psql provides variable substitution features similar to common Unix command shells. Variables are simply name/value pairs, where the value can be any string of any length. The name must consist of letters (including non-Latin letters), digits, and underscores.

To set a variable, use the psql meta-command \set. For example,

```
testdb=> \set foo bar
```

sets the variable `foo` to the value `bar`. To retrieve the content of the variable, precede the name with a colon, for example:

```
testdb=> \echo :foo
bar
```

This works in both regular SQL commands and meta-commands; there is more detail in SQL Interpolation, below.

If you call \set without a second argument, the variable is set, with an empty string as value. To unset (i.e., delete) a variable, use the command \unset. To show the values of all variables, call \set without any argument.

**Note:** The arguments of \set are subject to the same substitution rules as with other commands. Thus you can construct interesting references such as `\set :foo 'something'` and get “soft links” or “variable variables” of Perl or PHP fame, respectively. Unfortunately (or fortunately?), there is no way to do anything useful with these constructs. On the other hand, `\set bar :foo` is a perfectly valid way to copy a variable.

A number of these variables are treated specially by psql. They represent certain option settings that can be changed at run time by altering the value of the variable, or in some cases represent changeable state of psql. Although you can use these variables for other purposes, this is not recommended, as the program behavior might grow really strange really quickly. By convention, all specially treated variables’ names consist of all upper-case ASCII letters (and possibly digits and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes.

A list of all specially treated variables follows.

**AUTOCOMMIT**

When on (the default), each SQL command is automatically committed upon successful completion. To postpone commit in this mode, you must enter a BEGIN or START TRANSACTION SQL command. When off or unset, SQL commands are not committed until you explicitly issue COMMIT or END. The autocommit-off mode works by issuing an implicit BEGIN for you, just before any command that is not already in a transaction block and is not itself a BEGIN or other
transaction-control command, nor a command that cannot be executed inside a transaction block (such as VACUUM).

**Note:** In autocommit-off mode, you must explicitly abandon any failed transaction by entering ABORT or ROLLBACK. Also keep in mind that if you exit the session without committing, your work will be lost.

**Note:** The autocommit-on mode is PostgreSQL’s traditional behavior, but autocommit-off is closer to the SQL spec. If you prefer autocommit-off, you might wish to set it in the system-wide psqlrc file or your ~/.psqlrc file.

**COMP_KEYWORD_CASE**

Determines which letter case to use when completing an SQL key word. If set to lower or upper, the completed word will be in lower or upper case, respectively. If set to preserve-lower or preserve-upper (the default), the completed word will be in the case of the word already entered, but words being completed without anything entered will be in lower or upper case, respectively.

**DBNAME**

The name of the database you are currently connected to. This is set every time you connect to a database (including program start-up), but can be unset.

**ECHO**

If set to all, all nonempty input lines are printed to standard output as they are read. (This does not apply to lines read interactively.) To select this behavior on program start-up, use the switch -a. If set to queries, psql prints each query to standard output as it is sent to the server. The switch for this is -e. If set to errors, then only failed queries are displayed on standard error output. The switch for this is -b. If unset, or if set to none (or any other value than those above) then no queries are displayed.

**ECHO_HIDDEN**

When this variable is set to on and a backslash command queries the database, the query is first shown. This feature helps you to study PostgreSQL internals and provide similar functionality in your own programs. (To select this behavior on program start-up, use the switch -E.) If you set the variable to the value noexec, the queries are just shown but are not actually sent to the server and executed.

**ENCODING**

The current client character set encoding.

**FETCH_COUNT**

If this variable is set to an integer value > 0, the results of SELECT queries are fetched and displayed in groups of that many rows, rather than the default behavior of collecting the entire result set before display. Therefore only a limited amount of memory is used, regardless of the size of the result set. Settings of 100 to 1000 are commonly used when enabling this feature. Keep in mind that when using this feature, a query might fail after having already displayed some rows.

**Tip:** Although you can use any output format with this feature, the default aligned format tends to look bad because each group of FETCH_COUNT rows will be formatted separately,
leading to varying column widths across the row groups. The other output formats work better.

**HISTCONTROL**

If this variable is set to `ignore` space, lines which begin with a space are not entered into the history list. If set to a value of `ignoreup`, lines matching the previous history line are not entered. A value of `ignoreboth` combines the two options. If unset, or if set to `none` (or any other value than those above), all lines read in interactive mode are saved on the history list.

**Note:** This feature was shamelessly plagiarized from Bash.

**HISTFILE**

The file name that will be used to store the history list. The default value is `~/.psql_history`. For example, putting:

```
\set HISTFILE ~/.psql_history :DBNAME
```

in `~/.psqlrc` will cause psql to maintain a separate history for each database.

**Note:** This feature was shamelessly plagiarized from Bash.

**HISTSIZE**

The number of commands to store in the command history. The default value is 500.

**Note:** This feature was shamelessly plagiarized from Bash.

**HOST**

The database server host you are currently connected to. This is set every time you connect to a database (including program start-up), but can be unset.

**IGNOREEOF**

If unset, sending an EOF character (usually `Control+D`) to an interactive session of psql will terminate the application. If set to a numeric value, that many EOF characters are ignored before the application terminates. If the variable is set but has no numeric value, the default is 10.

**Note:** This feature was shamelessly plagiarized from Bash.

**LASTOID**

The value of the last affected OID, as returned from an `INSERT` or `\lo_import` command. This variable is only guaranteed to be valid until after the result of the next SQL command has been displayed.

**ON_ERROR_ROLLBACK**

When set to `on`, if a statement in a transaction block generates an error, the error is ignored and the transaction continues. When set to `interactive`, such errors are only ignored in interactive sessions, and not when reading script files. When unset or set to `off`, a statement in a transaction
block that generates an error aborts the entire transaction. The error rollback mode works by issuing an implicit \texttt{SAVEPOINT} for you, just before each command that is in a transaction block, and then rolling back to the savepoint if the command fails.

\textbf{ON\_ERROR\_STOP}

By default, command processing continues after an error. When this variable is set to \texttt{on}, processing will instead stop immediately. In interactive mode, \texttt{psql} will return to the command prompt; otherwise, \texttt{psql} will exit, returning error code 3 to distinguish this case from fatal error conditions, which are reported using error code 1. In either case, any currently running scripts (the top-level script, if any, and any other scripts which it may have invoked) will be terminated immediately. If the top-level command string contained multiple SQL commands, processing will stop with the current command.

\textbf{PORT}

The database server port to which you are currently connected. This is set every time you connect to a database (including program start-up), but can be unset.

\textbf{PROMPT1, PROMPT2, PROMPT3}

These specify what the prompts \texttt{psql} issues should look like. See \textit{Prompting} below.

\textbf{QUIET}

Setting this variable to \texttt{on} is equivalent to the command line option \texttt{-q}. It is probably not too useful in interactive mode.

\textbf{SINGLELINE}

Setting this variable to \texttt{on} is equivalent to the command line option \texttt{-S}.

\textbf{SINGLESTEP}

Setting this variable to \texttt{on} is equivalent to the command line option \texttt{-s}.

\textbf{USER}

The database user you are currently connected as. This is set every time you connect to a database (including program start-up), but can be unset.

\textbf{VERBOSITY}

This variable can be set to the values \texttt{default}, \texttt{verbose}, or \texttt{terse} to control the verbosity of error reports.

**SQL Interpolation**

A key feature of \texttt{psql} variables is that you can substitute (“interpolate”) them into regular SQL statements, as well as the arguments of meta-commands. Furthermore, \texttt{psql} provides facilities for ensuring that variable values used as SQL literals and identifiers are properly quoted. The syntax for interpolating a value without any quoting is to prepend the variable name with a colon (:). For example,

\begin{verbatim}
  testdb=> \set foo 'my_table'
  testdb=> SELECT * FROM :foo;
\end{verbatim}

would query the table \texttt{my_table}. Note that this may be unsafe: the value of the variable is copied literally, so it can contain unbalanced quotes, or even backslash commands. You must make sure that it makes sense where you put it.
When a value is to be used as an SQL literal or identifier, it is safest to arrange for it to be quoted. To quote the value of a variable as an SQL literal, write a colon followed by the variable name in single quotes. To quote the value as an SQL identifier, write a colon followed by the variable name in double quotes. These constructs deal correctly with quotes and other special characters embedded within the variable value. The previous example would be more safely written this way:

testdb=> \set foo 'my_table'
testdb=> SELECT * FROM :"foo";

Variable interpolation will not be performed within quoted SQL literals and identifiers. Therefore, a construction such as ':foo' doesn’t work to produce a quoted literal from a variable’s value (and it would be unsafe if it did work, since it wouldn’t correctly handle quotes embedded in the value).

One example use of this mechanism is to copy the contents of a file into a table column. First load the file into a variable and then interpolate the variable’s value as a quoted string:

testdb=> \set content 'cat my_file.txt'
testdb=> INSERT INTO my_table VALUES (:'content');

(Note that this still won’t work if my_file.txt contains NUL bytes. psql does not support embedded NUL bytes in variable values.)

Since colons can legally appear in SQL commands, an apparent attempt at interpolation (that is, :name, :name, or :"name") is not replaced unless the named variable is currently set. In any case, you can escape a colon with a backslash to protect it from substitution.

The colon syntax for variables is standard SQL for embedded query languages, such as ECPG. The colon syntaxes for array slices and type casts are PostgreSQL extensions, which can sometimes conflict with the standard usage. The colon-quote syntax for escaping a variable’s value as an SQL literal or identifier is a psql extension.

**Prompting**

The prompts psql issues can be customized to your preference. The three variables PROMPT1, PROMPT2, and PROMPT3 contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when psql requests a new command. Prompt 2 is issued when more input is expected during command entry, for example because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you are running an SQL COPY FROM STDIN command and you need to type in a row value on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (%) is encountered. Depending on the next character, certain other text is substituted instead. Defined substitutions are:

%M

The full host name (with domain name) of the database server, or [local] if the connection is over a Unix domain socket, or [local:/dir/name], if the Unix domain socket is not at the compiled in default location.

%m

The host name of the database server, truncated at the first dot, or [local] if the connection is over a Unix domain socket.
%>
The port number at which the database server is listening.

%n
The database session user name. (The expansion of this value might change during a database
session as the result of the command SET SESSION AUTHORIZATION.)

%/ The name of the current database.

%~
Like %/, but the output is ~ (tilde) if the database is your default database.

%#
If the session user is a database superuser, then a #, otherwise a >. (The expansion of this
value might change during a database session as the result of the command SET SESSION
AUTHORIZATION.)

%R
In prompt 1 normally =, but ^ if in single-line mode, or ! if the session is disconnected from
the database (which can happen if \connect fails). In prompt 2 %R is replaced by a character
that depends on why psql expects more input: = if the command simply wasn’t terminated yet,
but * if there is an unfinished /* ... */ comment, a single quote if there is an unfinished
quoted string, a double quote if there is an unfinished quoted identifier, a dollar sign if there is
an unfinished dollar-quoted string, or ( if there is an unmatched left parenthesis. In prompt 3 %R
doesn’t produce anything.

%x
Transaction status: an empty string when not in a transaction block, or * when in a transaction
block, or ! when in a failed transaction block, or ? when the transaction state is indeterminate
(for example, because there is no connection).

%1
The line number inside the current statement, starting from 1.

%digits
The character with the indicated octal code is substituted.

%:name:
The value of the psql variable name. See the section Variables for details.

%\"command\"
The output of command, similar to ordinary “back-tick” substitution.

%[ ... %]
Prompts can contain terminal control characters which, for example, change the color, back-
ground, or style of the prompt text, or change the title of the terminal window. In order for the
line editing features of Readline to work properly, these non-printing control characters must be
designated as invisible by surrounding them with %[ and %]. Multiple pairs of these can occur
within the prompt. For example:

testdb=> \set PROMPT1 '%\%033[1;33;40m\%n@%/%R\%\%033[0m\%' results in a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible,
color-capable terminals.
To insert a percent sign into your prompt, write %%. The default prompts are ‘%/%%’ for prompts 1 and 2, and ‘>>’ for prompt 3.

**Note:** This feature was shamelessly plagiarized from tcsh.

---

### Command-Line Editing

psql supports the Readline library for convenient line editing and retrieval. The command history is automatically saved when psql exits and is reloaded when psql starts up. Tab-completion is also supported, although the completion logic makes no claim to be an SQL parser. The queries generated by tab-completion can also interfere with other SQL commands, e.g. `SET TRANSACTION ISOLATION LEVEL`. If for some reason you do not like the tab completion, you can turn it off by putting this in a file named `.inputrc` in your home directory:

```bash
$if psql
set disable-completion on
$endif
```

(This is not a psql but a Readline feature. Read its documentation for further details.)

### Environment

**COLUMNS**

If `\pset columns` is zero, controls the width for the wrapped format and width for determining if wide output requires the pager or should be switched to the vertical format in expanded auto mode.

**PAGER**

If the query results do not fit on the screen, they are piped through this command. Typical values are `more` or `less`. The default is platform-dependent. Use of the pager can be disabled by setting `PAGER` to empty, or by using pager-related options of the `\pset` command.

**PGDATABASE**

**PGHOST**

**PGPORT**

**PGUSER**

Default connection parameters (see Section 31.14).

**PSQL_EDITOR**

**EDITOR**

**VISUAL**

Editor used by the `\e` and `\ef` commands. The variables are examined in the order listed; the first that is set is used.

The built-in default editors are `vi` on Unix systems and `notepad.exe` on Windows systems.
When \e or \ef is used with a line number argument, this variable specifies the command-line argument used to pass the starting line number to the user’s editor. For editors such as Emacs or vi, this is a plus sign. Include a trailing space in the value of the variable if there needs to be space between the option name and the line number. Examples:

```
PSQL_EDITOR_LINENUMBER_ARG='+'  
PSQL_EDITOR_LINENUMBER_ARG='--line '
```

The default is + on Unix systems (corresponding to the default editor vi, and useful for many other common editors); but there is no default on Windows systems.

**PSQL_HISTORY**

Alternative location for the command history file. Tilde (~) expansion is performed.

**PSQLRC**

Alternative location of the user’s .psqlrc file. Tilde (~) expansion is performed.

**SHELL**

Command executed by the `\!` command.

**TMPDIR**

Directory for storing temporary files. The default is /tmp.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 31.14).

## Files

**psqlrc** and ~/.psqlrc

Unless it is passed an -x or -c option, psql attempts to read and execute commands from the system-wide startup file (psqlrc) and then the user’s personal startup file (~/.psqlrc), after connecting to the database but before accepting normal commands. These files can be used to set up the client and/or the server to taste, typically with \set and SET commands.

The system-wide startup file is named psqlrc and is sought in the installation’s “system configuration” directory, which is most reliably identified by running `pg_config --sysconfdir`. By default this directory will be ./etc/ relative to the directory containing the PostgreSQL executables. The name of this directory can be set explicitly via the PGSYSCONFDIR environment variable.

The user’s personal startup file is named .psqlrc and is sought in the invoking user’s home directory. On Windows, which lacks such a concept, the personal startup file is named %APPDATA%\postgresql\psqlrc.conf. The location of the user’s startup file can be set explicitly via the PSQLRC environment variable.

Both the system-wide startup file and the user’s personal startup file can be made psql-version-specific by appending a dash and the PostgreSQL major or minor release number to the file name, for example ~/.psqlrc-9.2 or ~/.psqlrc-9.2.5. The most specific version-matching file will be read in preference to a non-version-specific file.

**.psql_history**

The command-line history is stored in the file ~/.psql_history, or %APPDATA%\postgresql\psql_history on Windows.
The location of the history file can be set explicitly via the `PSQL_HISTORY` environment variable.

**Notes**

- In an earlier life psql allowed the first argument of a single-letter backslash command to start directly after the command, without intervening whitespace. As of PostgreSQL 8.4 this is no longer allowed.

- psql works best with servers of the same or an older major version. Backslash commands are particularly likely to fail if the server is of a newer version than psql itself. However, backslash commands of the \d family should work with servers of versions back to 7.4, though not necessarily with servers newer than psql itself. The general functionality of running SQL commands and displaying query results should also work with servers of a newer major version, but this cannot be guaranteed in all cases.

If you want to use psql to connect to several servers of different major versions, it is recommended that you use the newest version of psql. Alternatively, you can keep a copy of psql from each major version around and be sure to use the version that matches the respective server. But in practice, this additional complication should not be necessary.

**Notes for Windows Users**

psql is built as a “console application”. Since the Windows console windows use a different encoding than the rest of the system, you must take special care when using 8-bit characters within psql. If psql detects a problematic console code page, it will warn you at startup. To change the console code page, two things are necessary:

- Set the code page by entering `cmd.exe /c chcp 1252`. (1252 is a code page that is appropriate for German; replace it with your value.) If you are using Cygwin, you can put this command in `/etc/profile`.
- Set the console font to Lucida Console, because the raster font does not work with the ANSI code page.

**Examples**

The first example shows how to spread a command over several lines of input. Notice the changing prompt:

```
testdb=> CREATE TABLE my_table ( 
testdb(> first integer not null default 0, 
testdb(> second text) 
testdb=> ; 
CREATE TABLE
```

Now look at the table definition again:

```
testdb=> \d my_table 
    Table "my_table"
```
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Type</th>
<th>Modifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>first</td>
<td>integer</td>
<td>not null default 0</td>
</tr>
<tr>
<td>second</td>
<td>text</td>
<td></td>
</tr>
</tbody>
</table>

Now we change the prompt to something more interesting:

testdb=> \set PROMPT1 '%n@%m %~%R%# '

Let’s assume you have filled the table with data and want to take a look at it:

peter@localhost testdb=> SELECT * FROM my_table;

<table>
<thead>
<tr>
<th>first</th>
<th>second</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>one</td>
</tr>
<tr>
<td>2</td>
<td>two</td>
</tr>
<tr>
<td>3</td>
<td>three</td>
</tr>
<tr>
<td>4</td>
<td>four</td>
</tr>
</tbody>
</table>

(4 rows)

You can display tables in different ways by using the \pset command:

peter@localhost testdb=> \pset border 2
Border style is 2.
peter@localhost testdb=> SELECT * FROM my_table;

<table>
<thead>
<tr>
<th>first</th>
<th>second</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>one</td>
</tr>
<tr>
<td>2</td>
<td>two</td>
</tr>
<tr>
<td>3</td>
<td>three</td>
</tr>
<tr>
<td>4</td>
<td>four</td>
</tr>
</tbody>
</table>

(4 rows)

peter@localhost testdb=> \pset border 0
Border style is 0.
peter@localhost testdb=> SELECT * FROM my_table;

<table>
<thead>
<tr>
<th>first</th>
<th>second</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>one</td>
</tr>
<tr>
<td>2</td>
<td>two</td>
</tr>
<tr>
<td>3</td>
<td>three</td>
</tr>
<tr>
<td>4</td>
<td>four</td>
</tr>
</tbody>
</table>

(4 rows)

peter@localhost testdb=> \pset border 1
Border style is 1.
peter@localhost testdb=> \pset format unaligned
Output format is unaligned.
peter@localhost testdb=> \pset fieldsep ","
Field separator is ",".
peter@localhost testdb=> \pset tuples_only
Showing only tuples.
peter@localhost testdb=> SELECT second, first FROM my_table;

one,1
two,2
three, 3
four, 4

Alternatively, use the short commands:

peter@localhost testdb=> \a \t \x
Output format is aligned.
Tuples only is off.
Expanded display is on.
peter@localhost testdb=> SELECT * FROM my_table;
- [ RECORD 1 ]-
  first | 1
  second | one
- [ RECORD 2 ]-
  first | 2
  second | two
- [ RECORD 3 ]-
  first | 3
  second | three
- [ RECORD 4 ]-
  first | 4
  second | four
reindexdb

Name
reindexdb — reindex a PostgreSQL database

Synopsis
reindexdb [connection-option...] [option...] [ --schema|--schema=... ] [ --table|--table=... ] [ --index|--index=... ] [ dbname ]
reindexdb [connection-option...] [option...] --all|--all
reindexdb [connection-option...] [option...] --system|--system=... [dbname]

Description
reindexdb is a utility for rebuilding indexes in a PostgreSQL database.
reindexdb is a wrapper around the SQL command REINDEX. There is no effective difference between
reindexing databases via this utility and via other methods for accessing the server.

Options
reindexdb accepts the following command-line arguments:

-a
--all
Reindex all databases.

[-d] dbname
[--dbname=] dbname
Specifies the name of the database to be reindexed. If this is not specified and -a (or --all) is
not used, the database name is read from the environment variable PGDATABASE. If that is not
set, the user name specified for the connection is used.

-e
--echo
Echo the commands that reindexdb generates and sends to the server.

-i index
--index=index
Recreate index only. Multiple indexes can be recreated by writing multiple -i switches.

-q
--quiet
Do not display progress messages.
reindexdb

- s
  --system
  Reindex database’s system catalogs.

- S schema
  --schema=schema
  Reindex schema only. Multiple schemas can be reindexed by writing multiple -S switches.

- t table
  --table=table
  Reindex table only. Multiple tables can be reindexed by writing multiple -t switches.

- v
  --verbose
  Print detailed information during processing.

- V
  --version
  Print the reindexdb version and exit.

- ?
  --help
  Show help about reindexdb command line arguments, and exit.

reindexdb also accepts the following command-line arguments for connection parameters:

- h host
  --host=host
  Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

- p port
  --port=port
  Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

- U username
  --username=username
  User name to connect as.

- w
  --no-password
  Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

- W
  --password
  Force reindexdb to prompt for a password before connecting to a database.

This option is never essential, since reindexdb will automatically prompt for a password if the server demands password authentication. However, reindexdb will waste a connection attempt
finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

`--maintenance-db=dbname`

Specifies the name of the database to connect to discover what other databases should be reindexed. If not specified, the `postgres` database will be used, and if that does not exist, `template1` will be used.

**Environment**

- `PGDATABASE`
- `PGHOST`
- `PGPORT`
- `PGUSER`

Default connection parameters

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 31.14).

**Diagnostics**

In case of difficulty, see REINDEX and psql for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

**Notes**

`reindexdb` might need to connect several times to the PostgreSQL server, asking for a password each time. It is convenient to have a `~/.pgpass` file in such cases. See Section 31.15 for more information.

**Examples**

To reindex the database `test`:

```
$ reindexdb test
```

To reindex the table `foo` and the index `bar` in a database named `abcd`:

```
$ reindexdb --table foo --index bar abcd
```

**See Also**

REINDEX
vacuumdb

Name
vacuumdb — garbage-collect and analyze a PostgreSQL database

Synopsis

vacuumdb [connection-option...] [option...] [ --table | -t table [ ( column [...] ) ] ] ...

vacuumdb [connection-option...] [option...] --all | -a

Description
vacuumdb is a utility for cleaning a PostgreSQL database. vacuumdb will also generate internal statistics used by the PostgreSQL query optimizer.

vacuumdb is a wrapper around the SQL command VACUUM. There is no effective difference between vacuuming and analyzing databases via this utility and via other methods for accessing the server.

Options
vacuumdb accepts the following command-line arguments:

- `--all`
  Vacuum all databases.

- `dbname`
  Specifies the name of the database to be cleaned or analyzed. If this is not specified and `--all` is not used, the database name is read from the environment variable PGDATABASE. If that is not set, the user name specified for the connection is used.

- `--echo`
  Echo the commands that vacuumdb generates and sends to the server.

- `--full`
  Perform “full” vacuuming.

- `--freeze`
  Aggressively “freeze” tuples.
Execute the vacuum or analyze commands in parallel by running \texttt{njobs} commands simultaneously. This option reduces the time of the processing but it also increases the load on the database server.

\texttt{vacuumdb} will open \texttt{njobs} connections to the database, so make sure your max\_connections setting is high enough to accommodate all connections.

Note that using this mode together with the \texttt{-f} (FULL) option might cause deadlock failures if certain system catalogs are processed in parallel.

\texttt{-q}  
\texttt{--quiet}

Do not display progress messages.

\texttt{-t table [ (column [,...]) ]}  
\texttt{--table=table [ (column [,...]) ]}

Clean or analyze table only. Column names can be specified only in conjunction with the \texttt{--analyze} or \texttt{--analyze-only} options. Multiple tables can be vacuumed by writing multiple \texttt{-t} switches.

\textbf{Tip:} If you specify columns, you probably have to escape the parentheses from the shell. (See examples below.)

\texttt{-v}  
\texttt{--verbose}

Print detailed information during processing.

\texttt{-V}  
\texttt{--version}

Print the vacuumdb version and exit.

\texttt{-z}  
\texttt{--analyze}

Also calculate statistics for use by the optimizer.

\texttt{-Z}  
\texttt{--analyze-only}

Only calculate statistics for use by the optimizer (no vacuum).

\texttt{--analyze-in-stages}

Only calculate statistics for use by the optimizer (no vacuum), like \texttt{--analyze-only}. Run several (currently three) stages of analyze with different configuration settings, to produce usable statistics faster.

This option is useful to analyze a database that was newly populated from a restored dump or by \texttt{pg_upgrade}. This option will try to create some statistics as fast as possible, to make the database usable, and then produce full statistics in the subsequent stages.

\texttt{-?}  
\texttt{--help}

Show help about vacuumdb command line arguments, and exit.
vacuumdb also accepts the following command-line arguments for connection parameters:

- **-h host**  
  --host=host  
  Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

- **-p port**  
  --port=port  
  Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

- **-U username**  
  --username=username  
  User name to connect as.

- **-w**  
  --no-password  
  Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

- **-W**  
  --password  
  Force vacuumdb to prompt for a password before connecting to a database.

  This option is never essential, since vacuumdb will automatically prompt for a password if the server demands password authentication. However, vacuumdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

- **--maintenance-db=dbname**  
  Specifies the name of the database to connect to discover what other databases should be vacuumed. If not specified, the postgres database will be used, and if that does not exist, template1 will be used.

---

**Environment**

PGDATABASE
PGHOST
PGPORT
PGUSER

Default connection parameters

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 31.14).
Diagnostics

In case of difficulty, see VACUUM and psql for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Notes

vacuumdb might need to connect several times to the PostgreSQL server, asking for a password each time. It is convenient to have a ~/.pgpass file in such cases. See Section 31.15 for more information.

Examples

To clean the database test:

$ vacuumdb test

To clean and analyze for the optimizer a database named bigdb:

$ vacuumdb --analyze bigdb

To clean a single table foo in a database named xyzzy, and analyze a single column bar of the table for the optimizer:

$ vacuumdb --analyze --verbose --table 'foo(bar)' xyzzy

VACUUM
III. PostgreSQL Server Applications

This part contains reference information for PostgreSQL server applications and support utilities. These commands can only be run usefully on the host where the database server resides. Other utility programs are listed in Reference II, *PostgreSQL Client Applications*. 
initdb

Name

initdb — create a new PostgreSQL database cluster

Synopsis

initdb [option...]|--pgdata|-D directory

Description

initdb creates a new PostgreSQL database cluster. A database cluster is a collection of databases that are managed by a single server instance.

Creating a database cluster consists of creating the directories in which the database data will live, generating the shared catalog tables (tables that belong to the whole cluster rather than to any particular database), and creating the template1 and postgres databases. When you later create a new database, everything in the template1 database is copied. (Therefore, anything installed in template1 is automatically copied into each database created later.) The postgres database is a default database meant for use by users, utilities and third party applications.

Although initdb will attempt to create the specified data directory, it might not have permission if the parent directory of the desired data directory is root-owned. To initialize in such a setup, create an empty data directory as root, then use chown to assign ownership of that directory to the database user account, then su to become the database user to run initdb.

initdb must be run as the user that will own the server process, because the server needs to have access to the files and directories that initdb creates. Since the server cannot be run as root, you must not run initdb as root either. (It will in fact refuse to do so.)

initdb initializes the database cluster’s default locale and character set encoding. The character set encoding, collation order (LC_COLLATE) and character set classes (LC_CTYPE, e.g. upper, lower, digit) can be set separately for a database when it is created. initdb determines those settings for the template1 database, which will serve as the default for all other databases.

To alter the default collation order or character set classes, use the --lc-collate and --lc-ctype options. Collation orders other than C or POSIX also have a performance penalty. For these reasons it is important to choose the right locale when running initdb.

The remaining locale categories can be changed later when the server is started. You can also use --locale to set the default for all locale categories, including collation order and character set classes. All server locale values (lc_*) can be displayed via SHOW ALL. More details can be found in Section 22.1.

To alter the default encoding, use the --encoding. More details can be found in Section 22.3.
Options

- **A authmethod**
  --auth=authmethod
  This option specifies the authentication method for local users used in pg_hba.conf (host and local lines). Do not use trust unless you trust all local users on your system. trust is the default for ease of installation.

- **--auth-host=authmethod**
  This option specifies the authentication method for local users via TCP/IP connections used in pg_hba.conf (host lines).

- **--auth-local=authmethod**
  This option specifies the authentication method for local users via Unix-domain socket connections used in pg_hba.conf (local lines).

- **-D directory**
  --pgdata=directory
  This option specifies the directory where the database cluster should be stored. This is the only information required by initdb, but you can avoid writing it by setting the PGDATA environment variable, which can be convenient since the database server (postgres) can find the database directory later by the same variable.

- **-E encoding**
  --encoding=encoding
 Selects the encoding of the template database. This will also be the default encoding of any database you create later, unless you override it there. The default is derived from the locale, or SQL_ASCII if that does not work. The character sets supported by the PostgreSQL server are described in Section 22.3.1.

- **-k**
  --data-checksums
  Use checksums on data pages to help detect corruption by the I/O system that would otherwise be silent. Enabling checksums may incur a noticeable performance penalty. This option can only be set during initialization, and cannot be changed later. If set, checksums are calculated for all objects, in all databases.

- **--locale=locale**
  Like --locale, but only sets the locale in the specified category.

- **--no-locale**
  Equivalent to --locale=C.
By default, `initdb` will wait for all files to be written safely to disk. This option causes `initdb` to return without waiting, which is faster, but means that a subsequent operating system crash can leave the data directory corrupt. Generally, this option is useful for testing, but should not be used when creating a production installation.

`--pwfile=filename`

Makes `initdb` read the database superuser’s password from a file. The first line of the file is taken as the password.

`--sync-only`

Safely write all database files to disk and exit. This does not perform any of the normal `initdb` operations.

`--text-search-config=CFG`

Sets the default text search configuration. See `default_text_search_config` for further information.

`--username=username`

Selects the user name of the database superuser. This defaults to the name of the effective user running `initdb`. It is really not important what the superuser’s name is, but one might choose to keep the customary name postgres, even if the operating system user’s name is different.

`--pwprompt`

Makes `initdb` prompt for a password to give the database superuser. If you don’t plan on using password authentication, this is not important. Otherwise you won’t be able to use password authentication until you have a password set up.

`--xlogdir=directory`

This option specifies the directory where the transaction log should be stored.

Other, less commonly used, options are also available:

`--debug`

Print debugging output from the bootstrap backend and a few other messages of lesser interest for the general public. The bootstrap backend is the program `initdb` uses to create the catalog tables. This option generates a tremendous amount of extremely boring output.

`directory`

Specifies where `initdb` should find its input files to initialize the database cluster. This is normally not necessary. You will be told if you need to specify their location explicitly.
initdb

-n
--noclean

By default, when initdb determines that an error prevented it from completely creating the
database cluster, it removes any files it might have created before discovering that it cannot
finish the job. This option inhibits tidying-up and is thus useful for debugging.

Other options:

-V
--version

Print the initdb version and exit.

-?
--help

Show help about initdb command line arguments, and exit.

Environment

PGDATA

Specifies the directory where the database cluster is to be stored; can be overridden using the -D
option.

TZ

Specifies the default time zone of the created database cluster. The value should be a full time
zone name (see Section 8.5.3).

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by
libpq (see Section 31.14).

Notes

initdb can also be invoked via pg_ctl initdb.

pg_ctl, postgres

**pg_archivecleanup**

**Name**

pg_archivecleanup — clean up PostgreSQL WAL archive files

**Synopsis**

pg_archivecleanup [option...] archivelocation oldestkeptwalfile

**Description**

pg_archivecleanup is designed to be used as an archive_cleanup_command to clean up WAL file archives when running as a standby server (see Section 25.2). pg_archivecleanup can also be used as a standalone program to clean WAL file archives.

To configure a standby server to use pg_archivecleanup, put this into its recovery.conf configuration file:

archive_cleanup_command = 'pg_archivecleanup archivelocation %r'

where archivelocation is the directory from which WAL segment files should be removed.

When used within archive_cleanup_command, all WAL files logically preceding the value of the %r argument will be removed from archivelocation. This minimizes the number of files that need to be retained, while preserving crash-restart capability. Use of this parameter is appropriate if the archivelocation is a transient staging area for this particular standby server, but not when the archivelocation is intended as a long-term WAL archive area, or when multiple standby servers are recovering from the same archive location.

When used as a standalone program all WAL files logically preceding the oldestkeptwalfile will be removed from archivelocation. In this mode, if you specify a .partial or .backup file name, then only the file prefix will be used as the oldestkeptwalfile. This treatment of .backup file name allows you to remove all WAL files archived prior to a specific base backup without error. For example, the following example will remove all files older than WAL file name 000000100000003700000010:

pg_archivecleanup -d archive 000000010000003700000010.00000020.backup

pg_archivecleanup: keep WAL file "archive/000000010000003700000010" and later
pg_archivecleanup: removing file "archive/00000001000000370000000F"
pg_archivecleanup: removing file "archive/00000001000000370000000E"

pg_archivecleanup assumes that archivelocation is a directory readable and writable by the server-owning user.
Options

pg_archivecleanup accepts the following command-line arguments:

- **d**
  Print lots of debug logging output on stderr.

- **n**
  Print the names of the files that would have been removed on stdout (performs a dry run).

- **V**
  --version
  Print the pg_archivecleanup version and exit.

- **x extension**
  When using the program as a standalone utility, provide an extension that will be stripped from all file names before deciding if they should be deleted. This is typically useful for cleaning up archives that have been compressed during storage, and therefore have had an extension added by the compression program. For example: -x .gz.

- **?**
  --help
  Show help about pg_archivecleanup command line arguments, and exit.

Notes

pg_archivecleanup is designed to work with PostgreSQL 8.0 and later when used as a standalone utility, or with PostgreSQL 9.0 and later when used as an archive cleanup command.

pg_archivecleanup is written in C and has an easy-to-modify source code, with specifically designated sections to modify for your own needs

Examples

On Linux or Unix systems, you might use:

```bash
archive_cleanup_command = 'pg_archivecleanup -d /mnt/standby/archive %r 2>>cleanup.log'
```

where the archive directory is physically located on the standby server, so that the archive_command is accessing it across NFS, but the files are local to the standby. This will:

- produce debugging output in cleanup.log
- remove no-longer-needed files from the archive directory

pg_standby
pg_controldata

Name
pg_controldata — display control information of a PostgreSQL database cluster

Synopsis
pg_controldata [option] [[-D] datadir]

Description
pg_controldata prints information initialized during initdb, such as the catalog version. It also shows information about write-ahead logging and checkpoint processing. This information is cluster-wide, and not specific to any one database.

This utility can only be run by the user who initialized the cluster because it requires read access to the data directory. You can specify the data directory on the command line, or use the environment variable PGDATA. This utility supports the options -V and --version, which print the pg_controldata version and exit. It also supports options -? and --help, which output the supported arguments.

Environment
PGDATA

Default data directory location
**pg_ctl**

**Name**

`pg_ctl` — initialize, start, stop, or control a PostgreSQL server

**Synopsis**

```
pg_ctl init[db] [-s] [-D datadir] [-o initdb-options]
pg_ctl reload [-s] [-D datadir]
pg_ctl status [-D datadir]
pg_ctl promote [-s] [-D datadir]
pg_ctl kill signal_name process_id
pg_ctl unregister [-N servicename]
```

**Description**

`pg_ctl` is a utility for initializing a PostgreSQL database cluster, starting, stopping, or restarting the PostgreSQL database server (postgres), or displaying the status of a running server. Although the server can be started manually, `pg_ctl` encapsulates tasks such as redirecting log output and properly detaching from the terminal and process group. It also provides convenient options for controlled shutdown.

The **init** or **initdb** mode creates a new PostgreSQL database cluster. A database cluster is a collection of databases that are managed by a single server instance. This mode invokes the **initdb** command. See initdb for details.

In **start** mode, a new server is launched. The server is started in the background, and its standard input is attached to `/dev/null` (or `nul` on Windows). On Unix-like systems, by default, the server’s
standard output and standard error are sent to pg_ctl’s standard output (not standard error). The standard output of pg_ctl should then be redirected to a file or piped to another process such as a log rotating program like rotatelogs; otherwise postgres will write its output to the controlling terminal (from the background) and will not leave the shell’s process group. On Windows, by default the server’s standard output and standard error are sent to the terminal. These default behaviors can be changed by using -l to append the server’s output to a log file. Use of either -l or output redirection is recommended.

In stop mode, the server that is running in the specified data directory is shut down. Three different shutdown methods can be selected with the -m option. “Smart” mode waits for all active clients to disconnect and any online backup to finish. If the server is in hot standby, recovery and streaming replication will be terminated once all clients have disconnected. “Fast” mode (the default) does not wait for clients to disconnect and will terminate an online backup in progress. All active transactions are rolled back and clients are forcibly disconnected, then the server is shut down. “Immediate” mode will abort all server processes immediately, without a clean shutdown. This will lead to a crash-recovery run on the next restart.

restart mode effectively executes a stop followed by a start. This allows changing the postgres command-line options. restart might fail if relative paths specified were specified on the command-line during server start.

reload mode simply sends the postgres process a SIGHUP signal, causing it to reread its configuration files (postgresql.conf, pg_hba.conf, etc.). This allows changing of configuration-file options that do not require a complete restart to take effect.

status mode checks whether a server is running in the specified data directory. If it is, the PID and the command line options that were used to invoke it are displayed. If the server is not running, the process returns an exit status of 3. If an accessible data directory is not specified, the process returns an exit status of 4.

In promote mode, the standby server that is running in the specified data directory is commanded to exit recovery and begin read-write operations.

kill mode allows you to send a signal to a specified process. This is particularly valuable for Microsoft Windows which does not have a kill command. Use --help to see a list of supported signal names.

register mode allows you to register a system service on Microsoft Windows. The -S option allows selection of service start type, either “auto” (start service automatically on system startup) or “demand” (start service on demand).

unregister mode allows you to unregister a system service on Microsoft Windows. This undoes the effects of the register command.

Options

-c
--core-file

Attempt to allow server crashes to produce core files, on platforms where this is possible, by lifting any soft resource limit placed on core files. This is useful in debugging or diagnosing problems by allowing a stack trace to be obtained from a failed server process.
-D datadir
--pgdata datadir

Specifies the file system location of the database configuration files. If this is omitted, the environment variable PGDATA is used.

-l filename
--log filename

Append the server log output to filename. If the file does not exist, it is created. The umask is set to 077, so access to the log file is disallowed to other users by default.

-m mode
--mode mode

Specifies the shutdown mode. mode can be smart, fast, or immediate, or the first letter of one of these three. If this is omitted, fast is used.

-o options

Specifies options to be passed directly to the postgres command; multiple option invocations are appended.

The options should usually be surrounded by single or double quotes to ensure that they are passed through as a group.

-o initdb-options

Specifies options to be passed directly to the initdb command.

The options should usually be surrounded by single or double quotes to ensure that they are passed through as a group.

-p path

Specifies the location of the postgres executable. By default the postgres executable is taken from the same directory as pg_ctl, or failing that, the hard-wired installation directory. It is not necessary to use this option unless you are doing something unusual and get errors that the postgres executable was not found.

In init mode, this option analogously specifies the location of the initdb executable.

-s silent

Print only errors, no informational messages.

-t --timeout

The maximum number of seconds to wait when waiting for startup or shutdown to complete. Defaults to the value of the PGCTLTIMEOUT environment variable or, if not set, to 60 seconds.

-v --version

Print the pg_ctl version and exit.

-w

Wait for the startup or shutdown to complete. Waiting is the default option for shutdowns, but not startups. When waiting for startup, pg_ctl repeatedly attempts to connect to the server. When waiting for shutdown, pg_ctl waits for the server to remove its PID file. This option allows the entry of an SSL passphrase on startup. pg_ctl returns an exit code based on the success of the startup or shutdown.
pg_ctl

-\W

Do not wait for startup or shutdown to complete. This is the default for start and restart modes.

-? --help

Show help about pg_ctl command line arguments, and exit.

Options for Windows

-\e source

Name of the event source for pg_ctl to use for logging to the event log when running as a Windows service. The default is PostgreSQL. Note that this only controls the logging from pg_ctl itself; once started, the server will use the event source specified by event_source. Should the server fail during early startup, it might also log using the default event source PostgreSQL.

-\N servicename

Name of the system service to register. The name will be used as both the service name and the display name.

-\P password

Password for the user to start the service.

-\S start-type

Start type of the system service to register. start-type can be auto, or demand, or the first letter of one of these two. If this is omitted, auto is used.

-\U username

User name for the user to start the service. For domain users, use the format DOMAIN\username.

Environment

PGCTLOUT

Default limit on the number of seconds to wait when waiting for startup or shutdown to complete. If not set, the default is 60 seconds.

PGDATA

Default data directory location.

pg_ctl, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 31.14). For additional server variables, see postgres.

Files

postmaster.pid

The existence of this file in the data directory is used to help pg_ctl determine if the server is currently running.
If this file exists in the data directory, `pg_ctl` (in `restart` mode) will pass the contents of the file as options to `postgres`, unless overridden by the `-o` option. The contents of this file are also displayed in `status` mode.

### Examples

#### Starting the Server

To start the server:

```
$ pg_ctl start
```

To start the server, waiting until the server is accepting connections:

```
$ pg_ctl -w start
```

To start the server using port 5433, and running without `fsync`, use:

```
$ pg_ctl -o "-F -p 5433" start
```

#### Stopping the Server

To stop the server, use:

```
$ pg_ctl stop
```

The `-m` option allows control over how the server shuts down:

```
$ pg_ctl stop -m fast
```

#### Restarting the Server

Restarting the server is almost equivalent to stopping the server and starting it again, except that `pg_ctl` saves and reuses the command line options that were passed to the previously running instance. To restart the server in the simplest form, use:

```
$ pg_ctl restart
```

To restart the server, waiting for it to shut down and restart:

```
$ pg_ctl -w restart
```
To restart using port 5433, disabling `fsync` upon restart:

```
$ pg_ctl -o "-F -p 5433" restart
```

### Showing the Server Status

Here is sample status output from `pg_ctl`:

```
$ pg_ctl status
pg_ctl: server is running (PID: 13718)
/usr/local/pgsql/bin/postgres "-D" "/usr/local/pgsql/data" "-p" "5433" "-B" "128"
```

This is the command line that would be invoked in restart mode.

### See Also

`initdb`, `postgres`
pg_resetxlog

Name

pg_resetxlog — reset the write-ahead log and other control information of a PostgreSQL database cluster

Synopsis

Description

pg_resetxlog clears the write-ahead log (WAL) and optionally resets some other control information stored in the pg_control file. This function is sometimes needed if these files have become corrupted. It should be used only as a last resort, when the server will not start due to such corruption.

After running this command, it should be possible to start the server, but bear in mind that the database might contain inconsistent data due to partially-committed transactions. You should immediately dump your data, run initdb, and reload. After reload, check for inconsistencies and repair as needed.

This utility can only be run by the user who installed the server, because it requires read/write access to the data directory. For safety reasons, you must specify the data directory on the command line. pg_resetxlog does not use the environment variable PGDATA.

If pg_resetxlog complains that it cannot determine valid data for pg_control, you can force it to proceed anyway by specifying the -f (force) option. In this case plausible values will be substituted for the missing data. Most of the fields can be expected to match, but manual assistance might be needed for the next OID, next transaction ID and epoch, next multitransaction ID and offset, and WAL starting address fields. These fields can be set using the options discussed below. If you are not able to determine correct values for all these fields, -f can still be used, but the recovered database must be treated with even more suspicion than usual: an immediate dump and reload is imperative.

Do not execute any data-modifying operations in the database before you dump, as any such action is likely to make the corruption worse.

The -o, -x, -e, -m, -O, -c and -l options allow the next OID, next transaction ID, next transaction ID’s epoch, next and oldest multitransaction ID, next multitransaction offset, oldest and newest transaction IDs for which the commit time can be retrieved, and WAL starting address values to be set manually. These are only needed when pg_resetxlog is unable to determine appropriate values by reading pg_control. Safe values can be determined as follows:

- A safe value for the next transaction ID (-x) can be determined by looking for the numerically largest file name in the directory pg_clog under the data directory, adding one, and then multiplying by 1048576. Note that the file names are in hexadecimal. It is usually easiest to specify the option value in hexadecimal too. For example, if 0011 is the largest entry in pg_clog, -x 0x1200000 will work (five trailing zeroes provide the proper multiplier).

- A safe value for the next multitransaction ID (first part of -m) can be determined by looking for the numerically largest file name in the directory pg_multixact/offsets under the data directory, adding one, and then multiplying by 65536. Conversely, a safe value for the oldest multitransaction
ID (second part of -m) can be determined by looking for the numerically smallest file name in the same directory and multiplying by 65536. As above, the file names are in hexadecimal, so the easiest way to do this is to specify the option value in hexadecimal and append four zeroes.

- A safe value for the next multitransaction offset (-O) can be determined by looking for the numerically largest file name in the directory `pg_multixact/members` under the data directory, adding one, and then multiplying by 52352. As above, the file names are in hexadecimal. There is no simple recipe such as the ones above of appending zeroes.

- A safe value for the oldest transaction ID for which the commit time can be retrieved (first part of -c) can be determined by looking for the numerically smallest file name in the directory `pg_commit_ts` under the data directory. Conversely, a safe value for the newest transaction ID for which the commit time can be retrieved (second part of -c) can be determined by looking for the numerically greatest file name in the same directory. As above, the file names are in hexadecimal.

- The WAL starting address (-l) should be larger than any WAL segment file name currently existing in the directory `pg_xlog` under the data directory. These names are also in hexadecimal and have three parts. The first part is the “timeline ID” and should usually be kept the same. For example, if `0000001000000320000004A` is the largest entry in `pg_xlog`, use `-l 0000001000000320000004B` or higher.

Note: `pg_resetxlog` itself looks at the files in `pg_xlog` and chooses a default `-l` setting beyond the last existing file name. Therefore, manual adjustment of `-l` should only be needed if you are aware of WAL segment files that are not currently present in `pg_xlog`, such as entries in an offline archive; or if the contents of `pg_xlog` have been lost entirely.

- There is no comparably easy way to determine a next OID that’s beyond the largest one in the database, but fortunately it is not critical to get the next-OID setting right.

- The transaction ID epoch is not actually stored anywhere in the database except in the field that is set by `pg_resetxlog`, so any value will work so far as the database itself is concerned. You might need to adjust this value to ensure that replication systems such as Slony-I and Skytools work correctly — if so, an appropriate value should be obtainable from the state of the downstream replicated database.

The `-n` (no operation) option instructs `pg_resetxlog` to print the values reconstructed from `pg_control` and values about to be changed, and then exit without modifying anything. This is mainly a debugging tool, but can be useful as a sanity check before allowing `pg_resetxlog` to proceed for real.

The `-V` and `--version` options print the `pg_resetxlog` version and exit. The options `-?` and `--help` show supported arguments, and exit.

Notes

This command must not be used when the server is running. `pg_resetxlog` will refuse to start up if it finds a server lock file in the data directory. If the server crashed then a lock file might have been left behind; in that case you can remove the lock file to allow `pg_resetxlog` to run. But before you do so, make doubly certain that there is no server process still alive.

`pg_resetxlog` works only with servers of the same major version.
pg_rewind

Name

pg_rewind — synchronize a PostgreSQL data directory with another data directory that was forked from the first one

Synopsis

gp_rewind[option...] [-D | --target-pgdata] directory { --source-pgdata=directory | --source-server=connstr }

Description

pg_rewind is a tool for synchronizing a PostgreSQL cluster with another copy of the same cluster, after the clusters’ timelines have diverged. A typical scenario is to bring an old master server back online after failover, as a standby that follows the new master.

The result is equivalent to replacing the target data directory with the source one. All files are copied, including configuration files. The advantage of pg_rewind over taking a new base backup, or tools like rsync, is that pg_rewind does not require reading through all unchanged files in the cluster. That makes it a lot faster when the database is large and only a small portion of it differs between the clusters.

pg_rewind examines the timeline histories of the source and target clusters to determine the point where they diverged, and expects to find WAL in the target cluster’s pg_xlog directory reaching all the way back to the point of divergence. In the typical failover scenario where the target cluster was shut down soon after the divergence, that is not a problem, but if the target cluster had run for a long time after the divergence, the old WAL files might not be present anymore. In that case, they can be manually copied from the WAL archive to the pg_xlog directory. Fetching missing files from a WAL archive automatically is currently not supported.

When the target server is started up for the first time after running pg_rewind, it will go into recovery mode and replay all WAL generated in the source server after the point of divergence. If some of the WAL was no longer available in the source server when pg_rewind was run, and therefore could not be copied by pg_rewind session, it needs to be made available when the target server is started up. That can be done by creating a recovery.conf file in the target data directory with a suitable restore_command.

pg_rewind requires that the target server either has the wal_log_hints option is enabled in postgresql.conf or that data checksums were enabled when the cluster was initialized with initdb. Neither of these are currently on by default. full_page_writes must also be enabled. That is the default.
**Warning**

If pg_rewind fails while processing, then the data folder of the target is likely not in a state that can be recovered. In such a case, taking a new fresh backup is recommended.

pg_rewind will fail immediately if it finds files it cannot write directly to. This can happen for example when the source and the target server use the same file mapping for read-only SSL keys and certificates. If such files are present on the target server it is recommended to remove them before running pg_rewind. After doing the rewind, some of those files may have been copied from the source, in which case it may be necessary to remove the data copied and restore back the set of links used before the rewind.

**Options**

pg_rewind accepts the following command-line arguments:

- `-D directory`
- `--target-pgdata=directory`

This option specifies the target data directory that is synchronized with the source. The target server must shut down cleanly before running pg_rewind

- `--source-pgdata=directory`

Specifies path to the data directory of the source server, to synchronize the target with. When `--source-pgdata` is used, the source server must be cleanly shut down.

- `--source-server=connstr`

Specifies a libpq connection string to connect to the source PostgreSQL server to synchronize the target with. The connection must be a normal (non-replication) connection with superuser access. The server must be up and running, and must not be in recovery mode.

- `-n`
- `--dry-run`

Do everything except actually modifying the target directory.

- `-P`
- `--progress`

Enables progress reporting. Turning this on will deliver an approximate progress report while copying data over from the source cluster.

- `--debug`

Print verbose debugging output that is mostly useful for developers debugging pg_rewind.

- `-V`
- `--version`

Display version information, then exit.

- `--help`

Show help, then exit.
Environment

When `--source-server` option is used, `pg_rewind` also uses the environment variables supported by libpq (see Section 31.14).

Notes

How it works

The basic idea is to copy everything from the new cluster to the old cluster, except for the blocks that we know to be the same.

1. Scan the WAL log of the old cluster, starting from the last checkpoint before the point where the new cluster’s timeline history forked off from the old cluster. For each WAL record, make a note of the data blocks that were touched. This yields a list of all the data blocks that were changed in the old cluster, after the new cluster forked off.
2. Copy all those changed blocks from the new cluster to the old cluster.
3. Copy all other files such as `clog` and configuration files from the new cluster to the old cluster, everything except the relation files.
4. Apply the WAL from the new cluster, starting from the checkpoint created at failover. (Strictly speaking, `pg_rewind` doesn’t apply the WAL, it just creates a backup label file indicating that when PostgreSQL is started, it will start replay from that checkpoint and apply all the required WAL.)
pg_test_fsync

Name

pg_test_fsync — determine fastest wal_sync_method for PostgreSQL

Synopsis

pg_test_fsync[option...]

Description

pg_test_fsync is intended to give you a reasonable idea of what the fastest wal_sync_method is on your specific system, as well as supplying diagnostic information in the event of an identified I/O problem. However, differences shown by pg_test_fsync might not make any significant difference in real database throughput, especially since many database servers are not speed-limited by their transaction logs. pg_test_fsync reports average file sync operation time in microseconds for each wal_sync_method, which can also be used to inform efforts to optimize the value of commit_delay.

Options

pg_test_fsync accepts the following command-line options:

- f
  --filename
  Specifies the file name to write test data in. This file should be in the same file system that the pg_xlog directory is or will be placed in. (pg_xlog contains the WAL files.) The default is pg_test_fsync.out in the current directory.

- s
  --secs-per-test
  Specifies the number of seconds for each test. The more time per test, the greater the test’s accuracy, but the longer it takes to run. The default is 5 seconds, which allows the program to complete in under 2 minutes.

- V
  --version
  Print the pg_test_fsync version and exit.

-?
  --help
  Show help about pg_test_fsync command line arguments, and exit.

postgres
**pg_test_timing**

**Name**

`pg_test_timing` — measure timing overhead

**Synopsis**

`pg_test_timing [option...]`

**Description**

`pg_test_timing` is a tool to measure the timing overhead on your system and confirm that the system time never moves backwards. Systems that are slow to collect timing data can give less accurate `EXPLAIN ANALYZE` results.

**Options**

`pg_test_timing` accepts the following command-line options:

- `-d duration`
  - `--duration=duration`
  
  Specifies the test duration, in seconds. Longer durations give slightly better accuracy, and are more likely to discover problems with the system clock moving backwards. The default test duration is 3 seconds.

- `--version`

- `--help`

  Show help about `pg_test_timing` command line arguments, and exit.

**Usage**

**Interpreting results**

Good results will show most (>90%) individual timing calls take less than one microsecond. Average per loop overhead will be even lower, below 100 nanoseconds. This example from an Intel i7-860 system using a TSC clock source shows excellent performance:

Testing timing overhead for 3 seconds.
Per loop time including overhead: 35.96 nsec
Histogram of timing durations:
Measuring executor timing overhead

When the query executor is running a statement using `EXPLAIN ANALYZE`, individual operations are timed as well as showing a summary. The overhead of your system can be checked by counting rows with the `psql` program:

```sql
CREATE TABLE t AS SELECT * FROM generate_series(1,100000);
\timing
SELECT COUNT(*) FROM t;
EXPLAIN ANALYZE SELECT COUNT(*) FROM t;
```

The i7-860 system measured runs the count query in 9.8 ms while the `EXPLAIN ANALYZE` version takes 16.6 ms, each processing just over 100,000 rows. That 6.8 ms difference means the timing overhead per row is 68 ns, about twice what `pg_test_timing` estimated it would be. Even that relatively small amount of overhead is making the fully timed count statement take almost 70% longer. On more substantial queries, the timing overhead would be less problematic.

Changing time sources

On some newer Linux systems, it’s possible to change the clock source used to collect timing data at any time. A second example shows the slowdown possible from switching to the slower acpi_pm time source, on the same system used for the fast results above:

```bash
# cat /sys/devices/system/clocksource/clocksource0/available_clocksource
tsc hpet acpi_pm
# echo acpi_pm > /sys/devices/system/clocksource/clocksource0/current_clocksource
# pg_test_timing
Per loop time including overhead: 722.92 nsec
```

In this configuration, the sample `EXPLAIN ANALYZE` above takes 115.9 ms. That’s 1061 nsec of timing overhead, again a small multiple of what’s measured directly by this utility. That much timing
overhead means the actual query itself is only taking a tiny fraction of the accounted for time, most of it is being consumed in overhead instead. In this configuration, any EXPLAIN ANALYZE totals involving many timed operations would be inflated significantly by timing overhead.

FreeBSD also allows changing the time source on the fly, and it logs information about the timer selected during boot:

```bash
# dmesg | grep "Timecounter"
Timecounter "ACPI-fast" frequency 3579545 Hz quality 900
Timecounter "i8254" frequency 1193182 Hz quality 0
Timecounters tick every 10.000 msec
Timecounter "TSC" frequency 2531787134 Hz quality 800
# sysctl kern.timecounter.hardware=TSC
kern.timecounter.hardware: ACPI-fast -> TSC
```

Other systems may only allow setting the time source on boot. On older Linux systems the "clock" kernel setting is the only way to make this sort of change. And even on some more recent ones, the only option you’ll see for a clock source is "jiffies". Jiffies are the older Linux software clock implementation, which can have good resolution when it’s backed by fast enough timing hardware, as in this example:

```bash
$ cat /sys/devices/system/clocksource/clocksource0/available_clocksource
  jiffies
$ dmesg | grep time.c
time.c: Using 3.579545 MHz WALL PM GTOD PIT/TSC timer.
time.c: Detected 2400.153 MHz processor.
$ pg_test_timing
Testing timing overhead for 3 seconds.
Per timing duration including loop overhead: 97.75 ns
Histogram of timing durations:
  < usec  % of total  count
    1  90.23734    27694571
    2  9.75277     2993204
    4  0.00981     3010
    8  0.00007     22
   16  0.00000     1
   32  0.00000     1
```

Clock hardware and timing accuracy

Collecting accurate timing information is normally done on computers using hardware clocks with various levels of accuracy. With some hardware the operating systems can pass the system clock time almost directly to programs. A system clock can also be derived from a chip that simply provides timing interrupts, periodic ticks at some known time interval. In either case, operating system kernels provide a clock source that hides these details. But the accuracy of that clock source and how quickly it can return results varies based on the underlying hardware.

Inaccurate time keeping can result in system instability. Test any change to the clock source very carefully. Operating system defaults are sometimes made to favor reliability over best accuracy. And if you are using a virtual machine, look into the recommended time sources compatible with it. Virtual hardware faces additional difficulties when emulating timers, and there are often per operating system settings suggested by vendors.
The Time Stamp Counter (TSC) clock source is the most accurate one available on current generation CPUs. It’s the preferred way to track the system time when it’s supported by the operating system and the TSC clock is reliable. There are several ways that TSC can fail to provide an accurate timing source, making it unreliable. Older systems can have a TSC clock that varies based on the CPU temperature, making it unusable for timing. Trying to use TSC on some older multicore CPUs can give a reported time that’s inconsistent among multiple cores. This can result in the time going backwards, a problem this program checks for. And even the newest systems can fail to provide accurate TSC timing with very aggressive power saving configurations.

Newer operating systems may check for the known TSC problems and switch to a slower, more stable clock source when they are seen. If your system supports TSC time but doesn’t default to that, it may be disabled for a good reason. And some operating systems may not detect all the possible problems correctly, or will allow using TSC even in situations where it’s known to be inaccurate.

The High Precision Event Timer (HPET) is the preferred timer on systems where it’s available and TSC is not accurate. The timer chip itself is programmable to allow up to 100 nanosecond resolution, but you may not see that much accuracy in your system clock.

Advanced Configuration and Power Interface (ACPI) provides a Power Management (PM) Timer, which Linux refers to as the acpi_pm. The clock derived from acpi_pm will at best provide 300 nanosecond resolution.

Timers used on older PC hardware include the 8254 Programmable Interval Timer (PIT), the real-time clock (RTC), the Advanced Programmable Interrupt Controller (APIC) timer, and the Cyclone timer. These timers aim for millisecond resolution.

pg_upgrade

Name

pg_upgrade — upgrade a PostgreSQL server instance

Synopsis

pg_upgrade -b oldbindir -B newbindir -d olddatadir -D newdatadir [option...]

Description

pg_upgrade (formerly called pg_migrator) allows data stored in PostgreSQL data files to be upgraded to a later PostgreSQL major version without the data dump/reload typically required for major version upgrades, e.g. from 8.4.7 to the current major release of PostgreSQL. It is not required for minor version upgrades, e.g. from 9.0.1 to 9.0.4.

Major PostgreSQL releases regularly add new features that often change the layout of the system tables, but the internal data storage format rarely changes. pg_upgrade uses this fact to perform rapid upgrades by creating new system tables and simply reusing the old user data files. If a future major release ever changes the data storage format in a way that makes the old data format unreadable, pg_upgrade will not be usable for such upgrades. (The community will attempt to avoid such situations.)

pg_upgrade does its best to make sure the old and new clusters are binary-compatible, e.g. by checking for compatible compile-time settings, including 32/64-bit binaries. It is important that any external modules are also binary compatible, though this cannot be checked by pg_upgrade.

pg_upgrade supports upgrades from 8.4.X and later to the current major release of PostgreSQL, including snapshot and alpha releases.

Options

pg_upgrade accepts the following command-line arguments:

- **-b bindir**
  --old-bindir=bindir
  the old PostgreSQL executable directory; environment variable PGBINOLD

- **-B bindir**
  --new-bindir=bindir
  the new PostgreSQL executable directory; environment variable PGBINNEW

- **-c**
  --check
  check clusters only, don’t change any data
-d datadir
--old-datadir=datadir
the old cluster data directory; environment variable PGDATAOLD

-D datadir
--new-datadir=datadir
the new cluster data directory; environment variable PGDATANEW

-j
--jobs
number of simultaneous processes or threads to use

-k
--link
use hard links instead of copying files to the new cluster

-o options
--old-options options
options to be passed directly to the old postgres command; multiple option invocations are appended

-O options
--new-options options
options to be passed directly to the new postgres command; multiple option invocations are appended

-p port
--old-port=port
the old cluster port number; environment variable PGPORTOLD

-P port
--new-port=port
the new cluster port number; environment variable PGPORTNEW

-r
--retain
retain SQL and log files even after successful completion

-U username
--username=username
cluster’s install user name; environment variable PGUSER

-v
--verbose
enable verbose internal logging

-V
--version
display version information, then exit

-?
--help
show help, then exit
Usage

These are the steps to perform an upgrade with `pg_upgrade`:

1. Optionally move the old cluster
   
   If you are using a version-specific installation directory, e.g. `/opt/PostgreSQL/9.1`, you do not need to move the old cluster. The graphical installers all use version-specific installation directories.

   If your installation directory is not version-specific, e.g. `/usr/local/pgsql`, it is necessary to move the current PostgreSQL install directory so it does not interfere with the new PostgreSQL installation. Once the current PostgreSQL server is shut down, it is safe to rename the PostgreSQL installation directory; assuming the old directory is `/usr/local/pgsql`, you can do:
   ```
   mv /usr/local/pgsql /usr/local/pgsql.old
   ```
   to rename the directory.

2. For source installs, build the new version
   
   Build the new PostgreSQL source with configure flags that are compatible with the old cluster. `pg_upgrade` will check `pg_controldata` to make sure all settings are compatible before starting the upgrade.

3. Install the new PostgreSQL binaries
   
   Install the new server’s binaries and support files. `pg_upgrade` is included in a default installation.

   For source installs, if you wish to install the new server in a custom location, use the `prefix` variable:
   ```
   make prefix=/usr/local/pgsql.new install
   ```

4. Initialize the new PostgreSQL cluster
   
   Initialize the new cluster using `initdb`. Again, use compatible `initdb` flags that match the old cluster. Many prebuilt installers do this step automatically. There is no need to start the new cluster.

5. Install custom shared object files
   
   Install any custom shared object files (or DLLs) used by the old cluster into the new cluster, e.g. `pgcrypto.so`, whether they are from `contrib` or some other source. Do not install the schema definitions, e.g. `CREATE EXTENSION pgcrypto`, because these will be upgraded from the old cluster. Also, any custom full text search files (dictionary, synonym, thesaurus, stop words) must also be copied to the new cluster.

6. Adjust authentication
   
   `pg_upgrade` will connect to the old and new servers several times, so you might want to set authentication to `peer` in `pg_hba.conf` or use a `~/.pgpass` file (see Section 31.15).

7. Stop both servers
   
   Make sure both database servers are stopped using, on Unix, e.g.:
   ```
   pg_ctl -D /opt/PostgreSQL/8.4 stop
   pg_ctl -D /opt/PostgreSQL/9.0 stop
   ```
   or on Windows, using the proper service names:
   ```
   NET STOP postgresql-8.4
   NET STOP postgresql-9.0
   ```

   Streaming replication and log-shipping standby servers can remain running until a later step.
8. Prepare for standby server upgrades

If you are upgrading standby servers using methods outlined in section step 10, verify that the old standby servers are caught up by running `pg_controldata` against the old primary and standby clusters. Verify that the “Latest checkpoint location” values match in all clusters. (There will be a mismatch if old standby servers were shut down before the old primary.) Also, change `wal_level` to `hot_standby` in the `postgresql.conf` file on the new primary cluster.

9. Run pg_upgrade

Always run the `pg_upgrade` binary of the new server, not the old one. `pg_upgrade` requires the specification of the old and new cluster’s data and executable (`bin`) directories. You can also specify user and port values, and whether you want the data linked instead of copied (the default).

If you use link mode, the upgrade will be much faster (no file copying) and use less disk space, but you will not be able to access your old cluster once you start the new cluster after the upgrade. Link mode also requires that the old and new cluster data directories be in the same file system. (Tablespaces and `pg_xlog` can be on different file systems.) See `pg_upgrade --help` for a full list of options.

The `--jobs` option allows multiple CPU cores to be used for copying/linking of files and to dump and reload database schemas in parallel; a good place to start is the maximum of the number of CPU cores and tablespaces. This option can dramatically reduce the time to upgrade a multi-database server running on a multiprocessor machine.

For Windows users, you must be logged into an administrative account, and then start a shell as the `postgres` user and set the proper path:

```bash
RUNAS /USER:postgres "CMD.EXE"
SET PATH=%PATH%;C:\Program Files\PostgreSQL\9.0\bin;
```

and then run `pg_upgrade` with quoted directories, e.g.:

```bash
pg_upgrade.exe
   --old-datadir "C:/Program Files/PostgreSQL/8.4/data"
   --new-datadir "C:/Program Files/PostgreSQL/9.0/data"
   --old-bindir "C:/Program Files/PostgreSQL/8.4/bin"
   --new-bindir "C:/Program Files/PostgreSQL/9.0/bin"
```

Once started, `pg_upgrade` will verify the two clusters are compatible and then do the upgrade. You can use `pg_upgrade --check` to perform only the checks, even if the old server is still running. `pg_upgrade --check` will also outline any manual adjustments you will need to make after the upgrade. If you are going to be using link mode, you should use the `--link` option with `--check` to enable link-mode-specific checks. `pg_upgrade` requires write permission in the current directory.

Obviously, no one should be accessing the clusters during the upgrade. `pg_upgrade` defaults to running servers on port 50432 to avoid unintended client connections. You can use the same port number for both clusters when doing an upgrade because the old and new clusters will not be running at the same time. However, when checking an old running server, the old and new port numbers must be different.

If an error occurs while restoring the database schema, `pg_upgrade` will exit and you will have to revert to the old cluster as outlined in step 16 below. To try `pg_upgrade` again, you will need to modify the old cluster so the `pg_upgrade` schema restore succeeds. If the problem is a `contrib` module, you might need to uninstall the `contrib` module from the old cluster and install it in the new cluster after the upgrade, assuming the module is not being used to store user data.

10. Upgrade Streaming Replication and Log-Shipping standby servers

If you used link mode and have Streaming Replication (see Section 25.2.5) or Log-Shipping (see Section 25.2) standby servers, you can follow these steps to quickly upgrade them. You will not
be running pg_upgrade on the standby servers, but rather rsync on the primary. Do not start any servers yet.

If you did not use link mode, do not have or do not want to use rsync, or want an easier solution, skip the instructions in this section and simply recreate the standby servers once pg_upgrade completes and the new primary is running.

a. Install the new PostgreSQL binaries on standby servers
   Make sure the new binaries and support files are installed on all standby servers.

b. Make sure the new standby data directories do not exist
   Make sure the new standby data directories do not exist or are empty. If initdb was run, delete the standby servers’ new data directories.

c. Install custom shared object files
   Install the same custom shared object files on the new standbys that you installed in the new primary cluster.

d. Stop standby servers
   If the standby servers are still running, stop them now using the above instructions.

e. Save configuration files
   Save any configuration files from the old standbys’ data directories you need to keep, e.g. postgresql.conf, recovery.conf, because these will be overwritten or removed in the next step.

f. Run rsync
   When using link mode, standby servers can be quickly upgraded using rsync. To accomplish this, from a directory on the primary server that is above the old and new database cluster directories, run this on the primary for each standby server:
   
   rsync --archive --delete --hard-links --size-only --no-inc-recursive old_cluster
   
   where old_cluster and new_cluster are relative to the current directory on the primary, and remote_dir is above the old and new cluster directories on the standby.

   The directory structure under the specified directories on the primary and standbys must match. Consult the rsync manual page for details on specifying the remote directory, e.g.
   
   rsync --archive --delete --hard-links --size-only --no-inc-recursive /opt/PostgreSQL/9.5
   
   /opt/PostgreSQL/9.6 standby.example.com:/opt/PostgreSQL
   
   You can verify what the command will do using rsync’s --dry-run option. While rsync must be run on the primary for at least one standby, it is possible to run rsync on an upgraded standby to upgrade other standbys, as long as the upgraded standby has not been started.

   What this does is to record the links created by pg_upgrade’s link mode that connect files in the old and new clusters on the primary server. It then finds matching files in the standby’s old cluster and creates links for them in the standby’s new cluster. Files that were not linked on the primary are copied from the primary to the standby. (They are usually small.) This provides rapid standby upgrades. Unfortunately, rsync needlessly copies files associated with temporary and unlogged tables because these files don’t normally exist on standby servers.

   If you have tablespaces, you will need to run a similar rsync command for each tablespace directory, e.g.: 
   
   rsync --archive --delete --hard-links --size-only --no-inc-recursive /vol1/pg_tblsp/PG_9.6_201608131 standby.example.com:/vol1/pg_tblsp
If you have relocated `pg_xlog` outside the data directories, `rsync` must be run on those directories too.

**g. Configure streaming replication and log-shipping standby servers**

Configure the servers for log shipping. (You do not need to run `pg_start_backup()` and `pg_stop_backup()` or take a file system backup as the standbys are still synchronized with the primary.)

11. **Restore `pg_hba.conf`**

If you modified `pg_hba.conf`, restore its original settings. It might also be necessary to adjust other configuration files in the new cluster to match the old cluster, e.g. `postgresql.conf`.

12. **Start the new server**

The new server can now be safely started, and then any rsync’ed standby servers.

13. **Post-Upgrade processing**

If any post-upgrade processing is required, `pg_upgrade` will issue warnings as it completes. It will also generate script files that must be run by the administrator. The script files will connect to each database that needs post-upgrade processing. Each script should be run using:

```
psql --username postgres --file script.sql postgres
```

The scripts can be run in any order and can be deleted once they have been run.

**Caution**

In general it is unsafe to access tables referenced in rebuild scripts until the rebuild scripts have run to completion; doing so could yield incorrect results or poor performance. Tables not referenced in rebuild scripts can be accessed immediately.

14. **Statistics**

Because optimizer statistics are not transferred by `pg_upgrade`, you will be instructed to run a command to regenerate that information at the end of the upgrade. You might need to set connection parameters to match your new cluster.

15. **Delete old cluster**

Once you are satisfied with the upgrade, you can delete the old cluster’s data directories by running the script mentioned when `pg_upgrade` completes. (Automatic deletion is not possible if you have user-defined tablespaces inside the old data directory.) You can also delete the old installation directories (e.g. `bin`, `share`).

16. **Reverting to old cluster**

If, after running `pg_upgrade`, you wish to revert to the old cluster, there are several options:

- If you ran `pg_upgrade` with `--check`, no modifications were made to the old cluster and you can re-use it anytime.

- If you ran `pg_upgrade` with `--link`, the data files are shared between the old and new cluster. If you started the new cluster, the new server has written to those shared files and it is unsafe to use the old cluster.

- If you ran `pg_upgrade` *without* `--link` or did not start the new server, the old cluster was not modified except that, if linking started, a `.old` suffix was appended to `$SPGDATA/global/pg_control`. To reuse the old cluster, possibly remove the `.old` suffix from `$SPGDATA/global/pg_control`; you can then restart the old cluster.
Notes

pg_upgrade does not support upgrading of databases containing these reg* OID-referencing system data types: regproc, regprocedure, regoper, regoperator, regconfig, and regdictionary. (regtype can be upgraded.)

All failure, rebuild, and reindex cases will be reported by pg_upgrade if they affect your installation; post-upgrade scripts to rebuild tables and indexes will be generated automatically. If you are trying to automate the upgrade of many clusters, you should find that clusters with identical database schemas require the same post-upgrade steps for all cluster upgrades; this is because the post-upgrade steps are based on the database schemas, and not user data.

For deployment testing, create a schema-only copy of the old cluster, insert dummy data, and upgrade that.

If you are upgrading a pre-PostgreSQL 9.2 cluster that uses a configuration-file-only directory, you must pass the real data directory location to pg_upgrade, and pass the configuration directory location to the server, e.g. `-d /real-data-directory -o `-D /configuration-directory'.

If using a pre-9.1 old server that is using a non-default Unix-domain socket directory or a default that differs from the default of the new cluster, set PGHOST to point to the old server’s socket location. (This is not relevant on Windows.)

If you want to use link mode and you do not want your old cluster to be modified when the new cluster is started, make a copy of the old cluster and upgrade that in link mode. To make a valid copy of the old cluster, use rsync to create a dirty copy of the old cluster while the server is running, then shut down the old server and run rsync --checksum again to update the copy with any changes to make it consistent. (--checksum is necessary because rsync only has file modification-time granularity of one second.) You might want to exclude some files, e.g. postmaster.pid, as documented in Section 24.3.3. If your file system supports file system snapshots or copy-on-write file copies, you can use that to make a backup of the old cluster and tablespaces, though the snapshot and copies must be created simultaneously or while the database server is down.

**pg_xlogdump**

**Name**

pg_xlogdump — display a human-readable rendering of the write-ahead log of a PostgreSQL database cluster

**Synopsis**

pg_xlogdump [option...] [startseg [endseg]]

**Description**

pg_xlogdump displays the write-ahead log (WAL) and is mainly useful for debugging or educational purposes. This utility can only be run by the user who installed the server, because it requires read-only access to the data directory.

**Options**

The following command-line options control the location and format of the output:

- **startseg**
  
  Start reading at the specified log segment file. This implicitly determines the path in which files will be searched for, and the timeline to use.

- **endseg**
  
  Stop after reading the specified log segment file.

- **-b**
  
  --bkp-details
  
  Output detailed information about backup blocks.

- **-e end**
  
  --end=end
  
  Stop reading at the specified log position, instead of reading to the end of the log stream.

- **-f**
  
  --follow
  
  After reaching the end of valid WAL, keep polling once per second for new WAL to appear.

- **-n limit**
  
  --limit=limit
  
  Display the specified number of records, then stop.
pg_xlogdump

-p path
--path=path
Directory in which to find log segment files. The default is to search for them in the pg_xlog subdirectory of the current directory.

-r rmgr
--rmgr=rmgr
Only display records generated by the specified resource manager. If list is passed as name, print a list of valid resource manager names, and exit.

-s start
--start=start
Log position at which to start reading. The default is to start reading the first valid log record found in the earliest file found.

-t timeline
--timeline=timeline
Timeline from which to read log records. The default is to use the value in startseg, if that is specified; otherwise, the default is 1.

-V
--version
Print the pg_xlogdump version and exit.

-x xid
--xid=xid
Only display records marked with the given transaction ID.

-z
--stats[=record]
Display summary statistics (number and size of records and full-page images) instead of individual records. Optionally generate statistics per-record instead of per-rmgr.

-?
--help
Show help about pg_xlogdump command line arguments, and exit.

Notes
Can give wrong results when the server is running.
Only the specified timeline is displayed (or the default, if none is specified). Records in other timelines are ignored.

pg_xlogdump cannot read WAL files with suffix .partial. If those files need to be read, .partial suffix needs to be removed from the file name.

**postgres**

**Name**
postgres — PostgreSQL database server

**Synopsis**
postgres [option...]

**Description**
postgres is the PostgreSQL database server. In order for a client application to access a database it connects (over a network or locally) to a running postgres instance. The postgres instance then starts a separate server process to handle the connection.

One postgres instance always manages the data of exactly one database cluster. A database cluster is a collection of databases that is stored at a common file system location (the “data area”). More than one postgres instance can run on a system at one time, so long as they use different data areas and different communication ports (see below). When postgres starts it needs to know the location of the data area. The location must be specified by the `-D` option or the PGDATA environment variable; there is no default. Typically, `-D` or PGDATA points directly to the data area directory created by initdb. Other possible file layouts are discussed in Section 18.2.

By default postgres starts in the foreground and prints log messages to the standard error stream. In practical applications postgres should be started as a background process, perhaps at boot time.

The postgres command can also be called in single-user mode. The primary use for this mode is during bootstrapping by initdb. Sometimes it is used for debugging or disaster recovery; note that running a single-user server is not truly suitable for debugging the server, since no realistic interprocess communication and locking will happen. When invoked in single-user mode from the shell, the user can enter queries and the results will be printed to the screen, but in a form that is more useful for developers than end users. In the single-user mode, the session user will be set to the user with ID 1, and implicit superuser powers are granted to this user. This user does not actually have to exist, so the single-user mode can be used to manually recover from certain kinds of accidental damage to the system catalogs.

**Options**
postgres accepts the following command-line arguments. For a detailed discussion of the options consult Chapter 18. You can save typing most of these options by setting up a configuration file. Some (safe) options can also be set from the connecting client in an application-dependent way to apply only for that session. For example, if the environment variable PGOPTIONS is set, then libpq-based clients will pass that string to the server, which will interpret it as postgres command-line options.
**General Purpose**

- **B** *nbuffers*
  Sets the number of shared buffers for use by the server processes. The default value of this parameter is chosen automatically by initdb. Specifying this option is equivalent to setting the shared_buffers configuration parameter.

- **c** *name=value*
  Sets a named run-time parameter. The configuration parameters supported by PostgreSQL are described in Chapter 18. Most of the other command line options are in fact short forms of such a parameter assignment. `-c` can appear multiple times to set multiple parameters.

- **C** *name*
  Prints the value of the named run-time parameter, and exits. (See the `-c` option above for details.) This can be used on a running server, and returns values from `postgresql.conf`, modified by any parameters supplied in this invocation. It does not reflect parameters supplied when the cluster was started.

  This option is meant for other programs that interact with a server instance, such as `pg_ctl`, to query configuration parameter values. User-facing applications should instead use `SHOW` or the `pg_settings` view.

- **d** *debug-level*
  Sets the debug level. The higher this value is set, the more debugging output is written to the server log. Values are from 1 to 5. It is also possible to pass `-d 0` for a specific session, which will prevent the server log level of the parent `postgres` process from being propagated to this session.

- **D** *datadir*
  Specifies the file system location of the database configuration files. See Section 18.2 for details.

- **e**
  Sets the default date style to “European”, that is DMY ordering of input date fields. This also causes the day to be printed before the month in certain date output formats. See Section 8.5 for more information.

- **F**
  Disables `fsync` calls for improved performance, at the risk of data corruption in the event of a system crash. Specifying this option is equivalent to disabling the `fsync` configuration parameter. Read the detailed documentation before using this!

- **h** *hostname*
  Specifies the IP host name or address on which `postgres` is to listen for TCP/IP connections from client applications. The value can also be a comma-separated list of addresses, or `*` to specify listening on all available interfaces. An empty value specifies not listening on any IP addresses, in which case only Unix-domain sockets can be used to connect to the server. Defaults to listening only on localhost. Specifying this option is equivalent to setting the `listen_addresses` configuration parameter.

- **i**
  Allows remote clients to connect via TCP/IP (Internet domain) connections. Without this option, only local connections are accepted. This option is equivalent to setting `listen_addresses` to `*` in `postgresql.conf` or via `-h`. 

1859
This option is deprecated since it does not allow access to the full functionality of listen_addresses. It’s usually better to set listen_addresses directly.

-\( k \) directory

Specifies the directory of the Unix-domain socket on which \texttt{postgres} is to listen for connections from client applications. The value can also be a comma-separated list of directories. An empty value specifies not listening on any Unix-domain sockets, in which case only TCP/IP sockets can be used to connect to the server. The default value is normally /tmp, but that can be changed at build time.Specifying this option is equivalent to setting the \texttt{unix_socket_directories} configuration parameter.

-\( l \)

Enables secure connections using SSL. PostgreSQL must have been compiled with support for SSL for this option to be available. For more information on using SSL, refer to Section 17.9.

-\( N \) \texttt{max-connections}

Sets the maximum number of client connections that this server will accept. The default value of this parameter is chosen automatically by initdb. Specifying this option is equivalent to setting the \texttt{max_connections} configuration parameter.

-\( o \) extra-options

The command-line-style arguments specified in \texttt{extra-options} are passed to all server processes started by this \texttt{postgres} process.

Spaces within \texttt{extra-options} are considered to separate arguments, unless escaped with a backslash (\); write "\" to represent a literal backslash. Multiple arguments can also be specified via multiple uses of -\( o \).

The use of this option is obsolete; all command-line options for server processes can be specified directly on the \texttt{postgres} command line.

-\( p \) port

Specifies the TCP/IP port or local Unix domain socket file extension on which \texttt{postgres} is to listen for connections from client applications. Defaults to the value of the \texttt{PGPORT} environment variable, or if \texttt{PGPORT} is not set, then defaults to the value established during compilation (normally 5432). If you specify a port other than the default port, then all client applications must specify the same port using either command-line options or \texttt{PGPORT}.

-\( s \)

Print time information and other statistics at the end of each command. This is useful for benchmarking or for use in tuning the number of buffers.

-\( S \) work-mem

Specifies the amount of memory to be used by internal sorts and hashes before resorting to temporary disk files. See the description of the \texttt{work_mem} configuration parameter in Section 18.4.1.

-\( V \) --version

Print the \texttt{postgres} version and exit.

--name=value

Sets a named run-time parameter; a shorter form of -\( c \).
--describe-config

This option dumps out the server’s internal configuration variables, descriptions, and defaults in tab-delimited COPY format. It is designed primarily for use by administration tools.

-?
--help

Show help about postgres command line arguments, and exit.

**Semi-internal Options**

The options described here are used mainly for debugging purposes, and in some cases to assist with recovery of severely damaged databases. There should be no reason to use them in a production database setup. They are listed here only for use by PostgreSQL system developers. Furthermore, these options might change or be removed in a future release without notice.

-f { s | i | o | b | t | n | m | h }

Forbids the use of particular scan and join methods: s and i disable sequential and index scans respectively, o, b and t disable index-only scans, bitmap index scans, and TID scans respectively, while n, m, and h disable nested-loop, merge and hash joins respectively.

Neither sequential scans nor nested-loop joins can be disabled completely; the -fs and -fn options simply discourage the optimizer from using those plan types if it has any other alternative.

-n

This option is for debugging problems that cause a server process to die abnormally. The ordinary strategy in this situation is to notify all other server processes that they must terminate and then reinitialize the shared memory and semaphores. This is because an errant server process could have corrupted some shared state before terminating. This option specifies that postgres will not reinitialize shared data structures. A knowledgeable system programmer can then use a debugger to examine shared memory and semaphore state.

-O

Allows the structure of system tables to be modified. This is used by initdb.

-P

Ignore system indexes when reading system tables, but still update the indexes when modifying the tables. This is useful when recovering from damaged system indexes.

-t p[arser] | p[lanner] | e[xecutor]

Print timing statistics for each query relating to each of the major system modules. This option cannot be used together with the -s option.

-T

This option is for debugging problems that cause a server process to die abnormally. The ordinary strategy in this situation is to notify all other server processes that they must terminate and then reinitialize the shared memory and semaphores. This is because an errant server process could have corrupted some shared state before terminating. This option specifies that postgres will stop all other server processes by sending the signal SIGSTOP, but will not cause them to terminate. This permits system programmers to collect core dumps from all server processes by hand.
postgres

-v protocol
   Specifies the version number of the frontend/backend protocol to be used for a particular session.
   This option is for internal use only.

-W seconds
   A delay of this many seconds occurs when a new server process is started, after it conducts the
   authentication procedure. This is intended to give an opportunity to attach to the server process
   with a debugger.

Options for Single-User Mode
The following options only apply to the single-user mode.

--single
   Selects the single-user mode. This must be the first argument on the command line.

database
   Specifies the name of the database to be accessed. This must be the last argument on the command
   line. If it is omitted it defaults to the user name.

-E
   Echo all commands.

-j
   Disables use of newline as a statement delimiter.

-r filename
   Send all server log output to filename. This option is only honored when supplied as a
   command-line option.

Environment

PGCLIENTENCODING
   Default character encoding used by clients. (The clients can override this individually.) This value
   can also be set in the configuration file.

