropriate \texttt{HINT} fields.

• Fix possible crashes from using \texttt{ereport()} too early during server startup (Tom Lane)

   The principal case we’ve seen in the field is a crash if the server is started in a directory it doesn’t have permission to read.

• Clear retry flags properly in OpenSSL socket write function (Alexander Kukushkin)

   This omission could result in a server lockup after unexpected loss of an SSL-encrypted connection.

• Fix length checking for Unicode identifiers (\texttt{U"..."} syntax) containing escapes (Tom Lane)

   A spurious truncation warning would be printed for such identifiers if the escaped form of the identifier was too long, but the identifier actually didn’t need truncation after de-escaping.

• Fix possible crash due to invalid plan for nested sub-selects, such as \texttt{WHERE (... x IN (SELECT ...)) ...) IN (SELECT ...)} (Tom Lane)

• Ensure that \texttt{ANALYZE} creates statistics for a table column even when all the values in it are “too wide” (Tom Lane)

   \texttt{ANALYZE} intentionally omits very wide values from its histogram and most-common-values calculations, but it neglected to do something sane in the case that all the sampled entries are too wide.

• In \texttt{ALTER TABLE ... SET TABLESPACE}, allow the database’s default tablespace to be used without a permissions check (Stephen Frost)

   \texttt{CREATE TABLE} has always allowed such usage, but \texttt{ALTER TABLE} didn’t get the memo.

• Fix “cannot accept a set” error when some arms of a \texttt{CASE} return a set and others don’t (Tom Lane)

• Fix checks for all-zero client addresses in \texttt{pgstat} functions (Kevin Grittner)

• Fix possible misclassification of multibyte characters by the text search parser (Tom Lane)

   Non-ASCII characters could be misclassified when using C locale with a multibyte encoding. On Cygwin, non-C locales could fail as well.

• Fix possible misbehavior in \texttt{plainto_tsquery()} (Heikki Linnakangas)

   Use \texttt{memmove()} not \texttt{memcpy()} for copying overlapping memory regions. There have been no field reports of this actually causing trouble, but it’s certainly risky.

• Accept \texttt{SHIFT_JIS} as an encoding name for locale checking purposes (Tatsuo Ishii)

• Fix misbehavior of \texttt{PQhost()} on Windows (Fujii Masao)

   It should return \texttt{localhost} if no host has been specified.

• Improve error handling in \texttt{libpq} and \texttt{psql} for failures during \texttt{COPY TO STDOUT/FROM STDIN} (Tom Lane)

   In particular this fixes an infinite loop that could occur in 9.2 and up if the server connection was lost during \texttt{COPY FROM STDIN}. Variants of that scenario might be possible in older versions, or with other client applications.

• Fix misaligned descriptors in \texttt{ecpg} (MauMau)

• In \texttt{ecpg}, handle lack of a hostname in the connection parameters properly (Michael Meskes)

• Fix performance regression in \texttt{contrib/dblink} connection startup (Joe Conway)
Appendix E. Release Notes

Avoid an unnecessary round trip when client and server encodings match.

- In contrib/isn, fix incorrect calculation of the check digit for ISMN values (Fabien Coelho)
- Ensure client-code-only installation procedure works as documented (Peter Eisentraut)
- In Mingw and Cygwin builds, install the libpq DLL in the bin directory (Andrew Dunstan)
  This duplicates what the MSVC build has long done. It should fix problems with programs like psql failing to start because they can’t find the DLL.
- Don’t generate plain-text HISTORY and src/test/regress/README files anymore (Tom Lane)
  These text files duplicated the main HTML and PDF documentation formats. The trouble involved in maintaining them greatly outweighs the likely audience for plain-text format. Distribution tarballs will still contain files by these names, but they’ll just be stubs directing the reader to consult the main documentation. The plain-text INSTALL file will still be maintained, as there is arguably a use-case for that.
- Update time zone data files to tzdata release 2013i for DST law changes in Jordan and historical changes in Cuba.
  In addition, the zones Asia/Riyadh87, Asia/Riyadh88, and Asia/Riyadh89 have been removed, as they are no longer maintained by IANA, and never represented actual civil timekeeping practice.

E.125. Release 8.4.19

Release date: 2013-12-05

This release contains a variety of fixes from 8.4.18. For information about new features in the 8.4 major release, see Section E.144.

E.125.1. Migration to Version 8.4.19

A dump/restore is not required for those running 8.4.X.

However, this release corrects a potential data corruption issue. See the first changelog entry below to find out whether your installation has been affected and what steps you can take if so.

Also, if you are upgrading from a version earlier than 8.4.17, see Section E.127.

E.125.2. Changes

- Fix VACUUM’s tests to see whether it can update relfrozenxid (Andres Freund)
  In some cases VACUUM (either manual or autovacuum) could incorrectly advance a table’s relfrozenxid value, allowing tuples to escape freezing, causing those rows to become invisible once $2^{31}$ transactions have elapsed. The probability of data loss is fairly low since multiple incorrect advancements would need to happen before actual loss occurs, but it’s not zero. Users upgrading from release 8.4.8 or earlier are not affected, but all later versions contain the bug.
The issue can be ameliorated by, after upgrading, vacuuming all tables in all databases while having `vacuum_freeze_table_age` set to zero. This will fix any latent corruption but will not be able to fix all pre-existing data errors. However, an installation can be presumed safe after performing this vacuuming if it has executed fewer than $2^{31}$ update transactions in its lifetime (check this with `SELECT txid_current() < 2^{31}`).

- Fix race condition in GIN index posting tree page deletion (Heikki Linnakangas)
  This could lead to transient wrong answers or query failures.
- Avoid flattening a subquery whose `SELECT` list contains a volatile function wrapped inside a sub-`SELECT` (Tom Lane)
  This avoids unexpected results due to extra evaluations of the volatile function.
- Fix planner’s processing of non-simple-variable subquery outputs nested within outer joins (Tom Lane)
  This error could lead to incorrect plans for queries involving multiple levels of subqueries within `JOIN` syntax.
- Fix premature deletion of temporary files (Andres Freund)
- Fix possible read past end of memory in rule printing (Peter Eisentraut)
- Fix array slicing of `int2vector` and `oidvector` values (Tom Lane)
  Expressions of this kind are now implicitly promoted to regular `int2` or `oid` arrays.
- Fix incorrect behaviors when using a SQL-standard, simple GMT offset timezone (Tom Lane)
  In some cases, the system would use the simple GMT offset value when it should have used the regular timezone setting that had prevailed before the simple offset was selected. This change also causes the `timeofday` function to honor the simple GMT offset zone.
- Prevent possible misbehavior when logging translations of Windows error codes (Tom Lane)
- Properly quote generated command lines in `pg_ctl` (Naoya Anzai and Tom Lane)
  This fix applies only to Windows.
- Fix `pg_dumpall` to work when a source database sets `default_transaction_read_only` via `ALTER DATABASE SET` (Kevin Grittner)
  Previously, the generated script would fail during restore.
- Fix `ecpg`’s processing of lists of variables declared `varchar` (Zoltán Böszörményi)
- Make `contrib/lo` defend against incorrect trigger definitions (Marc Cousin)
- Update time zone data files to `tzdata` release 2013h for DST law changes in Argentina, Brazil, Jordan, Libya, Liechtenstein, Morocco, and Palestine. Also, new timezone abbreviations WIB, WIT, WITA for Indonesia.

**E.126. Release 8.4.18**

*Release date: 2013-10-10*
Appendix E. Release Notes

This release contains a variety of fixes from 8.4.17. For information about new features in the 8.4 major release, see Section E.144.

E.126.1. Migration to Version 8.4.18

A dump/restore is not required for those running 8.4.X.

However, if you are upgrading from a version earlier than 8.4.17, see Section E.127.

E.126.2. Changes

- Prevent corruption of multi-byte characters when attempting to case-fold identifiers (Andrew Dunstan)
  PostgreSQL case-folds non-ASCII characters only when using a single-byte server encoding.
- Fix memory leak caused by lo_open() failure (Heikki Linnakangas)
- Fix memory overcommit bug when work_mem is using more than 24GB of memory (Stephen Frost)
- Fix deadlock bug in libpq when using SSL (Stephen Frost)
- Properly compute row estimates for boolean columns containing many NULL values (Andrew Gierth)
  Previously tests like col IS NOT TRUE and col IS NOT FALSE did not properly factor in NULL values when estimating plan costs.
- Prevent pushing down WHERE clauses into unsafe UNION/INTERSECT subqueries (Tom Lane)
  Subqueries of a UNION or INTERSECT that contain set-returning functions or volatile functions in their SELECT lists could be improperly optimized, leading to run-time errors or incorrect query results.
- Fix rare case of “failed to locate grouping columns” planner failure (Tom Lane)
- Improve view dumping code’s handling of dropped columns in referenced tables (Tom Lane)
- Fix possible deadlock during concurrent CREATE INDEX CONCURRENTLY operations (Tom Lane)
- Fix regexp_matches() handling of zero-length matches (Jeevan Chalke)
- Fix crash for overly-complex regular expressions (Heikki Linnakangas)
- Fix regular expression match failures for back references combined with non-greedy quantifiers (Jeevan Chalke)
- Prevent CREATE FUNCTION from checking SET variables unless function body checking is enabled (Tom Lane)
- Fix pgp_pub_decrypt() so it works for secret keys with passwords (Marko Kreen)
- Remove rare inaccurate warning during vacuum of index-less tables (Heikki Linnakangas)
- Avoid possible failure when performing transaction control commands (e.g ROLLBACK) in prepared queries (Tom Lane)
- Ensure that floating-point data input accepts standard spellings of “infinity” on all platforms (Tom Lane)
The C99 standard says that allowable spellings are inf, +inf, -inf, infinity, +infinity, and -infinity. Make sure we recognize these even if the platform’s `strtod` function doesn’t.

- Expand ability to compare rows to records and arrays (Rafal Rzepecki, Tom Lane)
- Update time zone data files to tzdata release 2013d for DST law changes in Israel, Morocco, Palestine, and Paraguay. Also, historical zone data corrections for Macquarie Island.

### E.127. Release 8.4.17

**Release date:** 2013-04-04

This release contains a variety of fixes from 8.4.16. For information about new features in the 8.4 major release, see Section E.144.

#### E.127.1. Migration to Version 8.4.17

A dump/restore is not required for those running 8.4.X.

However, this release corrects several errors in management of GiST indexes. After installing this update, it is advisable to **REINDEX** any GiST indexes that meet one or more of the conditions described below. Also, if you are upgrading from a version earlier than 8.4.10, see Section E.134.

#### E.127.2. Changes

- Reset OpenSSL randomness state in each postmaster child process (Marko Kreen)
  
  This avoids a scenario wherein random numbers generated by `contrib/pgcrypto` functions might be relatively easy for another database user to guess. The risk is only significant when the postmaster is configured with `ssl = on` but most connections don’t use SSL encryption. (CVE-2013-1900)

- Fix GiST indexes to not use “fuzzy” geometric comparisons when it’s not appropriate to do so (Alexander Korotkov)
  
  The core geometric types perform comparisons using “fuzzy” equality, but `gist_box_same` must do exact comparisons, else GiST indexes using it might become inconsistent. After installing this update, users should **REINDEX** any GiST indexes on `box`, `polygon`, `circle`, or `point` columns, since all of these use `gist_box_same`.

- Fix erroneous range-union and penalty logic in GiST indexes that use `contrib/btree_gist` for variable-width data types, that is `text`, `bytea`, `bit`, and `numeric` columns (Tom Lane)
  
  These errors could result in inconsistent indexes in which some keys that are present would not be found by searches, and also in useless index bloat. Users are advised to **REINDEX** such indexes after installing this update.

- Fix bugs in GiST page splitting code for multi-column indexes (Tom Lane)
These errors could result in inconsistent indexes in which some keys that are present would not be found by searches, and also in indexes that are unnecessarily inefficient to search. Users are advised to **REINDEX** multi-column GiST indexes after installing this update.

- Fix infinite-loop risk in regular expression compilation (Tom Lane, Don Porter)
- Fix potential null-pointer dereference in regular expression compilation (Tom Lane)
- Fix `to_char()` to use ASCII-only case-folding rules where appropriate (Tom Lane)
  
  This fixes misbehavior of some template patterns that should be locale-independent, but mishandled “i” and “ı” in Turkish locales.
- Fix unwanted rejection of timestamp `1999-12-31 24:00:00` (Tom Lane)
- Remove useless “picksplit doesn’t support secondary split” log messages (Josh Hansen, Tom Lane)
  
  This message seems to have been added in expectation of code that was never written, and probably never will be, since GiST’s default handling of secondary splits is actually pretty good. So stop nagging end users about it.
- Fix possible failure to send a session’s last few transaction commit/abort counts to the statistics collector (Tom Lane)
- Eliminate memory leaks in PL/Perl’s `spi_prepare()` function (Alex Hunsaker, Tom Lane)
- Fix `pg_dumpall` to handle database names containing “=” correctly (Heikki Linnakangas)
- Avoid crash in `pg_dump` when an incorrect connection string is given (Heikki Linnakangas)
- Ignore invalid indexes in `pg_dump` (Michael Paquier)
  
  Dumping invalid indexes can cause problems at restore time, for example if the reason the index creation failed was because it tried to enforce a uniqueness condition not satisfied by the table’s data. Also, if the index creation is in fact still in progress, it seems reasonable to consider it to be an uncommitted DDL change, which `pg_dump` wouldn’t be expected to dump anyway.
- Fix `contrib/pg_trgm`’s `similarity()` function to return zero for trigram-less strings (Tom Lane)
  
  Previously it returned `NaN` due to internal division by zero.
- Update time zone data files to tzdata release 2013b for DST law changes in Chile, Haiti, Morocco, Paraguay, and some Russian areas. Also, historical zone data corrections for numerous places.
  
  Also, update the time zone abbreviation files for recent changes in Russia and elsewhere: `CHOT`, `GET`, `IRKT`, `KGT`, `KRAI`, `MAGT`, `MAWT`, `MSK`, `NOVT`, `OMST`, `TTK`, `VLAT`, `WST`, `YAKT`, `YETK` now follow their current meanings, and `VOLT` (`Europe/Volgograd`) and `MIST` (`Antarctica/Macquarie`) are added to the default abbreviations list.

### E.128. Release 8.4.16

**Release date:** 2013-02-07

This release contains a variety of fixes from 8.4.15. For information about new features in the 8.4 major release, see Section E.144.
E.128.1. Migration to Version 8.4.16
A dump/restore is not required for those running 8.4.X.
However, if you are upgrading from a version earlier than 8.4.10, see Section E.134.

E.128.2. Changes

- Prevent execution of `enum_recv` from SQL (Tom Lane)
  The function was misdeclared, allowing a simple SQL command to crash the server. In principle an attacker might be able to use it to examine the contents of server memory. Our thanks to Sumit Soni (via Secunia SVCRP) for reporting this issue. (CVE-2013-0255)

- Update minimum recovery point when truncating a relation file (Heikki Linnakangas)
  Once data has been discarded, it’s no longer safe to stop recovery at an earlier point in the timeline.

- Fix SQL grammar to allow subscripting or field selection from a sub-SELECT result (Tom Lane)

- Protect against race conditions when scanning `pg_tablespace` (Stephen Frost, Tom Lane)
  `CREATE DATABASE` and `DROP DATABASE` could misbehave if there were concurrent updates of `pg_tablespace` entries.

- Prevent `DROP OWNED` from trying to drop whole databases or tablespaces (Álvaro Herrera)
  For safety, ownership of these objects must be reassigned, not dropped.

- Fix error in `vacuum_freeze_table_age` implementation (Andres Freund)
  In installations that have existed for more than `vacuum_freeze_min_age` transactions, this mistake prevented autovacuum from using partial-table scans, so that a full-table scan would always happen instead.

- Prevent misbehavior when a `RowExpr` or `XmlExpr` is parse-analyzed twice (Andres Freund, Tom Lane)
  This mistake could be user-visible in contexts such as `CREATE TABLE LIKE INCLUDING INDEXES`.

- Improve defenses against integer overflow in hashtable sizing calculations (Jeff Davis)

- Reject out-of-range dates in `to_date()` (Hitoshi Harada)

- Ensure that non-ASCII prompt strings are translated to the correct code page on Windows (Alexander Law, Noah Misch)
  This bug affected `psql` and some other client programs.

- Fix possible crash in `psql`’s `\?` command when not connected to a database (Meng Qingzhong)

- Fix one-byte buffer overrun in `libpq`’s `PQprintTuples` (Xi Wang)
  This ancient function is not used anywhere by PostgreSQL itself, but it might still be used by some client code.

- Make ecpglib use translated messages properly (Chen Huajun)

- Properly install `ecpg_compat` and `pgtypes` libraries on MSVC (Jiang Guiqing)
• Rearrange configure’s tests for supplied functions so it is not fooled by bogus exports from libedit/libreadline (Christoph Berg)
• Ensure Windows build number increases over time (Magnus Hagander)
• Make pgxs build executables with the right .exe suffix when cross-compiling for Windows (Zoltan Boszormenyi)
• Add new timezone abbreviation FET (Tom Lane)
  This is now used in some eastern-European time zones.

E.129. Release 8.4.15

Release date: 2012-12-06

This release contains a variety of fixes from 8.4.14. For information about new features in the 8.4 major release, see Section E.144.

E.129.1. Migration to Version 8.4.15

A dump/restore is not required for those running 8.4.X.
However, if you are upgrading from a version earlier than 8.4.10, see Section E.134.

E.129.2. Changes

• Fix multiple bugs associated with CREATE INDEX CONCURRENTLY (Andres Freund, Tom Lane)
  Fix CREATE INDEX CONCURRENTLY to use in-place updates when changing the state of an index’s pg_index row. This prevents race conditions that could cause concurrent sessions to miss updating the target index, thus resulting in corrupt concurrently-created indexes.
  Also, fix various other operations to ensure that they ignore invalid indexes resulting from a failed CREATE INDEX CONCURRENTLY command. The most important of these is VACUUM, because an auto-vacuum could easily be launched on the table before corrective action can be taken to fix or remove the invalid index.
• Avoid corruption of internal hash tables when out of memory (Hitoshi Harada)
• Fix planning of non-strict equivalence clauses above outer joins (Tom Lane)
  The planner could derive incorrect constraints from a clause equating a non-strict construct to something else, for example WHERE COALESCE(foo, 0) = 0 when foo is coming from the nullable side of an outer join.
• Improve planner’s ability to prove exclusion constraints from equivalence classes (Tom Lane)
• Fix partial-row matching in hashed subplans to handle cross-type cases correctly (Tom Lane)
Appendix E. Release Notes

This affects multicolumn NOT IN subplans, such as WHERE (a, b) NOT IN (SELECT x, y FROM ...) when for instance b and y are int4 and int8 respectively. This mistake led to wrong answers or crashes depending on the specific datatypes involved.

- Acquire buffer lock when re-fetching the old tuple for an AFTER ROW UPDATE/DELETE trigger (Andres Freund)

In very unusual circumstances, this oversight could result in passing incorrect data to the precheck logic for a foreign-key enforcement trigger. That could result in a crash, or in an incorrect decision about whether to fire the trigger.

- Fix ALTER COLUMN TYPE to handle inherited check constraints properly (Pavan Deolasee)

This worked correctly in pre-8.4 releases, and now works correctly in 8.4 and later.

- Fix REASSIGN OWNED to handle grants on tablespaces (Alvaro Herrera)

- Ignore incorrect pg_attribute entries for system columns for views (Tom Lane)

Views do not have any system columns. However, we forgot to remove such entries when converting a table to a view. That’s fixed properly for 9.3 and later, but in previous branches we need to defend against existing mis-converted views.

- Fix rule printing to dump INSERT INTO table DEFAULT VALUES correctly (Tom Lane)

- Guard against stack overflow when there are too many UNION/INTERSECT/EXCEPT clauses in a query (Tom Lane)

- Prevent platform-dependent failures when dividing the minimum possible integer value by -1 (Xi Wang, Tom Lane)

- Fix possible access past end of string in date parsing (Hitoshi Harada)

- Produce an understandable error message if the length of the path name for a Unix-domain socket exceeds the platform-specific limit (Tom Lane, Andrew Dunstan)

Formerly, this would result in something quite unhelpful, such as “Non-recoverable failure in name resolution”.

- Fix memory leaks when sending composite column values to the client (Tom Lane)

- Make pg_ctl more robust about reading the postmaster.pid file (Heikki Linnakangas)

  Fix race conditions and possible file descriptor leakage.

- Fix possible crash in psql if incorrectly-encoded data is presented and the client_encoding setting is a client-only encoding, such as SJIS (Jiang Guiqing)

- Fix bugs in the restore.sql script emitted by pg_dump in tar output format (Tom Lane)

  The script would fail outright on tables whose names include upper-case characters. Also, make the script capable of restoring data in --inserts mode as well as the regular COPY mode.

- Fix pg_restore to accept POSIX-conformant tar files (Brian Weaver, Tom Lane)

  The original coding of pg_dump’s tar output mode produced files that are not fully conformant with the POSIX standard. This has been corrected for version 9.3. This patch updates previous branches so that they will accept both the incorrect and the corrected formats, in hopes of avoiding compatibility problems when 9.3 comes out.
• Fix pg_resetxlog to locate postmaster.pid correctly when given a relative path to the data directory (Tom Lane)
   This mistake could lead to pg_resetxlog not noticing that there is an active postmaster using the data directory.
• Fix libpq’s lo_import() and lo_export() functions to report I/O errors properly (Tom Lane)
• Fix ecpg’s processing of nested structure pointer variables (Muhammad Usama)
• Make contrib/pageinspect’s btree page inspection functions take buffer locks while examining pages (Tom Lane)
• Fix pgxs support for building loadable modules on AIX (Tom Lane)
   Building modules outside the original source tree didn’t work on AIX.
• Update time zone data files to tzdata release 2012j for DST law changes in Cuba, Israel, Jordan, Libya, Palestine, Western Samoa, and portions of Brazil.

E.130. Release 8.4.14

Release date: 2012-09-24

This release contains a variety of fixes from 8.4.13. For information about new features in the 8.4 major release, see Section E.144.

E.130.1. Migration to Version 8.4.14

A dump/restore is not required for those running 8.4.X.

However, if you are upgrading from a version earlier than 8.4.10, see Section E.134.

E.130.2. Changes

• Fix planner’s assignment of executor parameters, and fix executor’s rescan logic for CTE plan nodes (Tom Lane)
   These errors could result in wrong answers from queries that scan the same WITH subquery multiple times.
• Improve page-splitting decisions in GiST indexes (Alexander Korotkov, Robert Haas, Tom Lane)
   Multi-column GiST indexes might suffer unexpected bloat due to this error.
• Fix cascading privilege revoke to stop if privileges are still held (Tom Lane)
   If we revoke a grant option from some role \( x \), but \( x \) still holds that option via a grant from someone else, we should not recursively revoke the corresponding privilege from role(s) \( y \) that \( x \) had granted it to.
• Fix handling of SIGFPE when PL/Perl is in use (Andres Freund)
Perl resets the process’s SIGFPE handler to SIG_IGN, which could result in crashes later on. Restore the normal Postgres signal handler after initializing PL/Perl.

- Prevent PL/Perl from crashing if a recursive PL/Perl function is redefined while being executed (Tom Lane)
- Work around possible misoptimization in PL/Perl (Tom Lane)

Some Linux distributions contain an incorrect version of pthread.h that results in incorrect compiled code in PL/Perl, leading to crashes if a PL/Perl function calls another one that throws an error.

- Update time zone data files to tzdata release 2012f for DST law changes in Fiji

## E.131. Release 8.4.13

**Release date:** 2012-08-17

This release contains a variety of fixes from 8.4.12. For information about new features in the 8.4 major release, see Section E.144.

### E.131.1. Migration to Version 8.4.13

A dump/restore is not required for those running 8.4.X. However, if you are upgrading from a version earlier than 8.4.10, see Section E.134.

### E.131.2. Changes

- Prevent access to external files/URLs via XML entity references (Noah Misch, Tom Lane)

  xml_parse() would attempt to fetch external files or URLs as needed to resolve DTD and entity references in an XML value, thus allowing unprivileged database users to attempt to fetch data with the privileges of the database server. While the external data wouldn’t get returned directly to the user, portions of it could be exposed in error messages if the data didn’t parse as valid XML; and in any case the mere ability to check existence of a file might be useful to an attacker. (CVE-2012-3489)

- Prevent access to external files/URLs via contrib/xml2’s xslt_process() (Peter Eisentraut)

  libxslt offers the ability to read and write both files and URLs through stylesheet commands, thus allowing unprivileged database users to both read and write data with the privileges of the database server. Disable that through proper use of libxslt’s security options. (CVE-2012-3489)

  Also, remove xslt_process()’s ability to fetch documents and stylesheets from external files/URLs. While this was a documented “feature”, it was long regarded as a bad idea. The fix for CVE-2012-3489 broke that capability, and rather than expend effort on trying to fix it, we’re just going to summarily remove it.

- Prevent too-early recycling of btree index pages (Noah Misch)
When we allowed read-only transactions to skip assigning XIDs, we introduced the possibility that a deleted btree page could be recycled while a read-only transaction was still in flight to it. This would result in incorrect index search results. The probability of such an error occurring in the field seems very low because of the timing requirements, but nonetheless it should be fixed.

- Fix crash-safety bug with newly-created-or-reset sequences (Tom Lane)

  If ALTER SEQUENCE was executed on a freshly created or reset sequence, and then precisely one nextval() call was made on it, and then the server crashed, WAL replay would restore the sequence to a state in which it appeared that no nextval() had been done, thus allowing the first sequence value to be returned again by the next nextval() call. In particular this could manifest for serial columns, since creation of a serial column’s sequence includes an ALTER SEQUENCE OWNED BY step.

- Ensure the backup_label file is fsync’d after pg_start_backup() (Dave Kerr)

- Back-patch 9.1 improvement to compress the fsync request queue (Robert Haas)

  This improves performance during checkpoints. The 9.1 change has now seen enough field testing to seem safe to back-patch.

- Only allow autovacuum to be auto-canceled by a directly blocked process (Tom Lane)

  The original coding could allow inconsistent behavior in some cases; in particular, an autovacuum could get canceled after less than deadlock_timeout grace period.

- Improve logging of autovacuum cancels (Robert Haas)

- Fix log collector so that log_truncate_on_rotation works during the very first log rotation after server start (Tom Lane)

- Fix WITH attached to a nested set operation (UNION/INTERSECT/EXCEPT) (Tom Lane)

- Ensure that a whole-row reference to a subquery doesn’t include any extra GROUP BY or ORDER BY columns (Tom Lane)

- Disallow copying whole-row references in CHECK constraints and index definitions during CREATE TABLE (Tom Lane)

  This situation can arise in CREATE TABLE with LIKE or INHERITS. The copied whole-row variable was incorrectly labeled with the row type of the original table not the new one. Rejecting the case seems reasonable for LIKE, since the row types might well diverge later. For INHERITS we should ideally allow it, with an implicit coercion to the parent table’s row type; but that will require more work than seems safe to back-patch.

- Fix memory leak in ARRAY(SELECT ...) subqueries (Heikki Linnakangas, Tom Lane)

- Fix extraction of common prefixes from regular expressions (Tom Lane)

  The code could get confused by quantified parenthesized subexpressions, such as ^{foo}?bar. This would lead to incorrect index optimization of searches for such patterns.

- Fix bugs with parsing signed \texttt{hh:mm} and \texttt{hh:mm:ss} fields in interval constants (Amit Kapila, Tom Lane)

- Report errors properly in contrib/xml2’s xslt_process() (Tom Lane)

- Update time zone data files to tzdata release 2012e for DST law changes in Morocco and Tokelau
E.132. Release 8.4.12

Release date: 2012-06-04

This release contains a variety of fixes from 8.4.11. For information about new features in the 8.4 major release, see Section E.144.

E.132.1. Migration to Version 8.4.12

A dump/restore is not required for those running 8.4.X.

However, if you are upgrading from a version earlier than 8.4.10, see Section E.134.

E.132.2. Changes

• Fix incorrect password transformation in contrib/pgcrypto’s DES crypt() function (Solar Designer)
  
  If a password string contained the byte value 0x80, the remainder of the password was ignored, causing the password to be much weaker than it appeared. With this fix, the rest of the string is properly included in the DES hash. Any stored password values that are affected by this bug will thus no longer match, so the stored values may need to be updated. (CVE-2012-2143)

• Ignore SECURITY DEFINER and SET attributes for a procedural language’s call handler (Tom Lane)
  
  Applying such attributes to a call handler could crash the server. (CVE-2012-2655)

• Allow numeric timezone offsets in timestamp input to be up to 16 hours away from UTC (Tom Lane)
  
  Some historical time zones have offsets larger than 15 hours, the previous limit. This could result in dumped data values being rejected during reload.

• Fix timestamp conversion to cope when the given time is exactly the last DST transition time for the current timezone (Tom Lane)
  
  This oversight has been there a long time, but was not noticed previously because most DST-using zones are presumed to have an indefinite sequence of future DST transitions.