PGDATA
   Default data directory location

PGDATESTYLE
   Default value of the DateStyle run-time parameter. (The use of this environment variable is
   deprecated.)

PGPORT
   Default port number (preferably set in the configuration file)
**Diagnostics**

A failure message mentioning `semget` or `shmget` probably indicates you need to configure your kernel to provide adequate shared memory and semaphores. For more discussion see Section 17.4. You might be able to postpone reconfiguring your kernel by decreasing `shared_buffers` to reduce the shared memory consumption of PostgreSQL, and/or by reducing `max_connections` to reduce the semaphore consumption.

A failure message suggesting that another server is already running should be checked carefully, for example by using the command

```
$ ps ax | grep postgres
```

or

```
$ ps -ef | grep postgres
```

depending on your system. If you are certain that no conflicting server is running, you can remove the lock file mentioned in the message and try again.

A failure message indicating inability to bind to a port might indicate that that port is already in use by some non-PostgreSQL process. You might also get this error if you terminate `postgres` and immediately restart it using the same port; in this case, you must simply wait a few seconds until the operating system closes the port before trying again. Finally, you might get this error if you specify a port number that your operating system considers to be reserved. For example, many versions of Unix consider port numbers under 1024 to be “trusted” and only permit the Unix superuser to access them.

**Notes**

The utility command `pg_ctl` can be used to start and shut down the `postgres` server safely and comfortably.

If at all possible, **do not** use `SIGKILL` to kill the main `postgres` server. Doing so will prevent `postgres` from freeing the system resources (e.g., shared memory and semaphores) that it holds before terminating. This might cause problems for starting a fresh `postgres` run.

To terminate the `postgres` server normally, the signals `SIGTERM`, `SIGINT`, or `SIGQUIT` can be used. The first will wait for all clients to terminate before quitting, the second will forcefully disconnect all clients, and the third will quit immediately without proper shutdown, resulting in a recovery run during restart.

The `SIGHUP` signal will reload the server configuration files. It is also possible to send `SIGHUP` to an individual server process, but that is usually not sensible.

To cancel a running query, send the `SIGINT` signal to the process running that command. To terminate a backend process cleanly, send `SIGTERM` to that process. See also `pg_cancel_backend` and `pg_terminate_backend` in Section 9.26.2 for the SQL-callable equivalents of these two actions.

The `postgres` server uses `SIGQUIT` to tell subordinate server processes to terminate without normal cleanup. This signal **should not** be used by users. It is also unwise to send `SIGKILL` to a server process — the main `postgres` process will interpret this as a crash and will force all the sibling processes to quit as part of its standard crash-recovery procedure.
Bugs

The -- options will not work on FreeBSD or OpenBSD. Use -c instead. This is a bug in the affected operating systems; a future release of PostgreSQL will provide a workaround if this is not fixed.

Usage

To start a single-user mode server, use a command like

```bash
postgres --single -D /usr/local/pgsql/data other-options my_database
```

Provide the correct path to the database directory with -D, or make sure that the environment variable PGDATA is set. Also specify the name of the particular database you want to work in.

Normally, the single-user mode server treats newline as the command entry terminator; there is no intelligence about semicolons, as there is in psql. To continue a command across multiple lines, you must type backslash just before each newline except the last one.

But if you use the -j command line switch, then newline does not terminate command entry. In this case, the server will read the standard input until the end-of-file (EOF) marker, then process the input as a single command string. Backslash-newline is not treated specially in this case.

To quit the session, type EOF (Control+D, usually). If you’ve used -j, two consecutive EOFs are needed to exit.

Note that the single-user mode server does not provide sophisticated line-editing features (no command history, for example). Single-User mode also does not do any background processing, like automatic checkpoints.

Examples

To start postgres in the background using default values, type:

```bash
$ nohup postgres >logfile 2>&1 < /dev/null &
```

To start postgres with a specific port, e.g. 1234:

```bash
$ postgres -p 1234
```

To connect to this server using psql, specify this port with the -p option:

```bash
$ psql -p 1234
```

or set the environment variable PGPORT:

```bash
$ export PGPORT=1234
$ psql
```

Named run-time parameters can be set in either of these styles:

```bash
$ postgres -c work_mem=1234
$ postgres --work_mem=1234
```
Either form overrides whatever setting might exist for `work_mem` in `postgresql.conf`. Notice that underscores in parameter names can be written as either underscore or dash on the command line. Except for short-term experiments, it’s probably better practice to edit the setting in `postgresql.conf` than to rely on a command-line switch to set a parameter.

VII. Internals

This part contains assorted information that might be of use to PostgreSQL developers.
Chapter 48. Overview of PostgreSQL Internals

Author: This chapter originated as part of Enhancement of the ANSI SQL Implementation of PostgreSQL, Stefan Simkovics’ Master’s Thesis prepared at Vienna University of Technology under the direction of O.Univ.Prof.Dr. Georg Gottlob and Univ.Ass. Mag. Katrin Seyr.

This chapter gives an overview of the internal structure of the backend of PostgreSQL. After having read the following sections you should have an idea of how a query is processed. This chapter does not aim to provide a detailed description of the internal operation of PostgreSQL, as such a document would be very extensive. Rather, this chapter is intended to help the reader understand the general sequence of operations that occur within the backend from the point at which a query is received, to the point at which the results are returned to the client.

48.1. The Path of a Query

Here we give a short overview of the stages a query has to pass in order to obtain a result.

1. A connection from an application program to the PostgreSQL server has to be established. The application program transmits a query to the server and waits to receive the results sent back by the server.

2. The parser stage checks the query transmitted by the application program for correct syntax and creates a query tree.

3. The rewrite system takes the query tree created by the parser stage and looks for any rules (stored in the system catalogs) to apply to the query tree. It performs the transformations given in the rule bodies.

   One application of the rewrite system is in the realization of views. Whenever a query against a view (i.e., a virtual table) is made, the rewrite system rewrites the user’s query to a query that accesses the base tables given in the view definition instead.

4. The planner/optimizer takes the (rewritten) query tree and creates a query plan that will be the input to the executor.

   It does so by first creating all possible paths leading to the same result. For example if there is an index on a relation to be scanned, there are two paths for the scan. One possibility is a simple sequential scan and the other possibility is to use the index. Next the cost for the execution of each path is estimated and the cheapest path is chosen. The cheapest path is expanded into a complete plan that the executor can use.

5. The executor recursively steps through the plan tree and retrieves rows in the way represented by the plan. The executor makes use of the storage system while scanning relations, performs sorts and joins, evaluates qualifications and finally hands back the rows derived.

In the following sections we will cover each of the above listed items in more detail to give a better understanding of PostgreSQL’s internal control and data structures.
48.2. How Connections are Established

PostgreSQL is implemented using a simple “process per user” client/server model. In this model there is one client process connected to exactly one server process. As we do not know ahead of time how many connections will be made, we have to use a master process that spawns a new server process every time a connection is requested. This master process is called postgres and listens at a specified TCP/IP port for incoming connections. Whenever a request for a connection is detected the postgres process spawns a new server process. The server tasks communicate with each other using semaphores and shared memory to ensure data integrity throughout concurrent data access.

The client process can be any program that understands the PostgreSQL protocol described in Chapter 50. Many clients are based on the C-language library libpq, but several independent implementations of the protocol exist, such as the Java JDBC driver.

Once a connection is established the client process can send a query to the backend (server). The query is transmitted using plain text, i.e., there is no parsing done in the frontend (client). The server parses the query, creates an execution plan, executes the plan and returns the retrieved rows to the client by transmitting them over the established connection.

48.3. The Parser Stage

The parser stage consists of two parts:

- The parser defined in gram.y and scan.l is built using the Unix tools bison and flex.
- The transformation process does modifications and augmentations to the data structures returned by the parser.

48.3.1. Parser

The parser has to check the query string (which arrives as plain text) for valid syntax. If the syntax is correct a parse tree is built up and handed back; otherwise an error is returned. The parser and lexer are implemented using the well-known Unix tools bison and flex.

The lexer is defined in the file scan.l and is responsible for recognizing identifiers, the SQL key words etc. For every key word or identifier that is found, a token is generated and handed to the parser.

The parser is defined in the file gram.y and consists of a set of grammar rules and actions that are executed whenever a rule is fired. The code of the actions (which is actually C code) is used to build up the parse tree.

The file scan.l is transformed to the C source file scan.c using the program flex and gram.y is transformed to gram.c using bison. After these transformations have taken place a normal C compiler can be used to create the parser. Never make any changes to the generated C files as they will be overwritten the next time flex or bison is called.

Note: The mentioned transformations and compilations are normally done automatically using the makefiles shipped with the PostgreSQL source distribution.
A detailed description of bison or the grammar rules given in gram.y would be beyond the scope of this paper. There are many books and documents dealing with flex and bison. You should be familiar with bison before you start to study the grammar given in gram.y otherwise you won’t understand what happens there.

### 48.3.2. Transformation Process

The parser stage creates a parse tree using only fixed rules about the syntactic structure of SQL. It does not make any lookups in the system catalogs, so there is no possibility to understand the detailed semantics of the requested operations. After the parser completes, the transformation process takes the tree handed back by the parser as input and does the semantic interpretation needed to understand which tables, functions, and operators are referenced by the query. The data structure that is built to represent this information is called the query tree.

The reason for separating raw parsing from semantic analysis is that system catalog lookups can only be done within a transaction, and we do not wish to start a transaction immediately upon receiving a query string. The raw parsing stage is sufficient to identify the transaction control commands (BEGIN, ROLLBACK, etc), and these can then be correctly executed without any further analysis. Once we know that we are dealing with an actual query (such as SELECT or UPDATE), it is okay to start a transaction if we’re not already in one. Only then can the transformation process be invoked.

The query tree created by the transformation process is structurally similar to the raw parse tree in most places, but it has many differences in detail. For example, a FuncCall node in the parse tree represents something that looks syntactically like a function call. This might be transformed to either a FuncExpr or Aggref node depending on whether the referenced name turns out to be an ordinary function or an aggregate function. Also, information about the actual data types of columns and expression results is added to the query tree.

### 48.4. The PostgreSQL Rule System

PostgreSQL supports a powerful rule system for the specification of views and ambiguous view updates. Originally the PostgreSQL rule system consisted of two implementations:

- The first one worked using row level processing and was implemented deep in the executor. The rule system was called whenever an individual row had been accessed. This implementation was removed in 1995 when the last official release of the Berkeley Postgres project was transformed into Postgres95.

- The second implementation of the rule system is a technique called query rewriting. The rewrite system is a module that exists between the parser stage and the planner/optimizer. This technique is still implemented.

The query rewriter is discussed in some detail in Chapter 38, so there is no need to cover it here. We will only point out that both the input and the output of the rewriter are query trees, that is, there is no change in the representation or level of semantic detail in the trees. Rewriting can be thought of as a form of macro expansion.
48.5. Planner/Optimizer

The task of the planner/optimizer is to create an optimal execution plan. A given SQL query (and hence, a query tree) can be actually executed in a wide variety of different ways, each of which will produce the same set of results. If it is computationally feasible, the query optimizer will examine each of these possible execution plans, ultimately selecting the execution plan that is expected to run the fastest.

Note: In some situations, examining each possible way in which a query can be executed would take an excessive amount of time and memory space. In particular, this occurs when executing queries involving large numbers of join operations. In order to determine a reasonable (not necessarily optimal) query plan in a reasonable amount of time, PostgreSQL uses a Genetic Query Optimizer (see Chapter 57) when the number of joins exceeds a threshold (see geqo_threshold).

The planner’s search procedure actually works with data structures called paths, which are simply cut-down representations of plans containing only as much information as the planner needs to make its decisions. After the cheapest path is determined, a full-fledged plan tree is built to pass to the executor. This represents the desired execution plan in sufficient detail for the executor to run it. In the rest of this section we’ll ignore the distinction between paths and plans.

48.5.1. Generating Possible Plans

The planner/optimizer starts by generating plans for scanning each individual relation (table) used in the query. The possible plans are determined by the available indexes on each relation. There is always the possibility of performing a sequential scan on a relation, so a sequential scan plan is always created. Assume an index is defined on a relation (for example a B-tree index) and a query contains the restriction relation.attribute OPR constant. If relation.attribute happens to match the key of the B-tree index and OPR is one of the operators listed in the index’s operator class, another plan is created using the B-tree index to scan the relation. If there are further indexes present and the restrictions in the query happen to match a key of an index, further plans will be considered. Index scan plans are also generated for indexes that have a sort ordering that can match the query’s ORDER BY clause (if any), or a sort ordering that might be useful for merge joining (see below).

If the query requires joining two or more relations, plans for joining relations are considered after all feasible plans have been found for scanning single relations. The three available join strategies are:

- **nested loop join**: The right relation is scanned once for every row found in the left relation. This strategy is easy to implement but can be very time consuming. (However, if the right relation can be scanned with an index scan, this can be a good strategy. It is possible to use values from the current row of the left relation as keys for the index scan of the right.)

- **merge join**: Each relation is sorted on the join attributes before the join starts. Then the two relations are scanned in parallel, and matching rows are combined to form join rows. This kind of join is more attractive because each relation has to be scanned only once. The required sorting might be achieved either by an explicit sort step, or by scanning the relation in the proper order using an index on the join key.

- **hash join**: the right relation is first scanned and loaded into a hash table, using its join attributes as hash keys. Next the left relation is scanned and the appropriate values of every row found are used as hash keys to locate the matching rows in the table.
When the query involves more than two relations, the final result must be built up by a tree of join steps, each with two inputs. The planner examines different possible join sequences to find the cheapest one.

If the query uses fewer than \texttt{geqo\_threshold} relations, a near-exhaustive search is conducted to find the best join sequence. The planner preferentially considers joins between any two relations for which there exist a corresponding join clause in the \texttt{WHERE} qualification (i.e., for which a restriction like \texttt{where rel1.attr1=rel2.attr2} exists). Join pairs with no join clause are considered only when there is no other choice, that is, a particular relation has no available join clauses to any other relation. All possible plans are generated for every join pair considered by the planner, and the one that is (estimated to be) the cheapest is chosen.

When \texttt{geqo\_threshold} is exceeded, the join sequences considered are determined by heuristics, as described in Chapter 57. Otherwise the process is the same.

The finished plan tree consists of sequential or index scans of the base relations, plus nested-loop, merge, or hash join nodes as needed, plus any auxiliary steps needed, such as sort nodes or aggregate-function calculation nodes. Most of these plan node types have the additional ability to do \emph{selection} (discarding rows that do not meet a specified Boolean condition) and \emph{projection} (computation of a derived column set based on given column values, that is, evaluation of scalar expressions where needed). One of the responsibilities of the planner is to attach selection conditions from the \texttt{WHERE} clause and computation of required output expressions to the most appropriate nodes of the plan tree.

### 48.6. Executor

The \texttt{executor} takes the plan created by the planner/optimizer and recursively processes it to extract the required set of rows. This is essentially a demand-pull pipeline mechanism. Each time a plan node is called, it must deliver one more row, or report that it is done delivering rows.

To provide a concrete example, assume that the top node is a MergeJoin node. Before any merge can be done two rows have to be fetched (one from each subplan). So the executor recursively calls itself to process the subplans (it starts with the subplan attached to \texttt{lefttree}). The new top node (the top node of the left subplan) is, let’s say, a Sort node and again recursion is needed to obtain an input row. The child node of the Sort might be a SeqScan node, representing actual reading of a table. Execution of this node causes the executor to fetch a row from the table and return it up to the calling node. The Sort node will repeatedly call its child to obtain all the rows to be sorted. When the input is exhausted (as indicated by the child node returning a NULL instead of a row), the Sort code performs the sort, and finally is able to return its first output row, namely the first one in sorted order. It keeps the remaining rows stored so that it can deliver them in sorted order in response to later demands.

The MergeJoin node similarly demands the first row from its right subplan. Then it compares the two rows to see if they can be joined; if so, it returns a join row to its caller. On the next call, or immediately if it cannot join the current pair of inputs, it advances to the next row of one table or the other (depending on how the comparison came out), and again checks for a match. Eventually, one subplan or the other is exhausted, and the MergeJoin node returns NULL to indicate that no more join rows can be formed.

Complex queries can involve many levels of plan nodes, but the general approach is the same: each node computes and returns its next output row each time it is called. Each node is also responsible for applying any selection or projection expressions that were assigned to it by the planner.

The executor mechanism is used to evaluate all four basic SQL query types: \texttt{SELECT}, \texttt{INSERT}, \texttt{UPDATE}, and \texttt{DELETE}. For \texttt{SELECT}, the top-level executor code only needs to send each row returned
by the query plan tree off to the client. For INSERT, each returned row is inserted into the target table specified for the INSERT. This is done in a special top-level plan node called ModifyTable. (A simple INSERT ... VALUES command creates a trivial plan tree consisting of a single Result node, which computes just one result row, and ModifyTable above it to perform the insertion. But INSERT ... SELECT can demand the full power of the executor mechanism.) For UPDATE, the planner arranges that each computed row includes all the updated column values, plus the TID (tuple ID, or row ID) of the original target row; this data is fed into a ModifyTable node, which uses the information to create a new updated row and mark the old row deleted. For DELETE, the only column that is actually returned by the plan is the TID, and the ModifyTable node simply uses the TID to visit each target row and mark it deleted.
Chapter 49. System Catalogs

The system catalogs are the place where a relational database management system stores schema metadata, such as information about tables and columns, and internal bookkeeping information. PostgreSQL’s system catalogs are regular tables. You can drop and recreate the tables, add columns, insert and update values, and severely mess up your system that way. Normally, one should not change the system catalogs by hand, there are always SQL commands to do that. (For example, CREATE DATABASE inserts a row into the pg_database catalog — and actually creates the database on disk.) There are some exceptions for particularly esoteric operations, such as adding index access methods.

49.1. Overview

Table 49-1 lists the system catalogs. More detailed documentation of each catalog follows below.

Most system catalogs are copied from the template database during database creation and are there-after database-specific. A few catalogs are physically shared across all databases in a cluster; these are noted in the descriptions of the individual catalogs.

</tbody>
</table>

### 49.2. pg_aggregate

The catalog `pg_aggregate` stores information about aggregate functions. An aggregate function is a function that operates on a set of values (typically one column from each row that matches a query condition) and returns a single value computed from all these values. Typical aggregate functions are `sum`, `count`, and `max`. Each entry in `pg_aggregate` is an extension of an entry in `pg_proc`. The
pg_proc entry carries the aggregate’s name, input and output data types, and other information that is similar to ordinary functions.

Table 49-2. pg_aggregate Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aggfnoid</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the aggregate function</td>
</tr>
<tr>

</tr>
<tr>
<td>agfginalextra</td>
<td>bool</td>
<td></td>
<td>True to pass extra dummy arguments to aggfinalfn</td>
</tr>
</tbody>
</table>
### Name | Type | References | Description
---|---|---|---
aggmfinalextra | bool |  | True to pass extra dummy arguments to `aggmfinalfn`.
aggsortop | oid | `pg_operator.oid` | Associated sort operator (zero if none).
aggtranstype | oid | `pg_type.oid` | Data type of the aggregate function’s internal transition (state) data.
aggtransspace | int4 |  | Approximate average size (in bytes) of the transition state data, or zero to use a default estimate.
aggmtranstype | oid | `pg_type.oid` | Data type of the aggregate function’s internal transition (state) data for moving-aggregate mode (zero if none).
aggmtransspace | int4 |  | Approximate average size (in bytes) of the transition state data for moving-aggregate mode, or zero to use a default estimate.
agginitval | text |  | The initial value of the transition state. This is a text field containing the initial value in its external string representation. If this field is null, the transition state value starts out null.
aggminitval | text |  | The initial value of the transition state for moving-aggregate mode. This is a text field containing the initial value in its external string representation. If this field is null, the transition state value starts out null.

New aggregate functions are registered with the `CREATE AGGREGATE` command. See Section 35.10 for more information about writing aggregate functions and the meaning of the transition func-
49.3. **pg_am**

The catalog `pg_am` stores information about index access methods. There is one row for each index access method supported by the system. The contents of this catalog are discussed in detail in Chapter 58.

49.4. pg_amop

The catalog pg_amop stores information about operators associated with access method operator families. There is one row for each operator that is a member of an operator family. A family member can be either a search operator or an ordering operator. An operator can appear in more than one family, but cannot appear in more than one search position nor more than one ordering position within a family. (It is allowed, though unlikely, for an operator to be used for both search and ordering purposes.)

Table 49-4. pg_amop Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>OID of the operator</td>
</tr>
<tr>
<td>amopmethod</td>
<td>oid</td>
<td>pg_am.oid</td>
<td>Index access method operator family is for</td>
</tr>
</tbody>
</table>
### Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>amopsortfamily</td>
<td>oid</td>
<td>pg_opfamily.oid</td>
<td>The B-tree operator family this entry sorts according to, if an ordering operator; zero if a search operator</td>
</tr>
</tbody>
</table>

A “search” operator entry indicates that an index of this operator family can be searched to find all rows satisfying `WHERE indexed_column operator constant`. Obviously, such an operator must return `boolean`, and its left-hand input type must match the index’s column data type.

An “ordering” operator entry indicates that an index of this operator family can be scanned to return rows in the order represented by `ORDER BY indexed_column operator constant`. Such an operator could return any sortable data type, though again its left-hand input type must match the index’s column data type. The exact semantics of the `ORDER BY` are specified by the `amopsortfamily` column, which must reference a B-tree operator family for the operator’s result type.

**Note:** At present, it’s assumed that the sort order for an ordering operator is the default for the referenced operator family, i.e., `ASC NULLS LAST`. This might someday be relaxed by adding additional columns to specify sort options explicitly.

An entry’s `amopmethod` must match the `opfmethod` of its containing operator family (including `amopmethod` here is an intentional denormalization of the catalog structure for performance reasons). Also, `amoplefttype` and `amoprighttype` must match the `oprleft` and `oprright` fields of the referenced `pg_operator` entry.

### 49.5. pg_amproc

The catalog `pg_amproc` stores information about support procedures associated with access method operator families. There is one row for each support procedure belonging to an operator family.

#### Table 49-5. pg_amproc Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>amprocfamily</td>
<td>oid</td>
<td>pg_opfamily.oid</td>
<td>The operator family this entry is for</td>
</tr>
<tr>
<td>amproclefttype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Left-hand input data type of associated operator</td>
</tr>
<tr>
<td>amprocrighttype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Right-hand input data type of associated operator</td>
</tr>
<tr>
<td>amprocnum</td>
<td>int2</td>
<td></td>
<td>Support procedure number</td>
</tr>
<tr>
<td>amproc</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the procedure</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

The usual interpretation of the `amproclefttype` and `amprocrighttype` fields is that they identify the left and right input types of the operator(s) that a particular support procedure supports. For some access methods these match the input data type(s) of the support procedure itself, for others not. There is a notion of “default” support procedures for an index, which are those with `amproclefttype` and `amprocrighttype` both equal to the index operator class's `opcintype`.

49.6. pg_attrdef

The catalog `pg_attrdef` stores column default values. The main information about columns is stored in `pg_attribute` (see below). Only columns that explicitly specify a default value (when the table is created or the column is added) will have an entry here.

Table 49-6. pg_attrdef Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>adrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table this column belongs to</td>
</tr>
<tr>
<td>adnum</td>
<td>int2</td>
<td>pg_attribute.attnum</td>
<td>The number of the column</td>
</tr>
<tr>
<td>adbin</td>
<td>pg_node_tree</td>
<td></td>
<td>The internal representation of the column default value</td>
</tr>
<tr>
<td>adsrc</td>
<td>text</td>
<td></td>
<td>A human-readable representation of the default value</td>
</tr>
</tbody>
</table>

The `adsrc` field is historical, and is best not used, because it does not track outside changes that might affect the representation of the default value. Reverse-compiling the `adbin` field (with `pg_get_expr` for example) is a better way to display the default value.

49.7. pg_attribute

The catalog `pg_attribute` stores information about table columns. There will be exactly one `pg_attribute` row for every column in every table in the database. (There will also be attribute entries for indexes, and indeed all objects that have `pg_class` entries.)

The term attribute is equivalent to column and is used for historical reasons.

Table 49-7. pg_attribute Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table this column belongs to</td>

</tr>
</thead>
<tbody>
<tr>
<td>attcacheoff</td>
<td>int4</td>
<td></td>
<td>Always -1 in storage, but when loaded into a row descriptor in memory this might be updated to cache the offset of the attribute within the row.</td>
</tr>
<tr>
<td>atttypmod</td>
<td>int4</td>
<td>atttypmod</td>
<td>records type-specific data supplied at table creation time (for example, the maximum length of a varchar column). It is passed to type-specific input functions and length coercion functions. The value will generally be -1 for types that do not need atttypmod.</td>
</tr>
<tr>
<td>attbyval</td>
<td>bool</td>
<td></td>
<td>A copy of pg_type.typbyval of this column’s type.</td>
</tr>
<tr>
<td>attstorage</td>
<td>char</td>
<td></td>
<td>Normally a copy of pg_type.typstorage of this column’s type.</td>
</tr>
<tr>
<td>attalign</td>
<td>char</td>
<td></td>
<td>A copy of pg_type.typalign of this column’s type.</td>
</tr>
<tr>
<td>attnotnull</td>
<td>bool</td>
<td></td>
<td>This represents a not-null constraint.</td>
</tr>
<tr>
<td>atthasdef</td>
<td>bool</td>
<td></td>
<td>This column has a default value, in which case there will be a corresponding entry in the pg_attrdef catalog that actually defines the value.</td>
</tr>
</tbody>
</table>
### Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attisdropped</td>
<td>bool</td>
<td></td>
<td>This column has been dropped and is no longer valid. A dropped column is still physically present in the table, but is ignored by the parser and so cannot be accessed via SQL.</td>
</tr>
<tr>
<td>attislocal</td>
<td>bool</td>
<td></td>
<td>This column is defined locally in the relation. Note that a column can be locally defined and inherited simultaneously.</td>
</tr>
<tr>
<td>attinhcount</td>
<td>int4</td>
<td></td>
<td>The number of direct ancestors this column has. A column with a nonzero number of ancestors cannot be dropped nor renamed.</td>
</tr>
<tr>
<td>attcollation</td>
<td>oid</td>
<td>pg_collation.oid</td>
<td>The defined collation of the column, or zero if the column is not of a collatable data type.</td>
</tr>
<tr>
<td>attacl</td>
<td>aclitem[]</td>
<td></td>
<td>Column-level access privileges, if any have been granted specifically on this column</td>
</tr>
<tr>
<td>attoptions</td>
<td>text[]</td>
<td></td>
<td>Attribute-level options, as “keyword=value” strings</td>
</tr>
<tr>
<td>attfdwoptions</td>
<td>text[]</td>
<td></td>
<td>Attribute-level foreign data wrapper options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

In a dropped column’s pg_attribute entry, atttypid is reset to zero, but attlen and the other fields copied from pg_type are still valid. This arrangement is needed to cope with the situation where the dropped column’s data type was later dropped, and so there is no pg_type row anymore. attlen and the other fields can be used to interpret the contents of a row of the table.

### 49.8. pg_authid

The catalog pg_authid contains information about database authorization identifiers (roles). A role subsumes the concepts of “users” and “groups”. A user is essentially just a role with the rolcanlogin flag set. Any role (with or without rolcanlogin) can have other roles as members;
see pg_auth_members.

Since this catalog contains passwords, it must not be publicly readable. pg_roles is a publicly readable view on pg_authid that blanks out the password field.

Chapter 20 contains detailed information about user and privilege management.

Because user identities are cluster-wide, pg_authid is shared across all databases of a cluster: there is only one copy of pg_authid per cluster, not one per database.

<table>
<thead>
<tr>
<th>Table 49-8. pg_authid Columns</th>

<tr>
<td>rolcreatedb</td>
</tr>
<tr>
<td>rolcанlogin</td>
</tr>
<tr>
<td>rolreplication</td>
</tr>
<tr>
<td>rolbypassrls</td>
</tr>
<tr>
<td>rolconnlimit</td>
</tr>
</tbody>
</table>
### 49.9. pg_auth_members

The catalog `pg_auth_members` shows the membership relations between roles. Any non-circular set of relationships is allowed.

Because user identities are cluster-wide, `pg_auth_members` is shared across all databases of a cluster: there is only one copy of `pg_auth_members` per cluster, not one per database.

#### Table 49-9. pg_auth_members Columns

<table>
<thead>
<tr>

<td>bool</td>
<td></td>
<td>True if <code>member</code> can grant membership in <code>roleid</code> to others</td>
</tr>
</tbody>
</table>

### 49.10. pg_cast

The catalog `pg_cast` stores data type conversion paths, both built-in and user-defined.

It should be noted that `pg_cast` does not represent every type conversion that the system knows how to perform; only those that cannot be deduced from some generic rule. For example, casting between...
a domain and its base type is not explicitly represented in \texttt{pg\_cast}. Another important exception is that “automatic I/O conversion casts”, those performed using a data type’s own I/O functions to convert to or from \texttt{text} or other string types, are not explicitly represented in \texttt{pg\_cast}.

<td>char</td>
<td></td>
<td>Indicates what contexts the cast can be invoked in. \texttt{e} means only as an explicit cast (using \texttt{CAST} or \texttt{::} syntax), \texttt{a} means implicitly in assignment to a target column, as well as explicitly. \texttt{i} means implicitly in expressions, as well as the other cases.</td>
</tr>
<tr>
<td>castmethod</td>
<td>char</td>
<td></td>
<td>Indicates how the cast is performed. \texttt{f} means that the function specified in the \texttt{castfunc} field is used. \texttt{i} means that the input/output functions are used. \texttt{b} means that the types are binary-coercible, thus no conversion is required.</td>
</tr>
</tbody>
</table>

The cast functions listed in \texttt{pg\_cast} must always take the cast source type as their first argument type, and return the cast destination type as their result type. A cast function can have up to three arguments. The second argument, if present, must be type \texttt{integer}; it receives the type modifier associated with the destination type, or \texttt{-1} if there is none. The third argument, if present, must be type \texttt{boolean}; it receives \texttt{true} if the cast is an explicit cast, \texttt{false} otherwise.
It is legitimate to create a `pg_cast` entry in which the source and target types are the same, if the associated function takes more than one argument. Such entries represent “length coercion functions” that coerce values of the type to be legal for a particular type modifier value.

When a `pg_cast` entry has different source and target types and a function that takes more than one argument, it represents converting from one type to another and applying a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

## 49.11. pg_class

The catalog `pg_class` catalogs tables and most everything else that has columns or is otherwise similar to a table. This includes indexes (but see also `pg_index`), sequences, views, materialized views, composite types, and TOAST tables; see `relkind`. Below, when we mean all of these kinds of objects we speak of “relations”. Not all columns are meaningful for all relation types.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>relname</td>
<td>name</td>
<td></td>
<td>Name of the table, index, view, etc.</td>
</tr>
<tr>
<td>relnamespace</td>
<td>oid</td>
<td><code>pg_namespace.oid</code></td>
<td>The OID of the namespace that contains this relation</td>
</tr>
<tr>
<td>reltype</td>
<td>oid</td>
<td><code>pg_type.oid</code></td>
<td>The OID of the data type that corresponds to this table’s row type, if any (zero for indexes, which have no <code>pg_type</code> entry)</td>
</tr>
<tr>
<td>reloftype</td>
<td>oid</td>
<td><code>pg_type.oid</code></td>
<td>For typed tables, the OID of the underlying composite type, zero for all other relations</td>
</tr>
<tr>
<td>relowner</td>
<td>oid</td>
<td><code>pg_authid.oid</code></td>
<td>Owner of the relation</td>
</tr>
<tr>
<td>relam</td>
<td>oid</td>
<td><code>pg_am.oid</code></td>
<td>If this is an index, the access method used (B-tree, hash, etc.)</td>
</tr>
<tr>
<td>relfilenode</td>
<td>oid</td>
<td></td>
<td>Name of the on-disk file of this relation; zero means this is a “mapped” relation whose disk file name is determined by low-level state</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------</td>
<td>-------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>reltablespace</td>
<td>oid</td>
<td>pg_tablespace.oid</td>
<td>The tablespace in which this relation is stored. If zero, the database’s default tablespace is implied. (Not meaningful if the relation has no on-disk file.)</td>
</tr>
<tr>
<td>relpages</td>
<td>int4</td>
<td></td>
<td>Size of the on-disk representation of this table in pages (of size BLCKSZ). This is only an estimate used by the planner. It is updated by VACUUM, ANALYZE, and a few DDL commands such as CREATE INDEX.</td>
</tr>
<tr>
<td>reltuples</td>
<td>float4</td>
<td></td>
<td>Number of rows in the table. This is only an estimate used by the planner. It is updated by VACUUM, ANALYZE, and a few DDL commands such as CREATE INDEX.</td>
</tr>
<tr>
<td>relallvisible</td>
<td>int4</td>
<td></td>
<td>Number of pages that are marked all-visible in the table’s visibility map. This is only an estimate used by the planner. It is updated by VACUUM, ANALYZE, and a few DDL commands such as CREATE INDEX.</td>
</tr>
<tr>
<td>reltoastrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>OID of the TOAST table associated with this table. 0 if none. The TOAST table stores large attributes “out of line” in a secondary table.</td>
</tr>
<tr>
<td>relhasindex</td>
<td>bool</td>
<td></td>
<td>True if this is a table and it has (or recently had) any indexes.</td>
</tr>
</tbody>
</table>
## Name | Type | Description
---|---|---
relisshared | bool | True if this table is shared across all databases in the cluster. Only certain system catalogs (such as `pg_database`) are shared.
relpersistence | char | `p` = permanent table, `u` = unlogged table, `t` = temporary table
relkind | char | `r` = ordinary table, `i` = index, `s` = sequence, `v` = view, `m` = materialized view, `c` = composite type, `t` = TOAST table, `f` = foreign table
relnatts | int2 | Number of user columns in the relation (system columns not counted). There must be this many corresponding entries in `pg_attribute`. See also `pg_attribute.attnum`.
relchecks | int2 | Number of CHECK constraints on the table; see `pg_constraint` catalog
relhasoids | bool | True if we generate an OID for each row of the relation
relhaspkey | bool | True if the table has (or once had) a primary key
relhasrules | bool | True if table has (or once had) rules; see `pg_rewrite` catalog
relhastriggers | bool | True if table has (or once had) triggers; see `pg_trigger` catalog
relhassubclass | bool | True if table has (or once had) any inheritance children
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>relrowsecurity</td>
<td>bool</td>
<td></td>
<td>True if table has row level security enabled; see pg_policy catalog</td>
</tr>
<tr>
<td>relforcerowsecurity</td>
<td>bool</td>
<td></td>
<td>True if row level security (when enabled) will also apply to table owner; see pg_policy catalog</td>
</tr>
<tr>
<td>relispopulated</td>
<td>bool</td>
<td></td>
<td>True if relation is populated (this is true for all relations other than some materialized views)</td>
</tr>
<tr>
<td>relreplident</td>
<td>char</td>
<td></td>
<td>Columns used to form “replica identity” for rows: d = default (primary key, if any), n = nothing, f = all columns i = index with indisreplident set, or default</td>
</tr>
<tr>
<td>relfrozenxid</td>
<td>xid</td>
<td></td>
<td>All transaction IDs before this one have been replaced with a permanent (“frozen”) transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to prevent transaction ID wraparound or to allow pg_clog to be shrunk. Zero (InvalidTransactionId) if the relation is not a table.</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>relminmxid</td>
<td>xid</td>
<td></td>
<td>All multixact IDs before this one have been replaced by a transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to prevent multixact ID wraparound or to allow pg_multixact to be shrunk. Zero (InvalidMultiXactId) if the relation is not a table.</td>
</tr>
<tr>
<td>relacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
<tr>
<td>reloptions</td>
<td>text[]</td>
<td></td>
<td>Access-method-specific options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

Several of the Boolean flags in pg_class are maintained lazily: they are guaranteed to be true if that’s the correct state, but may not be reset to false immediately when the condition is no longer true. For example, relhasindex is set by CREATE INDEX, but it is never cleared by DROP INDEX. Instead, VACUUM clears relhasindex if it finds the table has no indexes. This arrangement avoids race conditions and improves concurrency.

### 49.12. pg_collation

The catalog pg_collation describes the available collations, which are essentially mappings from an SQL name to operating system locale categories. See Section 22.2 for more information.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>collname</td>
<td>name</td>
<td></td>
<td>Collation name (unique per namespace and encoding)</td>
</tr>
<tr>
<td>collnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this collation</td>
</tr>
<tr>
<td>collowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the collation</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>collencoding</td>
<td>int4</td>
<td></td>
<td>Encoding in which the collation is applicable, or -1 if it works for any encoding</td>
</tr>
<tr>
<td>collcollate</td>
<td>name</td>
<td></td>
<td>LC_COLLATE for this collation object</td>
</tr>
<tr>
<td>collctype</td>
<td>name</td>
<td></td>
<td>LC_CTYPE for this collation object</td>
</tr>
</tbody>
</table>

Note that the unique key on this catalog is \((\text{collname}, \text{collencoding}, \text{collnamespace})\) not just \((\text{collname}, \text{collnamespace})\). PostgreSQL generally ignores all collations that do not have \text{collencoding} equal to either the current database’s encoding or -1, and creation of new entries with the same name as an entry with \text{collencoding} = -1 is forbidden. Therefore it is sufficient to use a qualified SQL name \((\text{schema.name})\) to identify a collation, even though this is not unique according to the catalog definition. The reason for defining the catalog this way is that initdb fills it in at cluster initialization time with entries for all locales available on the system, so it must be able to hold entries for all encodings that might ever be used in the cluster.

In the template0 database, it could be useful to create collations whose encoding does not match the database encoding, since they could match the encodings of databases later cloned from template0. This would currently have to be done manually.

49.13. \texttt{pg\_constraint}

The catalog \texttt{pg\_constraint} stores check, primary key, unique, foreign key, and exclusion constraints on tables. (Column constraints are not treated specially. Every column constraint is equivalent to some table constraint.) Not-null constraints are represented in the \texttt{pg\_attribute} catalog, not here.

User-defined constraint triggers (created with \texttt{CREATE CONSTRAINT TRIGGER}) also give rise to an entry in this table.

Check constraints on domains are stored here, too.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>

<td>If a foreign key, list of the equality operators for PK = PK comparisons</td>
</tr>
<tr>
<td>conffeqop</td>
<td>oid[]</td>
<td>pg_operator.oid</td>
<td>If a foreign key, list of the equality operators for FK = FK comparisons</td>
</tr>
<tr>
<td>conexclop</td>
<td>oid[]</td>
<td>pg_operator.oid</td>
<td>If an exclusion constraint, list of the per-column exclusion operators</td>
</tr>
<tr>
<td>conbin</td>
<td>pg_node_tree</td>
<td></td>
<td>If a check constraint, an internal representation of the expression</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>consrc</td>
<td>text</td>
<td></td>
<td>If a check constraint, a human-readable representation of the expression</td>
</tr>
</tbody>
</table>

In the case of an exclusion constraint, conkey is only useful for constraint elements that are simple column references. For other cases, a zero appears in conkey and the associated index must be consulted to discover the expression that is constrained. (conkey thus has the same contents as pg_index.indkey for the index.)

**Note:** consrc is not updated when referenced objects change; for example, it won’t track renaming of columns. Rather than relying on this field, it’s best to use pg_get_constraintdef() to extract the definition of a check constraint.

**Note:** pg_class.relchecks needs to agree with the number of check-constraint entries found in this table for each relation.

49.14. pg_conversion

The catalog pg_conversion describes encoding conversion procedures. See CREATE CONVERSION for more information.

Table 49-14. pg_conversion Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>

<td></td>
<td>True if this is the default conversion</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

49.15. pg_database

The catalog pg_database stores information about the available databases. Databases are created with the CREATE DATABASE command. Consult Chapter 21 for details about the meaning of some of the parameters.

Unlike most system catalogs, pg_database is shared across all databases of a cluster: there is only one copy of pg_database per cluster, not one per database.

Table 49-15. pg_database Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>

<tr>
<td>------------------</td>
<td>-----------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>datlastsysoid</td>
<td>oid</td>
<td></td>
<td>Last system OID in the database; useful particularly to pg_dump</td>
</tr>
<tr>
<td>datfrozenxid</td>
<td>xid</td>
<td></td>
<td>All transaction IDs before this one have been replaced with a permanent (&quot;frozen&quot;) transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent transaction ID wraparound or to allow pg_clog to be shrunk. It is the minimum of the per-table pg_class.relzspace values.</td>
</tr>
<tr>
<td>datminmxid</td>
<td>xid</td>
<td></td>
<td>All multixact IDs before this one have been replaced with a transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent multixact ID wraparound or to allow pg_multixact to be shrunk. It is the minimum of the per-table pg_class.relzspace values.</td>
</tr>
<tr>
<td>dattablespace</td>
<td>oid</td>
<td>pg_tablespace.oid</td>
<td>The default tablespace for the database. Within this database, all tables for which pg_class.reltablespace is zero will be stored in this tablespace; in particular, all the non-shared system catalogs will be there.</td>
</tr>
<tr>
<td>datacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
</tbody>
</table>
49.16. \texttt{pg\_db\_role\_setting}

The catalog \texttt{pg\_db\_role\_setting} records the default values that have been set for run-time configuration variables, for each role and database combination.

Unlike most system catalogs, \texttt{pg\_db\_role\_setting} is shared across all databases of a cluster: there is only one copy of \texttt{pg\_db\_role\_setting} per cluster, not one per database.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>setdatabase</td>
<td>oid</td>
<td>pg_database.oid</td>
<td>The OID of the database the setting is applicable to, or zero if not database-specific</td>
</tr>
<tr>
<td>setrole</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>The OID of the role the setting is applicable to, or zero if not role-specific</td>
</tr>
<tr>
<td>setconfig</td>
<td>text[]</td>
<td></td>
<td>Defaults for run-time configuration variables</td>
</tr>
</tbody>
</table>

49.17. \texttt{pg\_default\_acl}

The catalog \texttt{pg\_default\_acl} stores initial privileges to be assigned to newly created objects.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>defaclrole</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>The OID of the role associated with this entry</td>
</tr>
<tr>
<td>defaclnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace associated with this entry, or 0 if none</td>
</tr>
<tr>
<td>defaclobjtype</td>
<td>char</td>
<td></td>
<td>Type of object this entry is for: r = relation (table, view), S = sequence, f = function, T = type</td>
</tr>
<tr>
<td>defaclacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges that this type of object should have on creation</td>
</tr>
</tbody>
</table>
A `pg_default_acl` entry shows the initial privileges to be assigned to an object belonging to the indicated user. There are currently two types of entry: “global” entries with `defaclnamespace = 0`, and “per-schema” entries that reference a particular schema. If a global entry is present then it overrides the normal hard-wired default privileges for the object type. A per-schema entry, if present, represents privileges to be added to the global or hard-wired default privileges.

Note that when an ACL entry in another catalog is null, it is taken to represent the hard-wired default privileges for its object, not whatever might be in `pg_default_acl` at the moment. `pg_default_acl` is only consulted during object creation.

### 49.18. `pg_depend`

The catalog `pg_depend` records the dependency relationships between database objects. This information allows `DROP` commands to find which other objects must be dropped by `DROP CASCADE` or prevent dropping in the `DROP RESTRICT` case.

See also `pg_shdepend`, which performs a similar function for dependencies involving objects that are shared across a database cluster.

#### Table 49-18. `pg_depend` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>classid</td>
<td>oid</td>
<td><code>pg_class.oid</code></td>
<td>The OID of the system catalog the dependent object is in</td>
</tr>
<tr>
<td>objid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the specific dependent object</td>
</tr>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a table column, this is the column number (the objid and classid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>refclassid</td>
<td>oid</td>
<td><code>pg_class.oid</code></td>
<td>The OID of the system catalog the referenced object is in</td>
</tr>
<tr>
<td>refobjid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the specific referenced object</td>
</tr>
<tr>
<td>refobjsubid</td>
<td>int4</td>
<td></td>
<td>For a table column, this is the column number (the refobjid and refclassid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>deptype</td>
<td>char</td>
<td></td>
<td>A code defining the specific semantics of this dependency relationship; see text</td>
</tr>
</tbody>
</table>
In all cases, a `pg_depend` entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

**DEPENDENCY_NORMAL (n)**

A normal relationship between separately-created objects. The dependent object can be dropped without affecting the referenced object. The referenced object can only be dropped by specifying `CASCADE`, in which case the dependent object is dropped, too. Example: a table column has a normal dependency on its data type.

**DEPENDENCY_AUTO (a)**

The dependent object can be dropped separately from the referenced object, and should be automatically dropped (regardless of `RESTRICT` or `CASCADE` mode) if the referenced object is dropped. Example: a named constraint on a table is made autodependent on the table, so that it will go away if the table is dropped.

**DEPENDENCY_INTERNAL (i)**

The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation. A `DROP` of the dependent object will be disallowed outright (we’ll tell the user to issue a `DROP` against the referenced object, instead). A `DROP` of the referenced object will be propagated through to drop the dependent object whether `CASCADE` is specified or not. Example: a trigger that’s created to enforce a foreign-key constraint is made internally dependent on the constraint’s `pg_constraint` entry.

**DEPENDENCY_EXTENSION (e)**

The dependent object is a member of the `extension` that is the referenced object (see `pg_extension`). The dependent object can be dropped only via `DROP EXTENSION` on the referenced object. Functionally this dependency type acts the same as an internal dependency, but it’s kept separate for clarity and to simplify `pg_dump`.

**DEPENDENCY_PIN (p)**

There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by `initdb`. The columns for the dependent object contain zeroes.

Other dependency flavors might be needed in future.

### 49.19. `pg_description`

The catalog `pg_description` stores optional descriptions (comments) for each database object. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`’s `\d` commands. Descriptions of many built-in system objects are provided in the initial contents of `pg_description`.

See also `pg_shdescription`, which performs a similar function for descriptions involving objects that are shared across a database cluster.

#### Table 49-19. `pg_description` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this description pertains to</td>
</tr>
</tbody>
</table>
### Chapter 49. System Catalogs

#### 49.20. pg_enum

The `pg_enum` catalog contains entries showing the values and labels for each enum type. The internal representation of a given enum value is actually the OID of its associated row in `pg_enum`.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>enumtypid</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>The OID of the <code>pg_type</code> entry owning this enum value</td>
</tr>
<tr>
<td>enumsortorder</td>
<td>float4</td>
<td></td>
<td>The sort position of this enum value within its enum type</td>
</tr>
<tr>
<td>enumlabel</td>
<td>name</td>
<td></td>
<td>The textual label for this enum value</td>
</tr>
</tbody>
</table>

The OIDs for `pg_enum` rows follow a special rule: even-numbered OIDs are guaranteed to be ordered in the same way as the sort ordering of their enum type. That is, if two even OIDs belong to the same enum type, the smaller OID must have the smaller `enumsortorder` value. Odd-numbered OID values need bear no relationship to the sort order. This rule allows the enum comparison routines to avoid catalog lookups in many common cases. The routines that create and alter enum types attempt to assign even OIDs to enum values whenever possible.

When an enum type is created, its members are assigned sort-order positions `1...n`. But members added later might be given negative or fractional values of `enumsortorder`. The only requirement on these values is that they be correctly ordered and unique within each enum type.
### 49.21. pg_event_trigger

The catalog `pg_event_trigger` stores event triggers. See Chapter 37 for more information.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>evtname</td>
<td>name</td>
<td></td>
<td>Trigger name (must be unique)</td>
</tr>
<tr>
<td>evtevent</td>
<td>name</td>
<td></td>
<td>Identifies the event for which this trigger fires</td>
</tr>
<tr>
<td>evtowner</td>
<td>oid</td>
<td><code>pg_authid.oid</code></td>
<td>Owner of the event trigger</td>
</tr>
<tr>
<td>evtfoid</td>
<td>oid</td>
<td><code>pg_proc.oid</code></td>
<td>The function to be called</td>
</tr>
<tr>
<td>evtenabled</td>
<td>char</td>
<td></td>
<td>Controls in which session_replication_role modes the event trigger fires. D = trigger fires in &quot;origin&quot; and &quot;local&quot; modes, R = trigger is disabled, A = trigger fires in &quot;replica&quot; mode, A = trigger fires always.</td>
</tr>
<tr>
<td>evttags</td>
<td>text[]</td>
<td></td>
<td>Command tags for which this trigger will fire. If NULL, the firing of this trigger is not restricted on the basis of the command tag.</td>
</tr>
</tbody>
</table>

### 49.22. pg_extension

The catalog `pg_extension` stores information about the installed extensions. See Section 35.15 for details about extensions.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>extname</td>
<td>name</td>
<td></td>
<td>Name of the extension</td>
</tr>
<tr>
<td>extowner</td>
<td>oid</td>
<td><code>pg_authid.oid</code></td>
<td>Owner of the extension</td>
</tr>
</tbody>
</table>
**Chapter 49. System Catalogs**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>extnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>Schema containing the extension’s exported objects</td>
</tr>
<tr>
<td>extrelocatable</td>
<td>bool</td>
<td></td>
<td>True if extension can be relocated to another schema</td>
</tr>
<tr>
<td>extversion</td>
<td>text</td>
<td></td>
<td>Version name for the extension</td>
</tr>
<tr>
<td>extconfig</td>
<td>oid[ ]</td>
<td>pg_class.oid</td>
<td>Array of regclass OIDs for the extension’s configuration table(s), or NULL if none</td>
</tr>
<tr>
<td>extcondition</td>
<td>text[ ]</td>
<td></td>
<td>Array of WHERE-clause filter conditions for the extension’s configuration table(s), or NULL if none</td>
</tr>
</tbody>
</table>

Note that unlike most catalogs with a “namespace” column, `extnamespace` is not meant to imply that the extension belongs to that schema. Extension names are never schema-qualified. Rather, `extnamespace` indicates the schema that contains most or all of the extension’s objects. If `extrelocatable` is true, then this schema must in fact contain all schema-qualifiable objects belonging to the extension.

### 49.23. pg_foreign_data_wrapper

The catalog `pg_foreign_data_wrapper` stores foreign-data wrapper definitions. A foreign-data wrapper is the mechanism by which external data, residing on foreign servers, is accessed.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>fdwname</td>
<td>name</td>
<td></td>
<td>Name of the foreign-data wrapper</td>
</tr>
<tr>
<td>fdwowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the foreign-data wrapper</td>
</tr>
</tbody>
</table>
### Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fdwhandler</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>References a handler function that is responsible for supplying execution routines for the foreign-data wrapper. Zero if no handler is provided</td>
</tr>
<tr>
<td>fdwvalidator</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>References a validator function that is responsible for checking the validity of the options given to the foreign-data wrapper, as well as options for foreign servers and user mappings using the foreign-data wrapper. Zero if no validator is provided</td>
</tr>
<tr>
<td>fdwacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
<tr>
<td>fdwoptions</td>
<td>text[]</td>
<td></td>
<td>Foreign-data wrapper specific options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

#### 49.24. pg_foreign_server

The catalog pg_foreign_server stores foreign server definitions. A foreign server describes a source of external data, such as a remote server. Foreign servers are accessed via foreign-data wrappers.

**Table 49-24. pg_foreign_server Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>srvname</td>
<td>name</td>
<td></td>
<td>Name of the foreign server</td>
</tr>
<tr>
<td>srvowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the foreign server</td>
</tr>
<tr>
<td>srvfdw</td>
<td>oid</td>
<td>pg_foreign_data_wrapper.oid</td>
<td>OID of the foreign-data wrapper of this foreign server</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

### Table 49-25. pg_foreign_table Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ftrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>OID of the pg_class entry for this foreign table</td>
</tr>
<tr>
<td>ftserver</td>
<td>oid</td>
<td>pg_foreign_server.oid</td>
<td>OID of the foreign server for this foreign table</td>
</tr>
<tr>
<td>ftoptions</td>
<td>text[]</td>
<td></td>
<td>Foreign table options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

### 49.25. pg_foreign_table

The catalog pg_foreign_table contains auxiliary information about foreign tables. A foreign table is primarily represented by a pg_class entry, just like a regular table. Its pg_foreign_table entry contains the information that is pertinent only to foreign tables and not any other kind of relation.

### Table 49-26. pg_index Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>indexrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the pg_class entry for this index</td>
</tr>
</tbody>
</table>

### 49.26. pg_index

The catalog pg_index contains part of the information about indexes. The rest is mostly in pg_class.
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>indrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the pg_class entry for the table this index is for</td>

<tr>
<td>indimmediate</td>
<td>bool</td>
<td></td>
<td>If true, the uniqueness check is enforced immediately on insertion (irrelevant if indisunique is not true)</td>
</tr>
<tr>
<td>indisclustered</td>
<td>bool</td>
<td></td>
<td>If true, the table was last clustered on this index</td>
</tr>
<tr>
<td>indisvalid</td>
<td>bool</td>
<td></td>
<td>If true, the index is currently valid for queries. False means the index is possibly incomplete: it must still be modified by INSERT/UPDATE operations, but it cannot safely be used for queries. If it is unique, the uniquenss property is not guaranteed true either.</td>
</tr>
</tbody>
</table>
### Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>indcheckxmin</td>
<td>bool</td>
<td></td>
<td>If true, queries must not use the index until the xmin of this pg_index row is below their TransactionXmin event horizon, because the table may contain broken HOT chains with incompatible rows that they can see.</td>
</tr>
<tr>
<td>indisready</td>
<td>bool</td>
<td></td>
<td>If true, the index is currently ready for inserts. False means the index must be ignored by INSERT/UPDATE operations.</td>
</tr>
<tr>
<td>indislive</td>
<td>bool</td>
<td></td>
<td>If false, the index is in process of being dropped, and should be ignored for all purposes (including HOT-safety decisions).</td>
</tr>
<tr>
<td>indisreplident</td>
<td>bool</td>
<td></td>
<td>If true this index has been chosen as &quot;replica identity&quot; using ALTER TABLE ... REPLICA IDENTITY USING INDEX ...</td>
</tr>
<tr>
<td>indkey</td>
<td>int2vector</td>
<td>pg_attribute.attnum</td>
<td>This is an array of indnatts values that indicate which table columns this index indexes. For example a value of 1 3 would mean that the first and the third table columns make up the index key. A zero in this array indicates that the corresponding index attribute is an expression over the table columns, rather than a simple column reference.</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------</td>
<td>------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>

<td>pg_collation.oid</td>
<td>For each column in the index key, this contains the OID of the collation to use for the index.</td>
</tr>
<tr>
<td>indclass</td>
<td>oidvector</td>
<td>pg_opclass.oid</td>
<td>For each column in the index key, this contains the OID of the operator class to use. See pg_opclass for details.</td>
</tr>
<tr>
<td>indoption</td>
<td>int2vector</td>
<td></td>
<td>This is an array of indnatts values that store per-column flag bits. The meaning of the bits is defined by the index’s access method.</td>
</tr>
<tr>
<td>indexprs</td>
<td>pg_node_tree</td>
<td></td>
<td>Expression trees (in nodeToString() representation) for index attributes that are not simple column references. This is a list with one element for each zero entry in indkey. Null if all index attributes are simple references.</td>
</tr>
<tr>
<td>indpred</td>
<td>pg_node_tree</td>
<td></td>
<td>Expression tree (in nodeToString() representation) for partial index predicate. Null if not a partial index.</td>
</tr>
</tbody>
</table>

### 49.27. `pg_inherits`

The catalog `pg_inherits` records information about table inheritance hierarchies. There is one entry for each direct child table in the database. (Indirect inheritance can be determined by following chains of entries.)

#### Table 49-27. `pg_inherits` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inhrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the child table</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inhparent</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the parent table</td>
</tr>
<tr>
<td>inhseqno</td>
<td>int4</td>
<td></td>
<td>If there is more than one direct parent for a child table (multiple inheritance), this number tells the order in which the inherited columns are to be arranged. The count starts at 1.</td>
</tr>
</tbody>
</table>

### 49.28. pg_language

The catalog `pg_language` registers languages in which you can write functions or stored procedures. See `CREATE LANGUAGE` and Chapter 39 for more information about language handlers.

**Table 49-28. pg_language Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>lanname</td>
<td>name</td>
<td></td>
<td>Name of the language</td>
</tr>
<tr>
<td>lanowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the language</td>
</tr>
<tr>
<td>lanispl</td>
<td>bool</td>
<td></td>
<td>This is false for internal languages (such as SQL) and true for user-defined languages. Currently, <code>pg_dump</code> still uses this to determine which languages need to be dumped, but this might be replaced by a different mechanism in the future.</td>
</tr>
<tr>
<td>lanpltrusted</td>
<td>bool</td>
<td></td>
<td>True if this is a trusted language, which means that it is believed not to grant access to anything outside the normal SQL execution environment. Only superusers can create functions in untrusted languages.</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lanplcallfoid</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>For noninternal languages this references the language handler, which is a special function that is responsible for executing all functions that are written in the particular language.</td>
</tr>
<tr>
<td>laninline</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>This references a function that is responsible for executing “inline” anonymous code blocks (DO blocks). Zero if inline blocks are not supported.</td>
</tr>
<tr>
<td>lanvalidator</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>This references a language validator function that is responsible for checking the syntax and validity of new functions when they are created. Zero if no validator is provided.</td>
</tr>
<tr>
<td>lanacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details.</td>
</tr>
</tbody>
</table>

### 49.29. `pg_largeobject`

The catalog `pg_largeobject` holds the data making up “large objects”. A large object is identified by an OID assigned when it is created. Each large object is broken into segments or “pages” small enough to be conveniently stored as rows in `pg_largeobject`. The amount of data per page is defined to be `LOBLKSIZ`E (which is currently `BLCKSZ/4`, or typically 2 kB).

Prior to PostgreSQL 9.0, there was no permission structure associated with large objects. As a result, `pg_largeobject` was publicly readable and could be used to obtain the OIDs (and contents) of all large objects in the system. This is no longer the case; use `pg_largeobject_metadata` to obtain a list of large object OIDs.

#### Table 49-29. `pg_largeobject` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>loid</td>
<td>oid</td>
<td>pg_largeobject_metadata</td>
<td>Identifier of the large object that includes this page.</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>---------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>pageno</td>
<td>int4</td>
<td></td>
<td>Page number of this page within its large object (counting from zero)</td>
</tr>
</tbody>
</table>
| data      | bytea   |            | Actual data stored in the large object. This will never be more than LOBLKS
| size bytes and might be less. |

Each row of `pg_largeobject` holds data for one page of a large object, beginning at byte offset `(pageno * LOBLKSIZE)` within the object. The implementation allows sparse storage: pages might be missing, and might be shorter than `LOBLKSIZE` bytes even if they are not the last page of the object. Missing regions within a large object read as zeroes.

### 49.30. pg_largeobject_metadata

The catalog `pg_largeobject_metadata` holds metadata associated with large objects. The actual large object data is stored in `pg_largeobject`.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>lomowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the large object</td>
</tr>
<tr>
<td>lomacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
</tbody>
</table>

### 49.31. pg_namespace

The catalog `pg_namespace` stores namespaces. A namespace is the structure underlying SQL schemas: each namespace can have a separate collection of relations, types, etc. without name conflicts.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
</tbody>
</table>
49.32. \texttt{pg\_opclass}

The catalog \texttt{pg\_opclass} defines index access method operator classes. Each operator class defines semantics for index columns of a particular data type and a particular index access method. An operator class essentially specifies that a particular operator family is applicable to a particular indexable column data type. The set of operators from the family that are actually usable with the indexed column are whichever ones accept the column’s data type as their left-hand input.

Operator classes are described at length in Section 35.14.

Table 49-32. \texttt{pg\_opclass} Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{oid}</td>
<td>\texttt{oid}</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>\texttt{opcmethod}</td>
<td>\texttt{oid}</td>
<td>\texttt{pg_am.oid}</td>
<td>Index access method operator class is for</td>
</tr>
<tr>
<td>\texttt{opcname}</td>
<td>\texttt{name}</td>
<td></td>
<td>Name of this operator class</td>
</tr>
<tr>
<td>\texttt{opcnamespace}</td>
<td>\texttt{oid}</td>
<td>\texttt{pg_namespace.oid}</td>
<td>Namespace of this operator class</td>
</tr>
<tr>
<td>\texttt{opcowner}</td>
<td>\texttt{oid}</td>
<td>\texttt{pg_authid.oid}</td>
<td>Owner of the operator class</td>
</tr>
<tr>
<td>\texttt{opcfamily}</td>
<td>\texttt{oid}</td>
<td>\texttt{pg_opfamily.oid}</td>
<td>Operator family containing the operator class</td>
</tr>
<tr>
<td>\texttt{opcintype}</td>
<td>\texttt{oid}</td>
<td>\texttt{pg_type.oid}</td>
<td>Data type that the operator class indexes</td>
</tr>
<tr>
<td>\texttt{opcdefault}</td>
<td>\texttt{bool}</td>
<td></td>
<td>True if this operator class is the default for \texttt{opcintype}</td>
</tr>
<tr>
<td>\texttt{opckeytype}</td>
<td>\texttt{oid}</td>
<td>\texttt{pg_type.oid}</td>
<td>Type of data stored in index, or zero if same as \texttt{opcintype}</td>
</tr>
</tbody>
</table>

An operator class’s \texttt{opcmethod} must match the \texttt{opfmethod} of its containing operator family. Also, there must be no more than one \texttt{pg\_opclass} row having \texttt{opcdefault} true for any given combination of \texttt{opcmethod} and \texttt{opcintype}. 
49.33. **pg_operator**

The catalog `pg_operator` stores information about operators. See CREATE OPERATOR and Section 35.12 for more information.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>oprname</td>
<td>name</td>
<td></td>
<td>Name of the operator</td>
</tr>
<tr>
<td>oprnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this operator</td>
</tr>
<tr>
<td>oprowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the operator</td>
</tr>
<tr>
<td>oprkind</td>
<td>char</td>
<td>b = infix (“both”),</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>l = prefix (“left”),</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>r = postfix (“right”)</td>
<td></td>
</tr>
<tr>
<td>oprcanmerge</td>
<td>bool</td>
<td></td>
<td>This operator supports merge joins</td>
</tr>
<tr>
<td>oprcanhash</td>
<td>bool</td>
<td></td>
<td>This operator supports hash joins</td>
</tr>
<tr>
<td>oprleft</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Type of the left operand</td>
</tr>
<tr>
<td>oprright</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Type of the right operand</td>
</tr>
<tr>
<td>oprresult</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Type of the result</td>
</tr>
<tr>
<td>oprcom</td>
<td>oid</td>
<td>pg_operator.oid</td>
<td>Commutator of this operator, if any</td>
</tr>
<tr>
<td>oprnegate</td>
<td>oid</td>
<td>pg_operator.oid</td>
<td>Negator of this operator, if any</td>
</tr>
<tr>
<td>oprcode</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>Function that implements this operator</td>
</tr>
<tr>
<td>oprrest</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>Restriction selectivity estimation function for this operator</td>
</tr>
<tr>
<td>oprjoin</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>Join selectivity estimation function for this operator</td>
</tr>
</tbody>
</table>

Unused column contain zeroes. For example, `oprleft` is zero for a prefix operator.

49.34. **pg_opfamily**

The catalog `pg_opfamily` defines operator families. Each operator family is a collection of operators
and associated support routines that implement the semantics specified for a particular index access method. Furthermore, the operators in a family are all “compatible”, in a way that is specified by the access method. The operator family concept allows cross-data-type operators to be used with indexes and to be reasoned about using knowledge of access method semantics.

Operator families are described at length in Section 35.14.

Table 49-34. pg_opfamily Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>opfmethod</td>
<td>oid</td>
<td>pg_am.oid</td>
<td>Index access method operator family is for</td>
</tr>
<tr>
<td>opfname</td>
<td>name</td>
<td></td>
<td>Name of this operator family</td>
</tr>
<tr>
<td>opfnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>Namespace of this operator family</td>
</tr>
<tr>
<td>opfowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the operator family</td>
</tr>
</tbody>
</table>

The majority of the information defining an operator family is not in its pg_opfamily row, but in the associated rows in pg_amop, pg_amproc, and pg_opclass.

49.35. pg_pltemplate

The catalog pg_pltemplate stores “template” information for procedural languages. A template for a language allows the language to be created in a particular database by a simple CREATE LANGUAGE command, with no need to specify implementation details.

Unlike most system catalogs, pg_pltemplate is shared across all databases of a cluster: there is only one copy of pg_pltemplate per cluster, not one per database. This allows the information to be accessible in each database as it is needed.

Table 49-35. pg_pltemplate Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tmplname</td>
<td>name</td>
<td>Name of the language this template is for</td>
</tr>
<tr>
<td>tmpltrusted</td>
<td>boolean</td>
<td>True if language is considered trusted</td>
</tr>
<tr>
<td>tmpldbcreate</td>
<td>boolean</td>
<td>True if language may be created by a database owner</td>
</tr>
<tr>
<td>tmplhandler</td>
<td>text</td>
<td>Name of call handler function</td>
</tr>
<tr>
<td>tmplinline</td>
<td>text</td>
<td>Name of anonymous-block handler function, or null if none</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tmplvalidator</td>
<td>text</td>
<td>Name of validator function, or null if none</td>
</tr>
<tr>
<td>tmpllibrary</td>
<td>text</td>
<td>Path of shared library that implements language</td>
</tr>
<tr>
<td>tmplacl</td>
<td>aclitem[]</td>
<td>Access privileges for template (not actually used)</td>
</tr>
</tbody>
</table>

There are not currently any commands that manipulate procedural language templates; to change the built-in information, a superuser must modify the table using ordinary `INSERT`, `DELETE`, or `UPDATE` commands.

**Note:** It is likely that `pg_pltemplate` will be removed in some future release of PostgreSQL, in favor of keeping this knowledge about procedural languages in their respective extension installation scripts.

## 49.36. pg_policy

The catalog `pg_policy` stores row level security policies for tables. A policy includes the kind of command that it applies to (possibly all commands), the roles that it applies to, the expression to be added as a security-barrier qualification to queries that include the table, and the expression to be added as a `WITH CHECK` option for queries that attempt to add new records to the table.

**Table 49-36. pg_policy Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>polname</td>
<td>name</td>
<td></td>
<td>The name of the policy</td>
</tr>
<tr>
<td>polrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table to which the policy applies</td>
</tr>
<tr>
<td>polcmd</td>
<td>char</td>
<td></td>
<td>The command type to which the policy is applied: r for SELECT, a for INSERT, w for UPDATE, d for DELETE, or * for all</td>
</tr>
<tr>
<td>polroles</td>
<td>oid[]</td>
<td>pg_authid.oid</td>
<td>The roles to which the policy is applied</td>
</tr>
<tr>
<td>polqual</td>
<td>pg_node_tree</td>
<td></td>
<td>The expression tree to be added to the security barrier qualifications for queries that use the table</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

### 49.37. pg_proc

The catalog `pg_proc` stores information about functions (or procedures). See CREATE FUNCTION and Section 35.3 for more information.

The table contains data for aggregate functions as well as plain functions. If `proisagg` is true, there should be a matching row in `pg_aggregate`.

**Table 49-37. pg_proc Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>proname</td>
<td>name</td>
<td></td>
<td>Name of the function</td>
</tr>
<tr>
<td>pronamespace</td>

<td>pg_type.oid</td>
<td>An array with the data types of the function arguments. This includes all arguments (including OUT and INOUT arguments); however, if all the arguments are IN arguments, this field will be null. Note that subscripting is 1-based, whereas for historical reasons proargtypes is subscripted from 0.</td>
</tr>
<tr>
<td>proargmodes</td>
<td>char[]</td>
<td></td>
<td>An array with the modes of the function arguments, encoded as i for IN arguments, o for OUT arguments, b for INOUT arguments, v for VARIADIC arguments, t for TABLE arguments. If all the arguments are IN arguments, this field will be null. Note that subscripts correspond to positions of proallargtypes not proargtypes.</td>
</tr>
<tr>
<td>proargnames</td>
<td>text[]</td>
<td></td>
<td>An array with the names of the function arguments. Arguments without a name are set to empty strings in the array. If none of the arguments have a name, this field will be null. Note that subscripts correspond to positions of proallargtypes not proargtypes.</td>
</tr>
</tbody>
</table>
### Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proargdefaults</td>
<td>pg_node_tree</td>
<td></td>
<td>Expression trees (in nodeToString() representation) for default values. This is a list with pronargdefaults elements, corresponding to the last ( N ) input arguments (i.e., the last ( N ) proargtypes positions). If none of the arguments have defaults, this field will be null.</td>
</tr>
<tr>
<td>protrftypes</td>
<td>oid[]</td>
<td></td>
<td>Data type OIDs for which to apply transforms.</td>
</tr>
<tr>
<td>prosrc</td>
<td>text</td>
<td></td>
<td>This tells the function handler how to invoke the function. It might be the actual source code of the function for interpreted languages, a link symbol, a file name, or just about anything else, depending on the implementation language/call convention.</td>
</tr>
<tr>
<td>probin</td>
<td>text</td>
<td></td>
<td>Additional information about how to invoke the function. Again, the interpretation is language-specific.</td>
</tr>
<tr>
<td>proconfig</td>
<td>text[]</td>
<td></td>
<td>Function’s local settings for run-time configuration variables</td>
</tr>
<tr>
<td>proacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details.</td>
</tr>
</tbody>
</table>

For compiled functions, both built-in and dynamically loaded, prosrc contains the function’s C-language name (link symbol). For all other currently-known language types, prosrc contains the function’s source text. probin is unused except for dynamically-loaded C functions, for which it gives the name of the shared library file containing the function.
49.38. **pg_range**

The catalog `pg_range` stores information about range types. This is in addition to the types’ entries in `pg_type`.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rngtypeid</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>OID of the range type</td>
</tr>
<tr>
<td>rngsubtype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>OID of the element type (subtype) of this range type</td>
</tr>
<tr>
<td>rngcollation</td>
<td>oid</td>
<td>pg_collation.oid</td>
<td>OID of the collation used for range comparisons, or 0 if none</td>
</tr>
<tr>
<td>rngsubopc</td>
<td>oid</td>
<td>pg_opclass.oid</td>
<td>OID of the subtype’s operator class used for range comparisons</td>
</tr>
<tr>
<td>rngcanonical</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the function to convert a range value into canonical form, or 0 if none</td>
</tr>
<tr>
<td>rngsubdiff</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the function to return the difference between two element values as double precision, or 0 if none</td>
</tr>
</tbody>
</table>

`rngsubopc` (plus `rngcollation`, if the element type is collatable) determines the sort ordering used by the range type. `rngcanonical` is used when the element type is discrete. `rngsubdiff` is optional but should be supplied to improve performance of GiST indexes on the range type.

49.39. **pg_replication_origin**

The `pg_replication_origin` catalog contains all replication origins created. For more on replication origins see Chapter 47.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>roident</td>
<td>Oid</td>
<td></td>
<td>A unique, cluster-wide identifier for the replication origin. Should never leave the system.</td>
</tr>
</tbody>
</table>
### 49.40. pg_rewrite

The catalog pg_rewrite stores rewrite rules for tables and views.

#### Table 49-40. pg_rewrite Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>Controls in which session_replication_role modes the rule fires. O = rule fires in “origin” and “local” modes, D = rule is disabled, R = rule fires in “replica” mode, A = rule fires always.</td>
</tr>
<tr>
<td>is_instead</td>
<td>bool</td>
<td></td>
<td>True if the rule is an INSTEAD rule</td>
</tr>
<tr>
<td>ev_qual</td>
<td>pg_node_tree</td>
<td></td>
<td>Expression tree (in the form of a nodeToString() representation) for the rule’s qualifying condition</td>
</tr>
<tr>
<td>ev_action</td>
<td>pg_node_tree</td>
<td></td>
<td>Query tree (in the form of a nodeToString() representation) for the rule’s action</td>
</tr>
</tbody>
</table>

**Note:** pg_class.relhasrules must be true if a table has any rules in this catalog.
49.41. pg_seclabel

The catalog `pg_seclabel` stores security labels on database objects. Security labels can be manipulated with the SECURITY LABEL command. For an easier way to view security labels, see Section 49.72.

See also `pg_shseclabel`, which performs a similar function for security labels of database objects that are shared across a database cluster.

Table 49-41. pg_seclabel Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this security label pertains to</td>
</tr>
<tr>

<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a security label on a table column, this is the column number (the objoid and classoid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>provider</td>
<td>text</td>
<td></td>
<td>The label provider associated with this label.</td>
</tr>
<tr>
<td>label</td>
<td>text</td>
<td></td>
<td>The security label applied to this object.</td>
</tr>
</tbody>
</table>

49.42. pg_shdepend

The catalog `pg_shdepend` records the dependency relationships between database objects and shared objects, such as roles. This information allows PostgreSQL to ensure that those objects are unreferenced before attempting to delete them.

See also `pg_depend`, which performs a similar function for dependencies involving objects within a single database.

Unlike most system catalogs, `pg_shdepend` is shared across all databases of a cluster: there is only one copy of `pg_shdepend` per cluster, not one per database.

Table 49-42. pg_shdepend Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>--------</td>
<td>------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>dbid</td>
<td>oid</td>
<td>pg_database.oid</td>
<td>The OID of the database the dependent object is in, or zero for a shared object</td>
</tr>
<tr>
<td>classid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog the dependent object is in</td>
</tr>
<tr>
<td>objid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the specific dependent object</td>
</tr>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a table column, this is the column number (the objid and classid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>refclassid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog the referenced object is in (must be a shared catalog)</td>
</tr>
<tr>
<td>refobjid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the specific referenced object</td>
</tr>
<tr>
<td>deptype</td>
<td>char</td>
<td></td>
<td>A code defining the specific semantics of this dependency relationship; see text</td>
</tr>
</tbody>
</table>

In all cases, a pg_shdepend entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by deptype:

**SHARED_DEPENDENCY_OWNER (o)**

The referenced object (which must be a role) is the owner of the dependent object.

**SHARED_DEPENDENCY_ACL (a)**

The referenced object (which must be a role) is mentioned in the ACL (access control list, i.e., privileges list) of the dependent object. (A SHARED_DEPENDENCY_ACL entry is not made for the owner of the object, since the owner will have a SHARED_DEPENDENCY_OWNER entry anyway.)

**SHARED_DEPENDENCY_POLICY (r)**

The referenced object (which must be a role) is mentioned as the target of a dependent policy object.

**SHARED_DEPENDENCY_PIN (p)**

There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by initdb. The columns for the dependent object contain zeroes.

Other dependency flavors might be needed in future. Note in particular that the current definition only supports roles as referenced objects.
49.43. pg_shdescription

The catalog pg_shdescription stores optional descriptions (comments) for shared database objects. Descriptions can be manipulated with the COMMENT command and viewed with psql's `\d` commands.

See also pg_description, which performs a similar function for descriptions involving objects within a single database.

Unlike most system catalogs, pg_shdescription is shared across all databases of a cluster: there is only one copy of pg_shdescription per cluster, not one per database.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this description pertains to</td>
</tr>
<tr>
<td>classoid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>description</td>
<td>text</td>
<td></td>
<td>Arbitrary text that serves as the description of this object</td>
</tr>
</tbody>
</table>

49.44. pg_shseclabel

The catalog pg_shseclabel stores security labels on shared database objects. Security labels can be manipulated with the SECURITY LABEL command. For an easier way to view security labels, see Section 49.72.

See also pg_seclabel, which performs a similar function for security labels involving objects within a single database.

Unlike most system catalogs, pg_shseclabel is shared across all databases of a cluster: there is only one copy of pg_shseclabel per cluster, not one per database.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this security label pertains to</td>
</tr>
<tr>

<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>provider</td>
<td>text</td>
<td></td>
<td>The label provider associated with this label</td>
</tr>
</tbody>
</table>
49.45. pg_statistic

The catalog pg_statistic stores statistical data about the contents of the database. Entries are created by ANALYZE and subsequently used by the query planner. Note that all the statistical data is inherently approximate, even assuming that it is up-to-date.

Normally there is one entry, with stainherit = false, for each table column that has been analyzed. If the table has inheritance children, a second entry with stainherit = true is also created. This row represents the column's statistics over the inheritance tree, i.e., statistics for the data you'd see with SELECT column FROM table*, whereas the stainherit = false row represents the results of SELECT column FROM ONLY table.

pg_statistic also stores statistical data about the values of index expressions. These are described as if they were actual data columns; in particular, starelid references the index. No entry is made for an ordinary non-expression index column, however, since it would be redundant with the entry for the underlying table column. Currently, entries for index expressions always have stainherit = false.

Since different kinds of statistics might be appropriate for different kinds of data, pg_statistic is designed not to assume very much about what sort of statistics it stores. Only extremely general statistics (such as nullness) are given dedicated columns in pg_statistic. Everything else is stored in “slots”, which are groups of associated columns whose content is identified by a code number in one of the slot’s columns. For more information see src/include/catalog/pg_statistic.h.

pg_statistic should not be readable by the public, since even statistical information about a table's contents might be considered sensitive. (Example: minimum and maximum values of a salary column might be quite interesting.) pg_stats is a publicly readable view on pg_statistic that only exposes information about those tables that are readable by the current user.

Table 49-45. pg_statistic Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</thead>
<tbody>
<tr>
<td>stavaluesN</td>
<td>anyarray</td>
<td></td>
<td>Column data values of the appropriate kind for the Nth “slot”, or null if the slot kind does not store any data values. Each array’s element values are actually of the specific column’s data type, or a related type such as an array’s element type, so there is no way to define these columns’ type more specifically than anyarray.</td>
</tr>
</tbody>
</table>

### 49.46. pg_tablespace

The catalog `pg_tablespace` stores information about the available tablespaces. Tables can be placed in particular tablespaces to aid administration of disk layout.

Unlike most system catalogs, `pg_tablespace` is shared across all databases of a cluster: there is only one copy of `pg_tablespace` per cluster, not one per database.

#### Table 49-46. pg_tablespace Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>spcname</td>
<td>name</td>
<td></td>
<td>Tablespace name</td>
</tr>
<tr>
<td>spcowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the tablespace, usually the user who created it</td>
</tr>
<tr>
<td>spcacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
<tr>
<td>spcoptions</td>
<td>text[]</td>
<td></td>
<td>Tablespace-level options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

### 49.47. pg_transform

The catalog `pg_transform` stores information about transforms, which are a mechanism to adapt data types to procedural languages. See CREATE TRANSFORM for more information.
Table 49-47. pg_transform Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>trftype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>OID of the data type this transform is for</td>
</tr>
<tr>
<td>trflang</td>
<td>oid</td>
<td>pg_language.oid</td>
<td>OID of the language this transform is for</td>
</tr>
<tr>
<td>trffromsql</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>The OID of the function to use when converting the data type for input to the procedural language (e.g., function parameters). Zero is stored if this operation is not supported.</td>
</tr>
<tr>
<td>trftosql</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>The OID of the function to use when converting output from the procedural language (e.g., return values) to the data type. Zero is stored if this operation is not supported.</td>
</tr>
</tbody>
</table>

49.48. pg_trigger

The catalog pg_trigger stores triggers on tables and views. See CREATE TRIGGER for more information.

Table 49-48. pg_trigger Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>tgrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table this trigger is on</td>
</tr>
<tr>
<td>tgnname</td>
<td>name</td>
<td></td>
<td>Trigger name (must be unique among triggers of same table)</td>
</tr>
<tr>
<td>tgfoid</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>The function to be called</td>
</tr>
<tr>
<td>tgttype</td>
<td>int2</td>
<td></td>
<td>Bit mask identifying trigger firing conditions</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------------</td>
<td>--------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>tgenabled</td>
<td>char</td>
<td></td>
<td>Controls in which session_replication_role modes the trigger fires. (O) = trigger fires in “origin” and “local” modes, (D) = trigger is disabled, (R) = trigger fires in “replica” mode, (A) = trigger fires always.</td>
</tr>
<tr>
<td>tgisinternal</td>
<td>bool</td>
<td></td>
<td>True if trigger is internally generated (usually, to enforce the constraint identified by tconstraint)</td>
</tr>
<tr>
<td>tgconstrrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table referenced by a referential integrity constraint</td>
</tr>
<tr>
<td>tgconstrindid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The index supporting a unique, primary key, referential integrity, or exclusion constraint</td>
</tr>
<tr>
<td>tgconstraint</td>
<td>oid</td>
<td>pg_constraint.oid</td>
<td>The (pg_constraint) entry associated with the trigger, if any</td>
</tr>
<tr>
<td>tgdeferrable</td>
<td>bool</td>
<td></td>
<td>True if constraint trigger is deferrable</td>
</tr>
<tr>
<td>tginitdeferred</td>
<td>bool</td>
<td></td>
<td>True if constraint trigger is initially deferred</td>
</tr>
<tr>
<td>tgnargs</td>
<td>int2</td>
<td></td>
<td>Number of argument strings passed to trigger function</td>
</tr>
<tr>
<td>tgattr</td>
<td>int2vector</td>
<td>pg_attribute.attnum</td>
<td>Column numbers, if trigger is column-specific; otherwise an empty array</td>
</tr>
<tr>
<td>tgargs</td>
<td>bytea</td>
<td></td>
<td>Argument strings to pass to trigger, each NULL-terminated</td>
</tr>
<tr>
<td>tgqual</td>
<td>pg_node_tree</td>
<td></td>
<td>Expression tree (in nodeToString() representation) for the trigger’s WHEN condition, or null if none</td>
</tr>
</tbody>
</table>
Currently, column-specific triggering is supported only for UPDATE events, and so tgattr is relevant only for that event type. tgytype might contain bits for other event types as well, but those are presumed to be table-wide regardless of what is in tgattr.

**Note:** When tgconstraint is nonzero, tgconstrrelid, tgconstrindid, tgdeferrable, and tginitdeferred are largely redundant with the referenced pg_constraint entry. However, it is possible for a non-deferrable trigger to be associated with a deferrable constraint: foreign key constraints can have some deferrable and some non-deferrable triggers.

**Note:** pg_class.relhastriggers must be true if a relation has any triggers in this catalog.

### 49.49. pgTsConfig

The pgTsConfig catalog contains entries representing text search configurations. A configuration specifies a particular text search parser and a list of dictionaries to use for each of the parser’s output token types. The parser is shown in the pgTsConfig entry, but the token-to-dictionary mapping is defined by subsidiary entries in pgTsConfigMap.

PostgreSQL’s text search features are described at length in Chapter 12.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>cfgname</td>
<td>name</td>
<td></td>
<td>Text search configuration name</td>
</tr>
<tr>
<td>cfgnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this configuration</td>
</tr>
<tr>
<td>cfgowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the configuration</td>
</tr>
<tr>
<td>cfgparser</td>
<td>oid</td>
<td>pg_ts_parser.oid</td>
<td>The OID of the text search parser for this configuration</td>
</tr>
</tbody>
</table>

### 49.50. pgTsConfigMap

The pgTsConfigMap catalog contains entries showing which text search dictionaries should be consulted, and in what order, for each output token type of each text search configuration’s parser.

PostgreSQL’s text search features are described at length in Chapter 12.
Chapter 49. System Catalogs

Table 49-50. `pg_ts_config_map` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mapcfg</td>
<td>oid</td>
<td><code>pg_ts_config.oid</code></td>
<td>The OID of the <code>pg_ts_config</code> entry owning this map entry</td>
</tr>
<tr>
<td>maptokentype</td>
<td>integer</td>
<td></td>
<td>A token type emitted by the configuration’s parser</td>
</tr>
<tr>
<td>mapseqno</td>
<td>integer</td>

<td>Order in which to consult this entry (lower <code>mapseqno</code>s first)</td>
</tr>
<tr>
<td>mapdict</td>
<td>oid</td>
<td><code>pg_ts_dict.oid</code></td>
<td>The OID of the text search dictionary to consult</td>
</tr>
</tbody>
</table>

49.51. `pg_ts_dict`

The `pg_ts_dict` catalog contains entries defining text search dictionaries. A dictionary depends on a text search template, which specifies all the implementation functions needed; the dictionary itself provides values for the user-settable parameters supported by the template. This division of labor allows dictionaries to be created by unprivileged users. The parameters are specified by a text string `dictinitoption`, whose format and meaning vary depending on the template.

PostgreSQL’s text search features are described at length in Chapter 12.