• Fix text to name and char to name casts to perform string truncation correctly in multibyte encodings (Karl Schnaitter)

• Fix memory copying bug in to_tsquery() (Heikki Linnakangas)

• Fix planner’s handling of outer PlaceHolderVars within subqueries (Tom Lane)
  
  This bug concerns sub-SELECTs that reference variables coming from the nullable side of an outer join of the surrounding query. In 9.1, queries affected by this bug would fail with “ERROR: Upper-level PlaceHolderVar found where not expected”. But in 9.0 and 8.4, you’d silently get possibly-wrong answers, since the value transmitted into the subquery wouldn’t go to null when it should.

• Fix slow session startup when pg_attribute is very large (Tom Lane)
If `pg_attribute` exceeds one-fourth of `shared_buffers`, cache rebuilding code that is sometimes needed during session start would trigger the synchronized-scan logic, causing it to take many times longer than normal. The problem was particularly acute if many new sessions were starting at once.

- Ensure sequential scans check for query cancel reasonably often (Merlin Moncure)
  A scan encountering many consecutive pages that contain no live tuples would not respond to interrupts meanwhile.

- Ensure the Windows implementation of `PGSemaphoreLock()` clears `ImmediateInterruptOK` before returning (Tom Lane)
  This oversight meant that a query-cancel interrupt received later in the same query could be accepted at an unsafe time, with unpredictable but not good consequences.

- Show whole-row variables safely when printing views or rules (Abbas Butt, Tom Lane)
  Corner cases involving ambiguous names (that is, the name could be either a table or column name of the query) were printed in an ambiguous way, risking that the view or rule would be interpreted differently after dump and reload. Avoid the ambiguous case by attaching a no-op cast.

- Fix `COPY FROM` to properly handle null marker strings that correspond to invalid encoding (Tom Lane)
  A null marker string such as `E'\0'` should work, and did work in the past, but the case got broken in 8.4.

- Ensure autovacuum worker processes perform stack depth checking properly (Heikki Linnakangas)
  Previously, infinite recursion in a function invoked by `auto-Analyze` could crash worker processes.

- Fix logging collector to not lose log coherency under high load (Andrew Dunstan)
  The collector previously could fail to reassemble large messages if it got too busy.

- Fix logging collector to ensure it will restart file rotation after receiving SIGHUP (Tom Lane)

- Fix `WAL` replay logic for `GIN` indexes to not fail if the index was subsequently dropped (Tom Lane)

- Fix memory leak in PL/pgSQL’s `RETURN NEXT` command (Joe Conway)

- Fix PL/pgSQL’s `GET DIAGNOSTICS` command when the target is the function’s first variable (Tom Lane)

- Fix potential access off the end of memory in `psql`’s expanded display (`\x`) mode (Peter Eisentraut)

- Fix several performance problems in `pg_dump` when the database contains many objects (Jeff Janes, Tom Lane)
  `pg_dump` could get very slow if the database contained many schemas, or if many objects are in dependency loops, or if there are many owned sequences.

- Fix `contrib/dblink`’s `dblink_exec()` to not leak temporary database connections upon error (Tom Lane)

- Fix `contrib/dblink` to report the correct connection name in error messages (Kyotaro Horiguchi)

- Update time zone data files to tzdata release 2012c for DST law changes in Antarctica, Armenia, Chile, Cuba, Falkland Islands, Gaza, Haiti, Hebron, Morocco, Syria, and Tokelau Islands; also historical corrections for Canada.
E.133. Release 8.4.11

Release date: 2012-02-27

This release contains a variety of fixes from 8.4.10. For information about new features in the 8.4 major release, see Section E.144.

E.133.1. Migration to Version 8.4.11

A dump/restore is not required for those running 8.4.X.

However, if you are upgrading from a version earlier than 8.4.10, see Section E.134.

E.133.2. Changes

- Require execute permission on the trigger function for `CREATE TRIGGER` (Robert Haas)
  
  This missing check could allow another user to execute a trigger function with forged input data, by installing it on a table he owns. This is only of significance for trigger functions marked `SECURITY DEFINER`, since otherwise trigger functions run as the table owner anyway. (CVE-2012-0866)

- Remove arbitrary limitation on length of common name in SSL certificates (Heikki Linnakangas)

  Both libpq and the server truncated the common name extracted from an SSL certificate at 32 bytes. Normally this would cause nothing worse than an unexpected verification failure, but there are some rather-implausible scenarios in which it might allow one certificate holder to impersonate another. The victim would have to have a common name exactly 32 bytes long, and the attacker would have to persuade a trusted CA to issue a certificate in which the common name has that string as a prefix. Impersonating a server would also require some additional exploit to redirect client connections. (CVE-2012-0867)

- Convert newlines to spaces in names written in pg_dump comments (Robert Haas)

  pg_dump was incautious about sanitizing object names that are emitted within SQL comments in its output script. A name containing a newline would at least render the script syntactically incorrect. Maliciously crafted object names could present a SQL injection risk when the script is reloaded. (CVE-2012-0868)

- Fix btree index corruption from insertions concurrent with vacuuming (Tom Lane)

  An index page split caused by an insertion could sometimes cause a concurrently-running `VACUUM` to miss removing index entries that it should remove. After the corresponding table rows are removed, the dangling index entries would cause errors (such as “could not read block N in file …”) or worse, silently wrong query results after unrelated rows are re-inserted at the now-free table locations. This bug has been present since release 8.2, but occurs so infrequently that it was not diagnosed until now. If you have reason to suspect that it has happened in your database, reindexing the affected index will fix things.

- Update per-column permissions, not only per-table permissions, when changing table owner (Tom Lane)
Appendix E. Release Notes

Failure to do this meant that any previously granted column permissions were still shown as having been granted by the old owner. This meant that neither the new owner nor a superuser could revoke the now-untraceable-to-table-owner permissions.

- Allow non-existent values for some settings in `ALTER USER/DATABASE SET` (Heikki Linnakangas)
  Allow `default_text_search_config`, `default_tablespace`, and `temp_tablespaces` to be set to names that are not known. This is because they might be known in another database where the setting is intended to be used, or for the tablespace cases because the tablespace might not be created yet. The same issue was previously recognized for `search_path`, and these settings now act like that one.

- Avoid crashing when we have problems deleting table files post-commit (Tom Lane)
  Dropping a table should lead to deleting the underlying disk files only after the transaction commits. In event of failure then (for instance, because of wrong file permissions) the code is supposed to just emit a warning message and go on, since it’s too late to abort the transaction. This logic got broken as of release 8.4, causing such situations to result in a PANIC and an unrestartable database.

- Track the OID counter correctly during WAL replay, even when it wraps around (Tom Lane)
  Previously the OID counter would remain stuck at a high value until the system exited replay mode. The practical consequences of that are usually nil, but there are scenarios wherein a standby server that’s been promoted to master might take a long time to advance the OID counter to a reasonable value once values are needed.

- Fix regular expression back-references with * attached (Tom Lane)
  Rather than enforcing an exact string match, the code would effectively accept any string that satisfies the pattern sub-expression referenced by the back-reference symbol.
  A similar problem still afflicts back-references that are embedded in a larger quantified expression, rather than being the immediate subject of the quantifier. This will be addressed in a future PostgreSQL release.

- Fix recently-introduced memory leak in processing of inet/cidr values (Heikki Linnakangas)
  A patch in the December 2011 releases of PostgreSQL caused memory leakage in these operations, which could be significant in scenarios such as building a btree index on such a column.

- Fix dangling pointer after `CREATE TABLE AS/SELECT INTO` in a SQL-language function (Tom Lane)
  In most cases this only led to an assertion failure in assert-enabled builds, but worse consequences seem possible.

- Avoid double close of file handle in syslogger on Windows (MauMau)
  Ordinarily this error was invisible, but it would cause an exception when running on a debug version of Windows.

- Fix I/O-conversion-related memory leaks in `plpgsql` (Andres Freund, Jan Urbanski, Tom Lane)
  Certain operations would leak memory until the end of the current function.

- Improve `pg_dump`’s handling of inherited table columns (Tom Lane)
  `pg_dump` mishandled situations where a child column has a different default expression than its parent column. If the default is textually identical to the parent’s default, but not actually the same (for instance, because of schema search path differences) it would not be recognized as different, so that after dump
Appendix E. Release Notes

and restore the child would be allowed to inherit the parent’s default. Child columns that are NOT NULL where their parent is not could also be restored subtly incorrectly.

• Fix pg_restore’s direct-to-database mode for INSERT-style table data (Tom Lane)
  Direct-to-database restores from archive files made with --inserts or --column-inserts options fail when using pg_restore from a release dated September or December 2011, as a result of an oversight in a fix for another problem. The archive file itself is not at fault, and text-mode output is okay.

• Allow AT option in ecpg DEALLOCATE statements (Michael Meskes)
  The infrastructure to support this has been there for awhile, but through an oversight there was still an error check rejecting the case.

• Fix error in contrib/intarray’s int[] & int[] operator (Guillaume Lelarge)
  If the smallest integer the two input arrays have in common is 1, and there are smaller values in either array, then 1 would be incorrectly omitted from the result.

• Fix error detection in contrib/pgcrypto’s encrypt_iv() and decrypt_iv() (Marko Kreen)
  These functions failed to report certain types of invalid-input errors, and would instead return random garbage values for incorrect input.

• Fix one-byte buffer overrun in contrib/test_parser (Paul Guyot)
  The code would try to read one more byte than it should, which would crash in corner cases. Since contrib/test_parser is only example code, this is not a security issue in itself, but bad example code is still bad.

• Use __sync_lock_test_and_set() for spinlocks on ARM, if available (Martin Pitt)
  This function replaces our previous use of the SWPB instruction, which is deprecated and not available on ARMv6 and later. Reports suggest that the old code doesn’t fail in an obvious way on recent ARM boards, but simply doesn’t interlock concurrent accesses, leading to bizarre failures in multiprocess operation.

• Use -fexcess-precision=standard option when building with gcc versions that accept it (Andrew Dunstan)
  This prevents assorted scenarios wherein recent versions of gcc will produce creative results.

• Allow use of threaded Python on FreeBSD (Chris Rees)
  Our configure script previously believed that this combination wouldn’t work; but FreeBSD fixed the problem, so remove that error check.

E.134. Release 8.4.10

Release date: 2011-12-05

This release contains a variety of fixes from 8.4.9. For information about new features in the 8.4 major release, see Section E.144.
E.134.1. Migration to Version 8.4.10

A dump/restore is not required for those running 8.4.X.

However, a longstanding error was discovered in the definition of the `information_schema.referential_constraints` view. If you rely on correct results from that view, you should replace its definition as explained in the first changelog item below.

Also, if you are upgrading from a version earlier than 8.4.8, see Section E.136.

E.134.2. Changes

• Fix bugs in `information_schema.referential_constraints` view (Tom Lane)

  This view was being insufficiently careful about matching the foreign-key constraint to the depended-on primary or unique key constraint. That could result in failure to show a foreign key constraint at all, or showing it multiple times, or claiming that it depends on a different constraint than the one it really does.

  Since the view definition is installed by initdb, merely upgrading will not fix the problem. If you need to fix this in an existing installation, you can (as a superuser) drop the `information_schema` schema then re-create it by sourcing `SHAREDIR/information_schema.sql` (Run `pg_config --sharedir` if you’re uncertain where `SHAREDIR` is.) This must be repeated in each database to be fixed.

• Fix incorrect replay of WAL records for GIN index updates (Tom Lane)

  This could result in transiently failing to find index entries after a crash, or on a hot-standby server. The problem would be repaired by the next `VACUUM` of the index, however.

• Fix TOAST-related data corruption during `CREATE TABLE dest AS SELECT * FROM src` or `INSERT INTO dest SELECT * FROM src` (Tom Lane)

  If a table has been modified by `ALTER TABLE ADD COLUMN`, attempts to copy its data verbatim to another table could produce corrupt results in certain corner cases. The problem can only manifest in this precise form in 8.4 and later, but we patched earlier versions as well in case there are other code paths that could trigger the same bug.

• Fix race condition during toast table access from stale syscache entries (Tom Lane)

  The typical symptom was transient errors like “missing chunk number 0 for toast value NNNNN in pg_toast_2619”, where the cited toast table would always belong to a system catalog.

• Track dependencies of functions on items used in parameter default expressions (Tom Lane)

  Previously, a referenced object could be dropped without having dropped or modified the function, leading to misbehavior when the function was used. Note that merely installing this update will not fix the missing dependency entries; to do that, you’d need to CREATE OR REPLACE each such function afterwards. If you have functions whose defaults depend on non-built-in objects, doing so is recommended.

• Allow inlining of set-returning SQL functions with multiple OUT parameters (Tom Lane)

• Make `DatumGetInetP()` unpack inet datums that have a 1-byte header, and add a new macro, `DatumGetInetPP()`, that does not (Heikki Linnakangas)
This change affects no core code, but might prevent crashes in add-on code that expects `DatumGetInetP()` to produce an unpacked datum as per usual convention.

- **Improve locale support in money type’s input and output (Tom Lane)**
  Aside from not supporting all standard `lc_monetary` formatting options, the input and output functions were inconsistent, meaning there were locales in which dumped money values could not be re-read.

- **Don’t let `transform_null_equals` affect `CASE foo WHEN NULL ...` constructs (Heikki Linnakangas)**
  `transform_null_equals` is only supposed to affect `foo = NULL` expressions written directly by the user, not equality checks generated internally by this form of `CASE`.

- **Change foreign-key trigger creation order to better support self-referential foreign keys (Tom Lane)**
  For a cascading foreign key that references its own table, a row update will fire both the `ON UPDATE` trigger and the `CHECK` trigger as one event. The `ON UPDATE` trigger must execute first, else the `CHECK` will check a non-final state of the row and possibly throw an inappropriate error. However, the firing order of these triggers is determined by their names, which generally sort in creation order since the triggers have auto-generated names following the convention “RI_ConstraintTrigger_NNNN”. A proper fix would require modifying that convention, which we will do in 9.2, but it seems risky to change it in existing releases. So this patch just changes the creation order of the triggers. Users encountering this type of error should drop and re-create the foreign key constraint to get its triggers into the right order.

- **Avoid floating-point underflow while tracking buffer allocation rate (Greg Matthews)**
  While harmless in itself, on certain platforms this would result in annoying kernel log messages.

- **Preserve configuration file name and line number values when starting child processes under Windows (Tom Lane)**
  Formerly, these would not be displayed correctly in the `pg_settings` view.

- **Preserve blank lines within commands in `psql`’s command history (Robert Haas)**
  The former behavior could cause problems if an empty line was removed from within a string literal, for example.

- **Fix pg_dump to dump user-defined casts between auto-generated types, such as table rowtypes (Tom Lane)**

- **Use the preferred version of `xsubpp` to build PL/Perl, not necessarily the operating system’s main copy (David Wheeler and Alex Hunsaker)**

- **Fix incorrect coding in `contrib/dict_int` and `contrib/dict_xsyn` (Tom Lane)**
  Some functions incorrectly assumed that memory returned by `palloc()` is guaranteed zeroed.

- **Honor query cancel interrupts promptly in `pgstatindex()` (Robert Haas)**

- **Ensure VPATH builds properly install all server header files (Peter Eisentraut)**

- **Shorten file names reported in verbose error messages (Peter Eisentraut)**
  Regular builds have always reported just the name of the C file containing the error message call, but VPATH builds formerly reported an absolute path name.

- **Fix interpretation of Windows timezone names for Central America (Tom Lane)**
Map “Central America Standard Time” to \texttt{CST6}, not \texttt{CST6CDT}, because DST is generally not observed anywhere in Central America.

- Update time zone data files to \texttt{tzdata} release 2011n for DST law changes in Brazil, Cuba, Fiji, Palestine, Russia, and Samoa; also historical corrections for Alaska and British East Africa.

\section*{E.135. Release 8.4.9}

\textbf{Release date:} 2011-09-26

This release contains a variety of fixes from 8.4.8. For information about new features in the 8.4 major release, see Section E.144.

\subsection*{E.135.1. Migration to Version 8.4.9}

A dump/restore is not required for those running 8.4.X.

However, if you are upgrading from a version earlier than 8.4.8, see Section E.136.

\subsection*{E.135.2. Changes}

- Fix bugs in indexing of in-doubt HOT-updated tuples (Tom Lane)
  These bugs could result in index corruption after reindexing a system catalog. They are not believed to affect user indexes.

- Fix multiple bugs in GiST index page split processing (Heikki Linnakangas)
  The probability of occurrence was low, but these could lead to index corruption.

- Fix possible buffer overrun in \texttt{tsvector\_concat()} (Tom Lane)
  The function could underestimate the amount of memory needed for its result, leading to server crashes.

- Fix crash in \texttt{xml\_recv} when processing a “standalone” parameter (Tom Lane)

- Make \texttt{pg\_options\_to\_table} return NULL for an option with no value (Tom Lane)
  Previously such cases would result in a server crash.

- Avoid possibly accessing off the end of memory in \texttt{ANALYZE} and in SJIS-2004 encoding conversion (Noah Misch)
  This fixes some very-low-probability server crash scenarios.

- Prevent intermittent hang in interactions of startup process with bgwriter process (Simon Riggs)
  This affected recovery in non-hot-standby cases.

- Fix race condition in relcache init file invalidation (Tom Lane)
There was a window wherein a new backend process could read a stale init file but miss the inval messages that would tell it the data is stale. The result would be bizarre failures in catalog accesses, typically “could not read block 0 in file ...” later during startup.

- Fix memory leak at end of a GiST index scan (Tom Lane)
  Commands that perform many separate GiST index scans, such as verification of a new GiST-based exclusion constraint on a table already containing many rows, could transiently require large amounts of memory due to this leak.

- Fix incorrect memory accounting (leading to possible memory bloat) in tuplestores supporting holdable cursors and plpgsql’s RETURN NEXT command (Tom Lane)

- Fix performance problem when constructing a large, lossy bitmap (Tom Lane)

- Fix join selectivity estimation for unique columns (Tom Lane)
  This fixes an erroneous planner heuristic that could lead to poor estimates of the result size of a join.

- Fix nested PlaceHolderVar expressions that appear only in sub-select target lists (Tom Lane)
  This mistake could result in outputs of an outer join incorrectly appearing as NULL.

- Allow nested EXISTS queries to be optimized properly (Tom Lane)

- Fix array- and path-creating functions to ensure padding bytes are zeroes (Tom Lane)
  This avoids some situations where the planner will think that semantically-equal constants are not equal, resulting in poor optimization.

- Fix EXPLAIN to handle gating Result nodes within inner-indexscan subplans (Tom Lane)
  The usual symptom of this oversight was “bogus varno” errors.

- Work around gcc 4.6.0 bug that breaks WAL replay (Tom Lane)
  This could lead to loss of committed transactions after a server crash.

- Fix dump bug for VALUES in a view (Tom Lane)

- Disallow SELECT FOR UPDATE/SHARE on sequences (Tom Lane)
  This operation doesn’t work as expected and can lead to failures.

- Fix VACUUM so that it always updates pg_class.reltuples/relpages (Tom Lane)
  This fixes some scenarios where autovacuum could make increasingly poor decisions about when to vacuum tables.

- Defend against integer overflow when computing size of a hash table (Tom Lane)

- Fix cases where CLUSTER might attempt to access already-removed TOAST data (Tom Lane)

- Fix portability bugs in use of credentials control messages for “peer” authentication (Tom Lane)

- Fix SSPI login when multiple roundtrips are required (Ahmed Shinwari, Magnus Hagander)
  The typical symptom of this problem was “The function requested is not supported” errors during SSPI login.

- Throw an error if pg_hba.conf contains hostssl but SSL is disabled (Tom Lane)
  This was concluded to be more user-friendly than the previous behavior of silently ignoring such lines.

- Fix typo in pg_srand48 seed initialization (Andres Freund)
This led to failure to use all bits of the provided seed. This function is not used on most platforms (only those without \texttt{srandom}), and the potential security exposure from a less-random-than-expected seed seems minimal in any case.

- Avoid integer overflow when the sum of \texttt{LIMIT} and \texttt{OFFSET} values exceeds $2^{63}$ (Heikki Linnakangas)
- Add overflow checks to \texttt{int4} and \texttt{int8} versions of \texttt{generate_series()} (Robert Haas)
- Fix trailing-zero removal in \texttt{to_char()} (Marti Raudsepp)
  In a format with \texttt{FM} and no digit positions after the decimal point, zeroes to the left of the decimal point could be removed incorrectly.
- Fix \texttt{pg\_size\_pretty()} to avoid overflow for inputs close to $2^{63}$ (Tom Lane)
- Weaken \texttt{plpgsql}'s check for typmod matching in record values (Tom Lane)
  An overly enthusiastic check could lead to discarding length modifiers that should have been kept.
- Correctly handle quotes in locale names during \texttt{initdb} (Heikki Linnakangas)
  The case can arise with some Windows locales, such as “People’s Republic of China”.
- Fix \texttt{pg\_upgrade} to preserve toast tables’ \texttt{relfrozenxids} during an upgrade from 8.3 (Bruce Momjian)
  Failure to do this could lead to \texttt{pg\_clog} files being removed too soon after the upgrade.
- In \texttt{pg\_ctl}, support silent mode for service registrations on Windows (MauMau)
- Fix \texttt{psql}'s counting of script file line numbers during \texttt{COPY} from a different file (Tom Lane)
- Fix \texttt{pg\_restore}’s direct-to-database mode for \texttt{standard\_conforming\_strings} (Tom Lane)
  \texttt{pg\_restore} could emit incorrect commands when restoring directly to a database server from an archive file that had been made with \texttt{standard\_conforming\_strings} set to \texttt{on}.
- Be more user-friendly about unsupported cases for parallel \texttt{pg\_restore} (Tom Lane)
  This change ensures that such cases are detected and reported before any restore actions have been taken.
- Fix write-past-buffer-end and memory leak in \texttt{libpq}'s LDAP service lookup code (Albe Laurenz)
- In \texttt{libpq}, avoid failures when using nonblocking I/O and an SSL connection (Martin Pihlak, Tom Lane)
- Improve \texttt{libpq}'s handling of failures during connection startup (Tom Lane)
  In particular, the response to a server report of \texttt{fork()} failure during SSL connection startup is now saner.
- Improve \texttt{libpq}'s error reporting for SSL failures (Tom Lane)
- Fix \texttt{PQsetValue()} to avoid possible crash when adding a new tuple to a \texttt{PGresult} originally obtained from a server query (Andrew Chernow)
- Make \texttt{ecpg\_lib} write double values with 15 digits precision (Akira Kurosawa)
- In \texttt{ecpg\_lib}, be sure \texttt{LC\_NUMERIC} setting is restored after an error (Michael Meskes)
- Apply upstream fix for blowfish signed-character bug (CVE-2011-2483) (Tom Lane)
  \texttt{contrib/pg\_crypto}'s blowfish encryption code could give wrong results on platforms where char is signed (which is most), leading to encrypted passwords being weaker than they should be.
- Fix memory leak in \texttt{contrib/seg} (Heikki Linnakangas)
Appendix E. Release Notes

• Fix pgstatindex() to give consistent results for empty indexes (Tom Lane)
• Allow building with perl 5.14 (Alex Hunsaker)
• Update configure script’s method for probing existence of system functions (Tom Lane)
  The version of autoconf we used in 8.3 and 8.2 could be fooled by compilers that perform link-time
  optimization.
• Fix assorted issues with build and install file paths containing spaces (Tom Lane)
• Update time zone data files to tzdata release 2011i for DST law changes in Canada, Egypt, Russia,
  Samoa, and South Sudan.

E.136. Release 8.4.8

Release date: 2011-04-18

This release contains a variety of fixes from 8.4.7. For information about new features in the 8.4 major
release, see Section E.144.

E.136.1. Migration to Version 8.4.8

A dump/restore is not required for those running 8.4.X.

However, if your installation was upgraded from a previous major release by running pg_upgrade,
you should take action to prevent possible data loss due to a now-fixed bug in pg_upgrade. The
recommended solution is to run VACUUM FREEZE on all TOAST tables. More information is available at

Also, if you are upgrading from a version earlier than 8.4.2, see Section E.142.

E.136.2. Changes

• Fix pg_upgrade’s handling of TOAST tables (Bruce Momjian)
  The pg_class.relfrozenxid value for TOAST tables was not correctly copied into the new instal-
 lation during pg_upgrade. This could later result in pg_clog files being discarded while they were
  still needed to validate tuples in the TOAST tables, leading to “could not access status of transaction”
  failures.
  This error poses a significant risk of data loss for installations that have been upgraded with pg_upgrade.
  This patch corrects the problem for future uses of pg_upgrade, but does not in itself cure the issue in
  installations that have been processed with a buggy version of pg_upgrade.
• Suppress incorrect “PD_ALL_VISIBLE flag was incorrectly set” warning (Heikki Linnakangas)
  VACUUM would sometimes issue this warning in cases that are actually valid.

Appendix E. Release Notes

- **Disallow including a composite type in itself (Tom Lane)**
  This prevents scenarios wherein the server could recurse infinitely while processing the composite type. While there are some possible uses for such a structure, they don’t seem compelling enough to justify the effort required to make sure it always works safely.

- **Avoid potential deadlock during catalog cache initialization (Nikhil Sontakke)**
  In some cases the cache loading code would acquire share lock on a system index before locking the index’s catalog. This could deadlock against processes trying to acquire exclusive locks in the other, more standard order.

- **Fix dangling-pointer problem in BEFORE ROW UPDATE trigger handling when there was a concurrent update to the target tuple (Tom Lane)**
  This bug has been observed to result in intermittent “cannot extract system attribute from virtual tuple” failures while trying to do UPDATE RETURNING ctid. There is a very small probability of more serious errors, such as generating incorrect index entries for the updated tuple.

- **Disallow DROP TABLE when there are pending deferred trigger events for the table (Tom Lane)**
  Formerly the DROP would go through, leading to “could not open relation with OID nnn” errors when the triggers were eventually fired.

- **Prevent crash triggered by constant-false WHERE conditions during GEQO optimization (Tom Lane)**

- **Improve planner’s handling of semi-join and anti-join cases (Tom Lane)**

- **Fix selectivity estimation for text search to account for NULLs (Jesper Krogh)**

- **Improve PL/pgSQL’s ability to handle row types with dropped columns (Pavel Stehule)**
  This is a back-patch of fixes previously made in 9.0.

- **Fix PL/Python memory leak involving array slices (Daniel Popowich)**

- **Fix pg_restore to cope with long lines (over 1KB) in TOC files (Tom Lane)**

- **Put in more safeguards against crashing due to division-by-zero with overly enthusiastic compiler optimization (Aurelien Jarno)**

- **Support use of dlopen() in FreeBSD and OpenBSD on MIPS (Tom Lane)**
  There was a hard-wired assumption that this system function was not available on MIPS hardware on these systems. Use a compile-time test instead, since more recent versions have it.

- **Fix compilation failures on HP-UX (Heikki Linnakangas)**

- **Fix version-incompatibility problem with libintl on Windows (Hiroshi Inoue)**

- **Fix usage of xcopy in Windows build scripts to work correctly under Windows 7 (Andrew Dunstan)**
  This affects the build scripts only, not installation or usage.

- **Fix path separator used by pg_regress on Cygwin (Andrew Dunstan)**

- **Update time zone data files to tzdata release 2011f for DST law changes in Chile, Cuba, Falkland Islands, Morocco, Samoa, and Turkey; also historical corrections for South Australia, Alaska, and Hawaii.**
E.137. Release 8.4.7

Release date: 2011-01-31

This release contains a variety of fixes from 8.4.6. For information about new features in the 8.4 major release, see Section E.144.

E.137.1. Migration to Version 8.4.7

A dump/restore is not required for those running 8.4.X. However, if you are upgrading from a version earlier than 8.4.2, see Section E.142.

E.137.2. Changes

- Avoid failures when EXPLAIN tries to display a simple-form CASE expression (Tom Lane)
  
  If the CASE’s test expression was a constant, the planner could simplify the CASE into a form that confused the expression-display code, resulting in “unexpected CASE WHEN clause” errors.

- Fix assignment to an array slice that is before the existing range of subscripts (Tom Lane)
  
  If there was a gap between the newly added subscripts and the first pre-existing subscript, the code miscalculated how many entries needed to be copied from the old array’s null bitmap, potentially leading to data corruption or crash.

- Avoid unexpected conversion overflow in planner for very distant date values (Tom Lane)
  
  The date type supports a wider range of dates than can be represented by the timestamp types, but the planner assumed it could always convert a date to timestamp with impunity.

- Fix pg_restore’s text output for large objects (BLOBs) when standard_conforming_strings is on (Tom Lane)
  
  Although restoring directly to a database worked correctly, string escaping was incorrect if pg_restore was asked for SQL text output and standard_conforming_strings had been enabled in the source database.