Table 49-51. `pg_ts_dict` Columns

<table>

<td>The OID of the text search template for this dictionary</td>
</tr>
<tr>
<td>dictinitoption</td>
<td>text</td>
<td></td>
<td>Initialization option string for the template</td>
</tr>
</tbody>
</table>
49.52. pg_ts_parser

The `pg_ts_parser` catalog contains entries defining text search parsers. A parser is responsible for splitting input text into lexemes and assigning a token type to each lexeme. Since a parser must be implemented by C-language-level functions, creation of new parsers is restricted to database superusers. PostgreSQL’s text search features are described at length in Chapter 12.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>

</tr>
<tr>
<td>prsstart</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the parser’s startup function</td>
</tr>
<tr>
<td>prstoken</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the parser’s next-token function</td>
</tr>
<tr>
<td>prsend</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the parser’s shutdown function</td>
</tr>
<tr>
<td>prsheadline</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the parser’s headline function</td>
</tr>
<tr>
<td>prslextype</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the parser’s lextype function</td>
</tr>
</tbody>
</table>

49.53. pg_ts_template

The `pg_ts_template` catalog contains entries defining text search templates. A template is the implementation skeleton for a class of text search dictionaries. Since a template must be implemented by C-language-level functions, creation of new templates is restricted to database superusers. PostgreSQL’s text search features are described at length in Chapter 12.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>

<td></td>
<td>Text search template name</td>
</tr>
<tr>
<td>tmplnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this template</td>
</tr>
</tbody>
</table>
49.54. \texttt{pg\_type}

The catalog \texttt{pg\_type} stores information about data types. Base types and enum types (scalar types) are created with \texttt{CREATE TYPE}, and domains with \texttt{CREATE DOMAIN}. A composite type is automatically created for each table in the database, to represent the row structure of the table. It is also possible to create composite types with \texttt{CREATE TYPE AS}.

Table 49-54. \texttt{pg\_type} Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>

<tr>
<td>--------</td>
<td>------</td>
<td>------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| typalign | char |            | typalign is the alignment required when storing a value of this type. It applies to storage on disk as well as most representations of the value inside PostgreSQL. When multiple values are stored consecutively, such as in the representation of a complete row on disk, padding is inserted before a datum of this type so that it begins on the specified boundary. The alignment reference is the beginning of the first datum in the sequence. Possible values are:  
  • c = char alignment, i.e., no alignment needed.  
  • s = short alignment (2 bytes on most machines).  
  • i = int alignment (4 bytes on most machines).  
  • d = double alignment (8 bytes on many machines, but by no means all).  

**Note:** For types used in system tables, it is critical that the size and alignment defined in `pg_type` agree with the way that the compiler will lay out the column in a structure representing a table row.
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
</table>
| typstorage    | char  |            | `typstorage` tells for varlena types (those with `typlen = -1`) if the type is prepared for toasting and what the default strategy for attributes of this type should be. Possible values are:  
  • `p`: Value must always be stored plain.  
  • `e`: Value can be stored in a “secondary” relation (if relation has one, see `pg_class.reltoastrelid`).  
  • `m`: Value can be stored compressed inline.  
  • `x`: Value can be stored compressed inline or stored in “secondary” storage.  
  Note that `m` columns can also be moved out to secondary storage, but only as a last resort (e and x columns are moved first). |
<p>| typnotnull    | bool  |            | <code>typnotnull</code> represents a not-null constraint on a type. Used for domains only.                                                                                                                              |
| typbasetype   | oid   | pg_type.oid| If this is a domain (see <code>typtype</code>), then <code>typbasetype</code> identifies the type that this one is based on. Zero if this type is not a domain.                                                                         |</p>
<table>
<thead>

<td>oid</td>
<td>pg_foreign_server.oid</td>
<td>The OID of the foreign server that contains this mapping</td>
</tr>
<tr>
<td>umoptions</td>
<td>text[]</td>
<td></td>
<td>User mapping specific options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

49.56. System Views

In addition to the system catalogs, PostgreSQL provides a number of built-in views. Some system views provide convenient access to some commonly used queries on the system catalogs. Other views provide access to internal server state.

The information schema (Chapter 34) provides an alternative set of views which overlap the functionality of the system views. Since the information schema is SQL-standard whereas the views described here are PostgreSQL-specific, it’s usually better to use the information schema if it provides all the information you need.

Table 49-57 lists the system views described here. More detailed documentation of each view follows below. There are some additional views that provide access to the results of the statistics collector; they are described in Table 27-2.

Except where noted, all the views described here are read-only.

Table 49-57. System Views

<table>
<thead>
<tr>

<td>views</td>
</tr>
</tbody>
</table>

### 49.57. pg_available_extensions

The `pg_available_extensions` view lists the extensions that are available for installation. See also the `pg_extension` catalog, which shows the extensions currently installed.

**Table 49-58. pg_available_extensions Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
<td>Extension name</td>
</tr>
<tr>
<td>default_version</td>
<td>text</td>
<td>Name of default version, or NULL if none is specified</td>
</tr>
<tr>
<td>installed_version</td>
<td>text</td>
<td>Currently installed version of the extension, or NULL if not installed</td>
</tr>
<tr>
<td>comment</td>
<td>text</td>
<td>Comment string from the extension’s control file</td>
</tr>
</tbody>
</table>

The `pg_available_extensions` view is read only.

### 49.58. pg_available_extension_versions

The `pg_available_extension_versions` view lists the specific extension versions that are available for installation. See also the `pg_extension` catalog, which shows the extensions currently in-
49.59. **pg_available_extension_versions**

The **pg_available_extension_versions** view lists the currently available extension versions. It includes information about the installed versions of extensions, such as their names, versions, and installation status.

**Table 49-59. pg_available_extension_versions Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
<td>Extension name</td>
</tr>
<tr>
<td>version</td>
<td>text</td>
<td>Version name</td>
</tr>
<tr>
<td>installed</td>
<td>bool</td>
<td>True if this version of this extension is currently installed</td>
</tr>
<tr>
<td>superuser</td>
<td>bool</td>
<td>True if only superusers are allowed to install this extension</td>
</tr>
<tr>
<td>relocatable</td>
<td>bool</td>
<td>True if extension can be relocated to another schema</td>
</tr>
<tr>
<td>schema</td>
<td>name</td>
<td>Name of the schema that the extension must be installed into, or NULL if partially or fully relocatable</td>
</tr>
<tr>
<td>requires</td>
<td>name[]</td>
<td>Names of prerequisite extensions, or NULL if none</td>
</tr>
<tr>
<td>comment</td>
<td>text</td>
<td>Comment string from the extension’s control file</td>
</tr>
</tbody>
</table>

The **pg_available_extension_versions** view is read only.

49.59. **pg_cursors**

The **pg_cursors** view lists the cursors that are currently available. Cursors can be defined in several ways:

- via the DECLARE statement in SQL
- via the Bind message in the frontend/backend protocol, as described in Section 50.2.3
- via the Server Programming Interface (SPI), as described in Section 44.1

The **pg_cursors** view displays cursors created by any of these means. Cursors only exist for the duration of the transaction that defines them, unless they have been declared **WITH HOLD**. Therefore, non-holdable cursors are only present in the view until the end of their creating transaction.

**Note:** Cursors are used internally to implement some of the components of PostgreSQL, such as procedural languages. Therefore, the **pg_cursors** view might include cursors that have not been explicitly created by the user.

**Table 49-60. pg_cursors Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
<td>The name of the cursor</td>
</tr>
<tr>
<td>statement</td>
<td>text</td>
<td>The verbatim query string submitted to declare this cursor</td>
</tr>
<tr>
<td>is_holdable</td>
<td>boolean</td>
<td>true if the cursor is holdable (that is, it can be accessed after the transaction that declared the cursor has committed); false otherwise</td>
</tr>
<tr>
<td>is_binary</td>
<td>boolean</td>
<td>true if the cursor was declared BINARY; false otherwise</td>
</tr>
<tr>
<td>is_scrollable</td>
<td>boolean</td>
<td>true if the cursor is scrollable (that is, it allows rows to be retrieved in a nonsequential manner); false otherwise</td>
</tr>
<tr>
<td>creation_time</td>
<td>timestamptz</td>
<td>The time at which the cursor was declared</td>
</tr>
</tbody>
</table>

The `pg_cursors` view is read only.

49.60. `pg_file_settings`

The view `pg_file_settings` provides a summary of the contents of the server’s configuration file(s). A row appears in this view for each “name = value” entry appearing in the files, with annotations indicating whether the value could be applied successfully. Additional row(s) may appear for problems not linked to a “name = value” entry, such as syntax errors in the files.

This view is helpful for checking whether planned changes in the configuration files will work, or for diagnosing a previous failure. Note that this view reports on the current contents of the files, not on what was last applied by the server. (The `pg_settings` view is usually sufficient to determine that.)

The `pg_file_settings` view can be read only by superusers.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sourcefile</td>
<td>text</td>
<td>Full path name of the configuration file</td>
</tr>
<tr>
<td>sourceline</td>
<td>integer</td>
<td>Line number within the configuration file where the entry appears</td>
</tr>
<tr>
<td>seqno</td>
<td>integer</td>
<td>Order in which the entries are processed (1..n)</td>
</tr>
<tr>
<td>name</td>
<td>text</td>
<td>Configuration parameter name</td>
</tr>
<tr>
<td>setting</td>
<td>text</td>
<td>Value to be assigned to the parameter</td>
</tr>
<tr>
<td>applied</td>
<td>boolean</td>
<td>True if the value can be applied successfully</td>
</tr>
</tbody>
</table>
If the configuration file contains syntax errors or invalid parameter names, the server will not attempt to apply any settings from it, and therefore all the applied fields will read as false. In such a case there will be one or more rows with non-null error fields indicating the problem(s). Otherwise, individual settings will be applied if possible. If an individual setting cannot be applied (e.g., invalid value, or the setting cannot be changed after server start) it will have an appropriate message in the error field. Another way that an entry might have applied = false is that it is overridden by a later entry for the same parameter name; this case is not considered an error so nothing appears in the error field.

See Section 18.1 for more information about the various ways to change run-time parameters.

### 49.61. pg_group

The view pg_group exists for backwards compatibility; it emulates a catalog that existed in PostgreSQL before version 8.1. It shows the names and members of all roles that are marked as not rolcanlogin, which is an approximation to the set of roles that are being used as groups.

Table 49-62. pg_group Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>groname</td>
<td>name</td>
<td>pg_authid.rolname</td>
<td>Name of the group</td>
</tr>
<tr>
<td>grosysid</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>ID of this group</td>
</tr>
<tr>
<td>grolist</td>
<td>oid[]</td>
<td>pg_authid.oid</td>
<td>An array containing the IDs of the roles in this group</td>
</tr>
</tbody>
</table>

### 49.62. pg_indexes

The view pg_indexes provides access to useful information about each index in the database.

Table 49-63. pg_indexes Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td>pg_namespace.nspname</td>
<td>Name of schema containing table and index</td>
</tr>
<tr>

<td>name</td>
<td>pg_class.relname</td>
<td>Name of table the index is for</td>
</tr>
<tr>
<td>indexname</td>
<td>name</td>
<td>pg_class.relname</td>
<td>Name of index</td>
</tr>
<tr>
<td>tablespace</td>
<td>name</td>
<td>pg_tablespace.spcname</td>
<td>Name of tablespace containing index (null if default for database)</td>
</tr>
</tbody>
</table>
### 49.63. pg_locks

The view `pg_locks` provides access to information about the locks held by open transactions within the database server. See Chapter 13 for more discussion of locking.

`pg_locks` contains one row per active lockable object, requested lock mode, and relevant transaction. Thus, the same lockable object might appear many times, if multiple transactions are holding or waiting for locks on it. However, an object that currently has no locks on it will not appear at all.

There are several distinct types of lockable objects: whole relations (e.g., tables), individual pages of relations, individual tuples of relations, transaction IDs (both virtual and permanent IDs), and general database objects (identified by class OID and object OID, in the same way as in `pg_description` or `pg_depend`). Also, the right to extend a relation is represented as a separate lockable object. Also, “advisory” locks can be taken on numbers that have user-defined meanings.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>locktype</td>

</tbody>
</table>
### Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>text</td>
<td></td>
<td>Name of the lock mode held or desired by this process (see Section 13.3.1 and Section 13.2.3)</td>
</tr>
<tr>
<td>granted</td>
<td>boolean</td>
<td></td>
<td>True if lock is held, false if lock is awaited</td>
</tr>
<tr>
<td>fastpath</td>
<td>boolean</td>
<td></td>
<td>True if lock was taken via fast path, false if taken via main lock table</td>
</tr>
</tbody>
</table>

**granted** is true in a row representing a lock held by the indicated transaction. False indicates that this transaction is currently waiting to acquire this lock, which implies that some other transaction is holding a conflicting lock mode on the same lockable object. The waiting transaction will sleep until the other lock is released (or a deadlock situation is detected). A single transaction can be waiting to acquire at most one lock at a time.

Every transaction holds an exclusive lock on its virtual transaction ID for its entire duration. If a permanent ID is assigned to the transaction (which normally happens only if the transaction changes the state of the database), it also holds an exclusive lock on its permanent transaction ID until it ends. When one transaction finds it necessary to wait specifically for another transaction, it does so by attempting to acquire share lock on the other transaction ID (either virtual or permanent ID depending on the situation). That will succeed only when the other transaction terminates and releases its locks.

Although tuples are a lockable type of object, information about row-level locks is stored on disk, not in memory, and therefore row-level locks normally do not appear in this view. If a transaction is waiting for a row-level lock, it will usually appear in the view as waiting for the permanent transaction ID of the current holder of that row lock.

Advisory locks can be acquired on keys consisting of either a single bigint value or two integer values. A bigint key is displayed with its high-order half in the classid column, its low-order half in the objid column, and objsubid equal to 1. The original bigint value can be reassembled with the expression (classid::bigint << 32) | objid::bigint. Integer keys are displayed with the first key in the classid column, the second key in the objid column, and objsubid equal to 2. The actual meaning of the keys is up to the user. Advisory locks are local to each database, so the database column is meaningful for an advisory lock.

**pg_locks** provides a global view of all locks in the database cluster, not only those relevant to the current database. Although its relation column can be joined against pg_class.oid to identify locked relations, this will only work correctly for relations in the current database (those for which the database column is either the current database’s OID or zero).

The pid column can be joined to the pid column of the pg_stat_activity view to get more information on the session holding or waiting to hold each lock, for example

```sql
SELECT * FROM pg_locks pl LEFT JOIN pg_stat_activity psa
ON pl.pid = psa.pid;
```

Also, if you are using prepared transactions, the virtualtransaction column can be joined to the transaction column of the pg_prepared_xacts view to get more information on prepared transactions that hold locks. (A prepared transaction can never be waiting for a lock, but it continues to hold the locks it acquired while running.) For example:
SELECT * FROM pg_locks pl LEFT JOIN pg_prepared_xacts ppx
  ON pl.virtualtransaction = '-1/' || ppx.transaction;

The `pg_locks` view displays data from both the regular lock manager and the predicate lock manager, which are separate systems; in addition, the regular lock manager subdivides its locks into regular and fast-path locks. This data is not guaranteed to be entirely consistent. When the view is queried, data on fast-path locks (with `fastpath = true`) is gathered from each backend one at a time, without freezing the state of the entire lock manager, so it is possible for locks to be taken or released while information is gathered. Note, however, that these locks are known not to conflict with any other lock currently in place. After all backends have been queried for fast-path locks, the remainder of the regular lock manager is locked as a unit, and a consistent snapshot of all remaining locks is collected as an atomic action. After unlocking the regular lock manager, the predicate lock manager is similarly locked and all predicate locks are collected as an atomic action. Thus, with the exception of fast-path locks, each lock manager will deliver a consistent set of results, but as we do not lock both lock managers simultaneously, it is possible for locks to be taken or released after we interrogate the regular lock manager and before we interrogate the predicate lock manager.

Locking the regular and/or predicate lock manager could have some impact on database performance if this view is very frequently accessed. The locks are held only for the minimum amount of time necessary to obtain data from the lock managers, but this does not completely eliminate the possibility of a performance impact.

### 49.64. `pg_matviews`

The view `pg_matviews` provides access to useful information about each materialized view in the database.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td>pg_namespace.nspname</td>
<td>Name of schema containing materialized view</td>

<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>definition</td>
<td>text</td>
<td></td>
<td>Materialized view definition (a reconstructed SELECT query)</td>
</tr>
</tbody>
</table>

### 49.65. pg_policies

The view `pg_policies` provides access to useful information about each row-level security policy in the database.

**Table 49-66. pg_policies Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td>pg_namespace.nspname</td>
<td>Name of schema containing table policy is on</td>
</tr>
<tr>
<td>tablename</td>

<td>name</td>
<td>pg_policy.polname</td>
<td>Name of policy</td>
</tr>
<tr>
<td>roles</td>
<td>name[]</td>
<td></td>
<td>The roles to which this policy applies</td>
</tr>
<tr>
<td>cmd</td>
<td>text</td>
<td></td>
<td>The command type to which the policy is applied</td>
</tr>
<tr>
<td>qual</td>
<td>text</td>
<td></td>
<td>The expression added to the security barrier qualifications for queries that this policy applies to</td>
</tr>
<tr>
<td>with_check</td>
<td>text</td>
<td></td>
<td>The expression added to the WITH CHECK qualifications for queries that attempt to add rows to this table</td>
</tr>
</tbody>
</table>

### 49.66. pg_prepared_statements

The `pg_prepared_statements` view displays all the prepared statements that are available in the current session. See PREPARE for more information about prepared statements.

`pg_prepared_statements` contains one row for each prepared statement. Rows are added to the view when a new prepared statement is created and removed when a prepared statement is released (for example, via the DEALLOCATE command).
Chapter 49. System Catalogs

Table 49-67. pg_prepared_statements Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
<td>The identifier of the prepared statement</td>
</tr>
<tr>
<td>statement</td>
<td>text</td>
<td>The query string submitted by the client to create this prepared statement.</td>
</tr>
<tr>
<td>prepare_time</td>
<td>timestamp</td>
<td>The time at which the prepared statement was created</td>
</tr>
<tr>
<td>parameter_types</td>
<td>regtype[]</td>
<td>The expected parameter types for the prepared statement in the form of an array of regtype. The OID corresponding to an element of this array can be obtained by casting the regtype value to oid.</td>
</tr>
<tr>
<td>from_sql</td>
<td>boolean</td>
<td>true if the prepared statement was created via the PREPARE SQL statement; false if the statement was prepared via the frontend/backend protocol</td>
</tr>
</tbody>
</table>

The pg_prepared_statements view is read only.

49.67. pg_prepared_xacts

The view pg_prepared_xacts displays information about transactions that are currently prepared for two-phase commit (see PREPARE TRANSACTION for details).

pg_prepared_xacts contains one row per prepared transaction. An entry is removed when the transaction is committed or rolled back.

Table 49-68. pg_prepared_xacts Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>transaction</td>
<td>xid</td>
<td></td>
<td>Numeric transaction identifier of the prepared transaction</td>
</tr>
</tbody>
</table>
### 49.68. `pg_replication_origin_status`

The `pg_replication_origin_status` view contains information about how far replay for a certain origin has progressed. For more on replication origins see Chapter 47.

#### Table 49-69. `pg_replication_origin_status` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>

<td><code>pg_lsn</code></td>
<td></td>
<td>This node’s LSN at which <code>remote_lsn</code> has been replicated. Used to flush commit records before persisting data to disk when using asynchronous commits.</td>
</tr>
</tbody>
</table>
49.69. pg_replication_slots

The `pg_replication_slots` view provides a listing of all replication slots that currently exist on the database cluster, along with their current state.

For more on replication slots, see Section 25.2.6 and Chapter 46.

### Table 49-70. pg_replication_slots Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>slot_name</td>
<td>name</td>
<td></td>
<td>A unique, cluster-wide identifier for the replication slot</td>
</tr>

<td>pg_lsn</td>
<td></td>
<td>The address (LSN) of oldest WAL which still might be required by the consumer of this slot and thus won’t be automatically removed during checkpoints.</td>
</tr>
</tbody>
</table>

### 49.70. **pg_roles**

The view **pg_roles** provides access to information about database roles. This is simply a publicly readable view of **pg_authid** that blanks out the password field.

This view explicitly exposes the OID column of the underlying table, since that is needed to do joins to other catalogs.

**Table 49-71. pg_roles Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rolname</td>
<td>name</td>
<td></td>
<td>Role name</td>
</tr>
<tr>

<td>bool</td>
<td></td>
<td>Role can create databases</td>
</tr>
<tr>
<td>rolcanlogin</td>
<td>bool</td>
<td></td>
<td>Role can log in. That is, this role can be given as the initial session authorization identifier</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rolreplication</td>
<td>bool</td>
<td></td>
<td>Role is a replication role. That is, this role can initiate streaming replication (see Section 25.2.5) and set/unset the system backup mode using <code>pg_start_backup</code> and <code>pg_stop_backup</code></td>
</tr>
<tr>
<td>rolconnlimit</td>
<td>int4</td>
<td></td>
<td>For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit.</td>
</tr>
<tr>
<td>rolpassword</td>
<td>text</td>
<td></td>
<td>Not the password (always reads as ********)</td>
</tr>
<tr>
<td>rolvaliduntil</td>
<td>timestamptz</td>
<td></td>
<td>Password expiry time (only used for password authentication); null if no expiration</td>
</tr>
<tr>
<td>rolbypassrls</td>
<td>bool</td>
<td></td>
<td>Role bypasses every row level security policy, see Section 5.7 for more information.</td>
</tr>
<tr>
<td>rolconfig</td>
<td>text[]</td>
<td></td>
<td>Role-specific defaults for run-time configuration variables</td>
</tr>
<tr>
<td>oid</td>
<td>oid</td>
<td><code>pg_authid.oid</code></td>
<td>ID of role</td>
</tr>
</tbody>
</table>

49.71. \texttt{pg\_rules}

The view \texttt{pg\_rules} provides access to useful information about query rewrite rules.

Table 49-72. \texttt{pg\_rules} Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td><code>pg_namespace.nspname</code></td>
<td>Name of schema containing table</td>
</tr>
<tr>
<td>tablename</td>
<td>name</td>
<td><code>pg_class.relnamem</code></td>
<td>Name of table the rule is for</td>
</tr>
<tr>
<td>rulename</td>
<td>name</td>
<td><code>pg_rewrite.rulename</code></td>
<td>Name of rule</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>definition</td>
<td>text</td>
<td></td>
<td>Rule definition (a reconstructed creation command)</td>
</tr>
</tbody>
</table>

The `pg_rules` view excludes the `ON SELECT` rules of views and materialized views; those can be seen in `pg_views` and `pg_matviews`.

### 49.72. `pg_seclabels`

The view `pg_seclabels` provides information about security labels. It is an easier-to-query version of the `pg_seclabel` catalog.

#### Table 49-73. `pg_seclabels` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this security label pertains to</td>
</tr>
<tr>
<td>classoid</td>
<td>oid</td>
<td><code>pg_class.oid</code></td>
<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a security label on a table column, this is the column number (the objoid and classoid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>objtype</td>
<td>text</td>
<td></td>
<td>The type of object to which this label applies, as text.</td>
</tr>
<tr>
<td>objnamespace</td>
<td>oid</td>
<td><code>pg_namespace.oid</code></td>
<td>The OID of the namespace for this object, if applicable; otherwise NULL.</td>
</tr>
<tr>
<td>objname</td>
<td>text</td>
<td></td>
<td>The name of the object to which this label applies, as text.</td>
</tr>
<tr>
<td>provider</td>
<td>text</td>
<td><code>pg_seclabel.provider</code></td>
<td>The label provider associated with this label.</td>
</tr>
<tr>
<td>label</td>
<td>text</td>
<td><code>pg_seclabel.label</code></td>
<td>The security label applied to this object.</td>
</tr>
</tbody>
</table>
**49.73. pg_settings**

The view `pg_settings` provides access to run-time parameters of the server. It is essentially an alternative interface to the `SHOW` and `SET` commands. It also provides access to some facts about each parameter that are not directly available from `SHOW`, such as minimum and maximum values.

### Table 49-74. pg_settings Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
<td>Run-time configuration parameter name</td>
</tr>
<tr>
<td>setting</td>
<td>text</td>
<td>Current value of the parameter</td>
</tr>
<tr>

<tr>
<td>extra_desc</td>
<td>text</td>
<td>Additional, more detailed description of the parameter</td>
</tr>
<tr>
<td>context</td>
<td>text</td>
<td>Context required to set the parameter’s value (see below)</td>
</tr>
<tr>
<td>vartype</td>
<td>text</td>
<td>Parameter type (<code>bool</code>, <code>enum</code>, <code>integer</code>, <code>real</code>, or <code>string</code>)</td>
</tr>
<tr>
<td>source</td>
<td>text</td>
<td>Source of the current parameter value</td>
</tr>
<tr>
<td>min_val</td>
<td>text</td>
<td>Minimum allowed value of the parameter (null for non-numeric values)</td>
</tr>
<tr>
<td>max_val</td>
<td>text</td>
<td>Maximum allowed value of the parameter (null for non-numeric values)</td>
</tr>
<tr>
<td>enumvals</td>
<td>text[]</td>
<td>Allowed values of an enum parameter (null for non-enum values)</td>
</tr>
<tr>
<td>boot_val</td>
<td>text</td>
<td>Parameter value assumed at server startup if the parameter is not otherwise set</td>
</tr>
<tr>
<td>reset_val</td>
<td>text</td>
<td>Value that <code>RESET</code> would reset the parameter to in the current session</td>
</tr>
<tr>
<td>sourcefile</td>
<td>text</td>
<td>Configuration file the current value was set in (null for values set from sources other than configuration files, or when examined by a non-superuser); helpful when using <code>include</code> directives in configuration files</td>
</tr>
</tbody>
</table>
### Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sourceline</td>
<td>integer</td>
<td>Line number within the configuration file the current value was set at (null for values set from sources other than configuration files, or when examined by a non-superuser)</td>
</tr>
<tr>
<td>pending_restart</td>
<td>boolean</td>
<td>true if the value has been changed in the configuration file but needs a restart; or false otherwise.</td>
</tr>
</tbody>
</table>

There are several possible values of context. In order of decreasing difficulty of changing the setting, they are:

- **internal**
  
  These settings cannot be changed directly; they reflect internally determined values. Some of them may be adjustable by rebuilding the server with different configuration options, or by changing options supplied to `initdb`.

- **postmaster**
  
  These settings can only be applied when the server starts, so any change requires restarting the server. Values for these settings are typically stored in the `postgresql.conf` file, or passed on the command line when starting the server. Of course, settings with any of the lower context types can also be set at server start time.

- **sighup**
  
  Changes to these settings can be made in `postgresql.conf` without restarting the server. Send a SIGHUP signal to the postmaster to cause it to re-read `postgresql.conf` and apply the changes. The postmaster will also forward the SIGHUP signal to its child processes so that they all pick up the new value.

- **superuser-backend**
  
  Changes to these settings can be made in `postgresql.conf` without restarting the server. They can also be set for a particular session in the connection request packet (for example, via libpq’s `PGOPTIONS` environment variable), but only if the connecting user is a superuser. However, these settings never change in a session after it is started. If you change them in `postgresql.conf`, send a SIGHUP signal to the postmaster to cause it to re-read `postgresql.conf`. The new values will only affect subsequently-launched sessions.

- **backend**
  
  Changes to these settings can be made in `postgresql.conf` without restarting the server. They can also be set for a particular session in the connection request packet (for example, via libpq’s `PGOPTIONS` environment variable); any user can make such a change for his session. However, these settings never change in a session after it is started. If you change them in `postgresql.conf`, send a SIGHUP signal to the postmaster to cause it to re-read `postgresql.conf`. The new values will only affect subsequently-launched sessions.

- **superuser**
  
  These settings can be set from `postgresql.conf`, or within a session via the `SET` command; but only superusers can change them via `SET`. Changes in `postgresql.conf` will affect existing sessions only if no session-local value has been established with `SET`.  

---

1963
user

These settings can be set from `postgresql.conf`, or within a session via the `SET` command. Any user is allowed to change his session-local value. Changes in `postgresql.conf` will affect existing sessions only if no session-local value has been established with `SET`.

See Section 18.1 for more information about the various ways to change these parameters.

The `pg_settings` view cannot be inserted into or deleted from, but it can be updated. An `UPDATE` applied to a row of `pg_settings` is equivalent to executing the `SET` command on that named parameter. The change only affects the value used by the current session. If an `UPDATE` is issued within a transaction that is later aborted, the effects of the `UPDATE` command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another `UPDATE` or `SET`.

### 49.74. `pg_shadow`

The view `pg_shadow` exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows properties of all roles that are marked as `rolcanlogin` in `pg_authid`.

The name stems from the fact that this table should not be readable by the public since it contains passwords. `pg_user` is a publicly readable view on `pg_shadow` that blanks out the password field.

#### Table 49-75. `pg_shadow` Columns

<table>
<thead>
<tr>

<td>-------------------------------------------------------</td>
</tr>
<tr>
<td>useconfig</td>
<td>text[]</td>
<td></td>
<td>Session defaults for run-time configuration variables</td>
</tr>
</tbody>
</table>

### 49.75. pg_stats

The view `pg_stats` provides access to the information stored in the `pg_statistic` catalog. This view allows access only to rows of `pg_statistic` that correspond to tables the user has permission to read, and therefore it is safe to allow public read access to this view.

`pg_stats` is also designed to present the information in a more readable format than the underlying catalog — at the cost that its schema must be extended whenever new slot types are defined for `pg_statistic`.

#### Table 49-76. pg_stats Columns

<table>

<td>-------------</td>
<td>------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>histogram_bounds</td>
<td>anyarray</td>
<td></td>
<td>A list of values that divide the column’s values into groups of approximately equal population. The values in most_common_vals, if present, are omitted from this histogram calculation. (This column is null if the column data type does not have a &lt; operator or if the most_common_vals list accounts for the entire population.)</td>
</tr>
<tr>
<td>correlation</td>
<td>real</td>
<td></td>
<td>Statistical correlation between physical row ordering and logical ordering of the column values. This ranges from -1 to +1. When the value is near -1 or +1, an index scan on the column will be estimated to be cheaper than when it is near zero, due to reduction of random access to the disk. (This column is null if the column data type does not have a &lt; operator.)</td>
</tr>
<tr>
<td>most_common elems</td>
<td>anyarray</td>
<td></td>
<td>A list of non-null element values most often appearing within values of the column. (Null for scalar types.)</td>
</tr>
</tbody>
</table>
### Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>most_common_elem_freqs</td>
<td>real[]</td>
<td></td>
<td>A list of the frequencies of the most common element values, i.e., the fraction of rows containing at least one instance of the given value. Two or three additional values follow the per-element frequencies; these are the minimum and maximum of the preceding per-element frequencies, and optionally the frequency of null elements. (Null when <code>most_common_elems</code> is.)</td>
</tr>
<tr>
<td>elem_count_histogram</td>
<td>real[]</td>
<td></td>
<td>A histogram of the counts of distinct non-null element values within the values of the column, followed by the average number of distinct non-null elements. (Null for scalar types.)</td>
</tr>
</tbody>
</table>

The maximum number of entries in the array fields can be controlled on a column-by-column basis using the `ALTER TABLE SET STATISTICS` command, or globally by setting the `default_statistics_target` run-time parameter.

### 49.76. pg_tables

The view `pg_tables` provides access to useful information about each table in the database.

#### Table 49-77. pg_tables Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td>pg_namespace.nspname</td>
<td>Name of schema containing table</td>
</tr>
<tr>

<td>name</td>
<td>pg_class.relname</td>
<td>Name of table</td>
</tr>
<tr>
<td>tableowner</td>
<td>name</td>
<td>pg_authid.rolname</td>
<td>Name of table’s owner</td>
</tr>
<tr>
<td>tablespace</td>
<td>name</td>
<td>pg_tablespace.spcname</td>
<td>Name of tablespace containing table (null if default for database)</td>
</tr>
</tbody>
</table>
49.77. `pg_timezone_abbrevs`

The view `pg_timezone_abbrevs` provides a list of time zone abbreviations that are currently recognized by the datetime input routines. The contents of this view change when the timezone_abbreviations run-time parameter is modified.

**Table 49-78. `pg_timezone_abbrevs` Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>abbrev</td>
<td>text</td>
<td>Time zone abbreviation</td>
</tr>
<tr>
<td>utc_offset</td>
<td>interval</td>
<td>Offset from UTC (positive means east of Greenwich)</td>
</tr>
<tr>
<td>is_dst</td>
<td>boolean</td>
<td>True if this is a daylight-savings abbreviation</td>
</tr>
</tbody>
</table>

While most timezone abbreviations represent fixed offsets from UTC, there are some that have historically varied in value (see Section B.3 for more information). In such cases this view presents their current meaning.

49.78. `pg_timezone_names`

The view `pg_timezone_names` provides a list of time zone names that are recognized by `SET TIMEZONE`, along with their associated abbreviations, UTC offsets, and daylight-savings status. (Technically, PostgreSQL uses UT1 rather than UTC because leap seconds are not handled.) Unlike the abbreviations shown in `pg_timezone_abbrevs`, many of these names imply a set of daylight-savings transition date rules. Therefore, the associated information changes across local DST boundaries. The displayed information is computed based on the current value of `CURRENT_TIMESTAMP`.

**Table 49-79. `pg_timezone_names` Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
<td>Time zone name</td>
</tr>
<tr>
<td>abbrev</td>
<td>text</td>
<td>Time zone abbreviation</td>
</tr>
<tr>
<td>utc_offset</td>
<td>interval</td>
<td>Offset from UTC (positive means east of Greenwich)</td>
</tr>
</tbody>
</table>
49.79. **pg_user**

The view `pg_user` provides access to information about database users. This is simply a publicly readable view of `pg_shadow` that blanks out the password field.

### Table 49-80. pg_user Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>usename</td>
<td>name</td>
<td>User name</td>
</tr>
<tr>
<td>usesysid</td>
<td>oid</td>
<td>ID of this user</td>
</tr>
<tr>
<td>usecreatedb</td>
<td>bool</td>
<td>User can create databases</td>
</tr>
<tr>
<td>usesuper</td>
<td>bool</td>
<td>User is a superuser</td>
</tr>
<tr>
<td>userrepl</td>
<td>bool</td>
<td>User can initiate streaming replication and put the system in and out of backup mode.</td>
</tr>
<tr>
<td>usebypassrls</td>
<td>bool</td>
<td>User bypasses every row level security policy, see Section 5.7 for more information.</td>
</tr>
<tr>
<td>passwd</td>
<td>text</td>
<td>Not the password (always reads as *********)</td>
</tr>
<tr>
<td>valuntil</td>
<td>abstime</td>
<td>Password expiry time (only used for password authentication)</td>
</tr>
<tr>
<td>useconfig</td>
<td>text[]</td>
<td>Session defaults for run-time configuration variables</td>
</tr>
</tbody>
</table>

49.80. **pg_user_mappings**

The view `pg_user_mappings` provides access to information about user mappings. This is essentially a publicly readable view of `pg_user_mapping` that leaves out the options field if the user has no rights to use it.

### Table 49-81. pg_user_mappings Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>umid</td>
<td>oid</td>
<td><code>pg_user_mapping.oid</code></td>
<td>OID of the user mapping</td>
</tr>
<tr>
<td>srvid</td>
<td>oid</td>
<td><code>pg_foreign_server.oid</code></td>
<td>The OID of the foreign server that contains this mapping</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

### Table 49-81. pg_foreign_server Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>srvname</td>
<td>name</td>
<td>pg_foreign_server.srvname</td>
<td>Name of the foreign server</td>
</tr>
<tr>
<td>umuser</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>OID of the local role being mapped, 0 if the user mapping is public</td>
</tr>
<tr>
<td>username</td>
<td>name</td>
<td></td>
<td>Name of the local user to be mapped</td>
</tr>
<tr>
<td>umoptions</td>
<td>text[]</td>
<td></td>
<td>User mapping specific options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

To protect password information stored as a user mapping option, the `umoptions` column will read as null unless one of the following applies:

- current user is the user being mapped, and owns the server or holds USAGE privilege on it
- current user is the server owner and mapping is for PUBLIC
- current user is a superuser

### 49.81. pg_views

The view `pg_views` provides access to useful information about each view in the database.

#### Table 49-82. pg_views Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>

<td>View definition (a reconstructed SELECT query)</td>
</tr>
</tbody>
</table>

1971
Chapter 50. Frontend/Backend Protocol

PostgreSQL uses a message-based protocol for communication between frontends and backends (clients and servers). The protocol is supported over TCP/IP and also over Unix-domain sockets. Port number 5432 has been registered with IANA as the customary TCP port number for servers supporting this protocol, but in practice any non-privileged port number can be used.

This document describes version 3.0 of the protocol, implemented in PostgreSQL 7.4 and later. For descriptions of the earlier protocol versions, see previous releases of the PostgreSQL documentation. A single server can support multiple protocol versions. The initial startup-request message tells the server which protocol version the client is attempting to use. If the major version requested by the client is not supported by the server, the connection will be rejected (for example, this would occur if the client requested protocol version 4.0, which does not exist as of this writing). If the minor version requested by the client is not supported by the server (e.g. the client requests version 3.1, but the server supports only 3.0), the server may either reject the connection or may respond with a NegotiateProtocolVersion message containing the highest minor protocol version which it supports. The client may then choose either to continue with the connection using the specified protocol version or to abort the connection.

In order to serve multiple clients efficiently, the server launches a new “backend” process for each client. In the current implementation, a new child process is created immediately after an incoming connection is detected. This is transparent to the protocol, however. For purposes of the protocol, the terms “backend” and “server” are interchangeable; likewise “frontend” and “client” are interchangeable.

50.1. Overview

The protocol has separate phases for startup and normal operation. In the startup phase, the frontend opens a connection to the server and authenticates itself to the satisfaction of the server. (This might involve a single message, or multiple messages depending on the authentication method being used.) If all goes well, the server then sends status information to the frontend, and finally enters normal operation. Except for the initial startup-request message, this part of the protocol is driven by the server.

During normal operation, the frontend sends queries and other commands to the backend, and the backend sends back query results and other responses. There are a few cases (such as NOTIFY) wherein the backend will send unsolicited messages, but for the most part this portion of a session is driven by frontend requests.

Termination of the session is normally by frontend choice, but can be forced by the backend in certain cases. In any case, when the backend closes the connection, it will roll back any open (incomplete) transaction before exiting.

Within normal operation, SQL commands can be executed through either of two sub-protocols. In the “simple query” protocol, the frontend just sends a textual query string, which is parsed and immediately executed by the backend. In the “extended query” protocol, processing of queries is separated into multiple steps: parsing, binding of parameter values, and execution. This offers flexibility and performance benefits, at the cost of extra complexity.

Normal operation has additional sub-protocols for special operations such as COPY.
50.1.1. Messaging Overview

All communication is through a stream of messages. The first byte of a message identifies the message type, and the next four bytes specify the length of the rest of the message (this length count includes itself, but not the message-type byte). The remaining contents of the message are determined by the message type. For historical reasons, the very first message sent by the client (the startup message) has no initial message-type byte.

To avoid losing synchronization with the message stream, both servers and clients typically read an entire message into a buffer (using the byte count) before attempting to process its contents. This allows easy recovery if an error is detected while processing the contents. In extreme situations (such as not having enough memory to buffer the message), the receiver can use the byte count to determine how much input to skip before it resumes reading messages.

Conversely, both servers and clients must take care never to send an incomplete message. This is commonly done by marshaling the entire message in a buffer before beginning to send it. If a communications failure occurs partway through sending or receiving a message, the only sensible response is to abandon the connection, since there is little hope of recovering message-boundary synchronization.

50.1.2. Extended Query Overview

In the extended-query protocol, execution of SQL commands is divided into multiple steps. The state retained between steps is represented by two types of objects: prepared statements and portals. A prepared statement represents the result of parsing and semantic analysis of a textual query string. A prepared statement is not in itself ready to execute, because it might lack specific values for parameters. A portal represents a ready-to-execute or already-partially-executed statement, with any missing parameter values filled in. (For SELECT statements, a portal is equivalent to an open cursor, but we choose to use a different term since cursors don’t handle non-SELECT statements.)

The overall execution cycle consists of a parse step, which creates a prepared statement from a textual query string; a bind step, which creates a portal given a prepared statement and values for any needed parameters; and an execute step that runs a portal’s query. In the case of a query that returns rows (SELECT, SHOW, etc), the execute step can be told to fetch only a limited number of rows, so that multiple execute steps might be needed to complete the operation.

The backend can keep track of multiple prepared statements and portals (but note that these exist only within a session, and are never shared across sessions). Existing prepared statements and portals are referenced by names assigned when they were created. In addition, an “unnamed” prepared statement and portal exist. Although these behave largely the same as named objects, operations on them are optimized for the case of executing a query only once and then discarding it, whereas operations on named objects are optimized on the expectation of multiple uses.

50.1.3. Formats and Format Codes

Data of a particular data type might be transmitted in any of several different formats. As of PostgreSQL 7.4 the only supported formats are “text” and “binary”, but the protocol makes provision for future extensions. The desired format for any value is specified by a format code. Clients can specify a format code for each transmitted parameter value and for each column of a query result. Text has format code zero, binary has format code one, and all other format codes are reserved for future definition.

The text representation of values is whatever strings are produced and accepted by the input/output conversion functions for the particular data type. In the transmitted representation, there is no trailing
null character; the frontend must add one to received values if it wants to process them as C strings. (The text format does not allow embedded nulls, by the way.)

Binary representations for integers use network byte order (most significant byte first). For other data types consult the documentation or source code to learn about the binary representation. Keep in mind that binary representations for complex data types might change across server versions; the text format is usually the more portable choice.

50.2. Message Flow

This section describes the message flow and the semantics of each message type. (Details of the exact representation of each message appear in Section 50.5.) There are several different sub-protocols depending on the state of the connection: start-up, query, function call, \texttt{COPY}, and termination. There are also special provisions for asynchronous operations (including notification responses and command cancellation), which can occur at any time after the start-up phase.

50.2.1. Start-up

To begin a session, a frontend opens a connection to the server and sends a startup message. This message includes the names of the user and of the database the user wants to connect to; it also identifies the particular protocol version to be used. (Optionally, the startup message can include additional settings for run-time parameters.) The server then uses this information and the contents of its configuration files (such as \texttt{pg\_hba.conf}) to determine whether the connection is provisionally acceptable, and what additional authentication is required (if any).

The server then sends an appropriate authentication request message, to which the frontend must reply with an appropriate authentication response message (such as a password). For all authentication methods except GSSAPI and SSPI, there is at most one request and one response. In some methods, no response at all is needed from the frontend, and so no authentication request occurs. For GSSAPI and SSPI, multiple exchanges of packets may be needed to complete the authentication.

The authentication cycle ends with the server either rejecting the connection attempt (ErrorResponse), or sending AuthenticationOk.

The possible messages from the server in this phase are:

- **ErrorResponse**
  The connection attempt has been rejected. The server then immediately closes the connection.

- **AuthenticationOk**
  The authentication exchange is successfully completed.

- **AuthenticationKerberosV5**
  The frontend must now take part in a Kerberos V5 authentication dialog (not described here, part of the Kerberos specification) with the server. If this is successful, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. This is no longer supported.

- **AuthenticationCleartextPassword**
  The frontend must now send a PasswordMessage containing the password in clear-text form. If this is the correct password, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse.
Chapter 50. Frontend/Backend Protocol

AuthenticationMD5Password

The frontend must now send a PasswordMessage containing the password (with user name) encrypted via MD5, then encrypted again using the 4-byte random salt specified in the AuthenticationMD5Password message. If this is the correct password, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. The actual PasswordMessage can be computed in SQL as `concat('md5', md5(concat(md5(concat(password, username)), random-salt)))`. (Keep in mind the `md5()` function returns its result as a hex string.)

AuthenticationSCMCredential

This response is only possible for local Unix-domain connections on platforms that support SCM credential messages. The frontend must issue an SCM credential message and then send a single data byte. (The contents of the data byte are uninteresting; it’s only used to ensure that the server waits long enough to receive the credential message.) If the credential is acceptable, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. (This message type is only issued by pre-9.1 servers. It may eventually be removed from the protocol specification.)

AuthenticationGSS

The frontend must now initiate a GSSAPI negotiation. The frontend will send a PasswordMessage with the first part of the GSSAPI data stream in response to this. If further messages are needed, the server will respond with AuthenticationGSSContinue.

AuthenticationSSPI

The frontend must now initiate a SSPI negotiation. The frontend will send a PasswordMessage with the first part of the SSPI data stream in response to this. If further messages are needed, the server will respond with AuthenticationGSSContinue.

AuthenticationGSSContinue

This message contains the response data from the previous step of GSSAPI or SSPI negotiation (AuthenticationGSS, AuthenticationSSPI or a previous AuthenticationGSSContinue). If the GSSAPI or SSPI data in this message indicates more data is needed to complete the authentication, the frontend must send that data as another PasswordMessage. If GSSAPI or SSPI authentication is completed by this message, the server will next send AuthenticationOk to indicate successful authentication or ErrorResponse to indicate failure.

NegotiateProtocolVersion

The server does not support the minor protocol version requested by the client, but does support an earlier version of the protocol; this message indicates the highest supported minor version. This message will also be sent if the client requested unsupported protocol options (i.e. beginning with `_pq_`) in the startup packet. This message will be followed by an ErrorResponse or a message indicating the success or failure of authentication.

If the frontend does not support the authentication method requested by the server, then it should immediately close the connection.

After having received AuthenticationOk, the frontend must wait for further messages from the server. In this phase a backend process is being started, and the frontend is just an interested bystander. It is still possible for the startup attempt to fail (ErrorResponse) or the server to decline support for the requested minor protocol version (NegotiateProtocolVersion), but in the normal case the backend will send some ParameterStatus messages, BackendKeyData, and finally ReadyForQuery.
During this phase the backend will attempt to apply any additional run-time parameter settings that were given in the startup message. If successful, these values become session defaults. An error causes ErrorResponse and exit.

The possible messages from the backend in this phase are:

**BackendKeyData**

This message provides secret-key data that the frontend must save if it wants to be able to issue cancel requests later. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

**ParameterStatus**

This message informs the frontend about the current (initial) setting of backend parameters, such as client_encoding or DateStyle. The frontend can ignore this message, or record the settings for its future use; see Section 50.2.6 for more details. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

**ReadyForQuery**

Start-up is completed. The frontend can now issue commands.

**ErrorResponse**

Start-up failed. The connection is closed after sending this message.

**NoticeResponse**

A warning message has been issued. The frontend should display the message but continue listening for ReadyForQuery or ErrorResponse.

The ReadyForQuery message is the same one that the backend will issue after each command cycle. Depending on the coding needs of the frontend, it is reasonable to consider ReadyForQuery as starting a command cycle, or to consider ReadyForQuery as ending the start-up phase and each subsequent command cycle.

### 50.2.2. Simple Query

A simple query cycle is initiated by the frontend sending a Query message to the backend. The message includes an SQL command (or commands) expressed as a text string. The backend then sends one or more response messages depending on the contents of the query command string, and finally a ReadyForQuery response message. ReadyForQuery informs the frontend that it can safely send a new command. (It is not actually necessary for the frontend to wait for ReadyForQuery before issuing another command, but the frontend must then take responsibility for figuring out what happens if the earlier command fails and already-issued later commands succeed.)

The possible response messages from the backend are:

**CommandComplete**

An SQL command completed normally.

**CopyInResponse**

The backend is ready to copy data from the frontend to a table; see Section 50.2.5.

**CopyOutResponse**

The backend is ready to copy data from a table to the frontend; see Section 50.2.5.
Chapter 50. Frontend/Backend Protocol

RowDescription
Indicates that rows are about to be returned in response to a SELECT, FETCH, etc query. The contents of this message describe the column layout of the rows. This will be followed by a DataRow message for each row being returned to the frontend.

DataRow
One of the set of rows returned by a SELECT, FETCH, etc query.

EmptyQueryResponse
An empty query string was recognized.

ErrorResponse
An error has occurred.

ReadyForQuery
Processing of the query string is complete. A separate message is sent to indicate this because the query string might contain multiple SQL commands. (CommandComplete marks the end of processing one SQL command, not the whole string.) ReadyForQuery will always be sent, whether processing terminates successfully or with an error.

NoticeResponse
A warning message has been issued in relation to the query. Notices are in addition to other responses, i.e., the backend will continue processing the command.

The response to a SELECT query (or other queries that return row sets, such as EXPLAIN or SHOW) normally consists of RowDescription, zero or more DataRow messages, and then CommandComplete. COPY to or from the frontend invokes special protocol as described in Section 50.2.5. All other query types normally produce only a CommandComplete message.

Since a query string could contain several queries (separated by semicolons), there might be several such response sequences before the backend finishes processing the query string. ReadyForQuery is issued when the entire string has been processed and the backend is ready to accept a new query string.

If a completely empty (no contents other than whitespace) query string is received, the response is EmptyQueryResponse followed by ReadyForQuery.

In the event of an error, ErrorResponse is issued followed by ReadyForQuery. All further processing of the query string is aborted by ErrorResponse (even if more queries remained in it). Note that this might occur partway through the sequence of messages generated by an individual query.

In simple Query mode, the format of retrieved values is always text, except when the given command is a FETCH from a cursor declared with the BINARY option. In that case, the retrieved values are in binary format. The format codes given in the RowDescription message tell which format is being used.

A frontend must be prepared to accept ErrorResponse and NoticeResponse messages whenever it is expecting any other type of message. See also Section 50.2.6 concerning messages that the backend might generate due to outside events.

Recommended practice is to code frontends in a state-machine style that will accept any message type at any time that it could make sense, rather than wiring in assumptions about the exact sequence of messages.
50.2.3. Extended Query

The extended query protocol breaks down the above-described simple query protocol into multiple steps. The results of preparatory steps can be re-used multiple times for improved efficiency. Furthermore, additional features are available, such as the possibility of supplying data values as separate parameters instead of having to insert them directly into a query string.

In the extended protocol, the frontend first sends a Parse message, which contains a textual query string, optionally some information about data types of parameter placeholders, and the name of a destination prepared-statement object (an empty string selects the unnamed prepared statement). The response is either ParseComplete or ErrorResponse. Parameter data types can be specified by OID; if not given, the parser attempts to infer the data types in the same way as it would do for untyped literal string constants.

Note: A parameter data type can be left unspecified by setting it to zero, or by making the array of parameter type OIDs shorter than the number of parameter symbols \( n \) used in the query string. Another special case is that a parameter's type can be specified as \texttt{void} (that is, the OID of the \texttt{void} pseudotype). This is meant to allow parameter symbols to be used for function parameters that are actually OUT parameters. Ordinarily there is no context in which a \texttt{void} parameter could be used, but if such a parameter symbol appears in a function's parameter list, it is effectively ignored. For example, a function call such as \texttt{foo($1,$2,$3,$4)} could match a function with two IN and two OUT arguments, if \$3 and \$4 are specified as having type \texttt{void}.

Note: The query string contained in a Parse message cannot include more than one SQL statement; else a syntax error is reported. This restriction does not exist in the simple-query protocol, but it does exist in the extended protocol, because allowing prepared statements or portals to contain multiple commands would complicate the protocol unduly.

If successfully created, a named prepared-statement object lasts till the end of the current session, unless explicitly destroyed. An unnamed prepared statement lasts only until the next Parse statement specifying the unnamed statement as destination is issued. (Note that a simple Query message also destroys the unnamed statement.) Named prepared statements must be explicitly closed before they can be redefined by another Parse message, but this is not required for the unnamed statement. Named prepared statements can also be created and accessed at the SQL command level, using \texttt{PREPARE} and \texttt{EXECUTE}.

Once a prepared statement exists, it can be readied for execution using a Bind message. The Bind message gives the name of the source prepared statement (empty string denotes the unnamed prepared statement), the name of the destination portal (empty string denotes the unnamed portal), and the values to use for any parameter placeholders present in the prepared statement. The supplied parameter set must match those needed by the prepared statement. (If you declared any \texttt{void} parameters in the Parse message, pass NULL values for them in the Bind message.) Bind also specifies the format to use for any data returned by the query; the format can be specified overall, or per-column. The response is either BindComplete or ErrorResponse.

Note: The choice between text and binary output is determined by the format codes given in Bind, regardless of the SQL command involved. The \texttt{BINARY} attribute in cursor declarations is irrelevant when using extended query protocol.
Query planning typically occurs when the Bind message is processed. If the prepared statement has no parameters, or is executed repeatedly, the server might save the created plan and re-use it during subsequent Bind messages for the same prepared statement. However, it will do so only if it finds that a generic plan can be created that is not much less efficient than a plan that depends on the specific parameter values supplied. This happens transparently so far as the protocol is concerned.

If successfully created, a named portal object lasts till the end of the current transaction, unless explicitly destroyed. An unnamed portal is destroyed at the end of the transaction, or as soon as the next Bind statement specifying the unnamed portal as destination is issued. (Note that a simple Query message also destroys the unnamed portal.) Named portals must be explicitly closed before they can be redefined by another Bind message, but this is not required for the unnamed portal. Named portals can also be created and accessed at the SQL command level, using DECLARE CURSOR and FETCH.

Once a portal exists, it can be executed using an Execute message. The Execute message specifies the portal name (empty string denotes the unnamed portal) and a maximum result-row count (zero meaning “fetch all rows”). The result-row count is only meaningful for portals containing commands that return row sets; in other cases the command is always executed to completion, and the row count is ignored. The possible responses to Execute are the same as those described above for queries issued via simple query protocol, except that Execute doesn’t cause ReadyForQuery or RowDescription to be issued.

If Execute terminates before completing the execution of a portal (due to reaching a nonzero result-row count), it will send a PortalSuspended message; the appearance of this message tells the frontend that another Execute should be issued against the same portal to complete the operation. The CommandComplete message indicating completion of the source SQL command is not sent until the portal’s execution is completed. Therefore, an Execute phase is always terminated by the appearance of exactly one of these messages: CommandComplete, EmptyQueryResponse (if the portal was created from an empty query string), ErrorResponse, or PortalSuspended.

At completion of each series of extended-query messages, the frontend should issue a Sync message. This parameterless message causes the backend to close the current transaction if it’s not inside a BEGIN/COMMIT transaction block (“close” meaning to commit if no error, or roll back if error). Then a ReadyForQuery response is issued. The purpose of Sync is to provide a resynchronization point for error recovery. When an error is detected while processing any extended-query message, the backend issues ErrorResponse, then reads and discards messages until a Sync is reached, then issues ReadyForQuery and returns to normal message processing. (But note that no skipping occurs if an error is detected while processing Sync — this ensures that there is one and only one ReadyForQuery sent for each Sync.)

Note: Sync does not cause a transaction block opened with BEGIN to be closed. It is possible to detect this situation since the ReadyForQuery message includes transaction status information.

In addition to these fundamental, required operations, there are several optional operations that can be used with extended-query protocol.

The Describe message (portal variant) specifies the name of an existing portal (or an empty string for the unnamed portal). The response is a RowDescription message describing the rows that will be returned by executing the portal; or a NoData message if the portal does not contain a query that will return rows; or ErrorResponse if there is no such portal.

The Describe message (statement variant) specifies the name of an existing prepared statement (or an empty string for the unnamed prepared statement). The response is a ParameterDescription message describing the parameters needed by the statement, followed by a RowDescription message describing the rows that will be returned when the statement is eventually executed (or a NoData message if the
statement will not return rows). ErrorResponse is issued if there is no such prepared statement. Note that since Bind has not yet been issued, the formats to be used for returned columns are not yet known to the backend; the format code fields in the RowDescription message will be zeroes in this case.

**Tip:** In most scenarios the frontend should issue one or the other variant of Describe before issuing Execute, to ensure that it knows how to interpret the results it will get back.

The Close message closes an existing prepared statement or portal and releases resources. It is not an error to issue Close against a nonexistent statement or portal name. The response is normally CloseComplete, but could be ErrorResponse if some difficulty is encountered while releasing resources. Note that closing a prepared statement implicitly closes any open portals that were constructed from that statement.

The Flush message does not cause any specific output to be generated, but forces the backend to deliver any data pending in its output buffers. A Flush must be sent after any extended-query command except Sync, if the frontend wishes to examine the results of that command before issuing more commands. Without Flush, messages returned by the backend will be combined into the minimum possible number of packets to minimize network overhead.

**Note:** The simple Query message is approximately equivalent to the series Parse, Bind, portal Describe, Execute, Close, Sync, using the unnamed prepared statement and portal objects and no parameters. One difference is that it will accept multiple SQL statements in the query string, automatically performing the bind/describe/execute sequence for each one in succession. Another difference is that it will not return ParseComplete, BindComplete, CloseComplete, or NoData messages.

### 50.2.4. Function Call

The Function Call sub-protocol allows the client to request a direct call of any function that exists in the database’s `pg_proc` system catalog. The client must have execute permission for the function.

**Note:** The Function Call sub-protocol is a legacy feature that is probably best avoided in new code. Similar results can be accomplished by setting up a prepared statement that does `SELECT function($1, ...)`. The Function Call cycle can then be replaced with Bind/Execute.

A Function Call cycle is initiated by the frontend sending a FunctionCall message to the backend. The backend then sends one or more response messages depending on the results of the function call, and finally a ReadyForQuery response message. ReadyForQuery informs the frontend that it can safely send a new query or function call.

The possible response messages from the backend are:

- **ErrorResponse**
  - An error has occurred.

- **FunctionCallResponse**
  - The function call was completed and returned the result given in the message. (Note that the Function Call protocol can only handle a single scalar result, not a row type or set of results.)
ReadyForQuery

Processing of the function call is complete. ReadyForQuery will always be sent, whether processing terminates successfully or with an error.

NoticeResponse

A warning message has been issued in relation to the function call. Notices are in addition to other responses, i.e., the backend will continue processing the command.

50.2.5. COPY Operations

The `COPY` command allows high-speed bulk data transfer to or from the server. Copy-in and copy-out operations each switch the connection into a distinct sub-protocol, which lasts until the operation is completed.

Copy-in mode (data transfer to the server) is initiated when the backend executes a `COPY FROM STDIN` SQL statement. The backend sends a CopyInResponse message to the frontend. The frontend should then send zero or more CopyData messages, forming a stream of input data. (The message boundaries are not required to have anything to do with row boundaries, although that is often a reasonable choice.) The frontend can terminate the copy-in mode by sending either a CopyDone message (allowing successful termination) or a CopyFail message (which will cause the `COPY` SQL statement to fail with an error). The backend then reverts to the command-processing mode it was in before the `COPY` started, which will be either simple or extended query protocol. It will next send either CommandComplete (if successful) or ErrorResponse (if not).

In the event of a backend-detected error during copy-in mode (including receipt of a CopyFail message), the backend will issue an ErrorResponse message. If the `COPY` command was issued via an extended-query message, the backend will now discard frontend messages until a Sync message is received, then it will issue ReadyForQuery and return to normal processing. If the `COPY` command was issued in a simple Query message, the rest of that message is discarded and ReadyForQuery is issued. In either case, any subsequent CopyData, CopyDone, or CopyFail messages issued by the frontend will simply be dropped.

The backend will ignore Flush and Sync messages received during copy-in mode. Receipt of any other non-copy message type constitutes an error that will abort the copy-in state as described above. (The exception for Flush and Sync is for the convenience of client libraries that always send Flush or Sync after an Execute message, without checking whether the command to be executed is a `COPY FROM STDIN`.)

Copy-out mode (data transfer from the server) is initiated when the backend executes a `COPY TO STDOUT` SQL statement. The backend sends a CopyOutResponse message to the frontend, followed by zero or more CopyData messages (always one per row), followed by CopyDone. The backend then reverts to the command-processing mode it was in before the `COPY` started, and sends CommandComplete. The frontend cannot abort the transfer (except by closing the connection or issuing a Cancel request), but it can discard unwanted CopyData and CopyDone messages.

In the event of a backend-detected error during copy-out mode, the backend will issue an ErrorResponse message and revert to normal processing. The frontend should treat receipt of ErrorResponse as terminating the copy-out mode.

It is possible for NoticeResponse and ParameterStatus messages to be interspersed between CopyData messages; frontends must handle these cases, and should be prepared for other asynchronous message types as well (see Section 50.2.6). Otherwise, any message type other than CopyData or CopyDone may be treated as terminating copy-out mode.
There is another Copy-related mode called copy-both, which allows high-speed bulk data transfer to and from the server. Copy-both mode is initiated when a backend in walsender mode executes a `START_REPLICATION` statement. The backend sends a CopyBothResponse message to the frontend. Both the backend and the frontend may then send CopyData messages until either end sends a CopyDone message. After the client sends a CopyDone message, the connection goes from copy-both mode to copy-out mode, and the client may not send any more CopyData messages. Similarly, when the server sends a CopyDone message, the connection goes into copy-in mode, and the server may not send any more CopyData messages. After both sides have sent a CopyDone message, the copy mode is terminated, and the backend reverts to the command-processing mode. In the event of a backend-detected error during copy-both mode, the backend will issue an ErrorResponse message, discard frontend messages until a Sync message is received, and then issue ReadyForQuery and return to normal processing. The frontend should treat receipt of ErrorResponse as terminating the copy in both directions; no CopyDone should be sent in this case. See Section 50.3 for more information on the subprotocol transmitted over copy-both mode.

The CopyInResponse, CopyOutResponse and CopyBothResponse messages include fields that inform the frontend of the number of columns per row and the format codes being used for each column. (As of the present implementation, all columns in a given `COPY` operation will use the same format, but the message design does not assume this.)

## 50.2.6. Asynchronous Operations

There are several cases in which the backend will send messages that are not specifically prompted by the frontend’s command stream. Frontends must be prepared to deal with these messages at any time, even when not engaged in a query. At minimum, one should check for these cases before beginning to read a query response.

It is possible for NoticeResponse messages to be generated due to outside activity; for example, if the database administrator commands a “fast” database shutdown, the backend will send a NoticeResponse indicating this fact before closing the connection. Accordingly, frontends should always be prepared to accept and display NoticeResponse messages, even when the connection is nominally idle.

ParameterStatus messages will be generated whenever the active value changes for any of the parameters the backend believes the frontend should know about. Most commonly this occurs in response to a `SET` SQL command executed by the frontend, and this case is effectively synchronous — but it is also possible for parameter status changes to occur because the administrator changed a configuration file and then sent the SIGHUP signal to the server. Also, if a `SET` command is rolled back, an appropriate ParameterStatus message will be generated to report the current effective value.

At present there is a hard-wired set of parameters for which ParameterStatus will be generated: they are `server_version`, `server_encoding`, `client_encoding`, `application_name`, `is_superuser`, `session_authorization`, `DateStyle`, `IntervalStyle`, `TimeZone`, `integer_datetimes`, and `standard_conforming_strings`. (`server_encoding`, `TimeZone`, and `integer_datetimes` were not reported by releases before 8.0; `standard_conforming_strings` was not reported by releases before 8.1; `IntervalStyle` was not reported by releases before 8.4; `application_name` was not reported by releases before 9.0.) Note that `server_version`, `server_encoding` and `integer_datetimes` are pseudo-parameters that cannot change after startup. This set might change in the future, or even become configurable. Accordingly, a frontend should simply ignore ParameterStatus for parameters that it does not understand or care about.

If a frontend issues a `LISTEN` command, then the backend will send a NotificationResponse message (not to be confused with NoticeResponse!) whenever a `NOTIFY` command is executed for the same
channel name.

**Note:** At present, NotificationResponse can only be sent outside a transaction, and thus it will not occur in the middle of a command-response series, though it might occur just before ReadyForQuery. It is unwise to design frontend logic that assumes that, however. Good practice is to be able to accept NotificationResponse at any point in the protocol.

### 50.2.7. Canceling Requests in Progress

During the processing of a query, the frontend might request cancellation of the query. The cancel request is not sent directly on the open connection to the backend for reasons of implementation efficiency: we don’t want to have the backend constantly checking for new input from the frontend during query processing. Cancel requests should be relatively infrequent, so we make them slightly cumbersome in order to avoid a penalty in the normal case.

To issue a cancel request, the frontend opens a new connection to the server and sends a CancelRequest message, rather than the StartupMessage message that would ordinarily be sent across a new connection. The server will process this request and then close the connection. For security reasons, no direct reply is made to the cancel request message.

A CancelRequest message will be ignored unless it contains the same key data (PID and secret key) passed to the frontend during connection start-up. If the request matches the PID and secret key for a currently executing backend, the processing of the current query is aborted. (In the existing implementation, this is done by sending a special signal to the backend process that is processing the query.)

The cancellation signal might or might not have any effect — for example, if it arrives after the backend has finished processing the query, then it will have no effect. If the cancellation is effective, it results in the current command being terminated early with an error message.

The upshot of all this is that for reasons of both security and efficiency, the frontend has no direct way to tell whether a cancel request has succeeded. It must continue to wait for the backend to respond to the query. Issuing a cancel simply improves the odds that the current query will finish soon, and improves the odds that it will fail with an error message instead of succeeding.

Since the cancel request is sent across a new connection to the server and not across the regular frontend/backend communication link, it is possible for the cancel request to be issued by any process, not just the frontend whose query is to be canceled. This might provide additional flexibility when building multiple-process applications. It also introduces a security risk, in that unauthorized persons might try to cancel queries. The security risk is addressed by requiring a dynamically generated secret key to be supplied in cancel requests.

### 50.2.8. Termination

The normal, graceful termination procedure is that the frontend sends a Terminate message and immediately closes the connection. On receipt of this message, the backend closes the connection and terminates.

In rare cases (such as an administrator-commanded database shutdown) the backend might disconnect without any frontend request to do so. In such cases the backend will attempt to send an error or notice message giving the reason for the disconnection before it closes the connection.
Other termination scenarios arise from various failure cases, such as core dump at one end or the other, loss of the communications link, loss of message-boundary synchronization, etc. If either frontend or backend sees an unexpected closure of the connection, it should clean up and terminate. The frontend has the option of launching a new backend by recontacting the server if it doesn’t want to terminate itself. Closing the connection is also advisable if an unrecognizable message type is received, since this probably indicates loss of message-boundary sync.

For either normal or abnormal termination, any open transaction is rolled back, not committed. One should note however that if a frontend disconnects while a non-SELECT query is being processed, the backend will probably finish the query before noticing the disconnection. If the query is outside any transaction block (BEGIN ... COMMIT sequence) then its results might be committed before the disconnection is recognized.

### 50.2.9. SSL Session Encryption

If PostgreSQL was built with SSL support, frontend/backend communications can be encrypted using SSL. This provides communication security in environments where attackers might be able to capture the session traffic. For more information on encrypting PostgreSQL sessions with SSL, see Section 17.9.

To initiate an SSL-encrypted connection, the frontend initially sends an SSLRequest message rather than a StartupMessage. The server then responds with a single byte containing S or N, indicating that it is willing or unwilling to perform SSL, respectively. The frontend might close the connection at this point if it is dissatisfied with the response. To continue after S, perform an SSL startup handshake (not described here, part of the SSL specification) with the server. If this is successful, continue with sending the usual StartupMessage. In this case the StartupMessage and all subsequent data will be SSL-encrypted. To continue after N, send the usual StartupMessage and proceed without encryption.

The frontend should also be prepared to handle an ErrorMessage response to SSLRequest from the server. This would only occur if the server predates the addition of SSL support to PostgreSQL. (Such servers are now very ancient, and likely do not exist in the wild anymore.) In this case the connection must be closed, but the frontend might choose to open a fresh connection and proceed without requesting SSL.

An initial SSLRequest can also be used in a connection that is being opened to send a CancelRequest message.

While the protocol itself does not provide a way for the server to force SSL encryption, the administrator can configure the server to reject unencrypted sessions as a byproduct of authentication checking.

### 50.3. Streaming Replication Protocol

To initiate streaming replication, the frontend sends the replication parameter in the startup message. A Boolean value of true tells the backend to go into walsender mode, wherein a small set of replication commands can be issued instead of SQL statements. Only the simple query protocol can be used in walsender mode. Replication commands are logged in the server log when log_replication_commands is enabled. Passing database as the value instructs walsender to connect to the database specified in the dbname parameter, which will allow the connection to be used for logical replication from that database.

For the purpose of testing replication commands, you can make a replication connection via psql or any other libpq-using tool with a connection string including the replication option, e.g.:
psql "dbname=postgres replication=database" -c "IDENTIFY_SYSTEM;"

However it is often more useful to use `pg_receivexlog` (for physical replication) or `pg_recvlogical` (for logical replication).

The commands accepted in walsender mode are:

**IDENTIFY_SYSTEM**

Requests the server to identify itself. Server replies with a result set of a single row, containing four fields:

- `systemid`
  - The unique system identifier identifying the cluster. This can be used to check that the base backup used to initialize the standby came from the same cluster.

- `timeline`
  - Current TimelineID. Also useful to check that the standby is consistent with the master.

- `xlogpos`
  - Current xlog flush location. Useful to get a known location in the transaction log where streaming can start.

- `dbname`
  - Database connected to or NULL.

**TIMELINE_HISTORY** `tli`

Requests the server to send over the timeline history file for timeline `tli`. Server replies with a result set of a single row, containing two fields:

- `filename`
  - Filename of the timeline history file, e.g. `00000002.history`.

- `content`
  - Contents of the timeline history file.

**CREATE_REPLICATION_SLOT** `slot_name { PHYSICAL | LOGICAL output_plugin }`

Create a physical or logical replication slot. See Section 25.2.6 for more about replication slots.

- `slot_name`
  - The name of the slot to create. Must be a valid replication slot name (see Section 25.2.6.1).

- `output_plugin`
  - The name of the output plugin used for logical decoding (see Section 46.6).

**START_REPLICATION** `[SLOT slot_name] [PHYSICAL] XXX/XXX [TIMELINE tli]`

Instructs server to start streaming WAL, starting at WAL position `XXX/XXX`. If `TIMELINE` option is specified, streaming starts on timeline `tli`; otherwise, the server’s current timeline is selected. The server can reply with an error, e.g. if the requested section of WAL has already been recycled. On success, server responds with a CopyBothResponse message, and then starts to stream WAL to the frontend.
If a slot’s name is provided via \texttt{slot\_name}, it will be updated as replication progresses so that the server knows which WAL segments, and if \texttt{hot\_standby\_feedback} is on which transactions, are still needed by the standby.

If the client requests a timeline that’s not the latest, but is part of the history of the server, the server will stream all the WAL on that timeline starting from the requested startpoint, up to the point where the server switched to another timeline. If the client requests streaming at exactly the end of an old timeline, the server responds immediately with CommandComplete without entering COPY mode.

After streaming all the WAL on a timeline that is not the latest one, the server will end streaming by exiting the COPY mode. When the client acknowledges this by also exiting COPY mode, the server sends a result set with one row and two columns, indicating the next timeline in this server’s history. The first column is the next timeline’s ID, and the second column is the XLOG position where the switch happened. Usually, the switch position is the end of the WAL that was streamed, but there are corner cases where the server can send some WAL from the old timeline that has not itself replayed before promoting. Finally, the server sends CommandComplete message, and is ready to accept a new command.

WAL data is sent as a series of CopyData messages. (This allows other information to be intermixed; in particular the server can send an ErrorResponse message if it encounters a failure after beginning to stream.) The payload of each CopyData message from server to the client contains a message of one of the following formats:

\textbf{XLogData (B)}

\begin{itemize}
  \item Byte1(’w’)
    \hspace{1cm} Identifies the message as WAL data.
  \item Int64
    \hspace{1cm} The starting point of the WAL data in this message.
  \item Int64
    \hspace{1cm} The current end of WAL on the server.
  \item Int64
    \hspace{1cm} The server’s system clock at the time of transmission, as microseconds since midnight on 2000-01-01.
  \item Byte
    \hspace{1cm} A section of the WAL data stream.
\end{itemize}

A single WAL record is never split across two XLogData messages. When a WAL record crosses a WAL page boundary, and is therefore already split using continuation records, it can be split at the page boundary. In other words, the first main WAL record and its continuation records can be sent in different XLogData messages.

\textbf{Primary keepalive message (B)}

\begin{itemize}
  \item Byte1(’k’)
    \hspace{1cm} Identifies the message as a sender keepalive.
\end{itemize}
Int64

The current end of WAL on the server.

Int64

The server’s system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte1

1 means that the client should reply to this message as soon as possible, to avoid a timeout disconnect. 0 otherwise.

The receiving process can send replies back to the sender at any time, using one of the following message formats (also in the payload of a CopyData message):

Standby status update (F)

Byte1('r')

Identifies the message as a receiver status update.

Int64

The location of the last WAL byte + 1 received and written to disk in the standby.

Int64

The location of the last WAL byte + 1 flushed to disk in the standby.

Int64

The location of the last WAL byte + 1 applied in the standby.

Int64

The client’s system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte1

If 1, the client requests the server to reply to this message immediately. This can be used to ping the server, to test if the connection is still healthy.

Hot Standby feedback message (F)

Byte1('h')

Identifies the message as a Hot Standby feedback message.

Int64

The client’s system clock at the time of transmission, as microseconds since midnight on 2000-01-01.
Int32
The standby’s current xmin. This may be 0, if the standby is sending notification that
Hot Standby feedback will no longer be sent on this connection. Later non-zero mes-
sages may reinitiate the feedback mechanism.

Int32
The standby’s current epoch.

START_REPLICATION SLOT slot_name LOGICAL XXX/XXX [(option_name [option_value] [
[, ... ])]
Instructs server to start streaming WAL for logical replication, starting at WAL position
XXX/XXX. The server can reply with an error, e.g. if the requested section of WAL has already
been recycled. On success, server responds with a CopyBothResponse message, and then starts
to stream WAL to the frontend.

The messages inside the CopyBothResponse messages are of the same format documented for
START_REPLICATION ... PHYSICAL.

The output plugin associated with the selected slot is used to process the output for streaming.

SLOT slot_name
The name of the slot to stream changes from. This parameter is required, and must corre-
spond to an existing logical replication slot created with CREATE_REPLICATION_SLOT in
LOGICAL mode.

XXX/XXX
The WAL position to begin streaming at.

option_name
The name of an option passed to the slot’s logical decoding plugin.

option_value
Optional value, in the form of a string constant, associated with the specified option.

DROP_REPLICATION_SLOT slot_name
Drops a replication slot, freeing any reserved server-side resources. If the slot is currently in use
by an active connection, this command fails.

slot_name
The name of the slot to drop.

BASE_BACKUP [LABEL ‘label’] [PROGRESS] [FAST] [WAL] [NOWAIT] [MAX_RATE rate]
[TABLESPACE_MAP]
Instructs the server to start streaming a base backup. The system will automatically be put in
backup mode before the backup is started, and taken out of it when the backup is complete. The
following options are accepted:

LABEL ‘label’
Sets the label of the backup. If none is specified, a backup label of base backup will
be used. The quoting rules for the label are the same as a standard SQL string with stan-
dard_conforming_strings turned on.
Chapter 50. Frontend/Backend Protocol

PROGRESS

Request information required to generate a progress report. This will send back an approximate size in the header of each tablespace, which can be used to calculate how far along the stream is done. This is calculated by enumerating all the file sizes once before the transfer is even started, and may as such have a negative impact on the performance - in particular it may take longer before the first data is streamed. Since the database files can change during the backup, the size is only approximate and may both grow and shrink between the time of approximation and the sending of the actual files.

FAST

Request a fast checkpoint.

WAL

Include the necessary WAL segments in the backup. This will include all the files between start and stop backup in the pg_xlog directory of the base directory tar file.

NOWAIT

By default, the backup will wait until the last required xlog segment has been archived, or emit a warning if log archiving is not enabled. Specifying NOWAIT disables both the waiting and the warning, leaving the client responsible for ensuring the required log is available.

MAX_RATE rate

Limit (throttle) the maximum amount of data transferred from server to client per unit of time. The expected unit is kilobytes per second. If this option is specified, the value must either be equal to zero or it must fall within the range from 32 kB through 1 GB (inclusive). If zero is passed or the option is not specified, no restriction is imposed on the transfer.

TABLESPACE_MAP

Include information about symbolic links present in the directory pg_tblspc in a file named tablespace_map. The tablespace map file includes each symbolic link name as it exists in the directory pg_tblspc/ and the full path of that symbolic link.

When the backup is started, the server will first send two ordinary result sets, followed by one or more CopyResponse results.

The first ordinary result set contains the starting position of the backup, in a single row with two columns. The first column contains the start position given in XLogRecPtr format, and the second column contains the corresponding timeline ID.

The second ordinary result set has one row for each tablespace. The fields in this row are:

spcoid

The oid of the tablespace, or NULL if it’s the base directory.

spclocation

The full path of the tablespace directory, or NULL if it’s the base directory.

size

The approximate size of the tablespace, if progress report has been requested; otherwise it’s NULL.
Chapter 50. Frontend/Backend Protocol

After the second regular result set, one or more CopyResponse results will be sent, one for PGDATA and one for each additional tablespace other than pg_default and pg_global. The data in the CopyResponse results will be a tar format (following the “ustar interchange format” specified in the POSIX 1003.1-2008 standard) dump of the tablespace contents, except that the two trailing blocks of zeroes specified in the standard are omitted. After the tar data is complete, a final ordinary result set will be sent, containing the WAL end position of the backup, in the same format as the start position.

The tar archive for the data directory and each tablespace will contain all files in the directories, regardless of whether they are PostgreSQL files or other files added to the same directory. The only excluded files are:
- postmaster.pid
- postmaster.opts
- various temporary files created during the operation of the PostgreSQL server
- pg_xlog, including subdirectories. If the backup is run with WAL files included, a synthesized version of pg_xlog will be included, but it will only contain the files necessary for the backup to work, not the rest of the contents.
- pg_replslot is copied as an empty directory.
- Files other than regular files and directories, such as symbolic links and special device files, are skipped. (Symbolic links in pg_tblspc are maintained.)

Owner, group and file mode are set if the underlying file system on the server supports it.

Once all tablespaces have been sent, a final regular result set will be sent. This result set contains the end position of the backup, given in XLogRecPtr format as a single column in a single row.

50.4. Message Data Types

This section describes the base data types used in messages.

\textbf{Int}_n(i)

An \( n \)-bit integer in network byte order (most significant byte first). If \( i \) is specified it is the exact value that will appear, otherwise the value is variable. Eg. Int16, Int32(42).

\textbf{Int}_n[k]

An array of \( k \) \( n \)-bit integers, each in network byte order. The array length \( k \) is always determined by an earlier field in the message. Eg. Int16[M].

\textbf{String}(s)

A null-terminated string (C-style string). There is no specific length limitation on strings. If \( s \) is specified it is the exact value that will appear, otherwise the value is variable. Eg. String, String(“user”).

\textbf{Note}: \textit{There is no predefined limit} on the length of a string that can be returned by the backend. Good coding strategy for a frontend is to use an expandable buffer so that anything that fits in memory can be accepted. If that’s not feasible, read the full string and discard trailing characters that don’t fit into your fixed-size buffer.
Byte \( n(c) \)

Exactly \( n \) bytes. If the field width \( n \) is not a constant, it is always determinable from an earlier field in the message. If \( c \) is specified it is the exact value. Eg. Byte2, Byte1(\'n\').

50.5. Message Formats

This section describes the detailed format of each message. Each is marked to indicate that it can be sent by a frontend (F), a backend (B), or both (F & B). Notice that although each message includes a byte count at the beginning, the message format is defined so that the message end can be found without reference to the byte count. This aids validity checking. (The CopyData message is an exception, because it forms part of a data stream; the contents of any individual CopyData message cannot be interpretable on their own.)

AuthenticationOk (B)

Byte1(‘R’)

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(0)

Specifies that the authentication was successful.

AuthenticationKerberosV5 (B)

Byte1(‘R’)

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(2)

Specifies that Kerberos V5 authentication is required.

AuthenticationCleartextPassword (B)

Byte1(‘R’)

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(3)

Specifies that a clear-text password is required.
Chapter 50. Frontend/Backend Protocol

AuthenticationMD5Password (B)

Byte1('R')
Identifies the message as an authentication request.
Int32(12)
Length of message contents in bytes, including self.
Int32(5)
Specifies that an MD5-encrypted password is required.
Byte4
The salt to use when encrypting the password.

AuthenticationSCMCredential (B)

Byte1('R')
Identifies the message as an authentication request.
Int32(8)
Length of message contents in bytes, including self.
Int32(6)
Specifies that an SCM credentials message is required.

AuthenticationGSS (B)

Byte1('R')
Identifies the message as an authentication request.
Int32(8)
Length of message contents in bytes, including self.
Int32(7)
Specifies that GSSAPI authentication is required.

AuthenticationSSPI (B)

Byte1('R')
Identifies the message as an authentication request.
Int32(8)
Length of message contents in bytes, including self.
Int32(9)
Specifies that SSPI authentication is required.
Chapter 50. Frontend/Backend Protocol

AuthenticationGSSContinue (B)

Byte1(‘R’)
Identifies the message as an authentication request.

Int32
Length of message contents in bytes, including self.

Int32(8)
Specifies that this message contains GSSAPI or SSPI data.

Byte
GSSAPI or SSPI authentication data.

BackendKeyData (B)

Byte1(‘K’)
Identifies the message as cancellation key data. The frontend must save these values if it
wishes to be able to issue CancelRequest messages later.

Int32(12)
Length of message contents in bytes, including self.

Int32
The process ID of this backend.

Int32
The secret key of this backend.

Bind (F)

Byte1(‘B’)
Identifies the message as a Bind command.

Int32
Length of message contents in bytes, including self.

String
The name of the destination portal (an empty string selects the unnamed portal).

String
The name of the source prepared statement (an empty string selects the unnamed prepared
statement).

Int16
The number of parameter format codes that follow (denoted c below). This can be zero to
indicate that there are no parameters or that the parameters all use the default format (text);
or one, in which case the specified format code is applied to all parameters; or it can equal
the actual number of parameters.
Chapter 50. Frontend/Backend Protocol

Int16[c]

The parameter format codes. Each must presently be zero (text) or one (binary).

Int16

The number of parameter values that follow (possibly zero). This must match the number
of parameters needed by the query.

Next, the following pair of fields appear for each parameter:

Int32

The length of the parameter value, in bytes (this count does not include itself). Can be zero.
As a special case, -1 indicates a NULL parameter value. No value bytes follow in the NULL
case.

Byte n

The value of the parameter, in the format indicated by the associated format code. n is the
above length.

After the last parameter, the following fields appear:

Int16

The number of result-column format codes that follow (denoted \( R \) below). This can be zero
to indicate that there are no result columns or that the result columns should all use the
default format (text); or one, in which case the specified format code is applied to all result
columns (if any); or it can equal the actual number of result columns of the query.

Int16[R]

The result-column format codes. Each must presently be zero (text) or one (binary).

BindComplete (B)

Byte1(‘2’)

Identifies the message as a Bind-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

CancelRequest (F)

Int32(16)

Length of message contents in bytes, including self.

Int32(80877102)

The cancel request code. The value is chosen to contain 1234 in the most significant 16
bits, and 5678 in the least significant 16 bits. (To avoid confusion, this code must not be the
same as any protocol version number.)

Int32

The process ID of the target backend.
Int32
   The secret key for the target backend.

Close (F)

Byte1(‘C’)
   Identifies the message as a Close command.
Int32
   Length of message contents in bytes, including self.
Byte1
   ‘s’ to close a prepared statement; or ‘p’ to close a portal.
String
   The name of the prepared statement or portal to close (an empty string selects the unnamed
   prepared statement or portal).

CloseComplete (B)

Byte1(‘3’)
   Identifies the message as a Close-complete indicator.
Int32(4)
   Length of message contents in bytes, including self.

CommandComplete (B)

Byte1(‘C’)
   Identifies the message as a command-completed response.
Int32
   Length of message contents in bytes, including self.
String
   The command tag. This is usually a single word that identifies which SQL command was
   completed.
   For an INSERT command, the tag is INSERT oid rows, where rows is the number of rows
   inserted. oid is the object ID of the inserted row if rows is 1 and the target table has OIDs;
   otherwise oid is 0.
   For a DELETE command, the tag is DELETE rows where rows is the number of rows
   deleted.
   For an UPDATE command, the tag is UPDATE rows where rows is the number of rows
   updated.
   For a SELECT or CREATE TABLE AS command, the tag is SELECT rows where rows is the
   number of rows retrieved.
For a \texttt{MOVE} command, the tag is \texttt{MOVE rows} where \texttt{rows} is the number of rows the cursor’s position has been changed by.

For a \texttt{FETCH} command, the tag is \texttt{FETCH rows} where \texttt{rows} is the number of rows that have been retrieved from the cursor.

For a \texttt{COPY} command, the tag is \texttt{COPY rows} where \texttt{rows} is the number of rows copied. (Note: the row count appears only in PostgreSQL 8.2 and later.)

\textbf{CopyData (F \& B)}

\begin{itemize}
  \item Byte1(‘d’)\newline  Identifies the message as \texttt{COPY} data.
  \item Int32\newline  Length of message contents in bytes, including self.
  \item Byte\(n\)\newline  Data that forms part of a \texttt{COPY} data stream. Messages sent from the backend will always correspond to single data rows, but messages sent by frontends might divide the data stream arbitrarily.
\end{itemize}

\textbf{CopyDone (F \& B)}

\begin{itemize}
  \item Byte1(‘c’)\newline  Identifies the message as a \texttt{COPY}-complete indicator.
  \item Int32(4)\newline  Length of message contents in bytes, including self.
\end{itemize}

\textbf{CopyFail (F)}

\begin{itemize}
  \item Byte1(‘f’)\newline  Identifies the message as a \texttt{COPY}-failure indicator.
  \item Int32\newline  Length of message contents in bytes, including self.
  \item String\newline  An error message to report as the cause of failure.
\end{itemize}

\textbf{CopyInResponse (B)}

\begin{itemize}
  \item Byte1(‘G’)\newline  Identifies the message as a Start Copy In response. The frontend must now send copy-in data (if not prepared to do so, send a CopyFail message).
  \item Int32\newline  Length of message contents in bytes, including self.
\end{itemize}
Chapter 50. Frontend/Backend Protocol

Int8
0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16
The number of columns in the data to be copied (denoted \( N \) below).

Int16[\( N \)]
The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

CopyOutResponse (B)

Byte1(‘H’)
Identifies the message as a Start Copy Out response. This message will be followed by copy-out data.

Int32
Length of message contents in bytes, including self.

Int8
0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16
The number of columns in the data to be copied (denoted \( N \) below).

Int16[\( N \)]
The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

CopyBothResponse (B)

Byte1(‘W’)
Identifies the message as a Start Copy Both response. This message is used only for Streaming Replication.

Int32
Length of message contents in bytes, including self.

Int8
0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16
The number of columns in the data to be copied (denoted \( N \) below).
Chapter 50. Frontend/Backend Protocol

Int16[N]

The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

DataRow (B)

Byte1(‘D’)

Identifies the message as a data row.

Int32

Length of message contents in bytes, including self.

Int16

The number of column values that follow (possibly zero).

Next, the following pair of fields appear for each column:

Int32

The length of the column value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL column value. No value bytes follow in the NULL case.

Byte n

The value of the column, in the format indicated by the associated format code. n is the above length.

Describe (F)

Byte1(‘D’)

Identifies the message as a Describe command.

Int32

Length of message contents in bytes, including self.

Byte1

’s’ to describe a prepared statement; or ’p’ to describe a portal.

String

The name of the prepared statement or portal to describe (an empty string selects the un-named prepared statement or portal).

EmptyQueryResponse (B)

Byte1(‘I’)

Identifies the message as a response to an empty query string. (This substitutes for CommandComplete.)
Chapter 50. Frontend/Backend Protocol

Int32(4)

Length of message contents in bytes, including self.

ErrorResponse (B)

Byte1('E')

Identifies the message as an error.

Int32

Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:

Byte1

A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in Section 50.6. Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

String

The field value.

Execute (F)

Byte1('E')

Identifies the message as an Execute command.

Int32

Length of message contents in bytes, including self.

String

The name of the portal to execute (an empty string selects the unnamed portal).

Int32

Maximum number of rows to return, if portal contains a query that returns rows (ignored otherwise). Zero denotes "no limit".

Flush (F)

Byte1('H')

Identifies the message as a Flush command.

Int32(4)

Length of message contents in bytes, including self.
FunctionCall (F)

Byte1('F')

Identifies the message as a function call.

Int32

Length of message contents in bytes, including self.

Int32

Specifies the object ID of the function to call.

Int16

The number of argument format codes that follow (denoted \( c \) below). This can be zero to indicate that there are no arguments or that the arguments all use the default format (text); or one, in which case the specified format code is applied to all arguments; or it can equal the actual number of arguments.

Int16[\( c \)]

The argument format codes. Each must presently be zero (text) or one (binary).

Int16

Specifies the number of arguments being supplied to the function.

Next, the following pair of fields appear for each argument:

Int32

The length of the argument value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL argument value. No value bytes follow in the NULL case.

Byte\( n \)

The value of the argument, in the format indicated by the associated format code. \( n \) is the above length.

After the last argument, the following field appears:

Int16

The format code for the function result. Must presently be zero (text) or one (binary).

FunctionCallResponse (B)

Byte1('V')

Identifies the message as a function call result.

Int32

Length of message contents in bytes, including self.

Int32

The length of the function result value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL function result. No value bytes follow in the NULL case.
Chapter 50. Frontend/Backend Protocol

Byte $n$

The value of the function result, in the format indicated by the associated format code. $n$ is
the above length.

NegotiateProtocolVersion (B)

Byte1(‘v’)

Identifies the message as a protocol version negotiation message.

Int32

Length of message contents in bytes, including self.

Int32

Newest minor protocol version supported by the server for the major protocol version re-
quested by the client.

Int32

Number of protocol options not recognized by the server.

Then, for protocol option not recognized by the server, there is the following:

String

The option name.

NoData (B)

Byte1(‘n’)

Identifies the message as a no-data indicator.

Int32(4)

Length of message contents in bytes, including self.

NoticeResponse (B)

Byte1(‘N’)

Identifies the message as a notice.

Int32

Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a termi-
nator. Fields can appear in any order. For each field there is the following:

Byte1

A code identifying the field type; if zero, this is the message terminator and no string fol-
lows. The presently defined field types are listed in Section 50.6. Since more field types
might be added in future, frontends should silently ignore fields of unrecognized type.
Chapter 50. Frontend/Backend Protocol

String
The field value.

NotificationResponse (B)

Byte1(‘A’)
Identifies the message as a notification response.
Int32
Length of message contents in bytes, including self.
Int32
The process ID of the notifying backend process.
String
The name of the channel that the notify has been raised on.
String
The “payload” string passed from the notifying process.

ParameterDescription (B)

Byte1(‘t’)
Identifies the message as a parameter description.
Int32
Length of message contents in bytes, including self.
Int16
The number of parameters used by the statement (can be zero).
Then, for each parameter, there is the following:
Int32
Specifies the object ID of the parameter data type.

ParameterStatus (B)

Byte1(‘S’)
Identifies the message as a run-time parameter status report.
Int32
Length of message contents in bytes, including self.
String
The name of the run-time parameter being reported.
Chapter 50. Frontend/Backend Protocol

String
The current value of the parameter.

Parse (F)

Byte1(’P’)
Identifies the message as a Parse command.

Int32
Length of message contents in bytes, including self.

String
The name of the destination prepared statement (an empty string selects the unnamed prepared statement).

String
The query string to be parsed.

Int16
The number of parameter data types specified (can be zero). Note that this is not an indication of the number of parameters that might appear in the query string, only the number that the frontend wants to prespecify types for.

Then, for each parameter, there is the following:

Int32
Specifies the object ID of the parameter data type. Placing a zero here is equivalent to leaving the type unspecified.

ParseComplete (B)

Byte1(’1’)
Identifies the message as a Parse-complete indicator.

Int32(4)
Length of message contents in bytes, including self.

PasswordMessage (F)

Byte1(’p’)
Identifies the message as a password response. Note that this is also used for GSSAPI and SSPI response messages (which is really a design error, since the contained data is not a null-terminated string in that case, but can be arbitrary binary data).

Int32
Length of message contents in bytes, including self.
String
The password (encrypted, if requested).

PortalSuspended (B)

Byte1('s')
Identifies the message as a portal-suspended indicator. Note this only appears if an Execute message’s row-count limit was reached.
Int32(4)
Length of message contents in bytes, including self.

Query (F)

Byte1('Q')
Identifies the message as a simple query.
Int32
Length of message contents in bytes, including self.
String
The query string itself.

ReadyForQuery (B)

Byte1('Z')
Identifies the message type. ReadyForQuery is sent whenever the backend is ready for a new query cycle.
Int32(5)
Length of message contents in bytes, including self.
Byte1
Current backend transaction status indicator. Possible values are 'I' if idle (not in a transaction block); 'T' if in a transaction block; or 'E' if in a failed transaction block (queries will be rejected until block is ended).

RowDescription (B)

Byte1('T')
Identifies the message as a row description.
Int32
Length of message contents in bytes, including self.
Chapter 50. Frontend/Backend Protocol

Int16

Specifies the number of fields in a row (can be zero).

Then, for each field, there is the following:

String

The field name.

Int32

If the field can be identified as a column of a specific table, the object ID of the table; otherwise zero.

Int16

If the field can be identified as a column of a specific table, the attribute number of the column; otherwise zero.

Int32

The object ID of the field's data type.

Int16

The data type size (see `pg_type.typlen`). Note that negative values denote variable-width types.

Int32

The type modifier (see `pg_attribute.atttypmod`). The meaning of the modifier is type-specific.

Int16

The format code being used for the field. Currently will be zero (text) or one (binary). In a RowDescription returned from the statement variant of Describe, the format code is not yet known and will always be zero.

SSLRequest (F)

Int32(8)

Length of message contents in bytes, including self.

Int32(80877103)

The SSL request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5679 in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

StartupMessage (F)

Int32

Length of message contents in bytes, including self.

Int32(196608)

The protocol version number. The most significant 16 bits are the major version number (3 for the protocol described here). The least significant 16 bits are the minor version number (0 for the protocol described here).
The protocol version number is followed by one or more pairs of parameter name and value strings. A zero byte is required as a terminator after the last name/value pair. Parameters can appear in any order. user is required, others are optional. Each parameter is specified as:

**String**

The parameter name. Currently recognized names are:

- **user**
  - The database user name to connect as. Required; there is no default.
- **database**
  - The database to connect to. Defaults to the user name.
- **options**
  - Command-line arguments for the backend. (This is deprecated in favor of setting individual run-time parameters.) Spaces within this string are considered to separate arguments, unless escaped with a backslash (\); write ```\``` to represent a literal backslash.

In addition to the above, other parameters may be listed. Parameter names beginning with `_pq_` are reserved for use as protocol extensions, while others are treated as run-time parameters to be set at backend start time. Such settings will be applied during backend start (after parsing the command-line arguments if any) and will act as session defaults.

**String**

The parameter value.

---

**Sync (F)**

- **Byte1(‘S’)**
  - Identifies the message as a Sync command.
- **Int32(4)**
  - Length of message contents in bytes, including self.

**Terminate (F)**

- **Byte1(‘X’)**
  - Identifies the message as a termination.
- **Int32(4)**
  - Length of message contents in bytes, including self.

---

### 50.6. Error and Notice Message Fields

This section describes the fields that can appear in ErrorResponse and NoticeResponse messages. Each field type has a single-byte identification token. Note that any given field type should appear at most once per message.
Severity: the field contents are ERROR, FATAL, or PANIC (in an error message), or WARNING, NOTICE, DEBUG, INFO, or LOG (in a notice message), or a localized translation of one of these. Always present.

Code: the SQLSTATE code for the error (see Appendix A). Not localizable. Always present.

Message: the primary human-readable error message. This should be accurate but terse (typically one line). Always present.

Detail: an optional secondary error message carrying more detail about the problem. Might run to multiple lines.

Hint: an optional suggestion what to do about the problem. This is intended to differ from Detail in that it offers advice (potentially inappropriate) rather than hard facts. Might run to multiple lines.

Position: the field value is a decimal ASCII integer, indicating an error cursor position as an index into the original query string. The first character has index 1, and positions are measured in characters not bytes.

Internal position: this is defined the same as the P field, but it is used when the cursor position refers to an internally generated command rather than the one submitted by the client. The q field will always appear when this field appears.

Internal query: the text of a failed internally-generated command. This could be, for example, a SQL query issued by a PL/pgSQL function.

Where: an indication of the context in which the error occurred. Presently this includes a call stack traceback of active procedural language functions and internally-generated queries. The trace is one entry per line, most recent first.

Schema name: if the error was associated with a specific database object, the name of the schema containing that object, if any.

Table name: if the error was associated with a specific table, the name of the table. (Refer to the schema name field for the name of the table’s schema.)

Column name: if the error was associated with a specific table column, the name of the column. (Refer to the schema and table name fields to identify the table.)
Chapter 50. Frontend/Backend Protocol

Data type name: if the error was associated with a specific data type, the name of the data type. (Refer to the schema name field for the name of the data type’s schema.)

Constraint name: if the error was associated with a specific constraint, the name of the constraint. Refer to fields listed above for the associated table or domain. (For this purpose, indexes are treated as constraints, even if they weren’t created with constraint syntax.)

File: the file name of the source-code location where the error was reported.

Line: the line number of the source-code location where the error was reported.

Routine: the name of the source-code routine reporting the error.

Note: The fields for schema name, table name, column name, data type name, and constraint name are supplied only for a limited number of error types; see Appendix A. Frontends should not assume that the presence of any of these fields guarantees the presence of another field. Core error sources observe the interrelationships noted above, but user-defined functions may use these fields in other ways. In the same vein, clients should not assume that these fields denote contemporary objects in the current database.

The client is responsible for formatting displayed information to meet its needs; in particular it should break long lines as needed. Newline characters appearing in the error message fields should be treated as paragraph breaks, not line breaks.

50.7. Summary of Changes since Protocol 2.0

This section provides a quick checklist of changes, for the benefit of developers trying to update existing client libraries to protocol 3.0.

The initial startup packet uses a flexible list-of-strings format instead of a fixed format. Notice that session default values for run-time parameters can now be specified directly in the startup packet. (Actually, you could do that before using the options field, but given the limited width of options and the lack of any way to quote whitespace in the values, it wasn’t a very safe technique.)

All messages now have a length count immediately following the message type byte (except for startup packets, which have no type byte). Also note that PasswordMessage now has a type byte.

ErrorResponse and NoticeResponse (’E’ and ‘N’) messages now contain multiple fields, from which the client code can assemble an error message of the desired level of verbosity. Note that individual fields will typically not end with a newline, whereas the single string sent in the older protocol always did.

The ReadyForQuery (’Z’) message includes a transaction status indicator.

The distinction between BinaryRow and DataRow message types is gone; the single DataRow message type serves for returning data in all formats. Note that the layout of DataRow has changed to make it easier to parse. Also, the representation of binary values has changed: it is no longer directly tied to the server’s internal representation.
There is a new “extended query” sub-protocol, which adds the frontend message types Parse, Bind, Execute, Describe, Close, Flush, and Sync, and the backend message types ParseComplete, BindComplete, PortalSuspended, ParameterDescription, NoData, and CloseComplete. Existing clients do not have to concern themselves with this sub-protocol, but making use of it might allow improvements in performance or functionality.

COPY data is now encapsulated into CopyData and CopyDone messages. There is a well-defined way to recover from errors during COPY. The special “\.” last line is not needed anymore, and is not sent during COPY OUT. (It is still recognized as a terminator during COPY IN, but its use is deprecated and will eventually be removed.) Binary COPY is supported. The CopyInResponse and CopyOutResponse messages include fields indicating the number of columns and the format of each column.

The layout of FunctionCall and FunctionCallResponse messages has changed. FunctionCall can now support passing NULL arguments to functions. It also can handle passing parameters and retrieving results in either text or binary format. There is no longer any reason to consider FunctionCall a potential security hole, since it does not offer direct access to internal server data representations.

The backend sends ParameterStatus (‘S’) messages during connection startup for all parameters it considers interesting to the client library. Subsequently, a ParameterStatus message is sent whenever the active value changes for any of these parameters.

The RowDescription (‘T’) message carries new table OID and column number fields for each column of the described row. It also shows the format code for each column.

The CursorResponse (‘P’) message is no longer generated by the backend.

The NotificationResponse (‘A’) message has an additional string field, which can carry a “payload” string passed from the NOTIFY event sender.

The EmptyQueryResponse (‘I’) message used to include an empty string parameter; this has been removed.
Chapter 51. PostgreSQL Coding Conventions

51.1. Formatting

Source code formatting uses 4 column tab spacing, with tabs preserved (i.e., tabs are not expanded to spaces). Each logical indentation level is one additional tab stop.

Layout rules (brace positioning, etc) follow BSD conventions. In particular, curly braces for the controlled blocks of if, while, switch, etc go on their own lines.

Limit line lengths so that the code is readable in an 80-column window. (This doesn’t mean that you must never go past 80 columns. For instance, breaking a long error message string in arbitrary places just to keep the code within 80 columns is probably not a net gain in readability.)

Do not use C++ style comments (// comments). Strict ANSI C compilers do not accept them. For the same reason, do not use C++ extensions such as declaring new variables mid-block.

The preferred style for multi-line comment blocks is

```c
/*
 * comment text begins here
 * and continues here
 */
```

Note that comment blocks that begin in column 1 will be preserved as-is by pgindent, but it will reflow indented comment blocks as though they were plain text. If you want to preserve the line breaks in an indented block, add dashes like this:

```c
/*----------
 * comment text begins here
 * and continues here
 *----------
 */
```

While submitted patches do not absolutely have to follow these formatting rules, it’s a good idea to do so. Your code will get run through pgindent before the next release, so there’s no point in making it look nice under some other set of formatting conventions. A good rule of thumb for patches is “make the new code look like the existing code around it”.

The src/tools directory contains sample settings files that can be used with the emacs, xemacs or vim editors to help ensure that they format code according to these conventions.

The text browsing tools more and less can be invoked as:

```bash
more -x4
less -x4
```

to make them show tabs appropriately.
51.2. Reporting Errors Within the Server

Error, warning, and log messages generated within the server code should be created using `ereport`, or its older cousin `elog`. The use of this function is complex enough to require some explanation.

There are two required elements for every message: a severity level (ranging from `DEBUG` to `PANIC`) and a primary message text. In addition there are optional elements, the most common of which is an error identifier code that follows the SQL spec’s SQLSTATE conventions. `ereport` itself is just a shell function, that exists mainly for the syntactic convenience of making message generation look like a function call in the C source code. The only parameter accepted directly by `ereport` is the severity level. The primary message text and any optional message elements are generated by calling auxiliary functions, such as `errmsg`, within the `ereport` call.

A typical call to `ereport` might look like this:

```c
ereport(ERROR,
    (errcode(ERRCODE_DIVISION_BY_ZERO),
     errmsg("division by zero")));
```

This specifies error severity level `ERROR` (a run-of-the-mill error). The `errcode` call specifies the SQLSTATE error code using a macro defined in `src/include/utils/errcodes.h`. The `errmsg` call provides the primary message text. Notice the extra set of parentheses surrounding the auxiliary function calls — these are annoying but syntactically necessary.

Here is a more complex example:

```c
ereport(ERROR,
    (errcode(ERRCODE_AMBIGUOUS_FUNCTION),
     errmsg("function \$s is not unique",
           func_signature_string(funcname, nargs,
                                NIL, actual_arg_types)),
     errhint("Unable to choose a best candidate function. "
            "You might need to add explicit typecasts.")));
```

This illustrates the use of format codes to embed run-time values into a message text. Also, an optional “hint” message is provided.

If the severity level is `ERROR` or higher, `ereport` aborts the execution of the user-defined function and does not return to the caller. If the severity level is lower than `ERROR`, `ereport` returns normally.

The available auxiliary routines for `ereport` are:

- `errcode(sqlerrcode)` specifies the SQLSTATE error identifier code for the condition. If this routine is not called, the error identifier defaults to `ERRCODE_INTERNAL_ERROR` when the error severity level is `ERROR` or higher, `ERRCODE_WARNING` when the error level is `WARNING`, otherwise (for `NOTICE` and below) `ERRCODE_SUCCESSFUL_COMPLETION`. While these defaults are often convenient, always think whether they are appropriate before omitting the `errcode()` call.

- `errmsg(const char *msg, ...)` specifies the primary error message text, and possibly run-time values to insert into it. Insertions are specified by `printf`-style format codes. In addition to the standard format codes accepted by `printf`, the format code `%m` can be used to insert the error message returned by `strerror` for the current value of `errno`.

\[1\] `%m` does not require any corresponding entry in the parameter list for `errmsg`. Note that the message string will be run through `gettext` for possible localization before format codes are processed.

---

1. That is, the value that was current when the `ereport` call was reached; changes of `errno` within the auxiliary reporting routines will not affect it. That would not be true if you were to write `strerror(errno)` explicitly in `errmsg`'s parameter list; accordingly, do not do so.

2011
Chapter 51. PostgreSQL Coding Conventions

- `errmsg_internal(const char *msg, ...)` is the same as `errmsg`, except that the message string will not be translated nor included in the internationalization message dictionary. This should be used for “cannot happen” cases that are probably not worth expending translation effort on.

- `errmsg_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)` is like `errmsg`, but with support for various plural forms of the message. `fmt_singular` is the English singular format, `fmt_plural` is the English plural format, `n` is the integer value that determines which plural form is needed, and the remaining arguments are formatted according to the selected format string. For more information see Section 52.2.2.

- `errdetail(const char *msg, ...)` supplies an optional “detail” message; this is to be used when there is additional information that seems inappropriate to put in the primary message. The message string is processed in just the same way as for `errmsg`.

- `errdetail_internal(const char *msg, ...)` is the same as `errdetail`, except that the message string will not be translated nor included in the internationalization message dictionary. This should be used for detail messages that are not worth expending translation effort on, for instance because they are too technical to be useful to most users.

- `errdetail_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)` is like `errdetail`, but with support for various plural forms of the message. For more information see Section 52.2.2.

- `errdetail_log(const char *msg, ...)` is the same as `errdetail` except that this string goes only to the server log, never to the client. If both `errdetail` (or one of its equivalents above) and `errdetail_log` are used then one string goes to the client and the other to the log. This is useful for error details that are too security-sensitive or too bulky to include in the report sent to the client.

- `errdetail_log_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)` is like `errdetail_log`, but with support for various plural forms of the message. For more information see Section 52.2.2.

- `errhint(const char *msg, ...)` supplies an optional “hint” message; this is to be used when offering suggestions about how to fix the problem, as opposed to factual details about what went wrong. The message string is processed in just the same way as for `errmsg`.

- `errcontext(const char *msg, ...)` is not normally called directly from an `ereport` message site; rather it is used in `error_context_stack` callback functions to provide information about the context in which an error occurred, such as the current location in a PL function. The message string is processed in just the same way as for `errmsg`. Unlike the other auxiliary functions, this can be called more than once per `ereport` call; the successive strings thus supplied are concatenated with separating newlines.

- `errposition(int cursorpos)` specifies the textual location of an error within a query string. Currently it is only useful for errors detected in the lexical and syntactic analysis phases of query processing.

- `errtable(Relation rel)` specifies a relation whose name and schema name should be included as auxiliary fields in the error report.

- `errtablecol(Relation rel, int attnum)` specifies a column whose name, table name, and schema name should be included as auxiliary fields in the error report.

- `errtableconstraint(Relation rel, const char *conname)` specifies a table constraint whose name, table name, and schema name should be included as auxiliary fields in the error report. Indexes should be considered to be constraints for this purpose, whether or not they have an associated `pg_constraint` entry. Be careful to pass the underlying heap relation, not the index itself, as `rel`. 

2012
Chapter 51. PostgreSQL Coding Conventions

- **errdatatype(Oid datatypeOid)** specifies a data type whose name and schema name should be included as auxiliary fields in the error report.

- **errdomainconstraint(Oid datatypeOid, const char *conname)** specifies a domain constraint whose name, domain name, and schema name should be included as auxiliary fields in the error report.

- **errcode_for_file_access()** is a convenience function that selects an appropriate SQLSTATE error identifier for a failure in a file-access-related system call. It uses the saved errno to determine which error code to generate. Usually this should be used in combination with %m in the primary error message text.

- **errcode_for_socket_access()** is a convenience function that selects an appropriate SQLSTATE error identifier for a failure in a socket-related system call.

- **errhidestmt(bool hide_stmt)** can be called to specify suppression of the STATEMENT: portion of a message in the postmaster log. Generally this is appropriate if the message text includes the current statement already.

**Note:** At most one of the functions errtable, errtablecol, errtableconstraint, errdatatype, or errdomainconstraint should be used in an ereport call. These functions exist to allow applications to extract the name of a database object associated with the error condition without having to examine the potentially-localized error message text. These functions should be used in error reports for which it's likely that applications would wish to have automatic error handling. As of PostgreSQL 9.3, complete coverage exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

There is an older function elog that is still heavily used. An elog call:

```c
elog(level, "format string", ...);
```

is exactly equivalent to:

```c
ereport(level, (errmsg_internal("format string", ...)));
```

Notice that the SQLSTATE error code is always defaulted, and the message string is not subject to translation. Therefore, elog should be used only for internal errors and low-level debug logging. Any message that is likely to be of interest to ordinary users should go through ereport. Nonetheless, there are enough internal “cannot happen” error checks in the system that elog is still widely used; it is preferred for those messages for its notational simplicity.

Advice about writing good error messages can be found in Section 51.3.

### 51.3. Error Message Style Guide

This style guide is offered in the hope of maintaining a consistent, user-friendly style throughout all the messages generated by PostgreSQL.

#### 51.3.1. What Goes Where

The primary message should be short, factual, and avoid reference to implementation details such as specific function names. “Short” means “should fit on one line under normal conditions”. Use a detail
message if needed to keep the primary message short, or if you feel a need to mention implementation
details such as the particular system call that failed. Both primary and detail messages should be
factual. Use a hint message for suggestions about what to do to fix the problem, especially if the
suggestion might not always be applicable.

For example, instead of:

IpcMemoryCreate: shmget(key=%d, size=%u, 0%o) failed: %m

(plus a long addendum that is basically a hint)

write:

Primary: could not create shared memory segment: %m
Detail: Failed syscall was shmget(key=%d, size=%u, 0%o).
Hint: the addendum

Rationale: keeping the primary message short helps keep it to the point, and lets clients lay out screen
space on the assumption that one line is enough for error messages. Detail and hint messages can be
relegated to a verbose mode, or perhaps a pop-up error-details window. Also, details and hints would
normally be suppressed from the server log to save space. Reference to implementation details is best
avoided since users don’t know the details anyway.

51.3.2. Formatting

Don’t put any specific assumptions about formatting into the message texts. Expect clients and the
server log to wrap lines to fit their own needs. In long messages, newline characters (\n) can be used
to indicate suggested paragraph breaks. Don’t end a message with a newline. Don’t use tabs or other
formatting characters. (In error context displays, newlines are automatically added to separate levels
of context such as function calls.)

Rationale: Messages are not necessarily displayed on terminal-type displays. In GUI displays or
browsers these formatting instructions are at best ignored.

51.3.3. Quotation Marks

English text should use double quotes when quoting is appropriate. Text in other languages should
consistently use one kind of quotes that is consistent with publishing customs and computer output of
other programs.

Rationale: The choice of double quotes over single quotes is somewhat arbitrary, but tends to be the
preferred use. Some have suggested choosing the kind of quotes depending on the type of object
according to SQL conventions (namely, strings single quoted, identifiers double quoted). But this is
a language-internal technical issue that many users aren’t even familiar with, it won’t scale to other
kinds of quoted terms, it doesn’t translate to other languages, and it’s pretty pointless, too.

51.3.4. Use of Quotes

Use quotes always to delimit file names, user-supplied identifiers, and other variables that might
contain words. Do not use them to mark up variables that will not contain words (for example, operator
names).
There are functions in the backend that will double-quote their own output at need (for example, `format_type_be()`). Do not put additional quotes around the output of such functions.

Rationale: Objects can have names that create ambiguity when embedded in a message. Be consistent about denoting where a plugged-in name starts and ends. But don’t clutter messages with unnecessary or duplicate quote marks.

### 51.3.5. Grammar and Punctuation

The rules are different for primary error messages and for detail/hint messages:

**Primary error messages:** Do not capitalize the first letter. Do not end a message with a period. Do not even think about ending a message with an exclamation point.

**Detail and hint messages:** Use complete sentences, and end each with a period. Capitalize the first word of sentences. Put two spaces after the period if another sentence follows (for English text; might be inappropriate in other languages).

**Error context strings:** Do not capitalize the first letter and do not end the string with a period. Context strings should normally not be complete sentences.

Rationale: Avoiding punctuation makes it easier for client applications to embed the message into a variety of grammatical contexts. Often, primary messages are not grammatically complete sentences anyway. (And if they’re long enough to be more than one sentence, they should be split into primary and detail parts.) However, detail and hint messages are longer and might need to include multiple sentences. For consistency, they should follow complete-sentence style even when there’s only one sentence.

### 51.3.6. Upper Case vs. Lower Case

Use lower case for message wording, including the first letter of a primary error message. Use upper case for SQL commands and key words if they appear in the message.

Rationale: It’s easier to make everything look more consistent this way, since some messages are complete sentences and some not.

### 51.3.7. Avoid Passive Voice

Use the active voice. Use complete sentences when there is an acting subject (“A could not do B”). Use telegram style without subject if the subject would be the program itself; do not use “I” for the program.

Rationale: The program is not human. Don’t pretend otherwise.

### 51.3.8. Present vs. Past Tense

Use past tense if an attempt to do something failed, but could perhaps succeed next time (perhaps after fixing some problem). Use present tense if the failure is certainly permanent.

There is a nontrivial semantic difference between sentences of the form:

```plaintext
could not open file "%s": %m
```
and:

cannot open file "%s"

The first one means that the attempt to open the file failed. The message should give a reason, such as “disk full” or “file doesn’t exist”. The past tense is appropriate because next time the disk might not be full anymore or the file in question might exist.

The second form indicates that the functionality of opening the named file does not exist at all in the program, or that it’s conceptually impossible. The present tense is appropriate because the condition will persist indefinitely.

Rationale: Granted, the average user will not be able to draw great conclusions merely from the tense of the message, but since the language provides us with a grammar we should use it correctly.

51.3.9. Type of the Object

When citing the name of an object, state what kind of object it is.

Rationale: Otherwise no one will know what “foo.bar.baz” refers to.

51.3.10. Brackets

Square brackets are only to be used (1) in command synopses to denote optional arguments, or (2) to denote an array subscript.

Rationale: Anything else does not correspond to widely-known customary usage and will confuse people.

51.3.11. Assembling Error Messages

When a message includes text that is generated elsewhere, embed it in this style:

could not open file %s: %m

Rationale: It would be difficult to account for all possible error codes to paste this into a single smooth sentence, so some sort of punctuation is needed. Putting the embedded text in parentheses has also been suggested, but it’s unnatural if the embedded text is likely to be the most important part of the message, as is often the case.

51.3.12. Reasons for Errors

Messages should always state the reason why an error occurred. For example:

BAD: could not open file %s

BETTER: could not open file %s (I/O failure)

If no reason is known you better fix the code.
51.3.13. Function Names

Don’t include the name of the reporting routine in the error text. We have other mechanisms for finding that out when needed, and for most users it’s not helpful information. If the error text doesn’t make as much sense without the function name, reword it.

BAD: pg_atoi: error in "z": cannot parse "z"
BETTER: invalid input syntax for integer: "z"

Avoid mentioning called function names, either; instead say what the code was trying to do:

BAD: open() failed: %m
BETTER: could not open file %s: %m

If it really seems necessary, mention the system call in the detail message. (In some cases, providing the actual values passed to the system call might be appropriate information for the detail message.)

Rationale: Users don’t know what all those functions do.

51.3.14. Tricky Words to Avoid

Unable. “Unable” is nearly the passive voice. Better use “cannot” or “could not”, as appropriate.

Bad. Error messages like “bad result” are really hard to interpret intelligently. It’s better to write why the result is “bad”, e.g., “invalid format”.

Illegal. “Illegal” stands for a violation of the law, the rest is “invalid”. Better yet, say why it’s invalid.

Unknown. Try to avoid “unknown”. Consider “error: unknown response”. If you don’t know what the response is, how do you know it’s erroneous? “Unrecognized” is often a better choice. Also, be sure to include the value being complained of.

BAD: unknown node type
BETTER: unrecognized node type: 42

Find vs. Exists. If the program uses a nontrivial algorithm to locate a resource (e.g., a path search) and that algorithm fails, it is fair to say that the program couldn’t “find” the resource. If, on the other hand, the expected location of the resource is known but the program cannot access it there then say that the resource doesn’t “exist”. Using “find” in this case sounds weak and confuses the issue.

May vs. Can vs. Might. “May” suggests permission (e.g., “You may borrow my rake.”), and has little use in documentation or error messages. “Can” suggests ability (e.g., “I can lift that log.”), and “might” suggests possibility (e.g., “It might rain today.”). Using the proper word clarifies meaning and assists translation.

Contractions. Avoid contractions, like “can’t”; use “cannot” instead.

51.3.15. Proper Spelling

Spell out words in full. For instance, avoid:

- spec
- stats
• parens
• auth
• xact

Rationale: This will improve consistency.

51.3.16. Localization

Keep in mind that error message texts need to be translated into other languages. Follow the guidelines in Section 52.2.2 to avoid making life difficult for translators.
Chapter 52. Native Language Support

52.1. For the Translator

PostgreSQL programs (server and client) can issue their messages in your favorite language — if the messages have been translated. Creating and maintaining translated message sets needs the help of people who speak their own language well and want to contribute to the PostgreSQL effort. You do not have to be a programmer at all to do this. This section explains how to help.

52.1.1. Requirements

We won’t judge your language skills — this section is about software tools. Theoretically, you only need a text editor. But this is only in the unlikely event that you do not want to try out your translated messages. When you configure your source tree, be sure to use the \\--enable-nls option. This will also check for the libintl library and the msgfmt program, which all end users will need anyway. To try out your work, follow the applicable portions of the installation instructions.

If you want to start a new translation effort or want to do a message catalog merge (described later), you will need the programs xgettext and msgmerge, respectively, in a GNU-compatible implementation. Later, we will try to arrange it so that if you use a packaged source distribution, you won’t need xgettext. (If working from Git, you will still need it.) GNU Gettext 0.10.36 or later is currently recommended.

Your local gettext implementation should come with its own documentation. Some of that is probably duplicated in what follows, but for additional details you should look there.

52.1.2. Concepts

The pairs of original (English) messages and their (possibly) translated equivalents are kept in message catalogs, one for each program (although related programs can share a message catalog) and for each target language. There are two file formats for message catalogs: The first is the “PO” file (for Portable Object), which is a plain text file with special syntax that translators edit. The second is the “MO” file (for Machine Object), which is a binary file generated from the respective PO file and is used while the internationalized program is run. Translators do not deal with MO files; in fact hardly anyone does.

The extension of the message catalog file is to no surprise either .po or .mo. The base name is either the name of the program it accompanies, or the language the file is for, depending on the situation. This is a bit confusing. Examples are psql.po (PO file for psql) or fr.mo (MO file in French).

The file format of the PO files is illustrated here:

```plaintext
msgid "original string"
msgstr "translated string"
msgid "more original"
```

2019
Chapter 52. Native Language Support

msgid "another translated"
"string can be broken up like this"

...

The msgid’s are extracted from the program source. (They need not be, but this is the most common way.) The msgstr lines are initially empty and are filled in with useful strings by the translator. The strings can contain C-style escape characters and can be continued across lines as illustrated. (The next line must start at the beginning of the line.)

The # character introduces a comment. If whitespace immediately follows the # character, then this is a comment maintained by the translator. There can also be automatic comments, which have a non-whitespace character immediately following the #. These are maintained by the various tools that operate on the PO files and are intended to aid the translator.

#. automatic comment
#: filename.c:1023
#, flags, flags

The #. style comments are extracted from the source file where the message is used. Possibly the programmer has inserted information for the translator, such as about expected alignment. The #: comment indicates the exact location(s) where the message is used in the source. The translator need not look at the program source, but he can if there is doubt about the correct translation. The #, comments contain flags that describe the message in some way. There are currently two flags: fuzzy is set if the message has possibly been outdated because of changes in the program source. The translator can then verify this and possibly remove the fuzzy flag. Note that fuzzy messages are not made available to the end user. The other flag is c-format, which indicates that the message is a printf-style format template. This means that the translation should also be a format string with the same number and type of placeholders. There are tools that can verify this, which key off the c-format flag.

52.1.3. Creating and Maintaining Message Catalogs

OK, so how does one create a “blank” message catalog? First, go into the directory that contains the program whose messages you want to translate. If there is a file nls.mk, then this program has been prepared for translation.

If there are already some .po files, then someone has already done some translation work. The files are named language.po, where language is the ISO 639-1 two-letter language code (in lower case)¹, e.g., fr.po for French. If there is really a need for more than one translation effort per language then the files can also be named language_region.po where region is the ISO 3166-1 two-letter country code (in upper case)², e.g., pt_BR.po for Portuguese in Brazil. If you find the language you wanted you can just start working on that file.

If you need to start a new translation effort, then first run the command:

```
make init-po
```

This will create a file programe_pot (.pot to distinguish it from PO files that are “in production”. The T stands for “template”). Copy this file to language.po and edit it. To make it known that the new language is available, also edit the file nls.mk and add the language (or language and country) code to the line that looks like:

2. http://www.iso.org/iso/country_names_and_code_elements

2020
AVAIL_LANGUAGES := de fr

(Other languages can appear, of course.)

As the underlying program or library changes, messages might be changed or added by the programmers. In this case you do not need to start from scratch. Instead, run the command:

make update-po

which will create a new blank message catalog file (the pot file you started with) and will merge it with the existing PO files. If the merge algorithm is not sure about a particular message it marks it “fuzzy” as explained above. The new PO file is saved with a .po.new extension.

52.1.4. Editing the PO Files

The PO files can be edited with a regular text editor. The translator should only change the area between the quotes after the msgstr directive, add comments, and alter the fuzzy flag. There is (unsurprisingly) a PO mode for Emacs, which I find quite useful.

The PO files need not be completely filled in. The software will automatically fall back to the original string if no translation (or an empty translation) is available. It is no problem to submit incomplete translations for inclusions in the source tree; that gives room for other people to pick up your work. However, you are encouraged to give priority to removing fuzzy entries after doing a merge. Remember that fuzzy entries will not be installed; they only serve as reference for what might be the right translation.

Here are some things to keep in mind while editing the translations:

- Make sure that if the original ends with a newline, the translation does, too. Similarly for tabs, etc.
- If the original is a printf format string, the translation also needs to be. The translation also needs to have the same format specifiers in the same order. Sometimes the natural rules of the language make this impossible or at least awkward. In that case you can modify the format specifiers like this:

  msgstr "Die Datei %2$s hat %1$u Zeichen."

  Then the first placeholder will actually use the second argument from the list. The digits$ needs to follow the % immediately, before any other format manipulators. (This feature really exists in the printf family of functions. You might not have heard of it before because there is little use for it outside of message internationalization.)

- If the original string contains a linguistic mistake, report that (or fix it yourself in the program source) and translate normally. The corrected string can be merged in when the program sources have been updated. If the original string contains a factual mistake, report that (or fix it yourself) and do not translate it. Instead, you can mark the string with a comment in the PO file.

- Maintain the style and tone of the original string. Specifically, messages that are not sentences (cannot open file %s) should probably not start with a capital letter (if your language distinguishes letter case) or end with a period (if your language uses punctuation marks). It might help to read Section 51.3.

- If you don’t know what a message means, or if it is ambiguous, ask on the developers’ mailing list. Chances are that English speaking end users might also not understand it or find it ambiguous, so it’s best to improve the message.
52.2. For the Programmer

52.2.1. Mechanics

This section describes how to implement native language support in a program or library that is part of the PostgreSQL distribution. Currently, it only applies to C programs.

Adding NLS Support to a Program

1. Insert this code into the start-up sequence of the program:

   ```c
   #ifdef ENABLE_NLS
   #include <locale.h>
   #endif
   ...
   #ifdef ENABLE_NLS
   setlocale(LC_ALL, "");
   bindtextdomain("progname", LOCALEDIR);
   textdomain("progname");
   #endif
   (The `progname` can actually be chosen freely.)
   
2. Wherever a message that is a candidate for translation is found, a call to `gettext()` needs to be inserted. E.g.:

   ```c
   fprintf(stderr, "panic level %d\n", lvl);
   would be changed to:
   ```

   ```c
   fprintf(stderr, gettext("panic level %d\n"), lvl);
   (gettext is defined as a no-op if NLS support is not configured.)
   
   This tends to add a lot of clutter. One common shortcut is to use:
   ```

   ```c
   #define _(x) gettext(x)
   ```

   Another solution is feasible if the program does much of its communication through one or a few functions, such as `ereport()` in the backend. Then you make this function call `gettext` internally on all input strings.

3. Add a file `nls.mk` in the directory with the program sources. This file will be read as a makefile. The following variable assignments need to be made here:

   ```
   CATALOG_NAME
   The program name, as provided in the `textdomain()` call.
   
   AVAIL_LANGUAGES
   List of provided translations — initially empty.
   
   GETTEXT_FILES
   List of files that contain translatable strings, i.e., those marked with `gettext` or an alternative solution. Eventually, this will include nearly all source files of the program. If this list gets too long you can make the first “file” be a + and the second word be a file that contains one file name per line.
   ```
GETTEXT_TRIGGERS

The tools that generate message catalogs for the translators to work on need to know what
function calls contain translatable strings. By default, only gettext() calls are known. If
you used _ or other identifiers you need to list them here. If the translatable string is not
the first argument, the item needs to be of the form func:2 (for the second argument). If
you have a function that supports pluralized messages, the item should look like func:1,2
(identifying the singular and plural message arguments).

The build system will automatically take care of building and installing the message catalogs.

52.2.2. Message-writing Guidelines

Here are some guidelines for writing messages that are easily translatable.

- Do not construct sentences at run-time, like:

  printf("Files were %s.\n", flag ? "copied" : "removed");

  The word order within the sentence might be different in other languages. Also, even if you re-
member to call gettext() on each fragment, the fragments might not translate well separately.
  It’s better to duplicate a little code so that each message to be translated is a coherent whole. Only
  numbers, file names, and such-like run-time variables should be inserted at run time into a message
text.

- For similar reasons, this won’t work:

  printf("copied %d file%s", n, n!=1 ? "s" : "");

  because it assumes how the plural is formed. If you figured you could solve it like this:

  if (n==1)
    printf("copied 1 file");
  else
    printf("copied %d files", n);

  then be disappointed. Some languages have more than two forms, with some peculiar rules. It’s
  often best to design the message to avoid the issue altogether, for instance like this:

  printf("number of copied files: %d", n);

  If you really want to construct a properly pluralized message, there is support for this, but it’s a
  bit awkward. When generating a primary or detail error message in ereport(), you can write
  something like this:

  errmsg_plural("copied %d file",
                "copied %d files",
                n,
                n)

  The first argument is the format string appropriate for English singular form, the second is the
format string appropriate for English plural form, and the third is the integer control value that
determines which plural form to use. Subsequent arguments are formatted per the format string as
usual. (Normally, the pluralization control value will also be one of the values to be formatted, so
it has to be written twice.) In English it only matters whether n is 1 or not 1, but in other languages
there can be many different plural forms. The translator sees the two English forms as a group and
has the opportunity to supply multiple substitute strings, with the appropriate one being selected
based on the run-time value of n.
If you need to pluralize a message that isn’t going directly to an `errmsg` or `errdetail` report, you have to use the underlying function `ngettext`. See the `gettext` documentation.

- If you want to communicate something to the translator, such as about how a message is intended to line up with other output, precede the occurrence of the string with a comment that starts with `translator`, e.g.:

  ```c
  /* translator: This message is not what it seems to be. */
  ```

  These comments are copied to the message catalog files so that the translators can see them.
Chapter 53. Writing A Procedural Language Handler

All calls to functions that are written in a language other than the current “version 1” interface for compiled languages (this includes functions in user-defined procedural languages, functions written in SQL, and functions using the version 0 compiled language interface) go through a call handler function for the specific language. It is the responsibility of the call handler to execute the function in a meaningful way, such as by interpreting the supplied source text. This chapter outlines how a new procedural language’s call handler can be written.

The call handler for a procedural language is a “normal” function that must be written in a compiled language such as C, using the version-1 interface, and registered with PostgreSQL as taking no arguments and returning the type language_handler. This special pseudotype identifies the function as a call handler and prevents it from being called directly in SQL commands. For more details on C language calling conventions and dynamic loading, see Section 35.9.

The call handler is called in the same way as any other function: It receives a pointer to a FunctionCallInfoData struct containing argument values and information about the called function, and it is expected to return a Datum result (and possibly set the isnull field of the FunctionCallInfoData structure, if it wishes to return an SQL null result). The difference between a call handler and an ordinary callee function is that the flinfo->fn_oid field of the FunctionCallInfoData structure will contain the OID of the actual function to be called, not of the call handler itself. The call handler must use this field to determine which function to execute. Also, the passed argument list has been set up according to the declaration of the target function, not of the call handler.

It’s up to the call handler to fetch the entry of the function from the pg_proc system catalog and to analyze the argument and return types of the called function. The AS clause from the CREATE FUNCTION command for the function will be found in the prosrc column of the pg_proc row. This is commonly source text in the procedural language, but in theory it could be something else, such as a path name to a file, or anything else that tells the call handler what to do in detail.

Often, the same function is called many times per SQL statement. A call handler can avoid repeated lookups of information about the called function by using the flinfo->fn_extra field. This will initially be NULL, but can be set by the call handler to point at information about the called function. On subsequent calls, if flinfo->fn_extra is already non-NULL then it can be used and the information lookup step skipped. The call handler must make sure that flinfo->fn_extra is made to point at memory that will live at least until the end of the current query, since an FmgrInfo data structure could be kept that long. One way to do this is to allocate the extra data in the memory context specified by flinfo->fn_mcxt; such data will normally have the same lifespan as the FmgrInfo itself. But the handler could also choose to use a longer-lived memory context so that it can cache function definition information across queries.

When a procedural-language function is invoked as a trigger, no arguments are passed in the usual way, but the FunctionCallInfoData’s context field points at a TriggerData structure, rather than being NULL as it is in a plain function call. A language handler should provide mechanisms for procedural-language functions to get at the trigger information.

This is a template for a procedural-language handler written in C:

```
#include "postgres.h"
```
Chapter 53. Writing A Procedural Language Handler

```c
#include "executor/spi.h"
#include "commands/trigger.h"
#include "fmgr.h"
#include "access/heapam.h"
#include "utils/syscache.h"
#include "catalog/pg_proc.h"
#include "catalog/pg_type.h"

#ifdef PG_MODULE_MAGIC
PG_MODULE_MAGIC;
#endif

PG_FUNCTION_INFO_V1(plsample_call_handler);

Datum plsample_call_handler(PG_FUNCTION_ARGS)
{
    Datum retval;
    if (CALLED_AS_TRIGGER(fcinfo))
    {
        /* Called as a trigger procedure */
        TriggerData *trigdata = (TriggerData *) fcinfo->context;
        retval = ...;
    }
    else
    {
        /* Called as a function */
        retval = ...;
    }
    return retval;
}
```

Only a few thousand lines of code have to be added instead of the dots to complete the call handler.

After having compiled the handler function into a loadable module (see Section 35.9.6), the following commands then register the sample procedural language:

```sql
CREATE FUNCTION plsample_call_handler() RETURNS language_handler
    AS 'filename'
    LANGUAGE C;
CREATE LANGUAGE plsample
    HANDLER plsample_call_handler;
```

Although providing a call handler is sufficient to create a minimal procedural language, there are two other functions that can optionally be provided to make the language more convenient to use. These are a validator and an inline handler. A validator can be provided to allow language-specific checking to be done during CREATE FUNCTION. An inline handler can be provided to allow the language to support anonymous code blocks executed via the DO command.
Chapter 53. Writing A Procedural Language Handler

If a validator is provided by a procedural language, it must be declared as a function taking a single parameter of type `oid`. The validator’s result is ignored, so it is customarily declared to return `void`. The validator will be called at the end of a `CREATE FUNCTION` command that has created or updated a function written in the procedural language. The passed-in OID is the OID of the function’s `pg_proc` row. The validator must fetch this row in the usual way, and do whatever checking is appropriate. First, call `CheckFunctionValidatorAccess()` to diagnose explicit calls to the validator that the user could not achieve through `CREATE FUNCTION`. Typical checks then include verifying that the function’s argument and result types are supported by the language, and that the function’s body is syntactically correct in the language. If the validator finds the function to be okay, it should just return. If it finds an error, it should report that via the normal `ereport()` error reporting mechanism. Throwing an error will force a transaction rollback and thus prevent the incorrect function definition from being committed.

Validator functions should typically honor the `check_function_bodies` parameter: if it is turned off then any expensive or context-sensitive checking should be skipped. If the language provides for code execution at compilation time, the validator must suppress checks that would induce such execution. In particular, this parameter is turned off by `pg_dump` so that it can load procedural language functions without worrying about side effects or dependencies of the function bodies on other database objects. (Because of this requirement, the call handler should avoid assuming that the validator has fully checked the function. The point of having a validator is not to let the call handler omit checks, but to notify the user immediately if there are obvious errors in a `CREATE FUNCTION` command.) While the choice of exactly what to check is mostly left to the discretion of the validator function, note that the core `CREATE FUNCTION` code only executes `SET` clauses attached to a function when `check_function_bodies` is on. Therefore, checks whose results might be affected by GUC parameters definitely should be skipped when `check_function_bodies` is off, to avoid false failures when reloading a dump.

If an inline handler is provided by a procedural language, it must be declared as a function taking a single parameter of type `internal`. The inline handler’s result is ignored, so it is customarily declared to return `void`. The inline handler will be called when a `DO` statement is executed specifying the procedural language. The parameter actually passed is a pointer to an `InlineCodeBlock` struct, which contains information about the `DO` statement’s parameters, in particular the text of the anonymous code block to be executed. The inline handler should execute this code and return.

It’s recommended that you wrap all these function declarations, as well as the `CREATE LANGUAGE` command itself, into an `extension` so that a simple `CREATE EXTENSION` command is sufficient to install the language. See Section 35.15 for information about writing extensions.

The procedural languages included in the standard distribution are good references when trying to write your own language handler. Look into the `src/pl` subdirectory of the source tree. The `CREATE LANGUAGE` reference page also has some useful details.
Chapter 54. Writing A Foreign Data Wrapper

All operations on a foreign table are handled through its foreign data wrapper, which consists of a set of functions that the core server calls. The foreign data wrapper is responsible for fetching data from the remote data source and returning it to the PostgreSQL executor. If updating foreign tables is to be supported, the wrapper must handle that, too. This chapter outlines how to write a new foreign data wrapper.

The foreign data wrappers included in the standard distribution are good references when trying to write your own. Look into the contrib subdirectory of the source tree. The CREATE FOREIGN DATA WRAPPER reference page also has some useful details.

Note: The SQL standard specifies an interface for writing foreign data wrappers. However, PostgreSQL does not implement that API, because the effort to accommodate it into PostgreSQL would be large, and the standard API hasn’t gained wide adoption anyway.

54.1. Foreign Data Wrapper Functions

The FDW author needs to implement a handler function, and optionally a validator function. Both functions must be written in a compiled language such as C, using the version-1 interface. For details on C language calling conventions and dynamic loading, see Section 35.9.

The handler function simply returns a struct of function pointers to callback functions that will be called by the planner, executor, and various maintenance commands. Most of the effort in writing an FDW is in implementing these callback functions. The handler function must be registered with PostgreSQL as taking no arguments and returning the special pseudo-type fdw_handler. The callback functions are plain C functions and are not visible or callable at the SQL level. The callback functions are described in Section 54.2.

The validator function is responsible for validating options given in CREATE and ALTER commands for its foreign data wrapper, as well as foreign servers, user mappings, and foreign tables using the wrapper. The validator function must be registered as taking two arguments, a text array containing the options to be validated, and an OID representing the type of object the options are associated with (in the form of the OID of the system catalog the object would be stored in, either ForeignDataWrapperRelationId, ForeignServerRelationId, UserMappingRelationId, or ForeignTableRelationId). If no validator function is supplied, options are not checked at object creation time or object alteration time.

54.2. Foreign Data Wrapper Callback Routines

The FDW handler function returns a malloc’d FdwRoutine struct containing pointers to the callback functions described below. The scan-related functions are required, the rest are optional.

The FdwRoutine struct type is declared in src/include/foreign/fdwapi.h, which see for additional details.
### 54.2.1. FDW Routines For Scanning Foreign Tables

```c
void GetForeignRelSize (PlannerInfo *root,
                     RelOptInfo *baserel,
                     Oid foreigntableid);
```

Obtain relation size estimates for a foreign table. This is called at the beginning of planning for a query that scans a foreign table. `root` is the planner’s global information about the query; `baserel` is the planner’s information about this table; and `foreigntableid` is the `pg_class` OID of the foreign table. (`foreigntableid` could be obtained from the planner data structures, but it’s passed explicitly to save effort.)

This function should update `baserel->rows` to be the expected number of rows returned by the table scan, after accounting for the filtering done by the restriction quals. The initial value of `baserel->rows` is just a constant default estimate, which should be replaced if at all possible. The function may also choose to update `baserel->width` if it can compute a better estimate of the average result row width.

See Section 54.4 for additional information.

```c
void GetForeignPaths (PlannerInfo *root,
                     RelOptInfo *baserel,
                     Oid foreigntableid);
```

Create possible access paths for a scan on a foreign table. This is called during query planning. The parameters are the same as for `GetForeignRelSize`, which has already been called.

This function must generate at least one access path (`ForeignPath` node) for a scan on the foreign table and must call `add_path` to add each such path to `baserel->pathlist`. It’s recommended to use `create_foreignscan_path` to build the `ForeignPath` nodes. The function can generate multiple access paths, e.g., a path which has valid `pathkeys` to represent a pre-sorted result. Each access path must contain cost estimates, and can contain any FDW-private information that is needed to identify the specific scan method intended.

See Section 54.4 for additional information.

```c
ForeignScan * GetForeignPlan (PlannerInfo *root,
                               RelOptInfo *baserel,
                               Oid foreigntableid,
                               ForeignPath *best_path,
                               List *tlist,
                               List *scan_clauses,
                               Plan *outer_plan);
```

Create a `ForeignScan` plan node from the selected foreign access path. This is called at the end of query planning. The parameters are as for `GetForeignRelSize`, plus the selected `ForeignPath` (previously produced by `GetForeignPaths` or `GetForeignJoinPaths`), the target list to be emitted by the plan node, the restriction clauses to be enforced by the plan node, and the outer subplan of the `ForeignScan`, which is used for rechecks performed by `RecheckForeignScan`. (If the path is for a join rather than a base relation, `foreigntableid` is `InvalidOid`.)

This function must create and return a `ForeignScan` plan node; it’s recommended to use `make_foreignscan` to build the `ForeignScan` node.
See Section 54.4 for additional information.

```c
void
BeginForeignScan (ForeignScanState *node, int eflags);
```

Begin executing a foreign scan. This is called during executor startup. It should perform any initialization needed before the scan can start, but not start executing the actual scan (that should be done upon the first call to `IterateForeignScan`). The `ForeignScanState` node has already been created, but its `fdw_state` field is still NULL. Information about the table to scan is accessible through the `ForeignScanState` node (in particular, from the underlying `ForeignScan` plan node, which contains any FDW-private information provided by `GetForeignPlan`). `eflags` contains flag bits describing the executor’s operating mode for this plan node.

Note that when `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for `ExplainForeignScan` and `EndForeignScan`.

```c
TupleTableSlot *
IterateForeignScan (ForeignScanState *node);
```

Fetch one row from the foreign source, returning it in a tuple table slot (the node’s `ScanTupleSlot` should be used for this purpose). Return NULL if no more rows are available. The tuple table slot infrastructure allows either a physical or virtual tuple to be returned; in most cases the latter choice is preferable from a performance standpoint. Note that this is called in a short-lived memory context that will be reset between invocations. Create a memory context in `BeginForeignScan` if you need longer-lived storage, or use the `es_query_cxt` of the node’s `EState`.

The rows returned must match the `fdw_scan_tlist` target list if one was supplied, otherwise they must match the row type of the foreign table being scanned. If you choose to optimize away fetching columns that are not needed, you should insert nulls in those column positions, or else generate a `fdw_scan_tlist` list with those columns omitted.

Note that PostgreSQL’s executor doesn’t care whether the rows returned violate any constraints that were defined on the foreign table — but the planner does care, and may optimize queries incorrectly if there are rows visible in the foreign table that do not satisfy a declared constraint. If a constraint is violated when the user has declared that the constraint should hold true, it may be appropriate to raise an error (just as you would need to do in the case of a data type mismatch).

```c
void
ReScanForeignScan (ForeignScanState *node);
```

Restart the scan from the beginning. Note that any parameters the scan depends on may have changed value, so the new scan does not necessarily return exactly the same rows.

```c
void
EndForeignScan (ForeignScanState *node);
```

End the scan and release resources. It is normally not important to release palloc’d memory, but for example open files and connections to remote servers should be cleaned up.
54.2.2. FDW Routines For Scanning Foreign Joins

If an FDW supports performing foreign joins remotely (rather than by fetching both tables’ data and doing the join locally), it should provide this callback function:

```c
void
GetForeignJoinPaths (PlannerInfo *root,
   RelOptInfo *joinrel,
   RelOptInfo *outerrel,
   RelOptInfo *innerrel,
   JoinType jointype,
   JoinPathExtraData *extra);
```

Create possible access paths for a join of two (or more) foreign tables that all belong to the same foreign server. This optional function is called during query planning. As with `GetForeignPaths`, this function should generate `ForeignPath` path(s) for the supplied `joinrel`, and call `add_path` to add these paths to the set of paths considered for the join. But unlike `GetForeignPaths`, it is not necessary that this function succeed in creating at least one path, since paths involving local joining are always possible.

Note that this function will be invoked repeatedly for the same join relation, with different combinations of inner and outer relations; it is the responsibility of the FDW to minimize duplicated work.

If a `ForeignPath` path is chosen for the join, it will represent the entire join process; paths generated for the component tables and subsidiary joins will not be used. Subsequent processing of the join path proceeds much as it does for a path scanning a single foreign table. One difference is that the `scanrelid` of the resulting `ForeignScan` plan node should be set to zero, since there is no single relation that it represents; instead, the `fs_relids` field of the `ForeignScan` node represents the set of relations that were joined. (The latter field is set up automatically by the core planner code, and need not be filled by the FDW.) Another difference is that, because the column list for a remote join cannot be found from the system catalogs, the FDW must fill `fdw_scan_tlist` with an appropriate list of `TargetEntry` nodes, representing the set of columns it will supply at run time in the tuples it returns.

See Section 54.4 for additional information.

54.2.3. FDW Routines For Updating Foreign Tables

If an FDW supports writable foreign tables, it should provide some or all of the following callback functions depending on the needs and capabilities of the FDW:

```c
void
AddForeignUpdateTargets (Query *parsetree,
   RangeTblEntry *target_rte,
   Relation target_relation);
```

`UPDATE` and `DELETE` operations are performed against rows previously fetched by the table-scanning functions. The FDW may need extra information, such as a row ID or the values of primary-key columns, to ensure that it can identify the exact row to update or delete. To support that, this function can add extra hidden, or “junk”, target columns to the list of columns that are to be retrieved from the foreign table during an `UPDATE` or `DELETE`.

To do that, add `TargetEntry` items to `parsetree->targetList`, containing expressions for the extra values to be fetched. Each such entry must be marked `resjunk = true`, and must have a distinct `resname` that will identify it at execution time. Avoid using names matching `ctidW`, `wholerow`, or
wholerowN, as the core system can generate junk columns of these names. If the extra expressions are more complex than simple Vars, they must be run through eval_const_expressions before adding them to the targetlist.

Although this function is called during planning, the information provided is a bit different from that available to other planning routines. parsetree is the parse tree for the UPDATE or DELETE command, while target_rte and target_relation describe the target foreign table.

If the AddForeignUpdateTargets pointer is set to NULL, no extra target expressions are added. (This will make it impossible to implement DELETE operations, though UPDATE may still be feasible if the FDW relies on an unchanging primary key to identify rows.)

List *
PlanForeignModify (PlannerInfo *root,
                      ModifyTable *plan,
                      Index resultRelation,
                      int subplan_index);

Perform any additional planning actions needed for an insert, update, or delete on a foreign table. This function generates the FDW-private information that will be attached to the ModifyTable plan node that performs the update action. This private information must have the form of a List, and will be delivered to BeginForeignModify during the execution stage.

root is the planner’s global information about the query. plan is the ModifyTable plan node, which is complete except for the fdwPrivLists field. resultRelation identifies the target foreign table by its range table index. subplan_index identifies which target of the ModifyTable plan node this is, counting from zero; use this if you want to index into plan->plans or other substructure of the plan node.

See Section 54.4 for additional information.

If the PlanForeignModify pointer is set to NULL, no additional plan-time actions are taken, and the fdw_private list delivered to BeginForeignModify will be NIL.

void
BeginForeignModify (ModifyTableState *mtstate,
                     ResultRelInfo *rinfo,
                     List *fdw_private,
                     int subplan_index,
                     int eflags);

Begin executing a foreign table modification operation. This routine is called during executor startup. It should perform any initialization needed prior to the actual table modifications. Subsequently, ExecForeignInsert, ExecForeignUpdate or ExecForeignDelete will be called for each tuple to be inserted, updated, or deleted.

mtstate is the overall state of the ModifyTable plan node being executed; global data about the plan and execution state is available via this structure. rinfo is the ResultRelInfo struct describing the target foreign table. (The ri_FdwState field of ResultRelInfo is available for the FDW to store any private state it needs for this operation.) fdw_private contains the private data generated by PlanForeignModify, if any. subplan_index identifies which target of the ModifyTable plan node this is. eflags contains flag bits describing the executor’s operating mode for this plan node.

Note that when (eflags & EXEC_FLAG_EXPLAIN_ONLY) is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for ExplainForeignModify and EndForeignModify.

If the BeginForeignModify pointer is set to NULL, no action is taken during executor startup.
TupleTableSlot *
ExecForeignInsert (EState *estate,
    ResultRelInfo *rinfo,
    TupleTableSlot *slot,
    TupleTableSlot *planSlot);

Insert one tuple into the foreign table. estate is global execution state for the query. rinfo is the ResultRelInfo struct describing the target foreign table. slot contains the tuple to be inserted; it will match the row-type definition of the foreign table. planSlot contains the tuple that was generated by the ModifyTable plan node’s subplan; it differs from slot in possibly containing additional “junk” columns. (The planSlot is typically of little interest for INSERT cases, but is provided for completeness.)

The return value is either a slot containing the data that was actually inserted (this might differ from the data supplied, for example as a result of trigger actions), or NULL if no row was actually inserted (again, typically as a result of triggers). The passed-in slot can be re-used for this purpose.

The data in the returned slot is used only if the INSERT query has a RETURNING clause or the foreign table has an AFTER ROW trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the RETURNING clause. Regardless, some slot must be returned to indicate success, or the query’s reported row count will be wrong.

If the ExecForeignInsert pointer is set to NULL, attempts to insert into the foreign table will fail with an error message.

TupleTableSlot *
ExecForeignUpdate (EState *estate,
    ResultRelInfo *rinfo,
    TupleTableSlot *slot,
    TupleTableSlot *planSlot);

Update one tuple in the foreign table. estate is global execution state for the query. rinfo is the ResultRelInfo struct describing the target foreign table. slot contains the new data for the tuple; it will match the row-type definition of the foreign table. planSlot contains the tuple that was generated by the ModifyTable plan node’s subplan; it differs from slot in possibly containing additional “junk” columns. In particular, any junk columns that were requested by AddForeignUpdateTargets will be available from this slot.

The return value is either a slot containing the row as it was actually updated (this might differ from the data supplied, for example as a result of trigger actions), or NULL if no row was actually updated (again, typically as a result of triggers). The passed-in slot can be re-used for this purpose.

The data in the returned slot is used only if the UPDATE query has a RETURNING clause or the foreign table has an AFTER ROW trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the RETURNING clause. Regardless, some slot must be returned to indicate success, or the query’s reported row count will be wrong.

If the ExecForeignUpdate pointer is set to NULL, attempts to update the foreign table will fail with an error message.

TupleTableSlot *
ExecForeignDelete (EState *estate,
    ResultRelInfo *rinfo,
    TupleTableSlot *slot,
    TupleTableSlot *planSlot);
Chapter 54. Writing A Foreign Data Wrapper

Delete one tuple from the foreign table. estate is global execution state for the query. rinfo is the ResultRelInfo struct describing the target foreign table. slot contains nothing useful upon call, but can be used to hold the returned tuple. planSlot contains the tuple that was generated by the ModifyTable plan node’s subplan; in particular, it will carry any junk columns that were requested by AddForeignUpdateTargets. The junk column(s) must be used to identify the tuple to be deleted.

The return value is either a slot containing the row that was deleted, or NULL if no row was deleted (typically as a result of triggers). The passed-in slot can be used to hold the tuple to be returned.

The data in the returned slot is used only if the DELETE query has a RETURNING clause or the foreign table has an AFTER ROW trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the RETURNING clause. Regardless, some slot must be returned to indicate success, or the query’s reported row count will be wrong.

If the ExecForeignDelete pointer is set to NULL, attempts to delete from the foreign table will fail with an error message.

```c
void
EndForeignModify (EState *estate,
                  ResultRelInfo *rinfo);
```

End the table update and release resources. It is normally not important to release palloc’d memory, but for example open files and connections to remote servers should be cleaned up.

If the EndForeignModify pointer is set to NULL, no action is taken during executor shutdown.

```c
int
IsForeignRelUpdatable (Relation rel);
```

Report which update operations the specified foreign table supports. The return value should be a bit mask of rule event numbers indicating which operations are supported by the foreign table, using the CmdType enumeration; that is, \((1 << \text{CMD\_UPDATE}) = 4\) for UPDATE, \((1 << \text{CMD\_INSERT}) = 8\) for INSERT, and \((1 << \text{CMD\_DELETE}) = 16\) for DELETE.

If the IsForeignRelUpdatable pointer is set to NULL, foreign tables are assumed to be insertable, updatable, or deletable if the FDW provides ExecForeignInsert, ExecForeignUpdate, or ExecForeignDelete respectively. This function is only needed if the FDW supports some tables that are updatable and some that are not. (Even then, it’s permissible to throw an error in the execution routine instead of checking in this function. However, this function is used to determine updatability for display in the information_schema views.)

### 54.2.4. FDW Routines For Row Locking

If an FDW wishes to support late row locking (as described in Section 54.5), it must provide the following callback functions:

```c
RowMarkType
GetForeignRowMarkType (RangeTblEntry *rte,
                       LockClauseStrength strength);
```

Report which row-marking option to use for a foreign table. rte is the RangeTblEntry node for the table and strength describes the lock strength requested by the relevant FOR UPDATE/SHARE clause, if any. The result must be a member of the RowMarkType enum type.
This function is called during query planning for each foreign table that appears in an UPDATE, DELETE, or SELECT FOR UPDATE/SHARE query and is not the target of UPDATE or DELETE.

If the GetForeignRowMarkType pointer is set to NULL, the ROW_MARK_COPY option is always used. (This implies that RefetchForeignRow will never be called, so it need not be provided either.)

See Section 54.5 for more information.

HeapTuple
RefetchForeignRow (EState *estate,
                    ExecRowMark *erm,
                    Datum rowid,
                    bool *updated);

Re-fetch one tuple from the foreign table, after locking it if required. estate is global execution state for the query. erm is the ExecRowMark struct describing the target foreign table and the row lock type (if any) to acquire. rowid identifies the tuple to be fetched. updated is an output parameter.

This function should return a palloc’ed copy of the fetched tuple, or NULL if the row lock couldn’t be obtained. The row lock type to acquire is defined by erm->markType, which is the value previously returned by GetForeignRowMarkType. (ROW_MARK_REFERENCE means to just re-fetch the tuple without acquiring any lock, and ROW_MARK_COPY will never be seen by this routine.)

In addition, *updated should be set to true if what was fetched was an updated version of the tuple rather than the same version previously obtained. (If the FDW cannot be sure about this, always returning true is recommended.)

Note that by default, failure to acquire a row lock should result in raising an error; a NULL return is only appropriate if the SKIP LOCKED option is specified by erm->waitPolicy.

The rowid is the ctid value previously read for the row to be re-fetched. Although the rowid value is passed as a Datum, it can currently only be a tid. The function API is chosen in hopes that it may be possible to allow other data types for row IDs in future.

If the RefetchForeignRow pointer is set to NULL, attempts to re-fetch rows will fail with an error message.

See Section 54.5 for more information.

bool
RecheckForeignScan (ForeignScanState *node, TupleTableSlot *slot);

Recheck that a previously-returned tuple still matches the relevant scan and join qualifiers, and possibly provide a modified version of the tuple. For foreign data wrappers which do not perform join pushdown, it will typically be more convenient to set this to NULL and instead set fdw_recheck_quals appropriately. When outer joins are pushed down, however, it isn’t sufficient to reapply the checks relevant to all the base tables to the result tuple, even if all needed attributes are present, because failure to match some qualifier might result in some attributes going to NULL, rather than in no tuple being returned. RecheckForeignScan can recheck qualifiers and return true if they are still satisfied and false otherwise, but it can also store a replacement tuple into the supplied slot.

To implement join pushdown, a foreign data wrapper will typically construct an alternative local join plan which is used only for rechecks; this will become the outer subplan of the ForeignScan. When a recheck is required, this subplan can be executed and the resulting tuple can be stored in the slot. This plan need not be efficient since no base table will return more than one row; for example, it may implement all joins as nested loops.
54.2.5. FDW Routines for EXPLAIN

```c
void ExplainForeignScan (ForeignScanState *node,
            ExplainState *es);
```

Print additional EXPLAIN output for a foreign table scan. This function can call ExplainPropertyText and related functions to add fields to the EXPLAIN output. The flag fields in es can be used to determine what to print, and the state of the ForeignScanState node can be inspected to provide run-time statistics in the EXPLAIN ANALYZE case.

If the ExplainForeignScan pointer is set to NULL, no additional information is printed during EXPLAIN.

```c
void ExplainForeignModify (ModifyTableState *mtstate,
                        ResultRelInfo *rinfo,
                        List *fdw_private,
                        int subplan_index,
                        struct ExplainState *es);
```

Print additional EXPLAIN output for a foreign table update. This function can call ExplainPropertyText and related functions to add fields to the EXPLAIN output. The flag fields in es can be used to determine what to print, and the state of the ModifyTableState node can be inspected to provide run-time statistics in the EXPLAIN ANALYZE case. The first four arguments are the same as for BeginForeignModify.

If the ExplainForeignModify pointer is set to NULL, no additional information is printed during EXPLAIN.

54.2.6. FDW Routines for ANALYZE

```c
bool AnalyzeForeignTable (Relation relation,
                     AcquireSampleRowsFunc *func,
                     BlockNumber *totalpages);
```

This function is called when ANALYZE is executed on a foreign table. If the FDW can collect statistics for this foreign table, it should return true, and provide a pointer to a function that will collect sample rows from the table in func, plus the estimated size of the table in pages in totalpages. Otherwise, return false.

If the FDW does not support collecting statistics for any tables, the AnalyzeForeignTable pointer can be set to NULL.

If provided, the sample collection function must have the signature

```c
int AcquireSampleRowsFunc (Relation relation, int elevel,
                    HeapTuple *rows, int targrows,
                    double *totalrows,
                    double *totaldeadrows);
```

A random sample of up to targrows rows should be collected from the table and stored into the caller-provided rows array. The actual number of rows collected must be returned. In addition, store
estimates of the total numbers of live and dead rows in the table into the output parameters totalrows and totaldeadrows. (Set totaldeadrows to zero if the FDW does not have any concept of dead rows.)

### 54.2.7. FDW Routines For IMPORT FOREIGN SCHEMA

```c
List *
ImportForeignSchema (ImportForeignSchemaStmt *stmt, Oid serverOid);
```

Obtain a list of foreign table creation commands. This function is called when executing IMPORT FOREIGN SCHEMA, and is passed the parse tree for that statement, as well as the OID of the foreign server to use. It should return a list of C strings, each of which must contain a CREATE FOREIGN TABLE command. These strings will be parsed and executed by the core server.

Within the `ImportForeignSchemaStmt` struct, `remote_schema` is the name of the remote schema from which tables are to be imported. `list_type` identifies how to filter table names: `FDW_IMPORT_SCHEMA_ALL` means that all tables in the remote schema should be imported (in this case `table_list` is empty), `FDW_IMPORT_SCHEMA_LIMIT_TO` means to include only tables listed in `table_list`, and `FDW_IMPORT_SCHEMA_EXCEPT` means to exclude the tables listed in `table_list`. `options` is a list of options used for the import process. The meanings of the options are up to the FDW. For example, an FDW could use an option to define whether the NOT NULL attributes of columns should be imported. These options need not have anything to do with those supported by the FDW as database object options.

The FDW may ignore the `local_schema` field of the `ImportForeignSchemaStmt`, because the core server will automatically insert that name into the parsed CREATE FOREIGN TABLE commands.

The FDW does not have to concern itself with implementing the filtering specified by `list_type` and `table_list`, either, as the core server will automatically skip any returned commands for tables excluded according to those options. However, it’s often useful to avoid the work of creating commands for excluded tables in the first place. The function `IsImportableForeignTable()` may be useful to test whether a given foreign-table name will pass the filter.

If the FDW does not support importing table definitions, the `ImportForeignSchema` pointer can be set to NULL.

### 54.3. Foreign Data Wrapper Helper Functions

Several helper functions are exported from the core server so that authors of foreign data wrappers can get easy access to attributes of FDW-related objects, such as FDW options. To use any of these functions, you need to include the header file `foreign/foreign.h` in your source file. That header also defines the struct types that are returned by these functions.

```c
ForeignDataWrapper *
GetForeignDataWrapper(Oid fdwid);
```

This function returns a `ForeignDataWrapper` object for the foreign-data wrapper with the given OID. A `ForeignDataWrapper` object contains properties of the FDW (see `foreign/foreign.h` for details).
GetForeignServer(Oid serverid);

This function returns a ForeignServer object for the foreign server with the given OID. A ForeignServer object contains properties of the server (see foreign/foreign.h for details).

UserMapping *
GetUserMapping(Oid userid, Oid serverid);

This function returns a UserMapping object for the user mapping of the given role on the given server. (If there is no mapping for the specific user, it will return the mapping for PUBLIC, or throw error if there is none.) A UserMapping object contains properties of the user mapping (see foreign/foreign.h for details).

ForeignTable *
GetForeignTable(Oid relid);

This function returns a ForeignTable object for the foreign table with the given OID. A ForeignTable object contains properties of the foreign table (see foreign/foreign.h for details).

List *
GetForeignColumnOptions(Oid relid, AttrNumber attnum);

This function returns the per-column FDW options for the column with the given foreign table OID and attribute number, in the form of a list of DefElem. NIL is returned if the column has no options.

Some object types have name-based lookup functions in addition to the OID-based ones:

ForeignDataWrapper *
GetForeignDataWrapperByName(const char *name, bool missing_ok);

This function returns a ForeignDataWrapper object for the foreign-data wrapper with the given name. If the wrapper is not found, return NULL if missing_ok is true, otherwise raise an error.

ForeignServer *
GetForeignServerByName(const char *name, bool missing_ok);

This function returns a ForeignServer object for the foreign server with the given name. If the server is not found, return NULL if missing_ok is true, otherwise raise an error.

54.4. Foreign Data Wrapper Query Planning

The FDW callback functions GetForeignRelSize, GetForeignPaths, GetForeignPlan, PlanForeignModify, and GetForeignJoinPaths must fit into the workings of the PostgreSQL planner. Here are some notes about what they must do.

The information in root and baserel can be used to reduce the amount of information that has to be fetched from the foreign table (and therefore reduce the cost). baserel->baserestrictinfo is particularly interesting, as it contains restriction quals (WHERE clauses) that should be used to filter the rows to be fetched. (The FDW itself is not required to enforce these quals, as the core executor can check them instead.) baserel->reltargetlist can be used to determine which columns need to be fetched; but note that it only lists columns that have to be emitted by the ForeignScan plan node, not columns that are used in qual evaluation but not output by the query.
Various private fields are available for the FDW planning functions to keep information in. Generally, whatever you store in FDW private fields should be palloc’d, so that it will be reclaimed at the end of planning.

*baserel-*->fdw_private is a void pointer that is available for FDW planning functions to store information relevant to the particular foreign table. The core planner does not touch it except to initialize it to NULL when the RelOptInfo node is created. It is useful for passing information forward from GetForeignRelSize to GetForeignPaths and/or GetForeignPaths to GetForeignPlan, thereby avoiding recalculation.

GetForeignPaths can identify the meaning of different access paths by storing private information in the fdw_private field of ForeignPath nodes. fdw_private is declared as a List pointer, but could actually contain anything since the core planner does not touch it. However, best practice is to use a representation that’s dumpable by nodeToString, for use with debugging support available in the backend.

GetForeignPlan can examine the fdw_private field of the selected ForeignPath node, and can generate fdw_exprs and fdw_private lists to be placed in the ForeignScan plan node, where they will be available at execution time. Both of these lists must be represented in a form that copyObject knows how to copy. The fdw_private list has no other restrictions and is not interpreted by the core backend in any way. The fdw_exprs list, if not NIL, is expected to contain expression trees that are intended to be executed at run time. These trees will undergo post-processing by the planner to make them fully executable.

In GetForeignPlan, generally the passed-in target list can be copied into the plan node as-is. The passed scan_clauses list contains the same clauses as baserel-*->baserestrictinfo, but may be re-ordered for better execution efficiency. In simple cases the FDW can just strip RestrictInfo nodes from the scan_clauses list (using extract_actual_clauses) and put all the clauses into the plan node’s qual list, which means that all the clauses will be checked by the executor at run time. More complex FDWs may be able to check some of the clauses internally, in which case those clauses can be removed from the plan node’s qual list so that the executor doesn’t waste time rechecking them.

As an example, the FDW might identify some restriction clauses of the form foreign_variable = sub_expression, which it determines can be executed on the remote server given the locally-evaluated value of the sub_expression. The actual identification of such a clause should happen during GetForeignPaths, since it would affect the cost estimate for the path. The path’s fdw_private field would probably include a pointer to the identified clause’s RestrictInfo node. Then GetForeignPlan would remove that clause from scan_clauses, but add the sub_expression to fdw_exprs to ensure that it gets massaged into executable form. It would probably also put control information into the plan node’s fdw_private field to tell the execution functions what to do at run time. The query transmitted to the remote server would involve something like WHERE foreign_variable = $1, with the parameter value obtained at run time from evaluation of the fdw_exprs expression tree.

Any clauses removed from the plan node’s qual list must instead be added to fdw_recheck_quals or rechecked by RecheckForeignScan in order to ensure correct behavior at the READ COMMITTED isolation level. When a concurrent update occurs for some other table involved in the query, the executor may need to verify that all of the original quals are still satisfied for the tuple, possibly against a different set of parameter values. Using fdw_recheck_quals is typically easier than implementing checks inside RecheckForeignScan, but this method will be insufficient when outer joins have been pushed down, since the join tuples in that case might have some fields go to NULL without rejecting the tuple entirely.

Another ForeignScan field that can be filled by FDWs is fdw_scan_tlist, which describes the tuples returned by the FDW for this plan node. For simple foreign table scans this can be set to NIL, implying that the returned tuples have the row type declared for the foreign table. A non-NIL value...
must be a target list (list of TargetEntry)s containing Vars and/or expressions representing the returned columns. This might be used, for example, to show that the FDW has omitted some columns that it noticed won’t be needed for the query. Also, if the FDW can compute expressions used by the query more cheaply than can be done locally, it could add those expressions to \texttt{fdw\_scan\_tlist}. Note that join plans (created from paths made by \texttt{GetForeignJoinPaths}) must always supply \texttt{fdw\_scan\_tlist} to describe the set of columns they will return.

The FDW should always construct at least one path that depends only on the table’s restriction clauses. In join queries, it might also choose to construct path(s) that depend on join clauses, for example \texttt{foreign\_variable = local\_variable}. Such clauses will not be found in baserel->baserestrictinfo but must be sought in the relation’s join lists. A path using such a clause is called a “parameterized path”. It must identify the other relations used in the selected join clause(s) with a suitable value of \texttt{param\_info}; use \texttt{get\_baserel\_parampathinfo} to compute that value. In \texttt{GetForeignPlan}, the \texttt{local\_variable} portion of the join clause would be added to \texttt{fdw\_exprs}, and then at run time the case works the same as for an ordinary restriction clause.

If an FDW supports remote joins, \texttt{GetForeignJoinPaths} should produce \texttt{ForeignPath}s for potential remote joins in much the same way as \texttt{GetForeignPaths} works for base tables. Information about the intended join can be passed forward to \texttt{GetForeignPlan} in the same ways described above. However, \texttt{baserestrictinfo} is not relevant for join relations; instead, the relevant join clauses for a particular join are passed to \texttt{GetForeignJoinPaths} as a separate parameter (\texttt{extra->restrictlist}).

When planning an \texttt{UPDATE} or \texttt{DELETE}, \texttt{PlanForeignModify} can look up the \texttt{RelOptInfo} struct for the foreign table and make use of the baserel->fdw_private data previously created by the scan-planning functions. However, in \texttt{INSERT} the target table is not scanned so there is no \texttt{RelOptInfo} for it. The \texttt{List} returned by \texttt{PlanForeignModify} has the same restrictions as the \texttt{fdw\_private} list of a \texttt{ForeignScan} plan node, that is it must contain only structures that \texttt{copyObject} knows how to copy.

\texttt{INSERT} with an \texttt{ON CONFLICT} clause does not support specifying the conflict target, as unique constraints or exclusion constraints on remote tables are not locally known. This in turn implies that \texttt{ON CONFLICT DO UPDATE} is not supported, since the specification is mandatory there.

## 54.5. Row Locking in Foreign Data Wrappers

If an FDW’s underlying storage mechanism has a concept of locking individual rows to prevent concurrent updates of those rows, it is usually worthwhile for the FDW to perform row-level locking with as close an approximation as practical to the semantics used in ordinary PostgreSQL tables. There are multiple considerations involved in this.

One key decision to be made is whether to perform early locking or late locking. In early locking, a row is locked when it is first retrieved from the underlying store, while in late locking, the row is locked only when it is known that it needs to be locked. (The difference arises because some rows may be discarded by locally-checked restriction or join conditions.) Early locking is much simpler and avoids extra round trips to a remote store, but it can cause locking of rows that need not have been locked, resulting in reduced concurrency or even unexpected deadlocks. Also, late locking is only possible if the row to be locked can be uniquely re-identified later. Preferably the row identifier should identify a specific version of the row, as PostgreSQL TIDs do.

By default, PostgreSQL ignores locking considerations when interfacing to FDWs, but an FDW can perform early locking without any explicit support from the core code. The API functions described in Section 54.2.4, which were added in PostgreSQL 9.5, allow an FDW to use late locking if it wishes.
Chapter 54. Writing A Foreign Data Wrapper

An additional consideration is that in READ COMMITTED isolation mode, PostgreSQL may need to re-check restriction and join conditions against an updated version of some target tuple. Rechecking join conditions requires re-obtaining copies of the non-target rows that were previously joined to the target tuple. When working with standard PostgreSQL tables, this is done by including the TIDs of the non-target tables in the column list projected through the join, and then re-fetching non-target rows when required. This approach keeps the join data set compact, but it requires inexpensive re-fetch capability, as well as a TID that can uniquely identify the row version to be re-fetched. By default, therefore, the approach used with foreign tables is to include a copy of the entire row fetched from a foreign table in the column list projected through the join. This puts no special demands on the FDW but can result in reduced performance of merge and hash joins. An FDW that is capable of meeting the re-fetch requirements can choose to do it the first way.

For an UPDATE or DELETE on a foreign table, it is recommended that the ForeignScan operation on the target table perform early locking on the rows that it fetches, perhaps via the equivalent of SELECT FOR UPDATE. An FDW can detect whether a table is an UPDATE/DELETE target at plan time by comparing its relid to root->parse->resultRelation, or at execution time by using ExecRelationIsTargetRelation(). An alternative possibility is to perform late locking within the ExecForeignUpdate or ExecForeignDelete callback, but no special support is provided for this.

For foreign tables that are specified to be locked by a SELECT FOR UPDATE/SHARE command, the ForeignScan operation can again perform early locking by fetching tuples with the equivalent of SELECT FOR UPDATE. To perform late locking instead, provide the callback functions defined in Section 54.2.4. In GetForeignRowMarkType, select rowmark option ROW_MARK_EXCLUSIVE, ROW_MARK_NOKEYEXCLUSIVE, ROW_MARK_SHARE, or ROW_MARK_KEYSHARE depending on the requested lock strength. (The core code will act the same regardless of which of these four options you choose.) Elsewhere, you can detect whether a foreign table was specified to be locked by this type of command by using get_plan_rowmark at plan time, or ExecFindRowMark at execution time; you must check not only whether a non-null rowmark struct is returned, but that its strength field is not LCS_NONE.

Lastly, for foreign tables that are used in an UPDATE, DELETE or SELECT FOR UPDATE/SHARE command but are not specified to be row-locked, you can override the default choice to copy entire rows by having GetForeignRowMarkType select option ROW_MARK_REFERENCE when it sees lock strength LCS_NONE. This will cause RefetchForeignRow to be called with that value for markType; it should then re-fetch the row without acquiring any new lock. (If you have a GetForeignRowMarkType function but don’t wish to re-fetch unlocked rows, select option ROW_MARK_COPY for LCS_NONE.)

See src/include/nodes/lockoptions.h, the comments for RowMarkType and PlanRowMark in src/include/nodes/plannodes.h, and the comments for ExecRowMark in src/include/nodes/execnodes.h for additional information.
Chapter 55. Writing A Table Sampling Method

PostgreSQL’s implementation of the `TABLESAMPLE` clause supports custom table sampling methods, in addition to the `BERNOULLI` and `SYSTEM` methods that are required by the SQL standard. The sampling method determines which rows of the table will be selected when the `TABLESAMPLE` clause is used.

At the SQL level, a table sampling method is represented by a single SQL function, typically implemented in C, having the signature

```
method_name(internal) RETURNS tsm_handler
```

The name of the function is the same method name appearing in the `TABLESAMPLE` clause. The `internal` argument is a dummy (always having value zero) that simply serves to prevent this function from being called directly from a SQL command. The result of the function must be a `palloc`ed struct of type `TsmRoutine`, which contains pointers to support functions for the sampling method. These support functions are plain C functions and are not visible or callable at the SQL level. The support functions are described in Section 55.1.

In addition to function pointers, the `TsmRoutine` struct must provide these additional fields:

- `List *parameterTypes`
  - This is an OID list containing the data type OIDs of the parameter(s) that will be accepted by the `TABLESAMPLE` clause when this sampling method is used. For example, for the built-in methods, this list contains a single item with value `FLOAT4OID`, which represents the sampling percentage. Custom sampling methods can have more or different parameters.

- `bool repeatable_across_queries`
  - If `true`, the sampling method can deliver identical samples across successive queries, if the same parameters and `REPEATABLE` seed value are supplied each time and the table contents have not changed. When this is `false`, the `REPEATABLE` clause is not accepted for use with the sampling method.

- `bool repeatable_across_scans`
  - If `true`, the sampling method can deliver identical samples across successive scans in the same query (assuming unchanging parameters, seed value, and snapshot). When this is `false`, the planner will not select plans that would require scanning the sampled table more than once, since that might result in inconsistent query output.

The `TsmRoutine` struct type is declared in `src/include/access/tsmapi.h`, which see for additional details.

The table sampling methods included in the standard distribution are good references when trying to write your own. Look into the `src/backend/access/tablesample` subdirectory of the source tree for the built-in sampling methods, and into the `contrib` subdirectory for add-on methods.

55.1. Sampling Method Support Functions

The TSM handler function returns a `palloc`ed `TsmRoutine` struct containing pointers to the support functions described below. Most of the functions are required, but some are optional, and those point-
void SampleScanGetSampleSize (PlannerInfo *root, 
    RelOptInfo *baserel, 
    List *paramexprs, 
    BlockNumber *pages, 
    double *tuples);

This function is called during planning. It must estimate the number of relation pages that will be read 
during a sample scan, and the number of tuples that will be selected by the scan. (For example, these 
might be determined by estimating the sampling fraction, and then multiplying the baserel->pages 
and baserel->tuples numbers by that, being sure to round the results to integral values.) The 
paramexprs list holds the expression(s) that are parameters to the TABLESAMPLE clause. It is recom-
mended to use estimate_expression_value() to try to reduce these expressions to constants, if 
their values are needed for estimation purposes; but the function must provide size estimates even if 
they cannot be reduced, and it should not fail even if the values appear invalid (remember that they’re 
only estimates of what the run-time values will be). The pages and tuples parameters are outputs.

void InitSampleScan (SampleScanState *node, 
    int eflags);

Initialize for execution of a SampleScan plan node. This is called during executor startup. It should 
perform any initialization needed before processing can start. The SampleScanState node has 
already been created, but its tsm_state field is NULL. The InitSampleScan function can 
palloc whatever internal state data is needed by the sampling method, and store a pointer to it in 
node->tsm_state. Information about the table to scan is accessible through other fields of the 
SampleScanState node (but note that the node->ss.ss_currentScanDesc scan descriptor is 
not set up yet). eflags contains flag bits describing the executor’s operating mode for this plan 
node.

When (eflags & EXEC_FLAG_EXPLAIN_ONLY) is true, the scan will not actually be performed, 
so this function should only do the minimum required to make the node state valid for EXPLAIN and 
EndSampleScan.

This function can be omitted (set the pointer to NULL), in which case BeginSampleScan must 
perform all initialization needed by the sampling method.

void BeginSampleScan (SampleScanState *node, 
    Datum *params, 
    int nparams, 
    uint32 seed);

Begin execution of a sampling scan. This is called just before the first attempt to fetch a tuple, and 
may be called again if the scan needs to be restarted. Information about the table to scan is accessible 
through fields of the SampleScanState node (but note that the node->ss.ss_currentScanDesc 
scan descriptor is not set up yet). The params array, of length nparams, contains the values of the 
parameters supplied in the TABLESAMPLE clause. These will have the number and types specified in 
the sampling method’s parameterTypes list, and have been checked to not be null. seed contains a 
seed to use for any random numbers generated within the sampling method; it is either a hash derived 
from the REPEATABLE value if one was given, or the result of random() if not.
This function may adjust the fields `node->use_bulkread` and `node->use_pagemode`. If `node->use_bulkread` is true, which it is by default, the scan will use a buffer access strategy that encourages recycling buffers after use. It might be reasonable to set this to false if the scan will visit only a small fraction of the table’s pages. If `node->use_pagemode` is true, which it is by default, the scan will perform visibility checking in a single pass for all tuples on each visited page. It might be reasonable to set this to false if the scan will select only a small fraction of the tuples on each visited page. That will result in fewer tuple visibility checks being performed, though each one will be more expensive because it will require more locking.

If the sampling method is marked `repeatable_across_scans`, it must be able to select the same set of tuples during a rescan as it did originally, that is a fresh call of `BeginSampleScan` must lead to selecting the same tuples as before (if the `TABLESAMPLE` parameters and seed don’t change).