- Fix erroneous parsing of tsquery values containing ... & !(subexpression) | ...(Tom Lane)
  
  Queries containing this combination of operators were not executed correctly. The same error existed in contrib/intarray’s query_int type and contrib/ltree’s ltxtquery type.

- Fix buffer overrun in contrib/intarray’s input function for the query_int type (Apple)
  
  This bug is a security risk since the function’s return address could be overwritten. Thanks to Apple Inc’s security team for reporting this issue and supplying the fix. (CVE-2010-4015)

- Fix bug in contrib/seg’s GiST picksplit algorithm (Alexander Korotkov)
  
  This could result in considerable inefficiency, though not actually incorrect answers, in a GiST index on a seg column. If you have such an index, consider REINDEXing it after installing this update. (This is identical to the bug that was fixed in contrib/cube in the previous update.)
E.138. Release 8.4.6

Release date: 2010-12-16

This release contains a variety of fixes from 8.4.5. For information about new features in the 8.4 major release, see Section E.144.

E.138.1. Migration to Version 8.4.6

A dump/restore is not required for those running 8.4.X. However, if you are upgrading from a version earlier than 8.4.2, see Section E.142.

E.138.2. Changes

• Force the default `wal_sync_method` to be `fdatasync` on Linux (Tom Lane, Marti Raudsepp)
  The default on Linux has actually been `fdatasync` for many years, but recent kernel changes caused PostgreSQL to choose `open_data_sync` instead. This choice did not result in any performance improvement, and caused outright failures on certain filesystems, notably `ext4` with the `data=journal` mount option.

• Fix assorted bugs in WAL replay logic for GIN indexes (Tom Lane)
  This could result in “bad buffer id: 0” failures or corruption of index contents during replication.

• Fix recovery from base backup when the starting checkpoint WAL record is not in the same WAL segment as its redo point (Jeff Davis)

• Fix persistent slowdown of autovacuum workers when multiple workers remain active for a long time (Tom Lane)
  The effective `vacuum_cost_limit` for an autovacuum worker could drop to nearly zero if it processed enough tables, causing it to run extremely slowly.

• Add support for detecting register-stack overrun on IA64 (Tom Lane)
  The IA64 architecture has two hardware stacks. Full prevention of stack-overrun failures requires checking both.

• Add a check for stack overflow in `copyObject()` (Tom Lane)
  Certain code paths could crash due to stack overflow given a sufficiently complex query.

• Fix detection of page splits in temporary GiST indexes (Heikki Linnakangas)
  It is possible to have a “concurrent” page split in a temporary index, if for example there is an open cursor scanning the index when an insertion is done. GiST failed to detect this case and hence could deliver wrong results when execution of the cursor continued.

• Fix error checking during early connection processing (Tom Lane)
  The check for too many child processes was skipped in some cases, possibly leading to postmaster crash when attempting to add the new child process to fixed-size arrays.

• Improve efficiency of window functions (Tom Lane)
Certain cases where a large number of tuples needed to be read in advance, but `work_mem` was large enough to allow them all to be held in memory, were unexpectedly slow. `percent_rank()`,
`cume_dist()` and `ntile()` in particular were subject to this problem.

- Avoid memory leakage while `ANALYZE`ing complex index expressions (Tom Lane)
- Ensure an index that uses a whole-row Var still depends on its table (Tom Lane)
  
  An index declared like `create index i on t (foo(t.*))` would not automatically get dropped when its table was dropped.
- Do not “inline” a SQL function with multiple `OUT` parameters (Tom Lane)
  
  This avoids a possible crash due to loss of information about the expected result rowtype.
- Behave correctly if `ORDER BY`, `LIMIT`, `FOR UPDATE`, or `WITH` is attached to the `VALUES` part of `INSERT ... VALUES` (Tom Lane)
- Fix constant-folding of `COALESCE()` expressions (Tom Lane)
  
  The planner would sometimes attempt to evaluate sub-expressions that in fact could never be reached, possibly leading to unexpected errors.
- Fix postmaster crash when connection acceptance (`accept()` or one of the calls made immediately after it) fails, and the postmaster was compiled with GSSAPI support (Alexander Chernikov)
- Fix missed unlink of temporary files when `log_temp_files` is active (Tom Lane)
  
  If an error occurred while attempting to emit the log message, the unlink was not done, resulting in accumulation of temp files.
- Add print functionality for `InhRelation` nodes (Tom Lane)
  
  This avoids a failure when `debug_print_parse` is enabled and certain types of query are executed.
- Fix incorrect calculation of distance from a point to a horizontal line segment (Tom Lane)
  
  This bug affected several different geometric distance-measurement operators.
- Fix incorrect calculation of transaction status in ecpg (Itagaki Takahiro)
- Fix PL/pgSQL’s handling of “simple” expressions to not fail in recursion or error-recovery cases (Tom Lane)
- Fix PL/Python’s handling of set-returning functions (Jan Urbanski)
  
  Attempts to call SPI functions within the iterator generating a set result would fail.
- Fix bug in contrib/cube’s GiST picksplit algorithm (Alexander Korotkov)
  
  This could result in considerable inefficiency, though not actually incorrect answers, in a GiST index on a `cube` column. If you have such an index, consider `REINDEX`ing it after installing this update.
- Don’t emit “identifier will be truncated” notices in contrib/dblink except when creating new connections (Itagaki Takahiro)
- Fix potential coredump on missing public key in contrib/pgcrypto (Marti Raudsepp)
- Fix memory leak in contrib/xml2’s XPath query functions (Tom Lane)
- Update time zone data files to tzdata release 2010o for DST law changes in Fiji and Samoa; also historical corrections for Hong Kong.
E.139. Release 8.4.5

Release date: 2010-10-04

This release contains a variety of fixes from 8.4.4. For information about new features in the 8.4 major release, see Section E.144.

E.139.1. Migration to Version 8.4.5

A dump/restore is not required for those running 8.4.X. However, if you are upgrading from a version earlier than 8.4.2, see Section E.142.

E.139.2. Changes

- Use a separate interpreter for each calling SQL userid in PL/Perl and PL/Tcl (Tom Lane)

  This change prevents security problems that can be caused by subverting Perl or Tcl code that will be executed later in the same session under another SQL user identity (for example, within a SECURITY DEFINER function). Most scripting languages offer numerous ways that that might be done, such as redefining standard functions or operators called by the target function. Without this change, any SQL user with Perl or Tcl language usage rights can do essentially anything with the SQL privileges of the target function’s owner.

  The cost of this change is that intentional communication among Perl and Tcl functions becomes more difficult. To provide an escape hatch, PL/PerlU and PL/TclU functions continue to use only one interpreter per session. This is not considered a security issue since all such functions execute at the trust level of a database superuser already.

  It is likely that third-party procedural languages that claim to offer trusted execution have similar security issues. We advise contacting the authors of any PL you are depending on for security-critical purposes.

  Our thanks to Tim Bunce for pointing out this issue (CVE-2010-3433).

- Prevent possible crashes in pg_get_expr() by disallowing it from being called with an argument that is not one of the system catalog columns it’s intended to be used with (Heikki Linnakangas, Tom Lane)

- Treat exit code 128 (ERROR_WAIT_NO_CHILDREN) as non-fatal on Windows (Magnus Hagander)

  Under high load, Windows processes will sometimes fail at startup with this error code. Formerly the postmaster treated this as a panic condition and restarted the whole database, but that seems to be an overreaction.

- Fix incorrect placement of placeholder evaluation (Tom Lane)

  This bug could result in query outputs being non-null when they should be null, in cases where the inner side of an outer join is a sub-select with non-strict expressions in its output list.

- Fix possible duplicate scans of UNION ALL member relations (Tom Lane)

- Fix “cannot handle unplanned sub-select” error (Tom Lane)
This occurred when a sub-select contains a join alias reference that expands into an expression containing another sub-select.

- Fix mishandling of whole-row Vars that reference a view or sub-select and appear within a nested sub-select (Tom Lane)
- Fix mishandling of cross-type IN comparisons (Tom Lane)
  This could result in failures if the planner tried to implement an IN join with a sort-then-unique-then-plain-join plan.
- Fix computation of ANALYZE statistics for tsvector columns (Jan Urbanski)
  The original coding could produce incorrect statistics, leading to poor plan choices later.
- Improve planner's estimate of memory used by array_agg(), string_agg(), and similar aggregate functions (Hitoshi Harada)
  The previous drastic underestimate could lead to out-of-memory failures due to inappropriate choice of a hash-aggregation plan.
- Fix failure to mark cached plans as transient (Tom Lane)
  If a plan is prepared while CREATE INDEX CONCURRENTLY is in progress for one of the referenced tables, it is supposed to be re-planned once the index is ready for use. This was not happening reliably.
- Reduce PANIC to ERROR in some occasionally-reported btree failure cases, and provide additional detail in the resulting error messages (Tom Lane)
  This should improve the system’s robustness with corrupted indexes.
- Fix incorrect search logic for partial-match queries with GIN indexes (Tom Lane)
  Cases involving AND/OR combination of several GIN index conditions didn’t always give the right answer, and were sometimes much slower than necessary.
- Prevent show_session_authorization() from crashing within autovacuum processes (Tom Lane)
- Defend against functions returning setof record where not all the returned rows are actually of the same rowtype (Tom Lane)
- Fix possible corruption of pending trigger event lists during subtransaction rollback (Tom Lane)
  This could lead to a crash or incorrect firing of triggers.
- Fix possible failure when hashing a pass-by-reference function result (Tao Ma, Tom Lane)
- Improve merge join’s handling of NULLs in the join columns (Tom Lane)
  A merge join can now stop entirely upon reaching the first NULL, if the sort order is such that NULLs sort high.
- Take care to fsync the contents of lockfiles (both postmaster.pid and the socket lockfile) while writing them (Tom Lane)
  This omission could result in corrupted lockfile contents if the machine crashes shortly after postmaster start. That could in turn prevent subsequent attempts to start the postmaster from succeeding, until the lockfile is manually removed.
- Avoid recursion while assigning XIDs to heavily-nested subtransactions (Andres Freund, Robert Haas)
  The original coding could result in a crash if there was limited stack space.
• Avoid holding open old WAL segments in the walwriter process (Magnus Hagander, Heikki Linnakan-gas)
  The previous coding would prevent removal of no-longer-needed segments.
• Fix log_line_prefix's %i escape, which could produce junk early in backend startup (Tom Lane)
• Prevent misinterpretation of partially-specified relation options for TOAST tables (Itagaki Takahiro)
  In particular, fillfactor would be read as zero if any other reloption had been set for the table, leading to serious bloat.
• Fix inheritance count tracking in ALTER TABLE ... ADD CONSTRAINT (Robert Haas)
• Fix possible data corruption in ALTER TABLE ... SET TABLESPACE when archiving is enabled (Jeff Davis)
• Allow CREATE DATABASE and ALTER DATABASE ... SET TABLESPACE to be interrupted by query-cancel (Guillaume Lelarge)
• Improve CREATE INDEX’s checking of whether proposed index expressions are immutable (Tom Lane)
• Fix REASSIGN OWNED to handle operator classes and families (Asko Tiidumaa)
• Fix possible core dump when comparing two empty tsquery values (Tom Lane)
• Fix LIKE’s handling of patterns containing % followed by _ (Tom Lane)
  We’ve fixed this before, but there were still some incorrectly-handled cases.
• Re-allow input of Julian dates prior to 0001-01-01 AD (Tom Lane)
  Input such as ‘J100000’::date worked before 8.4, but was unintentionally broken by added error-checking.
• Fix PL/pgSQL to throw an error, not crash, if a cursor is closed within a FOR loop that is iterating over that cursor (Heikki Linnakangas)
• In PL/Python, defend against null pointer results from PyCObject_AsVoidPtr and PyCObject_FromVoidPtr (Peter Eisentraut)
• In libpq, fix full SSL certificate verification for the case where both host and hostaddr are specified (Tom Lane)
• Make psql recognize DISCARD ALL as a command that should not be encased in a transaction block in autocommit-off mode (Itagaki Takahiro)
• Fix some issues in pg_dump’s handling of SQL/MED objects (Tom Lane)
  Notably, pg_dump would always fail if run by a non-superuser, which was not intended.
• Improve pg_dump and pg_restore’s handling of non-seekable archive files (Tom Lane, Robert Haas)
  This is important for proper functioning of parallel restore.
• Improve parallel pg_restore’s ability to cope with selective restore (-L option) (Tom Lane)
  The original code tended to fail if the -L file commanded a non-default restore ordering.
• Fix ecpg to process data from RETURNING clauses correctly (Michael Meskes)
• Fix some memory leaks in ecpg (Zoltan Boszormenyi)
• Improve contrib/dblink’s handling of tables containing dropped columns (Tom Lane)
Appendix E. Release Notes

- Fix connection leak after “duplicate connection name” errors in contrib/dblink (Itagaki Takahiro)
- Fix contrib/dblink to handle connection names longer than 62 bytes correctly (Itagaki Takahiro)
- Add hstore(text, text) function to contrib/hstore (Robert Haas)

This function is the recommended substitute for the now-deprecated => operator. It was back-patched so that future-proofed code can be used with older server versions. Note that the patch will be effective only after contrib/hstore is installed or reinstalled in a particular database. Users might prefer to execute the CREATE FUNCTION command by hand, instead.

- Update build infrastructure and documentation to reflect the source code repository’s move from CVS to Git (Magnus Hagander and others)
- Update time zone data files to tzdata release 2010l for DST law changes in Egypt and Palestine; also historical corrections for Finland.

This change also adds new names for two Micronesian timezones: Pacific/Chuuk is now preferred over Pacific/Truk (and the preferred abbreviation is CHUT not TRUT) and Pacific/Pohnpei is preferred over Pacific/Ponape.

- Make Windows’ “N. Central Asia Standard Time” timezone map to Asia/Novosibirsk, not Asia/Almaty (Magnus Hagander)

Microsoft changed the DST behavior of this zone in the timezone update from KB976098. Asia/Novosibirsk is a better match to its new behavior.

E.140. Release 8.4.4

Release date: 2010-05-17

This release contains a variety of fixes from 8.4.3. For information about new features in the 8.4 major release, see Section E.144.

E.140.1. Migration to Version 8.4.4

A dump/restore is not required for those running 8.4.X. However, if you are upgrading from a version earlier than 8.4.2, see Section E.142.

E.140.2. Changes

- Enforce restrictions in plperl using an opmask applied to the whole interpreter, instead of using Safe.pm (Tim Bunce, Andrew Dunstan)

Recent developments have convinced us that Safe.pm is too insecure to rely on for making plperl trustable. This change removes use of Safe.pm altogether, in favor of using a separate interpreter with an opcode mask that is always applied. Pleasant side effects of the change include that it is now possible to use Perl’s strict pragma in a natural way in plperl, and that Perl’s $a and $b variables work as expected in sort routines, and that function compilation is significantly faster. (CVE-2010-1169)
Appendix E. Release Notes

- Prevent PL/Tcl from executing untrustworthy code from `pltcl_modules` (Tom)

  PL/Tcl’s feature for autoloading Tcl code from a database table could be exploited for trojan-horse attacks, because there was no restriction on who could create or insert into that table. This change disables the feature unless `pltcl_modules` is owned by a superuser. (However, the permissions on the table are not checked, so installations that really need a less-than-secure modules table can still grant suitable privileges to trusted non-superusers.) Also, prevent loading code into the unrestricted “normal” Tcl interpreter unless we are really going to execute a `pltclu` function. (CVE-2010-1170)

- Fix data corruption during WAL replay of `ALTER ... SET TABLESPACE` (Tom)

  When `archive_mode` is on, `ALTER ... SET TABLESPACE` generates a WAL record whose replay logic was incorrect. It could write the data to the wrong place, leading to possibly-unrecoverable data corruption. Data corruption would be observed on standby slaves, and could occur on the master as well if a database crash and recovery occurred after committing the `ALTER` and before the next checkpoint.

- Fix possible crash if a cache reset message is received during rebuild of a relcache entry (Heikki)

  This error was introduced in 8.4.3 while fixing a related failure.

- Apply per-function GUC settings while running the language validator for the function (Itagaki Takahiro)

  This avoids failures if the function’s code is invalid without the setting; an example is that SQL functions may not parse if the `search_path` is not correct.

- Do constraint exclusion for inherited `UPDATE` and `DELETE` target tables when `constraint_exclusion = partition` (Tom)

  Due to an oversight, this setting previously only caused constraint exclusion to be checked in `SELECT` commands.

- Do not allow an unprivileged user to reset superuser-only parameter settings (Alvaro)

  Previously, if an unprivileged user ran `ALTER USER ... RESET ALL` for himself, or `ALTER DATABASE ... RESET ALL` for a database he owns, this would remove all special parameter settings for the user or database, even ones that are only supposed to be changeable by a superuser. Now, the `ALTER` will only remove the parameters that the user has permission to change.

- Avoid possible crash during backend shutdown if shutdown occurs when a `CONTEXT` addition would be made to log entries (Tom)

  In some cases the context-printing function would fail because the current transaction had already been rolled back when it came time to print a log message.

- Fix erroneous handling of `%r` parameter in `recovery_end_command` (Heikki)

  The value always came out zero.

- Ensure the archiver process responds to changes in `archive_command` as soon as possible (Tom)

- Fix `pl/pgsql`’s `CASE` statement to not fail when the case expression is a query that returns no rows (Tom)

- Update `pl/perl`’s `ppport.h` for modern Perl versions (Andrew)

- Fix assorted memory leaks in `pl/python` (Andreas Freund, Tom)

- Handle empty-string connect parameters properly in `ecpg` (Michael)

- Prevent infinite recursion in `psql` when expanding a variable that refers to itself (Tom)
• Fix psql’s `\copy` to not add spaces around a dot within `\copy (select ...)` (Tom)

  Addition of spaces around the decimal point in a numeric literal would result in a syntax error.

• Avoid formatting failure in psql when running in a locale context that doesn’t match the `client_encoding` (Tom)

• Fix unnecessary “GIN indexes do not support whole-index scans” errors for unsatisfiable queries using `contrib/intarray` operators (Tom)

• Ensure that `contrib/pgstattuple` functions respond to cancel interrupts promptly (Tatsuhito Kashiwara)

• Make server startup deal properly with the case that `shmget()` returns `EINVAL` for an existing shared memory segment (Tom)

  This behavior has been observed on BSD-derived kernels including OS X. It resulted in an entirely-misleading startup failure complaining that the shared memory request size was too large.

• Avoid possible crashes in syslogger process on Windows (Heikki)

• Deal more robustly with incomplete time zone information in the Windows registry (Magnus)

• Update the set of known Windows time zone names (Magnus)

• Update time zone data files to tzdata release 2010j for DST law changes in Argentina, Australian Antarctic, Bangladesh, Mexico, Morocco, Pakistan, Palestine, Russia, Syria, Tunisia; also historical corrections for Taiwan.

  Also, add `PKST` (Pakistan Summer Time) to the default set of timezone abbreviations.

### E.141. Release 8.4.3

**Release date:** 2010-03-15

This release contains a variety of fixes from 8.4.2. For information about new features in the 8.4 major release, see Section E.144.

#### E.141.1. Migration to Version 8.4.3

A dump/restore is not required for those running 8.4.X. However, if you are upgrading from a version earlier than 8.4.2, see Section E.142.

#### E.141.2. Changes

• Add new configuration parameter `ssl_renegotiation_limit` to control how often we do session key renegotiation for an SSL connection (Magnus)

  This can be set to zero to disable renegotiation completely, which may be required if a broken SSL library is used. In particular, some vendors are shipping stopgap patches for CVE-2009-3555 that cause renegotiation attempts to fail.
Appendix E. Release Notes

- Fix possible deadlock during backend startup (Tom)
- Fix possible crashes due to not handling errors during relcache reload cleanly (Tom)
- Fix possible crash due to use of dangling pointer to a cached plan (Tatsuo)
- Fix possible crash due to overenthusiastic invalidation of cached plan for ROLLBACK (Tom)
- Fix possible crashes when trying to recover from a failure in subtransaction start (Tom)
- Fix server memory leak associated with use of savepoints and a client encoding different from server’s encoding (Tom)
- Fix incorrect WAL data emitted during end-of-recovery cleanup of a GIST index page split (Yoichi Hirai)
  This would result in index corruption, or even more likely an error during WAL replay, if we were unlucky enough to crash during end-of-recovery cleanup after having completed an incomplete GIST insertion.
- Fix bug in WAL redo cleanup method for GIN indexes (Heikki)
- Fix incorrect comparison of scan key in GIN index search (Teodor)
- Make substring() for bit types treat any negative length as meaning “all the rest of the string” (Tom)
  The previous coding treated only -1 that way, and would produce an invalid result value for other negative values, possibly leading to a crash (CVE-2010-0442).
- Fix integer-to-bit-string conversions to handle the first fractional byte correctly when the output bit width is wider than the given integer by something other than a multiple of 8 bits (Tom)
- Fix some cases of pathologically slow regular expression matching (Tom)
- Fix bug occurring when trying to inline a SQL function that returns a set of a composite type that contains dropped columns (Tom)
- Fix bug with trying to update a field of an element of a composite-type array column (Tom)
- Avoid failure when EXPLAIN has to print a FieldStore or assignment ArrayRef expression (Tom)
  These cases can arise now that EXPLAIN VERBOSE tries to print plan node target lists.
- Avoid an unnecessary coercion failure in some cases where an undecorated literal string appears in a subquery within UNION/INTERSECT/EXCEPT (Tom)
  This fixes a regression for some cases that worked before 8.4.
- Avoid undesirable rowtype compatibility check failures in some cases where a whole-row Var has a rowtype that contains dropped columns (Tom)
- Fix the STOP WAL LOCATION entry in backup history files to report the next WAL segment’s name when the end location is exactly at a segment boundary (Itagaki Takahiro)
- Always pass the catalog ID to an option validator function specified in CREATE FOREIGN DATA WRAPPER (Martin Pihlak)
- Fix some more cases of temporary-file leakage (Heikki)
  This corrects a problem introduced in the previous minor release. One case that failed is when a plpgsql function returning set is called within another function’s exception handler.
Add support for doing **FULL JOIN ON FALSE** (Tom)

This prevents a regression from pre-8.4 releases for some queries that can now be simplified to a constant-false join condition.

Improve constraint exclusion processing of boolean-variable cases, in particular make it possible to exclude a partition that has a “bool_column = false” constraint (Tom)

Prevent treating an **INOUT** cast as representing binary compatibility (Heikki)

Include column name in the message when warning about inability to grant or revoke column-level privileges (Stephen Frost)

This is more useful than before and helps to prevent confusion when a `REVOKE` generates multiple messages, which formerly appeared to be duplicates.

When reading `pg_hba.conf` and related files, do not treat `@something` as a file inclusion request if the `@` appears inside quote marks; also, never treat `@` by itself as a file inclusion request (Tom)

This prevents erratic behavior if a role or database name starts with `@`. If you need to include a file whose path name contains spaces, you can still do so, but you must write `@"/path to/file"` rather than putting the quotes around the whole construct.

Prevent infinite loop on some platforms if a directory is named as an inclusion target in `pg_hba.conf` and related files (Tom)

Fix possible infinite loop if SSL_read or SSL_write fails without setting errno (Tom)

This is reportedly possible with some Windows versions of openssl.

Disallow GSSAPI authentication on local connections, since it requires a hostname to function correctly (Magnus)

Protect ecpg against applications freeing strings unexpectedly (Michael)

Make ecpg report the proper SQLSTATE if the connection disappears (Michael)

Fix translation of cell contents in psql `\d` output (Heikki)

Fix psql’s `numericlocale` option to not format strings it shouldn’t in latex and troff output formats (Heikki)

Fix a small per-query memory leak in psql (Tom)

Make psql return the correct exit status (3) when `ON_ERROR_STOP` and `--single-transaction` are both specified and an error occurs during the implied `COMMIT` (Bruce)

Fix `pg_dump`’s output of permissions for foreign servers (Heikki)

Fix possible crash in parallel `pg_restore` due to out-of-range dependency IDs (Tom)

Fix `plpgsql` failure in one case where a composite column is set to NULL (Tom)

Fix possible failure when calling PL/Perl functions from PL/PerlU or vice versa (Tim Bunce)

Add `volatile` markings in PL/Python to avoid possible compiler-specific misbehavior (Zdenek Kotala)

Ensure PL/Tcl initializes the Tcl interpreter fully (Tom)

The only known symptom of this oversight is that the Tcl `clock` command misbehaves if using Tcl 8.5 or later.
• Prevent `ExecutorEnd` from being run on portals created within a failed transaction or subtransaction (Tom)

  This is known to cause issues when using `contrib/auto_explain`.

• Prevent crash in `contrib/dblink` when too many key columns are specified to a `dblink_build_sql_*` function (Rushabh Lathia, Joe Conway)

• Allow zero-dimensional arrays in `contrib/ltree` operations (Tom)

  This case was formerly rejected as an error, but it’s more convenient to treat it the same as a zero-element array. In particular this avoids unnecessary failures when an `ltree` operation is applied to the result of `ARRAY(SELECT ...)` and the sub-select returns no rows.

• Fix assorted crashes in `contrib/xml2` caused by sloppy memory management (Tom)

• Make building of `contrib/xml2` more robust on Windows (Andrew)

• Fix race condition in Windows signal handling (Radu Ilie)

  One known symptom of this bug is that rows in `pg_listener` could be dropped under heavy load.

• Make the configure script report failure if the C compiler does not provide a working 64-bit integer datatype (Tom)

  This case has been broken for some time, and no longer seems worth supporting, so just reject it at configure time instead.

• Update time zone data files to `tzdata` release 2010e for DST law changes in Bangladesh, Chile, Fiji, Mexico, Paraguay, Samoa.

---

### E.142. Release 8.4.2

**Release date:** 2009-12-14

This release contains a variety of fixes from 8.4.1. For information about new features in the 8.4 major release, see Section E.144.

### E.142.1. Migration to Version 8.4.2

A dump/restore is not required for those running 8.4.X. However, if you have any hash indexes, you should `REINDEX` them after updating to 8.4.2, to repair possible damage.

### E.142.2. Changes

• Protect against indirect security threats caused by index functions changing session-local state (Gurjeet Singh, Tom)

  This change prevents allegedly-immutable index functions from possibly subverting a superuser’s session (CVE-2009-4136).
Appendix E. Release Notes

- Reject SSL certificates containing an embedded null byte in the common name (CN) field (Magnus)
  This prevents unintended matching of a certificate to a server or client name during SSL validation (CVE-2009-4034).

- Fix hash index corruption (Tom)
  The 8.4 change that made hash indexes keep entries sorted by hash value failed to update the bucket splitting and compaction routines to preserve the ordering. So application of either of those operations could lead to permanent corruption of an index, in the sense that searches might fail to find entries that are present. To deal with this, it is recommended to `REINDEX` any hash indexes you may have after installing this update.

- Fix possible crash during backend-startup-time cache initialization (Tom)

- Avoid crash on empty thesaurus dictionary (Tom)

- Prevent signals from interrupting `VACUUM` at unsafe times (Alvaro)
  This fix prevents a PANIC if a `VACUUM FULL` is canceled after it’s already committed its tuple movements, as well as transient errors if a plain `VACUUM` is interrupted after having truncated the table.

- Fix possible crash due to integer overflow in hash table size calculation (Tom)
  This could occur with extremely large planner estimates for the size of a hashjoin’s result.

- Fix crash if a `DROP` is attempted on an internally-dependent object (Tom)

- Fix very rare crash in `inet/cidr` comparisons (Chris Mikkelson)

- Ensure that shared tuple-level locks held by prepared transactions are not ignored (Heikki)

- Fix premature drop of temporary files used for a cursor that is accessed within a subtransaction (Heikki)

- Fix memory leak in syslogger process when rotating to a new CSV logfile (Tom)

- Fix memory leak in postmaster when re-parsing `pg_hba.conf` (Tom)

- Fix Windows permission-downgrade logic (Jesse Morris)
  This fixes some cases where the database failed to start on Windows, often with misleading error messages such as “could not locate matching postgres executable”.

- Make `FOR UPDATE/SHARE` in the primary query not propagate into `WITH` queries (Tom)
  For example, in

  ```sql
  WITH w AS (SELECT * FROM foo) SELECT * FROM w, bar ... FOR UPDATE
  the FOR UPDATE will now affect bar but not foo. This is more useful and consistent than the original
  8.4 behavior, which tried to propagate FOR UPDATE into the WITH query but always failed due to
  assorted implementation restrictions. It also follows the design rule that WITH queries are executed as
  if independent of the main query.
  ```

- Fix bug with a `WITH RECURSIVE` query immediately inside another one (Tom)

- Fix concurrency bug in hash indexes (Tom)
  Concurrent insertions could cause index scans to transiently report wrong results.

- Fix incorrect logic for GiST index page splits, when the split depends on a non-first column of the index (Paul Ramsey)

- Fix wrong search results for a multi-column GIN index with `fastupdate` enabled (Teodor)
• Fix bugs in WAL entry creation for GIN indexes (Tom)
  These bugs were masked when full_page_writes was on, but with it off a WAL replay failure was
certain if a crash occurred before the next checkpoint.
• Don’t error out if recycling or removing an old WAL file fails at the end of checkpoint (Heikki)
  It’s better to treat the problem as non-fatal and allow the checkpoint to complete. Future checkpoints
  will retry the removal. Such problems are not expected in normal operation, but have been seen to be
  caused by misdesigned Windows anti-virus and backup software.
• Ensure WAL files aren’t repeatedly archived on Windows (Heikki)
  This is another symptom that could happen if some other process interfered with deletion of a no-
  longer-needed file.
• Fix PAM password processing to be more robust (Tom)
  The previous code is known to fail with the combination of the Linux pam_krb5 PAM module with
  Microsoft Active Directory as the domain controller. It might have problems elsewhere too, since it was
  making unjustified assumptions about what arguments the PAM stack would pass to it.
• Raise the maximum authentication token (Kerberos ticket) size in GSSAPI and SSPI authentication
  methods (Ian Turner)
  While the old 2000-byte limit was more than enough for Unix Kerberos implementations, tickets issued
  by Windows Domain Controllers can be much larger.
• Ensure that domain constraints are enforced in constructs like ARRAY[...]:domain, where the do-
  main is over an array type (Heikki)
• Fix foreign-key logic for some cases involving composite-type columns as foreign keys (Tom)
• Ensure that a cursor’s snapshot is not modified after it is created (Alvaro)
  This could lead to a cursor delivering wrong results if later operations in the same transaction modify
  the data the cursor is supposed to return.
• Fix CREATE TABLE to properly merge default expressions coming from different inheritance parent
  tables (Tom)
  This used to work but was broken in 8.4.
• Re-enable collection of access statistics for sequences (Akira Kurosawa)
  This used to work but was broken in 8.3.
• Fix processing of ownership dependencies during CREATE OR REPLACE FUNCTION (Tom)
• Fix incorrect handling of WHERE \( x=x \) conditions (Tom)
  In some cases these could get ignored as redundant, but they aren’t — they’re equivalent to \( x \text{ IS NOT NULL} \).
• Fix incorrect plan construction when using hash aggregation to implement DISTINCT for textually
  identical volatile expressions (Tom)
• Fix Assert failure for a volatile SELECT DISTINCT ON expression (Tom)
• Fix ts_stat() to not fail on an empty tsvector value (Tom)
• Make text search parser accept underscores in XML attributes (Peter)
• Fix encoding handling in xml binary input (Heikki)
  If the XML header doesn’t specify an encoding, we now assume UTF-8 by default; the previous han-
  dling was inconsistent.
• Fix bug with calling plperl from plperl or vice versa (Tom)
  An error exit from the inner function could result in crashes due to failure to re-select the correct Perl
  interpreter for the outer function.
• Fix session-lifespan memory leak when a PL/Perl function is redefined (Tom)
• Ensure that Perl arrays are properly converted to PostgreSQL arrays when returned by a set-returning
  PL/Perl function (Andrew Dunstan, Abhijit Menon-Sen)
  This worked correctly already for non-set-returning functions.
• Fix rare crash in exception processing in PL/Python (Peter)
• Fix ecpg problem with comments in DECLARE CURSOR statements (Michael)
• Fix ecpg to not treat recently-added keywords as reserved words (Tom)
  This affected the keywords CALLED, CATALOG, DEFINER, ENUM, FOLLOWING, INVOKER, OPTIONS,
  PARTITION, PRECEDING, RANGE, SECURITY, SERVER, UNBOUNDED, and WRAPPER.
• Re-allow regular expression special characters in psql’s \df function name parameter (Tom)
• In contrib/fuzzystrmatch, correct the calculation of levenshtein distances with non-default
  costs (Marcin Mank)
• In contrib/pg_standby, disable triggering failover with a signal on Windows (Fujii Masao)
  This never did anything useful, because Windows doesn’t have Unix-style signals, but recent changes
  made it actually crash.
• Put FREEZE and VERBOSE options in the right order in the VACUUM command that contrib/vaccumdb
  produces (Heikki)
• Fix possible leak of connections when contrib/dblink encounters an error (Tatsuhito Kasahara)
• Ensure psql’s flex module is compiled with the correct system header definitions (Tom)
  This fixes build failures on platforms where --enable-largefile causes incompatible changes in
  the generated code.
• Make the postmaster ignore any application_name parameter in connection request packets, to im-
  prove compatibility with future libpq versions (Tom)
• Update the timezone abbreviation files to match current reality (Joachim Wieland)
  This includes adding IDT to the default timezone abbreviation set.
• Update time zone data files to tzdata release 2009s for DST law changes in Antarctica, Argentina,
  Bangladesh, Fiji, Novokuznetsk, Pakistan, Palestine, Samoa, Syria; also historical corrections for Hong
  Kong.
E.143. Release 8.4.1

Release date: 2009-09-09

This release contains a variety of fixes from 8.4. For information about new features in the 8.4 major release, see Section E.144.

E.143.1. Migration to Version 8.4.1

A dump/restore is not required for those running 8.4.X.

E.143.2. Changes

• Fix WAL page header initialization at the end of archive recovery (Heikki)
  This could lead to failure to process the WAL in a subsequent archive recovery.
• Fix “cannot make new WAL entries during recovery” error (Tom)
• Fix problem that could make expired rows visible after a crash (Tom)
  This bug involved a page status bit potentially not being set correctly after a server crash.
• Disallow RESET ROLE and RESET SESSION AUTHORIZATION inside security-definer functions
  (Tom, Heikki)
  This covers a case that was missed in the previous patch that disallowed SET ROLE and SET SESSION
  AUTHORIZATION inside security-definer functions. (See CVE-2007-6600)
• Make LOAD of an already-loaded loadable module into a no-op (Tom)
  Formerly, LOAD would attempt to unload and re-load the module, but this is unsafe and not all that useful.
• Make window function PARTITION BY and ORDER BY items always be interpreted as simple expres-
  sions (Tom)
  In 8.4.0 these lists were parsed following the rules used for top-level GROUP BY and ORDER BY lists.
  But this was not correct per the SQL standard, and it led to possible circularity.
• Fix several errors in planning of semi-joins (Tom)
  These led to wrong query results in some cases where IN or EXISTS was used together with another
  join.
• Fix handling of whole-row references to subqueries that are within an outer join (Tom)
  An example is SELECT COUNT(ss.*) FROM ... LEFT JOIN (SELECT ...) ss ON .... Here,
  ss.* would be treated as ROW(NULL,NULL,...) for null-extended join rows, which is not the same
  as a simple NULL. Now it is treated as a simple NULL.
• Fix Windows shared-memory allocation code (Tsutomu Yamada, Magnus)
  This bug led to the often-reported “could not reattach to shared memory” error message.
• Fix locale handling with plperl (Heikki)
Appendix E. Release Notes

This bug could cause the server’s locale setting to change when a plperl function is called, leading to data corruption.

- Fix handling of reloptions to ensure setting one option doesn’t force default values for others (Itagaki Takahiro)
- Ensure that a “fast shutdown” request will forcibly terminate open sessions, even if a “smart shutdown” was already in progress (Fujii Masao)
- Avoid memory leak for array_agg() in GROUP BY queries (Tom)
- Treat to_char(..., ’TH’) as an uppercase ordinal suffix with ’HH’/’HH12’ (Heikki)
  It was previously handled as ’th’ (lowercase).
- Include the fractional part in the result of EXTRACT(second) and EXTRACT(milliseconds) for time and time with time zone inputs (Tom)
  This has always worked for floating-point datetime configurations, but was broken in the integer date-time code.
- Fix overflow for INTERVAL, ‘x ms’ when x is more than 2 million and integer datetimes are in use (Alex Hunsaker)
- Improve performance when processing toasted values in index scans (Tom)
  This is particularly useful for PostGIS5.
- Fix a typo that disabled commit_delay (Jeff Janes)
- Output early-startup messages to postmaster.log if the server is started in silent mode (Tom)
  Previously such error messages were discarded, leading to difficulty in debugging.
- Remove translated FAQs (Peter)
  They are now on the wiki6. The main FAQ was moved to the wiki some time ago.
- Fix pg_ctl to not go into an infinite loop if postgresql.conf is empty (Jeff Davis)
- Fix several errors in pg_dump’s --binary-upgrade mode (Bruce, Tom)
  pg_dump --binary-upgrade is used by pg_migrator.
- Fix contrib/xml2’s xslt_process() to properly handle the maximum number of parameters (twenty) (Tom)
- Improve robustness of libpq’s code to recover from errors during COPY FROM STDIN (Tom)
- Avoid including conflicting readline and editline header files when both libraries are installed (Zdenek Kotala)
- Work around gcc bug that causes “floating-point exception” instead of “division by zero” on some platforms (Tom)
- Update time zone data files to tzdata release 2009l for DST law changes in Bangladesh, Egypt, Mauritius.

5. http://postgis.net/
E.144. Release 8.4

Release date: 2009-07-01

E.144.1. Overview

After many years of development, PostgreSQL has become feature-complete in many areas. This release shows a targeted approach to adding features (e.g., authentication, monitoring, space reuse), and adds capabilities defined in the later SQL standards. The major areas of enhancement are:

- Windowing Functions
- Common Table Expressions and Recursive Queries
- Default and variadic parameters for functions
- Parallel Restore
- Column Permissions
- Per-database locale settings
- Improved hash indexes
- Improved join performance for EXISTS and NOT EXISTS queries
- Easier-to-use Warm Standby
- Automatic sizing of the Free Space Map
- Visibility Map (greatly reduces vacuum overhead for slowly-changing tables)
- Version-aware psql (backslash commands work against older servers)
- Support SSL certificates for user authentication
- Per-function runtime statistics
- Easy editing of functions in psql
- New contrib modules: pg_stat_statements, auto_explain, citext, btree_gin

The above items are explained in more detail in the sections below.

E.144.2. Migration to Version 8.4

A dump/restore using pg_dump is required for those wishing to migrate data from any previous release. Observe the following incompatibilities:

E.144.2.1. General

- Use 64-bit integer datetimes by default (Neil Conway)

  Previously this was selected by configure's --enable-integer-datetimes option. To retain the old behavior, build with --disable-integer-datetimes.
• Remove ipcclean utility command (Bruce)
  The utility only worked on a few platforms. Users should use their operating system tools instead.

E.144.2.2. Server Settings

• Change default setting for log_min_messages to warning (previously it was notice) to reduce log file volume (Tom)
• Change default setting for max_prepared_transactions to zero (previously it was 5) (Tom)
• Make debug_print_parse, debug_print_rewritten, and debug_print_plan output appear at LOG message level, not DEBUG1 as formerly (Tom)
• Make debug_pretty_print default to on (Tom)
• Remove explain_pretty_print parameter (no longer needed) (Tom)
• Make log_temp_files settable by superusers only, like other logging options (Simon Riggs)
• Remove automatic appending of the epoch timestamp when no % escapes are present in log_filename (Robert Haas)
  This change was made because some users wanted a fixed log filename, for use with an external log rotation tool.
• Remove log_restartpoints from recovery.conf; instead use log_checkpoints (Simon)
• Remove krb_realm and krb_server_hostname; these are now set in pg_hba.conf instead (Magnus)
• There are also significant changes in pg_hba.conf, as described below.

E.144.2.3. Queries

• Change TRUNCATE and LOCK to apply to child tables of the specified table(s) (Peter)
  These commands now accept an ONLY option that prevents processing child tables; this option must be used if the old behavior is needed.
• SELECT DISTINCT and UNION/INTERSECT/EXCEPT no longer always produce sorted output (Tom)
  Previously, these types of queries always removed duplicate rows by means of Sort/Unique processing (i.e., sort then remove adjacent duplicates). Now they can be implemented by hashing, which will not produce sorted output. If an application relied on the output being in sorted order, the recommended fix is to add an ORDER BY clause. As a short-term workaround, the previous behavior can be restored by disabling enable_hashagg, but that is a very performance-expensive fix. SELECT DISTINCT ON never uses hashing, however, so its behavior is unchanged.
• Force child tables to inherit CHECK constraints from parents (Alex Hunsaker, Nikhil Sontakke, Tom)
  Formerly it was possible to drop such a constraint from a child table, allowing rows that violate the constraint to be visible when scanning the parent table. This was deemed inconsistent, as well as contrary to SQL standard.
• Disallow negative \texttt{LIMIT} or \texttt{OFFSET} values, rather than treating them as zero (Simon)

• Disallow \texttt{LOCK TABLE} outside a transaction block (Tom)
  Such an operation is useless because the lock would be released immediately.

• Sequences now contain an additional \texttt{start_value} column (Zoltan Boszormenyi)
  This supports \texttt{ALTER SEQUENCE ... RESTART}.

\section*{E.144.2.4. \ Functions and Operators}

• Make numeric zero raised to a fractional power return $0$, rather than throwing an error, and make numeric zero raised to the zero power return $1$, rather than error (Bruce)
  This matches the longstanding \texttt{float8} behavior.

• Allow unary minus of floating-point values to produce minus zero (Tom)
  The changed behavior is more IEEE-standard compliant.

• Throw an error if an escape character is the last character in a \texttt{LIKE} pattern (i.e., it has nothing to escape) (Tom)
  Previously, such an escape character was silently ignored, thus possibly masking application logic errors.

• Remove \texttt{~==} and \texttt{~<>} operators formerly used for \texttt{LIKE} index comparisons (Tom)
  Pattern indexes now use the regular equality operator.

• \texttt{xpath()} now passes its arguments to libxml without any changes (Andrew)
  This means that the XML argument must be a well-formed XML document. The previous coding attempted to allow XML fragments, but it did not work well.

• Make \texttt{xmlelement()} format attribute values just like content values (Peter)
  Previously, attribute values were formatted according to the normal SQL output behavior, which is sometimes at odds with XML rules.

• Rewrite memory management for libxml-using functions (Tom)
  This change should avoid some compatibility problems with use of libxml in PL/Perl and other add-on code.

• Adopt a faster algorithm for hash functions (Kenneth Marshall, based on work of Bob Jenkins)
  Many of the built-in hash functions now deliver different results on little-endian and big-endian platforms.

\subsection*{E.144.2.4.1. Temporal Functions and Operators}

• \texttt{DateStyle} no longer controls interval output formatting; instead there is a new variable \texttt{IntervalStyle} (Ron Mayer)

• Improve consistency of handling of fractional seconds in \texttt{timestamp} and interval output (Ron Mayer)
This may result in displaying a different number of fractional digits than before, or rounding instead of truncating.

- Make `to_char()`’s localized month/day names depend on `LC_TIME`, not `LC_MESSAGES` (Euler Taveira de Oliveira)
- Cause `to_date()` and `to_timestamp()` to more consistently report errors for invalid input (Brendan Jurd)
  Previous versions would often ignore or silently misread input that did not match the format string. Such cases will now result in an error.
- Fix `to_timestamp()` to not require upper/lower case matching for meridian (`AM/PM`) and era (`BC/AD`) format designations (Brendan Jurd)
  For example, input value `ad` now matches the format string `AD`.

**E.144.3. Changes**

Below you will find a detailed account of the changes between PostgreSQL 8.4 and the previous major release.

**E.144.3.1. Performance**

- Improve optimizer statistics calculations (Jan Urbanski, Tom)
  In particular, estimates for full-text-search operators are greatly improved.
- Allow `SELECT DISTINCT` and `UNION/INTERSECT/EXCEPT` to use hashing (Tom)
  This means that these types of queries no longer automatically produce sorted output.
- Create explicit concepts of semi-joins and anti-joins (Tom)
  This work formalizes our previous ad-hoc treatment of `IN (SELECT ...)` clauses, and extends it to `EXISTS` and `NOT EXISTS` clauses. It should result in significantly better planning of `EXISTS` and `NOT EXISTS` queries. In general, logically equivalent `IN` and `EXISTS` clauses should now have similar performance, whereas previously `IN` often won.
- Improve optimization of sub-selects beneath outer joins (Tom)
  Formerly, a sub-select or view could not be optimized very well if it appeared within the nullable side of an outer join and contained non-strict expressions (for instance, constants) in its result list.
- Improve the performance of `text_position()` and related functions by using Boyer-Moore-Horspool searching (David Rowley)
  This is particularly helpful for long search patterns.
- Reduce I/O load of writing the statistics collection file by writing the file only when requested (Martin Pihlak)
- Improve performance for bulk inserts (Robert Haas, Simon)
Appendix E. Release Notes

- Increase the default value of `default_statistics_target` from 10 to 100 (Greg Sabino Mullane, Tom)
  
  The maximum value was also increased from 1000 to 10000.
- Perform `constraint_exclusion` checking by default in queries involving inheritance or `UNION ALL` (Tom)
  
  A new `constraint_exclusion` setting, `partition`, was added to specify this behavior.
- Allow I/O read-ahead for bitmap index scans (Greg Stark)
  
  The amount of read-ahead is controlled by `effective_io_concurrency`. This feature is available only if the kernel has `posix_fadvise()` support.
- Inline simple set-returning SQL functions in `FROM` clauses (Richard Rowell)
- Improve performance of multi-batch hash joins by providing a special case for join key values that are especially common in the outer relation (Bryce Cutt, Ramon Lawrence)
- Reduce volume of temporary data in multi-batch hash joins by suppressing “physical tlist” optimization (Michael Henderson, Ramon Lawrence)
- Avoid waiting for idle-in-transaction sessions during `CREATE INDEX CONCURRENTLY` (Simon)
- Improve performance of shared cache invalidation (Tom)

E.144.3.2. Server

E.144.3.2.1. Settings

- Convert many `postgresql.conf` settings to enumerated values so that `pg_settings` can display the valid values (Magnus)
- Add `cursor_tuple_fraction` parameter to control the fraction of a cursor’s rows that the planner assumes will be fetched (Robert Hell)
- Allow underscores in the names of custom variable classes in `postgresql.conf` (Tom)

E.144.3.2.2. Authentication and security

- Remove support for the (insecure) `crypt` authentication method (Magnus)
  
  This effectively obsoletes pre-PostgreSQL 7.2 client libraries, as there is no longer any non-plaintext password method that they can use.
- Support regular expressions in `pg_ident.conf` (Magnus)
- Allow Kerberos/GSSAPI parameters to be changed without restarting the postmaster (Magnus)
- Support SSL certificate chains in server certificate file (Andrew Gierth)
  
  Including the full certificate chain makes the client able to verify the certificate without having all intermediate CA certificates present in the local store, which is often the case for commercial CAs.
• Report appropriate error message for combination of MD5 authentication and db_user_namespace enabled (Bruce)

E.144.3.2.3. pg_hba.conf

• Change all authentication options to use name=value syntax (Magnus)

  This makes incompatible changes to the ldap, pam and ident authentication methods. All pg_hba.conf entries with these methods need to be rewritten using the new format.

• Remove the ident sameuser option, instead making that behavior the default if no usermap is specified (Magnus)

• Allow a usermap parameter for all external authentication methods (Magnus)

  Previously a usermap was only supported for ident authentication.

• Add clientcert option to control requesting of a client certificate (Magnus)

  Previously this was controlled by the presence of a root certificate file in the server’s data directory.

• Add cert authentication method to allow user authentication via SSL certificates (Magnus)

  Previously SSL certificates could only verify that the client had access to a certificate, not authenticate a user.

• Allow krb5, gssapi and sspi realm and krb5 host settings to be specified in pg_hba.conf (Magnus)

  These override the settings in postgresql.conf.

• Add include_realm parameter for krb5, gssapi, and sspi methods (Magnus)

  This allows identical usernames from different realms to be authenticated as different database users using usermaps.

• Parse pg_hba.conf fully when it is loaded, so that errors are reported immediately (Magnus)

  Previously, most errors in the file wouldn’t be detected until clients tried to connect, so an erroneous file could render the system unusable. With the new behavior, if an error is detected during reload then the bad file is rejected and the postmaster continues to use its old copy.

• Show all parsing errors in pg_hba.conf instead of aborting after the first one (Selena Deckelmann)

• Support ident authentication over Unix-domain sockets on Solaris (Garick Hamlin)

E.144.3.2.4. Continuous Archiving

• Provide an option to pg_start_backup() to force its implied checkpoint to finish as quickly as possible (Tom)

  The default behavior avoids excess I/O consumption, but that is pointless if no concurrent query activity is going on.

• Make pg_stop_backup() wait for modified WAL files to be archived (Simon)

  This guarantees that the backup is valid at the time pg_stop_backup() completes.
• When archiving is enabled, rotate the last WAL segment at shutdown so that all transactions can be archived immediately (Guillaume Smet, Heikki)
• Delay “smart” shutdown while a continuous archiving base backup is in progress (Laurenz Albe)
• Cancel a continuous archiving base backup if “fast” shutdown is requested (Laurenz Albe)
• Allow recovery.conf boolean variables to take the same range of string values as postgresql.conf boolean variables (Bruce)

E.144.3.2.5. Monitoring

• Add pg_conf_load_time() to report when the PostgreSQL configuration files were last loaded (George Gensure)
• Add pg_terminate_backend() to safely terminate a backend (the SIGTERM signal works also) (Tom, Bruce)
  While it’s always been possible to SIGTERM a single backend, this was previously considered unsupported; and testing of the case found some bugs that are now fixed.
• Add ability to track user-defined functions’ call counts and runtimes (Martin Pihlak)
  Function statistics appear in a new system view, pg_stat_user_functions. Tracking is controlled by the new parameter track_functions.
• Allow specification of the maximum query string size in pg_stat_activity via new track_activity_query_size parameter (Thomas Lee)
• Increase the maximum line length sent to syslog, in hopes of improving performance (Tom)
• Add read-only configuration variables segment_size, wal_block_size, and wal_segment_size (Bernd Helmle)
• When reporting a deadlock, report the text of all queries involved in the deadlock to the server log (Itagaki Takahiro)
• Add pg_stat_get_activity(pid) function to return information about a specific process id (Magnus)
• Allow the location of the server’s statistics file to be specified via stats_temp_directory (Magnus)
  This allows the statistics file to be placed in a RAM-resident directory to reduce I/O requirements. On startup/shutdown, the file is copied to its traditional location ($PGDATA/global/) so it is preserved across restarts.

E.144.3.3. Queries

• Add support for WINDOW functions (Hitoshi Harada)
• Add support for WITH clauses (CTEs), including WITH RECURSIVE (Yoshiyuki Asaba, Tatsuo Ishii, Tom)
• Add TABLE command (Peter)
TABLE tablename is a SQL standard short-hand for SELECT * FROM tablename.

- Allow AS to be optional when specifying a SELECT (or RETURNING) column output label (Hiroshi Saito)

  This works so long as the column label is not any PostgreSQL keyword; otherwise AS is still needed.

- Support set-returning functions in SELECT result lists even for functions that return their result via a tuplestore (Tom)

  In particular, this means that functions written in PL/pgSQL and other PL languages can now be called this way.

- Support set-returning functions in the output of aggregation and grouping queries (Tom)

- Allow SELECT FOR UPDATE/SHARE to work on inheritance trees (Tom)

- Add infrastructure for SQL/MED (Martin Pihlak, Peter)

  There are no remote or external SQL/MED capabilities yet, but this change provides a standardized and future-proof system for managing connection information for modules like dblink and plproxy.

- Invalidate cached plans when referenced schemas, functions, operators, or operator classes are modified (Martin Pihlak, Tom)

  This improves the system’s ability to respond to on-the-fly DDL changes.

- Allow comparison of composite types and allow arrays of anonymous composite types (Tom)

  This allows constructs such as row(1, 1.1) = any (array[row(7, 7.7), row(1, 1.0)]). This is particularly useful in recursive queries.

- Add support for Unicode string literal and identifier specifications using code points, e.g. U\0061\0061 (Peter)

- Reject \000 in string literals and COPY data (Tom)

  Previously, this was accepted but had the effect of terminating the string contents.

- Improve the parser’s ability to report error locations (Tom)

  An error location is now reported for many semantic errors, such as mismatched datatypes, that previously could not be localized.

### E.144.3.3.1. TRUNCATE

- Support statement-level ON TRUNCATE triggers (Simon)

- Add RESTART/CONTINUE IDENTITY options for TRUNCATE TABLE (Zoltan Boszormenyi)

  The start value of a sequence can be changed by ALTER SEQUENCE START WITH.

- Allow TRUNCATE tab1, tab1 to succeed (Bruce)

- Add a separate TRUNCATE permission (Robert Haas)

### E.144.3.3.2. EXPLAIN

- Make EXPLAIN VERBOSE show the output columns of each plan node (Tom)
Previously \texttt{EXPLAIN VERBOSE} output an internal representation of the query plan. (That behavior is now available via \texttt{debug_print_plan}.)

- Make \texttt{EXPLAIN} identify subplans and initplans with individual labels (Tom)
- Make \texttt{EXPLAIN} honor \texttt{debug_print_plan} (Tom)
- Allow \texttt{EXPLAIN} on \texttt{CREATE TABLE AS} (Peter)

\textbf{E.144.3.3. LIMIT/OFFSET}

- Allow sub-selects in \texttt{LIMIT} and \texttt{OFFSET} (Tom)
- Add SQL-standard syntax for \texttt{LIMIT/OFFSET} capabilities (Peter)

\begin{verbatim}
To wit, OFFSET num \{ROW|ROWS\} FETCH \{FIRST|NEXT\} \[num\] \{ROW|ROWS\} ONLY.
\end{verbatim}

\textbf{E.144.3.4. Object Manipulation}

- Add support for column-level privileges (Stephen Frost, KaiGai Kohei)
- Refactor multi-object \texttt{DROP} operations to reduce the need for \texttt{CASCADE} (Alex Hunsaker)

  For example, if table \texttt{B} has a dependency on table \texttt{A}, the command \texttt{DROP TABLE A, B} no longer requires the \texttt{CASCADE} option.
- Fix various problems with concurrent \texttt{DROP} commands by ensuring that locks are taken before we begin to drop dependencies of an object (Tom)
- Improve reporting of dependencies during \texttt{DROP} commands (Tom)
- Add with [NO] DATA clause to \texttt{CREATE TABLE AS}, per the SQL standard (Peter, Tom)
- Add support for user-defined I/O conversion casts (Heikki)
- Allow \texttt{CREATE AGGREGATE} to use an internal transition datatype (Tom)
- Add LIKE clause to \texttt{CREATE TYPE} (Tom)

  This simplifies creation of data types that use the same internal representation as an existing type.
- Allow specification of the type category and “preferred” status for user-defined base types (Tom)

  This allows more control over the coercion behavior of user-defined types.
- Allow \texttt{CREATE OR REPLACE VIEW} to add columns to the end of a view (Robert Haas)

\textbf{E.144.3.4.1. ALTER}

- Add \texttt{ALTER TYPE RENAME} (Petr Jelinek)
- Add \texttt{ALTER SEQUENCE \ldots RESTART} (with no parameter) to reset a sequence to its initial value (Zoltan Boszormenyi)
- Modify the \texttt{ALTER TABLE} syntax to allow all reasonable combinations for tables, indexes, sequences, and views (Tom)
This change allows the following new syntaxes:

- ALTER SEQUENCE OWNER TO
- ALTER VIEW ALTER COLUMN SET/DROP DEFAULT
- ALTER VIEW OWNER TO
- ALTER VIEW SET SCHEMA

There is no actual new functionality here, but formerly you had to say ALTER TABLE to do these things, which was confusing.

- Add support for the syntax ALTER TABLE ... ALTER COLUMN ... SET DATA TYPE (Peter)

  This is SQL-standard syntax for functionality that was already supported.

- Make ALTER TABLE SET WITHOUT OIDS rewrite the table to physically remove OID values (Tom)

  Also, add ALTER TABLE SET WITH OIDS to rewrite the table to add OIDS.

### E.144.3.4.2. Database Manipulation

- Improve reporting of CREATE/DROP/RENAME DATABASE failure when uncommitted prepared transactions are the cause (Tom)
- Make LC_COLLATE and LC_CTYPE into per-database settings (Radek Strnad, Heikki)

  This makes collation similar to encoding, which was always configurable per database.

- Improve checks that the database encoding, collation (LC_COLLATE), and character classes (LC_CTYPE) match (Heikki, Tom)

  Note in particular that a new database’s encoding and locale settings can be changed only when copying from template0. This prevents possibly copying data that doesn’t match the settings.

- Add ALTER DATABASE SET TABLESPACE to move a database to a new tablespace (Guillaume Lelarge, Bernd Helmle)

### E.144.3.5. Utility Operations

- Add a VERBOSE option to the CLUSTER command and clusterdb (Jim Cox)
- Decrease memory requirements for recording pending trigger events (Tom)

#### E.144.3.5.1. Indexes

- Dramatically improve the speed of building and accessing hash indexes (Tom Raney, Shreya Bhargava)

  This allows hash indexes to be sometimes faster than btree indexes. However, hash indexes are still not crash-safe.