```c
BlockNumber
NextSampleBlock (SampleScanState *node);
```

Returns the block number of the next page to be scanned, or `InvalidBlockNumber` if no pages remain to be scanned.

This function can be omitted (set the pointer to NULL), in which case the core code will perform a sequential scan of the entire relation. Such a scan can use synchronized scanning, so that the sampling method cannot assume that the relation pages are visited in the same order on each scan.

```c
OffsetNumber
NextSampleTuple (SampleScanState *node, BlockNumber blockno, OffsetNumber maxoffset);
```

Returns the offset number of the next tuple to be sampled on the specified page, or `InvalidOffsetNumber` if no tuples remain to be sampled. `maxoffset` is the largest offset number in use on the page.

**Note:** `NextSampleTuple` is not explicitly told which of the offset numbers in the range 1 .. `maxoffset` actually contain valid tuples. This is not normally a problem since the core code ignores requests to sample missing or invisible tuples; that should not result in any bias in the sample. However, if necessary, the function can examine `node->ss.ss_currentScanDesc->rs_vistuples[]` to identify which tuples are valid and visible. (This requires `node->use_pagemode` to be true.)

**Note:** `NextSampleTuple` must not assume that `blockno` is the same page number returned by the most recent `NextSampleBlock` call. It was returned by some previous `NextSampleBlock` call, but the core code is allowed to call `NextSampleBlock` in advance of actually scanning pages, so as to support prefetching. It is OK to assume that once sampling of a given page begins, successive `NextSampleTuple` calls all refer to the same page until `InvalidOffsetNumber` is returned.

```c
void
EndSampleScan (SampleScanState *node);
```

End the scan and release resources. It is normally not important to release palloc’d memory, but any externally-visible resources should be cleaned up. This function can be omitted (set the pointer to NULL) in the common case where no such resources exist.
Chapter 56. Writing A Custom Scan Provider

PostgreSQL supports a set of experimental facilities which are intended to allow extension modules to add new scan types to the system. Unlike a foreign data wrapper, which is only responsible for knowing how to scan its own foreign tables, a custom scan provider can provide an alternative method of scanning any relation in the system. Typically, the motivation for writing a custom scan provider will be to allow the use of some optimization not supported by the core system, such as caching or some form of hardware acceleration. This chapter outlines how to write a new custom scan provider.

Implementing a new type of custom scan is a three-step process. First, during planning, it is necessary to generate access paths representing a scan using the proposed strategy. Second, if one of those access paths is selected by the planner as the optimal strategy for scanning a particular relation, the access path must be converted to a plan. Finally, it must be possible to execute the plan and generate the same results that would have been generated for any other access path targeting the same relation.

### 56.1. Creating Custom Scan Paths

A custom scan provider will typically add paths for a base relation by setting the following hook, which is called after the core code has generated what it believes to be the complete and correct set of access paths for the relation.

```c
typedef void (*set_rel_pathlist_hook_type) (PlannerInfo *root, RelOptInfo *rel, Index rti, RangeTblEntry *rte);
extern PGDLLIMPORT set_rel_pathlist_hook_type set_rel_pathlist_hook;
```

Although this hook function can be used to examine, modify, or remove paths generated by the core system, a custom scan provider will typically confine itself to generating `CustomPath` objects and adding them to `rel` using `add_path`. The custom scan provider is responsible for initializing the `CustomPath` object, which is declared like this:

```c
typedef struct CustomPath
{
    Path     path;
    uint32   flags;
    List     *custom_paths;
    List     *custom_private;
    const CustomPathMethods *methods;
} CustomPath;
```

`path` must be initialized as for any other path, including the row-count estimate, start and total cost, and sort ordering provided by this path. `flags` is a bit mask, which should include `CUSTOMPATH_SUPPORT_BACKWARD_SCAN` if the custom path can support a backward scan and `CUSTOMPATH_SUPPORT_MARK_RESTORE` if it can support mark and restore. Both capabilities are optional. An optional `custom_paths` is a list of `Path` nodes used by this custom-path node; these will be transformed into `Plan` nodes by planner. `custom_private` can be used to store the custom
Chapter 56. Writing A Custom Scan Provider

path’s private data. Private data should be stored in a form that can be handled by nodeToString, so that debugging routines that attempt to print the custom path will work as designed. methods must point to a (usually statically allocated) object implementing the required custom path methods, of which there are currently only two, as further detailed below.

A custom scan provider can also provide join paths. Just as for base relations, such a path must produce the same output as would normally be produced by the join it replaces. To do this, the join provider should set the following hook, and then within the hook function, create CustomPath path(s) for the join relation.

typedef void (*set_join_pathlist_hook_type) (PlannerInfo *root,
   RelOptInfo *joinrel,
   RelOptInfo *outerrel,
   RelOptInfo *innerrel,
   JoinType jointype,
   JoinPathExtraData *extra);

extern PGDLLIMPORT set_join_pathlist_hook_type set_join_pathlist_hook;

This hook will be invoked repeatedly for the same join relation, with different combinations of inner and outer relations; it is the responsibility of the hook to minimize duplicated work.

56.1.1. Custom Scan Path Callbacks

Plan *(*PlanCustomPath) (PlannerInfo *root,
   RelOptInfo *rel,
   CustomPath *best_path,
   List *tlist,
   List *clauses,
   List *custom_plans);

Convert a custom path to a finished plan. The return value will generally be a CustomScan object, which the callback must allocate and initialize. See Section 56.2 for more details.

void (*TextOutCustomPath) (StringInfo str,
   const CustomPath *node);

Generate additional output when nodeToString is invoked on this custom path. This callback is optional. Since nodeToString will automatically dump all fields in the structure that it can see, including custom_private, this is only useful if the CustomPath is actually embedded in a larger struct containing additional fields.

56.2. Creating Custom Scan Plans

A custom scan is represented in a finished plan tree using the following structure:

typedef struct CustomScan
{
    Scan     scan;
    uint32   flags;
    List     *custom_plans;
    List     *custom_exprs;
    List     *custom_private;
}
List *custom_scan_tlist;
Bitmapset *custom_relids;
const CustomScanMethods *methods;
} CustomScan;

Scan must be initialized as for any other scan, including estimated costs, target lists, qualifications, and so on. flags is a bit mask with the same meaning as in CustomPath. custom_plans can be used to store child Plan nodes. custom_exprs should be used to store expression trees that will need to be fixed up by setrefs.c and subselect.c, while custom_private should be used to store other private data that is only used by the custom scan provider itself. custom_scan_tlist can be NIL when scanning a base relation, indicating that the custom scan returns scan tuples that match the base relation’s row type. Otherwise it is a target list describing the actual scan tuples.

custom_scan_tlist must be provided for joins, and could be provided for scans if the custom scan provider can compute some non-Var expressions. custom_scan_tlist can be provided for joins, and could be provided for scans if the custom scan provider can compute some non-Var expressions. custom_relids is set by the core code to the set of relations (range table indexes) that this scan node handles; except when this scan is replacing a join, it will have only one member. methods must point to a (usually statically allocated) object implementing the required custom scan methods, which are further detailed below.

When a CustomScan scans a single relation, scan.scanrelid must be the range table index of the table to be scanned. When it replaces a join, scan.scanrelid should be zero.

Plan trees must be able to be duplicated using copyObject, so all the data stored within the “custom” fields must consist of nodes that that function can handle. Furthermore, custom scan providers cannot substitute a larger structure that embeds a CustomScan for the structure itself, as would be possible for a CustomPath or CustomScanState.

56.2.1. Custom Scan Plan Callbacks

Node *(*CreateCustomScanState) (CustomScan *cscan);

Allocate a CustomScanState for this CustomScan. The actual allocation will often be larger than required for an ordinary CustomScanState, because many providers will wish to embed that as the first field of a larger structure. The value returned must have the node tag and methods set appropriately, but other fields should be left as zeroes at this stage; after ExecInitCustomScan performs basic initialization, the BeginCustomScan callback will be invoked to give the custom scan provider a chance to do whatever else is needed.

void (*TextOutCustomScan) (StringInfo str,
   const CustomScan *node);

Generate additional output when nodeToString is invoked on this custom plan node. This callback is optional. Since nodeToString will automatically dump all fields in the structure, including the substructure of the “custom” fields, there is usually not much need for this callback.

56.3. Executing Custom Scans

When a CustomScan is executed, its execution state is represented by a CustomScanState, which
is declared as follows:

```c
typedef struct CustomScanState {
    ScanState ss;
    uint32 flags;
    const CustomExecMethods *methods;
} CustomScanState;
```

`ss` is initialized as for any other scan state, except that if the scan is for a join rather than a base
relation, `ss.ss_currentRelation` is left NULL. `flags` is a bit mask with the same meaning as in
`CustomPath` and `CustomScan`. `methods` must point to a (usually statically allocated) object
implementing the required custom scan state methods, which are further detailed below. Typically, a
`CustomScanState`, which need not support `copyObject`, will actually be a larger structure embed-
ing the above as its first member.

### 56.3.1. Custom Scan Execution Callbacks

```c
void (*BeginCustomScan) (CustomScanState *node, 
    EState *estate, 
    int eflags);
```

Complete initialization of the supplied `CustomScanState`. Standard fields have been initialized by
`ExecInitCustomScan`, but any private fields should be initialized here.

```c
TupleTableSlot *(*ExecCustomScan) (CustomScanState *node);
```

Fetch the next scan tuple. If any tuples remain, it should fill `ps_ResultTupleSlot` with the next
tuple in the current scan direction, and then return the tuple slot. If not, `NULL` or an empty slot should
be returned.

```c
void (*EndCustomScan) (CustomScanState *node);
```

Clean up any private data associated with the `CustomScanState`. This method is required, but it
does not need to do anything if there is no associated data or it will be cleaned up automatically.

```c
void (*ReScanCustomScan) (CustomScanState *node);
```

Rewind the current scan to the beginning and prepare to rescan the relation.

```c
void (*MarkPosCustomScan) (CustomScanState *node);
```

Save the current scan position so that it can subsequently be restored by the
`RestrPosCustomScan` callback. This callback is optional, and need only be supplied if the
`CUSTOMPATH_SUPPORT_MARK_RESTORE` flag is set.

```c
void (*RestrPosCustomScan) (CustomScanState *node);
```

Restore the previous scan position as saved by the `MarkPosCustomScan` callback. This callback is
optional, and need only be supplied if the `CUSTOMPATH_SUPPORT_MARK_RESTORE` flag is set.
```c
void (*ExplainCustomScan) (CustomScanState *node,
                           List *ancestors,
                           ExplainState *es);
```

Output additional information for `EXPLAIN` of a custom-scan plan node. This callback is optional. Common data stored in the `ScanState`, such as the target list and scan relation, will be shown even without this callback, but the callback allows the display of additional, private state.
Chapter 57. Genetic Query Optimizer

Author: Written by Martin Utesch (<utesch@aut.tu-freiberg.de>) for the Institute of Automatic Control at the University of Mining and Technology in Freiberg, Germany.

57.1. Query Handling as a Complex Optimization Problem

Among all relational operators the most difficult one to process and optimize is the join. The number of possible query plans grows exponentially with the number of joins in the query. Further optimization effort is caused by the support of a variety of join methods (e.g., nested loop, hash join, merge join in PostgreSQL) to process individual joins and a diversity of indexes (e.g., B-tree, hash, GiST and GIN in PostgreSQL) as access paths for relations.

The normal PostgreSQL query optimizer performs a near-exhaustive search over the space of alternative strategies. This algorithm, first introduced in IBM’s System R database, produces a near-optimal join order, but can take an enormous amount of time and memory space when the number of joins in the query grows large. This makes the ordinary PostgreSQL query optimizer inappropriate for queries that join a large number of tables.

The Institute of Automatic Control at the University of Mining and Technology, in Freiberg, Germany, encountered some problems when it wanted to use PostgreSQL as the backend for a decision support knowledge based system for the maintenance of an electrical power grid. The DBMS needed to handle large join queries for the inference machine of the knowledge based system. The number of joins in these queries made using the normal query optimizer infeasible.

In the following we describe the implementation of a genetic algorithm to solve the join ordering problem in a manner that is efficient for queries involving large numbers of joins.

57.2. Genetic Algorithms

The genetic algorithm (GA) is a heuristic optimization method which operates through randomized search. The set of possible solutions for the optimization problem is considered as a population of individuals. The degree of adaptation of an individual to its environment is specified by its fitness.

The coordinates of an individual in the search space are represented by chromosomes, in essence a set of character strings. A gene is a subsection of a chromosome which encodes the value of a single parameter being optimized. Typical encodings for a gene could be binary or integer.

Through simulation of the evolutionary operations recombination, mutation, and selection new generations of search points are found that show a higher average fitness than their ancestors.
According to the comp.ai.genetic FAQ it cannot be stressed too strongly that a GA is not a pure random search for a solution to a problem. A GA uses stochastic processes, but the result is distinctly non-random (better than random).

Figure 57-1. Structured Diagram of a Genetic Algorithm

P(t)  generation of ancestors at a time t
P'(t) generation of descendants at a time t

57.3. Genetic Query Optimization (GEQO) in PostgreSQL

The GEQO module approaches the query optimization problem as though it were the well-known traveling salesman problem (TSP). Possible query plans are encoded as integer strings. Each string represents the join order from one relation of the query to the next. For example, the join tree

```
/\  /
/\  2
/\  3
  4  1
```

is encoded by the integer string '4-1-3-2', which means, first join relation '4' and '1', then '3', and then '2', where 1, 2, 3, 4 are relation IDs within the PostgreSQL optimizer.

Specific characteristics of the GEQO implementation in PostgreSQL are:

- Usage of a **steady state** GA (replacement of the least fit individuals in a population, not whole-generational replacement) allows fast convergence towards improved query plans. This is essential for query handling with reasonable time;
• Usage of *edge recombination crossover* which is especially suited to keep edge losses low for the solution of the TSP by means of a GA;
• Mutation as genetic operator is deprecated so that no repair mechanisms are needed to generate legal TSP tours.

Parts of the GEQO module are adapted from D. Whitley’s Genitor algorithm.
The GEQO module allows the PostgreSQL query optimizer to support large join queries effectively through non-exhaustive search.

### 57.3.1. Generating Possible Plans with GEQO

The GEQO planning process uses the standard planner code to generate plans for scans of individual relations. Then join plans are developed using the genetic approach. As shown above, each candidate join plan is represented by a sequence in which to join the base relations. In the initial stage, the GEQO code simply generates some possible join sequences at random. For each join sequence considered, the standard planner code is invoked to estimate the cost of performing the query using that join sequence. (For each step of the join sequence, all three possible join strategies are considered; and all the initially-determined relation scan plans are available. The estimated cost is the cheapest of these possibilities.) Join sequences with lower estimated cost are considered “more fit” than those with higher cost. The genetic algorithm discards the least fit candidates. Then new candidates are generated by combining genes of more-fit candidates — that is, by using randomly-chosen portions of known low-cost join sequences to create new sequences for consideration. This process is repeated until a preset number of join sequences have been considered; then the best one found at any time during the search is used to generate the finished plan.

This process is inherently nondeterministic, because of the randomized choices made during both the initial population selection and subsequent “mutation” of the best candidates. To avoid surprising changes of the selected plan, each run of the GEQO algorithm restarts its random number generator with the current `geqo_seed` parameter setting. As long as `geqo_seed` and the other GEQO parameters are kept fixed, the same plan will be generated for a given query (and other planner inputs such as statistics). To experiment with different search paths, try changing `geqo_seed`.

### 57.3.2. Future Implementation Tasks for PostgreSQL GEQO

Work is still needed to improve the genetic algorithm parameter settings. In file `src/backend/optimizer/geqo/geqo_main.c`, routines `gimme_pool_size` and `gimme_number_generations`, we have to find a compromise for the parameter settings to satisfy two competing demands:

• Optimality of the query plan
• Computing time

In the current implementation, the fitness of each candidate join sequence is estimated by running the standard planner’s join selection and cost estimation code from scratch. To the extent that different candidates use similar sub-sequences of joins, a great deal of work will be repeated. This could be made significantly faster by retaining cost estimates for sub-joins. The problem is to avoid expending unreasonable amounts of memory on retaining that state.
At a more basic level, it is not clear that solving query optimization with a GA algorithm designed for TSP is appropriate. In the TSP case, the cost associated with any substring (partial tour) is independent of the rest of the tour, but this is certainly not true for query optimization. Thus it is questionable whether edge recombination crossover is the most effective mutation procedure.

Chapter 58. Index Access Method Interface Definition

This chapter defines the interface between the core PostgreSQL system and index access methods, which manage individual index types. The core system knows nothing about indexes beyond what is specified here, so it is possible to develop entirely new index types by writing add-on code.

All indexes in PostgreSQL are what are known technically as secondary indexes; that is, the index is physically separate from the table file that it describes. Each index is stored as its own physical relation and so is described by an entry in the pg_class catalog. The contents of an index are entirely under the control of its index access method. In practice, all index access methods divide indexes into standard-size pages so that they can use the regular storage manager and buffer manager to access the index contents. (All the existing index access methods furthermore use the standard page layout described in Section 63.6, and they all use the same format for index tuple headers; but these decisions are not forced on an access method.)

An index is effectively a mapping from some data key values to tuple identifiers, or TIDs, of row versions (tuples) in the index’s parent table. A TID consists of a block number and an item number within that block (see Section 63.6). This is sufficient information to fetch a particular row version from the table. Indexes are not directly aware that under MVCC, there might be multiple extant versions of the same logical row; to an index, each tuple is an independent object that needs its own index entry. Thus, an update of a row always creates all-new index entries for the row, even if the key values did not change. (HOT tuples are an exception to this statement; but indexes do not deal with those, either.) Index entries for dead tuples are reclaimed (by vacuuming) when the dead tuples themselves are reclaimed.

58.1. Catalog Entries for Indexes

Each index access method is described by a row in the pg_am system catalog (see Section 49.3). The principal contents of a pg_am row are references to pg_proc entries that identify the index access functions supplied by the access method. The APIs for these functions are defined later in this chapter. In addition, the pg_am row specifies a few fixed properties of the access method, such as whether it can support multicolumn indexes. There is not currently any special support for creating or deleting pg_am entries; anyone able to write a new access method is expected to be competent to insert an appropriate row for themselves.

To be useful, an index access method must also have one or more operator families and operator classes defined in pg_opfamily, pg_opclass, pg_amop, and pg_amproc. These entries allow the planner to determine what kinds of query qualifications can be used with indexes of this access method. Operator families and classes are described in Section 35.14, which is prerequisite material for reading this chapter.

An individual index is defined by a pg_class entry that describes it as a physical relation, plus a pg_index entry that shows the logical content of the index — that is, the set of index columns it has and the semantics of those columns, as captured by the associated operator classes. The index columns (key values) can be either simple columns of the underlying table or expressions over the table rows. The index access method normally has no interest in where the index key values come from (it is always handed precomputed key values) but it will be very interested in the operator class
information in `pg_index`. Both of these catalog entries can be accessed as part of the `Relation` data structure that is passed to all operations on the index.

Some of the flag columns of `pg_am` have nonobvious implications. The requirements of `amcanunique` are discussed in Section 58.5. The `amcanmulticol` flag asserts that the access method supports multicol index entries, while `amoptionalkey` asserts that it allows scans where no indexable restriction clause is given for the first index column. When `amcanmulticol` is false, `amoptionalkey` essentially says whether the access method supports full-index scans without any restriction clause. Access methods that support multiple index columns must support scans that omit restrictions on any or all of the columns after the first; however they are permitted to require some restriction to appear for the first index column, and this is signaled by setting `amoptionalkey` false. One reason that an index AM might set `amoptionalkey` false is if it doesn’t index null values. Since most indexable operators are strict and hence cannot return true for null inputs, it is at first sight attractive to not store index entries for null values: they could never be returned by an index scan anyway. However, this argument fails when an index scan has no restriction clause for a given index column. In practice this means that indexes that have `amoptionalkey` true must index nulls, since the planner might decide to use such an index with no scan keys at all. A related restriction is that an index access method that supports multiple index columns must support indexing null values in columns after the first, because the planner will assume the index can be used for queries that do not restrict these columns. For example, consider an index on `(a, b)` and a query with `WHERE a = 4`. The system will assume the index can be used to scan for rows with `a = 4`, which is wrong if the index omits rows where `b` is null. It is, however, OK to omit rows where the first indexed column is null. An index access method that does index nulls may also set `amsearchnulls`, indicating that it supports `IS NULL` and `IS NOT NULL` clauses as search conditions.

### 58.2. Index Access Method Functions

The index construction and maintenance functions that an index access method must provide are:

```c
def IndexBuildResult *
    ambuild (Relation heapRelation,
             Relation indexRelation,
             IndexInfo *indexInfo);
```

Build a new index. The index relation has been physically created, but is empty. It must be filled in with whatever fixed data the access method requires, plus entries for all tuples already existing in the table. Ordinarily the `ambuild` function will call `IndexBuildHeapScan()` to scan the table for existing tuples and compute the keys that need to be inserted into the index. The function must return a malloc’d struct containing statistics about the new index.

```c
void
    ambuildempty (Relation indexRelation);
```

Build an empty index, and write it to the initialization fork (INIT_FORKNUM) of the given relation. This method is called only for unlogged tables; the empty index written to the initialization fork will be copied over the main relation fork on each server restart.

```c
bool
    aminsert (Relation indexRelation,
              Datum *values,
              bool *isnull,
              ItemPointer heap_tid,
```
Insert a new tuple into an existing index. The `values` and `isnull` arrays give the key values to be indexed, and `heap_tid` is the TID to be indexed. If the access method supports unique indexes (its `pg_am.amcanunique` flag is true) then `checkUnique` indicates the type of uniqueness check to perform. This varies depending on whether the unique constraint is deferrable; see Section 58.5 for details. Normally the access method only needs the `heapRelation` parameter when performing uniqueness checking (since then it will have to look into the heap to verify tuple liveness).

The function’s Boolean result value is significant only when `checkUnique` is `UNIQUE_CHECK_PARTIAL`. In this case a `TRUE` result means the new entry is known unique, whereas `FALSE` means it might be non-unique (and a deferred uniqueness check must be scheduled). For other cases a constant `FALSE` result is recommended.

Some indexes might not index all tuples. If the tuple is not to be indexed, `amininsert` should just return without doing anything.

Delete tuple(s) from the index. This is a “bulk delete” operation that is intended to be implemented by scanning the whole index and checking each entry to see if it should be deleted. The passed-in `callback` function must be called, in the style `callback(TID, callback_state) returns bool`, to determine whether any particular index entry, as identified by its referenced TID, is to be deleted. Must return either NULL or a palloc’d struct containing statistics about the effects of the deletion operation. It is OK to return NULL if no information needs to be passed on to `amvacuumcleanup`.

Because of limited `maintenance_work_mem`, `ambulkdelete` might need to be called more than once when many tuples are to be deleted. The `stats` argument is the result of the previous call for this index (it is NULL for the first call within a VACUUM operation). This allows the AM to accumulate statistics across the whole operation. Typically, `ambulkdelete` will modify and return the same struct if the passed `stats` is not null.

Clean up after a VACUUM operation (zero or more `ambulkdelete` calls). This does not have to do anything beyond returning index statistics, but it might perform bulk cleanup such as reclaiming empty index pages. `stats` is whatever the last `ambulkdelete` call returned, or NULL if `ambulkdelete` was not called because no tuples needed to be deleted. If the result is not NULL it must be a palloc’d struct. The statistics it contains will be used to update `pg_class`, and will be reported by VACUUM if `VERBOSE` is given. It is OK to return NULL if the index was not changed at all during the VACUUM operation, but otherwise correct stats should be returned.

As of PostgreSQL 8.4, `amvacuumcleanup` will also be called at completion of an ANALYZE operation. In this case `stats` is always NULL and any return value will be ignored. This case can be distinguished by checking `info->analyze_only`. It is recommended that the access method do nothing except post-insert cleanup in such a call, and that only in an autovacuum worker process.
bool amcanreturn (Relation indexRelation, int attno);

Check whether the index can support index-only scans on the given column, by returning the indexed column values for an index entry in the form of an IndexTuple. The attribute number is 1-based, i.e. the first columns attno is 1. Returns TRUE if supported, else FALSE. If the access method does not support index-only scans at all, the amcanreturn field in its pg_am row can be set to zero.

void amcostestimate (PlannerInfo *root,
            IndexPath *path,
            double loop_count,
            Cost *indexStartupCost,
            Cost *indexTotalCost,
            Selectivity *indexSelectivity,
            double *indexCorrelation);

Estimate the costs of an index scan. This function is described fully in Section 58.6, below.

bytea * amoptions (ArrayType *reloptions,
             bool validate);

Parse and validate the reloptions array for an index. This is called only when a non-null reloptions array exists for the index. reloptions is a text array containing entries of the form name=value. The function should construct a bytea value, which will be copied into the rd_options field of the index’s relcache entry. The data contents of the bytea value are open for the access method to define; most of the standard access methods use struct StdRdOptions. When validate is true, the function should report a suitable error message if any of the options are unrecognized or have invalid values; when validate is false, invalid entries should be silently ignored. (validate is false when loading options already stored in pg_catalog; an invalid entry could only be found if the access method has changed its rules for options, and in that case ignoring obsolete entries is appropriate.) It is OK to return NULL if default behavior is wanted.

The purpose of an index, of course, is to support scans for tuples matching an indexable WHERE condition, often called a qualifier or scan key. The semantics of index scanning are described more fully in Section 58.3, below. An index access method can support “plain” index scans, “bitmap” index scans, or both. The scan-related functions that an index access method must or may provide are:

IndexScanDesc ambeginscan (Relation indexRelation,
                    int nkeys,
                    int norderbys);

Prepare for an index scan. The nkeys and norderbys parameters indicate the number of quals and ordering operators that will be used in the scan; these may be useful for space allocation purposes. Note that the actual values of the scan keys aren’t provided yet. The result must be a malloc’d struct. For implementation reasons the index access method must create this struct by calling RelationGetIndexScan(). In most cases ambeginscan does little beyond making that call and perhaps acquiring locks; the interesting parts of index-scan startup are in amrescan.

void amrescan (IndexScanDesc scan,
        ScanKey keys,
Start or restart an index scan, possibly with new scan keys. (To restart using previously-passed keys, NULL is passed for keys and/or orderbys.) Note that it is not allowed for the number of keys or order-by operators to be larger than what was passed to ambeginscan. In practice the restart feature is used when a new outer tuple is selected by a nested-loop join and so a new key comparison value is needed, but the scan key structure remains the same.

boolean amgettuple (IndexScanDesc scan, ScanDirection direction);

Fetch the next tuple in the given scan, moving in the given direction (forward or backward in the index). Returns TRUE if a tuple was obtained, FALSE if no matching tuples remain. In the TRUE case the tuple TID is stored into the scan structure. Note that “success” means only that the index contains an entry that matches the scan keys, not that the tuple necessarily still exists in the heap or will pass the caller’s snapshot test. On success, amgettuple must also set scan->xs_recheck to TRUE or FALSE. FALSE means it is certain that the index entry matches the scan keys. TRUE means this is not certain, and the conditions represented by the scan keys must be rechecked against the heap tuple after fetching it. This provision supports “lossy” index operators. Note that rechecking will extend only to the scan conditions; a partial index predicate (if any) is never rechecked by amgettuple callers.

If the index supports index-only scans (i.e., amcanreturn returns TRUE for it), then on success the AM must also check scan->xs_want_itup, and if that is true it must return the original indexed data for the index entry, in the form of an IndexTuple pointer stored at scan->xs_itup, with tuple descriptor scan->xs_itupdesc. (Management of the data referenced by the pointer is the access method’s responsibility. The data must remain good at least until the next amgettuple, amrescan, or amendscan call for the scan.)

The amgettuple function need only be provided if the access method supports “plain” index scans. If it doesn’t, the amgettuple field in its pg_am row must be set to zero.

int64 amgetbitmap (IndexScanDesc scan, TIDBitmap *tbm);

Fetch all tuples in the given scan and add them to the caller-supplied TIDBitmap (that is, OR the set of tuple IDs into whatever set is already in the bitmap). The number of tuples fetched is returned (this might be just an approximate count, for instance some AMs do not detect duplicates). While inserting tuple IDs into the bitmap, amgetbitmap can indicate that rechecking of the scan conditions is required for specific tuple IDs. This is analogous to the xs_recheck output parameter of amgettuple. Note: in the current implementation, support for this feature is conflated with support for lossy storage of the bitmap itself, and therefore callers recheck both the scan conditions and the partial index predicate (if any) for recheckable tuples. That might not always be true, however. amgetbitmap and amgettuple cannot be used in the same index scan; there are other restrictions too when using amgetbitmap, as explained in Section 58.3.

The amgetbitmap function need only be provided if the access method supports “bitmap” index scans. If it doesn’t, the amgetbitmap field in its pg_am row must be set to zero.
End a scan and release resources. The scan struct itself should not be freed, but any locks or pins taken internally by the access method must be released.

```c
void
ammarkpos (IndexScanDesc scan);
```

Mark current scan position. The access method need only support one remembered scan position per scan.

```c
void
amrestrpos (IndexScanDesc scan);
```

Restore the scan to the most recently marked position.

By convention, the pg_proc entry for an index access method function should show the correct number of arguments, but declare them all as type internal (since most of the arguments have types that are not known to SQL, and we don’t want users calling the functions directly anyway). The return type is declared as void, internal, or boolean as appropriate. The only exception is amoptions, which should be correctly declared as taking text[] and bool and returning bytea. This provision allows client code to execute amoptions to test validity of options settings.

58.3. Index Scanning

In an index scan, the index access method is responsible for regurgitating the TIDs of all the tuples it has been told about that match the scan keys. The access method is not involved in actually fetching those tuples from the index’s parent table, nor in determining whether they pass the scan’s time qualification test or other conditions.

A scan key is the internal representation of a WHERE clause of the form index_key operator constant, where the index key is one of the columns of the index and the operator is one of the members of the operator family associated with that index column. An index scan has zero or more scan keys, which are implicitly ANDed — the returned tuples are expected to satisfy all the indicated conditions.

The access method can report that the index is lossy, or requires rechecks, for a particular query. This implies that the index scan will return all the entries that pass the scan key, plus possibly additional entries that do not. The core system’s index-scan machinery will then apply the index conditions again to the heap tuple to verify whether or not it really should be selected. If the recheck option is not specified, the index scan must return exactly the set of matching entries.

Note that it is entirely up to the access method to ensure that it correctly finds all and only the entries passing all the given scan keys. Also, the core system will simply hand off all the WHERE clauses that match the index keys and operator families, without any semantic analysis to determine whether they are redundant or contradictory. As an example, given \texttt{WHERE }x > 4 \texttt{ AND } x > 14\texttt{ where }x\texttt{ is a b-tree indexed column, it is left to the b-tree amrescan function to realize that the first scan key is redundant and can be discarded. The extent of preprocessing needed during amrescan will depend on the extent to which the index access method needs to reduce the scan keys to a “normalized” form.

Some access methods return index entries in a well-defined order, others do not. There are actually two different ways that an access method can support sorted output:

- Access methods that always return entries in the natural ordering of their data (such as btree) should set pg_am.amcanorderby to true. Currently, such access methods must use btree-compatible strategy numbers for their equality and ordering operators.
• Access methods that support ordering operators should set `pg_am.amcanorderbyop` to true. This indicates that the index is capable of returning entries in an order satisfying `ORDER BY index_key` operator constant. Scan modifiers of that form can be passed to `amrescan` as described previously.

The `amgettuple` function has a direction argument, which can be either `ForwardScanDirection` (the normal case) or `BackwardScanDirection`. If the first call after `amrescan` specifies `BackwardScanDirection`, then the set of matching index entries is to be scanned back-to-front rather than in the normal front-to-back direction, so `amgettuple` must return the last matching tuple in the index, rather than the first one as it normally would. (This will only occur for access methods that set `amcanorder` to true.) After the first call, `amgettuple` must be prepared to advance the scan in either direction from the most recently returned entry. (But if `pg_am.amcanbackward` is false, all subsequent calls will have the same direction as the first one.) Access methods that support ordered scans must support “marking” a position in a scan and later returning to the marked position. The same position might be restored multiple times. However, only one position need be remembered per scan; a new `ammarkpos` call overrides the previously marked position. An access method that does not support ordered scans should still provide mark and restore functions in `pg_am`, but it is sufficient to have them throw errors if called.

Both the scan position and the mark position (if any) must be maintained consistently in the face of concurrent insertions or deletions in the index. It is OK if a freshly-inserted entry is not returned by a scan that would have found the entry if it had existed when the scan started, or for the scan to return such an entry upon rescanning or backing up even though it had not been returned the first time through. Similarly, a concurrent delete might or might not be reflected in the results of a scan. What is important is that insertions or deletions not cause the scan to miss or multiply return entries that were not themselves being inserted or deleted.

If the index stores the original indexed data values (and not some lossy representation of them), it is useful to support index-only scans, in which the index returns the actual data not just the TID of the heap tuple. This will only work if the visibility map shows that the TID is on an all-visible page; else the heap tuple must be visited anyway to check MVCC visibility. But that is no concern of the access method’s.

Instead of using `amgettuple`, an index scan can be done with `amgetbitmap` to fetch all tuples in one call. This can be noticeably more efficient than `amgettuple` because it allows avoiding lock/unlock cycles within the access method. In principle `amgetbitmap` should have the same effects as repeated `amgettuple` calls, but we impose several restrictions to simplify matters. First of all, `amgetbitmap` returns all tuples at once and marking or restoring scan positions isn’t supported. Secondly, the tuples are returned in a bitmap which doesn’t have any specific ordering, which is why `amgetbitmap` doesn’t take a direction argument. (Ordering operators will never be supplied for such a scan, either.) Also, there is no provision for index-only scans with `amgetbitmap`, since there is no way to return the contents of index tuples. Finally, `amgetbitmap` does not guarantee any locking of the returned tuples, with implications spelled out in Section 58.4.

Note that it is permitted for an access method to implement only `amgetbitmap` and not `amgettuple`, or vice versa, if its internal implementation is unsuited to one API or the other.

### 58.4. Index Locking Considerations

Index access methods must handle concurrent updates of the index by multiple processes. The core PostgreSQL system obtains `AccessShareLock` on the index during an index scan, and
RowExclusiveLock when updating the index (including plain VACUUM). Since these lock types do
not conflict, the access method is responsible for handling any fine-grained locking it might need. An
exclusive lock on the index as a whole will be taken only during index creation, destruction, or
REINDEX.

Building an index type that supports concurrent updates usually requires extensive and subtle analysis
of the required behavior. For the b-tree and hash index types, you can read about the design decisions
involved in src/backend/access/nbtree/README and src/backend/access/hash/README.

Aside from the index’s own internal consistency requirements, concurrent updates create issues about
consistency between the parent table (the heap) and the index. Because PostgreSQL separates ac-
cesses and updates of the heap from those of the index, there are windows in which the index might
be inconsistent with the heap. We handle this problem with the following rules:

- A new heap entry is made before making its index entries. (Therefore a concurrent index scan is
likely to fail to see the heap entry. This is okay because the index reader would be uninterested in
an uncommitted row anyway. But see Section 58.5.)

- When a heap entry is to be deleted (by VACUUM), all its index entries must be removed first.

- An index scan must maintain a pin on the index page holding the item last returned by
amgettuple, and ambulkdelete cannot delete entries from pages that are pinned by other
backends. The need for this rule is explained below.

Without the third rule, it is possible for an index reader to see an index entry just before it is removed
by VACUUM, and then to arrive at the corresponding heap entry after that was removed by VACUUM.
This creates no serious problems if that item number is still unused when the reader reaches it, since
an empty item slot will be ignored by heap_fetch(). But what if a third backend has already re-
used the item slot for something else? When using an MVCC-compliant snapshot, there is no problem
because the new occupant of the slot is certain to be too new to pass the snapshot test. However, with
a non-MVCC-compliant snapshot (such as SnapshotAny), it would be possible to accept and return
a row that does not in fact match the scan keys. We could defend against this scenario by requiring the
scan keys to be rechecked against the heap row in all cases, but that is too expensive. Instead, we use
a pin on an index page as a proxy to indicate that the reader might still be “in flight” from the index
every to the matching heap entry. Making ambulkdelete block on such a pin ensures that VACUUM
cannot delete the heap entry before the reader is done with it. This solution costs little in run time,
and adds blocking overhead only in the rare cases where there actually is a conflict.

This solution requires that index scans be “synchronous”: we have to fetch each heap tuple imme-
diately after scanning the corresponding index entry. This is expensive for a number of reasons. An
“asynchronous” scan in which we collect many TIDs from the index, and only visit the heap tuples
sometime later, requires much less index locking overhead and can allow a more efficient heap access
pattern. Per the above analysis, we must use the synchronous approach for non-MVCC-compliant
snapshots, but an asynchronous scan is workable for a query using an MVCC snapshot.

In an amgetbitmap index scan, the access method does not keep an index pin on any of the returned
tuples. Therefore it is only safe to use such scans with MVCC-compliant snapshots.

When the ampredlocks flag is not set, any scan using that index access method within a serializable
transaction will acquire a nonblocking predicate lock on the full index. This will generate a read-write
conflict with the insert of any tuple into that index by a concurrent serializable transaction. If certain
patterns of read-write conflicts are detected among a set of concurrent serializable transactions, one
of those transactions may be canceled to protect data integrity. When the flag is set, it indicates that
the index access method implements finer-grained predicate locking, which will tend to reduce the
frequency of such transaction cancellations.
58.5. Index Uniqueness Checks

PostgreSQL enforces SQL uniqueness constraints using *unique indexes*, which are indexes that disallow multiple entries with identical keys. An access method that supports this feature sets `pg_am.amcanunique` true. (At present, only b-tree supports it.)

Because of MVCC, it is always necessary to allow duplicate entries to exist physically in an index: the entries might refer to successive versions of a single logical row. The behavior we actually want to enforce is that no MVCC snapshot could include two rows with equal index keys. This breaks down into the following cases that must be checked when inserting a new row into a unique index:

- If a conflicting valid row has been deleted by the current transaction, it’s okay. (In particular, since an UPDATE always deletes the old row version before inserting the new version, this will allow an UPDATE on a row without changing the key.)
- If a conflicting row has been inserted by an as-yet-uncommitted transaction, the would-be inserter must wait to see if that transaction commits. If it rolls back then there is no conflict. If it commits without deleting the conflicting row again, there is a uniqueness violation. (In practice we just wait for the other transaction to end and then redo the visibility check in toto.)
- Similarly, if a conflicting valid row has been deleted by an as-yet-uncommitted transaction, the would-be inserter must wait for that transaction to commit or abort, and then repeat the test.

Furthermore, immediately before reporting a uniqueness violation according to the above rules, the access method must recheck the liveness of the row being inserted. If it is committed dead then no violation should be reported. (This case cannot occur during the ordinary scenario of inserting a row that’s just been created by the current transaction. It can happen during `CREATE UNIQUE INDEX CONCURRENTLY`, however.)

We require the index access method to apply these tests itself, which means that it must reach into the heap to check the commit status of any row that is shown to have a duplicate key according to the index contents. This is without a doubt ugly and non-modular, but it saves redundant work: if we did a separate probe then the index lookup for a conflicting row would be essentially repeated while finding the place to insert the new row’s index entry. What’s more, there is no obvious way to avoid race conditions unless the conflict check is an integral part of insertion of the new index entry.

If the unique constraint is deferrable, there is additional complexity: we need to be able to insert an index entry for a new row, but defer any uniqueness-violation error until end of statement or even later. To avoid unnecessary repeat searches of the index, the index access method should do a preliminary uniqueness check during the initial insertion. If this shows that there is definitely no conflicting live tuple, we are done. Otherwise, we schedule a recheck to occur when it is time to enforce the constraint. If, at the time of the recheck, both the inserted tuple and some other tuple with the same key are live, then the error must be reported. (Note that for this purpose, “live” actually means “any tuple in the index entry’s HOT chain is live”.) To implement this, the `aminsert` function is passed a `checkUnique` parameter having one of the following values:

- `UNIQUE_CHECK_NO` indicates that no uniqueness checking should be done (this is not a unique index).
- `UNIQUE_CHECK_YES` indicates that this is a non-deferrable unique index, and the uniqueness check must be done immediately, as described above.
- `UNIQUE_CHECK_PARTIAL` indicates that the unique constraint is deferrable. PostgreSQL will use this mode to insert each row’s index entry. The access method must allow duplicate entries into the
index, and report any potential duplicates by returning FALSE from \texttt{aminsert}. For each row for which FALSE is returned, a deferred recheck will be scheduled.

The access method must identify any rows which might violate the unique constraint, but it is not an error for it to report false positives. This allows the check to be done without waiting for other transactions to finish; conflicts reported here are not treated as errors and will be rechecked later, by which time they may no longer be conflicts.

- \texttt{UNIQUE\_CHECK\_EXISTING} indicates that this is a deferred recheck of a row that was reported as a potential uniqueness violation. Although this is implemented by calling \texttt{aminsert}, the access method must \textit{not} insert a new index entry in this case. The index entry is already present. Rather, the access method must check to see if there is another live index entry. If so, and if the target row is also still live, report error.

It is recommended that in a \texttt{UNIQUE\_CHECK\_EXISTING} call, the access method further verify that the target row actually does have an existing entry in the index, and report error if not. This is a good idea because the index tuple values passed to \texttt{aminsert} will have been recomputed. If the index definition involves functions that are not really immutable, we might be checking the wrong area of the index. Checking that the target row is found in the recheck verifies that we are scanning for the same tuple values as were used in the original insertion.

### 58.6. Index Cost Estimation Functions

The \texttt{amcostestimate} function is given information describing a possible index scan, including lists of \texttt{WHERE} and \texttt{ORDER BY} clauses that have been determined to be usable with the index. It must return estimates of the cost of accessing the index and the selectivity of the \texttt{WHERE} clauses (that is, the fraction of parent-table rows that will be retrieved during the index scan). For simple cases, nearly all the work of the cost estimator can be done by calling standard routines in the optimizer; the point of having an \texttt{amcostestimate} function is to allow index access methods to provide index-type-specific knowledge, in case it is possible to improve on the standard estimates.

Each \texttt{amcostestimate} function must have the signature:

```
void amcostestimate (PlannerInfo *root,
    IndexPath *path,
    double loop_count,
    Cost *indexStartupCost,
    Cost *indexTotalCost,
    Selectivity *indexSelectivity,
    double *indexCorrelation);
```

The first three parameters are inputs:

- \texttt{root}
  
  The planner’s information about the query being processed.

- \texttt{path}
  
  The index access path being considered. All fields except cost and selectivity values are valid.
The number of repetitions of the index scan that should be factored into the cost estimates. This will typically be greater than one when considering a parameterized scan for use in the inside of a nestloop join. Note that the cost estimates should still be for just one scan; a larger \texttt{loop\_count} means that it may be appropriate to allow for some caching effects across multiple scans.

The last four parameters are pass-by-reference outputs:

- \texttt{indexStartUpCost}
  - Set to cost of index start-up processing
- \texttt{indexTotalCost}
  - Set to total cost of index processing
- \texttt{indexSelectivity}
  - Set to index selectivity
- \texttt{indexCorrelation}
  - Set to correlation coefficient between index scan order and underlying table’s order

Note that cost estimate functions must be written in C, not in SQL or any available procedural language, because they must access internal data structures of the planner/optimizer.

The index access costs should be computed using the parameters used by \texttt{src/backend/optimizer/path/costsize.c}: a sequential disk block fetch has cost \texttt{seq\_page\_cost}, a nonsequential fetch has cost \texttt{random\_page\_cost}, and the cost of processing one index row should usually be taken as \texttt{cpu\_index\_tuple\_cost}. In addition, an appropriate multiple of \texttt{cpu\_operator\_cost} should be charged for any comparison operators invoked during index processing (especially evaluation of the indexquals themselves).

The access costs should include all disk and CPU costs associated with scanning the index itself, but not the costs of retrieving or processing the parent-table rows that are identified by the index.

The “start-up cost” is the part of the total scan cost that must be expended before we can begin to fetch the first row. For most indexes this can be taken as zero, but an index type with a high start-up cost might want to set it nonzero.

The \texttt{indexSelectivity} should be set to the estimated fraction of the parent table rows that will be retrieved during the index scan. In the case of a lossy query, this will typically be higher than the fraction of rows that actually pass the given qual conditions.

The \texttt{indexCorrelation} should be set to the correlation (ranging between -1.0 and 1.0) between the index order and the table order. This is used to adjust the estimate for the cost of fetching rows from the parent table.

When \texttt{loop\_count} is greater than one, the returned numbers should be averages expected for any one scan of the index.

Cost Estimation

A typical cost estimator will proceed as follows:

1. Estimate and return the fraction of parent-table rows that will be visited based on the given qual conditions. In the absence of any index-type-specific knowledge, use the standard optimizer function \texttt{clauselist\_selectivity}():

\begin{verbatim}

\end{verbatim}
**Chapter 58. Index Access Method Interface Definition**

```c
*indexSelectivity = clauselist_selectivity(root, path->indexquals,
   path->indexinfo->rel->relid,
   JOIN_INNER, NULL);
```

2. Estimate the number of index rows that will be visited during the scan. For many index types this
   is the same as `indexSelectivity` times the number of rows in the index, but it might be more.
   (Note that the index’s size in pages and rows is available from the `path->indexinfo` struct.)

3. Estimate the number of index pages that will be retrieved during the scan. This might be just
   `indexSelectivity` times the index’s size in pages.

4. Compute the index access cost. A generic estimator might do this:

```c
  /*
   * Our generic assumption is that the index pages will be read
   * sequentially, so they cost seq_page_cost each, not random_page_cost.
   * Also, we charge for evaluation of the indexquals at each index row.
   * All the costs are assumed to be paid incrementally during the scan.
   */
  cost_qual_eval(&index_qual_cost, path->indexquals, root);
  *indexStartupCost = index_qual_cost.startup;
  *indexTotalCost = seq_page_cost * numIndexPages +
       (cpu_index_tuple_cost + index_qual_cost.per_tuple) * numIndexTuples;
```

However, the above does not account for amortization of index reads across repeated index scans.

5. Estimate the index correlation. For a simple ordered index on a single field, this can be retrieved
   from `pg_statistic`. If the correlation is not known, the conservative estimate is zero (no correla-
   tion).

Examples of cost estimator functions can be found in `src/backend/utils/adt/selfuncs.c`. 

Chapter 59. GiST Indexes

59.1. Introduction

GiST stands for Generalized Search Tree. It is a balanced, tree-structured access method, that acts as a base template in which to implement arbitrary indexing schemes. B-trees, R-trees and many other indexing schemes can be implemented in GiST.

One advantage of GiST is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from the University of California at Berkeley’s GiST Indexing Project web site¹ and Marcel Kornacker’s thesis, Access Methods for Next-Generation Database Systems². The GiST implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their web site³.

59.2. Built-in Operator Classes

The core PostgreSQL distribution includes the GiST operator classes shown in Table 59-1. (Some of the optional modules described in Appendix F provide additional GiST operator classes.)

Table 59-1. Built-in GiST Operator Classes

<table>
<thead>
<tr>
<th>Name</th>
<th>Indexed Data Type</th>
<th>Indexable Operators</th>
<th>Ordering Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td>box_ops</td>
<td>box</td>
<td>&quot;&amp;&amp;&quot; &quot;&amp;&quot; &quot;&lt;&quot; &quot;&lt;&quot; &quot;</td>
<td>&gt; &quot;</td>
</tr>
<tr>
<td>circle_ops</td>
<td>circle</td>
<td>&quot;&amp;&amp;&quot; &quot;&amp;&quot; &quot;&lt;&quot; &quot;&lt;&quot; &quot;</td>
<td>&gt; &quot;</td>
</tr>
<tr>
<td>inet_ops</td>
<td>inet, cidr</td>
<td>&quot;&amp;&amp;&quot; &quot;&gt;&gt;&quot; &quot;&gt;&gt;&quot; &quot;</td>
<td>&gt; &quot;</td>
</tr>
<tr>
<td>point_ops</td>
<td>point</td>
<td>&quot;&gt;&gt;&quot; &quot;^&quot; &quot;&lt;&lt;&quot; &quot;&lt;&lt;&quot; &quot;</td>
<td>@ &quot;</td>
</tr>
<tr>
<td>poly_ops</td>
<td>polygon</td>
<td>&quot;&amp;&amp;&quot; &quot;&amp;&quot; &quot;&lt;&quot; &quot;&lt;&quot; &quot;</td>
<td>&gt; &quot;</td>
</tr>
<tr>
<td>range_ops</td>
<td>any range type</td>
<td>&quot;&amp;&amp;&quot; &quot;&amp;&quot; &quot;&lt;&quot; &quot;&lt;&quot; &quot;</td>
<td>&gt; &quot;</td>
</tr>
<tr>
<td>tsquery_ops</td>
<td>tsquery</td>
<td>&quot;&lt;&lt;&quot; &quot;&lt;&lt;&quot; &quot;&lt;&lt;&quot; &quot;</td>
<td>&quot;@ &quot;</td>
</tr>
<tr>
<td>tsvector_ops</td>
<td>tsvector</td>
<td>&quot;@&quot; &quot;@&quot; &quot;@&quot; &quot;@&quot; &quot;</td>
<td>&quot;@ &quot;</td>
</tr>
</tbody>
</table>

¹. http://gist.cs.berkeley.edu/
For historical reasons, the `inet_ops` operator class is not the default class for types `inet` and `cidr`. To use it, mention the class name in `CREATE INDEX`, for example:

```
CREATE INDEX ON my_table USING GIST (my_inet_column inet_ops);
```

### 59.3. Extensibility

Traditionally, implementing a new index access method meant a lot of difficult work. It was necessary to understand the inner workings of the database, such as the lock manager and Write-Ahead Log. The GiST interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GiST layer itself takes care of concurrency, logging and searching the tree structure.

This extensibility should not be confused with the extensibility of the other standard search trees in terms of the data they can handle. For example, PostgreSQL supports extensible B-trees and hash indexes. That means that you can use PostgreSQL to build a B-tree or hash over any data type you want. But B-trees only support range predicates (`<`, `=`, `>`), and hash indexes only support equality queries.

So if you index, say, an image collection with a PostgreSQL B-tree, you can only issue queries such as “is imagex equal to imagey”, “is imagex less than imagey” and “is imagex greater than imagey”. Depending on how you define “equals”, “less than” and “greater than” in this context, this could be useful. However, by using a GiST based index, you could create ways to ask domain-specific questions, perhaps “find all images of horses” or “find all over-exposed images”.

All it takes to get a GiST access method up and running is to implement several user-defined methods, which define the behavior of keys in the tree. Of course these methods have to be pretty fancy to support fancy queries, but for all the standard queries (B-trees, R-trees, etc.) they’re relatively straightforward. In short, GiST combines extensibility along with generality, code reuse, and a clean interface.

There are seven methods that an index operator class for GiST must provide, and two that are optional. Correctness of the index is ensured by proper implementation of the `same`, `consistent` and `union` methods, while efficiency (size and speed) of the index will depend on the `penalty` and `picksplit` methods. The remaining two basic methods are `compress` and `decompress`, which allow an index to have internal tree data of a different type than the data it indexes. The leaves are to be of the indexed data type, while the other tree nodes can be of any C struct (but you still have to follow PostgreSQL data type rules here, see about `varlena` for variable sized data). If the tree’s internal data type exists at the SQL level, the `STORAGE` option of the `CREATE OPERATOR CLASS` command can be used. The optional eighth method is `distance`, which is needed if the operator class wishes to support ordered scans (nearest-neighbor searches). The optional ninth method `fetch` is needed if the operator class wishes to support index-only scans.

**consistent**

Given an index entry `p` and a query value `q`, this function determines whether the index entry is “consistent” with the query; that is, could the predicate “`indexed_column indexable_operator q`” be true for any row represented by the index entry? For a leaf index entry this is equivalent to testing the indexable condition, while for an internal tree node this determines whether it is necessary to scan the subtree of the index represented by the tree node. When the result is `true`, a `recheck` flag must also be returned. This indicates whether the predicate is certainly true or only possibly true. If `recheck = false` then the index has tested
the predicate condition exactly, whereas if \texttt{recheck = true} the row is only a candidate match. In that case the system will automatically evaluate the \texttt{indexable_operator} against the actual row value to see if it is really a match. This convention allows GiST to support both lossless and lossy index structures.

The SQL declaration of the function must look like this:

\begin{verbatim}
CREATE OR REPLACE FUNCTION my_consistent(internal, data_type, smallint, oid, internal)
RETURNS bool
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
\end{verbatim}

And the matching code in the C module could then follow this skeleton:

\begin{verbatim}
Datum
my_consistent(PG_FUNCTION_ARGS)
{
  GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
data_type *query = PG_GETARG_DATA_TYPE_P(1);
StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
/* Oid subtype = PG_GETARG_OID(3); */
bool *recheck = (bool *) PG_GETARG_POINTER(4);
data_type *key = DatumGetDataType(entry->key);
bool retval;

  /*
  * determine return value as a function of strategy, key and query.
  *
  * Use GIST_LEAF(entry) to know where you’re called in the index tree,
  * which comes handy when supporting the = operator for example (you could
  * check for non empty union() in non-leaf nodes and equality in leaf
  * nodes).
  */

  *recheck = true;   /* or false if check is exact */

  PG_RETURN_BOOL(retval);
}
\end{verbatim}

Here, \texttt{key} is an element in the index and \texttt{query} the value being looked up in the index. The \texttt{StrategyNumber} parameter indicates which operator of your operator class is being applied — it matches one of the operator numbers in the \texttt{CREATE OPERATOR CLASS} command. Depending on what operators you have included in the class, the data type of \texttt{query} could vary with the operator, but the above skeleton assumes it doesn’t.

\begin{verbatim}
union

This method consolidates information in the tree. Given a set of entries, this function generates a new index entry that represents all the given entries.

The SQL declaration of the function must look like this:

\begin{verbatim}
CREATE OR REPLACE FUNCTION my_union(internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
\end{verbatim}

And the matching code in the C module could then follow this skeleton:

\begin{verbatim}
PG_FUNCTION_INFO_V1(my_union);
\end{verbatim}
Datum
my_union(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
    GISTENTRY *ent = entryvec->vector;
    data_type *out,
        *tmp,
        *old;
    int numranges,
        i = 0;

    numranges = entryvec->n;
    tmp = DatumGetDataType(ent[0].key);
    out = tmp;

    if (numranges == 1)
    {
        out = data_type_deep_copy(tmp);
        PG_RETURN_DATA_TYPE_P(out);
    }

    for (i = 1; i <= numranges; i++)
    {
        old = out;
        tmp = DatumGetDataType(ent[i].key);
        out = my_union_implementation(out, tmp);
    }

    PG_RETURN_DATA_TYPE_P(out);
}

As you can see, in this skeleton we’re dealing with a data type where union(X, Y, Z) =
union(union(X, Y), Z). It’s easy enough to support data types where this is not the case, by
implementing the proper union algorithm in this GiST support method.

The union implementation function should return a pointer to newly palloc()ed memory. You
can’t just return whatever the input is.

compress

Converts the data item into a format suitable for physical storage in an index page.

The SQL declaration of the function must look like this:
CREATE OR REPLACE FUNCTION my_compress(internal)
RETURNS internal
AS ‘MODULE_PATHNAME’
LANGUAGE C STRICT;

And the matching code in the C module could then follow this skeleton:

PG_FUNCTION_INFO_V1(my_compress);

Datum
my_compress(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *retval;

    if (entry->leafkey)
Chapter 59. GiST Indexes

{ /* replace entry->key with a compressed version */
  compressed_data_type *compressed_data = palloc(sizeof(compressed_data_type));

  /* fill *compressed_data from entry->key ... */
  retval = palloc(sizeof(GISTENTRY));
  gistentryinit(*retval, PointerGetDatum(compressed_data),
    entry->rel, entry->page, entry->offset, FALSE);
} else
{
  /* typically we needn’t do anything with non-leaf entries */
  retval = entry;
}

PG_RETURN_POINTER(retval);
}

You have to adapt compressed_data_type to the specific type you’re converting to in order to compress your leaf nodes, of course.

decompress

The reverse of the compress method. Converts the index representation of the data item into a format that can be manipulated by the other GiST methods in the operator class.

The SQL declaration of the function must look like this:

CREATE OR REPLACE FUNCTION my_decompress(internal)
RETURNS internal
AS ‘MODULE_PATHNAME’
LANGUAGE C STRICT;

And the matching code in the C module could then follow this skeleton:

PG_FUNCTION_INFO_V1(my_decompress);

Datum
my_decompress(PG_FUNCTION_ARGS)
{
  PG_RETURN_POINTER(PG_GETARG_POINTER(0));
}

The above skeleton is suitable for the case where no decompression is needed.

penalty

Returns a value indicating the “cost” of inserting the new entry into a particular branch of the tree. Items will be inserted down the path of least penalty in the tree. Values returned by penalty should be non-negative. If a negative value is returned, it will be treated as zero.

The SQL declaration of the function must look like this:

CREATE OR REPLACE FUNCTION my_penalty(internal, internal, internal)
RETURNS internal
AS ‘MODULE_PATHNAME’
LANGUAGE C STRICT; -- in some cases penalty functions need not be strict

And the matching code in the C module could then follow this skeleton:

PG_FUNCTION_INFO_V1(my_penalty);

Datum
my_penalty(PG_FUNCTION_ARGS)
Chapter 59. GiST Indexes

{  
    GISTENTRY *origentry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *newentry = (GISTENTRY *) PG_GETARG_POINTER(1);
    float *penalty = (float *) PG_GETARG_POINTER(2);
    data_type *orig = DatumGetDataType(origentry->key);
    data_type *new = DatumGetDataType(newentry->key);

    *penalty = my_penalty_implementation(orig, new);
    PG_RETURN_POINTER(penalty);
}

The penalty function is crucial to good performance of the index. It’ll get used at insertion time to determine which branch to follow when choosing where to add the new entry in the tree.

At query time, the more balanced the index, the quicker the lookup.

\textbf{picksplit}

When an index page split is necessary, this function decides which entries on the page are to stay on the old page, and which are to move to the new page.

The SQL declaration of the function must look like this:

\begin{verbatim}
CREATE OR REPLACE FUNCTION my_picksplit(internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
\end{verbatim}

And the matching code in the C module could then follow this skeleton:

\begin{verbatim}
PG_FUNCTION_INFO_V1(my_picksplit);

Datum my_picksplit(PG_FUNCTION_ARGS)
{
  GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
  OffsetNumber maxoff = entryvec->n - 1;
  GISTENTRY *ent = entryvec->vector;
  GIST_SPLITVEC *v = (GIST_SPLITVEC *) PG_GETARG_POINTER(1);
  int i,
      nbytes;
  OffsetNumber *left,
      *right;
  data_type *tmp_union;
  data_type *unionL;
  data_type *unionR;
  GISTENTRY **raw_entryvec;

  maxoff = entryvec->n - 1;
  nbytes = (maxoff + 1) * sizeof(OffsetNumber);

  v->spl_left = (OffsetNumber *) palloc(nbytes);
  left = v->spl_left;
  v->spl_nleft = 0;

  v->spl_right = (OffsetNumber *) palloc(nbytes);
  right = v->spl_right;
  v->spl_nright = 0;

  unionL = NULL;
  unionR = NULL;
}
\end{verbatim}
/ Initialize the raw entry vector. */
raw_entryvec = (GISTENTRY **) malloc(entryvec->n * sizeof(void *));
for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
    raw_entryvec[i] = &(entryvec->vector[i]);

for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
{
    int real_index = raw_entryvec[i] - entryvec->vector;
    tmp_union = DatumGetDataType(entryvec->vector[real_index].key);
    Assert(tmp_union != NULL);
    /*
    * Choose where to put the index entries and update unionL and unionR
    * accordingly. Append the entries to either v_spl_left or
    * v_spl_right, and care about the counters.
    */
    if (my_choice_is_left(unionL, curl, unionR, curr))
    {
        if (unionL == NULL)
            unionL = tmp_union;
        else
            unionL = my_union_implementation(unionL, tmp_union);
        *left = real_index;
        ++left;
        ++(v->spl_nleft);
    }
    else
    {
        /*
        * Same on the right
        */
    }
}

v->spl_ldatum = DataTypeGetDatum(unionL);
v->spl_rdatum = DataTypeGetDatum(unionR);
PG_RETURN_POINTER(v);

Like penalty, the picksplit function is crucial to good performance of the index. Designing
suitable penalty and picksplit implementations is where the challenge of implementing
well-performing GiST indexes lies.

same

Returns true if two index entries are identical, false otherwise.

The SQL declaration of the function must look like this:
CREATE OR REPLACE FUNCTION my_same(internal, internal, internal)
RETURNS internal
AS ‘MODULE_PATHNAME’
LANGUAGE C STRICT;

And the matching code in the C module could then follow this skeleton:
PG_FUNCTION_INFO_V1(my_same);
Chapter 59. GiST Indexes

Datum
my_same(PG_FUNCTION_ARGS)
{
    prefix_range *v1 = PG_GETARG_PREFIX_RANGE_P(0);
    prefix_range *v2 = PG_GETARG_PREFIX_RANGE_P(1);
    bool *result = (bool *) PG_GETARG_POINTER(2);
    *result = my_eq(v1, v2);
    PG_RETURN_POINTER(result);
}

For historical reasons, the same function doesn’t just return a Boolean result; instead it has to store the flag at the location indicated by the third argument.

distance

Given an index entry p and a query value q, this function determines the index entry’s “distance” from the query value. This function must be supplied if the operator class contains any ordering operators. A query using the ordering operator will be implemented by returning index entries with the smallest “distance” values first, so the results must be consistent with the operator’s semantics. For a leaf index entry the result just represents the distance to the index entry: for an internal tree node, the result must be the smallest distance that any child entry could have.

The SQL declaration of the function must look like this:

CREATE OR REPLACE FUNCTION my_distance(internal, data_type, smallint, oid)
RETURNS float8
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

And the matching code in the C module could then follow this skeleton:

PG_FUNCTION_INFO_V1(my_distance);

Datum
my_distance(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    data_type *query = PG_GETARG_DATA_TYPE_P(1);
    StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
    /* Oid subtype = PG_GETARG_OID(3); */
    /* bool *recheck = (bool *) PG_GETARG_POINTER(4); */
    data_type *key = DatumGetDataType(entry->key);
    double retval;

    /*
    * determine return value as a function of strategy, key and query.
    */

    PG_RETURN_FLOAT8(retval);
}

The arguments to the distance function are identical to the arguments of the consistent function.

Some approximation is allowed when determining the distance, so long as the result is never greater than the entry’s actual distance. Thus, for example, distance to a bounding box is usually sufficient in geometric applications. For an internal tree node, the distance returned must not be greater than the distance to any of the child nodes. If the returned distance is not exact, the function must set *recheck to true. (This is not necessary for internal tree nodes; for them, the
calculation is always assumed to be inexact.) In this case the executor will calculate the accurate distance after fetching the tuple from the heap, and reorder the tuples if necessary.

If the distance function returns \*recheck = true for any leaf node, the original ordering operator’s return type must be float8 or float4, and the distance function’s result values must be comparable to those of the original ordering operator, since the executor will sort using both distance function results and recalculated ordering-operator results. Otherwise, the distance function’s result values can be any finite float8 values, so long as the relative order of the result values matches the order returned by the ordering operator. (Infinity and minus infinity are used internally to handle cases such as nulls, so it is not recommended that distance functions return these values.)

fetch

Converts the compressed index representation of the data item into the original data type, for index-only scans. The returned data must be an exact, non-lossy copy of the originally indexed value.

The SQL declaration of the function must look like this:

CREATE OR REPLACE FUNCTION my_fetch(internal) 
RETURNS internal 
AS 'MODULE_PATHNAME' 
LANGUAGE C STRICT;

The argument is a pointer to a GISTENTRY struct. On entry, its 'key' field contains a non-NULL leaf datum in its compressed form. The return value is another GISTENTRY struct, whose 'key' field contains the same datum in the original, uncompressed form. If the opclass’ compress function does nothing for leaf entries, the fetch method can return the argument as is.

The matching code in the C module could then follow this skeleton:

PG_FUNCTION_INFO_V1(my_fetch);

Datum my_fetch(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    input_data_type *in = DatumGetP(entry->key);
    fetched_data_type *fetched_data;
    GISTENTRY *retval;

    retval = palloc(sizeof(GISTENTRY));
    fetched_data = palloc(sizeof(fetched_data_type));

    /*
     * Convert 'fetched_data' into the a Datum of the original datatype.
     */

    /* fill *retval from fetch_data. */
    gistentryinit(*retval, PointerGetDatum(converted_datum), entry->rel, entry->page, entry->offset, FALSE);

    PG_RETURN_POINTER(retval);
}

If the compress method is lossy for leaf entries, the operator class cannot support index-only scans, and must not define a 'fetch' function.

All the GiST support methods are normally called in short-lived memory contexts; that is, CurrentMemoryContext will get reset after each tuple is processed. It is therefore not very
important to worry about pfree’ing everything you palloc. However, in some cases it’s useful for a support method to cache data across repeated calls. To do that, allocate the longer-lived data in fcininfo->flinfo->fn_mcxt, and keep a pointer to it in fcininfo->flinfo->fn_extra. Such data will survive for the life of the index operation (e.g., a single GiST index scan, index build, or index tuple insertion). Be careful to pfree the previous value when replacing a fn_extra value, or the leak will accumulate for the duration of the operation.

59.4. Implementation

59.4.1. GiST buffering build

Building large GiST indexes by simply inserting all the tuples tends to be slow, because if the index tuples are scattered across the index and the index is large enough to not fit in cache, the insertions need to perform a lot of random I/O. Beginning in version 9.2, PostgreSQL supports a more efficient method to build GiST indexes based on buffering, which can dramatically reduce the number of random I/Os needed for non-ordered data sets. For well-ordered data sets the benefit is smaller or non-existent, because only a small number of pages receive new tuples at a time, and those pages fit in cache even if the index as whole does not.

However, buffering index build needs to call the penalty function more often, which consumes some extra CPU resources. Also, the buffers used in the buffering build need temporary disk space, up to the size of the resulting index. Buffering can also influence the quality of the resulting index, in both positive and negative directions. That influence depends on various factors, like the distribution of the input data and the operator class implementation.

By default, a GiST index build switches to the buffering method when the index size reaches effective_cache_size. It can be manually turned on or off by the buffering parameter to the CREATE INDEX command. The default behavior is good for most cases, but turning buffering off might speed up the build somewhat if the input data is ordered.

59.5. Examples

The PostgreSQL source distribution includes several examples of index methods implemented using GiST. The core system currently provides text search support (indexing for tsvector and tsquery) as well as R-Tree equivalent functionality for some of the built-in geometric data types (see src/backend/access/gist/gistproc.c). The following contrib modules also contain GiST operator classes:

btree_gist

B-tree equivalent functionality for several data types
cube

Indexing for multidimensional cubes*hstore

Module for storing (key, value) pairs
intarray

    RD-Tree for one-dimensional array of int4 values

ltree

    Indexing for tree-like structures

pg_trgm

    Text similarity using trigram matching

seg

    Indexing for “float ranges”
Chapter 60. SP-GiST Indexes

60.1. Introduction

SP-GiST is an abbreviation for space-partitioned GiST. SP-GiST supports partitioned search trees, which facilitate development of a wide range of different non-balanced data structures, such as quad-trees, k-d trees, and radix trees (tries). The common feature of these structures is that they repeatedly divide the search space into partitions that need not be of equal size. Searches that are well matched to the partitioning rule can be very fast.

These popular data structures were originally developed for in-memory usage. In main memory, they are usually designed as a set of dynamically allocated nodes linked by pointers. This is not suitable for direct storing on disk, since these chains of pointers can be rather long which would require too many disk accesses. In contrast, disk-based data structures should have a high fanout to minimize I/O. The challenge addressed by SP-GiST is to map search tree nodes to disk pages in such a way that a search need access only a few disk pages, even if it traverses many nodes.

Like GiST, SP-GiST is meant to allow the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from Purdue University’s SP-GiST Indexing Project web site¹. The SP-GiST implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their web site².

60.2. Built-in Operator Classes

The core PostgreSQL distribution includes the SP-GiST operator classes shown in Table 60-1.

Table 60-1. Built-in SP-GiST Operator Classes

<table>
<thead>
<tr>
<th>Name</th>
<th>Indexed Data Type</th>
<th>Indexable Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td>kd_point_ops</td>
<td>point</td>
<td>&lt;&lt; &lt;^ ^&gt; &gt;^ ~=</td>
</tr>
<tr>
<td>quad_point_ops</td>
<td>point</td>
<td>&lt;&lt; &lt;^ ^&gt; &gt;^ ~=</td>
</tr>
<tr>
<td>range_ops</td>
<td>any range type</td>
<td>&lt;= &lt;^ ^&gt; ~</td>
</tr>
<tr>
<td>text_ops</td>
<td>text</td>
<td>&lt;= =&gt; ~</td>
</tr>
</tbody>
</table>

Of the two operator classes for type point, quad_point_ops is the default. kd_point_ops supports the same operators but uses a different index data structure which may offer better performance in some applications.

60.3. Extensibility

SP-GiST offers an interface with a high level of abstraction, requiring the access method developer to implement only methods specific to a given data type. The SP-GiST core is responsible for efficient disk mapping and searching the tree structure. It also takes care of concurrency and logging considerations.

Leaf tuples of an SP-GiST tree contain values of the same data type as the indexed column. Leaf tuples at the root level will always contain the original indexed data value, but leaf tuples at lower levels might contain only a compressed representation, such as a suffix. In that case the operator class support functions must be able to reconstruct the original value using information accumulated from the inner tuples that are passed through to reach the leaf level.

Inner tuples are more complex, since they are branching points in the search tree. Each inner tuple contains a set of one or more nodes, which represent groups of similar leaf values. A node contains a downlink that leads to either another, lower-level inner tuple, or a short list of leaf tuples that all lie on the same index page. Each node has a label that describes it; for example, in a radix tree the node label could be the next character of the string value. Optionally, an inner tuple can have a prefix value that describes all its members. In a radix tree this could be the common prefix of the represented strings. The prefix value is not necessarily really a prefix, but can be any data needed by the operator class; for example, in a quad-tree it can store the central point that the four quadrants are measured with respect to. A quad-tree inner tuple would then also contain four nodes corresponding to the quadrants around this central point.

Some tree algorithms require knowledge of level (or depth) of the current tuple, so the SP-GiST core provides the possibility for operator classes to manage level counting while descending the tree. There is also support for incrementally reconstructing the represented value when that is needed.

Note: The SP-GiST core code takes care of null entries. Although SP-GiST indexes do store entries for nulls in indexed columns, this is hidden from the index operator class code: no null index entries or search conditions will ever be passed to the operator class methods. (It is assumed that SP-GiST operators are strict and so cannot succeed for null values.) Null values are therefore not discussed further here.

There are five user-defined methods that an index operator class for SP-GiST must provide. All five follow the convention of accepting two internal arguments, the first of which is a pointer to a C struct containing input values for the support method, while the second argument is a pointer to a C struct where output values must be placed. Four of the methods just return void, since all their results appear in the output struct; but leaf_consistent additionally returns a boolean result. The methods must not modify any fields of their input structs. In all cases, the output struct is initialized to zeroes before calling the user-defined method.

The five user-defined methods are:

config

Returns static information about the index implementation, including the data type OIDs of the prefix and node label data types.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_config(internal, internal) RETURNS void ...
```

The first argument is a pointer to a spgConfigIn C struct, containing input data for the function. The second argument is a pointer to a spgConfigOut C struct, which the function must fill with result data.
typedef struct spgConfigIn
{
    Oid attType; /* Data type to be indexed */
} spgConfigIn;

typedef struct spgConfigOut
{
    Oid prefixType; /* Data type of inner-tuple prefixes */
    Oid labelType; /* Data type of inner-tuple node labels */
    bool canReturnData; /* Opclass can reconstruct original data */
    bool longValuesOK; /* Opclass can cope with values > 1 page */
} spgConfigOut;

attType is passed in order to support polymorphic index operator classes; for ordinary fixed-data-type operator classes, it will always have the same value and so can be ignored.

For operator classes that do not use prefixes, prefixType can be set to VOIDOID. Likewise, for operator classes that do not use node labels, labelType can be set to VOIDOID. canReturnData should be set true if the operator class is capable of reconstructing the originally-supplied index value. longValuesOK should be set true only when the attType is of variable length and the operator class is capable of segmenting long values by repeated suffixing (see Section 60.4.1).

choose

Chooses a method for inserting a new value into an inner tuple.

The SQL declaration of the function must look like this:

CREATE FUNCTION my_choose(internal, internal) RETURNS void ... The first argument is a pointer to a spgChooseIn C struct, containing input data for the function. The second argument is a pointer to a spgChooseOut C struct, which the function must fill with result data.

typedef struct spgChooseIn
{
    Datum datum; /* original datum to be indexed */
    Datum leafDatum; /* current datum to be stored at leaf */
    int level; /* current level (counting from zero) */

    /* Data from current inner tuple */
    bool allTheSame; /* tuple is marked all-the-same? */
    bool hasPrefix; /* tuple has a prefix? */
    Datum prefixDatum; /* if so, the prefix value */
    int nNodes; /* number of nodes in the inner tuple */
    Datum *nodeLabels; /* node label values (NULL if none) */
} spgChooseIn;

typedef enum spgChooseResultType
{
    spgMatchNode = 1, /* descend into existing node */
    spgAddNode, /* add a node to the inner tuple */
    spgSplitTuple /* split inner tuple (change its prefix) */
} spgChooseResultType;

typedef struct spgChooseOut
{
    spgChooseResultType resultType; /* action code, see above */
    union
    {
        /* Result data */
    }
} spgChooseOut;
Chapter 60. SP-GiST Indexes

```c
struct /* results for spgMatchNode */
{
    int nodeN; /* descend to this node (index from 0) */
    int levelAdd; /* increment level by this much */
    Datum restDatum; /* new leaf datum */
} matchNode;

struct /* results for spgAddNode */
{
    Datum nodeLabel; /* new node’s label */
    int nodeN; /* where to insert it (index from 0) */
} addNode;

struct /* results for spgSplitTuple */
{
    bool prefixHasPrefix; /* tuple should have a prefix? */
    Datum prefixPrefixDatum; /* if so, its value */
    Datum nodeLabel; /* node’s label */

    bool postfixHasPrefix; /* tuple should have a prefix? */
    Datum postfixPrefixDatum; /* if so, its value */
} splitTuple;

result; /* Info to form new inner tuple with one node */

result; /* Info to form new lower-level inner tuple with all old nodes */

spgChooseOut;
```

datum is the original datum that was to be inserted into the index. leafDatum is initially the same as datum, but can change at lower levels of the tree if the choose or picksplit methods change it. When the insertion search reaches a leaf page, the current value of leafDatum is what will be stored in the newly created leaf tuple. level is the current inner tuple’s level, starting at zero for the root level. allTheSame is true if the current inner tuple is marked as containing multiple equivalent nodes (see Section 60.4.3). hasPrefix is true if the current inner tuple contains a prefix; if so, prefixDatum is its value. nNodes is the number of child nodes contained in the inner tuple, and nodeLabels is an array of their label values, or NULL if there are no labels.

The choose function can determine either that the new value matches one of the existing child nodes, or that a new child node must be added, or that the new value is inconsistent with the tuple prefix and so the inner tuple must be split to create a less restrictive prefix.

If the new value matches one of the existing child nodes, set resultType to spgMatchNode. Set nodeN to the index (from zero) of that node in the node array. Set levelAdd to the increment in level caused by descending through that node, or leave it as zero if the operator class does not use levels. Set restDatum to equal datum if the operator class does not modify datums from one level to the next, or otherwise set it to the modified value to be used as leafDatum at the next level.

If a new child node must be added, set resultType to spgAddNode. Set nodeLabel to the label to be used for the new node, and set nodeN to the index (from zero) at which to insert the node in the node array. After the node has been added, the choose function will be called again with the modified inner tuple; that call should result in an spgMatchNode result.

If the new value is inconsistent with the tuple prefix, set resultType to spgSplitTuple. This action moves all the existing nodes into a new lower-level inner tuple, and replaces the existing inner tuple with a tuple having a single node that links to the new lower-level inner tuple. Set prefixHasPrefix to indicate whether the new upper tuple should have a prefix, and if so set prefixPrefixDatum to the prefix value. This new prefix value must be sufficiently less restrictive than the original to accept the new value to be indexed, and it should be no longer
than the original prefix. Set nodeLabel to the label to be used for the node that will point to the new lower-level inner tuple. Set postfixHasPrefix to indicate whether the new lower-level inner tuple should have a prefix, and if so set postfixPrefixDatum to the prefix value. The combination of these two prefixes and the additional label must have the same meaning as the original prefix, because there is no opportunity to alter the node labels that are moved to the new lower-level tuple, nor to change any child index entries. After the node has been split, the choose function will be called again with the replacement inner tuple. That call will usually result in an spgAddNode result, since presumably the node label added in the split step will not match the new value; so after that, there will be a third call that finally returns spgMatchNode and allows the insertion to descend to the leaf level.

picksplit

Decides how to create a new inner tuple over a set of leaf tuples.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_picksplit(internal, internal) RETURNS void ...
```

The first argument is a pointer to a spgPickSplitIn C struct, containing input data for the function. The second argument is a pointer to a spgPickSplitOut C struct, which the function must fill with result data.