- Make hash indexes store only the hash code, not the full value of the indexed column (Xiao Meng)

  This greatly reduces the size of hash indexes for long indexed values, improving performance.
Appendix E. Release Notes

- Implement fast update option for GIN indexes (Teodor, Oleg)
  This option greatly improves update speed at a small penalty in search speed.
- \texttt{xxx\_pattern\_ops} indexes can now be used for simple equality comparisons, not only for \texttt{LIKE} (Tom)

\textbf{E.144.3.5.2. Full Text Indexes}

- Remove the requirement to use \texttt{@@@} when doing GIN weighted lookups on full text indexes (Tom, Teodor)
  The normal \texttt{@@} text search operator can be used instead.
- Add an optimizer selectivity function for \texttt{@@} text search operations (Jan Urbanski)
- Allow prefix matching in full text searches (Teodor Sigaev, Oleg Bartunov)
- Support multi-column GIN indexes (Teodor Sigaev)
- Improve support for Nepali language and Devanagari alphabet (Teodor)

\textbf{E.144.3.5.3. VACUUM}

- Track free space in separate per-relation “fork” files (Heikki)
  Free space discovered by \texttt{VACUUM} is now recorded in \texttt{*\_fsm} files, rather than in a fixed-sized shared memory area. The \texttt{max\_fsm\_pages} and \texttt{max\_fsm\_relations} settings have been removed, greatly simplifying administration of free space management.
- Add a visibility map to track pages that do not require vacuuming (Heikki)
  This allows \texttt{VACUUM} to avoid scanning all of a table when only a portion of the table needs vacuuming. The visibility map is stored in per-relation “fork” files.
- Add \texttt{vacuum\_freeze\_table\_age} parameter to control when \texttt{VACUUM} should ignore the visibility map and do a full table scan to freeze tuples (Heikki)
- Track transaction snapshots more carefully (Alvaro)
  This improves \texttt{VACUUM}’s ability to reclaim space in the presence of long-running transactions.
- Add ability to specify per-relation autovacuum and TOAST parameters in \texttt{CREATE TABLE} (Alvaro, Euler Taveira de Oliveira)
  Autovacuum options used to be stored in a system table.
- Add \texttt{--freeze} option to \texttt{vacuumdb} (Bruce)

\textbf{E.144.3.6. Data Types}

- Add a \texttt{CaseSensitive} option for text search synonym dictionaries (Simon)
- Improve the precision of \texttt{NUMERIC} division (Tom)
• Add basic arithmetic operators for \texttt{int2} with \texttt{int8} (Tom)
  This eliminates the need for explicit casting in some situations.
• Allow UUID input to accept an optional hyphen after every fourth digit (Robert Haas)
• Allow \texttt{on/off} as input for the boolean data type (Itagaki Takahiro)
• Allow spaces around \texttt{NaN} in the input string for type \texttt{numeric} (Sam Mason)

\textbf{E.144.3.6.1. Temporal Data Types}

• Reject year 0 BC and years 000 and 0000 (Tom)
  Previously these were interpreted as 1 BC. (Note: years 0 and 00 are still assumed to be the year 2000.)
• Include \texttt{SGT} (Singapore time) in the default list of known time zone abbreviations (Tom)
• Support \texttt{infinity} and \texttt{-infinity} as values of type \texttt{date} (Tom)
• Make parsing of \texttt{interval} literals more standard-compliant (Tom, Ron Mayer)
  For example, \texttt{INTERVAL '1' YEAR} now does what it’s supposed to.
• Allow \texttt{interval} fractional-seconds precision to be specified after the \texttt{second} keyword, for SQL standard compliance (Tom)
  Formerly the precision had to be specified after the keyword \texttt{interval}. (For backwards compatibility, this syntax is still supported, though deprecated.) Data type definitions will now be output using the standard format.
• Support the ISO 8601 \texttt{interval} syntax (Ron Mayer, Kevin Grittner)
  For example, \texttt{INTERVAL 'P1Y2M3DT4H5M6.7S'} is now supported.
• Add \texttt{IntervalStyle} parameter which controls how \texttt{interval} values are output (Ron Mayer)
  Valid values are: \texttt{postgres}, \texttt{postgres_verbose}, \texttt{sql_standard}, \texttt{iso_8601}. This setting also controls the handling of negative \texttt{interval} input when only some fields have positive/negative designations.
• Improve consistency of handling of fractional seconds in \texttt{timestamp} and \texttt{interval} output (Ron Mayer)

\textbf{E.144.3.6.2. Arrays}

• Improve the handling of casts applied to \texttt{ARRAY[]} constructs, such as \texttt{ARRAY[...]}::\texttt{integer[]} (Brendan Jurd)
  Formerly PostgreSQL attempted to determine a data type for the \texttt{ARRAY[]} construct without reference to the ensuing cast. This could fail unnecessarily in many cases, in particular when the \texttt{ARRAY[]} construct was empty or contained only ambiguous entries such as \texttt{NULL}. Now the cast is consulted to determine the type that the array elements must be.
• Make SQL-syntax \texttt{ARRAY} dimensions optional to match the SQL standard (Peter)
• Add \texttt{array_ndims()} to return the number of dimensions of an array (Robert Haas)
Appendix E. Release Notes

- Add `array_length()` to return the length of an array for a specified dimension (Jim Nasby, Robert Haas, Peter Eisentraut)
- Add aggregate function `array_agg()`, which returns all aggregated values as a single array (Robert Haas, Jeff Davis, Peter)
- Add `unnest()`, which converts an array to individual row values (Tom)
  
  This is the opposite of `array_agg()`.

- Add `array_fill()` to create arrays initialized with a value (Pavel Stehule)
- Add `generate_subscripts()` to simplify generating the range of an array’s subscripts (Pavel Stehule)

### E.144.3.6.3. Wide-Value Storage (TOAST)

- Consider TOAST compression on values as short as 32 bytes (previously 256 bytes) (Greg Stark)
- Require 25% minimum space savings before using TOAST compression (previously 20% for small values and any-savings-at-all for large values) (Greg)
- Improve TOAST heuristics for rows that have a mix of large and small toastable fields, so that we prefer to push large values out of line and don’t compress small values unnecessarily (Greg, Tom)

### E.144.3.7. Functions

- Document that `setseed()` allows values from -1 to 1 (not just 0 to 1), and enforce the valid range (Kris Jurka)
- Add server-side function `lo_import(filename, oid)` (Tatsuo)
- Add `quote_nullable()`, which behaves like `quote_literal()` but returns the string NULL for a null argument (Brendan Jurd)
- Improve full text search `headline()` function to allow extracting several fragments of text (Sushant Sinha)
- Add `suppress_redundant_updates_trigger()` trigger function to avoid overhead for non-data-changing updates (Andrew)
- Add `div(numeric, numeric)` to perform numeric division without rounding (Tom)
- Add `timestamp` and `timestamptz` versions of `generate_series()` (Hitoshi Harada)

### E.144.3.7.1. Object Information Functions

- Implement `current_query()` for use by functions that need to know the currently running query (Tomas Doran)
- Add `pg_get_keywords()` to return a list of the parser keywords (Dave Page)
- Add `pg_get_functiondef()` to see a function’s definition (Abhijit Menon-Sen)
• Allow the second argument of `pg_get_expr()` to be zero when deparsing an expression that does not contain variables (Tom)

• Modify `pg_relation_size()` to use `regclass` (Heikki)
  
  `pg_relation_size(data_type_name)` no longer works.

• Add `boot_val` and `reset_val` columns to `pg_settings` output (Greg Smith)

• Add source file name and line number columns to `pg_settings` output for variables set in a configuration file (Magnus, Alvaro)
  
  For security reasons, these columns are only visible to superusers.

• Add support for `CURRENT_CATALOG`, `CURRENT_SCHEMA`, `SET CATALOG`, `SET SCHEMA` (Peter)
  
  These provide SQL-standard syntax for existing features.

• Add `pg_typeof()` which returns the data type of any value (Brendan Jurd)

• Make `version()` return information about whether the server is a 32- or 64-bit binary (Bruce)

• Fix the behavior of information schema columns `is_insertable_into` and `is_updatable` to be consistent (Peter)

• Improve the behavior of information schema `datetime_precision` columns (Peter)
  
  These columns now show zero for `date` columns, and 6 (the default precision) for `time`, `timestamp`, and `interval` without a declared precision, rather than showing null as formerly.

• Convert remaining builtin set-returning functions to use `OUT` parameters (Jaime Casanova)
  
  This makes it possible to call these functions without specifying a column list: `pg_show_all_settings()`, `pg_lock_status()`, `pg_prepared_xact()`, `pg_prepared_statement()`, `pg_cursor()`

• Make `pg_*_is_visible()` and `has_*_privilege()` functions return `NULL` for invalid OIDs, rather than reporting an error (Tom)

• Extend `has_*_privilege()` functions to allow inquiring about the OR of multiple privileges in one call (Stephen Frost, Tom)

• Add `has_column_privilege()` and `has_any_column_privilege()` functions (Stephen Frost, Tom)

---

**E.144.3.7.2. Function Creation**

• Support variadic functions (functions with a variable number of arguments) (Pavel Stehule)
  
  Only trailing arguments can be optional, and they all must be of the same data type.

• Support default values for function arguments (Pavel Stehule)

• Add `CREATE FUNCTION ... RETURNS TABLE` clause (Pavel Stehule)

• Allow SQL-language functions to return the output of an `INSERT/UPDATE/DELETE RETURNING` clause (Tom)
E.144.3.7.3. PL/pgSQL Server-Side Language

- Support `EXECUTE USING` for easier insertion of data values into a dynamic query string (Pavel Stehule)
- Allow looping over the results of a cursor using a `FOR` loop (Pavel Stehule)
- Support `RETURN QUERY EXECUTE` (Pavel Stehule)
- Improve the `RAISE` command (Pavel Stehule)
  - Support `DETAIL` and `HINT` fields
  - Support specification of the `SQLSTATE` error code
  - Support an exception name parameter
  - Allow `RAISE` without parameters in an exception block to re-throw the current error
- Allow specification of `SQLSTATE` codes in `EXCEPTION` lists (Pavel Stehule)
  This is useful for handling custom `SQLSTATE` codes.
- Support the `CASE` statement (Pavel Stehule)
- Make `RETURN QUERY` set the special `FOUND` and `GET DIAGNOSTICS ROW_COUNT` variables (Pavel Stehule)
- Make `FETCH` and `MOVE` set the `GET DIAGNOSTICS ROW_COUNT` variable (Andrew Gierth)
- Make `EXIT` without a label always exit the innermost loop (Tom)
  Formerly, if there were a `BEGIN` block more closely nested than any loop, it would exit that block instead. The new behavior matches Oracle(TM) and is also what was previously stated by our own documentation.
- Make processing of string literals and nested block comments match the main SQL parser’s processing (Tom)
  In particular, the format string in `RAISE` now works the same as any other string literal, including being subject to `standard_conforming_strings`. This change also fixes other cases in which valid commands would fail when `standard_conforming_strings` is on.
- Avoid memory leakage when the same function is called at varying exception-block nesting depths (Tom)

E.144.3.8. Client Applications

- Fix `pg_ctl` `restart` to preserve command-line arguments (Bruce)
- Add `-w/--no-password` option that prevents password prompting in all utilities that have a `-W/--password` option (Peter)
- Remove `-q` (quiet) option of `createdb`, `createuser`, `dropdb`, `dropuser` (Peter)
  These options have had no effect since PostgreSQL 8.3.
Appendix E. Release Notes

E.144.3.8.1. psql

- Remove verbose startup banner; now just suggest help (Joshua Drake)
- Make help show common backslash commands (Greg Sabino Mullane)
- Add \pset format wrapped mode to wrap output to the screen width, or file/pipe output too if \pset columns is set (Bryce Nesbitt)
- Allow all supported spellings of boolean values in \pset, rather than just on and off (Bruce)
  Formerly, any string other than “off” was silently taken to mean true. psql will now complain about unrecognized spellings (but still take them as true).
- Use the pager for wide output (Bruce)
- Require a space between a one-letter backslash command and its first argument (Bernd Helmle)
  This removes a historical source of ambiguity.
- Improve tab completion support for schema-qualified and quoted identifiers (Greg Sabino Mullane)
- Add optional on/off argument for \timing (David Fetter)
- Display access control rights on multiple lines (Brendan Jurd, Andreas Scherbaum)
- Make \l show database access privileges (Andrew Gilligan)
- Make \l+ show database sizes, if permissions allow (Andrew Gilligan)
- Add the \ef command to edit function definitions (Abhijit Menon-Sen)

E.144.3.8.2. psql \d* commands

- Make \d* commands that do not have a pattern argument show system objects only if the $S$ modifier is specified (Greg Sabino Mullane, Bruce)
  The former behavior was inconsistent across different variants of \d, and in most cases it provided no easy way to see just user objects.
- Improve \d* commands to work with older PostgreSQL server versions (back to 7.4), not only the current server version (Guillaume Lelarge)
- Make \d show foreign-key constraints that reference the selected table (Kenneth D’Souza)
- Make \d on a sequence show its column values (Euler Taveira de Oliveira)
- Add column storage type and other relation options to the \d+ display (Gregory Stark, Euler Taveira de Oliveira)
- Show relation size in \dt+ output (Dickson S. Guedes)
- Show the possible values of enum types in \dT+ (David Fetter)
- Allow \dc to accept a wildcard pattern, which matches either datatype involved in the cast (Tom)
- Add a function type column to \df’s output, and add options to list only selected types of functions (David Fetter)
- Make \df not hide functions that take or return type cstring (Tom)
Previously, such functions were hidden because most of them are datatype I/O functions, which were deemed uninteresting. The new policy about hiding system functions by default makes this wart unnecessary.

E.144.3.8.3. pg_dump

- Add a `--no-tablespaces` option to `pg_dump/pg_dumpall/pg_restore` so that dumps can be restored to clusters that have non-matching tablespace layouts (Gavin Roy)
- Remove `-d` and `-D` options from `pg_dump` and `pg_dumpall` (Tom)
  These options were too frequently confused with the option to select a database name in other PostgreSQL client applications. The functionality is still available, but you must now spell out the long option name `--inserts` or `--column-inserts`.
- Remove `-i/--ignore-version` option from `pg_dump` and `pg_dumpall` (Tom)
  Use of this option does not throw an error, but it has no effect. This option was removed because the version checks are necessary for safety.
- Disable `statement_timeout` during dump and restore (Joshua Drake)
- Add `pg_dump/pg_dumpall` option `--lock-wait-timeout` (David Gould)
  This allows dumps to fail if unable to acquire a shared lock within the specified amount of time.
- Reorder `pg_dump --data-only` output to dump tables referenced by foreign keys before the referencing tables (Tom)
  This allows data loads when foreign keys are already present. If circular references make a safe ordering impossible, a `NOTICE` is issued.
- Allow `pg_dump`, `pg_dumpall`, and `pg_restore` to use a specified role (Benedek László)
- Allow `pg_restore` to use multiple concurrent connections to do the restore (Andrew)
  The number of concurrent connections is controlled by the option `--jobs`. This is supported only for custom-format archives.

E.144.3.9. Programming Tools

E.144.3.9.1. libpq

- Allow the `OID` to be specified when importing a large object, via new function `lo_import_with_oid()` (Tatsuo)
- Add “events” support (Andrew Chernow, Merlin Moncure)
  This adds the ability to register callbacks to manage private data associated with `PGconn` and `PGresult` objects.
- Improve error handling to allow the return of multiple error messages as multi-line error reports (Magnus)
Appendix E. Release Notes

- Make PQexecParams() and related functions return PGRES_EMPTY_QUERY for an empty query (Tom)
  They previously returned PGRES_COMMAND_OK.
- Document how to avoid the overhead of WSACleanup() on Windows (Andrew Chernow)
- Do not rely on Kerberos tickets to determine the default database username (Magnus)
  Previously, a Kerberos-capable build of libpq would use the principal name from any available Kerberos
  ticket as default database username, even if the connection wasn’t using Kerberos authentication. This
  was deemed inconsistent and confusing. The default username is now determined the same way with or
  without Kerberos. Note however that the database username must still match the ticket when Kerberos
  authentication is used.

E.144.3.9.2. libpq SSL (Secure Sockets Layer) support

- Fix certificate validation for SSL connections (Magnus)
  libpq now supports verifying both the certificate and the name of the server when making SSL connec-
  tions. If a root certificate is not available to use for verification, SSL connections will fail. The sslmode
  parameter is used to enable certificate verification and set the level of checking. The default is still not
  to do any verification, allowing connections to SSL-enabled servers without requiring a root certificate
  on the client.
- Support wildcard server certificates (Magnus)
  If a certificate CN starts with *, it will be treated as a wildcard when matching the hostname, allowing
  the use of the same certificate for multiple servers.
- Allow the file locations for client certificates to be specified (Mark Woodward, Alvaro, Magnus)
- Add a PQinitOpenSSL function to allow greater control over OpenSSL/libcrypto initialization (An-
  drew Chernow)
- Make libpq unregister its OpenSSL callbacks when no database connections remain open (Bruce, Mag-
  nus, Russell Smith)
  This is required for applications that unload the libpq library, otherwise invalid OpenSSL callbacks will
  remain.

E.144.3.9.3. ecpg

- Add localization support for messages (Euler Taveira de Oliveira)
- ecpg parser is now automatically generated from the server parser (Michael)
  Previously the ecpg parser was hand-maintained.

E.144.3.9.4. Server Programming Interface (SPI)

- Add support for single-use plans with out-of-line parameters (Tom)
- Add new SPI_OK_REWRITTEN return code for SPI_execute() (Heikki)
Appendix E. Release Notes

This is used when a command is rewritten to another type of command.

- Remove unnecessary inclusions from `executor/spi.h` (Tom)
  SPI-using modules might need to add some `#include` lines if they were depending on `spi.h` to include things for them.

E.144.3.10. Build Options

- Update build system to use Autoconf 2.61 (Peter)
- Require GNU bison for source code builds (Peter)
  This has effectively been required for several years, but now there is no infrastructure claiming to support other parser tools.
- Add `pg_config --htmldir` option (Peter)
- Pass `float4` by value inside the server (Zoltan Boszormenyi)
  Add configure option `--disable-float4-byval` to use the old behavior. External C functions that use old-style (version 0) call convention and pass or return `float4` values will be broken by this change, so you may need the configure option if you have such functions and don’t want to update them.
- Pass `float8, int8` and related datatypes by value inside the server on 64-bit platforms (Zoltan Boszormenyi)
  Add configure option `--disable-float8-byval` to use the old behavior. As above, this change might break old-style external C functions.
- Add configure options `--with-segsize, --with-blocksize, --with-wal-blocksize, --with-wal-segsize` (Zdenek Kotala, Tom)
  This simplifies build-time control over several constants that previously could only be changed by editing `pg_config_manual.h`.
- Allow threaded builds on Solaris 2.5 (Bruce)
- Use the system’s `getopt_long()` on Solaris (Zdenek Kotala, Tom)
  This makes option processing more consistent with what Solaris users expect.
- Add support for the Sun Studio compiler on Linux (Julius Stroffek)
- Append the major version number to the backend gettext domain, and the `soname` major version number to libraries’ gettext domain (Peter)
  This simplifies parallel installations of multiple versions.
- Add support for code coverage testing with gcov (Michelle Caisse)
- Allow out-of-tree builds on Mingw and Cygwin (Richard Evans)
- Fix the use of Mingw as a cross-compiling source platform (Peter)
E.144.3.11. Source Code

- Support 64-bit time zone data files (Heikki)
  This adds support for daylight saving time (DST) calculations beyond the year 2038.
- Deprecate use of platform’s `time_t` data type (Tom)
  Some platforms have migrated to 64-bit `time_t`, some have not, and Windows can’t make up its mind what it’s doing. Define `pg_time_t` to have the same meaning as `time_t`, but always be 64 bits (unless the platform has no 64-bit integer type), and use that type in all module APIs and on-disk data formats.
- Fix bug in handling of the time zone database when cross-compiling (Richard Evans)
- Link backend object files in one step, rather than in stages (Peter)
- Improve gettext support to allow better translation of plurals (Peter)
- Add message translation support to the PL languages (Alvaro, Peter)
- Add more DTrace probes (Robert Lor)
- Enable DTrace support on Mac OS X Leopard and other non-Solaris platforms (Robert Lor)
- Simplify and standardize conversions between C strings and `text` datums, by providing common functions for the purpose (Brendan Jurd, Tom)
- Clean up the `include/catalog/` header files so that frontend programs can include them without including `postgres.h` (Zdenek Kotala)
- Make `name` char-aligned, and suppress zero-padding of `name` entries in indexes (Tom)
- Recover better if dynamically-loaded code executes `exit()` (Tom)
- Add a hook to let plug-ins monitor the executor (Itagaki Takahiro)
- Add a hook to allow the planner’s statistics lookup behavior to be overridden (Simon Riggs)
- Add `shmem_startup_hook()` for custom shared memory requirements (Tom)
- Replace the index access method `amgetmulti` entry point with `amgetbitmap`, and extend the API for `amgettuple` to support run-time determination of operator lossiness (Heikki, Tom, Teodor)
  The API for GIN and GiST opclass `consistent` functions has been extended as well.
- Add support for partial-match searches in GIN indexes (Teodor Sigaev, Oleg Bartunov)
- Replace `pg_class` column `reltriggers` with boolean `relhastriggers` (Simon)
  Also remove unused `pg_class` columns `relukeys`, `relfkeys`, and `relrefs`.
- Add a `relistemp` column to `pg_class` to ease identification of temporary tables (Tom)
- Move platform FAQs into the main documentation (Peter)
- Prevent parser input files from being built with any conflicts (Peter)
- Add support for the `KOI8U` (Ukrainian) encoding (Peter)
- Add Japanese message translations (Japan PostgreSQL Users Group)
  This used to be maintained as a separate project.
- Fix problem when setting `LC_MESSAGES` on MSVC-built systems (Hirosi Inoue, Hiroshi Saito, Magnus)
E.144.3.12. Contrib

- Add `contrib/auto_explain` to automatically run `EXPLAIN` on queries exceeding a specified duration (Itagaki Takahiro, Tom)
- Add `contrib/btree_gin` to allow GIN indexes to handle more datatypes (Oleg, Teodor)
- Add `contrib/citext` to provide a case-insensitive, multibyte-aware text data type (David Wheeler)
- Add `contrib/pg_stat_statements` for server-wide tracking of statement execution statistics (Itagaki Takahiro)
- Add duration and query mode options to `contrib/pgbench` (Itagaki Takahiro)
- Make `contrib/pgbench` use table names `pgbench_accounts`, `pgbench_branches`, `pgbench_history`, and `pgbench_tellers`, rather than just `accounts`, `branches`, `history`, and `tellers` (Tom)
  
  This is to reduce the risk of accidentally destroying real data by running `pgbench`.
- Fix `contrib/pgstattuple` to handle tables and indexes with over 2 billion pages (Tatsuhito Kasa-hara)
- In `contrib/fuzzystrmatch`, add a version of the Levenshtein string-distance function that allows the user to specify the costs of insertion, deletion, and substitution (Volkan Yazici)
- Make `contrib/ltree` support multibyte encodings (laser)
- Enable `contrib/dblink` to use connection information stored in the SQL/MED catalogs (Joe Conway)
- Improve `contrib/dblink`’s reporting of errors from the remote server (Joe Conway)
- Make `contrib/dblink` set `client_encoding` to match the local database’s encoding (Joe Conway)
  
  This prevents encoding problems when communicating with a remote database that uses a different encoding.
- Make sure `contrib/dblink` uses a password supplied by the user, and not accidentally taken from the server’s `.pgpass` file (Joe Conway)
  
  This is a minor security enhancement.
- Add `fsm_page_contents()` to `contrib/pageinspect` (Heikki)
- Modify `get_raw_page()` to support free space map (`*_fsm`) files. Also update `contrib/pg_freespacemap`.
- Add support for multibyte encodings to `contrib/pg_trgm` (Teodor)
- Rewrite `contrib/intagg` to use new functions `array_agg()` and `unnest()` (Tom)
- Make `contrib/pg_standby` recover all available WAL before failover (Fujii Masao, Simon, Heikki)
  
  To make this work safely, you now need to set the new `recovery_end_command` option in `recovery.conf` to clean up the trigger file after failover. `pg_standby` will no longer remove the trigger file itself.
- `contrib/pg_standby`’s `-l` option is now a no-op, because it is unsafe to use a symlink (Simon)
E.145. Release 8.3.23

Release date: 2013-02-07

This release contains a variety of fixes from 8.3.22. For information about new features in the 8.3 major release, see Section E.168.

This is expected to be the last PostgreSQL release in the 8.3.X series. Users are encouraged to update to a newer release branch soon.

E.145.1. Migration to Version 8.3.23

A dump/restore is not required for those running 8.3.X.

However, if you are upgrading from a version earlier than 8.3.17, see Section E.151.

E.145.2. Changes

• Prevent execution of `enum_recv` from SQL (Tom Lane)
  The function was misdeclared, allowing a simple SQL command to crash the server. In principle an attacker might be able to use it to examine the contents of server memory. Our thanks to Sumit Soni (via Secunia SVCRP) for reporting this issue. (CVE-2013-0255)

• Fix SQL grammar to allow subscripting or field selection from a sub-SELECT result (Tom Lane)

• Protect against race conditions when scanning `pg_tablespace` (Stephen Frost, Tom Lane)
  `CREATE DATABASE` and `DROP DATABASE` could misbehave if there were concurrent updates of `pg_tablespace` entries.

• Prevent `DROP OWNED` from trying to drop whole databases or tablespaces (Álvaro Herrera)
  For safety, ownership of these objects must be reassigned, not dropped.

• Prevent misbehavior when a `RowExpr` or `XmlExpr` is parse-analyzed twice (Andres Freund, Tom Lane)
  This mistake could be user-visible in contexts such as `CREATE TABLE LIKE INCLUDING INDEXES`.

• Improve defenses against integer overflow in hashtable sizing calculations (Jeff Davis)

• Ensure that non-ASCII prompt strings are translated to the correct code page on Windows (Alexander Law, Noah Misch)
  This bug affected `psql` and some other client programs.

• Fix possible crash in `psql`’s `\?` command when not connected to a database (Meng Qingzhong)

• Fix one-byte buffer overrun in `libpq`’s `pqprintTuples` (Xi Wang)
  This ancient function is not used anywhere by PostgreSQL itself, but it might still be used by some client code.

• Rearrange configure’s tests for supplied functions so it is not fooled by bogus exports from `libedit/libreadline` (Christoph Berg)

• Ensure Windows build number increases over time (Magnus Hagander)
• Make pgxs build executables with the right .exe suffix when cross-compiling for Windows (Zoltan Boszormenyi)
• Add new timezone abbreviation FET (Tom Lane)
  This is now used in some eastern-European time zones.

E.146. Release 8.3.22

Release date: 2012-12-06

This release contains a variety of fixes from 8.3.21. For information about new features in the 8.3 major release, see Section E.168.

The PostgreSQL community will stop releasing updates for the 8.3.X release series in February 2013. Users are encouraged to update to a newer release branch soon.

E.146.1. Migration to Version 8.3.22

A dump/restore is not required for those running 8.3.X.

However, if you are upgrading from a version earlier than 8.3.17, see Section E.151.

E.146.2. Changes

• Fix multiple bugs associated with CREATE INDEX CONCURRENTLY (Andres Freund, Tom Lane)
  Fix CREATE INDEX CONCURRENTLY to use in-place updates when changing the state of an index’s pg_index row. This prevents race conditions that could cause concurrent sessions to miss updating the target index, thus resulting in corrupt concurrently-created indexes.

  Also, fix various other operations to ensure that they ignore invalid indexes resulting from a failed CREATE INDEX CONCURRENTLY command. The most important of these is VACUUM, because an auto-vacuum could easily be launched on the table before corrective action can be taken to fix or remove the invalid index.

• Avoid corruption of internal hash tables when out of memory (Hitoshi Harada)

• Fix planning of non-strict equivalence clauses above outer joins (Tom Lane)
  The planner could derive incorrect constraints from a clause equating a non-strict construct to something else, for example WHERE COALESCE(foo, 0) = 0 when foo is coming from the nullable side of an outer join.

• Improve planner’s ability to prove exclusion constraints from equivalence classes (Tom Lane)

• Fix partial-row matching in hashed subplans to handle cross-type cases correctly (Tom Lane)
  This affects multicolumn NOT IN subplans, such as WHERE (a, b) NOT IN (SELECT x, y FROM ...) when for instance b and y are int4 and int8 respectively. This mistake led to wrong answers or crashes depending on the specific datatypes involved.
• Acquire buffer lock when re-fetching the old tuple for an A\-FTER ROW UPDATE/DELETE trigger (And-

dres Freund)
In very unusual circumstances, this oversight could result in passing incorrect data to the precheck
logic for a foreign-key enforcement trigger. That could result in a crash, or in an incorrect decision
about whether to fire the trigger.
• Fix REASSIGN OWNED to handle grants on tablespaces (Álvaro Herrera)
• Ignore incorrect pg_attribute entries for system columns for views (Tom Lane)
Views do not have any system columns. However, we forgot to remove such entries when converting
a table to a view. That’s fixed properly for 9.3 and later, but in previous branches we need to defend
against existing mis-converted views.
• Fix rule printing to dump INSERT INTO table DEFAULT VALUES correctly (Tom Lane)
• Guard against stack overflow when there are too many UNION/INTERSECT/EXCEPT clauses in a query
(Tom Lane)
• Prevent platform-dependent failures when dividing the minimum possible integer value by -1 (Xi Wang,
Tom Lane)
• Fix possible access past end of string in date parsing (Hitoshi Harada)
• Produce an understandable error message if the length of the path name for a Unix-domain socket
exceeds the platform-specific limit (Tom Lane, Andrew Dunstan)
Formerly, this would result in something quite unhelpful, such as “Non-recoverable failure in name
resolution”.
• Fix memory leaks when sending composite column values to the client (Tom Lane)
• Make pg_ctl more robust about reading the postmaster.pid file (Heikki Linnakangas)
Fix race conditions and possible file descriptor leakage.
• Fix possible crash in psql if incorrectly-encoded data is presented and the client_encoding setting
is a client-only encoding, such as SJIS (Jiang Guiqing)
• Fix bugs in the restore.sql script emitted by pg_dump in tar output format (Tom Lane)
The script would fail outright on tables whose names include upper-case characters. Also, make the
script capable of restoring data in --inserts mode as well as the regular COPY mode.
• Fix pg_restore to accept POSIX-conformant tar files (Brian Weaver, Tom Lane)
The original coding of pg_dump’s tar output mode produced files that are not fully conformant with
the POSIX standard. This has been corrected for version 9.3. This patch updates previous branches so
that they will accept both the incorrect and the corrected formats, in hopes of avoiding compatibility
problems when 9.3 comes out.
• Fix pg_resetxlog to locate postmaster.pid correctly when given a relative path to the data directory
(Tom Lane)
This mistake could lead to pg_resetxlog not noticing that there is an active postmaster using the data
directory.
• Fix libpq’s lo_import() and lo_export() functions to report file I/O errors properly (Tom Lane)
• Fix ecpg’s processing of nested structure pointer variables (Muhammad Usama)
• Make contrib/pageinspect’s btree page inspection functions take buffer locks while examining pages (Tom Lane)

• Fix pgxs support for building loadable modules on AIX (Tom Lane)

  Building modules outside the original source tree didn’t work on AIX.

• Update time zone data files to tzdata release 2012j for DST law changes in Cuba, Israel, Jordan, Libya, Palestine, Western Samoa, and portions of Brazil.

E.147. Release 8.3.21

Release date: 2012-09-24

This release contains a variety of fixes from 8.3.20. For information about new features in the 8.3 major release, see Section E.168.

The PostgreSQL community will stop releasing updates for the 8.3.X release series in February 2013. Users are encouraged to update to a newer release branch soon.

E.147.1. Migration to Version 8.3.21

A dump/restore is not required for those running 8.3.X.

However, if you are upgrading from a version earlier than 8.3.17, see Section E.151.

E.147.2. Changes

• Improve page-splitting decisions in GiST indexes (Alexander Korotkov, Robert Haas, Tom Lane)

  Multi-column GiST indexes might suffer unexpected bloat due to this error.

• Fix cascading privilege revoke to stop if privileges are still held (Tom Lane)

  If we revoke a grant option from some role X, but X still holds that option via a grant from someone else, we should not recursively revoke the corresponding privilege from role(s) Y that X had granted it to.

• Fix handling of SIGFPE when PL/Perl is in use (Andres Freund)

  Perl resets the process’s SIGFPE handler to SIG_IGN, which could result in crashes later on. Restore the normal Postgres signal handler after initializing PL/Perl.

• Prevent PL/Perl from crashing if a recursive PL/Perl function is redefined while being executed (Tom Lane)

• Work around possible misoptimization in PL/Perl (Tom Lane)

  Some Linux distributions contain an incorrect version of pthread.h that results in incorrect compiled code in PL/Perl, leading to crashes if a PL/Perl function calls another one that throws an error.

• Update time zone data files to tzdata release 2012f for DST law changes in Fiji
Appendix E. Release Notes

E.148. Release 8.3.20

Release date: 2012-08-17

This release contains a variety of fixes from 8.3.19. For information about new features in the 8.3 major release, see Section E.168.

The PostgreSQL community will stop releasing updates for the 8.3.X release series in February 2013. Users are encouraged to update to a newer release branch soon.

E.148.1. Migration to Version 8.3.20

A dump/restore is not required for those running 8.3.X.

However, if you are upgrading from a version earlier than 8.3.17, see Section E.151.

E.148.2. Changes

• Prevent access to external files/URLs via XML entity references (Noah Misch, Tom Lane)
  
  `$xml_parse()` would attempt to fetch external files or URLs as needed to resolve DTD and entity references in an XML value, thus allowing unprivileged database users to attempt to fetch data with the privileges of the database server. While the external data wouldn’t get returned directly to the user, portions of it could be exposed in error messages if the data didn’t parse as valid XML; and in any case the mere ability to check existence of a file might be useful to an attacker. (CVE-2012-3489)

• Prevent access to external files/URLs via contrib/xml2’s `xslt_process()` (Peter Eisentraut)
  
  libxslt offers the ability to read and write both files and URLs through stylesheet commands, thus allowing unprivileged database users to both read and write data with the privileges of the database server. Disable that through proper use of libxslt’s security options. (CVE-2012-3488)

  Also, remove `xslt_process()`’s ability to fetch documents and stylesheets from external files/URLs. While this was a documented “feature”, it was long regarded as a bad idea. The fix for CVE-2012-3489 broke that capability, and rather than expend effort on trying to fix it, we’re just going to summarily remove it.

• Prevent too-early recycling of btree index pages (Noah Misch)
  
  When we allowed read-only transactions to skip assigning XIDs, we introduced the possibility that a deleted btree page could be recycled while a read-only transaction was still in flight to it. This would result in incorrect index search results. The probability of such an error occurring in the field seems very low because of the timing requirements, but nonetheless it should be fixed.

• Fix crash-safety bug with newly-created-or-reset sequences (Tom Lane)
  
  If `ALTER SEQUENCE` was executed on a freshly created or reset sequence, and then precisely one `nextval()` call was made on it, and then the server crashed, WAL replay would restore the sequence to a state in which it appeared that no `nextval()` had been done, thus allowing the first sequence value to be returned again by the next `nextval()` call. In particular this could manifest for serial columns, since creation of a serial column’s sequence includes an `ALTER SEQUENCE OWNED BY` step.

• Ensure the `backup_label` file is `fsync`d after `pg_start_backup()` (Dave Kerr)
• Back-patch 9.1 improvement to compress the fsync request queue (Robert Haas)
  This improves performance during checkpoints. The 9.1 change has now seen enough field testing to
  seem safe to back-patch.
• Only allow autovacuum to be auto-canceled by a directly blocked process (Tom Lane)
  The original coding could allow inconsistent behavior in some cases; in particular, an autovacuum could
  get canceled after less than deadlock_timeout grace period.
• Improve logging of autovacuum cancels (Robert Haas)
• Fix log collector so that log_truncate_on_rotation works during the very first log rotation after
  server start (Tom Lane)
• Ensure that a whole-row reference to a subquery doesn’t include any extra GROUP BY or ORDER BY
  columns (Tom Lane)
• Disallow copying whole-row references in CHECK constraints and index definitions during CREATE
  TABLE (Tom Lane)
  This situation can arise in CREATE TABLE with LIKE or INHERITS. The copied whole-row variable
  was incorrectly labeled with the row type of the original table not the new one. Rejecting the case
  seems reasonable for LIKE, since the row types might well diverge later. For INHERITS we should
  ideally allow it, with an implicit coercion to the parent table’s row type; but that will require more work
  than seems safe to back-patch.
• Fix memory leak in ARRAY(SELECT ...) subqueries (Heikki Linnakangas, Tom Lane)
• Fix extraction of common prefixes from regular expressions (Tom Lane)
  The code could get confused by quantified parenthesized subexpressions, such as ^{foo}?bar. This
  would lead to incorrect index optimization of searches for such patterns.
• Report errors properly in contrib/xml2’s xslt_process() (Tom Lane)
• Update time zone data files to tzdata release 2012e for DST law changes in Morocco and Tokelau

E.149. Release 8.3.19

Release date: 2012-06-04
This release contains a variety of fixes from 8.3.18. For information about new features in the 8.3 major
release, see Section E.168.

E.149.1. Migration to Version 8.3.19
A dump/restore is not required for those running 8.3.X.
However, if you are upgrading from a version earlier than 8.3.17, see Section E.151.
E.149.2. Changes

- Fix incorrect password transformation in contrib/pgcrypto's DES crypt() function (Solar Designer)
  
  If a password string contained the byte value 0x80, the remainder of the password was ignored, causing the password to be much weaker than it appeared. With this fix, the rest of the string is properly included in the DES hash. Any stored password values that are affected by this bug will thus no longer match, so the stored values may need to be updated. (CVE-2012-2143)

- Ignore SECURITY DEFINER and SET attributes for a procedural language’s call handler (Tom Lane)
  
  Applying such attributes to a call handler could crash the server. (CVE-2012-2655)

- Allow numeric timezone offsets in timestamp input to be up to 16 hours away from UTC (Tom Lane)
  
  Some historical time zones have offsets larger than 15 hours, the previous limit. This could result in dumped data values being rejected during reload.

- Fix timestamp conversion to cope when the given time is exactly the last DST transition time for the current timezone (Tom Lane)
  
  This oversight has been there a long time, but was not noticed previously because most DST-using zones are presumed to have an indefinite sequence of future DST transitions.

- Fix text to name and char to name casts to perform string truncation correctly in multibyte encodings (Karl Schnaitter)

- Fix memory copying bug in to_tsquery() (Heikki Linnakangas)

- Fix slow session startup when pg_attribute is very large (Tom Lane)
  
  If pg_attribute exceeds one-fourth of shared_buffers, cache rebuilding code that is sometimes needed during session start would trigger the synchronized-scan logic, causing it to take many times longer than normal. The problem was particularly acute if many new sessions were starting at once.

- Ensure sequential scans check for query cancel reasonably often (Merlin Moncure)
  
  A scan encountering many consecutive pages that contain no live tuples would not respond to interrupts meanwhile.

- Ensure the Windows implementation of PGSemaphoreLock() clears ImmediateInterruptOK before returning (Tom Lane)
  
  This oversight meant that a query-cancel interrupt received later in the same query could be accepted at an unsafe time, with unpredictable but not good consequences.

- Show whole-row variables safely when printing views or rules (Abbas Butt, Tom Lane)
  
  Corner cases involving ambiguous names (that is, the name could be either a table or column name of the query) were printed in an ambiguous way, risking that the view or rule would be interpreted differently after dump and reload. Avoid the ambiguous case by attaching a no-op cast.

- Ensure autovacuum worker processes perform stack depth checking properly (Heikki Linnakangas)
  
  Previously, infinite recursion in a function invoked by auto-analyze could crash worker processes.

- Fix logging collector to not lose log coherency under high load (Andrew Dunstan)
  
  The collector previously could fail to reassemble large messages if it got too busy.
Appendix E. Release Notes

- Fix logging collector to ensure it will restart file rotation after receiving SIGHUP (Tom Lane)
- Fix PL/pgSQL's GET DIAGNOSTICS command when the target is the function's first variable (Tom Lane)
- Fix several performance problems in pg_dump when the database contains many objects (Jeff Janes, Tom Lane)
  
  pg_dump could get very slow if the database contained many schemas, or if many objects are in dependency loops, or if there are many owned sequences.
- Fix contrib/dblink's dblink_exec() to not leak temporary database connections upon error (Tom Lane)
- Update time zone data files to tzdata release 2012c for DST law changes in Antarctica, Armenia, Chile, Cuba, Falkland Islands, Gaza, Haiti, Hebron, Morocco, Syria, and Tokelau Islands; also historical corrections for Canada.

E.150. Release 8.3.18

Release date: 2012-02-27

This release contains a variety of fixes from 8.3.17. For information about new features in the 8.3 major release, see Section E.168.

E.150.1. Migration to Version 8.3.18

A dump/restore is not required for those running 8.3.X. However, if you are upgrading from a version earlier than 8.3.17, see Section E.151.

E.150.2. Changes

- Require execute permission on the trigger function for CREATE TRIGGER (Robert Haas)
  
  This missing check could allow another user to execute a trigger function with forged input data, by installing it on a table he owns. This is only of significance for trigger functions marked SECURITY DEFINER, since otherwise trigger functions run as the table owner anyway. (CVE-2012-0866)
- Convert newlines to spaces in names written in pg_dump comments (Robert Haas)
  
  pg_dump was incautious about sanitizing object names that are emitted within SQL comments in its output script. A name containing a newline would at least render the script syntactically incorrect. Maliciously crafted object names could present a SQL injection risk when the script is reloaded. (CVE-2012-0868)
- Fix btree index corruption from insertions concurrent with vacuuming (Tom Lane)
  
  An index page split caused by an insertion could sometimes cause a concurrently-running VACUUM to miss removing index entries that it should remove. After the corresponding table rows are removed,
Appendix E. Release Notes

the dangling index entries would cause errors (such as “could not read block N in file ...”) or worse, silently wrong query results after unrelated rows are re-inserted at the now-free table locations. This bug has been present since release 8.2, but occurs so infrequently that it was not diagnosed until now. If you have reason to suspect that it has happened in your database, reindexing the affected index will fix things.

• Allow non-existent values for some settings in ALTER USER/DATABASE SET (Heikki Linnakangas)

  Allow default_text_search_config, default_tablespace, and temp_tablespaces to be set to names that are not known. This is because they might be known in another database where the setting is intended to be used, or for the tablespace cases because the tablespace might not be created yet. The same issue was previously recognized for search_path, and these settings now act like that one.

• Track the OID counter correctly during WAL replay, even when it wraps around (Tom Lane)

  Previously the OID counter would remain stuck at a high value until the system exited replay mode. The practical consequences of that are usually nil, but there are scenarios wherein a standby server that’s been promoted to master might take a long time to advance the OID counter to a reasonable value once values are needed.

• Fix regular expression back-references with * attached (Tom Lane)

  Rather than enforcing an exact string match, the code would effectively accept any string that satisfies the pattern sub-expression referenced by the back-reference symbol.

  A similar problem still afflicts back-references that are embedded in a larger quantified expression, rather than being the immediate subject of the quantifier. This will be addressed in a future PostgreSQL release.

• Fix recently-introduced memory leak in processing of inet/cidr values (Heikki Linnakangas)

  A patch in the December 2011 releases of PostgreSQL caused memory leakage in these operations, which could be significant in scenarios such as building a btree index on such a column.

• Avoid double close of file handle in syslogger on Windows (MauMau)

  Ordinarily this error was invisible, but it would cause an exception when running on a debug version of Windows.

• Fix I/O-conversion-related memory leaks in plpgsql (Andres Freund, Jan Urbanski, Tom Lane)

  Certain operations would leak memory until the end of the current function.

• Improve pg_dump’s handling of inherited table columns (Tom Lane)

  pg_dump mishandled situations where a child column has a different default expression than its parent column. If the default is textually identical to the parent’s default, but not actually the same (for instance, because of schema search path differences) it would not be recognized as different, so that after dump and restore the child would be allowed to inherit the parent’s default. Child columns that are NOT NULL where their parent is not could also be restored subtly incorrectly.

• Fix pg_restore’s direct-to-database mode for INSERT-style table data (Tom Lane)

  Direct-to-database restores from archive files made with --inserts or --column-inserts options fail when using pg_restore from a release dated September or December 2011, as a result of an oversight in a fix for another problem. The archive file itself is not at fault, and text-mode output is okay.

• Fix error in contrib/intarray’s int[] & int[] operator (Guillaume Lelarge)
If the smallest integer the two input arrays have in common is 1, and there are smaller values in either array, then 1 would be incorrectly omitted from the result.

• Fix error detection in contrib/pgcrypto’s encrypt_iv() and decrypt_iv() (Marko Kreen)
  These functions failed to report certain types of invalid-input errors, and would instead return random garbage values for incorrect input.

• Fix one-byte buffer overrun in contrib/test_parser (Paul Guyot)
  The code would try to read one more byte than it should, which would crash in corner cases. Since contrib/test_parser is only example code, this is not a security issue in itself, but bad example code is still bad.

• Use __sync_lock_test_and_set() for spinlocks on ARM, if available (Martin Pitt)
  This function replaces our previous use of the SWPB instruction, which is deprecated and not available on ARMv6 and later. Reports suggest that the old code doesn’t fail in an obvious way on recent ARM boards, but simply doesn’t interlock concurrent accesses, leading to bizarre failures in multiprocess operation.

• Use -fexcess-precision=standard option when building with gcc versions that accept it (Andrew Dunstan)
  This prevents assorted scenarios wherein recent versions of gcc will produce creative results.

• Allow use of threaded Python on FreeBSD (Chris Rees)
  Our configure script previously believed that this combination wouldn’t work; but FreeBSD fixed the problem, so remove that error check.

E.151. Release 8.3.17

Release date: 2011-12-05
This release contains a variety of fixes from 8.3.16. For information about new features in the 8.3 major release, see Section E.168.

E.151.1. Migration to Version 8.3.17

A dump/restore is not required for those running 8.3.X.
However, a longstanding error was discovered in the definition of the information_schema.referential_constraints view. If you rely on correct results from that view, you should replace its definition as explained in the first changelog item below.
Also, if you are upgrading from a version earlier than 8.3.8, see Section E.160.

E.151.2. Changes

• Fix bugs in information_schema.referential_constraints view (Tom Lane)
This view was being insufficiently careful about matching the foreign-key constraint to the depended-on primary or unique key constraint. That could result in failure to show a foreign key constraint at all, or showing it multiple times, or claiming that it depends on a different constraint than the one it really does.

Since the view definition is installed by initdb, merely upgrading will not fix the problem. If you need to fix this in an existing installation, you can (as a superuser) drop the `information_schema` schema then re-create it by sourcing `SHAREDIR/information_schema.sql`. (Run `pg_config --sharedir` if you’re uncertain where `SHAREDIR` is.) This must be repeated in each database to be fixed.

- **Fix TOAST-related data corruption during** `CREATE TABLE dest AS SELECT * FROM src` or `INSERT INTO dest SELECT * FROM src` *(Tom Lane)*

  If a table has been modified by `ALTER TABLE ADD COLUMN`, attempts to copy its data verbatim to another table could produce corrupt results in certain corner cases. The problem can only manifest in this precise form in 8.4 and later, but we patched earlier versions as well in case there are other code paths that could trigger the same bug.

- **Fix race condition during toast table access from stale syscache entries** *(Tom Lane)*

  The typical symptom was transient errors like “missing chunk number 0 for toast value NNNNN in `pg_toast_2619`”, where the cited toast table would always belong to a system catalog.

- **Make `DatumGetInetP()` unpack inet datums that have a 1-byte header, and add a new macro, `DatumGetInetPP()`**, that does not *(Heikki Linnakangas)*

  This change affects no core code, but might prevent crashes in add-on code that expects `DatumGetInetP()` to produce an unpacked datum as per usual convention.

- **Improve locale support in `money` type’s input and output** *(Tom Lane)*

  Aside from not supporting all standard `lc_monetary` formatting options, the input and output functions were inconsistent, meaning there were locales in which dumped `money` values could not be re-read.

- **Don’t let `transform_null_equals` affect `CASE foo WHEN NULL ...` constructs** *(Heikki Linnakangas)*

  `transform_null_equals` is only supposed to affect `foo = NULL` expressions written directly by the user, not equality checks generated internally by this form of `CASE`.

- **Change foreign-key trigger creation order to better support self-referential foreign keys** *(Tom Lane)*

  For a cascading foreign key that references its own table, a row update will fire both the `ON UPDATE` trigger and the `CHECK` trigger as one event. The `ON UPDATE` trigger must execute first, else the `CHECK` will check a non-final state of the row and possibly throw an inappropriate error. However, the firing order of these triggers is determined by their names, which generally sort in creation order since the triggers have auto-generated names following the convention “RI_ConstraintTrigger_NNNNN”. A proper fix would require modifying that convention, which we will do in 9.2, but it seems risky to change it in existing releases. So this patch just changes the creation order of the triggers. Users encountering this type of error should drop and re-create the foreign key constraint to get its triggers into the right order.

- **Avoid floating-point underflow while tracking buffer allocation rate** *(Greg Matthews)*

  While harmless in itself, on certain platforms this would result in annoying kernel log messages.

- **Preserve blank lines within commands in `psql`’s command history** *(Robert Haas)*
The former behavior could cause problems if an empty line was removed from within a string literal, for example.

- Fix `pg_dump` to dump user-defined casts between auto-generated types, such as table rowtypes (Tom Lane)
- Use the preferred version of `xsubpp` to build PL/Perl, not necessarily the operating system’s main copy (David Wheeler and Alex Hunsaker)
- Fix incorrect coding in `contrib/dict_int` and `contrib/dict_xsyn` (Tom Lane)
  Some functions incorrectly assumed that memory returned by `palloc()` is guaranteed zeroed.
- Honor query cancel interrupts promptly in `pgstatindex()` (Robert Haas)
- Ensure VPATH builds properly install all server header files (Peter Eisentraut)
- Shorten file names reported in verbose error messages (Peter Eisentraut)
  Regular builds have always reported just the name of the C file containing the error message call, but VPATH builds formerly reported an absolute path name.
- Fix interpretation of Windows timezone names for Central America (Tom Lane)
  Map “Central America Standard Time” to `CST6`, not `CST6CDT`, because DST is generally not observed anywhere in Central America.
- Update time zone data files to `tzdata` release 2011n for DST law changes in Brazil, Cuba, Fiji, Palestine, Russia, and Samoa; also historical corrections for Alaska and British East Africa.

### E.152. Release 8.3.16

**Release date:** 2011-09-26

This release contains a variety of fixes from 8.3.15. For information about new features in the 8.3 major release, see Section E.168.

### E.152.1. Migration to Version 8.3.16

A dump/restore is not required for those running 8.3.X. However, if you are upgrading from a version earlier than 8.3.8, see Section E.160.

### E.152.2. Changes

- Fix bugs in indexing of in-doubt HOT-updated tuples (Tom Lane)
  These bugs could result in index corruption after reindexing a system catalog. They are not believed to affect user indexes.
- Fix multiple bugs in GiST index page split processing (Heikki Linnakangas)
  The probability of occurrence was low, but these could lead to index corruption.
• Fix possible buffer overrun in tsvector_concat() (Tom Lane)
  The function could underestimate the amount of memory needed for its result, leading to server crashes.
• Fix crash in xml_recv when processing a “standalone” parameter (Tom Lane)
• Avoid possibly accessing off the end of memory in ANALYZE and in SJIS-2004 encoding conversion
  (Noah Misch)
  This fixes some very-low-probability server crash scenarios.
• Fix race condition in relcache init file invalidation (Tom Lane)
  There was a window wherein a new backend process could read a stale init file but miss the inval
  messages that would tell it the data is stale. The result would be bizarre failures in catalog accesses,
  typically “could not read block 0 in file ...” later during startup.
• Fix memory leak at end of a GiST index scan (Tom Lane)
  Commands that perform many separate GiST index scans, such as verification of a new GiST-based
  exclusion constraint on a table already containing many rows, could transiently require large amounts
  of memory due to this leak.
• Fix performance problem when constructing a large, lossy bitmap (Tom Lane)
• Fix array- and path-creating functions to ensure padding bytes are zeroes (Tom Lane)
  This avoids some situations where the planner will think that semantically-equal constants are not equal,
  resulting in poor optimization.
• Work around gcc 4.6.0 bug that breaks WAL replay (Tom Lane)
  This could lead to loss of committed transactions after a server crash.
• Fix dump bug for VALUES in a view (Tom Lane)
• Disallow SELECT FOR UPDATE/SHARE on sequences (Tom Lane)
  This operation doesn’t work as expected and can lead to failures.
• Defend against integer overflow when computing size of a hash table (Tom Lane)
• Fix cases where CLUSTER might attempt to access already-removed TOAST data (Tom Lane)
• Fix portability bugs in use of credentials control messages for “peer” authentication (Tom Lane)
• Fix SSPI login when multiple roundtrips are required (Ahmed Shinwari, Magnus Hagander)
  The typical symptom of this problem was “The function requested is not supported” errors during SSPI
  login.
• Fix typo in pg_srand48 seed initialization (Andres Freund)
  This led to failure to use all bits of the provided seed. This function is not used on most platforms (only
  those without srand), and the potential security exposure from a less-random-than-expected seed
  seems minimal in any case.
• Avoid integer overflow when the sum of LIMIT and OFFSET values exceeds 2^63 (Heikki Linnakangas)
• Add overflow checks to int4 and int8 versions of generate_series() (Robert Haas)
• Fix trailing-zero removal in to_char() (Marti Raudsepp)
In a format with FM and no digit positions after the decimal point, zeroes to the left of the decimal point could be removed incorrectly.

- Fix `pg_size_pretty()` to avoid overflow for inputs close to $2^{63}$ (Tom Lane)
- In `pg_ctl`, support silent mode for service registrations on Windows (MauMau)
- Fix `psql`'s counting of script file line numbers during `COPY` from a different file (Tom Lane)
- Fix `pg_restore`'s direct-to-database mode for `standard_conforming_strings` (Tom Lane)
  `pg_restore` could emit incorrect commands when restoring directly to a database server from an archive file that had been made with `standard_conforming_strings` set to on.
- Fix write-past-buffer-end and memory leak in `libpq`'s LDAP service lookup code (Albe Laurenz)
- In `libpq`, avoid failures when using nonblocking I/O and an SSL connection (Martin Pihlak, Tom Lane)
- Improve `libpq`'s handling of failures during connection startup (Tom Lane)
  In particular, the response to a server report of `fork()` failure during SSL connection startup is now saner.
- Improve `libpq`'s error reporting for SSL failures (Tom Lane)
- Make `ecpglib` write double values with 15 digits precision (Akira Kurosawa)
- In `ecpglib`, be sure `LC_NUMERIC` setting is restored after an error (Michael Meskes)
- Apply upstream fix for blowfish signed-character bug (CVE-2011-2483) (Tom Lane)
  `contrib/pg_crypto`'s blowfish encryption code could give wrong results on platforms where char is signed (which is most), leading to encrypted passwords being weaker than they should be.
- Fix memory leak in `contrib/seg` (Heikki Linnakangas)
- Fix `pgstatindex()` to give consistent results for empty indexes (Tom Lane)
- Allow building with perl 5.14 (Alex Hunsaker)
- Update configure script's method for probing existence of system functions (Tom Lane)
  The version of autoconf we used in 8.3 and 8.2 could be fooled by compilers that perform link-time optimization.
- Fix assorted issues with build and install file paths containing spaces (Tom Lane)
- Update time zone data files to `tzdata` release 2011i for DST law changes in Canada, Egypt, Russia, Samoa, and South Sudan.

### E.153. Release 8.3.15

**Release date:** 2011-04-18

This release contains a variety of fixes from 8.3.14. For information about new features in the 8.3 major release, see Section E.168.
Appendix E. Release Notes

E.153.1. Migration to Version 8.3.15
A dump/restore is not required for those running 8.3.X. However, if you are upgrading from a version earlier than 8.3.8, see Section E.160.

E.153.2. Changes

• Disallow including a composite type in itself (Tom Lane)
  This prevents scenarios wherein the server could recurse infinitely while processing the composite type. While there are some possible uses for such a structure, they don’t seem compelling enough to justify the effort required to make sure it always works safely.

• Avoid potential deadlock during catalog cache initialization (Nikhil Sontakke)
  In some cases the cache loading code would acquire share lock on a system index before locking the index’s catalog. This could deadlock against processes trying to acquire exclusive locks in the other, more standard order.

• Fix dangling-pointer problem in BEFORE_ROW_UPDATE trigger handling when there was a concurrent update to the target tuple (Tom Lane)
  This bug has been observed to result in intermittent “cannot extract system attribute from virtual tuple” failures while trying to do UPDATE RETURNING ctid. There is a very small probability of more serious errors, such as generating incorrect index entries for the updated tuple.

• Disallow DROP TABLE when there are pending deferred trigger events for the table (Tom Lane)
  Formerly the DROP would go through, leading to “could not open relation with OID nnn” errors when the triggers were eventually fired.

• Fix PL/Python memory leak involving array slices (Daniel Popowich)

• Fix pg_restore to cope with long lines (over 1KB) in TOC files (Tom Lane)

• Put in more safeguards against crashing due to division-by-zero with overly enthusiastic compiler optimization (Aurelien Jarno)

• Support use of dlopen() in FreeBSD and OpenBSD on MIPS (Tom Lane)
  There was a hard-wired assumption that this system function was not available on MIPS hardware on these systems. Use a compile-time test instead, since more recent versions have it.

• Fix compilation failures on HP-UX (Heikki Linnakangas)

• Fix version-incompatibility problem with libintl on Windows (Hiroshi Inoue)

• Fix usage of xcopy in Windows build scripts to work correctly under Windows 7 (Andrew Dunstan)
  This affects the build scripts only, not installation or usage.

• Fix path separator used by pg_regress on Cygwin (Andrew Dunstan)

• Update time zone data files to tzdata release 2011f for DST law changes in Chile, Cuba, Falkland Islands, Morocco, Samoa, and Turkey; also historical corrections for South Australia, Alaska, and Hawaii.
E.154. Release 8.3.14

Release date: 2011-01-31

This release contains a variety of fixes from 8.3.13. For information about new features in the 8.3 major release, see Section E.168.

E.154.1. Migration to Version 8.3.14

A dump/restore is not required for those running 8.3.X. However, if you are upgrading from a version earlier than 8.3.8, see Section E.160.

E.154.2. Changes

- Avoid failures when EXPLAIN tries to display a simple-form CASE expression (Tom Lane)
  If the CASE’s test expression was a constant, the planner could simplify the CASE into a form that confused the expression-display code, resulting in “unexpected CASE WHEN clause” errors.
- Fix assignment to an array slice that is before the existing range of subscripts (Tom Lane)
  If there was a gap between the newly added subscripts and the first pre-existing subscript, the code mis-calculated how many entries needed to be copied from the old array’s null bitmap, potentially leading to data corruption or crash.
- Avoid unexpected conversion overflow in planner for very distant date values (Tom Lane)
  The date type supports a wider range of dates than can be represented by the timestamp types, but the planner assumed it could always convert a date to timestamp with impunity.
- Fix pg_restore’s text output for large objects (BLOBs) when standard_conforming_strings is on (Tom Lane)
  Although restoring directly to a database worked correctly, string escaping was incorrect if pg_restore was asked for SQL text output and standard_conforming_strings had been enabled in the source database.
- Fix erroneous parsing of tsquery values containing ... & !(subexpression) | ... (Tom Lane)
  Queries containing this combination of operators were not executed correctly. The same error existed in contrib/intarray’s query_int type and contrib/ltrie’s ltxquery type.
- Fix buffer overrun in contrib/intarray’s input function for the query_int type (Apple)
  This bug is a security risk since the function’s return address could be overwritten. Thanks to Apple Inc’s security team for reporting this issue and supplying the fix. (CVE-2010-4015)
- Fix bug in contrib/seg’s GiST picksplit algorithm (Alexander Korotkov)
  This could result in considerable inefficiency, though not actually incorrect answers, in a GiST index on a seg column. If you have such an index, consider REINDEXing it after installing this update. (This is identical to the bug that was fixed in contrib/cube in the previous update.)
E.155. Release 8.3.13

Release date: 2010-12-16

This release contains a variety of fixes from 8.3.12. For information about new features in the 8.3 major release, see Section E.168.

E.155.1. Migration to Version 8.3.13

A dump/restore is not required for those running 8.3.X. However, if you are upgrading from a version earlier than 8.3.8, see Section E.160.

E.155.2. Changes

- Force the default wal_sync_method to be fdatasync on Linux (Tom Lane, Marti Raudsepp)
  
  The default on Linux has actually been fdatasync for many years, but recent kernel changes caused PostgreSQL to choose open_datasync instead. This choice did not result in any performance improvement, and caused outright failures on certain filesystems, notably ext4 with the data=journal mount option.

- Fix assorted bugs in WAL replay logic for GIN indexes (Tom Lane)
  
  This could result in “bad buffer id: 0” failures or corruption of index contents during replication.

- Fix recovery from base backup when the starting checkpoint WAL record is not in the same WAL segment as its redo point (Jeff Davis)

- Fix persistent slowdown of autovacuum workers when multiple workers remain active for a long time (Tom Lane)
  
  The effective vacuum_cost_limit for an autovacuum worker could drop to nearly zero if it processed enough tables, causing it to run extremely slowly.

- Add support for detecting register-stack overrun on IA64 (Tom Lane)
  
  The IA64 architecture has two hardware stacks. Full prevention of stack-overrun failures requires checking both.

- Add a check for stack overflow in copyObject() (Tom Lane)
  
  Certain code paths could crash due to stack overflow given a sufficiently complex query.

- Fix detection of page splits in temporary GiST indexes (Heikki Linnakangas)
  
  It is possible to have a “concurrent” page split in a temporary index, if for example there is an open cursor scanning the index when an insertion is done. GiST failed to detect this case and hence could deliver wrong results when execution of the cursor continued.

- Avoid memory leakage while ANALYZE'ing complex index expressions (Tom Lane)

- Ensure an index that uses a whole-row Var still depends on its table (Tom Lane)
  
  An index declared like create index i on t (foo(t.*) would not automatically get dropped when its table was dropped.
Appendix E. Release Notes

- Do not “inline” a SQL function with multiple \texttt{OUT} parameters (Tom Lane)
  This avoids a possible crash due to loss of information about the expected result rowtype.

- Behave correctly if \texttt{ORDER BY}, \texttt{LIMIT}, \texttt{FOR UPDATE}, or \texttt{WITH} is attached to the \texttt{VALUES} part of \texttt{INSERT ... VALUES} (Tom Lane)

- Fix constant-folding of \texttt{COALESCE()} expressions (Tom Lane)
  The planner would sometimes attempt to evaluate sub-expressions that in fact could never be reached, possibly leading to unexpected errors.

- Fix postmaster crash when connection acceptance (\texttt{accept()} or one of the calls made immediately after it) fails, and the postmaster was compiled with GSSAPI support (Alexander Chernikov)

- Fix missed unlink of temporary files when \texttt{log_temp_files} is active (Tom Lane)
  If an error occurred while attempting to emit the log message, the unlink was not done, resulting in accumulation of temp files.

- Add print functionality for \texttt{InhRelation} nodes (Tom Lane)
  This avoids a failure when \texttt{debug_print_parse} is enabled and certain types of query are executed.

- Fix incorrect calculation of distance from a point to a horizontal line segment (Tom Lane)
  This bug affected several different geometric distance-measurement operators.

- Fix PL/pgSQL’s handling of “simple” expressions to not fail in recursion or error-recovery cases (Tom Lane)

- Fix PL/Python’s handling of set-returning functions (Jan Urbanski)

- Fix bug in \texttt{contrib/cube}'s GiST picksplit algorithm (Alexander Korotkov)
  This could result in considerable inefficiency, though not actually incorrect answers, in a GiST index on a \texttt{cube} column. If you have such an index, consider \texttt{REINDEX}ing it after installing this update.

- Don’t emit “identifier will be truncated” notices in \texttt{contrib/dblink} except when creating new connections (Itagaki Takahiro)

- Fix potential coredump on missing public key in \texttt{contrib/pgcrypto} (Marti Raudsepp)

- Fix memory leak in \texttt{contrib/xml2}'s XPath query functions (Tom Lane)

- Update time zone data files to \texttt{tzdata} release 2010\texttt{o} for DST law changes in Fiji and Samoa; also historical corrections for Hong Kong.

E.156. Release 8.3.12

\textbf{Release date:} 2010-10-04

This release contains a variety of fixes from 8.3.11. For information about new features in the 8.3 major release, see Section E.168.
E.156.1. Migration to Version 8.3.12

A dump/restore is not required for those running 8.3.X. However, if you are upgrading from a version earlier than 8.3.8, see Section E.160.

E.156.2. Changes

- Use a separate interpreter for each calling SQL userid in PL/Perl and PL/Tcl (Tom Lane)
  
  This change prevents security problems that can be caused by subverting Perl or Tcl code that will be executed later in the same session under another SQL user identity (for example, within a `SECURITY DEFINER` function). Most scripting languages offer numerous ways that that might be done, such as redefining standard functions or operators called by the target function. Without this change, any SQL user with Perl or Tcl language usage rights can do essentially anything with the SQL privileges of the target function’s owner.

  The cost of this change is that intentional communication among Perl and Tcl functions becomes more difficult. To provide an escape hatch, PL/PerlU and PL/TclU functions continue to use only one interpreter per session. This is not considered a security issue since all such functions execute at the trust level of a database superuser already.

  It is likely that third-party procedural languages that claim to offer trusted execution have similar security issues. We advise contacting the authors of any PL you are depending on for security-critical purposes.

  Our thanks to Tim Bunce for pointing out this issue (CVE-2010-3433).

- Prevent possible crashes in `pg_get_expr()` by disallowing it from being called with an argument that is not one of the system catalog columns it’s intended to be used with (Heikki Linnakangas, Tom Lane)

- Treat exit code 128 (`ERROR_WAIT_NO_CHILDREN`) as non-fatal on Windows (Magnus Hagander)
  
  Under high load, Windows processes will sometimes fail at startup with this error code. Formerly the postmaster treated this as a panic condition and restarted the whole database, but that seems to be an overreaction.

- Fix incorrect usage of non-strict OR join clauses in Append indexscans (Tom Lane)
  
  This is a back-patch of an 8.4 fix that was missed in the 8.3 branch. This corrects an error introduced in 8.3.8 that could cause incorrect results for outer joins when the inner relation is an inheritance tree or `UNION ALL` subquery.

- Fix possible duplicate scans of `UNION ALL` member relations (Tom Lane)

- Fix “cannot handle unplanned sub-select” error (Tom Lane)
  
  This occurred when a sub-select contains a join alias reference that expands into an expression containing another sub-select.

- Fix failure to mark cached plans as transient (Tom Lane)
  
  If a plan is prepared while `CREATE INDEX CONCURRENTLY` is in progress for one of the referenced tables, it is supposed to be re-planned once the index is ready for use. This was not happening reliably.
Appendix E. Release Notes

- Reduce PANIC to ERROR in some occasionally-reported btree failure cases, and provide additional detail in the resulting error messages (Tom Lane)
  This should improve the system’s robustness with corrupted indexes.
- Prevent show_session_authorization() from crashing within autovacuum processes (Tom Lane)
- Defend against functions returning setof record where not all the returned rows are actually of the same rowtype (Tom Lane)
- Fix possible failure when hashing a pass-by-reference function result (Tao Ma, Tom Lane)
- Improve merge join’s handling of NULLs in the join columns (Tom Lane)
  A merge join can now stop entirely upon reaching the first NULL, if the sort order is such that NULLs sort high.
- Take care to fsync the contents of lockfiles (both postmaster.pid and the socket lockfile) while writing them (Tom Lane)
  This omission could result in corrupted lockfile contents if the machine crashes shortly after postmaster start. That could in turn prevent subsequent attempts to start the postmaster from succeeding, until the lockfile is manually removed.
- Avoid recursion while assigning XIDs to heavily-nested subtransactions (Andres Freund, Robert Haas)
  The original coding could result in a crash if there was limited stack space.
- Avoid holding open old WAL segments in the walwriter process (Magnus Hagander, Heikki Linnakan-gas)
  The previous coding would prevent removal of no-longer-needed segments.
- Fix log_line_prefix’s \%i escape, which could produce junk early in backend startup (Tom Lane)
- Fix possible data corruption in ALTER TABLE ... SET TABLESPACE when archiving is enabled (Jeff Davis)
- Allow CREATE DATABASE and ALTER DATABASE ... SET TABLESPACE to be interrupted by query-cancel (Guillaume Lelarge)
- Fix REASSIGN OWNED to handle operator classes and families (Asko Tiidumaa)
- Fix possible core dump when comparing two empty tsquery values (Tom Lane)
- Fix LIKE’s handling of patterns containing \% followed by _ (Tom Lane)
  We’ve fixed this before, but there were still some incorrectly-handled cases.
- In PL/Python, defend against null pointer results from PyObject_AsVoidPtr and PyObject_FromVoidPtr (Peter Eisentraut)
- Make psql recognize DISCARD ALL as a command that should not be encased in a transaction block in autocommit-off mode (Itagaki Takahiro)
- Fix ecpg to process data from RETURNING clauses correctly (Michael Meskes)
- Improve contrib/dblink’s handling of tables containing dropped columns (Tom Lane)
- Fix connection leak after “duplicate connection name” errors in contrib/dblink (Itagaki Takahiro)
- Fix contrib/dblink to handle connection names longer than 62 bytes correctly (Itagaki Takahiro)
- Add hstore(text, text) function to contrib/hstore (Robert Haas)
This function is the recommended substitute for the now-deprecated `=>` operator. It was back-patched so that future-proofed code can be used with older server versions. Note that the patch will be effective only after `contrib/hstore` is installed or reinstalled in a particular database. Users might prefer to execute the `CREATE FUNCTION` command by hand, instead.

- Update build infrastructure and documentation to reflect the source code repository’s move from CVS to Git (Magnus Hagander and others)
- Update time zone data files to tzdata release 2010l for DST law changes in Egypt and Palestine; also historical corrections for Finland.

This change also adds new names for two Micronesian timezones: Pacific/Chuuk is now preferred over Pacific/Truk (and the preferred abbreviation is CHUT not TRUT) and Pacific/Pohnpei is preferred over Pacific/Ponape.

- Make Windows’ “N. Central Asia Standard Time” timezone map to Asia/Novosibirsk, not Asia/Almaty (Magnus Hagander)

Microsoft changed the DST behavior of this zone in the timezone update from KB976098. Asia/Novosibirsk is a better match to its new behavior.

### E.157. Release 8.3.11

**Release date:** 2010-05-17

This release contains a variety of fixes from 8.3.10. For information about new features in the 8.3 major release, see Section E.168.

#### E.157.1. Migration to Version 8.3.11

A dump/restore is not required for those running 8.3.X. However, if you are upgrading from a version earlier than 8.3.8, see Section E.160.

#### E.157.2. Changes

- Enforce restrictions in `plperl` using an opmask applied to the whole interpreter, instead of using `Safe.pm` (Tim Bunce, Andrew Dunstan)

Recent developments have convinced us that `Safe.pm` is too insecure to rely on for making `plperl` trustable. This change removes use of `Safe.pm` altogether, in favor of using a separate interpreter with an opcode mask that is always applied. Pleasant side effects of the change include that it is now possible to use Perl’s `strict` pragma in a natural way in `plperl`, and that Perl’s `$a` and `$b` variables work as expected in sort routines, and that function compilation is significantly faster. (CVE-2010-1169)

- Prevent PL/Tcl from executing untrustworthy code from `pltcl_modules` (Tom)

PL/Tcl’s feature for autoloading Tcl code from a database table could be exploited for trojan-horse attacks, because there was no restriction on who could create or insert into that table. This change
disables the feature unless pltcl_modules is owned by a superuser. (However, the permissions on the
table are not checked, so installations that really need a less-than-secure modules table can still grant
suitable privileges to trusted non-superusers.) Also, prevent loading code into the unrestricted “normal”
Tcl interpreter unless we are really going to execute a pltclu function. (CVE-2010-1170)

- Fix possible crash if a cache reset message is received during rebuild of a relcache entry (Heikki)
  This error was introduced in 8.3.10 while fixing a related failure.

- Apply per-function GUC settings while running the language validator for the function (Itagaki
  Takahiro)
  This avoids failures if the function’s code is invalid without the setting; an example is that SQL functions
  may not parse if the search_path is not correct.

- Do not allow an unprivileged user to reset superuser-only parameter settings (Alvaro)
  Previously, if an unprivileged user ran ALTER USER ... RESET ALL for himself, or ALTER
  DATABASE ... RESET ALL for a database he owns, this would remove all special parameter settings
  for the user or database, even ones that are only supposed to be changeable by a superuser. Now, the
  ALTER will only remove the parameters that the user has permission to change.

- Avoid possible crash during backend shutdown if shutdown occurs when a CONTEXT addition would be
  made to log entries (Tom)
  In some cases the context-printing function would fail because the current transaction had already been
  rolled back when it came time to print a log message.

- Ensure the archiver process responds to changes in archive_command as soon as possible (Tom)

- Update pl/perl’s ppport.h for modern Perl versions (Andrew)

- Fix assorted memory leaks in pl/python (Andreas Freund, Tom)

- Prevent infinite recursion in psql when expanding a variable that refers to itself (Tom)

- Fix psql’s \copy to not add spaces around a dot within \copy (select ...) (Tom)
  Addition of spaces around the decimal point in a numeric literal would result in a syntax error.

- Fix unnecessary “GIN indexes do not support whole-index scans” errors for unsatisfiable queries using
  contrib/intarray operators (Tom)

- Ensure that contrib/pgstattuple functions respond to cancel interrupts promptly (Tatsuhito Kasa-
hara)

- Make server startup deal properly with the case that shmget() returns EINVAL for an existing shared
  memory segment (Tom)
  This behavior has been observed on BSD-derived kernels including OS X. It resulted in an entirely-
  misleading startup failure complaining that the shared memory request size was too large.

- Avoid possible crashes in syslogger process on Windows (Heikki)

- Deal more robustly with incomplete time zone information in the Windows registry (Magnus)

- Update the set of known Windows time zone names (Magnus)

- Update time zone data files to tzdata release 2010j for DST law changes in Argentina, Australian
  Antarctic, Bangladesh, Mexico, Morocco, Pakistan, Palestine, Russia, Syria, Tunisia; also historical
  corrections for Taiwan.
Also, add **PKST** (Pakistan Summer Time) to the default set of timezone abbreviations.

### E.158. Release 8.3.10

**Release date:** 2010-03-15

This release contains a variety of fixes from 8.3.9. For information about new features in the 8.3 major release, see Section E.168.

#### E.158.1. Migration to Version 8.3.10

A dump/restore is not required for those running 8.3.X. However, if you are upgrading from a version earlier than 8.3.8, see Section E.160.

#### E.158.2. Changes

- Add new configuration parameter `ssl_renegotiation_limit` to control how often we do session key renegotiation for an SSL connection (Magnus)
  
  This can be set to zero to disable renegotiation completely, which may be required if a broken SSL library is used. In particular, some vendors are shipping stopgap patches for CVE-2009-3555 that cause renegotiation attempts to fail.

- Fix possible deadlock during backend startup (Tom)
- Fix possible crashes due to not handling errors during relcache reload cleanly (Tom)
- Fix possible crash due to use of dangling pointer to a cached plan (Tatsuo)
- Fix possible crashes when trying to recover from a failure in subtransaction start (Tom)

- Fix server memory leak associated with use of savepoints and a client encoding different from server’s encoding (Tom)

- Fix incorrect WAL data emitted during end-of-recovery cleanup of a GIST index page split (Yoichi Hirai)

  This would result in index corruption, or even more likely an error during WAL replay, if we were unlucky enough to crash during end-of-recovery cleanup after having completed an incomplete GIST insertion.

- Make `substring()` for bit types treat any negative length as meaning “all the rest of the string” (Tom)

  The previous coding treated only -1 that way, and would produce an invalid result value for other negative values, possibly leading to a crash (CVE-2010-0442).

- Fix integer-to-bit-string conversions to handle the first fractional byte correctly when the output bit width is wider than the given integer by something other than a multiple of 8 bits (Tom)

- Fix some cases of pathologically slow regular expression matching (Tom)
Appendix E. Release Notes

- Fix assorted crashes in xml processing caused by sloppy memory management (Tom)
  This is a back-patch of changes first applied in 8.4. The 8.3 code was known buggy, but the new code was sufficiently different to not want to back-patch it until it had gotten some field testing.
- Fix bug with trying to update a field of an element of a composite-type array column (Tom)
- Fix the STOP WAL LOCATION entry in backup history files to report the next WAL segment’s name when the end location is exactly at a segment boundary (Itagaki Takahiro)
- Fix some more cases of temporary-file leakage (Heikki)
  This corrects a problem introduced in the previous minor release. One case that failed is when a plpgsql function returning set is called within another function’s exception handler.
- Improve constraint exclusion processing of boolean-variable cases, in particular make it possible to exclude a partition that has a “bool_column = false” constraint (Tom)
- When reading pg_hba.conf and related files, do not treat @something as a file inclusion request if the @ appears inside quote marks; also, never treat @ by itself as a file inclusion request (Tom)
  This prevents erratic behavior if a role or database name starts with @. If you need to include a file whose path name contains spaces, you can still do so, but you must write @"/path to/file" rather than putting the quotes around the whole construct.
- Prevent infinite loop on some platforms if a directory is named as an inclusion target in pg_hba.conf and related files (Tom)
- Fix possible infinite loop if SSL_read or SSL_write fails without setting errno (Tom)
  This is reportedly possible with some Windows versions of openssl.
-Disallow GSSAPI authentication on local connections, since it requires a hostname to function correctly (Magnus)
- Make ecpg report the proper SQLSTATE if the connection disappears (Michael)
- Fix psql’s numericlocale option to not format strings it shouldn’t in latex and troff output formats (Heikki)
- Make psql return the correct exit status (3) when ON_ERROR_STOP and --single-transaction are both specified and an error occurs during the implied COMMIT (Bruce)
- Fix plpgsql failure in one case where a composite column is set to NULL (Tom)
- Fix possible failure when calling PL/Perl functions from PL/PerlU or vice versa (Tim Bunce)
- Add volatile markings in PL/Python to avoid possible compiler-specific misbehavior (Zdenek Kotala)
- Ensure PL/Tcl initializes the Tcl interpreter fully (Tom)
  The only known symptom of this oversight is that the Tcl clock command misbehaves if using Tcl 8.5 or later.
- Prevent crash in contrib/dblink when too many key columns are specified to a dblink_build_sql_* function (Rushabh Lathia, Joe Conway)
- Allow zero-dimensional arrays in contrib/ltree operations (Tom)
This case was formerly rejected as an error, but it’s more convenient to treat it the same as a zero-element array. In particular this avoids unnecessary failures when an ltree operation is applied to the result of \texttt{ARRAY(SELECT ...)} and the sub-select returns no rows.

- Fix assorted crashes in \texttt{contrib/xml2} caused by sloppy memory management (Tom)
- Make building of \texttt{contrib/xml2} more robust on Windows (Andrew)
- Fix race condition in Windows signal handling (Radu Ilie)
  One known symptom of this bug is that rows in \texttt{pg_listener} could be dropped under heavy load.
- Update time zone data files to \texttt{tzdata} release 2010e for DST law changes in Bangladesh, Chile, Fiji, Mexico, Paraguay, Samoa.

E.159. Release 8.3.9

Release date: 2009-12-14

This release contains a variety of fixes from 8.3.8. For information about new features in the 8.3 major release, see Section E.168.

E.159.1. Migration to Version 8.3.9

A dump/restore is not required for those running 8.3.X. However, if you are upgrading from a version earlier than 8.3.8, see Section E.160.

E.159.2. Changes

- Protect against indirect security threats caused by index functions changing session-local state (Gurjeet Singh, Tom)
  This change prevents allegedly-immutable index functions from possibly subverting a superuser’s session (CVE-2009-4136).
- Reject SSL certificates containing an embedded null byte in the common name (CN) field (Magnus)
  This prevents unintended matching of a certificate to a server or client name during SSL validation (CVE-2009-4034).
- Fix possible crash during backend-startup-time cache initialization (Tom)
- Avoid crash on empty thesaurus dictionary (Tom)
- Prevent signals from interrupting \texttt{VACUUM} at unsafe times (Alvaro)
  This fix prevents a PANIC if a \texttt{VACUUM FULL} is canceled after it’s already committed its tuple movements, as well as transient errors if a plain \texttt{VACUUM} is interrupted after having truncated the table.
- Fix possible crash due to integer overflow in hash table size calculation (Tom)
  This could occur with extremely large planner estimates for the size of a hashjoin’s result.
• Fix very rare crash in inet/cidr comparisons (Chris Mikkelson)
• Ensure that shared tuple-level locks held by prepared transactions are not ignored (Heikki)
• Fix premature drop of temporary files used for a cursor that is accessed within a subtransaction (Heikki)
• Fix memory leak in syslogger process when rotating to a new CSV logfile (Tom)
• Fix Windows permission-downgrade logic (Jesse Morris)
  This fixes some cases where the database failed to start on Windows, often with misleading error messages such as “could not locate matching postgres executable”.
• Fix incorrect logic for GiST index page splits, when the split depends on a non-first column of the index (Paul Ramsey)
• Don’t error out if recycling or removing an old WAL file fails at the end of checkpoint (Heikki)
  It’s better to treat the problem as non-fatal and allow the checkpoint to complete. Future checkpoints will retry the removal. Such problems are not expected in normal operation, but have been seen to be caused by misdesigned Windows anti-virus and backup software.
• Ensure WAL files aren’t repeatedly archived on Windows (Heikki)
  This is another symptom that could happen if some other process interfered with deletion of a no-longer-needed file.
• Fix PAM password processing to be more robust (Tom)
  The previous code is known to fail with the combination of the Linux pam_krb5 PAM module with Microsoft Active Directory as the domain controller. It might have problems elsewhere too, since it was making unjustified assumptions about what arguments the PAM stack would pass to it.
• Raise the maximum authentication token (Kerberos ticket) size in GSSAPI and SSPI authentication methods (Ian Turner)
  While the old 2000-byte limit was more than enough for Unix Kerberos implementations, tickets issued by Windows Domain Controllers can be much larger.
• Re-enable collection of access statistics for sequences (Akira Kurosawa)
  This used to work but was broken in 8.3.
• Fix processing of ownership dependencies during CREATE OR REPLACE FUNCTION (Tom)
• Fix incorrect handling of WHERE x=x conditions (Tom)
  In some cases these could get ignored as redundant, but they aren’t — they’re equivalent to x IS NOT NULL.
• Make text search parser accept underscores in XML attributes (Peter)
• Fix encoding handling in xml binary input (Heikki)
  If the XML header doesn’t specify an encoding, we now assume UTF-8 by default; the previous handling was inconsistent.
• Fix bug with calling plperl from plperlu or vice versa (Tom)
  An error exit from the inner function could result in crashes due to failure to re-select the correct Perl interpreter for the outer function.
• Fix session-lifespan memory leak when a PL/Perl function is redefined (Tom)

2695
Appendix E. Release Notes

- Ensure that Perl arrays are properly converted to PostgreSQL arrays when returned by a set-returning PL/Perl function (Andrew Dunstan, Abhijit Menon-Sen)
  This worked correctly already for non-set-returning functions.
- Fix rare crash in exception processing in PL/Python (Peter)
- In contrib/pg_standby, disable triggering failover with a signal on Windows (Fujii Masao)
  This never did anything useful, because Windows doesn’t have Unix-style signals, but recent changes made it actually crash.
- Ensure psql’s flex module is compiled with the correct system header definitions (Tom)
  This fixes build failures on platforms where --enable-largefile causes incompatible changes in the generated code.
- Make the postmaster ignore any application_name parameter in connection request packets, to improve compatibility with future libpq versions (Tom)
- Update the timezone abbreviation files to match current reality (Joachim Wieland)
  This includes adding IDT and SGT to the default timezone abbreviation set.
- Update time zone data files to tzdata release 2009s for DST law changes in Antarctica, Argentina, Bangladesh, Fiji, Novokuznetsk, Pakistan, Palestine, Samoa, Syria; also historical corrections for Hong Kong.

E.160. Release 8.3.8

Release date: 2009-09-09

This release contains a variety of fixes from 8.3.7. For information about new features in the 8.3 major release, see Section E.168.

E.160.1. Migration to Version 8.3.8

A dump/restore is not required for those running 8.3.X. However, if you have any hash indexes on interval columns, you must REINDEX them after updating to 8.3.8. Also, if you are upgrading from a version earlier than 8.3.5, see Section E.163.

E.160.2. Changes

- Fix Windows shared-memory allocation code (Tsutomu Yamada, Magnus)
  This bug led to the often-reported “could not reattach to shared memory” error message.
- Force WAL segment switch during pg_start_backup() (Heikki)
  This avoids corner cases that could render a base backup unusable.
Appendix E. Release Notes

- Disallow `RESET ROLE` and `RESET SESSION AUTHORIZATION` inside security-definer functions (Tom, Heikki)
  
  This covers a case that was missed in the previous patch that disallowed `SET ROLE` and `SET SESSION AUTHORIZATION` inside security-definer functions. (See CVE-2007-6600)

- Make `LOAD` of an already-loaded loadable module into a no-op (Tom)
  
  Formerly, `LOAD` would attempt to unload and re-load the module, but this is unsafe and not all that useful.

- Disallow empty passwords during LDAP authentication (Magnus)

- Fix handling of sub-SELECTs appearing in the arguments of an outer-level aggregate function (Tom)

- Fix bugs associated with fetching a whole-row value from the output of a Sort or Materialize plan node (Tom)

- Prevent `synchronize_seqscans` from changing the results of scrollable and `WITH HOLD` cursors (Tom)

- Revert planner change that disabled partial-index and constraint exclusion optimizations when there were more than 100 clauses in an AND or OR list (Tom)

- Fix hash calculation for data type `interval` (Tom)
  
  This corrects wrong results for hash joins on interval values. It also changes the contents of hash indexes on interval columns. If you have any such indexes, you must `REINDEX` them after updating.

- Treat `to_char(..., 'TH')` as an uppercase ordinal suffix with `'HH'/'HH12'` (Heikki)
  
  It was previously handled as `'th'` (lowercase).

- Fix overflow for `INTERVAL 'x ms'` when `x` is more than 2 million and integer datetimes are in use (Alex Hunsaker)

- Fix calculation of distance between a point and a line segment (Tom)
  
  This led to incorrect results from a number of geometric operators.

- Fix `money` data type to work in locales where currency amounts have no fractional digits, e.g. Japan (Itagaki Takahiro)

- Fix `LIKE` for case where pattern contains `%_` (Tom)

- Properly round datetime input like `00:12:57.9999999999999999999999999999` (Tom)

- Fix memory leaks in XML operations (Tom)

- Fix poor choice of page split point in GiST R-tree operator classes (Teodor)

- Ensure that a “fast shutdown” request will forcibly terminate open sessions, even if a “smart shutdown” was already in progress (Fujii Masao)

- Avoid performance degradation in bulk inserts into GIN indexes when the input values are (nearly) in sorted order (Tom)

- Correctly enforce NOT NULL domain constraints in some contexts in PL/pgSQL (Tom)

- Fix portability issues in plperl initialization (Andrew Dunstan)

- Fix `pg_ctl` to not go into an infinite loop if `postgresql.conf` is empty (Jeff Davis)

- Improve `pg_dump`’s efficiency when there are many large objects (Tamas Vincze)
• Use SIGUSR1, not SIGQUIT, as the failover signal for pg_standby (Heikki)

• Make pg_standby’s maxretries option behave as documented (Fujii Masao)

• Make contrib/hstore throw an error when a key or value is too long to fit in its data structure, rather than silently truncating it (Andrew Gierth)

• Fix contrib/xml2’s xslt_process() to properly handle the maximum number of parameters (twenty) (Tom)

• Improve robustness of libpq’s code to recover from errors during COPY FROM STDIN (Tom)

• Avoid including conflicting readline and editline header files when both libraries are installed (Zdenek Kotala)

• Update time zone data files to tzdata release 2009l for DST law changes in Bangladesh, Egypt, Jordan, Pakistan, Argentina/San_Luis, Cuba, Jordan (historical correction only), Mauritius, Morocco, Palestine, Syria, Tunisia.

E.161. Release 8.3.7

Release date: 2009-03-16

This release contains a variety of fixes from 8.3.6. For information about new features in the 8.3 major release, see Section E.168.

E.161.1. Migration to Version 8.3.7

A dump/restore is not required for those running 8.3.X. However, if you are upgrading from a version earlier than 8.3.5, see Section E.163.

E.161.2. Changes

• Prevent error recursion crashes when encoding conversion fails (Tom)

   This change extends fixes made in the last two minor releases for related failure scenarios. The previous fixes were narrowly tailored for the original problem reports, but we have now recognized that any error thrown by an encoding conversion function could potentially lead to infinite recursion while trying to report the error. The solution therefore is to disable translation and encoding conversion and report the plain-ASCII form of any error message, if we find we have gotten into a recursive error reporting situation. (CVE-2009-0922)

• Disallow CREATE CONVERSION with the wrong encodings for the specified conversion function (Heikki)

   This prevents one possible scenario for encoding conversion failure. The previous change is a backstop to guard against other kinds of failures in the same area.

• Fix xpath() to not modify the path expression unless necessary, and to make a saner attempt at it when necessary (Andrew)
The SQL standard suggests that xpath should work on data that is a document fragment, but libxml doesn’t support that, and indeed it’s not clear that this is sensible according to the XPath standard. xpath attempted to work around this mismatch by modifying both the data and the path expression, but the modification was buggy and could cause valid searches to fail. Now, xpath checks whether the data is in fact a well-formed document, and if so invokes libxml with no change to the data or path expression. Otherwise, a different modification method that is somewhat less likely to fail is used.

**Note:** The new modification method is still not 100% satisfactory, and it seems likely that no real solution is possible. This patch should therefore be viewed as a band-aid to keep from breaking existing applications unnecessarily. It is likely that PostgreSQL 8.4 will simply reject use of xpath on data that is not a well-formed document.

- Fix core dump when `to_char()` is given format codes that are inappropriate for the type of the data argument (Tom)
- Fix possible failure in text search when C locale is used with a multi-byte encoding (Teodor)
  Crashes were possible on platforms where wchar_t is narrower than int; Windows in particular.
- Fix extreme inefficiency in text search parser’s handling of an email-like string containing multiple @ characters (Heikki)
- Fix planner problem with sub-`SELECT` in the output list of a larger subquery (Tom)
  The known symptom of this bug is a “failed to locate grouping columns” error that is dependent on the datatype involved; but there could be other issues as well.
- Fix decompilation of `CASE WHEN` with an implicit coercion (Tom)
  This mistake could lead to Assert failures in an Assert-enabled build, or an “unexpected CASE WHEN clause” error message in other cases, when trying to examine or dump a view.
- Fix possible misassignment of the owner of a TOAST table’s rowtype (Tom)
  If `CLUSTER` or a rewriting variant of `ALTER TABLE` were executed by someone other than the table owner, the `pg_type` entry for the table’s TOAST table would end up marked as owned by that someone. This caused no immediate problems, since the permissions on the TOAST rowtype aren’t examined by any ordinary database operation. However, it could lead to unexpected failures if one later tried to drop the role that issued the command (in 8.1 or 8.2), or “owner of data type appears to be invalid” warnings from `pg_dump` after having done so (in 8.3).
- Change `UNLISTEN` to exit quickly if the current session has never executed any `LISTEN` command (Tom)
  Most of the time this is not a particularly useful optimization, but since `DISCARD ALL` invokes `UNLISTEN`, the previous coding caused a substantial performance problem for applications that made heavy use of `DISCARD ALL`.
- Fix PL/pgSQL to not treat `INTO` after `INSERT` as an INTO-variables clause anywhere in the string, not only at the start; in particular, don’t fail for `INSERT INTO` within `CREATE RULE` (Tom)
- Clean up PL/pgSQL error status variables fully at block exit (Ashesh Vashi and Dave Page)
This is not a problem for PL/pgSQL itself, but the omission could cause the PL/pgSQL Debugger to crash while examining the state of a function.

- Retry failed calls to `CallNamedPipe()` on Windows (Steve Marshall, Magnus)
  
  It appears that this function can sometimes fail transiently; we previously treated any failure as a hard error, which could confuse `LISTEN/NOTIFY` as well as other operations.

- Add `MUST` (Mauritius Island Summer Time) to the default list of known timezone abbreviations (Xavier Bugaud)

### E.162. Release 8.3.6

**Release date:** 2009-02-02

This release contains a variety of fixes from 8.3.5. For information about new features in the 8.3 major release, see Section E.168.

### E.162.1. Migration to Version 8.3.6

A dump/restore is not required for those running 8.3.X. However, if you are upgrading from a version earlier than 8.3.5, see Section E.163.

### E.162.2. Changes

- **Make** `DISCARD ALL` release advisory locks, in addition to everything it already did (Tom)
  
  This was decided to be the most appropriate behavior. This could affect existing applications, however.

- **Fix** whole-index GiST scans to work correctly (Teodor)
  
  This error could cause rows to be lost if a table is clustered on a GiST index.

- **Fix crash of** `xmlconcat(NULL)` (Peter)

- **Fix possible crash in** `ispell` dictionary if high-bit-set characters are used as flags (Teodor)
  
  This is known to be done by one widely available Norwegian dictionary, and the same condition may exist in others.

- **Fix misordering of pg_dump output for composite types** (Tom)
  
  The most likely problem was for user-defined operator classes to be dumped after indexes or views that needed them.

- **Improve handling of URLs** in `headline()` function (Teodor)

- **Improve handling of overlength headlines** in `headline()` function (Teodor)

- Prevent possible `Assert` failure or misconversion if an encoding conversion is created with the wrong conversion function for the specified pair of encodings (Tom, Heikki)

- Fix possible Assert failure if a statement executed in PL/pgSQL is rewritten into another kind of statement, for example if an INSERT is rewritten into an UPDATE (Heikki)
- Ensure that a snapshot is available to datatype input functions (Tom)
  
  This primarily affects domains that are declared with CHECK constraints involving user-defined stable or immutable functions. Such functions typically fail if no snapshot has been set.
- Make it safer for SPI-using functions to be used within datatype I/O; in particular, to be used in domain check constraints (Tom)
- Avoid unnecessary locking of small tables in VACUUM (Heikki)
- Fix a problem that sometimes kept ALTER TABLE ENABLE/DISABLE RULE from being recognized by active sessions (Tom)
- Fix a problem that made UPDATE RETURNING tableoid return zero instead of the correct OID (Tom)
- Allow functions declared as taking ANYARRAY to work on the pg_statistic columns of that type (Tom)
  
  This used to work, but was unintentionally broken in 8.3.
- Fix planner misestimation of selectivity when transitive equality is applied to an outer-join clause (Tom)
  
  This could result in bad plans for queries like ...
  
  from a left join b on a.al = b.bl
  
  where a.al = 42 ...
- Improve optimizer’s handling of long IN lists (Tom)
  
  This change avoids wasting large amounts of time on such lists when constraint exclusion is enabled.
- Prevent synchronous scan during GIN index build (Tom)
  
  Because GIN is optimized for inserting tuples in increasing TID order, choosing to use a synchronous scan could slow the build by a factor of three or more.
- Ensure that the contents of a holdable cursor don’t depend on the contents of TOAST tables (Tom)
  
  Previously, large field values in a cursor result might be represented as TOAST pointers, which would fail if the referenced table got dropped before the cursor is read, or if the large value is deleted and then vacuumed away. This cannot happen with an ordinary cursor, but it could with a cursor that is held past its creating transaction.
- Fix memory leak when a set-returning function is terminated without reading its whole result (Tom)
- Fix encoding conversion problems in XML functions when the database encoding isn’t UTF-8 (Tom)
- Fix contrib/dblink’s dblink_get_result(text, bool) function (Joe)
- Fix possible garbage output from contrib/sslinfo functions (Tom)
- Fix incorrect behavior of contrib/tsearch2 compatibility trigger when it’s fired more than once in a command (Teodor)
- Fix possible mis-signaling in autovacuum (Heikki)
- Support running as a service on Windows 7 beta (Dave and Magnus)
- Fix ecpg’s handling of varchar structs (Michael)
- Fix configure script to properly report failure when unable to obtain linkage information for PL/Perl (Andrew)
• Make all documentation reference **pgsql-bugs** and/or **pgsql-hackers** as appropriate, instead of the now-decommissioned **pgsql-ports** and **pgsql-patches** mailing lists (Tom)

• Update time zone data files to tzdata release 2009a (for Kathmandu and historical DST corrections in Switzerland, Cuba)

### E.163. Release 8.3.5

**Release date:** 2008-11-03

This release contains a variety of fixes from 8.3.4. For information about new features in the 8.3 major release, see Section E.168.

#### E.163.1. Migration to Version 8.3.5

A dump/restore is not required for those running 8.3.X. However, if you are upgrading from a version earlier than 8.3.1, see Section E.167. Also, if you were running a previous 8.3.X release, it is recommended to `REINDEX` all GiST indexes after the upgrade.

#### E.163.2. Changes

• Fix GiST index corruption due to marking the wrong index entry “dead” after a deletion (Teodor)

  This would result in index searches failing to find rows they should have found. Corrupted indexes can be fixed with `REINDEX`.

• Fix backend crash when the client encoding cannot represent a localized error message (Tom)

  We have addressed similar issues before, but it would still fail if the “character has no equivalent” message itself couldn’t be converted. The fix is to disable localization and send the plain ASCII error message when we detect such a situation.

• Fix possible crash in `bytea-to-XML` mapping (Michael McMaster)

• Fix possible crash when deeply nested functions are invoked from a trigger (Tom)

• Improve optimization of `expression IN (expression-list)` queries (Tom, per an idea from Robert Haas)

  Cases in which there are query variables on the right-hand side had been handled less efficiently in 8.2.x and 8.3.x than in prior versions. The fix restores 8.1 behavior for such cases.

• Fix mis-expansion of rule queries when a sub-`SELECT` appears in a function call in `FROM`, a multi-row `VALUES` list, or a `RETURNING` list (Tom)

  The usual symptom of this problem is an “unrecognized node type” error.

• Fix Assert failure during rescan of an `IS NULL` search of a GiST index (Teodor)

• Fix memory leak during rescan of a hashed aggregation plan (Neil)
• Ensure an error is reported when a newly-defined PL/pgSQL trigger function is invoked as a normal function (Tom)

• Force a checkpoint before CREATE DATABASE starts to copy files (Heikki)
  This prevents a possible failure if files had recently been deleted in the source database.

• Prevent possible collision of relfilenode numbers when moving a table to another tablespace with ALTER SET TABLESPACE (Heikki)
  The command tried to re-use the existing filename, instead of picking one that is known unused in the destination directory.

• Fix incorrect text search headline generation when single query item matches first word of text (Sushant Sinha)

• Fix improper display of fractional seconds in interval values when using a non-ISO datestyle in an --enable-integer-datetimes build (Ron Mayer)

• Make ILIKE compare characters case-insensitively even when they're escaped (Andrew)

• Ensure DISCARD is handled properly by statement logging (Tom)

• Fix incorrect logging of last-completed-transaction time during PITR recovery (Tom)

• Ensure SPI_getvalue and SPI_getbinval behave correctly when the passed tuple and tuple descriptor have different numbers of columns (Tom)
  This situation is normal when a table has had columns added or removed, but these two functions didn’t handle it properly. The only likely consequence is an incorrect error indication.

• Mark SessionReplicationRole as PGDLIMPORT so it can be used by Slony on Windows (Magnus)

• Fix small memory leak when using libpq’s gsslib parameter (Magnus)
  The space used by the parameter string was not freed at connection close.

• Ensure libgssapi is linked into libpq if needed (Markus Schaaf)

• Fix ecpg’s parsing of CREATE ROLE (Michael)

• Fix recent breakage of pg_ctl restart (Tom)

• Ensure pg_control is opened in binary mode (Itagaki Takahiro)
  pg_controldata and pg_resetxlog did this incorrectly, and so could fail on Windows.

• Update time zone data files to tzdata release 2008i (for DST law changes in Argentina, Brazil, Mauritius, Syria)

---

**E.164. Release 8.3.4**

**Release date:** 2008-09-22

This release contains a variety of fixes from 8.3.3. For information about new features in the 8.3 major release, see Section E.168.
E.164.1. Migration to Version 8.3.4

A dump/restore is not required for those running 8.3.X. However, if you are upgrading from a version earlier than 8.3.1, see Section E.167.

E.164.2. Changes

- Fix bug in btree WAL recovery code (Heikki)
  Recovery failed if the WAL ended partway through a page split operation.

- Fix potential use of wrong cutoff XID for HOT page pruning (Alvaro)
  This error created a risk of corruption in system catalogs that are consulted by `VACUUM`: dead tuple versions might be removed too soon. The impact of this on actual database operations would be minimal, since the system doesn’t follow MVCC rules while examining catalogs, but it might result in transiently wrong output from `pg_dump` or other client programs.

- Fix potential miscalculation of `datfrozenxid` (Alvaro)
  This error may explain some recent reports of failure to remove old `pg_clog` data.

- Fix incorrect HOT updates after `pg_class` is reindexed (Tom)
  Corruption of `pg_class` could occur if `REINDEX TABLE pg_class` was followed in the same session by an `ALTER TABLE RENAME` or `ALTER TABLE SET SCHEMA` command.

- Fix missed “combo cid” case (Karl Schnaitter)
  This error made rows incorrectly invisible to a transaction in which they had been deleted by multiple subtransactions that all aborted.

- Prevent autovacuum from crashing if the table it’s currently checking is deleted at just the wrong time (Alvaro)

- Widen local lock counters from 32 to 64 bits (Tom)
  This responds to reports that the counters could overflow in sufficiently long transactions, leading to unexpected “lock is already held” errors.

- Fix possible duplicate output of tuples during a GiST index scan (Teodor)

- Regenerate foreign key checking queries from scratch when either table is modified (Tom)
  Previously, 8.3 would attempt to replan the query, but would work from previously generated query text. This led to failures if a table or column was renamed.

- Fix missed permissions checks when a view contains a simple `UNION ALL` construct (Heikki)
  Permissions for the referenced tables were checked properly, but not permissions for the view itself.

- Add checks in executor startup to ensure that the tuples produced by an `INSERT` or `UPDATE` will match the target table’s current rowtype (Tom)
  This situation is believed to be impossible in 8.3, but it can happen in prior releases, so a check seems prudent.

- Fix possible repeated drops during `DROP OWNED` (Tom)
Appendix E. Release Notes

This would typically result in strange errors such as “cache lookup failed for relation NNN”.

- Fix several memory leaks in XML operations (Kris Jurka, Tom)
- Fix `xmlserialize()` to raise error properly for unacceptable target data type (Tom)
- Fix a couple of places that mis-handled multibyte characters in text search configuration file parsing (Tom)
  
  Certain characters occurring in configuration files would always cause “invalid byte sequence for encoding” failures.
- Provide file name and line number location for all errors reported in text search configuration files (Tom)
- Fix `AT TIME ZONE` to first try to interpret its timezone argument as a timezone abbreviation, and only try it as a full timezone name if that fails, rather than the other way around as formerly (Tom)
  
  The timestamp input functions have always resolved ambiguous zone names in this order. Making `AT TIME ZONE` do so as well improves consistency, and fixes a compatibility bug introduced in 8.1: in ambiguous cases we now behave the same as 8.0 and before did, since in the older versions `AT TIME ZONE` accepted only abbreviations.
- Fix date-time input functions to correctly detect integer overflow when running on a 64-bit platform (Tom)
- Prevent integer overflows during units conversion when displaying a configuration parameter that has units (Tom)
- Improve performance of writing very long log messages to syslog (Tom)
- Allow spaces in the suffix part of an LDAP URL in `pg_hba.conf` (Tom)
- Fix bug in backwards scanning of a cursor on a `SELECT DISTINCT ON` query (Tom)
- Fix planner bug that could improperly push down `IS NULL` tests below an outer join (Tom)
  
  This was triggered by occurrence of `IS NULL` tests for the same relation in all arms of an upper `OR` clause.
- Fix planner bug with nested sub-select expressions (Tom)
  
  If the outer sub-select has no direct dependency on the parent query, but the inner one does, the outer value might not get recalculated for new parent query rows.
- Fix planner to estimate that `GROUP BY` expressions yielding boolean results always result in two groups, regardless of the expressions’ contents (Tom)
  
  This is very substantially more accurate than the regular `GROUP BY` estimate for certain boolean tests like `col IS NULL`.
- Fix PL/pgSQL to not fail when a `FOR` loop’s target variable is a record containing composite-type fields (Tom)
- Fix PL/Tcl to behave correctly with Tcl 8.5, and to be more careful about the encoding of data sent to or from Tcl (Tom)
- Improve performance of `PQescapeBytea()` (Rudolf Leitgeb)
- On Windows, work around a Microsoft bug by preventing `libpq` from trying to send more than 64kB per system call (Magnus)
Appendix E. Release Notes

- Fix ecpg to handle variables properly in SET commands (Michael)
- Improve pg_dump and pg_restore’s error reporting after failure to send a SQL command (Tom)
- Fix pg_ctl to properly preserve postmaster command-line arguments across a restart (Bruce)
- Fix erroneous WAL file cutoff point calculation in pg_standby (Simon)
- Update time zone data files to tzdata release 2008f (for DST law changes in Argentina, Bahamas, Brazil, Mauritius, Morocco, Pakistan, Palestine, and Paraguay)

E.165. Release 8.3.3

Release date: 2008-06-12

This release contains one serious and one minor bug fix over 8.3.2. For information about new features in the 8.3 major release, see Section E.168.

E.165.1. Migration to Version 8.3.3

A dump/restore is not required for those running 8.3.X. However, if you are upgrading from a version earlier than 8.3.1, see Section E.167.

E.165.2. Changes

- Make pg_get_ruledef() parenthesize negative constants (Tom)
  Before this fix, a negative constant in a view or rule might be dumped as, say, -42::integer, which is subtly incorrect: it should be (-42)::integer due to operator precedence rules. Usually this would make little difference, but it could interact with another recent patch to cause PostgreSQL to reject what had been a valid SELECT DISTINCT view query. Since this could result in pg_dump output failing to reload, it is being treated as a high-priority fix. The only released versions in which dump output is actually incorrect are 8.3.1 and 8.2.7.

- Make ALTER AGGREGATE ... OWNER TO update pg_shdepend (Tom)
  This oversight could lead to problems if the aggregate was later involved in a DROP OWNED or REASSIGN OWNED operation.

E.166. Release 8.3.2

Release date: never released

This release contains a variety of fixes from 8.3.1. For information about new features in the 8.3 major release, see Section E.168.
Appendix E. Release Notes

E.166.1. Migration to Version 8.3.2

A dump/restore is not required for those running 8.3.X. However, if you are upgrading from a version earlier than 8.3.1, see Section E.167.

E.166.2. Changes

- Fix `ERRORDATA_STACK_SIZE` exceeded crash that occurred on Windows when using UTF-8 database encoding and a different client encoding (Tom)
- Fix incorrect archive truncation point calculation for the `%r` macro in `recovery_command` parameters (Simon)
  This could lead to data loss if a warm-standby script relied on `%r` to decide when to throw away WAL segment files.
- Fix `ALTER TABLE ADD COLUMN ... PRIMARY KEY` so that the new column is correctly checked to see if it’s been initialized to all non-nulls (Brendan Jurd)
  Previous versions neglected to check this requirement at all.
- Fix `REASSIGN OWNED` so that it works on procedural languages too (Alvaro)
- Fix problems with `SELECT FOR UPDATE/SHARE` occurring as a subquery in a query with a non-`SELECT` top-level operation (Tom)
- Fix possible `CREATE TABLE` failure when inheriting the “same” constraint from multiple parent relations that inherited that constraint from a common ancestor (Tom)
- Fix `pg_get_ruledef()` to show the alias, if any, attached to the target table of an `UPDATE` or `DELETE` (Tom)
- Restore the pre-8.3 behavior that an out-of-range block number in a TID being used in a TidScan plan results in silently not matching any rows (Tom)
  8.3.0 and 8.3.1 threw an error instead.
- Fix GIN bug that could result in too many LWLocks taken failure (Teodor)
- Fix broken GiST comparison function for `tsquery` (Teodor)
- Fix `tsvector_update_trigger()` and `ts_stat()` to accept domains over the types they expect to work with (Tom)
- Fix failure to support enum data types as foreign keys (Tom)
- Avoid possible crash when decompressing corrupted data (Zdenek Kotala)
- Fix race conditions between delayed unlinks and `DROP DATABASE` (Heikki)
  In the worst case this could result in deleting a newly created table in a new database that happened to get the same OID as the recently-dropped one; but of course that is an extremely low-probability scenario.
- Repair two places where SIGTERM exit of a backend could leave corrupted state in shared memory (Tom)
Neither case is very important if SIGTERM is used to shut down the whole database cluster together, but there was a problem if someone tried to SIGTERM individual backends.

- Fix possible crash due to incorrect plan generated for an \texttt{x IN (SELECT y FROM ...)} clause when \texttt{x} and \texttt{y} have different data types; and make sure the behavior is semantically correct when the conversion from \texttt{y}'s type to \texttt{x}'s type is lossy (Tom)

- Fix oversight that prevented the planner from substituting known \texttt{Param} values as if they were constants (Tom)

  This mistake partially disabled optimization of unnamed extended-Query statements in 8.3.0 and 8.3.1: in particular the \texttt{LIKE}-to-indexscan optimization would never be applied if the \texttt{LIKE} pattern was passed as a parameter, and constraint exclusion depending on a parameter value didn’t work either.

- Fix planner failure when an indexable \texttt{MIN} or \texttt{MAX} aggregate is used with \texttt{DISTINCT} or \texttt{ORDER BY} (Tom)

- Fix planner to ensure it never uses a “physical tlist” for a plan node that is feeding a \texttt{Sort} node (Tom)

  This led to the sort having to push around more data than it really needed to, since unused column values were included in the sorted data.

- Avoid unnecessary copying of query strings (Tom)

  This fixes a performance problem introduced in 8.3.0 when a very large number of commands are submitted as a single query string.

- Make \texttt{TransactionIdIsCurrentTransactionId()} use binary search instead of linear search when checking child-transaction XIDs (Heikki)

  This fixes some cases in which 8.3.0 was significantly slower than earlier releases.

- Fix conversions between ISO-8859-5 and other encodings to handle Cyrillic “Yo” characters (e and E with two dots) (Sergey Burladyan)

- Fix several datatype input functions, notably \texttt{array_in()}, that were allowing unused bytes in their results to contain uninitialized, unpredictable values (Tom)

  This could lead to failures in which two apparently identical literal values were not seen as equal, resulting in the parser complaining about unmatched \texttt{ORDER BY} and \texttt{DISTINCT} expressions.

- Fix a corner case in regular-expression substring matching (\texttt{substring(string from pattern)}) (Tom)

  The problem occurs when there is a match to the pattern overall but the user has specified a parenthesized subexpression and that subexpression hasn’t got a match. An example is \texttt{substring('foo' from 'foo(bar)?')}. This should return NULL, since \texttt{(bar)} isn’t matched, but it was mistakenly returning the whole-pattern match instead (ie, \texttt{foo}).

- Prevent cancellation of an auto-vacuum that was launched to prevent XID wraparound (Alvaro)

- Improve \texttt{ANALYZE}’s handling of in-doubt tuples (those inserted or deleted by a not-yet-committed transaction) so that the counts it reports to the stats collector are more likely to be correct (Pavan Deolasee)

- Fix initdb to reject a relative path for its \texttt{--xlogdir (-X)} option (Tom)

- Make \texttt{psql} print tab characters as an appropriate number of spaces, rather than \texttt{"\x09"} as was done in 8.3.0 and 8.3.1 (Bruce)
Appendix E. Release Notes

- Update time zone data files to tzdata release 2008c (for DST law changes in Morocco, Iraq, Choibalsan, Pakistan, Syria, Cuba, and Argentina/San_Luis)
- Add ECPGget_PGconn() function to ecpglib (Michael)
- Fix incorrect result from ecpg's PGTYPEStimestamp_sub() function (Michael)
- Fix handling of continuation line markers in ecpg (Michael)
- Fix possible crashes in contrib/cube functions (Tom)
- Fix core dump in contrib/xml2's xpath_table() function when the input query returns a NULL value (Tom)
- Fix contrib/xml2's makefile to not override CFLAGS, and make it auto-configure properly for libxslt present or not (Tom)

E.167. Release 8.3.1

Release date: 2008-03-17

This release contains a variety of fixes from 8.3.0. For information about new features in the 8.3 major release, see Section E.168.

E.167.1. Migration to Version 8.3.1

A dump/restore is not required for those running 8.3.X. However, you might need to REINDEX indexes on textual columns after updating, if you are affected by the Windows locale issue described below.

E.167.2. Changes

- Fix character string comparison for Windows locales that consider different character combinations as equal (Tom)
  This fix applies only on Windows and only when using UTF-8 database encoding. The same fix was made for all other cases over two years ago, but Windows with UTF-8 uses a separate code path that was not updated. If you are using a locale that considers some non-identical strings as equal, you may need to REINDEX to fix existing indexes on textual columns.
- Repair corner-case bugs in VACUUM FULL (Tom)
  A potential deadlock between concurrent VACUUM FULL operations on different system catalogs was introduced in 8.2. This has now been corrected. 8.3 made this worse because the deadlock could occur within a critical code section, making it a PANIC rather than just ERROR condition.
  Also, a VACUUM FULL that failed partway through vacuuming a system catalog could result in cache corruption in concurrent database sessions.
  Another VACUUM FULL bug introduced in 8.3 could result in a crash or out-of-memory report when dealing with pages containing no live tuples.
Appendix E. Release Notes

- Fix misbehavior of foreign key checks involving character or bit columns (Tom)
  If the referencing column were of a different but compatible type (for instance varchar), the constraint was enforced incorrectly.
- Avoid needless deadlock failures in no-op foreign-key checks (Stephan Szabo, Tom)
- Fix possible core dump when re-planning a prepared query (Tom)
  This bug affected only protocol-level prepare operations, not SQL PREPARE, and so tended to be seen only with JDBC, DBI, and other client-side drivers that use prepared statements heavily.
- Fix possible failure when re-planning a query that calls an SPI-using function (Tom)
- Fix failure in row-wise comparisons involving columns of different datatypes (Tom)
- Fix longstanding LISTEN/NOTIFY race condition (Tom)
  In rare cases a session that had just executed a LISTEN might not get a notification, even though one would be expected because the concurrent transaction executing NOTIFY was observed to commit later.
  A side effect of the fix is that a transaction that has executed a not-yet-committed LISTEN command will not see any row in pg_listener for the LISTEN, should it choose to look; formerly it would have. This behavior was never documented one way or the other, but it is possible that some applications depend on the old behavior.
- Disallow LISTEN and UNLISTEN within a prepared transaction (Tom)