```
typedef struct spgPickSplitIn
{
    int nTuples;     /* number of leaf tuples */
    Datum *datums;   /* their datums (array of length nTuples) */
    int level;       /* current level (counting from zero) */
} spgPickSplitIn;

typedef struct spgPickSplitOut
{
    bool hasPrefix;  /* new inner tuple should have a prefix? */
    Datum prefixDatum;  /* if so, its value */
    int nNodes;       /* number of nodes for new inner tuple */
    Datum *nodeLabels; /* their labels (or NULL for no labels) */
    int *mapTuplesToNodes; /* node index for each leaf tuple */
    Datum *leafTupleDatums; /* datum to store in each new leaf tuple */
} spgPickSplitOut;
```

nTuples is the number of leaf tuples provided. datums is an array of their datum values. level is the current level that all the leaf tuples share, which will become the level of the new inner tuple.

Set hasPrefix to indicate whether the new inner tuple should have a prefix, and if so set prefixDatum to the prefix value. Set nNodes to indicate the number of nodes that the new inner tuple will contain, and set nodeLabels to an array of their label values. (If the nodes do not require labels, set nodeLabels to NULL; see Section 60.4.2 for details.) Set mapTuplesToNodes to an array that gives the index (from zero) of the node that each leaf tuple should be assigned to. Set leafTupleDatums to an array of the values to be stored in the new leaf tuples (these will be the same as the input datums if the operator class does not modify datums from one level to the next). Note that the picksplit function is responsible for palloc’ing the nodeLabels, mapTuplesToNodes and leafTupleDatums arrays.

If more than one leaf tuple is supplied, it is expected that the picksplit function will classify them into more than one node; otherwise it is not possible to split the leaf tuples across multiple pages, which is the ultimate purpose of this operation. Therefore, if the picksplit function ends up placing all the leaf tuples in the same node, the core SP-GiST code will override that
decision and generate an inner tuple in which the leaf tuples are assigned at random to several identically-labeled nodes. Such a tuple is marked allTheSame to signify that this has happened. The choose and inner_consistent functions must take suitable care with such inner tuples. See Section 60.4.3 for more information.

picksplit can be applied to a single leaf tuple only in the case that the config function set longValuesOK to true and a larger-than-a-page input value has been supplied. In this case the point of the operation is to strip off a prefix and produce a new, shorter leaf datum value. The call will be repeated until a leaf datum short enough to fit on a page has been produced. See Section 60.4.1 for more information.

inner_consistent

Returns set of nodes (branches) to follow during tree search.

The SQL declaration of the function must look like this:

```sql
CREATE FUNCTION my_inner_consistent(internal, internal) RETURNS void ...
```

The first argument is a pointer to a spgInnerConsistentIn C struct, containing input data for the function. The second argument is a pointer to a spgInnerConsistentOut C struct, which the function must fill with result data.

```c
typedef struct spgInnerConsistentIn
{
    ScanKey scankeys;    /* array of operators and comparison values */
    int nkeys;           /* length of array */
    Datum reconstructedValue; /* value reconstructed at parent */
    int level;           /* current level (counting from zero) */
    bool returnData;     /* original data must be returned? */
    /* Data from current inner tuple */
    bool allTheSame;     /* tuple is marked all-the-same? */
    bool hasPrefix;      /* tuple has a prefix? */
    Datum prefixDatum;   /* if so, the prefix value */
    int nNodes;          /* number of nodes in the inner tuple */
    Datum *nodeLabels;   /* node label values (NULL if none) */
} spgInnerConsistentIn;
```

```c
typedef struct spgInnerConsistentOut
{
    int nNodes;    /* number of child nodes to be visited */
    int *nodeNumbers; /* their indexes in the node array */
    int *levelAdds;     /* increment level by this much for each */
    Datum *reconstructedValues; /* associated reconstructed values */
} spgInnerConsistentOut;
```

The array scankeys, of length nkeys, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them are interesting. (Note that nkeys = 0 implies that all index entries satisfy the query.) Usually the consistent function only cares about the sk_strategy and sk_argument fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check sk_flags to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. reconstructedValue is the value reconstructed for the parent tuple; it is (Datum) 0 at the root level or if the inner_consistent function did not provide a value at the parent level. level is the current inner tuple’s level, starting at zero for the root level. returnData is true if reconstructed data is required for this query; this will only be so if the config function asserted canReturnData. allTheSame is true if the current inner tuple is marked “all-the-same”; in this case all the nodes have the same label (if any) and so either all
or none of them match the query (see Section 60.4.3). hasPrefix is true if the current inner
tuple contains a prefix; if so, prefixDatum is its value. nNodes is the number of child nodes
contained in the inner tuple, and nodeLabels is an array of their label values, or NULL if the
nodes do not have labels.
nNodes must be set to the number of child nodes that need to be visited by the search, and
nodeNumbers must be set to an array of their indexes. If the operator class keeps track of levels,
set levelAdds to an array of the level increments required when descending to each node to be
visited. (Often these increments will be the same for all the nodes, but that’s not necessarily
so, so an array is used.) If value reconstruction is needed, set reconstructedValues to
an array of the values reconstructed for each child node to be visited; otherwise, leave
reconstructedValues as NULL. Note that the inner_consistent function is responsible
for palloc’ing the nodeNumbers, levelAdds and reconstructedValues arrays.

leaf_consistent

Returns true if a leaf tuple satisfies a query.

The SQL declaration of the function must look like this:

CREATE FUNCTION my_leaf_consistent(internal, internal) RETURNS bool ...
The first argument is a pointer to a spgLeafConsistentIn C struct, containing input data for
the function. The second argument is a pointer to a spgLeafConsistentOut C struct, which
the function must fill with result data.

typedef struct spgLeafConsistentIn
{
    ScanKey scankeys; /* array of operators and comparison values */
    int nkeys; /* length of array */
    Datum reconstructedValue; /* value reconstructed at parent */
    int level; /* current level (counting from zero) */
    bool returnData; /* original data must be returned? */
    Datum leafDatum; /* datum in leaf tuple */
} spgLeafConsistentIn;

typedef struct spgLeafConsistentOut
{
    Datum leafValue; /* reconstructed original data, if any */
    bool recheck; /* set true if operator must be rechecked */
} spgLeafConsistentOut;
The array scankeys, of length nkeys, describes the index search condition(s). These conditions
are combined with AND — only index entries that satisfy all of them satisfy the query. (Note that
nkeys = 0 implies that all index entries satisfy the query.) Usually the consistent function only
cares about the sk_strategy and sk_argument fields of each array entry, which respectively
give the indexable operator and comparison value. In particular it is not necessary to check
sk_flags to see if the comparison value is NULL, because the SP-GiST core code will filter
out such conditions. reconstructedValue is the value reconstructed for the parent tuple; it is
(Datum) 0 at the root level or if the inner_consistent function did not provide a value
at the parent level. level is the current leaf tuple’s level, starting at zero for the root level.
returnData is true if reconstructed data is required for this query; this will only be so if the
config function asserted canReturnData. leafDatum is the key value stored in the current
leaf tuple.

The function must return true if the leaf tuple matches the query, or false if not. In the true
case, if returnData is true then leafValue must be set to the value originally supplied to be
indexed for this leaf tuple. Also, recheck may be set to true if the match is uncertain and so the operator(s) must be re-applied to the actual heap tuple to verify the match.

All the SP-GiST support methods are normally called in a short-lived memory context; that is, CurrentMemoryContext will be reset after processing of each tuple. It is therefore not very important to worry about pfree’ing everything you palloc. (The config method is an exception: it should try to avoid leaking memory. But usually the config method need do nothing but assign constants into the passed parameter struct.)

If the indexed column is of a collatable data type, the index collation will be passed to all the support methods, using the standard PG_GET_COLLATION() mechanism.

60.4. Implementation

This section covers implementation details and other tricks that are useful for implementers of SP-GiST operator classes to know.

60.4.1. SP-GiST Limits

Individual leaf tuples and inner tuples must fit on a single index page (8KB by default). Therefore, when indexing values of variable-length data types, long values can only be supported by methods such as radix trees, in which each level of the tree includes a prefix that is short enough to fit on a page, and the final leaf level includes a suffix also short enough to fit on a page. The operator class should set longValuesOK to TRUE only if it is prepared to arrange for this to happen. Otherwise, the SP-GiST core will reject any request to index a value that is too large to fit on an index page.

Likewise, it is the operator class’s responsibility that inner tuples do not grow too large to fit on an index page; this limits the number of child nodes that can be used in one inner tuple, as well as the maximum size of a prefix value.

Another limitation is that when an inner tuple’s node points to a set of leaf tuples, those tuples must all be in the same index page. (This is a design decision to reduce seeking and save space in the links that chain such tuples together.) If the set of leaf tuples grows too large for a page, a split is performed and an intermediate inner tuple is inserted. For this to fix the problem, the new inner tuple must divide the set of leaf values into more than one node group. If the operator class’s picksplit function fails to do that, the SP-GiST core resorts to extraordinary measures described in Section 60.4.3.

60.4.2. SP-GiST Without Node Labels

Some tree algorithms use a fixed set of nodes for each inner tuple; for example, in a quad-tree there are always exactly four nodes corresponding to the four quadrants around the inner tuple’s centroid point. In such a case the code typically works with the nodes by number, and there is no need for explicit node labels. To suppress node labels (and thereby save some space), the picksplit function can return NULL for the nodeLabels array. This will in turn result in nodeLabels being NULL during subsequent calls to choose and inner_consistent. In principle, node labels could be used for some inner tuples and omitted for others in the same index.

When working with an inner tuple having unlabeled nodes, it is an error for choose to return spgAddNode, since the set of nodes is supposed to be fixed in such cases. Also, there is no provision for generating an unlabeled node in spgSplitTuple actions, since it is expected that an spgAddNode action will be needed as well.
60.4.3. “All-the-same” Inner Tuples

The SP-GiST core can override the results of the operator class’s `picksplit` function when `picksplit` fails to divide the supplied leaf values into at least two node categories. When this happens, the new inner tuple is created with multiple nodes that each have the same label (if any) that `picksplit` gave to the one node it did use, and the leaf values are divided at random among these equivalent nodes. The `allTheSame` flag is set on the inner tuple to warn the `choose` and `inner_consistent` functions that the tuple does not have the node set that they might otherwise expect.

When dealing with an `allTheSame` tuple, a `choose` result of `spgMatchNode` is interpreted to mean that the new value can be assigned to any of the equivalent nodes; the core code will ignore the supplied `nodeN` value and descend into one of the nodes at random (so as to keep the tree balanced). It is an error for `choose` to return `spgAddNode`, since that would make the nodes not all equivalent; the `spgSplitTuple` action must be used if the value to be inserted doesn’t match the existing nodes.

When dealing with an `allTheSame` tuple, the `inner_consistent` function should return either all or none of the nodes as targets for continuing the index search, since they are all equivalent. This may or may not require any special-case code, depending on how much the `inner_consistent` function normally assumes about the meaning of the nodes.

60.5. Examples

The PostgreSQL source distribution includes several examples of index operator classes for SP-GiST. The core system currently provides radix trees over text columns and two types of trees over points: quad-tree and k-d tree. Look into `src/backend/access/spgist/` to see the code.
Chapter 61. GIN Indexes

61.1. Introduction

GIN stands for Generalized Inverted Index. GIN is designed for handling cases where the items to be indexed are composite values, and the queries to be handled by the index need to search for element values that appear within the composite items. For example, the items could be documents, and the queries could be searches for documents containing specific words.

We use the word item to refer to a composite value that is to be indexed, and the word key to refer to an element value. GIN always stores and searches for keys, not item values per se.

A GIN index stores a set of (key, posting list) pairs, where a posting list is a set of row IDs in which the key occurs. The same row ID can appear in multiple posting lists, since an item can contain more than one key. Each key value is stored only once, so a GIN index is very compact for cases where the same key appears many times.

GIN is generalized in the sense that the GIN access method code does not need to know the specific operations that it accelerates. Instead, it uses custom strategies defined for particular data types. The strategy defines how keys are extracted from indexed items and query conditions, and how to determine whether a row that contains some of the key values in a query actually satisfies the query.

One advantage of GIN is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert. This is much the same advantage as using GiST.

The GIN implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov. There is more information about GIN on their website.

61.2. Built-in Operator Classes

The core PostgreSQL distribution includes the GIN operator classes shown in Table 61-1. (Some of the optional modules described in Appendix F provide additional GIN operator classes.)

Table 61-1. Built-in GIN Operator Classes

<table>

1. http://www.sai.msu.su/~megera/wiki/Gin
### 61.3. Extensibility

The GIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GIN layer itself takes care of concurrency, logging and searching the tree structure.

All it takes to get a GIN access method working is to implement a few user-defined methods, which define the behavior of keys in the tree and the relationships between keys, indexed items, and indexable queries. In short, GIN combines extensibility with generality, code reuse, and a clean interface.

There are three methods that an operator class for GIN must provide:

```c
int compare(Datum a, Datum b)
```

Compares two keys (not indexed items!) and returns an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second. Null

<td>tsvector</td>
<td>0 @ 000</td>
</tr>
</tbody>
</table>

Of the two operator classes for type jsonb, `jsonb_ops` is the default. `jsonb_path_ops` supports fewer operators but offers better performance for those operators. See Section 8.14.4 for details.
keys are never passed to this function.

Datum *extractValue(Datum itemValue, int32 *nkeys, bool **nullFlags)

Returns a palloc’d array of keys given an item to be indexed. The number of returned keys must be stored into *nkeys. If any of the keys can be null, also palloc an array of *nkeys bool fields, store its address at *nullFlags, and set these null flags as needed. *nullFlags can be left NULL (its initial value) if all keys are non-null. The return value can be NULL if the item contains no keys.

Datum *extractQuery(Datum query, int32 *nkeys, StrategyNumber n, bool **pmatch, Pointer **extra_data, bool **nullFlags, int32 *searchMode)

Returns a palloc’d array of keys given a value to be queried; that is, query is the value on the right-hand side of an indexable operator whose left-hand side is the indexed column. n is the strategy number of the operator within the operator class (see Section 35.14.2). Often, extractQuery will need to consult n to determine the data type of query and the method it should use to extract key values. The number of returned keys must be stored into *nkeys. If any of the keys can be null, also palloc an array of *nkeys bool fields, store its address at *nullFlags, and set these null flags as needed. *nullFlags can be left NULL (its initial value) if all keys are non-null. The return value can be NULL if the query contains no keys.

*searchMode is an output argument that allows extractQuery to specify details about how the search will be done. If *searchMode is set to GIN_SEARCH_MODE_DEFAULT (which is the value it is initialized to before call), only items that match at least one of the returned keys are considered candidate matches. If *searchMode is set to GIN_SEARCH_MODE_INCLUDE_EMPTY, then in addition to items containing at least one matching key, items that contain no keys at all are considered candidate matches. (This mode is useful for implementing is-subset-of operators, for example.) If *searchMode is set to GIN_SEARCH_MODE_ALL, then all non-null items in the index are considered candidate matches, whether they match any of the returned keys or not. (This mode is much slower than the other two choices, since it requires scanning essentially the entire index, but it may be necessary to implement corner cases correctly. An operator that needs this mode in most cases is probably not a good candidate for a GIN operator class.) The symbols to use for setting this mode are defined in access/gin.h.

*pmatch is an output argument for use when partial match is supported. To use it, extractQuery must allocate an array of *nkeys booleans and store its address at *pmatch. Each element of the array should be set to TRUE if the corresponding key requires partial match, FALSE if not. If *pmatch is set to NULL then GIN assumes partial match is not required. The variable is initialized to NULL before call, so this argument can simply be ignored by operator classes that do not support partial match.

*extra_data is an output argument that allows extractQuery to pass additional data to the consistent and comparePartial methods. To use it, extractQuery must allocate an array of *nkeys pointers and store its address at *extra_data, then store whatever it wants to into the individual pointers. The variable is initialized to NULL before call, so this argument can simply be ignored by operator classes that do not require extra data. If *extra_data is set, the whole array is passed to the consistent method, and the appropriate element to the comparePartial method.

An operator class must also provide a function to check if an indexed item matches the query. It comes in two flavors, a boolean consistent function, and a ternary triConsistent function. triConsistent covers the functionality of both, so providing triConsistent alone is sufficient. However, if the boolean variant is significantly cheaper to calculate, it can be advantageous to provide both. If only the boolean variant is provided, some optimizations that depend on refuting index items before fetching all the keys are disabled.
bool consistent(bool check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], bool *recheck, Datum queryKeys[], bool nullFlags[])

Returns TRUE if an indexed item satisfies the query operator with strategy number n (or might satisfy it, if the recheck indication is returned). This function does not have direct access to the indexed item’s value, since GIN does not store items explicitly. Rather, what is available is knowledge about which key values extracted from the query appear in a given indexed item. The check array has length nkeys, which is the same as the number of keys previously returned by extractQuery for this query datum. Each element of the check array is TRUE if the indexed item contains the corresponding query key, i.e., if (check[i] == TRUE) the i-th key of the extractQuery result array is present in the indexed item. The original query datum is passed in case the consistent method needs to consult it, and so are the queryKeys[] and nullFlags[] arrays previously returned by extractQuery. extra_data is the extra-data array returned by extractQuery, or NULL if none.

When extractQuery returns a null key in queryKeys[], the corresponding check[] element is TRUE if the indexed item contains a null key; that is, the semantics of check[] are like IS NOT DISTINCT FROM. The consistent function can examine the corresponding nullFlags[] element if it needs to tell the difference between a regular value match and a null match.

On success, *recheck should be set to TRUE if the heap tuple needs to be rechecked against the query operator, or FALSE if the index test is exact. That is, a FALSE return value guarantees that the heap tuple does not match the query; a TRUE return value with *recheck set to FALSE guarantees that the heap tuple does match the query; and a TRUE return value with *recheck set to TRUE means that the heap tuple might match the query, so it needs to be fetched and rechecked by evaluating the query operator directly against the originally indexed item.

GinTernaryValue triConsistent(GinTernaryValue check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], Datum queryKeys[], bool nullFlags[])

triConsistent is similar to consistent, but instead of a boolean check[], there are three possible values for each key: GIN_TRUE, GIN_FALSE and GIN_MAYBE. GIN_FALSE and GIN_TRUE have the same meaning as regular boolean values. GIN_MAYBE means that the presence of that key is not known. When GIN_MAYBE values are present, the function should only return GIN_TRUE if the item matches whether or not the index item contains the corresponding query keys. Likewise, the function must return GIN_FALSE only if the item does not match, whether or not it contains the GIN_MAYBE keys. If the result depends on the GIN_MAYBE entries, i.e. the match cannot be confirmed or refuted based on the known query keys, the function must return GIN_MAYBE.

When there are no GIN_MAYBE values in the check vector, GIN_MAYBE return value is equivalent of setting recheck flag in the boolean consistent function.

Optionally, an operator class for GIN can supply the following method:

int comparePartial(Datum partial_key, Datum key, StrategyNumber n, Pointer extra_data)

Compare a partial-match query key to an index key. Returns an integer whose sign indicates the result: less than zero means the index key does not match the query, but the index scan should continue; zero means that the index key does match the query; greater than zero indicates that the index scan should stop because no more matches are possible. The strategy number n of the operator that generated the partial match query is provided, in case its semantics are needed to determine when to end the scan. Also, extra_data is the corresponding element of the extra-data array made by extractQuery, or NULL if none. Null keys are never passed to this function.
To support “partial match” queries, an operator class must provide the `comparePartial` method, and its `extractQuery` method must set the `pmatch` parameter when a partial-match query is encountered. See Section 61.4.2 for details.

The actual data types of the various `Datum` values mentioned above vary depending on the operator class. The item values passed to `extractValue` are always of the operator class’s input type, and all key values must be of the class’s `STORAGE` type. The type of the `query` argument passed to `extractQuery`, `consistent` and `triConsistent` is whatever is specified as the right-hand input type of the class member operator identified by the strategy number. This need not be the same as the item type, so long as key values of the correct type can be extracted from it.

### 61.4. Implementation

Internally, a GIN index contains a B-tree index constructed over keys, where each key is an element of one or more indexed items (a member of an array, for example) and where each tuple in a leaf page contains either a pointer to a B-tree of heap pointers (a “posting tree”), or a simple list of heap pointers (a “posting list”) when the list is small enough to fit into a single index tuple along with the key value.

As of PostgreSQL 9.1, null key values can be included in the index. Also, placeholder nulls are included in the index for indexed items that are null or contain no keys according to `extractValue`. This allows searches that should find empty items to do so.

Multicolumn GIN indexes are implemented by building a single B-tree over composite values (column number, key value). The key values for different columns can be of different types.

#### 61.4.1. GIN Fast Update Technique

Updating a GIN index tends to be slow because of the intrinsic nature of inverted indexes: inserting or updating one heap row can cause many inserts into the index (one for each key extracted from the indexed item). As of PostgreSQL 8.4, GIN is capable of postponing much of this work by inserting new tuples into a temporary, unsorted list of pending entries. When the table is vacuumed, or if the pending list becomes larger than `gin_pending_list_limit`, the entries are moved to the main GIN data structure using the same bulk insert techniques used during initial index creation. This greatly improves GIN index update speed, even counting the additional vacuum overhead. Moreover the overhead work can be done by a background process instead of in foreground query processing.

The main disadvantage of this approach is that searches must scan the list of pending entries in addition to searching the regular index, and so a large list of pending entries will slow searches significantly. Another disadvantage is that, while most updates are fast, an update that causes the pending list to become “too large” will incur an immediate cleanup cycle and thus be much slower than other updates. Proper use of `autovacuum` can minimize both of these problems.

If consistent response time is more important than update speed, use of pending entries can be disabled by turning off the `fastupdate` storage parameter for a GIN index. See `CREATE INDEX` for details.

#### 61.4.2. Partial Match Algorithm

GIN can support “partial match” queries, in which the query does not determine an exact match for one or more keys, but the possible matches fall within a reasonably narrow range of key values (within
the key sorting order determined by the compare support method). The extractQuery method, instead of returning a key value to be matched exactly, returns a key value that is the lower bound of the range to be searched, and sets the pmatch flag true. The key range is then scanned using the comparePartial method. comparePartial must return zero for a matching index key, less than zero for a non-match that is still within the range to be searched, or greater than zero if the index key is past the range that could match.

61.5. GIN Tips and Tricks

Create vs. insert

Insertion into a GIN index can be slow due to the likelihood of many keys being inserted for each item. So, for bulk insertions into a table it is advisable to drop the GIN index and recreate it after finishing bulk insertion.

As of PostgreSQL 8.4, this advice is less necessary since delayed indexing is used (see Section 61.4.1 for details). But for very large updates it may still be best to drop and recreate the index.

maintenance_work_mem

Build time for a GIN index is very sensitive to the maintenance_work_mem setting; it doesn’t pay to skimp on work memory during index creation.

gin_pending_list_limit

During a series of insertions into an existing GIN index that has fastupdate enabled, the system will clean up the pending-entry list whenever the list grows larger than gin_pending_list_limit. To avoid fluctuations in observed response time, it’s desirable to have pending-list cleanup occur in the background (i.e., via autovacuum). Foreground cleanup operations can be avoided by increasing gin_pending_list_limit or making autovacuum more aggressive. However, enlarging the threshold of the cleanup operation means that if a foreground cleanup does occur, it will take even longer.

gin_pending_list_limit can be overridden for individual GIN indexes by changing storage parameters, and which allows each GIN index to have its own cleanup threshold. For example, it’s possible to increase the threshold only for the GIN index which can be updated heavily, and decrease it otherwise.

gin_fuzzy_search_limit

The primary goal of developing GIN indexes was to create support for highly scalable full-text search in PostgreSQL, and there are often situations when a full-text search returns a very large set of results. Moreover, this often happens when the query contains very frequent words, so that the large result set is not even useful. Since reading many tuples from the disk and sorting them could take a lot of time, this is unacceptable for production. (Note that the index search itself is very fast.)

To facilitate controlled execution of such queries, GIN has a configurable soft upper limit on the number of rows returned: the gin_fuzzy_search_limit configuration parameter. It is set to 0 (meaning no limit) by default. If a non-zero limit is set, then the returned set is a subset of the whole result set, chosen at random.

“Soft” means that the actual number of returned results could differ somewhat from the specified limit, depending on the query and the quality of the system’s random number generator.

From experience, values in the thousands (e.g., 5000 — 20000) work well.
61.6. Limitations

GIN assumes that indexable operators are strict. This means that `extractValue` will not be called at all on a null item value (instead, a placeholder index entry is created automatically), and `extractQuery` will not be called on a null query value either (instead, the query is presumed to be unsatisfiable). Note however that null key values contained within a non-null composite item or query value are supported.

61.7. Examples

The PostgreSQL source distribution includes GIN operator classes for `tsvector` and for one-dimensional arrays of all internal types. Prefix searching in `tsvector` is implemented using the GIN partial match feature. The following `contrib` modules also contain GIN operator classes:

- `btree_gin`
  - B-tree equivalent functionality for several data types
- `hstore`
  - Module for storing (key, value) pairs
- `intarray`
  - Enhanced support for `int[]`
- `pg_trgm`
  - Text similarity using trigram matching
Chapter 62. BRIN Indexes

62.1. Introduction

BRIN stands for Block Range Index. BRIN is designed for handling very large tables in which certain columns have some natural correlation with their physical location within the table. A block range is a group of pages that are physically adjacent in the table; for each block range, some summary info is stored by the index. For example, a table storing a store’s sale orders might have a date column on which each order was placed, and most of the time the entries for earlier orders will appear earlier in the table as well; a table storing a ZIP code column might have all codes for a city grouped together naturally.

BRIN indexes can satisfy queries via regular bitmap index scans, and will return all tuples in all pages within each range if the summary info stored by the index is consistent with the query conditions. The query executor is in charge of rechecking these tuples and discarding those that do not match the query conditions — in other words, these indexes are lossy. Because a BRIN index is very small, scanning the index adds little overhead compared to a sequential scan, but may avoid scanning large parts of the table that are known not to contain matching tuples.

The specific data that a BRIN index will store, as well as the specific queries that the index will be able to satisfy, depend on the operator class selected for each column of the index. Data types having a linear sort order can have operator classes that store the minimum and maximum value within each block range, for instance; geometrical types might store the bounding box for all the objects in the block range.

The size of the block range is determined at index creation time by the pages_per_range storage parameter. The number of index entries will be equal to the size of the relation in pages divided by the selected value for pages_per_range. Therefore, the smaller the number, the larger the index becomes (because of the need to store more index entries), but at the same time the summary data stored can be more precise and more data blocks can be skipped during an index scan.

62.1.1. Index Maintenance

At the time of creation, all existing index pages are scanned and a summary index tuple is created for each range, including the possibly-incomplete range at the end. As new pages are filled with data, page ranges that are already summarized will cause the summary information to be updated with data from the new tuples. When a new page is created that does not fall within the last summarized range, that range does not automatically acquire a summary tuple; those tuples remain unsummarized until a summarization run is invoked later, creating initial summaries. This process can be invoked manually using the brin_summarize_new_values(regclass) function, or automatically when VACUUM processes the table.

62.2. Built-in Operator Classes

The core PostgreSQL distribution includes the BRIN operator classes shown in Table 62-1.
The *minmax* operator classes store the minimum and the maximum values appearing in the indexed column within the range. The *inclusion* operator classes store a value which includes the values in the indexed column within the range.

62.3. Extensibility

The BRIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The BRIN layer itself takes care of concurrency, logging and searching the index structure.

All it takes to get a BRIN access method working is to implement a few user-defined methods, which define the behavior of summary values stored in the index and the way they interact with scan keys. In short, BRIN combines extensibility with generality, code reuse, and a clean interface.

There are four methods that an operator class for BRIN must provide:

BrinOpcInfo *opcInfo(Oid type_oid)

Returns internal information about the indexed columns’ summary data. The return value must point to a palloc’d BrinOpcInfo, which has this definition:

define struct BrinOpcInfo
{
  /* Number of columns stored in an index column of this opclass */
  uint16  oi_nstored;

  /* Opaque pointer for the opclass’ private use */
  void     *oi_opaque;

  /* Type cache entries of the stored columns */
  TypeCacheEntry *oi_typcache[FLEXIBLE_ARRAY_MEMBER];
} BrinOpcInfo;

BrinOpcInfo.oi_opaque can be used by the operator class routines to pass information between support procedures during an index scan.

bool consistent(BrinDesc *bdesc, BrinValues *column, ScanKey key)

Returns whether the ScanKey is consistent with the given indexed values for a range. The attribute number to use is passed as part of the scan key.

bool addValue(BrinDesc *bdesc, BrinValues *column, Datum newval, bool isnull)

Given an index tuple and an indexed value, modifies the indicated attribute of the tuple so that it additionally represents the new value. If any modification was done to the tuple, true is returned.

bool unionTuples(BrinDesc *bdesc, BrinValues *a, BrinValues *b)

Consolidates two index tuples. Given two index tuples, modifies the indicated attribute of the first of them so that it represents both tuples. The second tuple is not modified.

The core distribution includes support for two types of operator classes: minmax and inclusion. Operator class definitions using them are shipped for in-core data types as appropriate. Additional operator classes can be defined by the user for other data types using equivalent definitions, without having to write any source code; appropriate catalog entries being declared is enough. Note that assumptions about the semantics of operator strategies are embedded in the support procedures’ source code.

Operator classes that implement completely different semantics are also possible, provided implementations of the four main support procedures described above are written. Note that backwards compatibility across major releases is not guaranteed: for example, additional support procedures might be required in later releases.

To write an operator class for a data type that implements a totally ordered set, it is possible to use the minmax support procedures alongside the corresponding operators, as shown in Table 62-2. All operator class members (procedures and operators) are mandatory.
To write an operator class for a complex datatype which has values included within another type, it’s possible to use the inclusion support procedures alongside the corresponding operators, as shown in Table 62-3. It requires only a single additional function, which can be written in any language. More functions can be defined for additional functionality. All operators are optional. Some operators require other operators, as shown as dependencies on the table.

</table>

Support procedure numbers 1-10 are reserved for the BRIN internal functions, so the SQL level functions start with number 11. Support function number 11 is the main function required to build the index. It should accept two arguments with the same datatype as the opclass, and return the union of them. The inclusion opclass can store union values with different datatypes if it is defined with the STORAGE parameter. The return value of the union function should match the STORAGE datatype.

Support procedure numbers 12 and 14 are provided to support irregularities of built-in datatypes. Procedure number 12 is used to support network addresses from different families which are not mergeable. Procedure number 14 is used to support empty ranges. Procedure number 13 is an optional but recommended one, which allows the new value to be checked before it is passed to the union function. As the BRIN framework can shortcut some operations when the union is not changed, using this function can improve index performance.

Both minmax and inclusion opclasses support cross-datatype operators, though with these the dependencies become more complicated. The minmax opclass requires a full set of operators to be defined with both arguments having the same datatype. It allows additional datatypes to be supported by defining extra sets of operators. Inclusion opclass operator strategies are dependent on another operator strategy as shown in Table 62-3, or the same operator strategy as themselves. They require the dependency operator to be defined with the STORAGE datatype as the left-hand-side argument and the other supported datatype to be the right-hand-side argument of the supported operator. See float4_minmax_ops as an example of minmax, and box_inclusion_ops as an example of inclusion.
Chapter 63. Database Physical Storage

This chapter provides an overview of the physical storage format used by PostgreSQL databases.

63.1. Database File Layout

This section describes the storage format at the level of files and directories.

Traditionally, the configuration and data files used by a database cluster are stored together within the cluster’s data directory, commonly referred to as $PGDATA$ (after the name of the environment variable that can be used to define it). A common location for $PGDATA$ is `/var/lib/pgsql/data`. Multiple clusters, managed by different server instances, can exist on the same machine.

The $PGDATA$ directory contains several subdirectories and control files, as shown in Table 63-1. In addition to these required items, the cluster configuration files `postgresql.conf`, `pg_hba.conf`, and `pg_ident.conf` are traditionally stored in $PGDATA$, although it is possible to place them elsewhere.

Table 63-1. Contents of $PGDATA$

<table>

</tr>
</tbody>
</table>

For each database in the cluster there is a subdirectory within PGDATA/base, named after the database’s OID in pg_database. This subdirectory is the default location for the database’s files; in particular, its system catalogs are stored there.

Each table and index is stored in a separate file. For ordinary relations, these files are named after the table or index’s filenode number, which can be found in pg_class.relfilenode. But for temporary relations, the file name is of the form tBBB_FFF, where BBB is the backend ID of the backend which created the file, and FFF is the filenode number. In either case, in addition to the main file (a/k/a main fork), each table and index has a free space map (see Section 63.3), which stores information about free space available in the relation. The free space map is stored in a file named with the filenode number plus the suffix _fsm. Tables also have a visibility map, stored in a fork with the suffix _vm, to track which pages are known to have no dead tuples. The visibility map is described further in Section 63.4. Unlogged tables and indexes have a third fork, known as the initialization fork, which is stored in a fork with the suffix _init (see Section 63.5).

Caution
Note that while a table’s filenode often matches its OID, this is not necessarily the case; some operations, like TRUNCATE, REINDEX, CLUSTER and some forms of ALTER TABLE, can change the filenode while preserving the OID. Avoid assuming that filenode and table OID are the same. Also, for certain system catalogs including pg_class itself, pg_class.relfilenode contains zero. The actual filenode number of these catalogs is stored in a lower-level data structure, and can be obtained using the pg_relation_filenode() function.

When a table or index exceeds 1 GB, it is divided into gigabyte-sized segments. The first segment’s file name is the same as the filenode; subsequent segments are named filenode.1, filenode.2,
etc. This arrangement avoids problems on platforms that have file size limitations. (Actually, 1 GB is just the default segment size. The segment size can be adjusted using the configuration option \--with-segsize when building PostgreSQL.) In principle, free space map and visibility map forks could require multiple segments as well, though this is unlikely to happen in practice.

A table that has columns with potentially large entries will have an associated TOAST table, which is used for out-of-line storage of field values that are too large to keep in the table rows proper. pg_class.reltoastrelid links from a table to its TOAST table, if any. See Section 63.2 for more information.

The contents of tables and indexes are discussed further in Section 63.6.

Tablespaces make the scenario more complicated. Each user-defined tablespace has a symbolic link inside the PGDATA/pg_tblspc directory, which points to the physical tablespace directory (i.e., the location specified in the tablespace’s CREATE TABLESPACE command). This symbolic link is named after the tablespace’s OID. Inside the physical tablespace directory there is a subdirectory with a name that depends on the PostgreSQL server version, such as PG_9.0_20100805.1 (The reason for using this subdirectory is so that successive versions of the database can use the same CREATE TABLESPACE location value without conflicts.) Within the version-specific subdirectory, there is a subdirectory for each database that has elements in the tablespace, named after the database’s OID. Tables and indexes are stored within that directory, using the filenode naming scheme. The pg_default tablespace is not accessed through pg_tblspc, but corresponds to PGDATA/base. Similarly, the pg_global tablespace is not accessed through pg_tblspc, but corresponds to PGDATA/global.

The pg_relation_filepath() function shows the entire path (relative to PGDATA) of any relation. It is often useful as a substitute for remembering many of the above rules. But keep in mind that this function just gives the name of the first segment of the main fork of the relation — you may need to append a segment number and/or _fsm, _vm, or _init to find all the files associated with the relation.

Temporary files (for operations such as sorting more data than can fit in memory) are created within PGDATA/base/pgsql_tmp, or within a pgsql_tmp subdirectory of a tablespace directory if a tablespace other than pg_default is specified for them. The name of a temporary file has the form pgsql_tmpPPP.NNN, where PPP is the PID of the owning backend and NNN distinguishes different temporary files of that backend.

### 63.2. TOAST

This section provides an overview of TOAST (The Oversized-Attribute Storage Technique).

PostgreSQL uses a fixed page size (commonly 8 kB), and does not allow tuples to span multiple pages. Therefore, it is not possible to store very large field values directly. To overcome this limitation, large field values are compressed and/or broken up into multiple physical rows. This happens transparently to the user, with only small impact on most of the backend code. The technique is affectionately known as TOAST (or “the best thing since sliced bread”). The TOAST infrastructure is also used to improve handling of large data values in-memory.

Only certain data types support TOAST — there is no need to impose the overhead on data types that cannot produce large field values. To support TOAST, a data type must have a variable-length (\texttt{varlena}) representation, in which, ordinarily, the first four-byte word of any stored value contains the total length of the value in bytes (including itself). TOAST does not constrain the rest of the data type’s representation. The special representations collectively called \texttt{TOASTed values} work by modifying or reinterpreting this initial length word. Therefore, the C-level functions supporting a TOAST-able data type must be careful about how they handle potentially \texttt{TOASTed} input values: an input might not actually consist of a four-byte length word and contents until after it’s been \texttt{detoasted}.

2100
(This is normally done by invoking \texttt{PG\_DETOAST\_DATUM} before doing anything with an input value, but in some cases more efficient approaches are possible. See Section 35.11.1 for more detail.)

TOAST usurps two bits of the varlena length word (the high-order bits on big-endian machines, the low-order bits on little-endian machines), thereby limiting the logical size of any value of a TOAST-able data type to 1 GB ($2^{30}$ - 1 bytes). When both bits are zero, the value is an ordinary un-TOASTed value of the data type, and the remaining bits of the length word give the total datum size (including length word) in bytes. When the highest-order or lowest-order bit is set, the value has only a single-byte header instead of the normal four-byte header, and the remaining bits of that byte give the total datum size (including length byte) in bytes. This alternative supports space-efficient storage of values shorter than 127 bytes, while still allowing the data type to grow to 1 GB at need. Values with single-byte headers aren’t aligned on any particular boundary, whereas values with four-byte headers are aligned on at least a four-byte boundary; this omission of alignment padding provides additional space savings that is significant compared to short values. As a special case, if the remaining bits of a single-byte header are all zero (which would be impossible for a self-inclusive length), the value is a pointer to out-of-line data, with several possible alternatives as described below. The type and size of such a TOAST pointer are determined by a code stored in the second byte of the datum. Lastly, when the highest-order or lowest-order bit is clear but the adjacent bit is set, the content of the datum has been compressed and must be decompressed before use. In this case the remaining bits of the four-byte length word give the total size of the compressed datum, not the original data. Note that compression is also possible for out-of-line data but the varlena header does not tell whether it has occurred — the content of the TOAST pointer tells that, instead.

As mentioned, there are multiple types of TOAST pointer datums. The oldest and most common type is a pointer to out-of-line data stored in a TOAST table that is separate from, but associated with, the table containing the TOAST pointer datum itself. These on-disk pointer datums are created by the TOAST management code (in \texttt{access/heap/tuptoaster.c}) when a tuple to be stored on disk is too large to be stored as-is. Further details appear in Section 63.2.1. Alternatively, a TOAST pointer datum can contain a pointer to out-of-line data that appears elsewhere in memory. Such datums are necessarily short-lived, and will never appear on-disk, but they are very useful for avoiding copying and redundant processing of large data values. Further details appear in Section 63.2.2.

The compression technique used for either in-line or out-of-line compressed data is a fairly simple and very fast member of the LZ family of compression techniques. See \texttt{src/common/pg\_lzcompress.c} for the details.

### 63.2.1. Out-of-line, on-disk TOAST storage

If any of the columns of a table are TOAST-able, the table will have an associated TOAST table, whose OID is stored in the table’s \texttt{pg\_class.reltoastrelid} entry. On-disk TOASTed values are kept in the TOAST table, as described in more detail below.

Out-of-line values are divided (after compression if used) into chunks of at most \texttt{TOAST\_MAX\_CHUNK\_SIZE} bytes (by default this value is chosen so that four chunk rows will fit on a page, making it about 2000 bytes). Each chunk is stored as a separate row in the TOAST table belonging to the owning table. Every TOAST table has the columns \texttt{chunk\_id} (an OID identifying the particular TOASTed value), \texttt{chunk\_seq} (a sequence number for the chunk within its value), and \texttt{chunk\_data} (the actual data of the chunk). A unique index on \texttt{chunk\_id} and \texttt{chunk\_seq} provides fast retrieval of the values. A pointer datum representing an out-of-line on-disk TOASTed value therefore needs to store the OID of the TOAST table in which to look and the OID of the specific value (its \texttt{chunk\_id}). For convenience, pointer datums also store the logical datum size (original uncompressed data length) and physical stored size (different if compression was applied). Allowing for the varlena header bytes, the total size of an on-disk TOAST pointer datum is therefore 18 bytes.
regardless of the actual size of the represented value.

The TOAST management code is triggered only when a row value to be stored in a table is wider than \texttt{TOAST\_TUPLE\_THRESHOLD} bytes (normally 2 kB). The TOAST code will compress and/or move field values out-of-line until the row value is shorter than \texttt{TOAST\_TUPLE\_TARGET} bytes (also normally 2 kB) or no more gains can be had. During an UPDATE operation, values of unchanged fields are normally preserved as-is; so an UPDATE of a row with out-of-line values incurs no TOAST costs if none of the out-of-line values change.

The TOAST management code recognizes four different strategies for storing TOAST-able columns on disk:

- **PLAIN** prevents either compression or out-of-line storage; furthermore it disables use of single-byte headers for varlena types. This is the only possible strategy for columns of non-TOAST-able data types.

- **EXTENDED** allows both compression and out-of-line storage. This is the default for most TOAST-able data types. Compression will be attempted first, then out-of-line storage if the row is still too big.

- **EXTERNAL** allows out-of-line storage but not compression. Use of \texttt{EXTERNAL} will make substring operations on wide \texttt{text} and \texttt{bytea} columns faster (at the penalty of increased storage space) because these operations are optimized to fetch only the required parts of the out-of-line value when it is not compressed.

- **MAIN** allows compression but not out-of-line storage. (Actually, out-of-line storage will still be performed for such columns, but only as a last resort when there is no other way to make the row small enough to fit on a page.)

Each TOAST-able data type specifies a default strategy for columns of that data type, but the strategy for a given table column can be altered with \texttt{ALTER TABLE SET STORAGE}.

This scheme has a number of advantages compared to a more straightforward approach such as allowing row values to span pages. Assuming that queries are usually qualified by comparisons against relatively small key values, most of the work of the executor will be done using the main row entry. The big values of TOASTed attributes will only be pulled out (if selected at all) at the time the result set is sent to the client. Thus, the main table is much smaller and more of its rows fit in the shared buffer cache than would be the case without any out-of-line storage. Sort sets shrink also, and sorts will more often be done entirely in memory. A little test showed that a table containing typical HTML pages and their URLs was stored in about half of the raw data size including the TOAST table, and that the main table contained only about 10% of the entire data (the URLs and some small HTML pages). There was no run time difference compared to an un-TOASTed comparison table, in which all the HTML pages were cut down to 7 kB to fit.

### 63.2.2. Out-of-line, in-memory TOAST storage

TOAST pointers can point to data that is not on disk, but is elsewhere in the memory of the current server process. Such pointers obviously cannot be long-lived, but they are nonetheless useful. There are currently two sub-cases: pointers to \texttt{indirect} data and pointers to \texttt{expanded} data.

Indirect TOAST pointers simply point at a non-indirect varlena value stored somewhere in memory. This case was originally created merely as a proof of concept, but it is currently used during logical decoding to avoid possibly having to create physical tuples exceeding 1 GB (as pulling all out-of-line field values into the tuple might do). The case is of limited use since the creator of the pointer datum
is entirely responsible that the referenced data survives for as long as the pointer could exist, and there is no infrastructure to help with this.

Expanded TOAST pointers are useful for complex data types whose on-disk representation is not especially suited for computational purposes. As an example, the standard varlena representation of a PostgreSQL array includes dimensionality information, a nulls bitmap if there are any null elements, then the values of all the elements in order. When the element type itself is variable-length, the only way to find the $N$’th element is to scan through all the preceding elements. This representation is appropriate for on-disk storage because of its compactness, but for computations with the array it’s much nicer to have an “expanded” or “deconstructed” representation in which all the element starting locations have been identified. The TOAST pointer mechanism supports this need by allowing a pass-by-reference Datum to point to either a standard varlena value (the on-disk representation) or a TOAST pointer that points to an expanded representation somewhere in memory. The details of this expanded representation are up to the data type, though it must have a standard header and meet the other API requirements given in src/include/utils/expandeddatum.h. C-level functions working with the data type can choose to handle either representation. Functions that do not know about the expanded representation, but simply apply PG_DETOAST_DATUM to their inputs, will automatically receive the traditional varlena representation; so support for an expanded representation can be introduced incrementally, one function at a time.

TOAST pointers to expanded values are further broken down into read-write and read-only pointers. The pointed-to representation is the same either way, but a function that receives a read-write pointer is allowed to modify the referenced value in-place, whereas one that receives a read-only pointer must not; it must first create a copy if it wants to make a modified version of the value. This distinction and some associated conventions make it possible to avoid unnecessary copying of expanded values during query execution.

For all types of in-memory TOAST pointer, the TOAST management code ensures that no such pointer datum can accidentally get stored on disk. In-memory TOAST pointers are automatically expanded to normal in-line varlena values before storage — and then possibly converted to on-disk TOAST pointers, if the containing tuple would otherwise be too big.

### 63.3. Free Space Map

Each heap and index relation, except for hash indexes, has a Free Space Map (FSM) to keep track of available space in the relation. It’s stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a _fsm suffix. For example, if the filenode of a relation is 12345, the FSM is stored in a file called 12345_fsm, in the same directory as the main relation file.

The Free Space Map is organized as a tree of FSM pages. The bottom level FSM pages store the free space available on each heap (or index) page, using one byte to represent each such page. The upper levels aggregate information from the lower levels.

Within each FSM page is a binary tree, stored in an array with one byte per node. Each leaf node represents a heap page, or a lower level FSM page. In each non-leaf node, the higher of its children’s values is stored. The maximum value in the leaf nodes is therefore stored at the root.

See src/backend/storage/freespace/README for more details on how the FSM is structured, and how it’s updated and searched. The pg_freespacemap module can be used to examine the information stored in free space maps.
63.4. Visibility Map

Each heap relation has a Visibility Map (VM) to keep track of which pages contain only tuples that are known to be visible to all active transactions. It’s stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a \_vm suffix. For example, if the filenode of a relation is 12345, the VM is stored in a file called 12345\_vm, in the same directory as the main relation file. Note that indexes do not have VMs.

The visibility map simply stores one bit per heap page. A set bit means that all tuples on the page are known to be visible to all transactions. This means that the page does not contain any tuples that need to be vacuumed. This information can also be used by index-only scans to answer queries using only the index tuple.

The map is conservative in the sense that we make sure that whenever a bit is set, we know the condition is true, but if a bit is not set, it might or might not be true. Visibility map bits are only set by vacuum, but are cleared by any data-modifying operations on a page.

63.5. The Initialization Fork

Each unlogged table, and each index on an unlogged table, has an initialization fork. The initialization fork is an empty table or index of the appropriate type. When an unlogged table must be reset to empty due to a crash, the initialization fork is copied over the main fork, and any other forks are erased (they will be recreated automatically as needed).

63.6. Database Page Layout

This section provides an overview of the page format used within PostgreSQL tables and indexes. Sequences and TOAST tables are formatted just like a regular table.

In the following explanation, a byte is assumed to contain 8 bits. In addition, the term item refers to an individual data value that is stored on a page. In a table, an item is a row; in an index, an item is an index entry.

Every table and index is stored as an array of pages of a fixed size (usually 8 kB, although a different page size can be selected when compiling the server). In a table, all the pages are logically equivalent, so a particular item (row) can be stored in any page. In indexes, the first page is generally reserved as a metapage holding control information, and there can be different types of pages within the index, depending on the index access method.

Table 63-2 shows the overall layout of a page. There are five parts to each page.

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PageHeaderData</td>
<td>24 bytes long. Contains general information about the page, including free space pointers.</td>
</tr>
<tr>
<td>ItemIdData</td>
<td>Array of (offset,length) pairs pointing to the actual items. 4 bytes per item.</td>
</tr>
</tbody>
</table>

1. Actually, index access methods need not use this page format. All the existing index methods do use this basic format, but the data kept on index metapages usually doesn’t follow the item layout rules.
### Chapter 63. Database Physical Storage

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Free space</td>
<td>The unallocated space. New item pointers are allocated from the start of this area, new items from the end.</td>
</tr>
<tr>
<td>Items</td>
<td>The actual items themselves.</td>
</tr>
<tr>
<td>Special space</td>
<td>Index access method specific data. Different methods store different data. Empty in ordinary tables.</td>
</tr>
</tbody>
</table>

The first 24 bytes of each page consists of a page header (PageHeaderData). Its format is detailed in Table 63-3. The first field tracks the most recent WAL entry related to this page. The second field contains the page checksum if data checksums are enabled. Next is a 2-byte field containing flag bits. This is followed by three 2-byte integer fields (pd_lower, pd_upper, and pd_special). These contain byte offsets from the page start to the start of unallocated space, to the end of unallocated space, and to the start of the special space. The next 2 bytes of the page header, pd_pagesize_version, store both the page size and a version indicator. Beginning with PostgreSQL 8.3 the version number is 4; PostgreSQL 8.1 and 8.2 used version number 3; PostgreSQL 8.0 used version number 2; PostgreSQL 7.3 and 7.4 used version number 1; prior releases used version number 0. (The basic page layout and header format has not changed in most of these versions, but the layout of heap row headers has.) The page size is basically only present as a cross-check; there is no support for having more than one page size in an installation. The last field is a hint that shows whether pruning the page is likely to be profitable: it tracks the oldest un-pruned XMAX on the page.

#### Table 63-3. PageHeaderData Layout

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Length</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pd_lsn</td>
<td>PageXLogRecPtr</td>
<td>8 bytes</td>
<td>LSN: next byte after last byte of xlog record for last change to this page</td>
</tr>
<tr>
<td>pd_checksum</td>
<td>uint16</td>
<td>2 bytes</td>
<td>Page checksum</td>
</tr>
<tr>
<td>pd_flags</td>
<td>uint16</td>
<td>2 bytes</td>
<td>Flag bits</td>
</tr>
<tr>
<td>pd_lower</td>
<td>LocationIndex</td>
<td>2 bytes</td>
<td>Offset to start of free space</td>
</tr>
<tr>
<td>pd_upper</td>
<td>LocationIndex</td>
<td>2 bytes</td>
<td>Offset to end of free space</td>
</tr>
<tr>
<td>pd_special</td>
<td>LocationIndex</td>
<td>2 bytes</td>
<td>Offset to start of special space</td>
</tr>
<tr>
<td>pd_pagesize_version</td>
<td>uint16</td>
<td>2 bytes</td>
<td>Page size and layout version number information</td>
</tr>
<tr>
<td>pd_prune_xid</td>
<td>TransactionId</td>
<td>4 bytes</td>
<td>Oldest unpruned XMAX on page, or zero if none</td>
</tr>
</tbody>
</table>

All the details can be found in src/include/storage/bufpage.h.

Following the page header are item identifiers (ItemIdData), each requiring four bytes. An item identifier contains a byte-offset to the start of an item, its length in bytes, and a few attribute bits which affect its interpretation. New item identifiers are allocated as needed from the beginning of the
unallocated space. The number of item identifiers present can be determined by looking at \texttt{pd\_lower}, which is increased to allocate a new identifier. Because an item identifier is never moved until it is freed, its index can be used on a long-term basis to reference an item, even when the item itself is moved around on the page to compact free space. In fact, every pointer to an item (\texttt{ItemPointer}, also known as \texttt{CTID}) created by PostgreSQL consists of a page number and the index of an item identifier.

The items themselves are stored in space allocated backwards from the end of unallocated space. The exact structure varies depending on what the table is to contain. Tables and sequences both use a structure named \texttt{HeapTupleHeaderData}, described below.

The final section is the "special section" which can contain anything the access method wishes to store. For example, b-tree indexes store links to the page's left and right siblings, as well as some other data relevant to the index structure. Ordinary tables do not use a special section at all (indicated by setting \texttt{pd\_special} to equal the page size).

All table rows are structured in the same way. There is a fixed-size header (occupying 23 bytes on most machines), followed by an optional null bitmap, an optional object ID field, and the user data. The header is detailed in Table 63-4. The actual user data (columns of the row) begins at the offset indicated by \texttt{t\_hoff}, which must always be a multiple of the \texttt{MAXALIGN} distance for the platform. The null bitmap is only present if the \texttt{HEAP\_HASNULL} bit is set in \texttt{t\_infomask}. If it is present it begins just after the fixed header and occupies enough bytes to have one bit per data column (that is, \texttt{t\_natts} bits altogether). In this list of bits, a 1 bit indicates not-null, a 0 bit is a null. When the bitmap is not present, all columns are assumed not-null. The object ID is only present if the \texttt{HEAP\_HASOID} bit is set in \texttt{t\_infomask}. If present, it appears just before the \texttt{t\_hoff} boundary. Any padding needed to make \texttt{t\_hoff} a \texttt{MAXALIGN} multiple will appear between the null bitmap and the object ID. (This in turn ensures that the object ID is suitably aligned.)

### Table 63-4. \texttt{HeapTupleHeaderData} Layout

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Length</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{t_xmin}</td>
<td>TransactionId</td>
<td>4 bytes</td>
<td>insert XID stamp</td>
</tr>
<tr>
<td>\texttt{t_xmax}</td>
<td>TransactionId</td>
<td>4 bytes</td>
<td>delete XID stamp</td>
</tr>
<tr>
<td>\texttt{t_cid}</td>
<td>CommandId</td>
<td>4 bytes</td>
<td>insert and/or delete CID stamp (overlaps with \texttt{t_xvac})</td>
</tr>
<tr>
<td>\texttt{t_xvac}</td>
<td>TransactionId</td>
<td>4 bytes</td>
<td>XID for VACUUM operation moving a row version</td>
</tr>
<tr>
<td>\texttt{t_ctid}</td>
<td>ItemPointerData</td>
<td>6 bytes</td>
<td>current TID of this or newer row version</td>
</tr>
<tr>
<td>\texttt{t_infomask2}</td>
<td>uint16</td>
<td>2 bytes</td>
<td>number of attributes, plus various flag bits</td>
</tr>
<tr>
<td>\texttt{t_infomask}</td>
<td>uint16</td>
<td>2 bytes</td>
<td>various flag bits</td>
</tr>
<tr>
<td>\texttt{t_hoff}</td>
<td>uint8</td>
<td>1 byte</td>
<td>offset to user data</td>
</tr>
</tbody>
</table>

All the details can be found in \texttt{src/include/access/htup_details.h}.

Interpreting the actual data can only be done with information obtained from other tables, mostly \texttt{pg\_attribute}. The key values needed to identify field locations are \texttt{attlen} and \texttt{attalign}. There is no way to directly get a particular attribute, except when there are only fixed width fields and no null values. All this trickery is wrapped up in the functions \texttt{heap\_getattr}, \texttt{fastgetattr} and \texttt{heap\_getsysattr}.  

2106
To read the data you need to examine each attribute in turn. First check whether the field is NULL according to the null bitmap. If it is, go to the next. Then make sure you have the right alignment. If the field is a fixed width field, then all the bytes are simply placed. If it’s a variable length field (attlen = -1) then it’s a bit more complicated. All variable-length data types share the common header structure `struct varlena`, which includes the total length of the stored value and some flag bits. Depending on the flags, the data can be either inline or in a TOAST table; it might be compressed, too (see Section 63.2).
Chapter 64. BKI Backend Interface

Backend Interface (BKI) files are scripts in a special language that is understood by the PostgreSQL backend when running in the “bootstrap” mode. The bootstrap mode allows system catalogs to be created and filled from scratch, whereas ordinary SQL commands require the catalogs to exist already. BKI files can therefore be used to create the database system in the first place. (And they are probably not useful for anything else.)

initdb uses a BKI file to do part of its job when creating a new database cluster. The input file used by initdb is created as part of building and installing PostgreSQL by a program named genbki.pl, which reads some specially formatted C header files in the src/include/catalog/ directory of the source tree. The created BKI file is called postgres.bki and is normally installed in the share subdirectory of the installation tree.

Related information can be found in the documentation for initdb.

64.1. BKI File Format

This section describes how the PostgreSQL backend interprets BKI files. This description will be easier to understand if the postgres.bki file is at hand as an example.

BKI input consists of a sequence of commands. Commands are made up of a number of tokens, depending on the syntax of the command. Tokens are usually separated by whitespace, but need not be if there is no ambiguity. There is no special command separator; the next token that syntactically cannot belong to the preceding command starts a new one. (Usually you would put a new command on a new line, for clarity.) Tokens can be certain key words, special characters (parentheses, commas, etc.), numbers, or double-quoted strings. Everything is case sensitive.

Lines starting with # are ignored.

64.2. BKI Commands

create  tableName  tableoid  [bootstrap]  [shared_relation]  [without_oids]  [rowtype_oid oid] (name1 = type1 [FORCE NOT NULL | FORCE NULL ] [, name2 = type2 [FORCE NOT NULL | FORCE NULL ] , ...])

Create a table named tableName, and having the OID tableoid, with the columns given in parentheses.

The following column types are supported directly by bootstrap.c: bool, bytea, char (1 byte), name, int2, int4, regproc, regclass, regtype, text, oid, tid, xid, cid, int2vector, oidvector, _int4 (array), _text (array), _oid (array), _char (array), _aclitem (array). Although it is possible to create tables containing columns of other types, this cannot be done until after pg_type has been created and filled with appropriate entries. (That effectively means that only these column types can be used in bootstrapped tables, but non-bootstrap catalogs can contain any built-in type.)

When bootstrap is specified, the table will only be created on disk; nothing is entered into pg_class, pg_attribute, etc, for it. Thus the table will not be accessible by ordinary SQL
operations until such entries are made the hard way (with insert commands). This option is 
used for creating pg_class etc themselves.

The table is created as shared if shared_relation is specified. It will have OIDs unless 
without_oids is specified. The table’s row type OID (pg_type OID) can optionally be speci-
fied via the rowtype_oid clause; if not specified, an OID is automatically generated for it. (The 
rowtype_oid clause is useless if bootstrap is specified, but it can be provided anyway for 
documentation.)

open tablename

Open the table named tablename for insertion of data. Any currently open table is closed.

close [tablename]

Close the open table. The name of the table can be given as a cross-check, but this is not required.

insert [OID = oid_value] ( value1 value2 ...)

Insert a new row into the open table using value1, value2, etc., for its column values and 
oid_value for its OID. If oid_value is zero (0) or the clause is omitted, and the table has 
OIDs, then the next available OID is assigned.

NULL values can be specified using the special key word _null_. Values containing spaces 
must be double quoted.

declare [unique] index indexname indexoid on tablename using amname ( opclass1 
name1 [, ...])

Create an index named indexname, having OID indexoid, on the table named tablename, 
using the amname access method. The fields to index are called name1, name2 etc., and the 
operator classes to use are opclass1, opclass2 etc., respectively. The index file is created 
and appropriate catalog entries are made for it, but the index contents are not initialized by this 
command.

declare toast toasttableoid toastindexoid on tablename

Create a TOAST table for the table named tablename. The TOAST table is assigned OID 
toasttableoid and its index is assigned OID toastindexoid. As with declare index, 
filling of the index is postponed.

build indices

Fill in the indices that have previously been declared.

64.3. Structure of the Bootstrap BKI File

The open command cannot be used until the tables it uses exist and have entries for the table that is 
to be opened. (These minimum tables are pg_class, pg_attribute, pg_proc, and pg_type.) To 
allow those tables themselves to be filled, create with the bootstrap option implicitly opens the 
created table for data insertion.

Also, the declare index and declare toast commands cannot be used until the system catalogs 
they need have been created and filled in.

Thus, the structure of the postgres.bki file has to be:

1. create bootstrap one of the critical tables
2. insert data describing at least the critical tables
3. close
4. Repeat for the other critical tables.
5. create (without bootstrap) a noncritical table
6. open
7. insert desired data
8. close
9. Repeat for the other noncritical tables.
10. Define indexes and toast tables.
11. build indices

There are doubtless other, undocumented ordering dependencies.

64.4. Example

The following sequence of commands will create the table test_table with OID 420, having two columns cola and colb of type int4 and text, respectively, and insert two rows into the table:

create test_table 420 (cola = int4, colb = text)
open test_table
insert OID=421 ( 1 "value1" )
insert OID=422 ( 2 _null_ )
close test_table
Chapter 65. How the Planner Uses Statistics

This chapter builds on the material covered in Section 14.1 and Section 14.2 to show some additional details about how the planner uses the system statistics to estimate the number of rows each part of a query might return. This is a significant part of the planning process, providing much of the raw material for cost calculation.

The intent of this chapter is not to document the code in detail, but to present an overview of how it works. This will perhaps ease the learning curve for someone who subsequently wishes to read the code.

65.1. Row Estimation Examples

The examples shown below use tables in the PostgreSQL regression test database. The outputs shown are taken from version 8.3. The behavior of earlier (or later) versions might vary. Note also that since ANALYZE uses random sampling while producing statistics, the results will change slightly after any new ANALYZE.

Let’s start with a very simple query:

```
EXPLAIN SELECT * FROM tenk1;
```

```
QUERY PLAN

Seq Scan on tenk1 (cost=0.00..458.00 rows=10000 width=244)
```

How the planner determines the cardinality of tenk1 is covered in Section 14.2, but is repeated here for completeness. The number of pages and rows is looked up in pg_class:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 'tenk1';
```

```
relpages | reltuples
----------+-----------
358       | 10000
```

These numbers are current as of the last VACUUM or ANALYZE on the table. The planner then fetches the actual current number of pages in the table (this is a cheap operation, not requiring a table scan). If that is different from relpages then reltuples is scaled accordingly to arrive at a current number-of-rows estimate. In the example above, the value of relpages is up-to-date so the rows estimate is the same as reltuples.

Let’s move on to an example with a range condition in its WHERE clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE uniquel < 1000;
```

```
QUERY PLAN

Bitmap Heap Scan on tenk1 (cost=24.06..394.64 rows=1007 width=244)
  Recheck Cond: (uniquel < 1000)
  -> Bitmap Index Scan on tenk1_uniquel (cost=0.00..23.80 rows=1007 width=0)
    Index Cond: (uniquel < 1000)
```
Chapter 65. How the Planner Uses Statistics

The planner examines the WHERE clause condition and looks up the selectivity function for the operator < in pg_operator. This is held in the column oprrest, and the entry in this case is scalarltsel. The scalarltsel function retrieves the histogram for uniquel from pg_statistics. For manual queries it is more convenient to look in the simpler pg_stats view:

```sql
SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='unique1';
```

```
histogram_bounds
-----------------------------
{0,993,1997,3050,4040,5036,5957,7057,8029,9016,9995}
```

Next the fraction of the histogram occupied by “< 1000” is worked out. This is the selectivity. The histogram divides the range into equal frequency buckets, so all we have to do is locate the bucket that our value is in and count part of it and all of the ones before. The value 1000 is clearly in the second bucket (993-1997). Assuming a linear distribution of values inside each bucket, we can calculate the selectivity as:

\[
\text{selectivity} = \left(1 + \frac{1000 - \text{bucket}[2].\text{min}}{\text{bucket}[2].\text{max} - \text{bucket}[2].\text{min}}\right)/\text{num\_buckets}
\]

\[
= \left(1 + \frac{1000 - 993}{1997 - 993}\right)/10
\]

\[
= 0.100697
\]

that is, one whole bucket plus a linear fraction of the second, divided by the number of buckets. The estimated number of rows can now be calculated as the product of the selectivity and the cardinality of tenk1:

\[
\text{rows} = \text{rel\_cardinality} \times \text{selectivity}
\]

\[
= 10000 \times 0.100697
\]

\[
= 1007 \text{ (rounding off)}
\]

Next let’s consider an example with an equality condition in its WHERE clause:

```sql
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'CRAAAA';
```

```
QUERY PLAN
-----------------------------------
Seq Scan on tenk1 (cost=0.00..483.00 rows=30 width=244)
  Filter: (stringu1 = 'CRAAAA'::name)
```

Again the planner examines the WHERE clause condition and looks up the selectivity function for =, which is eqsel. For equality estimation the histogram is not useful; instead the list of most common values (MCVs) is used to determine the selectivity. Let’s have a look at the MCVs, with some additional columns that will be useful later:

```sql
SELECT null_frac, n_distinct, most_common_vals, most_common_freqs FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';
```

```
null_frac | 0
n_distinct | 676
most_common_vals | {EJAAAA, BAAAAA, CRAAAA, FCAAAA, FEAAAA, GSAAAA, JOAAAA, MCAAAA, NAAAAA, WAAAAAA}
most_common_freqs | {0.00333333, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003}
```

Since CRAAAA appears in the list of MCVs, the selectivity is merely the corresponding entry in the list of most common frequencies (MCFs):
selectivity = mcf[3]
- 0.003

As before, the estimated number of rows is just the product of this with the cardinality of tenk1:

\[
\text{rows} = 10000 \times 0.003
\]
\[
= 30
\]

Now consider the same query, but with a constant that is not in the MCV list:

EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'xxx';

QUERY PLAN

| Seq Scan on tenk1 (cost=0.00..483.00 rows=15 width=244) |
| Filter: (stringu1 = 'xxx'::name) |

This is quite a different problem: how to estimate the selectivity when the value is not in the MCV list. The approach is to use the fact that the value is not in the list, combined with the knowledge of the frequencies for all of the MCVs:

\[
\text{selectivity} = \frac{(1 - \text{sum(mvf)})}{(\text{num_distinct} - \text{num_mcv})}
\]
\[
= \frac{(1 - (0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003))}{(676 - 10)}
\]
\[
= 0.0014559
\]

That is, add up all the frequencies for the MCVs and subtract them from one, then divide by the number of other distinct values. This amounts to assuming that the fraction of the column that is not any of the MCVs is evenly distributed among all the other distinct values. Notice that there are no null values so we don’t have to worry about those (otherwise we’d subtract the null fraction from the numerator as well). The estimated number of rows is then calculated as usual:

\[
\text{rows} = 10000 \times 0.0014559
\]
\[
= 15 \text{ (rounding off)}
\]

The previous example with unique1 < 1000 was an oversimplification of what scalarltsel really does; now that we have seen an example of the use of MCVs, we can fill in some more detail. The example was correct as far as it went, because since unique1 is a unique column it has no MCVs (obviously, no value is any more common than any other value). For a non-unique column, there will normally be both a histogram and an MCV list, and the histogram does not include the portion of the column population represented by the MCVs. We do things this way because it allows more precise estimation. In this situation scalarltsel directly applies the condition (e.g., "< 1000") to each value of the MCV list, and adds up the frequencies of the MCVs for which the condition is true. This gives an exact estimate of the selectivity within the portion of the table that is MCVs. The histogram is then used in the same way as above to estimate the selectivity in the portion of the table that is not MCVs, and then the two numbers are combined to estimate the overall selectivity. For example, consider

EXPLAIN SELECT * FROM tenk1 WHERE stringu1 < 'IAAAAA';

QUERY PLAN

| Seq Scan on tenk1 (cost=0.00..483.00 rows=3077 width=244) |
Filter: (stringul < 'IAAAAA'::name)

We already saw the MCV information for stringul, and here is its histogram:

```sql
SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='stringul';
```

```
histogram_bounds
--------------------------------------------------------------------------------
{AAAAAA, CQAAAA, FRAAAA, IBAAAA, KRAAAA, NFAAAA, PSAAAA, SGAAAA, VAAAAA, XLAAAA, ZZZAA}
```

Checking the MCV list, we find that the condition stringul < 'IAAAAA' is satisfied by the first six entries and not the last four, so the selectivity within the MCV part of the population is

\[
\text{selectivity} = \sum \text{relevant mvfs} = 0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 = 0.01833333
\]

Summing all the MCFs also tells us that the total fraction of the population represented by MCVs is 0.03033333, and therefore the fraction represented by the histogram is 0.96966667 (again, there are no nulls, else we’d have to exclude them here). We can see that the value IAAAAA falls nearly at the end of the third histogram bucket. Using some rather cheesy assumptions about the frequency of different characters, the planner arrives at the estimate 0.298387 for the portion of the histogram population that is less than IAAAAA. We then combine the estimates for the MCV and non-MCV populations:

\[
\text{selectivity} = \text{mcv_selectivity} + \text{histogram_selectivity} \times \text{histogram_fraction} = 0.01833333 + 0.298387 \times 0.96966667 = 0.307669
\]

```
rows = 10000 \times 0.307669 = 3077 \text{ (rounding off)}
```

In this particular example, the correction from the MCV list is fairly small, because the column distribution is actually quite flat (the statistics showing these particular values as being more common than others are mostly due to sampling error). In a more typical case where some values are significantly more common than others, this complicated process gives a useful improvement in accuracy because the selectivity for the most common values is found exactly.

Now let’s consider a case with more than one condition in the `WHERE` clause:

```sql
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000 AND stringul = 'xxx';
```

```
QUERY PLAN
--------------------------------------------------------------------------------
Bitmap Heap Scan on tenk1 (cost=23.80..396.91 rows=1 width=244)
  Recheck Cond: (unique1 < 1000)
  Filter: (stringul = 'xxx'::name)
    -> Bitmap Index Scan on tenk1_unique1 (cost=0.00..23.80 rows=1007 width=0)
      Index Cond: (unique1 < 1000)
```

The planner assumes that the two conditions are independent, so that the individual selectivities of the clauses can be multiplied together:

\[
\text{selectivity} = \text{selectivity(unique1 < 1000) \times selectivity(stringul = 'xxx')} = 0.100697 \times 0.0014559 = 0.0001466
\]
Chapter 65. How the Planner Uses Statistics

rows = 10000 * 0.0001466
= 1 (rounding off)

Notice that the number of rows estimated to be returned from the bitmap index scan reflects only the condition used with the index; this is important since it affects the cost estimate for the subsequent heap fetches.

Finally we will examine a query that involves a join:

EXPLAIN SELECT * FROM tenk1 t1, tenk2 t2
WHERE t1.unique1 < 50 AND t1.unique2 = t2.unique2;

<table>
<thead>
<tr>
<th>QUERY PLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nested Loop (cost=4.64..456.23 rows=50 width=488)</td>
</tr>
<tr>
<td>-&gt; Bitmap Heap Scan on tenk1 t1 (cost=4.64..142.17 rows=50 width=244)</td>
</tr>
<tr>
<td>Recheck Cond: (unique1 &lt; 50)</td>
</tr>
<tr>
<td>-&gt; Bitmap Index Scan on tenk1_unique1 (cost=0.00..4.63 rows=50 width=0)</td>
</tr>
<tr>
<td>Index Cond: (unique1 &lt; 50)</td>
</tr>
<tr>
<td>-&gt; Index Scan using tenk2_unique2 on tenk2 t2 (cost=0.00..6.27 rows=1 width=244)</td>
</tr>
<tr>
<td>Index Cond: (unique2 = t1.unique2)</td>
</tr>
</tbody>
</table>

The restriction on `tenk1, unique1 < 50`, is evaluated before the nested-loop join. This is handled analogously to the previous range example. This time the value 50 falls into the first bucket of the `unique1` histogram:

selectivity = \( \frac{0 + (50 - \text{bucket}[1].\text{min})}{\text{bucket}[1].\text{max} - \text{bucket}[1].\text{min}} \) / num_buckets
= \( \frac{0 + (50 - 0)}{993 - 0} \) / 10
= 0.005035

rows = 10000 * 0.005035
= 50 (rounding off)

The restriction for the join is `t2.unique2 = t1.unique2`. The operator is just our familiar operator, however the selectivity function is obtained from the `oprjoin` column of `pg_operator`, and is `eqjoinsel`. `eqjoinsel` looks up the statistical information for both `tenk2` and `tenk1`:

```
SELECT tablename, null_frac, n_distinct, most_common_vals FROM pg_stats
WHERE tablename IN ('tenk1', 'tenk2') AND attname='unique2';
```

<table>
<thead>
<tr>
<th>tablename</th>
<th>null_frac</th>
<th>n_distinct</th>
<th>most_common_vals</th>
</tr>
</thead>
<tbody>
<tr>
<td>tenk1</td>
<td>0</td>
<td>-1</td>
<td></td>
</tr>
<tr>
<td>tenk2</td>
<td>0</td>
<td>-1</td>
<td></td>
</tr>
</tbody>
</table>

In this case there is no MCV information for `unique2` because all the values appear to be unique, so we use an algorithm that relies only on the number of distinct values for both relations together with their null fractions:

selectivity = \((1 - \text{null_frac1}) \times (1 - \text{null_frac2}) \times \min(1/\text{n_distinct1}, 1/\text{n_distinct2})\)
= \((1 - 0) \times (1 - 0) / \max(10000, 10000)\)
= 0.0001

This is, subtract the null fraction from one for each of the relations, and divide by the maximum of the numbers of distinct values. The number of rows that the join is likely to emit is calculated as the cardinality of the Cartesian product of the two inputs, multiplied by the selectivity:
Had there been MCV lists for the two columns, \texttt{eqjoinSel} would have used direct comparison of the MCV lists to determine the join selectivity within the part of the column populations represented by the MCVs. The estimate for the remainder of the populations follows the same approach shown here.

Notice that we showed \texttt{inner_cardinality} as 10000, that is, the unmodified size of \texttt{tenk2}. It might appear from inspection of the \texttt{EXPLAIN} output that the estimate of join rows comes from 50 * 1, that is, the number of outer rows times the estimated number of rows obtained by each inner index scan on \texttt{tenk2}. But this is not the case: the join relation size is estimated before any particular join plan has been considered. If everything is working well then the two ways of estimating the join size will produce about the same answer, but due to round-off error and other factors they sometimes diverge significantly.

For those interested in further details, estimation of the size of a table (before any \texttt{WHERE} clauses) is done in \texttt{src/backend/optimizer/util/plancat.c}. The generic logic for clause selectivities is in \texttt{src/backend/optimizer/path/clausesel.c}. The operator-specific selectivity functions are mostly found in \texttt{src/backend/utils/adt/selfuncs.c}.

### 65.2. Planner Statistics and Security

Access to the table \texttt{pg_statistic} is restricted to superusers, so that ordinary users cannot learn about the contents of the tables of other users from it. Some selectivity estimation functions will use a user-provided operator (either the operator appearing in the query or a related operator) to analyze the stored statistics. For example, in order to determine whether a stored most common value is applicable, the selectivity estimator will have to run the appropriate \texttt{=} operator to compare the constant in the query to the stored value. Thus the data in \texttt{pg_statistic} is potentially passed to user-defined operators. An appropriately crafted operator can intentionally leak the passed operands (for example, by logging them or writing them to a different table), or accidentally leak them by showing their values in error messages, in either case exposing data from \texttt{pg_statistic} to a user who should not be able to see it.

In order to prevent this, the following applies to all built-in selectivity estimation functions. When planning a query, in order to be able to use stored statistics, the current user must either have \texttt{SELECT} privilege on the table or the involved columns, or the operator used must be \texttt{LEAKPROOF} (more accurately, the function that the operator is based on). If not, then the selectivity estimator will behave as if no statistics are available, and the planner will proceed with default or fall-back assumptions.

If a user does not have the required privilege on the table or columns, then in many cases the query will ultimately receive a permission-denied error, in which case this mechanism is invisible in practice. But if the user is reading from a security-barrier view, then the planner might wish to check the statistics of an underlying table that is otherwise inaccessible to the user. In that case, the operator should be leak-proof or the statistics will not be used. There is no direct feedback about that, except that the plan might be suboptimal. If one suspects that this is the case, one could try running the query as a more privileged user, to see if a different plan results.

This restriction applies only to cases where the planner would need to execute a user-defined operator on one or more values from \texttt{pg_statistic}. Thus the planner is permitted to use generic statistical
information, such as the fraction of null values or the number of distinct values in a column, regardless of access privileges.

Selectivity estimation functions contained in third-party extensions that potentially operate on statistics with user-defined operators should follow the same security rules. Consult the PostgreSQL source code for guidance.
VIII. Appendixes
Appendix A. PostgreSQL Error Codes

All messages emitted by the PostgreSQL server are assigned five-character error codes that follow the SQL standard’s conventions for “SQLSTATE” codes. Applications that need to know which error condition has occurred should usually test the error code, rather than looking at the textual error message. The error codes are less likely to change across PostgreSQL releases, and also are not subject to change due to localization of error messages. Note that some, but not all, of the error codes produced by PostgreSQL are defined by the SQL standard; some additional error codes for conditions not defined by the standard have been invented or borrowed from other databases.

According to the standard, the first two characters of an error code denote a class of errors, while the last three characters indicate a specific condition within that class. Thus, an application that does not recognize the specific error code might still be able to infer what to do from the error class.

Table A-1 lists all the error codes defined in PostgreSQL 9.5.14. (Some are not actually used at present, but are defined by the SQL standard.) The error classes are also shown. For each error class there is a “standard” error code having the last three characters 000. This code is used only for error conditions that fall within the class but do not have any more-specific code assigned.

The symbol shown in the column “Condition Name” is the condition name to use in PL/pgSQL. Condition names can be written in either upper or lower case. (Note that PL/pgSQL does not recognize warning, as opposed to error, condition names; those are classes 00, 01, and 02.)

For some types of errors, the server reports the name of a database object (a table, table column, data type, or constraint) associated with the error; for example, the name of the unique constraint that caused a unique_violation error. Such names are supplied in separate fields of the error report message so that applications need not try to extract them from the possibly-localized human-readable text of the message. As of PostgreSQL 9.3, complete coverage for this feature exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

Appendix B. Date/Time Support

PostgreSQL uses an internal heuristic parser for all date/time input support. Dates and times are input as strings, and are broken up into distinct fields with a preliminary determination of what kind of information can be in the field. Each field is interpreted and either assigned a numeric value, ignored, or rejected. The parser contains internal lookup tables for all textual fields, including months, days of the week, and time zones.

This appendix includes information on the content of these lookup tables and describes the steps used by the parser to decode dates and times.

B.1. Date/Time Input Interpretation

The date/time type inputs are all decoded using the following procedure.

1. Break the input string into tokens and categorize each token as a string, time, time zone, or number.
   a. If the numeric token contains a colon (:), this is a time string. Include all subsequent digits and colons.
   b. If the numeric token contains a dash (-), slash (/), or two or more dots (.), this is a date string which might have a text month. If a date token has already been seen, it is instead interpreted as a time zone name (e.g., America/New_York).
   c. If the token is numeric only, then it is either a single field or an ISO 8601 concatenated date (e.g., 19990113 for January 13, 1999) or time (e.g., 141516 for 14:15:16).
   d. If the token starts with a plus (+) or minus (−), then it is either a numeric time zone or a special field.

2. If the token is a text string, match up with possible strings:
   a. Do a binary-search table lookup for the token as a time zone abbreviation.
   b. If not found, do a similar binary-search table lookup to match the token as either a special string (e.g., today), day (e.g., Thursday), month (e.g., January), or noise word (e.g., at, on).
   c. If still not found, throw an error.

3. When the token is a number or number field:
   a. If there are eight or six digits, and if no other date fields have been previously read, then interpret as a “concatenated date” (e.g., 19990118 or 990118). The interpretation is YYYYMMDD or YYMMDD.
   b. If the token is three digits and a year has already been read, then interpret as day of year.
   c. If four or six digits and a year has already been read, then interpret as a time (HHMM or HHMMSS).
Appendix B. Date/Time Support

d. If three or more digits and no date fields have yet been found, interpret as a year (this forces yy-mm-dd ordering of the remaining date fields).
e. Otherwise the date field ordering is assumed to follow the DateStyle setting: mm-dd-yy, dd-mm-yy, or yy-mm-dd. Throw an error if a month or day field is found to be out of range.

4. If BC has been specified, negate the year and add one for internal storage. (There is no year zero in the Gregorian calendar, so numerically 1 BC becomes year zero.)

5. If BC was not specified, and if the year field was two digits in length, then adjust the year to four digits. If the field is less than 70, then add 2000, otherwise add 1900.

Tip: Gregorian years AD 1-99 can be entered by using 4 digits with leading zeros (e.g., 0099 is AD 99).

B.2. Date/Time Key Words

Table B-1 shows the tokens that are recognized as names of months.

B.3. Date/Time Configuration Files

Since timezone abbreviations are not well standardized, PostgreSQL provides a means to customize the set of abbreviations accepted by the server. The timezone_abbreviations run-time parameter determines the active set of abbreviations. While this parameter can be altered by any database user, the possible values for it are under the control of the database administrator — they are in fact names of configuration files stored in `.../share/timezonesets/` of the installation directory. By adding or altering files in that directory, the administrator can set local policy for timezone abbreviations.

`timezone_abbreviations` can be set to any file name found in `.../share/timezonesets/`, if the file’s name is entirely alphabetic. (The prohibition against non-alphabetic characters in `timezone_abbreviations` prevents reading files outside the intended directory, as well as reading editor backup files and other extraneous files.)

A timezone abbreviation file can contain blank lines and comments beginning with `#`. Non-comment lines must have one of these formats:

```
zone_abbreviation offset
zone_abbreviation offset D
zone_abbreviation time_zone_name
@INCLUDE file_name
@OVERRIDE
```

A `zone_abbreviation` is just the abbreviation being defined. An `offset` is an integer giving the equivalent offset in seconds from UTC, positive being east from Greenwich and negative being west. For example, -18000 would be five hours west of Greenwich, or North American east coast standard time. D indicates that the zone name represents local daylight-saving time rather than standard time.

Alternatively, a `time_zone_name` can be given, referencing a zone name defined in the IANA timezone database. The zone’s definition is consulted to see whether the abbreviation is or has been in use in that zone, and if so, the appropriate meaning is used — that is, the meaning that was currently in use at the timestamp whose value is being determined, or the meaning in use immediately before that
Appendix B. Date/Time Support

if it wasn’t current at that time, or the oldest meaning if it was used only after that time. This behavior
is essential for dealing with abbreviations whose meaning has historically varied. It is also allowed to
define an abbreviation in terms of a zone name in which that abbreviation does not appear; then using
the abbreviation is just equivalent to writing out the zone name.

**Tip:** Using a simple integer *offset* is preferred when defining an abbreviation whose offset from
UTC has never changed, as such abbreviations are much cheaper to process than those that
require consulting a time zone definition.

The *@INCLUDE* syntax allows inclusion of another file in the `.../share/timezonesets/` directory.
Inclusion can be nested, to a limited depth.

The *@OVERRIDE* syntax indicates that subsequent entries in the file can override previous entries (typ-
ically, entries obtained from included files). Without this, conflicting definitions of the same timezone
abbreviation are considered an error.

In an unmodified installation, the file *Default* contains all the non-conflicting time zone abbrevia-
tions for most of the world. Additional files *Australia* and *India* are provided for those regions:
these files first include the *Default* file and then add or modify abbreviations as needed.

For reference purposes, a standard installation also contains files *Africa.txt*, *America.txt*, etc,
containing information about every time zone abbreviation known to be in use according to the
IANA timezone database. The zone name definitions found in these files can be copied and pasted
into a custom configuration file as needed. Note that these files cannot be directly referenced as
timezone_abbreviations settings, because of the dot embedded in their names.

**Note:** If an error occurs while reading the time zone abbreviation set, no new value is applied and
the old set is kept. If the error occurs while starting the database, startup fails.

---

**Caution**

Time zone abbreviations defined in the configuration file override non-timezone
meanings built into PostgreSQL. For example, the *Australia* configuration file
defines SAT (for South Australian Standard Time). When this file is active, SAT
will not be recognized as an abbreviation for Saturday.

---

**Caution**

If you modify files in `.../share/timezonesets/`, it is up to you to make back-
ups — a normal database dump will not include this directory.

---

B.4. History of Units

The SQL standard states that “Within the definition of a ‘datetime literal’, the ‘datetime values’ are
constrained by the natural rules for dates and times according to the Gregorian calendar”. PostgreSQL
follows the SQL standard’s lead by counting dates exclusively in the Gregorian calendar, even for
years before that calendar was in use. This rule is known as the *proleptic Gregorian calendar*.
Appendix B. Date/Time Support

The Julian calendar was introduced by Julius Caesar in 45 BC. It was in common use in the Western world until the year 1582, when countries started changing to the Gregorian calendar. In the Julian calendar, the tropical year is approximated as 365 1/4 days = 365.25 days. This gives an error of about 1 day in 128 years.

The accumulating calendar error prompted Pope Gregory XIII to reform the calendar in accordance with instructions from the Council of Trent. In the Gregorian calendar, the tropical year is approximated as 365 + 97 / 400 days = 365.2425 days. Thus it takes approximately 3300 years for the tropical year to shift one day with respect to the Gregorian calendar.

The approximation 365+97/400 is achieved by having 97 leap years every 400 years, using the following rules:

- Every year divisible by 4 is a leap year.
- However, every year divisible by 100 is not a leap year.
- However, every year divisible by 400 is a leap year after all.

So, 1700, 1800, 1900, 2100, and 2200 are not leap years. But 1600, 2000, and 2400 are leap years. By contrast, in the older Julian calendar all years divisible by 4 are leap years.

The papal bull of February 1582 decreed that 10 days should be dropped from October 1582 so that 15 October should follow immediately after 4 October. This was observed in Italy, Poland, Portugal, and Spain. Other Catholic countries followed shortly after, but Protestant countries were reluctant to change, and the Greek Orthodox countries didn’t change until the start of the 20th century. The reform was observed by Great Britain and its dominions (including what is now the USA) in 1752. Thus 2 September 1752 was followed by 14 September 1752. This is why Unix systems have the `cal` program produce the following:

```
$ cal 9 1752
September 1752
     S M Tu W Th F S
 1  2 14 15 16
17 18 19 20 21 22 23
24 25 26 27 28 29 30
```

But, of course, this calendar is only valid for Great Britain and dominions, not other places. Since it would be difficult and confusing to try to track the actual calendars that were in use in various places at various times, PostgreSQL does not try, but rather follows the Gregorian calendar rules for all dates, even though this method is not historically accurate.

Different calendars have been developed in various parts of the world, many predating the Gregorian system. For example, the beginnings of the Chinese calendar can be traced back to the 14th century BC. Legend has it that the Emperor Huangdi invented that calendar in 2637 BC. The People’s Republic of China uses the Gregorian calendar for civil purposes. The Chinese calendar is used for determining festivals.

The Julian Date system is another type of calendar, unrelated to the Julian calendar though it is confusingly named similarly to that calendar. The Julian Date system was invented by the French scholar Joseph Justus Scaliger (1540-1609) and probably takes its name from Scaliger’s father, the Italian scholar Julius Caesar Scaliger (1484-1558). In the Julian Date system, each day has a sequential number, starting from JD 0 (which is sometimes called the Julian Date). JD 0 corresponds to 1 January 4713 BC in the Julian calendar, or 24 November 4714 BC in the Gregorian calendar. Julian Date counting is most often used by astronomers for labeling their nightly observations, and therefore a date runs from noon UTC to the next noon UTC, rather than from midnight to midnight: JD 0 designates the 24 hours from noon UTC on 24 November 4714 BC to noon UTC on 25 November 4714 BC.
Although PostgreSQL supports Julian Date notation for input and output of dates (and also uses Julian dates for some internal datetime calculations), it does not observe the nicety of having dates run from noon to noon. PostgreSQL treats a Julian Date as running from midnight to midnight.
Appendix C. SQL Key Words

Table C-1 lists all tokens that are key words in the SQL standard and in PostgreSQL 9.5.14. Background information can be found in Section 4.1.1. (For space reasons, only the latest two versions of the SQL standard, and SQL-92 for historical comparison, are included. The differences between those and the other intermediate standard versions are small.)

SQL distinguishes between reserved and non-reserved key words. According to the standard, reserved key words are the only real key words; they are never allowed as identifiers. Non-reserved key words only have a special meaning in particular contexts and can be used as identifiers in other contexts. Most non-reserved key words are actually the names of built-in tables and functions specified by SQL. The concept of non-reserved key words essentially only exists to declare that some predefined meaning is attached to a word in some contexts.

In the PostgreSQL parser life is a bit more complicated. There are several different classes of tokens ranging from those that can never be used as an identifier to those that have absolutely no special status in the parser as compared to an ordinary identifier. (The latter is usually the case for functions specified by SQL.) Even reserved key words are not completely reserved in PostgreSQL, but can be used as column labels (for example, SELECT 55 AS CHECK, even though CHECK is a reserved key word).

In Table C-1 in the column for PostgreSQL we classify as “non-reserved” those key words that are explicitly known to the parser but are allowed as column or table names. Some key words that are otherwise non-reserved cannot be used as function or data type names and are marked accordingly. (Most of these words represent built-in functions or data types with special syntax. The function or type is still available but it cannot be redefined by the user.) Labeled “reserved” are those tokens that are not allowed as column or table names. Some reserved key words are allowable as names for functions or data types; this is also shown in the table. If not so marked, a reserved key word is only allowed as an “AS” column label name.

As a general rule, if you get spurious parser errors for commands that contain any of the listed key words as an identifier you should try to quote the identifier to see if the problem goes away.

It is important to understand before studying Table C-1 that the fact that a key word is not reserved in PostgreSQL does not mean that the feature related to the word is not implemented. Conversely, the presence of a key word does not indicate the existence of a feature.

Appendix D. SQL Conformance

This section attempts to outline to what extent PostgreSQL conforms to the current SQL standard. The following information is not a full statement of conformance, but it presents the main topics in as much detail as is both reasonable and useful for users.

The formal name of the SQL standard is ISO/IEC 9075 “Database Language SQL”. A revised version of the standard is released from time to time; the most recent update appearing in 2011. The 2011 version is referred to as ISO/IEC 9075:2011, or simply as SQL:2011. The versions prior to that were SQL:2008, SQL:2003, SQL:1999, and SQL-92. Each version replaces the previous one, so claims of conformance to earlier versions have no official merit. PostgreSQL development aims for conformance with the latest official version of the standard where such conformance does not contradict traditional features or common sense. Many of the features required by the SQL standard are supported, though sometimes with slightly differing syntax or function. Further moves towards conformance can be expected over time.

SQL-92 defined three feature sets for conformance: Entry, Intermediate, and Full. Most database management systems claiming SQL standard conformance were conforming at only the Entry level, since the entire set of features in the Intermediate and Full levels was either too voluminous or in conflict with legacy behaviors.

Starting with SQL:1999, the SQL standard defines a large set of individual features rather than the ineffectively broad three levels found in SQL-92. A large subset of these features represents the “Core” features, which every conforming SQL implementation must supply. The rest of the features are purely optional. Some optional features are grouped together to form “packages”, which SQL implementations can claim conformance to, thus claiming conformance to particular groups of features.

The standard versions beginning with SQL:2003 are also split into a number of parts. Each is known by a shorthand name. Note that these parts are not consecutively numbered.

- ISO/IEC 9075-1 Framework (SQL/Framework)
- ISO/IEC 9075-2 Foundation (SQL/Foundation)
- ISO/IEC 9075-3 Call Level Interface (SQL/CLI)
- ISO/IEC 9075-4 Persistent Stored Modules (SQL/PSM)
- ISO/IEC 9075-9 Management of External Data (SQL/MED)
- ISO/IEC 9075-10 Object Language Bindings (SQL/OLB)
- ISO/IEC 9075-11 Information and Definition Schemas (SQL/Schemata)
- ISO/IEC 9075-13 Routines and Types using the Java Language (SQL/JRT)
- ISO/IEC 9075-14 XML-related specifications (SQL/XML)

The PostgreSQL core covers parts 1, 2, 9, 11, and 14. Part 3 is covered by the ODBC driver, and part 13 is covered by the PL/Java plug-in, but exact conformance is currently not being verified for these components. There are currently no implementations of parts 4 and 10 for PostgreSQL.

PostgreSQL supports most of the major features of SQL:2011. Out of 179 mandatory features required for full Core conformance, PostgreSQL conforms to at least 160. In addition, there is a long list of
supported optional features. It might be worth noting that at the time of writing, no current version of any database management system claims full conformance to Core SQL:2011.

In the following two sections, we provide a list of those features that PostgreSQL supports, followed by a list of the features defined in SQL:2011 which are not yet supported in PostgreSQL. Both of these lists are approximate: There might be minor details that are nonconforming for a feature that is listed as supported, and large parts of an unsupported feature might in fact be implemented. The main body of the documentation always contains the most accurate information about what does and does not work.

**Note:** Feature codes containing a hyphen are subfeatures. Therefore, if a particular subfeature is not supported, the main feature is listed as unsupported even if some other subfeatures are supported.

D.2. Unsupported Features

The following features defined in SQL:2011 are not implemented in this release of PostgreSQL. In a few cases, equivalent functionality is available.

Appendix E. Release Notes

The release notes contain the significant changes in each PostgreSQL release, with major features and migration issues listed at the top. The release notes do not contain changes that affect only a few users or changes that are internal and therefore not user-visible. For example, the optimizer is improved in almost every release, but the improvements are usually observed by users as simply faster queries.

A complete list of changes for each release can be obtained by viewing the Git logs for each release. The postgres-committers email list\(^1\) records all source code changes as well. There is also a web interface\(^2\) that shows changes to specific files.

The name appearing next to each item represents the major developer for that item. Of course all changes involve community discussion and patch review, so each item is truly a community effort.

E.1. Release 9.5.14

Release date: 2018-08-09

This release contains a variety of fixes from 9.5.13. For information about new features in the 9.5 major release, see Section E.15.

E.1.1. Migration to Version 9.5.14

A dump/restore is not required for those running 9.5.X. However, if you are upgrading from a version earlier than 9.5.13, see Section E.2.

E.1.2. Changes

- Fix failure to reset libpq’s state fully between connection attempts (Tom Lane)

An unprivileged user of dblink or postgres_fdw could bypass the checks intended to prevent use of server-side credentials, such as a ~/.pgpass file owned by the operating-system user running the server. Servers allowing peer authentication on local connections are particularly vulnerable. Other attacks such as SQL injection into a postgres_fdw session are also possible. Attacking postgres_fdw in this way requires the ability to create a foreign server object with selected connection parameters, but any user with access to dblink could exploit the problem. In general, an attacker with the ability to select the connection parameters for a libpq-using application could cause mischief, though other plausible attack scenarios are harder to think of. Our thanks to Andrew Krasichkov for reporting this issue. (CVE-2018-10915)

- Fix INSERT ... ON CONFLICT UPDATE through a view that isn’t just SELECT * FROM ...

(Dean Rasheed, Amit Langote)

Erroneous expansion of an updatable view could lead to crashes or “attribute ... has the wrong type” errors, if the view’s SELECT list doesn’t match one-to-one with the underlying table’s columns.

---

\(^1\) https://archives.postgresql.org/pgsql-committers/
\(^2\) https://git.postgresql.org/gitweb?p=postgresql.git;a=summary
Furthermore, this bug could be leveraged to allow updates of columns that an attacking user lacks `UPDATE` privilege for, if that user has `INSERT` and `UPDATE` privileges for some other column(s) of the table. Any user could also use it for disclosure of server memory. (CVE-2018-10925)

- Ensure that updates to the `relfrozenxid` and `relminmxid` values for “nailed” system catalogs are processed in a timely fashion (Andres Freund)

Overoptimistic caching rules could prevent these updates from being seen by other sessions, leading to spurious errors and/or data corruption. The problem was significantly worse for shared catalogs, such as `pg_authid`, because the stale cache data could persist into new sessions as well as existing ones.

- Fix case where a freshly-promoted standby crashes before having completed its first post-recovery checkpoint (Michael Paquier, Kyotaro Horiguchi, Pavan Deolasee, Álvaro Herrera)

This led to a situation where the server did not think it had reached a consistent database state during subsequent WAL replay, preventing restart.

- Avoid emitting a bogus WAL record when recycling an all-zero btree page (Amit Kapila)

This mistake has been seen to cause assertion failures, and potentially it could result in unnecessary query cancellations on hot standby servers.

- During WAL replay, guard against corrupted record lengths exceeding 1GB (Michael Paquier)

Treat such a case as corrupt data. Previously, the code would try to allocate space and get a hard error, making recovery impossible.

- When ending recovery, delay writing the timeline history file as long as possible (Heikki Linnakan-gas)

This avoids some situations where a failure during recovery cleanup (such as a problem with a two-phase state file) led to inconsistent timeline state on-disk.

- Improve performance of WAL replay for transactions that drop many relations (Fujii Masao)

This change reduces the number of times that shared buffers are scanned, so that it is of most benefit when that setting is large.

- Improve performance of lock releasing in standby server WAL replay (Thomas Munro)

- Make logical WAL senders report streaming state correctly (Simon Riggs, Sawada Masahiko)

The code previously mis-detected whether or not it had caught up with the upstream server.

- Fix bugs in snapshot handling during logical decoding, allowing wrong decoding results in rare cases (Arseny Sher, Álvaro Herrera)

- Ensure a table’s cached index list is correctly rebuilt after an index creation fails partway through (Peter Geoghegan)

Previously, the failed index’s OID could remain in the list, causing problems later in the same session.

- Fix mishandling of empty uncompressed posting list pages in GIN indexes (Sivasubramanian Ra-masubramanian, Alexander Korotkov)

This could result in an assertion failure after `pg_upgrade` of a pre-9.4 GIN index (9.4 and later will not create such pages).

- Ensure that `VACUUM` will respond to signals within btree page deletion loops (Andres Freund)

Corrupted btree indexes could result in an infinite loop here, and that previously wasn’t interruptible without forcing a crash.

- Fix misoptimization of equivalence classes involving composite-type columns (Tom Lane)
This resulted in failure to recognize that an index on a composite column could provide the sort order needed for a mergejoin on that column.

- Fix SQL-standard `FETCH FIRST` syntax to allow parameters ($n$), as the standard expects (Andrew Gierth)
- Fix failure to schema-qualify some object names in `getObjectDescription` output (Kyotaro Horiguchi, Tom Lane)
  
  Names of collations, conversions, and text search objects were not schema-qualified when they should be.

- Widen `COPY FROM`'s current-line-number counter from 32 to 64 bits (David Rowley)
  
  This avoids two problems with input exceeding 4G lines: `COPY FROM WITH HEADER` would drop a line every 4G lines, not only the first line, and error reports could show a wrong line number.

- Add a string freeing function to ecpg's `pgtypes` library, so that cross-module memory management problems can be avoided on Windows (Takayuki Tsunakawa)
  
  On Windows, crashes can ensue if the `free` call for a given chunk of memory is not made from the same DLL that `malloc`ed the memory. The `pgtypes` library sometimes returns strings that it expects the caller to free, making it impossible to follow this rule. Add a `PGTYPESchar_free()` function that just wraps `free`, allowing applications to follow this rule.

- Fix ecpg's support for `long long` variables on Windows, as well as other platforms that declare `strtoll/strtoull` nonstandardly or not at all (Dang Minh Huong, Tom Lane)

- Fix misidentification of SQL statement type in PL/pgSQL, when a rule change causes a change in the semantics of a statement intra-session (Tom Lane)
  
  This error led to assertion failures, or in rare cases, failure to enforce the `INTO STRICT` option as expected.

- Fix password prompting in client programs so that echo is properly disabled on Windows when `stdin` is not the terminal (Matthew Stickney)

- Further fix mis-quoting of values for list-valued GUC variables in dumps (Tom Lane)
  
  The previous fix for quoting of `search_path` and other list-valued variables in `pg_dump` output turned out to misbehave for empty-string list elements, and it risked truncation of long file paths.

- Fix `pg_dump`'s failure to dump `REPLICA IDENTITY` properties for constraint indexes (Tom Lane)
  
  Manually created unique indexes were properly marked, but not those created by declaring `UNIQUE` or `PRIMARY KEY` constraints.

- Make `pg_upgrade` check that the old server was shut down cleanly (Bruce Momjian)
  
  The previous check could be fooled by an immediate-mode shutdown.

- Fix contrib/hstore_plperl to look through Perl scalar references, and to not crash if it doesn’t find a hash reference where it expects one (Tom Lane)

- Fix crash in contrib/ltree's `lca()` function when the input array is empty (Pierre Ducroquet)

- Fix various error-handling code paths in which an incorrect error code might be reported (Michael Paquier, Tom Lane, Magnus Hagander)

- Rearrange makefiles to ensure that programs link to freshly-built libraries (such as `libpq.so`) rather than ones that might exist in the system library directories (Tom Lane)
  
  This avoids problems when building on platforms that supply old copies of PostgreSQL libraries.

- Update time zone data files to tzdata release 2018e for DST law changes in North Korea, plus historical corrections for Czechoslovakia.
This update includes a redefinition of “daylight savings” in Ireland, as well as for some past years in Namibia and Czechoslovakia. In those jurisdictions, legally standard time is observed in summer, and daylight savings time in winter, so that the daylight savings offset is one hour behind standard time not one hour ahead. This does not affect either the actual UTC offset or the timezone abbreviations in use; the only known effect is that the `is_dst` column in the `pg_timezone_names` view will now be true in winter and false in summer in these cases.

E.2. Release 9.5.13

Release date: 2018-05-10

This release contains a variety of fixes from 9.5.12. For information about new features in the 9.5 major release, see Section E.15.

E.2.1. Migration to Version 9.5.13

A dump/restore is not required for those running 9.5.X.

However, if the function marking mistakes mentioned in the first changelog entry below affect you, you will want to take steps to correct your database catalogs.

Also, if you are upgrading from a version earlier than 9.5.12, see Section E.3.

E.2.2. Changes

- Fix incorrect volatility markings on a few built-in functions (Thomas Munro, Tom Lane)

  The functions `query_to_xml`, `cursor_to_xml`, `cursor_to_xmlschema`, `query_to_xmlschema`, and `query_to_xml_and_xmlschema` should be marked volatile because they execute user-supplied queries that might contain volatile operations. They were not, leading to a risk of incorrect query optimization. This has been repaired for new installations by correcting the initial catalog data, but existing installations will continue to contain the incorrect markings. Practical use of these functions seems to pose little hazard, but in case of trouble, it can be fixed by manually updating these functions’ `pg_proc` entries, for example `ALTER FUNCTION pg_catalog.query_to_xml(text, boolean, boolean, text) VOLATILE`. (Note that that will need to be done in each database of the installation.) Another option is to `pg_upgrade` the database to a version containing the corrected initial data.

- Avoid re-using TOAST value OIDs that match dead-but-not-yet-vacuumed TOAST entries (Pavan Deolasee)

  Once the OID counter has wrapped around, it’s possible to assign a TOAST value whose OID matches a previously deleted entry in the same TOAST table. If that entry were not yet vacuumed away, this resulted in “unexpected chunk number 0 (expected 1) for toast value nnnnn” errors, which would persist until the dead entry was removed by `VACUUM`. Fix by not selecting such OIDs when creating a new TOAST entry.

- Change `ANALYZE`’s algorithm for updating `pg_class.reltuples` (David Gould)

  Previously, pages not actually scanned by `ANALYZE` were assumed to retain their old tuple density. In a large table where `ANALYZE` samples only a small fraction of the pages, this meant that the
Appendix E. Release Notes

overall tuple density estimate could not change very much, so that `reltuples` would change nearly proportionally to changes in the table’s physical size (`relpages`) regardless of what was actually happening in the table. This has been observed to result in `reltuples` becoming so much larger than reality as to effectively shut off autovacuuming. To fix, assume that `ANALYZE`’s sample is a statistically unbiased sample of the table (as it should be), and just extrapolate the density observed within those pages to the whole table.

- Avoid deadlocks in concurrent `CREATE INDEX CONCURRENTLY` commands that are run under `SERIALIZABLE` or `REPEATABLE READ` transaction isolation (Tom Lane)
- Fix possible slow execution of `REFRESH MATERIALIZED VIEW CONCURRENTLY` (Thomas Munro)
- Fix `UPDATE/DELETE ... WHERE CURRENT OF` to not fail when the referenced cursor uses an index-only-scan plan (Yugo Nagata, Tom Lane)
- Fix incorrect planning of join clauses pushed into parameterized paths (Andrew Gierth, Tom Lane)
  This error could result in misclassifying a condition as a “join filter” for an outer join when it should be a plain “filter” condition, leading to incorrect join output.
- Fix possibly incorrect generation of an index-only-scan plan when the same table column appears in multiple index columns, and only some of those index columns use operator classes that can return the column value (Kyotaro Horiguchi)
- Fix misoptimization of `CHECK` constraints having provably-NULL subclauses of top-level `AND/OR` conditions (Tom Lane, Dean Rasheed)
  This could, for example, allow constraint exclusion to exclude a child table that should not be excluded from a query.
- Fix executor crash due to double free in some `GROUPING SET` usages (Peter Geoghegan)
- Avoid crash if a table rewrite event trigger is added concurrently with a command that could call such a trigger (Álvaro Herrera, Andrew Gierth, Tom Lane)
- Avoid failure if a query-cancel or session-termination interrupt occurs while committing a prepared transaction (Stas Kelvich)
- Fix query-lifespan memory leakage in repeatedly executed hash joins (Tom Lane)
- Fix overly strict sanity check in `heap_prepare_freeze_tuple` (Álvaro Herrera)
  This could result in incorrect “cannot freeze committed `xmax`” failures in databases that have been `pg_upgrade`’d from 9.2 or earlier.
- Prevent dangling-pointer dereference when a C-coded before-update row trigger returns the “old” tuple (Rushabh Lathia)
- Reduce locking during autovacuum worker scheduling (Jeff Janes)
  The previous behavior caused drastic loss of potential worker concurrency in databases with many tables.
- Ensure client hostname is copied while copying `pg_stat_activity` data to local memory (Edmund Horner)
  Previously the supposedly-local snapshot contained a pointer into shared memory, allowing the client hostname column to change unexpectedly if any existing session disconnected.
- Fix incorrect processing of multiple compound affixes in `ispell` dictionaries (Arthur Zakirov)
- Fix collation-aware searches (that is, indexscans using inequality operators) in SP-GiST indexes on text columns (Tom Lane)
Appendix E. Release Notes

Such searches would return the wrong set of rows in most non-C locales.

• Count the number of index tuples correctly during initial build of an SP-GiST index (Tomas Vondra)
  Previously, the tuple count was reported to be the same as that of the underlying table, which is wrong if the index is partial.

• Count the number of index tuples correctly during vacuuming of a GiST index (Andrey Borodin)
  Previously it reported the estimated number of heap tuples, which might be inaccurate, and is certainly wrong if the index is partial.

• Fix a corner case where a streaming standby gets stuck at a WAL continuation record (Kyotaro Horiguchi)

• In logical decoding, avoid possible double processing of WAL data when a walsender restarts (Craig Ringer)

• Allow scalarltsel and scalargtsel to be used on non-core datatypes (Tomas Vondra)

• Reduce libpq’s memory consumption when a server error is reported after a large amount of query output has been collected (Tom Lane)
  Discard the previous output before, not after, processing the error message. On some platforms, notably Linux, this can make a difference in the application’s subsequent memory footprint.

• Fix double-free crashes in ecpg (Patrick Krecker, Jeevan Ladhe)

• Fix ecpg to handle long long int variables correctly in MSVC builds (Michael Meskes, Andrew Gierth)

• Fix mis-quoting of values for list-valued GUC variables in dumps (Michael Paquier, Tom Lane)
  The local_preload_libraries, session_preload_libraries, shared_preload_libraries, and temp_tablespaces variables were not correctly quoted in pg_dump output. This would cause problems if settings for these variables appeared in CREATE FUNCTION ... SET or ALTER DATABASE/ROLE ... SET clauses.

• Fix pg_recvlogical to not fail against pre-v10 PostgreSQL servers (Michael Paquier)
  A previous fix caused pg_recvlogical to issue a command regardless of server version, but it should only be issued to v10 and later servers.

• Ensure that pg_rewind deletes files on the target server if they are deleted from the source server during the run (Takayuki Tsunakawa)
  Failure to do this could result in data inconsistency on the target, particularly if the file in question is a WAL segment.

• Fix pg_rewind to handle tables in non-default tablespaces correctly (Takayuki Tsunakawa)

• Fix overflow handling in PL/pgSQL integer FOR loops (Tom Lane)
  The previous coding failed to detect overflow of the loop variable on some non-gcc compilers, leading to an infinite loop.

• Adjust PL/Python regression tests to pass under Python 3.7 (Peter Eisentraut)

• Support testing PL/Python and related modules when building with Python 3 and MSVC (Andrew Dunstan)

• Support building with Microsoft Visual Studio 2015 (Michael Paquier)
  Various fixes needed for VS2015 compatibility were previously back-patched into the 9.5 branch, but this one was missed.
Appendix E. Release Notes

- Rename internal b64_encode and b64_decode functions to avoid conflict with Solaris 11.4 built-in functions (Rainer Orth)
- Sync our copy of the timezone library with IANA tzcode release 2018e (Tom Lane)
  This fixes the zic timezone data compiler to cope with negative daylight-savings offsets. While the PostgreSQL project will not immediately ship such timezone data, zic might be used with timezone data obtained directly from IANA, so it seems prudent to update zic now.
- Update time zone data files to tzdata release 2018d for DST law changes in Palestine and Antarctica (Casey Station), plus historical corrections for Portugal and its colonies, as well as Enderbury, Jamaica, Turks & Caicos Islands, and Uruguay.

E.3. Release 9.5.12

Release date: 2018-03-01

This release contains a variety of fixes from 9.5.11. For information about new features in the 9.5 major release, see Section E.15.

E.3.1. Migration to Version 9.5.12

A dump/restore is not required for those running 9.5.X.

However, if you run an installation in which not all users are mutually trusting, or if you maintain an application or extension that is intended for use in arbitrary situations, it is strongly recommended that you read the documentation changes described in the first changelog entry below, and take suitable steps to ensure that your installation or code is secure.

Also, the changes described in the second changelog entry below may cause functions used in index expressions or materialized views to fail during auto-analyze, or when reloading from a dump. After upgrading, monitor the server logs for such problems, and fix affected functions.

Also, if you are upgrading from a version earlier than 9.5.10, see Section E.5.

E.3.2. Changes

- Document how to configure installations and applications to guard against search-path-dependent trojan-horse attacks from other users (Noah Misch)
  Using a search_path setting that includes any schemas writable by a hostile user enables that user to capture control of queries and then run arbitrary SQL code with the permissions of the attacked user. While it is possible to write queries that are proof against such hijacking, it is notationally tedious, and it’s very easy to overlook holes. Therefore, we now recommend configurations in which no untrusted schemas appear in one’s search path. Relevant documentation appears in Section 5.8.6 (for database administrators and users), Section 31.1 (for application authors), Section 35.15.1 (for extension authors), and CREATE FUNCTION (for authors of SECURITY DEFINER functions). (CVE-2018-1058)

- Avoid use of insecure search_path settings in pg_dump and other client programs (Noah Misch, Tom Lane)
Appendix E. Release Notes

pg_dump, pg_upgrade, vacuumdb and other PostgreSQL-provided applications were themselves vulnerable to the type of hijacking described in the previous changelog entry; since these applications are commonly run by superusers, they present particularly attractive targets. To make them secure whether or not the installation as a whole has been secured, modify them to include only the pg_catalog schema in their search_path settings. Autovacuum worker processes now do the same, as well.

In cases where user-provided functions are indirectly executed by these programs — for example, user-provided functions in index expressions — the tighter search_path may result in errors, which will need to be corrected by adjusting those user-provided functions to not assume anything about what search path they are invoked under. That has always been good practice, but now it will be necessary for correct behavior. (CVE-2018-1058)

• Fix misbehavior of concurrent-update rechecks with CTE references appearing in subplans (Tom Lane)

  If a CTE (WITH clause reference) is used in an InitPlan or SubPlan, and the query requires a recheck due to trying to update or lock a concurrently-updated row, incorrect results could be obtained.

• Fix planner failures with overlapping mergejoin clauses in an outer join (Tom Lane)

  These mistakes led to “left and right pathkeys do not match in mergejoin” or “outer pathkeys do not match mergeclauses” planner errors in corner cases.

• Repair pg_upgrade’s failure to preserve relfrozenxid for materialized views (Tom Lane, Andres Freund)

  This oversight could lead to data corruption in materialized views after an upgrade, manifesting as “could not access status of transaction” or “found xmin from before relfrozenxid” errors. The problem would be more likely to occur in seldom-refreshed materialized views, or ones that were maintained only with REFRESH MATERIALIZED VIEW CONCURRENTLY.

  If such corruption is observed, it can be repaired by refreshing the materialized view (without CONCURRENTLY).

• Fix incorrect reporting of PL/Python function names in error CONTEXT stacks (Tom Lane)

  An error occurring within a nested PL/Python function call (that is, one reached via a SPI query from another PL/Python function) would result in a stack trace showing the inner function’s name twice, rather than the expected results. Also, an error in a nested PL/Python DO block could result in a null pointer dereference crash on some platforms.

• Allow contrib/auto_explain’s log_min_duration setting to range up to INT_MAX, or about 24 days instead of 35 minutes (Tom Lane)

E.4. Release 9.5.11

Release date: 2018-02-08

This release contains a variety of fixes from 9.5.10. For information about new features in the 9.5 major release, see Section E.15.

E.4.1. Migration to Version 9.5.11

A dump/restore is not required for those running 9.5.X.

However, if you are upgrading from a version earlier than 9.5.10, see Section E.5.
E.4.2. Changes

- Ensure that all temporary files made by pg_upgrade are non-world-readable (Tom Lane, Noah Misch)

pg_upgrade normally restricts its temporary files to be readable and writable only by the calling user. But the temporary file containing pg_dumpall -g output would be group- or world-readable, or even writable, if the user’s umask setting allows. In typical usage on multi-user machines, the umask and/or the working directory’s permissions would be tight enough to prevent problems; but there may be people using pg_upgrade in scenarios where this oversight would permit disclosure of database passwords to unfriendly eyes. (CVE-2018-1053)

- Fix vacuuming of tuples that were updated while key-share locked (Andres Freund, Álvaro Herrera)

In some cases VACUUM would fail to remove such tuples even though they are now dead, leading to assorted data corruption scenarios.

- Fix inadequate buffer locking in some LSN fetches (Jacob Champion, Asim Praveen, Ashwin Agrawal)

These errors could result in misbehavior under concurrent load. The potential consequences have not been characterized fully.

- Fix incorrect query results from cases involving flattening of subqueries whose outputs are used in GROUPING SETS (Heikki Linnakangas)

- Avoid unnecessary failure in a query on an inheritance tree that occurs concurrently with some child table being removed from the tree by ALTER TABLE NO INHERIT (Tom Lane)

- Fix spurious deadlock failures when multiple sessions are running CREATE INDEX CONCURRENTLY (Jeff Janes)

- Fix failures when an inheritance tree contains foreign child tables (Etsuro Fujita)

A mix of regular and foreign tables in an inheritance tree resulted in creation of incorrect plans for UPDATE and DELETE queries. This led to visible failures in some cases, notably when there are row-level triggers on a foreign child table.

- Repair failure with correlated sub-SELECT inside VALUES inside a LATERAL subquery (Tom Lane)

- Fix “could not devise a query plan for the given query” planner failure for some cases involving nested UNION ALL inside a lateral subquery (Tom Lane)

- Fix logical decoding to correctly clean up disk files for crashed transactions (Atsushi Torikoshi)

Logical decoding may spill WAL records to disk for transactions generating many WAL records. Normally these files are cleaned up after the transaction’s commit or abort record arrives; but if no such record is ever seen, the removal code misbehaved.

- Fix walsender timeout failure and failure to respond to interrupts when processing a large transaction (Petr Jelinek)

- Fix has_sequence_privilege() to support WITH GRANT OPTION tests, as other privilege-testing functions do (Joe Conway)

- In databases using UTF8 encoding, ignore any XML declaration that asserts a different encoding (Pavel Stehule, Noah Misch)

We always store XML strings in the database encoding, so allowing libxml to act on a declaration of another encoding gave wrong results. In encodings other than UTF8, we don’t promise to support non-ASCII XML data anyway, so retain the previous behavior for bug compatibility. This change affects only xpath() and related functions; other XML code paths already acted this way.
Appendix E. Release Notes

- Provide for forward compatibility with future minor protocol versions (Robert Haas, Badrul Chowdhury)

  Up to now, PostgreSQL servers simply rejected requests to use protocol versions newer than 3.0, so that there was no functional difference between the major and minor parts of the protocol version number. Allow clients to request versions 3.x without failing, sending back a message showing that the server only understands 3.0. This makes no difference at the moment, but back-patching this change should allow speedier introduction of future minor protocol upgrades.

- Cope with failure to start a parallel worker process (Amit Kapila, Robert Haas)

  Parallel query previously tended to hang indefinitely if a worker could not be started, as the result of fork() failure or other low-probability problems.

- Avoid unsafe alignment assumptions when working with __int128 (Tom Lane)

  Typically, compilers assume that __int128 variables are aligned on 16-byte boundaries, but our memory allocation infrastructure isn’t prepared to guarantee that, and increasing the setting of MAXALIGN seems infeasible for multiple reasons. Adjust the code to allow use of __int128 only when we can tell the compiler to assume lesser alignment. The only known symptom of this problem so far is crashes in some parallel aggregation queries.

- Prevent stack-overflow crashes when planning extremely deeply nested set operations (UNION/INTERSECT/EXCEPT) (Tom Lane)

- Fix null-pointer crashes for some types of LDAP URLs appearing in pg_hba.conf (Thomas Munro)

- Fix sample INSTR() functions in the PL/pgSQL documentation (Yugo Nagata, Tom Lane)

  These functions are stated to be Oracle® compatible, but they weren’t exactly. In particular, there was a discrepancy in the interpretation of a negative third parameter: Oracle thinks that a negative value indicates the last place where the target substring can begin, whereas our functions took it as the last place where the target can end. Also, Oracle throws an error for a zero or negative fourth parameter, whereas our functions returned zero.

  The sample code has been adjusted to match Oracle’s behavior more precisely. Users who have copied this code into their applications may wish to update their copies.

- Fix pg_dump to make ACL (permissions), comment, and security label entries reliably identifiable in archive output formats (Tom Lane)

  The “tag” portion of an ACL archive entry was usually just the name of the associated object. Make it start with the object type instead, bringing ACLs into line with the convention already used for comment and security label archive entries. Also, fix the comment and security label entries for the whole database, if present, to make their tags start with DATABASE so that they also follow this convention. This prevents false matches in code that tries to identify large-object-related entries by seeing if the tag starts with LARGE OBJECT. That could have resulted in misclassifying entries as data rather than schema, with undesirable results in a schema-only or data-only dump.

  Note that this change has user-visible results in the output of pg_restore --list.

- Rename pg_rewind's copy_file_range function to avoid conflict with new Linux system call of that name (Andres Freund)

  This change prevents build failures with newer glibc versions.

- In ecpg, detect indicator arrays that do not have the correct length and report an error (David Rader)

- Avoid triggering a libc assertion in contrib/hstore, due to use of memcpy() with equal source and destination pointers (Tomas Vondra)

- Provide modern examples of how to auto-start Postgres on macOS (Tom Lane)
The scripts in contrib/start-scripts/osx use infrastructure that’s been deprecated for over a decade, and which no longer works at all in macOS releases of the last couple of years. Add a new subdirectory contrib/start-scripts/macos containing scripts that use the newer launchd infrastructure.

- Fix incorrect selection of configuration-specific libraries for OpenSSL on Windows (Andrew Dunstan)
- Support linking to MinGW-built versions of libperl (Noah Misch)
  This allows building PL/Perl versions for Windows.
- Fix MSVC build to test whether 32-bit libperl needs -D_USE_32BIT_TIME_T (Noah Misch)
  Available Perl distributions are inconsistent about what they expect, and lack any reliable means of reporting it, so resort to a build-time test on what the library being used actually does.
- On Windows, install the crash dump handler earlier in postmaster startup (Takayuki Tsunakawa)
  This may allow collection of a core dump for some early-startup failures that did not produce a dump before.
- On Windows, avoid encoding-conversion-related crashes when emitting messages very early in postmaster startup (Takayuki Tsunakawa)
- Use our existing Motorola 68K spinlock code on OpenBSD as well as NetBSD (David Carlier)
- Add support for spinlocks on Motorola 88K (David Carlier)
- Update time zone data files to tzdata release 2018c for DST law changes in Brazil, Sao Tome and Principe, plus historical corrections for Bolivia, Japan, and South Sudan. The US/Pacific-New zone has been removed (it was only an alias for America/Los_Angeles anyway).

E.5. Release 9.5.10

Release date: 2017-11-09

This release contains a variety of fixes from 9.5.9. For information about new features in the 9.5 major release, see Section E.15.

E.5.1. Migration to Version 9.5.10

A dump/restore is not required for those running 9.5.X. However, if you use BRIN indexes, see the fourth changelog entry below. Also, if you are upgrading from a version earlier than 9.5.8, see Section E.7.

E.5.2. Changes

- Ensure that `INSERT ... ON CONFLICT DO UPDATE` checks table permissions and RLS policies in all cases (Dean Rasheed)
  The update path of `INSERT ... ON CONFLICT DO UPDATE` requires `SELECT` permission on the columns of the arbiter index, but it failed to check for that in the case of an arbiter specified by constraint name. In addition, for a table with row level security enabled, it failed to check updated
Appendix E. Release Notes

rows against the table’s SELECT policies (regardless of how the arbiter index was specified). (CVE-2017-15099)

• Fix crash due to rowtype mismatch in jsonb_populate_recordset() (Michael Paquier, Tom Lane)

These functions used the result rowtype specified in the FROM ... AS clause without checking that it matched the actual rowtype of the supplied tuple value. If it didn’t, that would usually result in a crash, though disclosure of server memory contents seems possible as well. (CVE-2017-15098)

• Fix sample server-start scripts to become $PGUSER before opening $PGLOG (Noah Misch)

Previously, the postmaster log file was opened while still running as root. The database owner could therefore mount an attack against another system user by making $PGLOG be a symbolic link to some other file, which would then become corrupted by appending log messages.

By default, these scripts are not installed anywhere. Users who have made use of them will need to manually recopy them, or apply the same changes to their modified versions. If the existing $PGLOG file is root-owned, it will need to be removed or renamed out of the way before restarting the server with the corrected script. (CVE-2017-12172)

• Fix BRIN index summarization to handle concurrent table extension correctly (Álvaro Herrera)

Previously, a race condition allowed some table rows to be omitted from the index. It may be necessary to reindex existing BRIN indexes to recover from past occurrences of this problem.

• Fix possible failures during concurrent updates of a BRIN index (Tom Lane)

These race conditions could result in errors like “invalid index offnum” or “inconsistent range map”.

• Fix crash when logical decoding is invoked from a SPI-using function, in particular any function written in a PL language (Tom Lane)

• Fix json_build_array(), json_build_object(), and their jsonb equivalents to handle explicit VARIADIC arguments correctly (Michael Paquier)

• Properly reject attempts to convert infinite float values to type numeric (Tom Lane, KaiGai Kohei)

Previously the behavior was platform-dependent.

• Fix corner-case crashes when columns have been added to the end of a view (Tom Lane)

• Record proper dependencies when a view or rule contains FieldSelect or FieldStore expression nodes (Tom Lane)

Lack of these dependencies could allow a column or data type DROP to go through when it ought to fail, thereby causing later uses of the view or rule to get errors. This patch does not do anything to protect existing views/rules, only ones created in the future.

• Correctly detect hashability of range data types (Tom Lane)

The planner mistakenly assumed that any range type could be hashed for use in hash joins or hash aggregation, but actually it must check whether the range’s subtype has hash support. This does not affect any of the built-in range types, since they’re all hashable anyway.

• Correctly ignore RelabelType expression nodes when determining relation distinctness (David Rowley)

This allows the intended optimization to occur when a subquery has a result column of type varchar.

• Fix low-probability loss of NOTIFY messages due to XID wraparound (Marko Tiikkaja, Tom Lane)
Appendix E. Release Notes

If a session executed no queries, but merely listened for notifications, for more than 2 billion transactions, it started to miss some notifications from concurrently-committing transactions.

- Avoid SIGBUS crash on Linux when a DSM memory request exceeds the space available in tmpfs (Thomas Munro)
- Prevent low-probability crash in processing of nested trigger firings (Tom Lane)
- Allow COPY’s FREEZE option to work when the transaction isolation level is REPEATABLE READ or higher (Noah Misch)
  
  This case was unintentionally broken by a previous bug fix.
- Correctly restore the umask setting when file creation fails in COPY or lo_export() (Peter Eisentraut)
- Give a better error message for duplicate column names in ANALYZE (Nathan Bossart)
- Fix mis-parsing of the last line in a non-newline-terminated pg_hba.conf file (Tom Lane)
- Fix pg_basebackup’s matching of tablespace paths to canonicalize both paths before comparing (Michael Paquier)
  
  This is particularly helpful on Windows.
- Fix libpq to not require user’s home directory to exist (Tom Lane)
  
  In v10, failure to find the home directory while trying to read ~/.pgpass was treated as a hard error, but it should just cause that file to not be found. Both v10 and previous release branches made the same mistake when reading ~/.pg_service.conf, though this was less obvious since that file is not sought unless a service name is specified.
- Fix libpq to guard against integer overflow in the row count of a PGresult (Michael Paquier)
- Fix ecpg’s handling of out-of-scope cursor declarations with pointer or array variables (Michael Meskes)
  
  In ecpglib, correctly handle backslashes in string literals depending on whether standard_conforming_strings is set (Tsunakawa Takayuki)
- Make ecpglib’s Informix-compatibility mode ignore fractional digits in integer input strings, as expected (Gao Zengqi, Michael Meskes)
- Fix missing temp-install prerequisites for check-like Make targets (Noah Misch)
  
  Some non-default test procedures that are meant to work like make check failed to ensure that the temporary installation was up to date.
- Sync our copy of the timezone library with IANA release tzcode2017c (Tom Lane)
  
  This fixes various issues; the only one likely to be user-visible is that the default DST rules for a POSIX-style zone name, if no posixrules file exists in the timezone data directory, now match current US law rather than what it was a dozen years ago.
- Update time zone data files to tzdata release 2017c for DST law changes in Fiji, Namibia, Northern Cyprus, Sudan, Tonga, and Turks & Caicos Islands, plus historical corrections for Alaska, Apia, Burma, Calcutta, Detroit, Ireland, Namibia, and Pago Pago.

E.6. Release 9.5.9

Release date: 2017-08-31
This release contains a small number of fixes from 9.5.8. For information about new features in the 9.5 major release, see Section E.15.

### E.6.1. Migration to Version 9.5.9

A dump/restore is not required for those running 9.5.X.

However, if you are upgrading from a version earlier than 9.5.8, see Section E.7.

### E.6.2. Changes

- Show foreign tables in `information_schema.table_privileges` view (Peter Eisentraut)

All other relevant `information_schema` views include foreign tables, but this one ignored them.

Since this view definition is installed by initdb, merely upgrading will not fix the problem. If you need to fix this in an existing installation, you can, as a superuser, do this in psql:

```sql
SET search_path TO information_schema;
CREATE OR REPLACE VIEW table_privileges AS
  SELECT CAST(u_grantor.rolname AS sql_identifier) AS grantor,
         CAST(grantee.rolname AS sql_identifier) AS grantee,
         CAST(current_database() AS sql_identifier) AS table_catalog,
         CAST(nc.nspname AS sql_identifier) AS table_schema,
         CAST(c.relname AS sql_identifier) AS table_name,
         CAST(c.prtype AS character_data) AS privilege_type,
         CASE WHEN pg_has_role(grantee.oid, c.relowner, 'USAGE')
              OR c.grantable
              THEN 'YES' ELSE 'NO' END AS is_grantable,
         CASE WHEN c.prtype = 'SELECT' THEN 'YES' ELSE 'NO' END AS with_hierarchy
  FROM (SELECT oid, relname, relnamespace, relkind, relowner, (aclexplode(coalesce(relacl, acldefault('r', relowner)))).* FROM pg_class
         AS c (oid, relname, relnamespace, relkind, relowner, grantor, grantee, prtype, grantable),
         pg_namespace nc,
         pg_authid u_grantor,
         pg_authid grantee
  WHERE c.relnamespace = nc.oid
    AND c.relkind IN ('r', 'v', 'f')
    AND c.grantee = grantee.oid
    AND c.grantor = u_grantor.oid
    AND c.prtype IN ('INSERT', 'SELECT', 'UPDATE', 'DELETE', 'TRUNCATE', 'REFERENCES', 'TRIGGER')
    AND (pg_has_role(u_grantor.oid, 'USAGE')
         OR pg_has_role(grantee.oid, 'USAGE')
         OR grantee.rolname = 'PUBLIC'))
```

This must be repeated in each database to be fixed, including `template0`. 

2201
• Clean up handling of a fatal exit (e.g., due to receipt of SIGTERM) that occurs while trying to execute a *ROLLBACK* of a failed transaction (Tom Lane)

This situation could result in an assertion failure. In production builds, the exit would still occur, but it would log an unexpected message about “cannot drop active portal”.

• Remove assertion that could trigger during a fatal exit (Tom Lane)

• Correctly identify columns that are of a range type or domain type over a composite type or domain type being searched for (Tom Lane)

Certain *ALTER* commands that change the definition of a composite type or domain type are supposed to fail if there are any stored values of that type in the database, because they lack the infrastructure needed to update or check such values. Previously, these checks could miss relevant values that are wrapped inside range types or sub-domains, possibly allowing the database to become inconsistent.

• Fix crash in pg_restore when using parallel mode and using a list file to select a subset of items to restore (Fabrizio de Royes Mello)

• Change ecpg’s parser to allow *RETURNING* clauses without attached C variables (Michael Meskes)

This allows ecpg programs to contain SQL constructs that use *RETURNING* internally (for example, inside a CTE) rather than using it to define values to be returned to the client.

• Improve selection of compiler flags for PL/Perl on Windows (Tom Lane)

This fix avoids possible crashes of PL/Perl due to inconsistent assumptions about the width of *time_t* values. A side-effect that may be visible to extension developers is that *USE_32BIT_TIME_T* is no longer defined globally in PostgreSQL Windows builds. This is not expected to cause problems, because type *time_t* is not used in any PostgreSQL API definitions.

• Fix make check to behave correctly when invoked via a non-GNU make program (Thomas Munro)

### E.7. Release 9.5.8

**Release date:** 2017-08-10

This release contains a variety of fixes from 9.5.7. For information about new features in the 9.5 major release, see Section E.15.

### E.7.1. Migration to Version 9.5.8

A dump/restore is not required for those running 9.5.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.5.7, see Section E.8.

### E.7.2. Changes

• Further restrict visibility of *pg_user_mappings.umoptions*, to protect passwords stored as user mapping options (Noah Misch)
Appendix E. Release Notes

The fix for CVE-2017-7486 was incorrect: it allowed a user to see the options in her own user mapping, even if she did not have USAGE permission on the associated foreign server. Such options might include a password that had been provided by the server owner rather than the user herself. Since information_schema.user_mapping_options does not show the options in such cases, pg_user_mappings should not either. (CVE-2017-7547)

By itself, this patch will only fix the behavior in newly initdb’d databases. If you wish to apply this change in an existing database, you will need to do the following:

1. Restart the postmaster after adding allow_system_table_mods = true to postgresql.conf. (In versions supporting ALTER SYSTEM, you can use that to make the configuration change, but you’ll still need a restart.)

2. In each database of the cluster, run the following commands as superuser:

   ```sql
   SET search_path = pg_catalog;
   CREATE OR REPLACE VIEW pg_user_mappings AS
   SELECT
       U.oid AS umid,
       S.oid AS srvid,
       S.srvname AS srvname,
       U.umuser AS umuser,
       CASE WHEN U.umuser = 0 THEN 'public'
       ELSE A.rolname END AS usename,
       CASE WHEN (U.umuser <> 0 AND A.rolname = current_user
       AND (pg_has_role(S.srvowner, 'USAGE')
       OR has_server_privilege(S.oid, 'USAGE')))
       OR (U.umuser = 0 AND pg_has_role(S.srvowner, 'USAGE'))
       OR (SELECT rolsuper FROM pg_authid WHERE rolname = current_user)
       THEN U.umoptions
       ELSE NULL END AS umoptions
   FROM pg_user_mapping U
   LEFT JOIN pg_authid A ON (A.oid = U.umuser)
   JOIN pg_foreign_server S ON (U.umserver = S.oid);
   ```

3. Do not forget to include the template0 and template1 databases, or the vulnerability will still exist in databases you create later. To fix template0, you’ll need to temporarily make it accept connections. In PostgreSQL 9.5 and later, you can use

   ```sql
   ALTER DATABASE template0 WITH ALLOW_CONNECTIONS true;
   ```

   and then after fixing template0, undo that with

   ```sql
   ALTER DATABASE template0 WITH ALLOW_CONNECTIONS false;
   ```

   In prior versions, instead use

   ```sql
   UPDATE pg_database SET datallowconn = true WHERE datname = 'template0';
   UPDATE pg_database SET datallowconn = false WHERE datname = 'template0';
   ```

4. Finally, remove the allow_system_table_mods configuration setting, and again restart the postmaster.

   • Disallow empty passwords in all password-based authentication methods (Heikki Linnakangas)

   libpq ignores empty password specifications, and does not transmit them to the server. So, if a user’s password has been set to the empty string, it’s impossible to log in with that password via
psql or other libpq-based clients. An administrator might therefore believe that setting the password to empty is equivalent to disabling password login. However, with a modified or non-libpq-based client, logging in could be possible, depending on which authentication method is configured. In particular the most common method, \texttt{md5}, accepted empty passwords. Change the server to reject empty passwords in all cases. (CVE-2017-7546)

- Make \texttt{lo\_put()} check for \texttt{UPDATE} privilege on the target large object (Tom Lane, Michael Paquier)

  \texttt{lo\_put()} should surely require the same permissions as \texttt{lowrite()}, but the check was missing, allowing any user to change the data in a large object. (CVE-2017-7548)

- Correct the documentation about the process for upgrading standby servers with pg\_upgrade (Bruce Momjian)

  The previous documentation instructed users to start/stop the primary server after running pg\_upgrade but before syncing the standby servers. This sequence is unsafe.

- Fix concurrent locking of tuple update chains (Álvaro Herrera)

  If several sessions concurrently lock a tuple update chain with nonconflicting lock modes using an old snapshot, and they all succeed, it was possible for some of them to nonetheless fail (and conclude there is no live tuple version) due to a race condition. This had consequences such as foreign-key checks failing to see a tuple that definitely exists but is being updated concurrently.

- Fix potential data corruption when freezing a tuple whose XMAX is a multixact with exactly one still-interesting member (Teodor Sigaev)

- Avoid integer overflow and ensuing crash when sorting more than one billion tuples in-memory (Sergey Koposov)

- On Windows, retry process creation if we fail to reserve the address range for our shared memory in the new process (Tom Lane, Amit Kapila)

  This is expected to fix infrequent child-process-launch failures that are probably due to interference from antivirus products.

- Fix low-probability corruption of shared predicate-lock hash table in Windows builds (Thomas Munro, Tom Lane)

- Avoid logging clean closure of an SSL connection as though it were a connection reset (Michael Paquier)

- Prevent sending SSL session tickets to clients (Tom Lane)

  This fixes prevents reconnection failures with ticket-aware client-side SSL code.

- Fix code for setting tcp\_keepalives\_idle on Solaris (Tom Lane)

- Fix statistics collector to honor inquiry messages issued just after a postmaster shutdown and immediate restart (Tom Lane)

  Statistics inquiries issued within half a second of the previous postmaster shutdown were effectively ignored.

- Ensure that the statistics collector’s receive buffer size is at least 100KB (Tom Lane)

  This reduces the risk of dropped statistics data on older platforms whose default receive buffer size is less than that.

- Fix possible creation of an invalid WAL segment when a standby is promoted just after it processes an \texttt{XLOG\_SWITCH} WAL record (Andres Freund)

- Fix walsender to exit promptly when client requests shutdown (Tom Lane)
Appendix E. Release Notes

- Fix SIGHUP and SIGUSR1 handling in walsender processes (Petr Jelinek, Andres Freund)
- Prevent walsender-triggered panics during shutdown checkpoints (Andres Freund, Michael Paquier)
- Fix unnecessarily slow restarts of walreceiver processes due to race condition in postmaster (Tom Lane)
- Fix leakage of small subtransactions spilled to disk during logical decoding (Andres Freund)
  This resulted in temporary files consuming excessive disk space.
- Reduce the work needed to build snapshots during creation of logical-decoding slots (Andres Freund, Michael Paquier)
- Fix race condition that could indefinitely delay creation of logical-decoding slots (Andres Freund, Petr Jelinek)
- Reduce overhead in processing syscache invalidation events (Tom Lane)
  This is particularly helpful for logical decoding, which triggers frequent cache invalidation.
- Fix cases where an INSERT or UPDATE assigns to more than one element of a column that is of domain-over-array type (Tom Lane)
- Allow window functions to be used in sub-SELECTs that are within the arguments of an aggregate function (Tom Lane)
- Move autogenerated array types out of the way during ALTER ... RENAME (Vik Fearing)
  Previously, we would rename a conflicting autogenerated array type out of the way during CREATE; this fix extends that behavior to renaming operations.
- Fix dangling pointer in ALTER TABLE when there is a comment on a constraint belonging to the table (David Rowley)
  Re-applying the comment to the reconstructed constraint could fail with a weird error message, or even crash.
- Ensure that ALTER USER ... SET accepts all the syntax variants that ALTER ROLE ... SET does (Peter Eisentraut)
- Properly update dependency info when changing a datatype I/O function’s argument or return type from opaque to the correct type (Heikki Linnakangas)
  CREATE TYPE updates I/O functions declared in this long-obsolete style, but it forgot to record a dependency on the type, allowing a subsequent DROP TYPE to leave broken function definitions behind.
- Reduce memory usage when ANALYZE processes a tsvector column (Heikki Linnakangas)
- Fix unnecessary precision loss and sloppy rounding when multiplying or dividing money values by integers or floats (Tom Lane)
- Tighten checks for whitespace in functions that parse identifiers, such as regprocedurein() (Tom Lane)
  Depending on the prevailing locale, these functions could misinterpret fragments of multibyte characters as whitespace.
- Use relevant #define symbols from Perl while compiling PL/Perl (Ashutosh Sharma, Tom Lane)
  This avoids portability problems, typically manifesting as a “handshake” mismatch during library load, when working with recent Perl versions.
• In libpq, reset GSS/SASL and SSPI authentication state properly after a failed connection attempt (Michael Paquier)

Failure to do this meant that when falling back from SSL to non-SSL connections, a GSS/SASL failure in the SSL attempt would always cause the non-SSL attempt to fail. SSPI did not fail, but it leaked memory.

• In psql, fix failure when COPY FROM STDIN is ended with a keyboard EOF signal and then another COPY FROM STDIN is attempted (Thomas Munro)

This misbehavior was observed on BSD-derived platforms (including macOS), but not on most others.

• Fix pg_dump and pg_restore to emit REFRESH MATERIALIZED VIEW commands last (Tom Lane)

This prevents errors during dump/restore when a materialized view refers to tables owned by a different user.

• Improve pg_dump/pg_restore’s reporting of error conditions originating in zlib (Vladimir Kunschikov, Álvaro Herrera)

• Fix pg_dump with the --clean option to drop event triggers as expected (Tom Lane)

It also now correctly assigns ownership of event triggers; before, they were restored as being owned by the superuser running the restore script.

• Fix pg_dump to not emit invalid SQL for an empty operator class (Daniel Gustafsson)

• Fix pg_dump output to stdout on Windows (Kuntal Ghosh)

A compressed plain-text dump written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

• Fix pg_get_ruledef() to print correct output for the ON SELECT rule of a view whose columns have been renamed (Tom Lane)

In some corner cases, pg_dump relies on pg_get_ruledef() to dump views, so that this error could result in dump/reload failures.

• Fix dumping of outer joins with empty constraints, such as the result of a NATURAL LEFT JOIN with no common columns (Tom Lane)

• Fix dumping of function expressions in the FROM clause in cases where the expression does not deparse into something that looks like a function call (Tom Lane)

• Fix pg_basebackup output to stdout on Windows (Haribabu Kommi)

A backup written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

• Fix pg_rewind to correctly handle files exceeding 2GB (Kuntal Ghosh, Michael Paquier)

Ordinarily such files won’t appear in PostgreSQL data directories, but they could be present in some cases.

• Fix pg_upgrade to ensure that the ending WAL record does not have wal_level = minimum (Bruce Momjian)

This condition could prevent upgraded standby servers from reconnecting.

• Fix pg_xlogdump’s computation of WAL record length (Andres Freund)

• In postgres_fdw, re-establish connections to remote servers after ALTER SERVER or ALTER USER MAPPING commands (Kyotaro Horiguchi)

This ensures that option changes affecting connection parameters will be applied promptly.
Appendix E. Release Notes

- In `postgres_fdw`, allow cancellation of remote transaction control commands (Robert Haas, Rafia Sabih)
  
  This change allows us to quickly escape a wait for an unresponsive remote server in many more cases than previously.

- Increase `MAX_SYSCACHE_CALLBACKS` to provide more room for extensions (Tom Lane)

- Always use `-fpIC`, not `-fpic`, when building shared libraries with `gcc` (Tom Lane)
  
  This supports larger extension libraries on platforms where it makes a difference.

- Fix unescaped-braces issue in our build scripts for Microsoft MSVC, to avoid a warning or error from recent Perl versions (Andrew Dunstan)

- In MSVC builds, handle the case where the openssl library is not within a `VC` subdirectory (Andrew Dunstan)

- In MSVC builds, add proper include path for `libxml2` header files (Andrew Dunstan)
  
  This fixes a former need to move things around in standard Windows installations of `libxml2`.

- In MSVC builds, recognize a Tcl library that is named `tcl86.lib` (Noah Misch)

- In MSVC builds, honor `PROVE_FLAGS` settings on `vcregress.pl`’s command line (Andrew Dunstan)

E.8. Release 9.5.7

Release date: 2017-05-11

This release contains a variety of fixes from 9.5.6. For information about new features in the 9.5 major release, see Section E.15.

E.8.1. Migration to Version 9.5.7

A dump/restore is not required for those running 9.5.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are using third-party replication tools that depend on “logical decoding”, see the fourth changelog entry below.

Also, if you are upgrading from a version earlier than 9.5.6, see Section E.9.

E.8.2. Changes

- Restrict visibility of `pg_user_mappings.umoptions`, to protect passwords stored as user mapping options (Michael Paquier, Feike Steenbergen)

  The previous coding allowed the owner of a foreign server object, or anyone he has granted server `USAGE` permission to, to see the options for all user mappings associated with that server. This might well include passwords for other users. Adjust the view definition to match the behavior of `information_schema.user_mapping_options`, namely that these options are visible to the
user being mapped, or if the mapping is for PUBLIC and the current user is the server owner, or if the current user is a superuser. (CVE-2017-7486)

By itself, this patch will only fix the behavior in newly initdb’d databases. If you wish to apply this change in an existing database, follow the corrected procedure shown in the changelog entry for CVE-2017-7547, in Section E.7.

• Prevent exposure of statistical information via leaky operators (Peter Eisentraut)

Some selectivity estimation functions in the planner will apply user-defined operators to values obtained from pg_statistic, such as most common values and histogram entries. This occurs before table permissions are checked, so a nefarious user could exploit the behavior to obtain these values for table columns he does not have permission to read. To fix, fall back to a default estimate if the operator’s implementation function is not certified leak-proof and the calling user does not have permission to read the table column whose statistics are needed. At least one of these criteria is satisfied in most cases in practice. (CVE-2017-7484)

• Restore libpq’s recognition of the PGREQUIRESSSL environment variable (Daniel Gustafsson)

Processing of this environment variable was unintentionally dropped in PostgreSQL 9.3, but its documentation remained. This creates a security hazard, since users might be relying on the environment variable to force SSL-encrypted connections, but that would no longer be guaranteed. Restore handling of the variable, but give it lower priority than PGSSLMODE, to avoid breaking configurations that work correctly with post-9.3 code. (CVE-2017-7485)

• Fix possibly-invalid initial snapshot during logical decoding (Petr Jelinek, Andres Freund)

The initial snapshot created for a logical decoding replication slot was potentially incorrect. This could cause third-party tools that use logical decoding to copy incomplete/inconsistent initial data. This was more likely to happen if the source server was busy at the time of slot creation, or if another logical slot already existed.

If you are using a replication tool that depends on logical decoding, and it should have copied a nonempty data set at the start of replication, it is advisable to recreate the replica after installing this update, or to verify its contents against the source server.

• Fix possible corruption of “init forks” of unlogged indexes (Robert Haas, Michael Paquier)

This could result in an unlogged index being set to an invalid state after a crash and restart. Such a problem would persist until the index was dropped and rebuilt.

• Fix incorrect reconstruction of pg_subtrans entries when a standby server replays a prepared but uncommitted two-phase transaction (Tom Lane)

In most cases this turned out to have no visible ill effects, but in corner cases it could result in circular references in pg_subtrans, potentially causing infinite loops in queries that examine rows modified by the two-phase transaction.

• Avoid possible crash in walsender due to failure to initialize a string buffer (Stas Kelvich, Fujii Masao)

• Fix possible crash when rescanning a nearest-neighbor index-only scan on a GiST index (Tom Lane)

• Fix postmaster’s handling of fork() failure for a background worker process (Tom Lane)

Previously, the postmaster updated portions of its state as though the process had been launched successfully, resulting in subsequent confusion.

• Fix crash or wrong answers when a GROUPING SETS column’s data type is hashable but not sortable (Pavan Deolasee)

• Avoid applying “physical targetlist” optimization to custom scans (Dmitry Ivanov, Tom Lane)
This optimization supposed that retrieving all columns of a tuple is inexpensive, which is true for ordinary Postgres tuples; but it might not be the case for a custom scan provider.

- Use the correct sub-expression when applying a FOR ALL row-level-security policy (Stephen Frost)
  In some cases the WITH CHECK restriction would be applied when the USING restriction is more appropriate.

- Ensure parsing of queries in extension scripts sees the results of immediately-preceding DDL (Julien Rouhaud, Tom Lane)
  Due to lack of a cache flush step between commands in an extension script file, non-utility queries might not see the effects of an immediately preceding catalog change, such as ALTER TABLE ... RENAME.

- Skip tablespace privilege checks when ALTER TABLE ... ALTER COLUMN TYPE rebuilds an existing index (Noah Misch)
  The command failed if the calling user did not currently have CREATE privilege for the tablespace containing the index. That behavior seems unhelpful, so skip the check, allowing the index to be rebuilt where it is.

- Fix ALTER TABLE ... VALIDATE CONSTRAINT to not recurse to child tables when the constraint is marked NO INHERIT (Amit Langote)
  This fix prevents unwanted “constraint does not exist” failures when no matching constraint is present in the child tables.

- Avoid dangling pointer in COPY ... TO when row-level security is active for the source table (Tom Lane)
  Usually this had no ill effects, but sometimes it would cause unexpected errors or crashes.

- Avoid accessing an already-closed relcache entry in CLUSTER and VACUUM FULL (Tom Lane)
  With some bad luck, this could lead to indexes on the target relation getting rebuilt with the wrong persistence setting.

- Fix VACUUM to account properly for pages that could not be scanned due to conflicting page pins (Andrew Gierth)
  This tended to lead to underestimation of the number of tuples in the table. In the worst case of a small heavily-contended table, VACUUM could incorrectly report that the table contained no tuples, leading to very bad planning choices.

- Ensure that bulk-tuple-transfer loops within a hash join are interruptible by query cancel requests (Tom Lane, Thomas Munro)

- Fix integer-overflow problems in interval comparison (Kyotaro Horiguchi, Tom Lane)
  The comparison operators for type interval could yield wrong answers for intervals larger than about 296000 years. Indexes on columns containing such large values should be reindexed, since they may be corrupt.

- Fix cursor_to_xml() to produce valid output with tableforest = false (Thomas Munro, Peter Eisentraut)
  Previously it failed to produce a wrapping <table> element.

- Fix roundoff problems in float8_timestamptz() and make_interval() (Tom Lane)
  These functions truncated, rather than rounded, when converting a floating-point value to integer microseconds; that could cause unexpectedly off-by-one results.
• Fix `pg_get_object_address()` to handle members of operator families correctly (Álvaro Herrera)

• Improve performance of `pg_timezone_names` view (Tom Lane, David Rowley)

• Reduce memory management overhead for contexts containing many large blocks (Tom Lane)

• Fix sloppy handling of corner-case errors from `lseek()` and `close()` (Tom Lane)
  Neither of these system calls are likely to fail in typical situations, but if they did, `fd.c` could get quite confused.

• Fix incorrect check for whether postmaster is running as a Windows service (Michael Paquier)
  This could result in attempting to write to the event log when that isn’t accessible, so that no logging happens at all.

• Fix `ecpg` to support `COMMIT PREPARED` and `ROLLBACK PREPARED` (Masahiko Sawada)

• Fix a double-free error when processing dollar-quoted string literals in `ecpg` (Michael Meskes)

• In `pg_dump`, fix incorrect schema and owner marking for comments and security labels of some types of database objects (Giuseppe Broccolo, Tom Lane)
  In simple cases this caused no ill effects; but for example, a schema-selective restore might omit comments it should include, because they were not marked as belonging to the schema of their associated object.

• Avoid emitting an invalid list file in `pg_restore -l` when SQL object names contain newlines (Tom Lane)
  Replace newlines by spaces, which is sufficient to make the output valid for `pg_restore -L`’s purposes.

• Fix `pg_upgrade` to transfer comments and security labels attached to “large objects” (blobs) (Stephen Frost)
  Previously, blobs were correctly transferred to the new database, but any comments or security labels attached to them were lost.

• Improve error handling in `contrib/adminpack`’s `pg_file_write()` function (Noah Misch)
  Notably, it failed to detect errors reported by `fclose()`.

• In `contrib/dblink`, avoid leaking the previous unnamed connection when establishing a new unnamed connection (Joe Conway)

• Fix `contrib/pg_trgm`’s extraction of trigrams from regular expressions (Tom Lane)
  In some cases it would produce a broken data structure that could never match anything, leading to GIN or GiST indexescans that use a trigram index not finding any matches to the regular expression.

• In `contrib/postgres_fdw`, transmit query cancellation requests to the remote server (Michael Paquier, Etsuro Fujita)
  Previously, a local query cancellation request did not cause an already-sent remote query to terminate early. This is a back-patch of work originally done for 9.6.

• Support Tcl 8.6 in MSVC builds (Álvaro Herrera)

• Sync our copy of the timezone library with IANA release tzcode2017b (Tom Lane)
  This fixes a bug affecting some DST transitions in January 2038.

• Update time zone data files to tzdata release 2017b for DST law changes in Chile, Haiti, and Mongolia, plus historical corrections for Ecuador, Kazakhstan, Liberia, and Spain. Switch to numeric
abbreviations for numerous time zones in South America, the Pacific and Indian oceans, and some Asian and Middle Eastern countries.

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the \texttt{pg_timezone_names} view nor used for output.

- Use correct daylight-savings rules for POSIX-style time zone names in MSVC builds (David Rowley)

The Microsoft MSVC build scripts neglected to install the \texttt{posixrules} file in the timezone directory tree. This resulted in the timezone code falling back to its built-in rule about what DST behavior to assume for a POSIX-style time zone name. For historical reasons that still corresponds to the DST rules the USA was using before 2007 (i.e., change on first Sunday in April and last Sunday in October). With this fix, a POSIX-style zone name will use the current and historical DST transition dates of the \texttt{US/Eastern} zone. If you don’t want that, remove the \texttt{posixrules} file, or replace it with a copy of some other zone file (see Section 8.5.3). Note that due to caching, you may need to restart the server to get such changes to take effect.

### E.9. Release 9.5.6

**Release date:** 2017-02-09

This release contains a variety of fixes from 9.5.5. For information about new features in the 9.5 major release, see Section E.15.

#### E.9.1. Migration to Version 9.5.6

A dump/restore is not required for those running 9.5.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted indexes.

Also, if you are upgrading from a version earlier than 9.5.5, see Section E.10.

#### E.9.2. Changes

- Fix a race condition that could cause indexes built with \texttt{CREATE INDEX CONCURRENTLY} to be corrupt (Pavan Deolasee, Tom Lane)

  If \texttt{CREATE INDEX CONCURRENTLY} was used to build an index that depends on a column not previously indexed, then rows updated by transactions that ran concurrently with the \texttt{CREATE INDEX} command could have received incorrect index entries. If you suspect this may have happened, the most reliable solution is to rebuild affected indexes after installing this update.

- Ensure that the special snapshot used for catalog scans is not invalidated by premature data pruning (Tom Lane)
Backends failed to account for this snapshot when advertising their oldest xmin, potentially allowing concurrent vacuuming operations to remove data that was still needed. This led to transient failures along the lines of “cache lookup failed for relation 1255”.

- Fix incorrect WAL logging for BRIN indexes (Kuntal Ghosh)

  The WAL record emitted for a BRIN “revmap” page when moving an index tuple to a different page was incorrect. Replay would make the related portion of the index useless, forcing it to be recomputed.

- Unconditionally WAL-log creation of the “init fork” for an unlogged table (Michael Paquier)

  Previously, this was skipped when wal_level = minimal, but actually it’s necessary even in that case to ensure that the unlogged table is properly reset to empty after a crash.

- Reduce interlocking on standby servers during the replay of btree index vacuuming operations (Simon Riggs)

  This change avoids substantial replication delays that sometimes occurred while replaying such operations.

- If the stats collector dies during hot standby, restart it (Takayuki Tsunakawa)

- Ensure that hot standby feedback works correctly when it’s enabled at standby server start (Ants Aasma, Craig Ringer)

- Check for interrupts while hot standby is waiting for a conflicting query (Simon Riggs)

- Avoid constantly respawning the autovacuum launcher in a corner case (Amit Khandekar)

  This fix avoids problems when autovacuum is nominally off and there are some tables that require freezing, but all such tables are already being processed by autovacuum workers.

- Fix check for when an extension member object can be dropped (Tom Lane)

  Extension upgrade scripts should be able to drop member objects, but this was disallowed for serial-column sequences, and possibly other cases.

- Make sure ALTER TABLE preserves index tablespace assignments when rebuilding indexes (Tom Lane, Michael Paquier)

  Previously, non-default settings of default_tablespace could result in broken indexes.

- Fix incorrect updating of trigger function properties when changing a foreign-key constraint’s deferrability properties with ALTER TABLE ... ALTER CONSTRAINT (Tom Lane)

  This led to odd failures during subsequent exercise of the foreign key, as the triggers were fired at the wrong times.

- Prevent dropping a foreign-key constraint if there are pending trigger events for the referenced relation (Tom Lane)

  This avoids “could not find trigger NNN” or “relation NNN has no triggers” errors.

- Fix ALTER TABLE ... SET DATA TYPE ... USING when child table has different column ordering than the parent (Álvaro Herrera)

  Failure to adjust the column numbering in the USING expression led to errors, typically “attribute N has wrong type”.

- Fix processing of OID column when a table with OIDs is associated to a parent with OIDs via ALTER TABLE ... INHERIT (Amit Langote)

  The OID column should be treated the same as regular user columns in this case, but it wasn’t, leading to odd behavior in later inheritance changes.
• **Fix** `CREATE OR REPLACE VIEW` to update the view query before attempting to apply the new view options (Dean Rasheed)

Previously the command would fail if the new options were inconsistent with the old view definition.

• **Report correct object identity during** `ALTER TEXT SEARCH CONFIGURATION` (Artur Zakirov)

The wrong catalog OID was reported to extensions such as logical decoding.

• **Fix commit timestamp mechanism to not fail when queried about** the special XIDs `FrozenTransactionId` and `BootstrapTransactionId` (Craig Ringer)

• **Check for serializability conflicts before reporting constraint-violation failures** (Thomas Munro)

When using serializable transaction isolation, it is desirable that any error due to concurrent transactions should manifest as a serialization failure, thereby cueing the application that a retry might succeed. Unfortunately, this does not reliably happen for duplicate-key failures caused by concurrent insertions. This change ensures that such an error will be reported as a serialization error if the application explicitly checked for the presence of a conflicting key (and did not find it) earlier in the transaction.

• **Fix incorrect use of view reloptions as regular table reloptions** (Tom Lane)

The symptom was spurious “ON CONFLICT is not supported on table ... used as a catalog table” errors when the target of `INSERT ... ON CONFLICT` is a view with cascade option.

• **Fix incorrect “target lists can have at most N entries” complaint when using** `ON CONFLICT` with wide tables (Tom Lane)

• **Prevent multicolumn expansion of** `foo.*` in an `UPDATE` source expression (Tom Lane)

This led to “UPDATE target count mismatch --- internal error”. Now the syntax is understood as a whole-row variable, as it would be in other contexts.

• **Ensure that column typmods are determined accurately for multi-row VALUES constructs** (Tom Lane)

This fixes problems occurring when the first value in a column has a determinable typmod (e.g., length for a `varchar` value) but later values don’t share the same limit.

• **Throw error for an unfinished Unicode surrogate pair at the end of a Unicode string** (Tom Lane)

Normally, a Unicode surrogate leading character must be followed by a Unicode surrogate trailing character, but the check for this was missed if the leading character was the last character in a Unicode string literal (`U&’...'`) or Unicode identifier (`U&"..."`).

• **Ensure that a purely negative text search query, such as !foo, matches empty tsvectors** (Tom Dunstan)

Such matches were found by GIN index searches, but not by sequential scans or GiST index searches.

• **Prevent crash when ts_rewrite() replaces a non-top-level subtree with an empty query** (Artur Zakirov)

• **Fix performance problems in ts_rewrite()** (Tom Lane)

• **Fix ts_rewrite()’s handling of nested NOT operators** (Tom Lane)

• **Improve speed of user-defined aggregates that use array_append() as transition function** (Tom Lane)

• **Fix array_fill() to handle empty arrays properly** (Tom Lane)
• Fix possible crash in `array_position()` or `array_positions()` when processing arrays of records (Junseok Yang)

• Fix one-byte buffer overrun in `quote_literal_cstr()` (Heikki Linnakangas)
  The overrun occurred only if the input consisted entirely of single quotes and/or backslashes.

• Prevent multiple calls of `pg_start_backup()` and `pg_stop_backup()` from running concurrently (Michael Paquier)
  This avoids an assertion failure, and possibly worse things, if someone tries to run these functions in parallel.

• Disable transform that attempted to remove no-op `AT TIME ZONE` conversions (Tom Lane)
  This resulted in wrong answers when the simplified expression was used in an index condition.

• Avoid discarding `interval-to-interval` casts that aren’t really no-ops (Tom Lane)
  In some cases, a cast that should result in zeroing out low-order `interval` fields was mistakenly deemed to be a no-op and discarded. An example is that casting from `INTERVAL MONTH` to `INTERVAL YEAR` failed to clear the months field.

• Fix bugs in transmitting GUC parameter values to parallel workers (Michael Paquier, Tom Lane)

• Ensure that cached plans are invalidated by changes in foreign-table options (Amit Langote, Etsuro Fujita, Ashutosh Bapat)

• Fix `pg_dump` to dump user-defined casts and transforms that use built-in functions (Stephen Frost)

• Fix `pg_restore` with `--create --if-exists` to behave more sanely if an archive contains unrecognized `DROP` commands (Tom Lane)
  This doesn’t fix any live bug, but it may improve the behavior in future if `pg_restore` is used with an archive generated by a later `pg_dump` version.

• Fix `pg_basebackup`’s rate limiting in the presence of slow I/O (Antonin Houska)
  If disk I/O was transiently much slower than the specified rate limit, the calculation overflowed, effectively disabling the rate limit for the rest of the run.

• Fix `pg_basebackup`’s handling of symlinked `pg_stat_tmp` and `pg_replslot` subdirectories (Magnus Hagander, Michael Paquier)

• Fix possible `pg_basebackup` failure on standby server when including WAL files (Amit Kapila, Robert Haas)

• Fix possible mishandling of expanded arrays in domain check constraints and `CASE` execution (Tom Lane)
  It was possible for a PL/pgSQL function invoked in these contexts to modify or even delete an array value that needs to be preserved for additional operations.

• Fix nested uses of PL/pgSQL functions in contexts such as domain check constraints evaluated during assignment to a PL/pgSQL variable (Tom Lane)

• Ensure that the Python exception objects we create for PL/Python are properly reference-counted (Rafa de la Torre, Tom Lane)
  This avoids failures if the objects are used after a Python garbage collection cycle has occurred.

• Fix PL/Tcl to support triggers on tables that have `.tupno` as a column name (Tom Lane)
  This matches the (previously undocumented) behavior of PL/Tcl’s `spi_exec` and `spi_execp` commands, namely that a magic `.tupno` column is inserted only if there isn’t a real column named that.
• Allow DOS-style line endings in ~/.pgpass files, even on Unix (Vik Fearing)

  This change simplifies use of the same password file across Unix and Windows machines.

• Fix one-byte buffer overrun if ecpg is given a file name that ends with a dot (Takayuki Tsunakawa)

• Fix psql’s tab completion for ALTER DEFAULT PRIVILEGES (Gilles Darold, Stephen Frost)

• In psql, treat an empty or all-blank setting of the PAGER environment variable as meaning “no pager” (Tom Lane)

  Previously, such a setting caused output intended for the pager to vanish entirely.

• Improve contrib/dblink’s reporting of low-level libpq errors, such as out-of-memory (Joe Conway)

• Teach contrib/dblink to ignore irrelevant server options when it uses a contrib/postgres_fdw foreign server as the source of connection options (Corey Huinker)

  Previously, if the foreign server object had options that were not also libpq connection options, an error occurred.

• Fix portability problems in contrib/pageinspect’s functions for GIN indexes (Peter Eisentraut, Tom Lane)

• On Windows, ensure that environment variable changes are propagated to DLLs built with debug options (Christian Ullrich)

• Sync our copy of the timezone library with IANA release tzcode2016j (Tom Lane)

  This fixes various issues, most notably that timezone data installation failed if the target directory didn’t support hard links.

• Update time zone data files to tzdata release 2016j for DST law changes in northern Cyprus (adding a new zone Asia/Famagusta), Russia (adding a new zone Europe/Saratov), Tonga, and Antarctica/Casey. Historical corrections for Italy, Kazakhstan, Malta, and Palestine. Switch to preferring numeric zone abbreviations for Tonga.

E.10. Release 9.5.5

Release date: 2016-10-27

This release contains a variety of fixes from 9.5.4. For information about new features in the 9.5 major release, see Section E.15.

E.10.1. Migration to Version 9.5.5

A dump/restore is not required for those running 9.5.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted free space maps.

Also, if you are upgrading from a version earlier than 9.5.2, see Section E.13.
E.10.2. Changes

- Fix WAL-logging of truncation of relation free space maps and visibility maps (Pavan Deolasee, Heikki Linnakangas)
  It was possible for these files to not be correctly restored during crash recovery, or to be written incorrectly on a standby server. Bogus entries in a free space map could lead to attempts to access pages that have been truncated away from the relation itself, typically producing errors like “could not read block XXX: read only 0 of 8192 bytes”. Checksum failures in the visibility map are also possible, if checksumming is enabled.
  Procedures for determining whether there is a problem and repairing it if so are discussed at https://wiki.postgresql.org/wiki/Free_Space_Map_Problems.

- Fix incorrect creation of GIN index WAL records on big-endian machines (Tom Lane)
  The typical symptom was “unexpected GIN leaf action” errors during WAL replay.

- Fix SELECT FOR UPDATE/SHARE to correctly lock tuples that have been updated by a subsequently-aborted transaction (Álvaro Herrera)
  In 9.5 and later, the SELECT would sometimes fail to return such tuples at all. A failure has not been proven to occur in earlier releases, but might be possible with concurrent updates.

- Fix EvalPlanQual rechecks involving CTE scans (Tom Lane)
  The recheck would always see the CTE as returning no rows, typically leading to failure to update rows that were recently updated.

- Fix deletion of speculatively inserted TOAST tuples when backing out of INSERT ... ON CONFLICT (Oskari Saarenmaa)
  In the race condition where two transactions try to insert conflicting tuples at about the same time, the loser would fail with an “attempted to delete invisible tuple” error if its insertion included any TOAST’ed fields.

- Don’t throw serialization errors for self-conflicting insertions in INSERT ... ON CONFLICT (Thomas Munro, Peter Geoghegan)

- Fix improper repetition of previous results from hashed aggregation in a subquery (Andrew Gierth)
  The test to see if we can reuse a previously-computed hash table of the aggregate state values neglected the possibility of an outer query reference appearing in an aggregate argument expression. A change in the value of such a reference should lead to recalculating the hash table, but did not.

- Fix query-lifespan memory leak in a bulk UPDATE on a table with a PRIMARY KEY or REPLICA IDENTITY index (Tom Lane)

- Fix COPY with a column name list from a table that has row-level security enabled (Adam Brightwell)

- Fix EXPLAIN to emit valid XML when track io timing is on (Markus Winand)
  Previously the XML output-format option produced syntactically invalid tags such as <I/O-Read-Time>. That is now rendered as <I-O-Read-Time>.

- Suppress printing of zeroes for unmeasured times in EXPLAIN (Maksim Milyutin)
  Certain option combinations resulted in printing zero values for times that actually aren’t ever measured in that combination. Our general policy in EXPLAIN is not to print such fields at all, so do that consistently in all cases.

- Fix statistics update for TRUNCATE in a prepared transaction (Stas Kelvich)
• Fix timeout length when VACUUM is waiting for exclusive table lock so that it can truncate the table (Simon Riggs)

The timeout was meant to be 50 milliseconds, but it was actually only 50 microseconds, causing VACUUM to give up on truncation much more easily than intended. Set it to the intended value.

• Fix bugs in merging inherited CHECK constraints while creating or altering a table (Tom Lane, Amit Langote)

Allow identical CHECK constraints to be added to a parent and child table in either order. Prevent merging of a valid constraint from the parent table with a NOT VALID constraint on the child. Likewise, prevent merging of a NO INHERIT child constraint with an inherited constraint.

• Show a sensible value in pg_settings.unit for min_wal_size and max_wal_size (Tom Lane)

• Remove artificial restrictions on the values accepted by numeric_in() and numeric_recv() (Tom Lane)

We allow numeric values up to the limit of the storage format (more than 1e100000), so it seems fairly pointless that numeric_in() rejected scientific-notation exponents above 1000. Likewise, it was silly for numeric_recv() to reject more than 1000 digits in an input value.

• Avoid very-low-probability data corruption due to testing tuple visibility without holding buffer lock (Thomas Munro, Peter Geoghegan, Tom Lane)

• Preserve commit timestamps across server restart (Julien Rouhaud, Craig Ringer)

With track_commit_timestamp turned on, old commit timestamps became inaccessible after a clean server restart.

• Fix logical WAL decoding to work properly when a subtransaction’s WAL output is large enough to spill to disk (Andres Freund)

• Fix possible sorting error when aborting use of abbreviated keys (Peter Geoghegan)

In the worst case, this could result in a corrupt btree index, which would need to be rebuilt using REINDEX. However, the situation is believed to be rare.

• Fix file descriptor leakage when truncating a temporary relation of more than 1GB (Andres Freund)

• Disallow starting a standalone backend with standby_mode turned on (Michael Paquier)

This can’t do anything useful, since there will be no WAL receiver process to fetch more WAL data; and it could result in misbehavior in code that wasn’t designed with this situation in mind.

• Properly initialize replication slot state when recycling a previously-used slot (Michael Paquier)

This failure to reset all of the fields of the slot could prevent VACUUM from removing dead tuples.

• Round shared-memory allocation request to a multiple of the actual huge page size when attempting to use huge pages on Linux (Tom Lane)

This avoids possible failures during munmap() on systems with atypical default huge page sizes. Except in crash-recovery cases, there were no ill effects other than a log message.

• Use a more random value for the dynamic shared memory control segment’s ID (Robert Haas, Tom Lane)

Previously, the same value would be chosen every time, because it was derived from random() but srand() had not yet been called. While relatively harmless, this was not the intended behavior.

• On Windows, retry creation of the dynamic shared memory control segment after an access-denied error (Kyotaro Horiguchi, Amit Kapila)
Appendix E. Release Notes

Windows sometimes returns `ERROR_ACCESS_DENIED` rather than `ERROR_ALREADY_EXISTS` when there is an existing segment. This led to postmaster startup failure due to believing that the former was an unrecoverable error.

- Fix PL/pgSQL to not misbehave with parameters and local variables of type `int2vector` or `oidvector` (Tom Lane)
- Don’t try to share SSL contexts across multiple connections in libpq (Heikki Linnakangas)
  This led to assorted corner-case bugs, particularly when trying to use different SSL parameters for different connections.
- Avoid corner-case memory leak in libpq (Tom Lane)
  The reported problem involved leaking an error report during `PQreset()`, but there might be related cases.
- Make ecpg’s `--help` and `--version` options work consistently with our other executables (Haribabu Kommi)
- Fix pgbench’s calculation of average latency (Fabien Coelho)
  The calculation was incorrect when there were `\sleep` commands in the script, or when the test duration was specified in number of transactions rather than total time.
- In pg_upgrade, check library loadability in name order (Tom Lane)
  This is a workaround to deal with cross-extension dependencies from language transform modules to their base language and data type modules.
- In pg_dump, never dump range constructor functions (Tom Lane)
  This oversight led to pg_upgrade failures with extensions containing range types, due to duplicate creation of the constructor functions.
- In pg_dump with `-C`, suppress `TABLESPACE` clause of `CREATE DATABASE` if `--no-tablespaces` is specified (Tom Lane)
- Make pg_receivexlog work correctly with `--synchronous` without slots (Gabriele Bartolini)
- Disallow specifying both `--source-server` and `--source-target` options to pg_rewind (Michael Banck)
- Make pg_rewind turn off `synchronous_commit` in its session on the source server (Michael Banck, Michael Paquier)
  This allows pg_rewind to work even when the source server is using synchronous replication that is not working for some reason.
- In pg_xlogdump, retry opening new WAL segments when using `--follow` option (Magnus Hagander)
  This allows for a possible delay in the server’s creation of the next segment.
- Fix pg_xlogdump to cope with a WAL file that begins with a continuation record spanning more than one page (Pavan Deolasee)
- Fix contrib/pg_buffercache to work when `shared_buffers` exceeds 256GB (KaiGai Kohei)
- Fix contrib/intarray/bench/bench.pl to print the results of the `EXPLAIN` it does when given the `-e` option (Daniel Gustafsson)
- Support OpenSSL 1.1.0 (Heikki Linnakangas)
- Install TAP test infrastructure so that it’s available for extension testing (Craig Ringer)
When PostgreSQL has been configured with --enable-tap-tests, "make install" will now install the Perl support files for TAP testing where PGXS can find them. This allows non-core extensions to use $(prove_check) without extra tests.

- In MSVC builds, include pg_recvlogical in a client-only installation (MauMau)
- Update Windows time zone mapping to recognize some time zone names added in recent Windows versions (Michael Paquier)
- Prevent failure of obsolete dynamic time zone abbreviations (Tom Lane)
  If a dynamic time zone abbreviation does not match any entry in the referenced time zone, treat it as equivalent to the time zone name. This avoids unexpected failures when IANA removes abbreviations from their time zone database, as they did in tzdata release 2016f and seem likely to do again in the future. The consequences were not limited to not recognizing the individual abbreviation; any mismatch caused the pg_timezone_abbrs view to fail altogether.
- Update time zone data files to tzdata release 2016h for DST law changes in Palestine and Turkey, plus historical corrections for Turkey and some regions of Russia. Switch to numeric abbreviations for some time zones in Antarctica, the former Soviet Union, and Sri Lanka.
  The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the pg_timezone_names view nor used for output.
  In this update, AMT is no longer shown as being in use to mean Armenia Time. Therefore, we have changed the Default abbreviation set to interpret it as Amazon Time, thus UTC-4 not UTC+4.

E.11. Release 9.5.4

Release date: 2016-08-11
This release contains a variety of fixes from 9.5.3. For information about new features in the 9.5 major release, see Section E.15.

E.11.1. Migration to Version 9.5.4
A dump/restore is not required for those running 9.5.X.
However, if you are upgrading from a version earlier than 9.5.2, see Section E.13.

E.11.2. Changes

- Fix possible mis-evaluation of nested CASE-WHEN expressions (Heikki Linnakangas, Michael Paquier, Tom Lane)
  A CASE expression appearing within the test value subexpression of another CASE could become confused about whether its own test value was null or not. Also, inlining of a SQL function implementing the equality operator used by a CASE expression could result in passing the wrong test value to functions called within a CASE expression in the SQL function’s body. If the test values
were of different data types, a crash might result; moreover such situations could be abused to allow
disclosure of portions of server memory. (CVE-2016-5423)

- Fix client programs’ handling of special characters in database and role names (Noah Misch,
  Nathan Bossart, Michael Paquier)
Numerous places in vacuumdb and other client programs could become confused by database and
role names containing double quotes or backslashes. Tighten up quoting rules to make that safe.
Also, ensure that when a conninfo string is used as a database name parameter to these programs,
it is correctly treated as such throughout.

Fix handling of paired double quotes in psql’s \connect and \password commands to match the
documentation.

Introduce a new -re-usage-previous option in psql’s \connect command to allow explicit control
of whether to re-use connection parameters from a previous connection. (Without this, the choice
is based on whether the database name looks like a conninfo string, as before.) This allows secure
handling of database names containing special characters in pg_dumpall scripts.

pg_dumpall now refuses to deal with database and role names containing carriage returns or new-
lines, as it seems impractical to quote those characters safely on Windows. In future we may reject
such names on the server side, but that step has not been taken yet.

These are considered security fixes because crafted object names containing special characters
could have been used to execute commands with superuser privileges the next time a superuser
executes pg_dumpall or other routine maintenance operations. (CVE-2016-5424)

- Fix corner-case misbehaviors for IS NULL/IS NOT NULL applied to nested composite values (And-
  rew Gierth, Tom Lane)
The SQL standard specifies that IS NULL should return TRUE for a row of all null values (thus
ROW(NULL,NULL) IS NULL yields TRUE), but this is not meant to apply recursively (thus
ROW(NULL, ROW(NULL,NULL)) IS NULL yields FALSE). The core executor got this right, but
certain planner optimizations treated the test as recursive (thus producing TRUE in both cases),
and contrib/postgres_fdw could produce remote queries that misbehaved similarly.

- Fix “unrecognized node type” error for INSERT ... ON CONFLICT within a recursive CTE (a
  WITH item) (Peter Geoghegan)

- Fix INSERT ... ON CONFLICT to successfully match index expressions or index predicates that
  are simplified during the planner’s expression preprocessing phase (Tom Lane)

- Correctly handle violations of exclusion constraints that apply to the target table of an INSERT
  ... ON CONFLICT command, but are not one of the selected arbiter indexes (Tom Lane)
  Such a case should raise a normal constraint-violation error, but it got into an infinite loop instead.

- Fix INSERT ... ON CONFLICT to not fail if the target table has a unique index on OID (Tom
  Lane)

- Make the inet and cidr data types properly reject IPv6 addresses with too many colon-separated
  fields (Tom Lane)

- Prevent crash in close_ps() (the point ## lseg operator) for NaN input coordinates (Tom
  Lane)
  Make it return NULL instead of crashing.

- Avoid possible crash in pg_get_expr() when inconsistent values are passed to it (Michael
  Paquier, Thomas Munro)

- Fix several one-byte buffer over-reads in to_number() (Peter Eisentraut)
Appendix E. Release Notes

In several cases the `to_number()` function would read one more character than it should from the input string. There is a small chance of a crash, if the input happens to be adjacent to the end of memory.

- Do not run the planner on the query contained in `CREATE MATERIALIZED VIEW` or `CREATE TABLE AS` when `WITH NO DATA` is specified (Michael Paquier, Tom Lane)

  This avoids some unnecessary failure conditions, for example if a stable function invoked by the materialized view depends on a table that doesn’t exist yet.

- Avoid unsafe intermediate state during expensive paths through `heap_update()` (Masahiko Sawada, Andres Freund)

  Previously, these cases locked the target tuple (by setting its XMAX) but did not WAL-log that action, thus risking data integrity problems if the page were spilled to disk and then a database crash occurred before the tuple update could be completed.

- Fix bit update during WAL replay of row locking operations (Andres Freund)

  The only known consequence of this problem is that row locks held by a prepared, but uncommitted, transaction might fail to be enforced after a crash and restart.

- Avoid unnecessary “could not serialize access” errors when acquiring `FOR KEY SHARE` row locks in serializable mode (Álvaro Herrera)

- Make sure “expanded” datums returned by a plan node are read-only (Tom Lane)

  This avoids failures in some cases where the result of a lower plan node is referenced in multiple places in upper nodes. So far as core PostgreSQL is concerned, only array values returned by PL/pgSQL functions are at risk; but extensions might use expanded datums for other things.

- Avoid crash in `postgres -c` when the specified variable has a null string value (Michael Paquier)

- Prevent unintended waits for the receiver in WAL sender processes (Kyotaro Horiguchi)

- Fix failure of logical decoding when a subtransaction contains no actual changes (Marko Tiikkaja, Andrew Gierth)

- Ensure that backends see up-to-date statistics for shared catalogs (Tom Lane)

  The statistics collector failed to update the statistics file for shared catalogs after a request from a regular backend. This problem was partially masked because the autovacuum launcher regularly makes requests that did cause such updates; however, it became obvious with autovacuum disabled.

- Avoid redundant writes of the statistics files when multiple backends request updates close together (Tom Lane, Tomas Vondra)

- Avoid consuming a transaction ID during `VACUUM` (Alexander Korotkov)

  Some cases in `VACUUM` unnecessarily caused an XID to be assigned to the current transaction. Normally this is negligible, but if one is up against the XID wraparound limit, consuming more XIDs during anti-wraparound vacuums is a very bad thing.

- Prevent possible failure when vacuuming multixact IDs in an installation that has been `pg_upgrade`d from pre-9.3 (Andrew Gierth, Álvaro Herrera)

  The usual symptom of this bug is errors like “`MultiXactId NNN has not been created yet -- apparent wraparound`.”

- When a manual `ANALYZE` specifies a column list, don’t reset the table’s `changes_since_analyze` counter (Tom Lane)
If we’re only analyzing some columns, we should not prevent routine auto-analyze from happening for the other columns.

- **Fix ANALYZE’s overestimation of n_distinct for a unique or nearly-unique column with many null entries (Tom Lane)**
  
The nulls could get counted as though they were themselves distinct values, leading to serious planner misestimates in some types of queries.

- **Prevent autovacuum from starting multiple workers for the same shared catalog (Álvaro Herrera)**
  
  Normally this isn’t much of a problem because the vacuum doesn’t take long anyway; but in the case of a severely bloated catalog, it could result in all but one worker uselessly waiting instead of doing useful work on other tables.

- **Fix bug in b-tree mark/restore processing (Kevin Grittner)**
  
  This error could lead to incorrect join results or assertion failures in a merge join whose inner source node is a b-tree indexscan.

- **Avoid duplicate buffer lock release when abandoning a b-tree index page deletion attempt (Tom Lane)**
  
  This mistake prevented VACUUM from completing in some cases involving corrupt b-tree indexes.

- **Fix building of large (bigger than shared_buffers) hash indexes (Tom Lane)**
  
  The code path used for large indexes contained a bug causing incorrect hash values to be inserted into the index, so that subsequent index searches always failed, except for tuples inserted into the index after the initial build.

- **Prevent infinite loop in GiST index build for geometric columns containing NaN component values (Tom Lane)**

- **Fix possible crash during a nearest-neighbor (ORDER BY distance) indexscan on a contrib/btree_gist index on an interval column (Peter Geoghegan)**

- **Fix “PANIC: failed to add BRIN tuple” error when attempting to update a BRIN index entry (Álvaro Herrera)**

- **Fix possible crash during background worker shutdown (Dmitry Ivanov)**

- **Fix PL/pgSQL’s handling of the INTO clause within IMPORT FOREIGN SCHEMA commands (Tom Lane)**

- **Fix contrib/btree_gin to handle the smallest possible bigint value correctly (Peter Eisentraut)**

- **Teach libpq to correctly decode server version from future servers (Peter Eisentraut)**
  
  It’s planned to switch to two-part instead of three-part server version numbers for releases after 9.6. Make sure that PQserverVersion() returns the correct value for such cases.

- **Fix ecpg’s code for unsigned long long array elements (Michael Meskes)**

- **In pg_dump with both -c and -C options, avoid emitting an unwanted CREATE SCHEMA public command (David Johnston, Tom Lane)**

- **Improve handling of SIGTERM/control-C in parallel pg_dump and pg_restore (Tom Lane)**
  
  Make sure that the worker processes will exit promptly, and also arrange to send query-cancel requests to the connected backends, in case they are doing something long-running such as a CREATE INDEX.

- **Fix error reporting in parallel pg_dump and pg_restore (Tom Lane)**
Previously, errors reported by pg_dump or pg_restore worker processes might never make it to the user’s console, because the messages went through the master process, and there were various deadlock scenarios that would prevent the master process from passing on the messages. Instead, just print everything to stderr. In some cases this will result in duplicate messages (for instance, if all the workers report a server shutdown), but that seems better than no message.

- Ensure that parallel pg_dump or pg_restore on Windows will shut down properly after an error (Kyotaro Horiguchi)

  Previously, it would report the error, but then just sit until manually stopped by the user.

- Make parallel pg_dump fail cleanly when run against a standby server (Magnus Hagander)

  This usage is not supported unless --no-synchronized-snapshots is specified, but the error was not handled very well.

- Make pg_dump behave better when built without zlib support (Kyotaro Horiguchi)

  It didn’t work right for parallel dumps, and emitted some rather pointless warnings in other cases.

- Make pg_basebackup accept -Z 0 as specifying no compression (Fujii Masao)

- Fix makefiles’ rule for building AIX shared libraries to be safe for parallel make (Noah Misch)

- Fix TAP tests and MSVC scripts to work when build directory’s path name contains spaces (Michael Paquier, Kyotaro Horiguchi)

- Be more predictable about reporting “statement timeout” versus “lock timeout” (Tom Lane)

  On heavily loaded machines, the regression tests sometimes failed due to reporting “lock timeout” even though the statement timeout should have occurred first.

- Make regression tests safe for Danish and Welsh locales (Jeff Janes, Tom Lane)

  Change some test data that triggered the unusual sorting rules of these locales.

- Update our copy of the timezone code to match IANA’s tzcode release 2016c (Tom Lane)

  This is needed to cope with anticipated future changes in the time zone data files. It also fixes some corner-case bugs in coping with unusual time zones.

- Update time zone data files to tzdata release 2016f for DST law changes in Kemerovo and Novosibirsk, plus historical corrections for Azerbaijan, Belarus, and Morocco.

**E.12. Release 9.5.3**

**Release date:** 2016-05-12

This release contains a variety of fixes from 9.5.2. For information about new features in the 9.5 major release, see Section E.15.

**E.12.1. Migration to Version 9.5.3**

A dump/restore is not required for those running 9.5.X.

However, if you are upgrading from a version earlier than 9.5.2, see Section E.13.
E.12.2. Changes

- Clear the OpenSSL error queue before OpenSSL calls, rather than assuming it’s clear already; and make sure we leave it clear afterwards (Peter Geoghegan, Dave Vitek, Peter Eisentraut)
  This change prevents problems when there are multiple connections using OpenSSL within a single process and not all the code involved follows the same rules for when to clear the error queue. Failures have been reported specifically when a client application uses SSL connections in libpq concurrently with SSL connections using the PHP, Python, or Ruby wrappers for OpenSSL. It’s possible for similar problems to arise within the server as well, if an extension module establishes an outgoing SSL connection.

- Fix “failed to build any n-way joins” planner error with a full join enclosed in the right-hand side of a left join (Tom Lane)

- Fix incorrect handling of equivalence-class tests in multilevel nestloop plans (Tom Lane)
  Given a three-or-more-way equivalence class of variables, such as \(X.X = Y.Y = Z.Z\), it was possible for the planner to omit some of the tests needed to enforce that all the variables are actually equal, leading to join rows being output that didn’t satisfy the \(WHERE\) clauses. For various reasons, erroneous plans were seldom selected in practice, so that this bug has gone undetected for a long time.

- Fix corner-case parser failures occurring when operator_precedence_warning is turned on (Tom Lane)
  An example is that \(SELECT (ARRAY[])::text[]\) gave an error, though it worked without the parentheses.

- Fix query-lifespan memory leak in GIN index scans (Julien Rouhaud)

- Fix query-lifespan memory leak and potential index corruption hazard in GIN index insertion (Tom Lane)
  The memory leak would typically not amount to much in simple queries, but it could be very substantial during a large GIN index build with high \(maintenance_work_mem\).

- Fix possible misbehavior of \(TH, th,\) and \(Y, YYYY\) format codes in \(to_timestamp()\) (Tom Lane)
  These could advance off the end of the input string, causing subsequent format codes to read garbage.

- Fix dumping of rules and views in which the \(array\) argument of a \(value\) operator \(ANY (array)\) construct is a sub-SELECT (Tom Lane)

- Disallow newlines in \(ALTER SYSTEM\) parameter values (Tom Lane)
  The configuration-file parser doesn’t support embedded newlines in string literals, so we mustn’t allow them in values to be inserted by \(ALTER SYSTEM\).

- Fix \(ALTER TABLE ... REPLICA IDENTITY USING INDEX\) to work properly if an index on \(OID\) is selected (David Rowley)

- Avoid possible misbehavior after failing to remove a tablespace symlink (Tom Lane)

- Fix crash in logical decoding on alignment-picky platforms (Tom Lane, Andres Freund)
  The failure occurred only with a transaction large enough to spill to disk and a primary-key change within that transaction.

- Avoid repeated requests for feedback from receiver while shutting down walsender (Nick Cleaton)
Appendix E. Release Notes

- Make `pg_regress` use a startup timeout from the `PGCTLTIMEOUT` environment variable, if that’s set (Tom Lane)
  This is for consistency with a behavior recently added to pg_ctl; it eases automated testing on slow machines.
- Fix `pg_upgrade` to correctly restore extension membership for operator families containing only one operator class (Tom Lane)
  In such a case, the operator family was restored into the new database, but it was no longer marked as part of the extension. This had no immediate ill effects, but would cause later `pg_dump` runs to emit output that would cause (harmless) errors on restore.
- Fix `pg_upgrade` to not fail when new-cluster TOAST rules differ from old (Tom Lane)
  `pg_upgrade` had special-case code to handle the situation where the new PostgreSQL version thinks that a table should have a TOAST table while the old version did not. That code was broken, so remove it, and instead do nothing in such cases; there seems no reason to believe that we can’t get along fine without a TOAST table if that was okay according to the old version’s rules.
- Fix atomic operations for PPC when using IBM’s XLC compiler (Noah Misch)
- Reduce the number of SysV semaphores used by a build configured with `--disable-spinlocks` (Tom Lane)
- Rename internal function `strtoi()` to `strtoint()` to avoid conflict with a NetBSD library function (Thomas Munro)
- Fix reporting of errors from `bind()` and `listen()` system calls on Windows (Tom Lane)
- Reduce verbosity of compiler output when building with Microsoft Visual Studio (Christian Ullrich)
- Support building with Visual Studio 2015 (Michael Paquier, Petr Jelínek)
  Note that builds made with VS2015 will not run on Windows versions before Windows Vista.
- Fix `putenv()` to work properly with Visual Studio 2013 (Michael Paquier)
- Avoid possibly-unsafe use of Windows’ `FormatMessage()` function (Christian Ullrich)
  Use the `FORMAT_MESSAGE_IGNORE_INSERTS` flag where appropriate. No live bug is known to exist here, but it seems like a good idea to be careful.
- Update time zone data files to tzdata release 2016d for DST law changes in Russia and Venezuela. There are new zone names `Europe/Kirov` and `Asia/Tomsk` to reflect the fact that these regions now have different time zone histories from adjacent regions.

E.13. Release 9.5.2

Release date: 2016-03-31
This release contains a variety of fixes from 9.5.1. For information about new features in the 9.5 major release, see Section E.15.

E.13.1. Migration to Version 9.5.2

A dump/restore is not required for those running 9.5.X.
Appendix E. Release Notes

However, you may need to **REINDEX** some indexes after applying the update, as per the first changelog entry below.

### E.13.2. Changes

- Disable abbreviated keys for string sorting in non-C locales (Robert Haas)

  PostgreSQL 9.5 introduced logic for speeding up comparisons of string data types by using the standard C library function `strxfrm()` as a substitute for `strcoll()`. It now emerges that most versions of glibc (Linux's implementation of the C library) have buggy implementations of `strxfrm()` that, in some locales, can produce string comparison results that do not match `strcoll()`. Until this problem can be better characterized, disable the optimization in all non-C locales. (C locale is safe since it uses neither `strcoll()` nor `strxfrm()`.)

  Unfortunately, this problem affects not only sorting but also entry ordering in B-tree indexes, which means that B-tree indexes on `text`, `varchar`, or `char` columns may now be corrupt if they sort according to an affected locale and were built or modified under PostgreSQL 9.5.0 or 9.5.1. Users should **REINDEX** indexes that might be affected.

  It is not possible at this time to give an exhaustive list of known-affected locales. C locale is known safe, and there is no evidence of trouble in English-based locales such as `en_US`, but some other popular locales such as `de_DE` are affected in most glibc versions.

- Maintain row-security status properly in cached plans (Stephen Frost)

  In a session that performs queries as more than one role, the plan cache might incorrectly re-use a plan that was generated for another role ID, thus possibly applying the wrong set of policies when row-level security (RLS) is in use. (CVE-2016-2193)

- Add must-be-superuser checks to some new contrib/pageinspect functions (Andreas Seltenreich)

  Most functions in the `pageinspect` extension that inspect `bytea` values disallow calls by non-superusers, but `brin_page_type()` and `brin_metapage_info()` failed to do so. Passing contrived `bytea` values to them might crash the server or disclose a few bytes of server memory. Add the missing permissions checks to prevent misuse. (CVE-2016-3065)

- Fix incorrect handling of indexed `ROW()` comparisons (Simon Riggs)

  Flaws in a minor optimization introduced in 9.5 caused incorrect results if the `ROW()` comparison matches the index ordering partially but not exactly (for example, differing column order, or the index contains both `ASC` and `DESC` columns). Pending a better solution, the optimization has been removed.

- Fix incorrect handling of NULL index entries in indexed `ROW()` comparisons (Tom Lane)

  An index search using a row comparison such as `ROW(a, b) > ROW(‘x’, ‘y’)` would stop upon reaching a NULL entry in the `b` column, ignoring the fact that there might be non-NULL `b` values associated with later values of `a`.

- Avoid unlikely data-loss scenarios due to renaming files without adequate `fsync()` calls before and after (Michael Paquier, Tomas Vondra, Andres Freund)

- Fix incorrect behavior when rechecking a just-modified row in a query that does **SELECT FOR UPDATE/SHARE** and contains some relations that need not be locked (Tom Lane)
Rows from non-locked relations were incorrectly treated as containing all NULLs during the recheck, which could result in incorrectly deciding that the updated row no longer passes the `WHERE` condition, or in incorrectly outputting NULLs.

- Fix bug in `json_to_record()` when a field of its input object contains a sub-object with a field name matching one of the requested output column names (Tom Lane)
- Fix nonsense result from two-argument form of `jsonb_object()` when called with empty arrays (Michael Paquier, Andrew Dunstan)
- Fix misbehavior in `jsonb_set()` when converting a path array element into an integer for use as an array subscript (Michael Paquier)
- Fix misformatting of negative time zone offsets by `to_char()`’s OF format code (Thomas Munro, Tom Lane)
- Fix possible incorrect logging of waits done by `INSERT ... ON CONFLICT` (Peter Geoghegan)
  Log messages would sometimes claim that the wait was due to an exclusion constraint although no such constraint was responsible.
- Ignore recovery_min_apply_delay parameter until recovery has reached a consistent state (Michael Paquier)
  Previously, standby servers would delay application of WAL records in response to `recovery_min_apply_delay` even while replaying the initial portion of WAL needed to make their database state valid. Since the standby is useless until it’s reached a consistent database state, this was deemed unhelpful.
- Correctly handle cases where `pg_subtrans` is close to XID wraparound during server startup (Jeff Janes)
- Fix assorted bugs in logical decoding (Andres Freund)
  Trouble cases included tuples larger than one page when replica identity is `FULL`, `UPDATES` that change a primary key within a transaction large enough to be spooled to disk, incorrect reports of “subxact logged without previous toplevel record”, and incorrect reporting of a transaction’s commit time.
- Fix planner error with nested security barrier views when the outer view has a `WHERE` clause containing a correlated subquery (Dean Rasheed)
- Fix memory leak in GIN index searches (Tom Lane)
- Fix corner-case crash due to trying to free `localeconv()` output strings more than once (Tom Lane)
- Fix parsing of affix files for `ispell` dictionaries (Tom Lane)
  The code could go wrong if the affix file contained any characters whose byte length changes during case-folding, for example ı in Turkish UTF8 locales.
- Avoid use of `sscanf()` to parse `ispell` dictionary files (Artur Zakirov)
  This dodges a portability problem on FreeBSD-derived platforms (including macOS).
- Fix atomic-operations code used on PPC with IBM’s `xlc` compiler (Noah Misch)
  This error led to rare failures of concurrent operations on that platform.
- Avoid a crash on old Windows versions (before 7SP1/2008R2SP1) with an AVX2-capable CPU and a Postgres build done with Visual Studio 2013 (Christian Ullrich)
  This is a workaround for a bug in Visual Studio 2013’s runtime library, which Microsoft have stated they will not fix in that version.

2227
• Fix psql’s tab completion logic to handle multibyte characters properly (Kyotaro Horiguchi, Robert Haas)

• Fix psql’s tab completion for SECURITY LABEL (Tom Lane)
  Pressing TAB after SECURITY LABEL might cause a crash or offering of inappropriate keywords.

• Make pg_ctl accept a wait timeout from the PGCTLTIMEOUT environment variable, if none is specified on the command line (Noah Misch)
  This eases testing of slower buildfarm members by allowing them to globally specify a longer-than-normal timeout for postmaster startup and shutdown.

• Fix incorrect test for Windows service status in pg_ctl (Manuel Mathar)
  The previous set of minor releases attempted to fix pg_ctl to properly determine whether to send log messages to Window’s Event Log, but got the test backwards.

• Fix pgbench to correctly handle the combination of -C and -M prepared options (Tom Lane)

• In pg_upgrade, skip creating a deletion script when the new data directory is inside the old data directory (Bruce Momjian)
  Blind application of the script in such cases would result in loss of the new data directory.

• In PL/Perl, properly translate empty Postgres arrays into empty Perl arrays (Alex Hunsaker)

• Make PL/Python cope with function names that aren’t valid Python identifiers (Jim Nasby)

• Fix multiple mistakes in the statistics returned by contrib/pgstattuple’s pgstatindex() function (Tom Lane)

• Remove dependency on psed in MSVC builds, since it’s no longer provided by core Perl (Michael Paquier, Andrew Dunstan)

• Update time zone data files to tzdata release 2016c for DST law changes in Azerbaijan, Chile, Haiti, Palestine, and Russia (Altai, Astrakhan, Kirov, Sakhalin, Ulyanovsk regions), plus historical corrections for Lithuania, Moldova, and Russia (Kaliningrad, Samara, Volgograd).

E.14. Release 9.5.1

Release date: 2016-02-11

This release contains a variety of fixes from 9.5.0. For information about new features in the 9.5 major release, see Section E.15.

E.14.1. Migration to Version 9.5.1

A dump/restore is not required for those running 9.5.X.

E.14.2. Changes

• Fix infinite loops and buffer-overrun problems in regular expressions (Tom Lane)
  Very large character ranges in bracket expressions could cause infinite loops in some cases, and memory overwrites in other cases. (CVE-2016-0773)
• Fix an oversight that caused hash joins to miss joining to some tuples of the inner relation in rare cases (Tomas Vondra, Tom Lane)

• Avoid pushdown of `HAVING` clauses when grouping sets are used (Andrew Gierth)

• Fix deparsing of `ON CONFLICT` arbiter `WHERE` clauses (Peter Geoghegan)

• Make `%h` and `%r` escapes in `log_line_prefix` work for messages emitted due to `log_connections` (Tom Lane)

  Previously, `%h/%r` started to work just after a new session had emitted the “connection received” log message; now they work for that message too.

• Avoid leaking a token handle during SSPI authentication (Christian Ullrich)

• Fix `psql`’s `\d` command to interpret its pattern argument the same way as other `\d` commands with potentially schema-qualified patterns do (Reece Hart)

• In `pg_ctl` on Windows, check service status to decide where to send output, rather than checking if standard output is a terminal (Michael Paquier)

• Fix assorted corner-case bugs in `pg_dump`’s processing of extension member objects (Tom Lane)

• Fix improper quoting of domain constraint names in `pg_dump` (Elvis Pranskevichus)

• Make `pg_dump` mark a view’s triggers as needing to be processed after its rule, to prevent possible failure during parallel `pg_restore` (Tom Lane)

• Install guards in `pgbench` against corner-case overflow conditions during evaluation of script-specified division or modulo operators (Fabien Coelho, Michael Paquier)

• Suppress useless warning message when `pg_receivexlog` connects to a pre-9.4 server (Marco Nenciarini)

• Avoid dump/reload problems when using both `plpython2` and `plpython3` (Tom Lane)

  In principle, both versions of PL/Python can be used in the same database, though not in the same session (because the two versions of `libpython` cannot safely be used concurrently). However, `pg_restore` and `pg_upgrade` both do things that can fall foul of the same-session restriction. Work around that by changing the timing of the check.

• Fix PL/Python regression tests to pass with Python 3.5 (Peter Eisentraut)

• Prevent certain PL/Java parameters from being set by non-superusers (Noah Misch)

  This change mitigates a PL/Java security bug (CVE-2016-0766), which was fixed in PL/Java by marking these parameters as superuser-only. To fix the security hazard for sites that update PostgreSQL more frequently than PL/Java, make the core code aware of them also.

• Fix `ecpg`-supplied header files to not contain comments continued from a preprocessor directive line onto the next line (Michael Meskes)

  Such a comment is rejected by `ecpg`. It’s not yet clear whether `ecpg` itself should be changed.

• Fix `hstore_to_json_loose()`’s test for whether an `hstore` value can be converted to a JSON number (Tom Lane)

  Previous this function could be fooled by non-alphanumeric trailing characters, leading to emitting syntactically-invalid JSON.

• In `contrib/postgres_fdw`, fix bugs triggered by use of `tableoid` in data-modifying commands (Etsuro Fujita, Robert Haas)

• Fix ill-advised restriction of `NAMEDATALEN` to be less than 256 (Robert Haas, Tom Lane)
Appendix E. Release Notes

- Improve reproducibility of build output by ensuring filenames are given to the linker in a fixed order (Christoph Berg)
  This avoids possible bitwise differences in the produced executable files from one build to the next.
- Ensure that dynloader.h is included in the installed header files in MSVC builds (Bruce Momjian, Michael Paquier)
- Update time zone data files to tzdata release 2016a for DST law changes in Cayman Islands, Metlakatla, and Trans-Baikal Territory (Zabaykalsky Krai), plus historical corrections for Pakistan.

E.15. Release 9.5

Release date: 2016-01-07

E.15.1. Overview

Major enhancements in PostgreSQL 9.5 include:

- Allow INSERTs that would generate constraint conflicts to be turned into UPDATES or ignored
- Add GROUP BY analysis features GROUPING SETS, CUBE and ROLLUP
- Add row-level security control
- Create mechanisms for tracking the progress of replication, including methods for identifying the origin of individual changes during logical replication
- Add Block Range Indexes (BRIN)
- Substantial performance improvements for sorting
- Substantial performance improvements for multi-CPU machines

The above items are explained in more detail in the sections below.

E.15.2. Migration to Version 9.5

A dump/restore using pg_dumpall, or use of pg_upgrade, is required for those wishing to migrate data from any previous release.

Version 9.5 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- Adjust operator precedence to match the SQL standard (Tom Lane)
  The precedence of <=, => and <> has been reduced to match that of <, > and =. The precedence of IS tests (e.g., x IS NULL) has been reduced to be just below these six comparison operators. Also, multi-keyword operators beginning with NOT now have the precedence of their base operator (for example, NOT BETWEEN now has the same precedence as BETWEEN) whereas before they had inconsistent precedence, behaving like NOT with respect to their left operand but like their base operator with respect to their right operand. The new configuration parameter operator_precedence_warning can be enabled to warn about queries in which these precedence changes result in different parsing choices.
• Change pg_ctl’s default shutdown mode from smart to fast (Bruce Momjian)
  This means the default behavior will be to forcibly cancel existing database sessions, not simply
  wait for them to exit.

• Use assignment cast behavior for data type conversions in PL/pgSQL assignments, rather than
  converting to and from text (Tom Lane)
  This change causes conversions of Booleans to strings to produce true or false, not t or f. Other type
  conversions may succeed in more cases than before; for example, assigning a numeric value 3.9 to an
  integer variable will now assign 4 rather than failing. If no assignment-grade cast is defined for the
  particular source and destination types, PL/pgSQL will fall back to its old I/O conversion behavior.

• Allow characters in server command-line options to be escaped with a backslash (Andres Freund)
  Formerly, spaces in the options string always separated options, so there was no way to include a
  space in an option value. Including a backslash in an option value now requires writing \\

• Change the default value of the GSSAPI include_realm parameter to 1, so that by default the
  realm is not removed from a GSS or SSPI principal name (Stephen Frost)

• Replace configuration parameter checkpoint_segments with min_wal_size and max_wal_size
  (Heikki Linnakangas)
  If you previously adjusted checkpoint_segments, the following formula will give you an
  approximately equivalent setting:
  \[\text{max_wal_size} = (3 \times \text{checkpoint_segments}) \times 16\text{MB}\]
  Note that the default setting for max_wal_size is much higher than the default
  checkpoint_segments used to be, so adjusting it might no longer be necessary.

• Control the Linux OOM killer via new environment variables PG_OOM_ADJUST_FILE and
  PG_OOM_ADJUST_VALUE, instead of compile-time options LINUX_OOM_SCORE_ADJ and
  LINUX_OOM_ADJ (Gurjeet Singh)

• Decommission server configuration parameter ssl_renegotiation_limit, which was depre-
  cated in earlier releases (Andres Freund)
  While SSL renegotiation is a good idea in theory, it has caused enough bugs to be considered a net
  negative in practice, and it is due to be removed from future versions of the relevant standards. We
  have therefore removed support for it from PostgreSQL. The ssl_renegotiation_limit pa-
  rameter still exists, but cannot be set to anything but zero (disabled). It’s not documented anymore,
  either.

• Remove server configuration parameter autocommit, which was already deprecated and non-
  operational (Tom Lane)

• Remove the pg_authid catalog’s rolcatupdate field, as it had no usefulness (Adam Brightwell)

• The pg_stat_replication system view’s sent field is now NULL, not zero, when it has no
  valid value (Magnus Hagander)

• Allow json and jsonb array extraction operators to accept negative subscripts, which count from
  the end of JSON arrays (Peter Geoghegan, Andrew Dunstan)

  Previously, these operators returned NULL for negative subscripts.
Appendix E. Release Notes

E.15.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 9.5 and the previous major release.

E.15.3.1. Server

E.15.3.1.1. Indexes

• Add Block Range Indexes (BRIN) (Álvaro Herrera)
  BRIN indexes store only summary data (such as minimum and maximum values) for ranges of heap blocks. They are therefore very compact and cheap to update; but if the data is naturally clustered, they can still provide substantial speedup of searches.

• Allow queries to perform accurate distance filtering of bounding-box-indexed objects (polygons, circles) using GiST indexes (Alexander Korotkov, Heikki Linnakangas)
  Previously, to exploit such an index a subquery had to be used to select a large number of rows ordered by bounding-box distance, and the result then had to be filtered further with a more accurate distance calculation.

• Allow GiST indexes to perform index-only scans (Anastasia Lubennikova, Heikki Linnakangas, Andreas Karlsson)

• Add configuration parameter gin_pending_list_limit to control the size of GIN pending lists (Fujii Masao)
  This value can also be set on a per-index basis as an index storage parameter. Previously the pending-list size was controlled by work_mem, which was awkward because appropriate values for work_mem are often much too large for this purpose.

• Issue a warning during the creation of hash indexes because they are not crash-safe (Bruce Momjian)

E.15.3.1.2. General Performance

• Improve the speed of sorting of varchar, text, and numeric fields via “abbreviated” keys (Peter Geoghegan, Andrew Gierth, Robert Haas)

• Extend the infrastructure that allows sorting to be performed by inlined, non-SQL-callable comparison functions to cover CREATE INDEX, REINDEX, and CLUSTER (Peter Geoghegan)

• Improve performance of hash joins (Tomas Vondra, Robert Haas)

• Improve concurrency of shared buffer replacement (Robert Haas, Amit Kapila, Andres Freund)

• Reduce the number of page locks and pins during index scans (Kevin Grittner)
  The primary benefit of this is to allow index vacuums to be blocked less often.

• Make per-backend tracking of buffer pins more memory-efficient (Andres Freund)

• Improve lock scalability (Andres Freund)
  This particularly addresses scalability problems when running on systems with multiple CPU sockets.

• Allow the optimizer to remove unnecessary references to left-joined subqueries (David Rowley)
• Allow pushdown of query restrictions into subqueries with window functions, where appropriate (David Rowley)

• Allow a non-leakproof function to be pushed down into a security barrier view if the function does not receive any view output columns (Dean Rasheed)

• Teach the planner to use statistics obtained from an expression index on a boolean-returning function, when a matching function call appears in WHERE (Tom Lane)

• Make ANALYZE compute basic statistics (null fraction and average column width) even for columns whose data type lacks an equality function (Oleksandr Shulgin)

• Speed up CRC (cyclic redundancy check) computations and switch to CRC-32C (Abhijit Menon-Sen, Heikki Linnakangas)

• Improve bitmap index scan performance (Teodor Sigaev, Tom Lane)

• Speed up CREATE INDEX by avoiding unnecessary memory copies (Robert Haas)

• Increase the number of buffer mapping partitions (Amit Kapila, Andres Freund, Robert Haas)

  This improves performance for highly concurrent workloads.

E.15.3.1.3. Monitoring

• Add per-table autovacuum logging control via new log_autovacuum_min_duration storage parameter (Michael Paquier)

• Add new configuration parameter cluster_name (Thomas Munro)

  This string, typically set in postgresql.conf, allows clients to identify the cluster. This name also appears in the process title of all server processes, allowing for easier identification of processes belonging to the same cluster.

• Prevent non-superusers from changing log_disconnections on connection startup (Fujii Masao)

E.15.3.1.4. SSL

• Check “Subject Alternative Names” in SSL server certificates, if present (Alexey Klyukin)

  When they are present, this replaces checks against the certificate’s “Common Name”.

• Add system view pg_stat_ssl to report SSL connection information (Magnus Hagander)

• Add libpq functions to return SSL information in an implementation-independent way (Heikki Linnakangas)

  While PQgetssl() can still be used to call OpenSSL functions, it is now considered deprecated because future versions of libpq might support other SSL implementations. When possible, use the new functions PQsslAttribute(), PQsslAttributeNames(), and PQsslInUse() to obtain SSL information in an SSL-implementation-independent way.

• Make libpq honor any OpenSSL thread callbacks (Jan Urbanski)

  Previously they were overwritten.
Appendix E. Release Notes

E.15.3.1.5. Server Settings

- Replace configuration parameter `checkpoint_segments` with `min_wal_size` and `max_wal_size` (Heikki Linnakangas)
  
  This change allows the allocation of a large number of WAL files without keeping them after they are no longer needed. Therefore the default for `max_wal_size` has been set to 1GB, much larger than the old default for `checkpoint_segments`. Also note that standby servers perform restartpoints to try to limit their WAL space consumption to `max_wal_size`; previously they did not pay any attention to `checkpoint_segments`.

- Control the Linux OOM killer via new environment variables `PG_OOM_ADJUST_FILE` and `PG_OOM_ADJUST_VALUE` (Gurjeet Singh)
  
  The previous OOM control infrastructure involved compile-time options `LINUX_OOM_SCORE_ADJ` and `LINUX_OOM_ADJ`, which are no longer supported. The new behavior is available in all builds.

- Allow recording of transaction commit time stamps when configuration parameter `track_commit_timestamp` is enabled (Álvaro Herrera, Petr Jelínek)
  
  Time stamp information can be accessed using functions `pg_xact_commit_timestamp()` and `pg_last_committed_xact()`.

- Allow local_preload_libraries to be set by `ALTER ROLE SET` (Peter Eisentraut, Kyotaro Horiguchi)

- Allow autovacuum workers to respond to configuration parameter changes during a run (Michael Paquier)

- Make configuration parameter `debug_assertions` read-only (Andres Freund)
  
  This means that assertions can no longer be turned off if they were enabled at compile time, allowing for more efficient code optimization. This change also removes the postgres `-A` option.

- Allow setting `effective_io_concurrency` on systems where it has no effect (Peter Eisentraut)

- Add system view `pg_file_settings` to show the contents of the server’s configuration files (Sawada Masahiko)

- Add `pending_restart` to the system view `pg_settings` to indicate a change has been made but will not take effect until a database restart (Peter Eisentraut)

- Allow `ALTER SYSTEM` values to be reset with `ALTER SYSTEM RESET` (Vik Fearing)
  
  This command removes the specified setting from `postgresql.auto.conf`.

E.15.3.2. Replication and Recovery

- Create mechanisms for tracking the progress of replication, including methods for identifying the origin of individual changes during logical replication (Andres Freund)
  
  This is helpful when implementing replication solutions.

- Rework truncation of the multixact commit log to be properly WAL-logged (Andres Freund)
  
  This makes things substantially simpler and more robust.

- Add `recovery.conf` parameter `recovery_target_action` to control post-recovery activity (Petr Jelínek)
  
  This replaces the old parameter `pause_at_recovery_target`.
Appendix E. Release Notes

• Add new archive_mode value always to allow standbys to always archive received WAL files (Fujii Masao)

• Add configuration parameter wal_retrieve_retry_interval to control WAL read retry after failure (Alexey Vasiliev, Michael Paquier)

  This is particularly helpful for warm standbys.

• Allow compression of full-page images stored in WAL (Rahila Syed, Michael Paquier)

  This feature reduces WAL volume, at the cost of more CPU time spent on WAL logging and WAL replay. It is controlled by a new configuration parameter wal_compression, which currently is off by default.

• Archive WAL files with suffix .partial during standby promotion (Heikki Linnakangas)

• Add configuration parameter log_replication_commands to log replication commands (Fujii Masao)

  By default, replication commands, e.g. IDENTIFY_SYSTEM, are not logged, even when log_statement is set to all.

• Report the processes holding replication slots in pg_replication_slots (Craig Ringer)

  The new output column is active_pid.

• Allow recovery.conf’s primary_conninfo setting to use connection URIs, e.g. postgres:// (Alexander Shulgin)

E.15.3.3. Queries

• Allow inserts that would generate constraint conflicts to be turned into updates or ignored (Peter Geoghegan, Heikki Linnakangas, Andres Freund)

  The syntax is INSERT ... ON CONFLICT DO NOTHING/UPDATE. This is the Postgres implementation of the popular UPSERT command.

• Add GROUP BY analysis features GROUPING SETS, CUBE and ROLLUP (Andrew Gierth, Atri Sharma)

• Allow setting multiple target columns in an update from the result of a single sub-SELECT (Tom Lane)

  This is accomplished using the syntax UPDATE tab SET (col1, col2, ...) = (SELECT ...).

• Add select option SKIP LOCKED to skip locked rows (Thomas Munro)

  This does not throw an error for locked rows like NOWAIT does.

• Add select option TABLESAMPLE to return a subset of a table (Petr Jelinek)

  This feature supports the SQL-standard table sampling methods. In addition, there are provisions for user-defined table sampling methods.

• Suggest possible matches for mistyped column names (Peter Geoghegan, Robert Haas)
E.15.3.4. Utility Commands

- Add more details about sort ordering in EXPLAIN output (Marius Timmer, Lukas Kreft, Arne Schef-
  fer)
  Details include COLLATE, DESC, USING, and NULLS FIRST/LAST.
- Make VACUUM log the number of pages skipped due to pins (Jim Nasby)
- Make TRUNCATE properly update the pg_stat* tuple counters (Alexander Shulgin)

E.15.3.4.1. REINDEX

- Allow REINDEX to reindex an entire schema using the SCHEMA option (Sawada Masahiko)
- Add VERBOSE option to REINDEX (Sawada Masahiko)
- Prevent REINDEX DATABASE and SCHEMA from outputting object names, unless VERBOSE is used
  (Simon Riggs)
- Remove obsolete FORCE option from REINDEX (Fujii Masao)

E.15.3.5. Object Manipulation

- Add row-level security control (Craig Ringer, KaiGai Kohei, Adam Brightwell, Dean Rasheed, 
  Stephen Frost)
  This feature allows row-by-row control over which users can add, modify, or even see rows in
  a table. This is controlled by new commands CREATE/ALTER/DROP POLICY and ALTER TABLE
  ... ENABLE/DISABLE ROW SECURITY.
- Allow changing of the WAL logging status of a table after creation with ALTER TABLE ... SET
  LOGGED / UNLOGGED (Fabrízio de Royes Mello)
- Add IF NOT EXISTS clause to CREATE TABLE AS, CREATE INDEX, CREATE SEQUENCE, and
  CREATE MATERIALIZED VIEW (Fabrízio de Royes Mello)
- Add support for IF EXISTS to ALTER TABLE ... RENAME CONSTRAINT (Bruce Momjian)
- Allow some DDL commands to accept CURRENT_USER or SESSION_USER, meaning the current
  user or session user, in place of a specific user name (Kyotaro Horiguchi, Álvaro Herrera)
  This feature is now supported in ALTER USER, ALTER GROUP, ALTER ROLE, GRANT, and
  ALTER object OWNER TO commands.
- Support comments on domain constraints (Álvaro Herrera)
- Reduce lock levels of some create and alter trigger and foreign key commands (Simon Riggs,
  Andreas Karlsson)
- Allow LOCK TABLE ... ROW EXCLUSIVE MODE for those with INSERT privileges on the target
  table (Stephen Frost)
  Previously this command required UPDATE, DELETE, or TRUNCATE privileges.
- Apply table and domain CHECK constraints in order by name (Tom Lane)
  The previous ordering was indeterminate.
Appendix E. Release Notes

• Allow CREATE/ALTER DATABASE to manipulate datistemplate and datallowconn (Vik Fearing)
  This allows these per-database settings to be changed without manually modifying the pg_database system catalog.

E.15.3.5.1. Foreign Tables

• Add support for IMPORT FOREIGN SCHEMA (Ronan Dunklau, Michael Paquier, Tom Lane)
  This command allows automatic creation of local foreign tables that match the structure of existing tables on a remote server.
• Allow CHECK constraints to be placed on foreign tables (Shigeru Hanada, Etsuro Fujita)
  Such constraints are assumed to be enforced on the remote server, and are not enforced locally. However, they are assumed to hold for purposes of query optimization, such as constraint exclusion.
• Allow foreign tables to participate in inheritance (Shigeru Hanada, Etsuro Fujita)
  To let this work naturally, foreign tables are now allowed to have check constraints marked as not valid, and to set storage and OID characteristics, even though these operations are effectively no-ops for a foreign table.
• Allow foreign data wrappers and custom scans to implement join pushdown (KaiGai Kohei)

E.15.3.5.2. Event Triggers

• Whenever a ddl_command_end event trigger is installed, capture details of DDL activity for it to inspect (Álvaro Herrera)
  This information is available through a set-returning function pg_event_trigger_ddl_commands(), or by inspection of C data structures if that function doesn’t provide enough detail.
• Allow event triggers on table rewrites caused by ALTER TABLE (Dimitri Fontaine)
• Add event trigger support for database-level COMMENT, SECURITY LABEL, and GRANT/REVOKE (Álvaro Herrera)
• Add columns to the output of pg_event_trigger_dropped_objects (Álvaro Herrera)
  This allows simpler processing of delete operations.

E.15.3.6. Data Types

• Allow the xml data type to accept empty or all-whitespace content values (Peter Eisentraut)
  This is required by the SQL/XML specification.
• Allow macaddr input using the format xxxx-xxxx-xxxx (Herwin Weststrate)
• Disallow non-SQL-standard syntax for interval with both precision and field specifications (Bruce Momjian)
  Per the standard, such type specifications should be written as, for example, INTERVAL MINUTE TO SECOND(2). PostgreSQL formerly allowed this to be written as INTERVAL(2) MINUTE TO SECOND, but it must now be written in the standard way.
Appendix E. Release Notes

- Add selectivity estimators for `inet/cidr` operators and improve estimators for text search functions (Emre Hasegeli, Tom Lane)
- Add data types `regrole` and `regnamespace` to simplify entering and pretty-printing the OID of a role or namespace (Kyotaro Horiguchi)

E.15.3.6.1. JSON

- Add `jsonb` functions `jsonb_set()` and `jsonb_pretty()` (Dmitry Dolgov, Andrew Dunstan, Petr Jelínek)
- Add `jsonb` generator functions `to_jsonb()`, `jsonb_object()`, `jsonb_build_object()`, `jsonb_build_array()`, `jsonb_agg()`, and `jsonb_object_agg()` (Andrew Dunstan)
  Equivalent functions already existed for type `json`.
- Reduce casting requirements to/from `json` and `jsonb` (Tom Lane)
- Allow `text`, `text array`, and `integer` values to be subtracted from `jsonb` documents (Dmitry Dolgov, Andrew Dunstan)
- Add `jsonb ||` operator (Dmitry Dolgov, Andrew Dunstan)
- Add `json_strip_nulls()` and `jsonb_strip_nulls()` functions to remove JSON null values from documents (Andrew Dunstan)

E.15.3.7. Functions

- Add `generate_series()` for numeric values (Plato Malugin)
- Allow `array_agg()` and `ARRAY()` to take arrays as inputs (Ali Akbar, Tom Lane)
- Add functions `array_position()` and `array_positions()` to return subscripts of array values (Pavel Stehule)
- Add a `point-to-polygon` distance operator `<->` (Alexander Korotkov)
- Allow multibyte characters as escapes in `SIMILAR TO` and `SUBSTRING` (Jeff Davis)
  Previously, only a single-byte character was allowed as an escape.
- Add a `width_bucket()` variant that supports any sortable data type and non-uniform bucket widths (Petr Jelínek)
- Add an optional `missing_ok` argument to `pg_read_file()` and related functions (Michael Paquier, Heikki Linnakangas)
- Allow `->` to specify named parameters in function calls (Pavel Stehule)
  Previously only `:=` could be used. This requires removing the possibility for `->` to be a user-defined operator. Creation of user-defined `->` operators has been issuing warnings since PostgreSQL 9.0.
- Add POSIX-compliant rounding for platforms that use PostgreSQL-supplied rounding functions (Pedro Gimeno Fortea)
E.15.3.7.1. System Information Functions and Views

- Add function `pg_get_object_address()` to return OIDs that uniquely identify an object, and function `pg_identify_object_as_address()` to return object information based on OIDs (Álvaro Herrera)
- Loosen security checks for viewing queries in `pg_stat_activity`, executing `pg_cancel_backend()`, and executing `pg_terminate_backend()` (Stephen Frost)
  Previously, only the specific role owning the target session could perform these operations; now membership in that role is sufficient.
- Add `pg_stat_get_snapshot_timestamp()` to output the time stamp of the statistics snapshot (Matt Kelly)
  This represents the last time the snapshot file was written to the file system.
- Add `mxid_age()` to compute multi-xid age (Bruce Momjian)

E.15.3.7.2. Aggregates

- Add `min() / max()` aggregates for `inet/cidr` data types (Haribabu Kommi)
- Use 128-bit integers, where supported, as accumulators for some aggregate functions (Andreas Karlsson)

E.15.3.8. Server-Side Languages

- Improve support for composite types in PL/Python (Ed Behn, Ronan Dunklau)
  This allows PL/Python functions to return arrays of composite types.
- Reduce lossiness of PL/Python floating-point value conversions (Marko Kreen)
- Allow specification of conversion routines between SQL data types and data types of procedural languages (Peter Eisentraut)
  This change adds new commands `CREATE/DROP TRANSFORM`. This also adds optional transformations between the hstore and ltree types to/from PL/Perl and PL/Python.

E.15.3.8.1. PL/pgSQL Server-Side Language

- Improve PL/pgSQL array performance (Tom Lane)
- Add an `ASSERT` statement in PL/pgSQL (Pavel Stehule)
- Allow more PL/pgSQL keywords to be used as identifiers (Tom Lane)

E.15.3.9. Client Applications

- Move `pg_archivecleanup`, `pg_test_fsync`, `pg_test_timing`, and `pg_xlogdump` from contrib to `src/bin` (Peter Eisentraut)
Appendix E. Release Notes

This should result in these programs being installed by default in most installations.

- Add `pg_rewind`, which allows re-synchronizing a master server after failback (Heikki Linnakangas)
- Allow `pg_receivexlog` to manage physical replication slots (Michael Paquier)
  This is controlled via new `--create-slot` and `--drop-slot` options.
- Allow `pg_receivexlog` to synchronously flush WAL to storage using new `--synchronous` option
  (Furuya Osamu, Fujii Masao)
  Without this, WAL files are fsync’ed only on close.
- Allow `vacuumdb` to vacuum in parallel using new `--jobs` option (Dilip Kumar)
- In `vacuumdb`, do not prompt for the same password repeatedly when multiple connections are necessary (Haribabu Kommi, Michael Paquier)
- Add `--verbose` option to `reindexdb` (Sawada Masahiko)
- Add `--stats` option to `pg_xlogdump` option (Abhijit Menon-Sen)

E.15.3.9.1. psql

- Allow `psql` to produce AsciiDoc output (Szymon Guz)
- Add an `errors` mode that displays only failed commands to `psql`’s `ECHO` variable (Pavel Stehule)
  This behavior can also be selected with `psql`’s `-b` option.
- Provide separate column, header, and border linestyle control in `psql`’s unicode linestyle (Pavel Stehule)
  Single or double lines are supported; the default is `single`.
- Add new option `%l` in `psql`’s `PROMPT` variables to display the current multiline statement line number (Sawada Masahiko)
- Add `\pset` option `pager_min_lines` to control pager invocation (Andrew Dunstan)
- Improve `psql` line counting used when deciding to invoke the pager (Andrew Dunstan)
  Previously, it effectively ignored the switch in such cases.
- Add `psql` tab completion when setting the `search_path` variable (Jeff Janes)
  Currently only the first schema can be tab-completed.
- Improve `psql`’s tab completion for triggers and rules (Andreas Karlsson)

E.15.3.9.1.1. Backslash Commands

- Add `psql` `\?` help sections `variables` and `options` (Pavel Stehule)
  `\? variables` shows `psql`’s special variables and `\? options` shows the command-line options.
  `\? commands` shows the meta-commands, which is the traditional output and remains the default.
  These help displays can also be obtained with the command-line option `--help=section`.
- Show tablespace size in `psql`’s `\db+` (Fabrízio de Royes Mello)
Appendix E. Release Notes

- Show data type owners in psql’s `\dT+` (Magnus Hagander)
- Allow psql’s `\watch` to output `\timing` information (Fujii Masao)
  Also prevent `--echo-hidden` from echoing `\watch` queries, since that is generally unwanted.
- Make psql’s `\sf` and `\ef` commands honor `ECHO_HIDDEN` (Andrew Dunstan)
- Improve psql tab completion for `\set`, `\unset`, and `:variable` names (Pavel Stehule)
- Allow tab completion of role names in psql `\c` commands (Ian Barwick)

E.15.3.9.2. pg_dump

- Allow pg_dump to share a snapshot taken by another session using `--snapshot` (Simon Riggs, Michael Paquier)
  The remote snapshot must have been exported by `pg_export_snapshot()` or logical replication slot creation. This can be used to share a consistent snapshot across multiple pg_dump processes.
- Support table sizes exceeding 8GB in tar archive format (Tom Lane)
  The POSIX standard for tar format does not allow elements of a tar archive to exceed 8GB, but most modern implementations of tar support an extension that does allow it. Use the extension format when necessary, rather than failing.
- Make pg_dump always print the server and pg_dump versions (Jing Wang)
  Previously, version information was only printed in `--verbose` mode.
- Remove the long-ignored `-i|--ignore-version` option from pg_dump, pg_dumpall, and pg_restore (Fujii Masao)

E.15.3.9.3. pg_ctl

- Support multiple pg_ctl `-o` options, concatenating their values (Bruce Momjian)
- Allow control of pg_ctl’s event source logging on MS Windows (MauMau)
  This only controls pg_ctl, not the server, which has separate settings in `postgresql.conf`.
- If the server’s listen address is set to a wildcard value (0.0.0.0 in IPv4 or :: in IPv6), connect via the loopback address rather than trying to use the wildcard address literally (Kondo Yuta)
  This fix primarily affects Windows, since on other platforms pg_ctl will prefer to use a Unix-domain socket.

E.15.3.9.4. pg_upgrade

- Move pg_upgrade from contrib to src/bin (Peter Eisentraut)
  In connection with this change, the functionality previously provided by the pg_upgrade_support module has been moved into the core server.
- Support multiple pg_upgrade `-of` options, concatenating their values (Bruce Momjian)
- Improve database collation comparisons in pg_upgrade (Heikki Linnakangas)
- Remove support for upgrading from 8.3 clusters (Bruce Momjian)
Appendix E. Release Notes

E.15.3.9.5. pgbench

- Move pgbench from contrib to src/bin (Peter Eisentraut)
- Fix calculation of TPS number “excluding connections establishing” (Tatsuo Ishii, Fabien Coelho)
  The overhead for connection establishment was miscalculated whenever the number of pgbench threads was less than the number of client connections. Although this is clearly a bug, we won’t back-patch it into pre-9.5 branches since it makes TPS numbers not comparable to previous results.
- Allow counting of pgbench transactions that take over a specified amount of time (Fabien Coelho)
  This is controlled by a new --latency-limit option.
- Allow pgbench to generate Gaussian/exponential distributions using \setrandom (Kondo Mitsumasa, Fabien Coelho)
- Allow pgbench’s \set command to handle arithmetic expressions containing more than one operator, and add % (modulo) to the set of operators it supports (Robert Haas, Fabien Coelho)

E.15.3.10. Source Code

- Simplify WAL record format (Heikki Linnakangas)
  This allows external tools to more easily track what blocks are modified.
- Improve the representation of transaction commit and abort WAL records (Andres Freund)
- Add atomic memory operations API (Andres Freund)
- Allow custom path and scan methods (KaiGai Kohei, Tom Lane)
  This allows extensions greater control over the optimizer and executor.
- Allow foreign data wrappers to do post-filter locking (Etsuro Fujita)
- Foreign tables can now take part in INSERT ... ON CONFLICT DO NOTHING queries (Peter Geoghegan, Heikki Linnakangas, Andres Freund)
  Foreign data wrappers must be modified to handle this. INSERT ... ON CONFLICT DO UPDATE is not supported on foreign tables.
- Improve hash_create()'s API for selecting simple-binary-key hash functions (Teodor Sigaev, Tom Lane)
- Improve parallel execution infrastructure (Robert Haas, Amit Kapila, Noah Misch, Rushabh Lathia, Jeevan Chalke)
- Remove Alpha (CPU) and Tru64 (OS) ports (Andres Freund)
- Remove swap-byte-based spinlock implementation for ARMv5 and earlier CPUs (Robert Haas)
  ARMv5’s weak memory ordering made this locking implementation unsafe. Spinlock support is still possible on newer gcc implementations with atomics support.
- Generate an error when excessively long (100+ character) file paths are written to tar files (Peter Eisentraut)
  Tar does not support such overly-long paths.
- Change index operator class for columns pg_seclabel.provider and pg_sha2clabel.provider to be text_pattern_ops (Tom Lane)
Appendix E. Release Notes

This avoids possible problems with these indexes when different databases of a cluster have different default collations.

- Change the spinlock primitives to function as compiler barriers (Robert Haas)

E.15.3.10.1. MS Windows

- Allow higher-precision time stamp resolution on Windows 8, Windows Server 2012, and later Windows systems (Craig Ringer)
- Install shared libraries to `bin` in MS Windows (Peter Eisentraut, Michael Paquier)
- Install `src/test/modules` together with `contrib` on MSVC builds (Michael Paquier)
- Allow `configure`'s `--with-extra-version` option to be honored by the MSVC build (Michael Paquier)
- Pass `PGFILEDESC` into MSVC contrib builds (Michael Paquier)
- Add icons to all MSVC-built binaries and version information to all MS Windows binaries (Noah Misch)
  
  MinGW already had such icons.
- Add optional-argument support to the internal `getopt_long()` implementation (Michael Paquier, Andres Freund)
  
  This is used by the MSVC build.

E.15.3.11. Additional Modules

- Add statistics for minimum, maximum, mean, and standard deviation times to `pg_stat_statements` (Mitsumasa Kondo, Andrew Dunstan)
- Add pgcrypto function `pgp_armor_headers()` to extract PGP armor headers (Marko Tiikkaja, Heikki Linnakangas)
- Allow empty replacement strings in `unaccent` (Mohammad Alhashash)
  
  This is useful in languages where diacritic signs are represented as separate characters.
- Allow multicharacter source strings in `unaccent` (Tom Lane)
  
  This could be useful in languages where diacritic signs are represented as separate characters. It also allows more complex unaccent dictionaries.
- Add `contrib` modules `tsm_system_rows` and `tsm_system_time` to allow additional table sampling methods (Petr Jelínek)
- Add GIN index inspection functions to `pageinspect` (Heikki Linnakangas, Peter Geoghegan, Michael Paquier)
- Add information about buffer pins to `pg_buffercache` display (Andres Freund)
- Allow `pgstattuple` to report approximate answers with less overhead using `pgstattuple_approx()` (Abhijit Menon-Sen)
- Move `dummy_seclabel`, `test_shm_mq`, `test_parser`, and `worker_spi` from `contrib` to `src/test/modules` (Álvaro Herrera)
These modules are only meant for server testing, so they do not need to be built or installed when packaging PostgreSQL.

E.16. Release 9.4.19

Release date: 2018-08-09

This release contains a variety of fixes from 9.4.18. For information about new features in the 9.4 major release, see Section E.35.

E.16.1. Migration to Version 9.4.19

A dump/restore is not required for those running 9.4.X. However, if you are upgrading from a version earlier than 9.4.18, see Section E.17.

E.16.2. Changes

• Fix failure to reset libpq’s state fully between connection attempts (Tom Lane)
  An unprivileged user of dblink or postgres_fdw could bypass the checks intended to prevent use of server-side credentials, such as a ~/.pgpass file owned by the operating-system user running the server. Servers allowing peer authentication on local connections are particularly vulnerable. Other attacks such as SQL injection into a postgres_fdw session are also possible. Attacking postgres_fdw in this way requires the ability to create a foreign server object with selected connection parameters, but any user with access to dblink could exploit the problem. In general, an attacker with the ability to select the connection parameters for a libpq-using application could cause mischief, though other plausible attack scenarios are harder to think of. Our thanks to Andrew Krasichkov for reporting this issue. (CVE-2018-10915)

• Ensure that updates to the relfrozenxid and relminmxid values for “nailed” system catalogs are processed in a timely fashion (Andres Freund)
  Overoptimistic caching rules could prevent these updates from being seen by other sessions, leading to spurious errors and/or data corruption. The problem was significantly worse for shared catalogs, such as pg_authid, because the stale cache data could persist into new sessions as well as existing ones.

• Fix case where a freshly-promoted standby crashes before having completed its first post-recovery checkpoint (Michael Paquier, Kyotaro Horiguchi, Pavan Deolasee, Álvaro Herrera)
  This led to a situation where the server did not think it had reached a consistent database state during subsequent WAL replay, preventing restart.

• Avoid emitting a bogus WAL record when recycling an all-zero btree page (Amit Kapila)
  This mistake has been seen to cause assertion failures, and potentially it could result in unnecessary query cancellations on hot standby servers.

• Improve performance of WAL replay for transactions that drop many relations (Fujii Masao)
  This change reduces the number of times that shared buffers are scanned, so that it is of most benefit when that setting is large.
• Improve performance of lock releasing in standby server WAL replay (Thomas Munro)
• Make logical WAL senders report streaming state correctly (Simon Riggs, Sawada Masahiko)
  The code previously mis-detected whether or not it had caught up with the upstream server.
• Fix bugs in snapshot handling during logical decoding, allowing wrong decoding results in rare cases (Arseny Sher, Álvaro Herrera)
• Ensure a table’s cached index list is correctly rebuilt after an index creation fails partway through (Peter Geoghegan)
  Previously, the failed index’s OID could remain in the list, causing problems later in the same session.
• Fix mishandling of empty uncompressed posting list pages in GIN indexes (Sivasubramanian Ramasubramanian, Alexander Korotkov)
  This could result in an assertion failure after pg_upgrade of a pre-9.4 GIN index (9.4 and later will not create such pages).
• Ensure that VACUUM will respond to signals within btree page deletion loops (Andres Freund)
  Corrupted btree indexes could result in an infinite loop here, and that previously wasn’t interruptible without forcing a crash.
• Fix misoptimization of equivalence classes involving composite-type columns (Tom Lane)
  This resulted in failure to recognize that an index on a composite column could provide the sort order needed for a mergejoin on that column.
• Fix SQL-standard FETCH FIRST syntax to allow parameters ($n$), as the standard expects (Andrew Gierth)
• Fix failure to schema-qualify some object names in getObjectDescription output (Kyotaro Horiguchi, Tom Lane)
  Names of collations, conversions, and text search objects were not schema-qualified when they should be.
• Widen COPY’s current-line-number counter from 32 to 64 bits (David Rowley)
  This avoids two problems with input exceeding 4G lines: COPY FROM WITH HEADER would drop a line every 4G lines, not only the first line, and error reports could show a wrong line number.
• Add a string freeing function to ecpg’s pgtypes library, so that cross-module memory management problems can be avoided on Windows (Takayuki Tsunakawa)
  On Windows, crashes can ensue if the free call for a given chunk of memory is not made from the same DLL that malloc’ed the memory. The pgtypes library sometimes returns strings that it expects the caller to free, making it impossible to follow this rule. Add a PGTYPESchar_free() function that just wraps free, allowing applications to follow this rule.
• Fix ecpg’s support for long long variables on Windows, as well as other platforms that declare strtoll/strtoull nonstandardly or not at all (Dang Minh Huong, Tom Lane)
• Fix misidentification of SQL statement type in PL/pgSQL, when a rule change causes a change in the semantics of a statement intra-session (Tom Lane)
  This error led to assertion failures, or in rare cases, failure to enforce the INTO STRICT option as expected.
• Fix password prompting in client programs so that echo is properly disabled on Windows when stdin is not the terminal (Matthew Stickney)
• Further fix mis-quoting of values for list-valued GUC variables in dumps (Tom Lane)
The previous fix for quoting of `search_path` and other list-valued variables in `pg_dump` output turned out to misbehave for empty-string list elements, and it risked truncation of long file paths.

- Fix `pg_dump`’s failure to dump `REPLICA IDENTITY` properties for constraint indexes (Tom Lane)
  Manually created unique indexes were properly marked, but not those created by declaring `UNIQUE` or `PRIMARY KEY` constraints.

- Make `pg_upgrade` check that the old server was shut down cleanly (Bruce Momjian)
  The previous check could be fooled by an immediate-mode shutdown.

- Fix crash in `contrib/ltrie`'s `lca()` function when the input array is empty (Pierre Ducroquet)

- Fix various error-handling code paths in which an incorrect error code might be reported (Michael Paquier, Tom Lane, Magnus Hagander)

- Rearrange makefiles to ensure that programs link to freshly-built libraries (such as `libpq.so`) rather than ones that might exist in the system library directories (Tom Lane)
  This avoids problems when building on platforms that supply old copies of PostgreSQL libraries.

- Update time zone data files to tzdata release 2018e for DST law changes in North Korea, plus historical corrections for Czechoslovakia.
  This update includes a redefinition of “daylight savings” in Ireland, as well as for some past years in Namibia and Czechoslovakia. In those jurisdictions, legally standard time is observed in summer, and daylight savings time in winter, so that the daylight savings offset is one hour behind standard time not one hour ahead. This does not affect either the actual UTC offset or the timezone abbreviations in use; the only known effect is that the `is_dst` column in the `pg_timezone_names` view will now be true in winter and false in summer in these cases.

---

**E.17. Release 9.4.18**

**Release date:** 2018-05-10

This release contains a variety of fixes from 9.4.17. For information about new features in the 9.4 major release, see Section E.35.

**E.17.1. Migration to Version 9.4.18**

A dump/restore is not required for those running 9.4.X. However, if the function marking mistakes mentioned in the first changelog entry below affect you, you will want to take steps to correct your database catalogs.

Also, if you are upgrading from a version earlier than 9.4.17, see Section E.18.

**E.17.2. Changes**

- Fix incorrect volatility markings on a few built-in functions (Thomas Munro, Tom Lane)
  The functions `query_to_xml`, `cursor_to_xml`, `cursor_to_xmlschema`, `query_to_xmlschema`, and `query_to_xml_and_xmlschema` should be marked volatile because they execute user-supplied queries that might contain volatile operations. They were not,
leading to a risk of incorrect query optimization. This has been repaired for new installations by correcting the initial catalog data, but existing installations will continue to contain the incorrect markings. Practical use of these functions seems to pose little hazard, but in case of trouble, it can be fixed by manually updating these functions’ pg_proc entries, for example ALTER FUNCTION pg_catalog.query_to_xml(text, boolean, boolean, text) VOLATILE. (Note that that will need to be done in each database of the installation.) Another option is to pg_upgrade the database to a version containing the corrected initial data.

- Avoid re-using TOAST value OIDs that match dead-but-not-yet-vacuumed TOAST entries (Pavan Deolasee)

   Once the OID counter has wrapped around, it’s possible to assign a TOAST value whose OID matches a previously deleted entry in the same TOAST table. If that entry were not yet vacuumed away, this resulted in “unexpected chunk number 0 (expected 1) for toast value nnnnn” errors, which would persist until the dead entry was removed by VACUUM. Fix by not selecting such OIDs when creating a new TOAST entry.

- Change ANALYZE’s algorithm for updating pg_class.reltuples (David Gould)

   Previously, pages not actually scanned by ANALYZE were assumed to retain their old tuple density. In a large table where ANALYZE samples only a small fraction of the pages, this meant that the overall tuple density estimate could not change very much, so that reltuples would change nearly proportionally to changes in the table’s physical size (relpages) regardless of what was actually happening in the table. This has been observed to result in reltuples becoming so much larger than reality as to effectively shut off autovacuuming. To fix, assume that ANALYZE’s sample is a statistically unbiased sample of the table (as it should be), and just extrapolate the density observed within those pages to the whole table.

- Avoid deadlocks in concurrent CREATE INDEX CONCURRENTLY commands that are run under SERIALIZABLE or REPEATABLE READ transaction isolation (Tom Lane)

- Fix possible slow execution of REFRESH MATERIALIZED VIEW CONCURRENTLY (Thomas Munro)

- Fix UPDATE/DELETE ... WHERE CURRENT OF to not fail when the referenced cursor uses an index-only-scan plan (Yugo Nagata, Tom Lane)

- Fix incorrect planning of join clauses pushed into parameterized paths (Andrew Gierth, Tom Lane)

   This error could result in misclassifying a condition as a “join filter” for an outer join when it should be a plain “filter” condition, leading to incorrect join output.

- Fix misoptimization of CHECK constraints having provably-NULL subclauses of top-level AND/OR conditions (Tom Lane, Dean Rasheed)

   This could, for example, allow constraint exclusion to exclude a child table that should not be excluded from a query.

- Avoid failure if a query-cancel or session-termination interrupt occurs while committing a prepared transaction (Stas Kelvich)

- Fix query-lifespan memory leakage in repeatedly executed hash joins (Tom Lane)

- Fix overly strict sanity check in heap_prepare_freeze_tuple (Álvaro Herrera)

   This could result in incorrect “cannot freeze committed xmax” failures in databases that have been pg_upgraded from 9.2 or earlier.

- Prevent dangling-pointer dereference when a C-coded before-update row trigger returns the “old” tuple (Rushabh Lathia)

- Reduce locking during autovacuum worker scheduling (Jeff Janes)
Appendix E. Release Notes

The previous behavior caused drastic loss of potential worker concurrency in databases with many tables.

- Ensure client hostname is copied while copying `pg_stat_activity` data to local memory (Edmund Horner)
  
  Previously the supposedly-local snapshot contained a pointer into shared memory, allowing the client hostname column to change unexpectedly if any existing session disconnected.

- Fix incorrect processing of multiple compound affixes in `ispell` dictionaries (Arthur Zakirov)

- Fix collation-aware searches (that is, indexscans using inequality operators) in SP-GiST indexes on text columns (Tom Lane)

  Such searches would return the wrong set of rows in most non-C locales.

- Count the number of index tuples correctly during initial build of an SP-GiST index (Tomas Vondra)
  
  Previously, the tuple count was reported to be the same as that of the underlying table, which is wrong if the index is partial.

- Count the number of index tuples correctly during vacuuming of a GiST index (Andrey Borodin)
  
  Previously it reported the estimated number of heap tuples, which might be inaccurate, and is certainly wrong if the index is partial.

- Fix a corner case where a streaming standby gets stuck at a WAL continuation record (Kyotaro Horiguchi)

- In logical decoding, avoid possible double processing of WAL data when a walsender restarts (Craig Ringer)

- Allow `scalarltsel` and `scalarmtsel` to be used on non-core datatypes (Tomas Vondra)

- Reduce `libpq`’s memory consumption when a server error is reported after a large amount of query output has been collected (Tom Lane)

  Discard the previous output before, not after, processing the error message. On some platforms, notably Linux, this can make a difference in the application’s subsequent memory footprint.

- Fix double-free crashes in `ecpg` (Patrick Krecker, Jeevan Ladhe)

- Fix `ecpg` to handle `long long int` variables correctly in MSVC builds (Michael Meskes, Andrew Gierth)

- Fix mis-quoting of values for list-valued GUC variables in dumps (Michael Paquier, Tom Lane)

  The `local_preload_libraries`, `session_preload_libraries`, `shared_preload_libraries`, and `temp_tablespaces` variables were not correctly quoted in `pg_dump` output. This would cause problems if settings for these variables appeared in `CREATE FUNCTION ... SET` or `ALTER DATABASE/ROLE ... SET` clauses.

- Fix `pg_recevlogical` to not fail against pre-v10 PostgreSQL servers (Michael Paquier)

  A previous fix caused `pg_recevlogical` to issue a command regardless of server version, but it should only be issued to v10 and later servers.

- Fix overflow handling in PL/pgSQL integer `FOR` loops (Tom Lane)

  The previous coding failed to detect overflow of the loop variable on some non-gcc compilers, leading to an infinite loop.

- Adjust PL/Python regression tests to pass under Python 3.7 (Peter Eisentraut)

- Support testing PL/Python and related modules when building with Python 3 and MSVC (Andrew Dunstan)
• Rename internal b64_encode and b64_decode functions to avoid conflict with Solaris 11.4 built-in functions (Rainer Orth)

• Sync our copy of the timezone library with IANA tzcode release 2018e (Tom Lane)
  This fixes the zic timezone data compiler to cope with negative daylight-savings offsets. While the PostgreSQL project will not immediately ship such timezone data, zic might be used with timezone data obtained directly from IANA, so it seems prudent to update zic now.

• Update time zone data files to tzdata release 2018d for DST law changes in Palestine and Antarctica (Casey Station), plus historical corrections for Portugal and its colonies, as well as Enderbury, Jamaica, Turks & Caicos Islands, and Uruguay.

## E.18. Release 9.4.17

**Release date:** 2018-03-01

This release contains a variety of fixes from 9.4.16. For information about new features in the 9.4 major release, see Section E.35.

### E.18.1. Migration to Version 9.4.17

A dump/restore is not required for those running 9.4.X.

However, if you run an installation in which not all users are mutually trusting, or if you maintain an application or extension that is intended for use in arbitrary situations, it is strongly recommended that you read the documentation changes described in the first changelog entry below, and take suitable steps to ensure that your installation or code is secure.

Also, the changes described in the second changelog entry below may cause functions used in index expressions or materialized views to fail during auto-analyze, or when reloading from a dump. After upgrading, monitor the server logs for such problems, and fix affected functions.

Also, if you are upgrading from a version earlier than 9.4.13, see Section E.22.

### E.18.2. Changes

• Document how to configure installations and applications to guard against search-path-dependent trojan-horse attacks from other users (Noah Misch)

  Using a `search_path` setting that includes any schemas writable by a hostile user enables that user to capture control of queries and then run arbitrary SQL code with the permissions of the attacked user. While it is possible to write queries that are proof against such hijacking, it is notationally tedious, and it’s very easy to overlook holes. Therefore, we now recommend configurations in which no untrusted schemas appear in one’s search path. Relevant documentation appears in Section 5.8.6 (for database administrators and users), Section 31.1 (for application authors), Section 35.15.1 (for extension authors), and CREATE FUNCTION (for authors of `SECURITY DEFINER` functions). (CVE-2018-1058)

• Avoid use of insecure `search_path` settings in `pg_dump` and other client programs (Noah Misch, Tom Lane)
pg_dump, pg_upgrade, vacuumdb and other PostgreSQL-provided applications were themselves vulnerable to the type of hijacking described in the previous changelog entry; since these applications are commonly run by superusers, they present particularly attractive targets. To make them secure whether or not the installation as a whole has been secured, modify them to include only the `pg_catalog` schema in their `search_path` settings. Autovacuum worker processes now do the same, as well.

In cases where user-provided functions are indirectly executed by these programs — for example, user-provided functions in index expressions — the tighter `search_path` may result in errors, which will need to be corrected by adjusting those user-provided functions to not assume anything about what search path they are invoked under. That has always been good practice, but now it will be necessary for correct behavior. (CVE-2018-1058)

- Fix misbehavior of concurrent-update rechecks with CTE references appearing in subplans (Tom Lane)
  
  If a CTE (`WITH` clause reference) is used in an InitPlan or SubPlan, and the query requires a recheck due to trying to update or lock a concurrently-updated row, incorrect results could be obtained.

- Fix planner failures with overlapping mergejoin clauses in an outer join (Tom Lane)
  
  These mistakes led to “left and right pathkeys do not match in mergejoin” or “outer pathkeys do not match mergeclauses” planner errors in corner cases.

- Repair `pg_upgrade`’s failure to preserve `relfrozenxid` for materialized views (Tom Lane, Andres Freund)
  
  This oversight could lead to data corruption in materialized views after an upgrade, manifesting as “could not access status of transaction” or “found xmin from before relfrozenxid” errors. The problem would be more likely to occur in seldom-refreshed materialized views, or ones that were maintained only with `REFRESH MATERIALIZED VIEW CONCURRENTLY`.

  If such corruption is observed, it can be repaired by refreshing the materialized view (without `CONCURRENTLY`).

- Fix incorrect reporting of PL/Python function names in error `CONTEXT` stacks (Tom Lane)
  
  An error occurring within a nested PL/Python function call (that is, one reached via a SPI query from another PL/Python function) would result in a stack trace showing the inner function’s name twice, rather than the expected results. Also, an error in a nested PL/Python `DO` block could result in a null pointer dereference crash on some platforms.

- Allow `contrib/auto_explain`’s `log_min_duration` setting to range up to `INT_MAX`, or about 24 days instead of 35 minutes (Tom Lane)

### E.19. Release 9.4.16

**Release date:** 2018-02-08

This release contains a variety of fixes from 9.4.15. For information about new features in the 9.4 major release, see Section E.35.

#### E.19.1. Migration to Version 9.4.16

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.13, see Section E.22.
E.19.2. Changes

- Ensure that all temporary files made by pg_upgrade are non-world-readable (Tom Lane, Noah Misch)
  pg_upgrade normally restricts its temporary files to be readable and writable only by the calling user. But the temporary file containing `pg_dumpall -g` output would be group- or world-readable, or even writable, if the user’s `umask` setting allows. In typical usage on multi-user machines, the `umask` and/or the working directory’s permissions would be tight enough to prevent problems; but there may be people using pg_upgrade in scenarios where this oversight would permit disclosure of database passwords to unfriendly eyes. (CVE-2018-1053)

- Fix vacuuming of tuples that were updated while key-share locked (Andres Freund, Álvaro Herrera)
  In some cases `VACUUM` would fail to remove such tuples even though they are now dead, leading to assorted data corruption scenarios.

- Fix inadequate buffer locking in some LSN fetches (Jacob Champion, Asim Praveen, Ashwin Agrawal)
  These errors could result in misbehavior under concurrent load. The potential consequences have not been characterized fully.

- Avoid unnecessary failure in a query on an inheritance tree that occurs concurrently with some child table being removed from the tree by `ALTER TABLE NO INHERIT` (Tom Lane)

- Fix spurious deadlock failures when multiple sessions are running `CREATE INDEX` concurrently (Jeff Janes)

- Repair failure with correlated sub-`SELECT` inside `VALUES` inside a `LATERAL` subquery (Tom Lane)

- Fix logical decoding to correctly clean up disk files for crashed transactions (Atsushi Torikoshi)
  Logical decoding may spill WAL records to disk for transactions generating many WAL records. Normally these files are cleaned up after the transaction’s commit or abort record arrives; but if no such record is ever seen, the removal code misbehaved.

- Fix walsender timeout failure and failure to respond to interrupts when processing a large transaction (Petr Jelinek)

- Fix `has_sequence_privilege()` to support `WITH GRANT OPTION` tests, as other privilege-testing functions do (Joe Conway)

- In databases using UTF8 encoding, ignore any XML declaration that asserts a different encoding (Pavel Stehule, Noah Misch)
  We always store XML strings in the database encoding, so allowing libxml to act on a declaration of another encoding gave wrong results. In encodings other than UTF8, we don’t promise to support non-ASCII XML data anyway, so retain the previous behavior for bug compatibility. This change affects only `xpath()` and related functions; other XML code paths already acted this way.

- Provide for forward compatibility with future minor protocol versions (Robert Haas, Badrul Chowdhury)
  Up to now, PostgreSQL servers simply rejected requests to use protocol versions newer than 3.0, so that there was no functional difference between the major and minor parts of the protocol version number. Allow clients to request versions 3.x without failing, sending back a message showing that
the server only understands 3.0. This makes no difference at the moment, but back-patching this change should allow speedier introduction of future minor protocol upgrades.

- Cope with failure to start a parallel worker process (Amit Kapila, Robert Haas)
  Parallel query previously tended to hang indefinitely if a worker could not be started, as the result of fork() failure or other low-probability problems.

- Prevent stack-overflow crashes when planning extremely deeply nested set operations (UNION/INTERSECT/EXCEPT) (Tom Lane)

- Fix null-pointer crashes for some types of LDAP URLs appearing in pg_hba.conf (Thomas Munro)

- Fix sample INSTR() functions in the PL/pgSQL documentation (Yugo Nagata, Tom Lane)
  These functions are stated to be Oracle® compatible, but they weren’t exactly. In particular, there was a discrepancy in the interpretation of a negative third parameter: Oracle thinks that a negative value indicates the last place where the target substring can begin, whereas our functions took it as the last place where the target can end. Also, Oracle throws an error for a zero or negative fourth parameter, whereas our functions returned zero.

  The sample code has been adjusted to match Oracle’s behavior more precisely. Users who have copied this code into their applications may wish to update their copies.

- Fix pg_dump to make ACL (permissions), comment, and security label entries reliably identifiable in archive output formats (Tom Lane)
  The “tag” portion of an ACL archive entry was usually just the name of the associated object. Make it start with the object type instead, bringing ACLs into line with the convention already used for comment and security label archive entries. Also, fix the comment and security label entries for the whole database, if present, to make their tags start with DATABASE so that they also follow this convention. This prevents false matches in code that tries to identify large-object-related entries by seeing if the tag starts with LARGE OBJECT. That could have resulted in misclassifying entries as data rather than schema, with undesirable results in a schema-only or data-only dump.

  Note that this change has user-visible results in the output of pg_restore --list.

  - In ecpg, detect indicator arrays that do not have the correct length and report an error (David Rader)
  - Avoid triggering a libc assertion in contrib/hstore, due to use of memcpy() with equal source and destination pointers (Tomas Vondra)
  - Provide modern examples of how to auto-start Postgres on macOS (Tom Lane)
    The scripts in contrib/start-scripts/osx use infrastructure that’s been deprecated for over a decade, and which no longer works at all in macOS releases of the last couple of years. Add a new subdirectory contrib/start-scripts/macos containing scripts that use the newer launchd infrastructure.

  - Fix incorrect selection of configuration-specific libraries for OpenSSL on Windows (Andrew Dunstan)
  - Support linking to MinGW-built versions of libperl (Noah Misch)
    This allows building PL/Perl with some common Perl distributions for Windows.
  - Fix MSVC build to test whether 32-bit libperl needs __D__USE_32BIT_TIME_T (Noah Misch)
    Available Perl distributions are inconsistent about what they expect, and lack any reliable means of reporting it, so resort to a build-time test on what the library being used actually does.

  - On Windows, install the crash dump handler earlier in postmaster startup (Takayuki Tsunakawa)
Appendix E. Release Notes

This may allow collection of a core dump for some early-startup failures that did not produce a dump before.

- On Windows, avoid encoding-conversion-related crashes when emitting messages very early in postmaster startup (Takayuki Tsunakawa)
- Use our existing Motorola 68K spinlock code on OpenBSD as well as NetBSD (David Carlier)
- Add support for spinlocks on Motorola 88K (David Carlier)
- Update time zone data files to tzdata release 2018c for DST law changes in Brazil, Sao Tome and Principe, plus historical corrections for Bolivia, Japan, and South Sudan. The US/Pacific-New zone has been removed (it was only an alias for America/Los_Angeles anyway).

E.20. Release 9.4.15

Release date: 2017-11-09

This release contains a variety of fixes from 9.4.14. For information about new features in the 9.4 major release, see Section E.35.

E.20.1. Migration to Version 9.4.15

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.13, see Section E.22.

E.20.2. Changes

- Fix crash due to rowtype mismatch in \texttt{json(b)}\_populate\_recordset() (Michael Paquier, Tom Lane)

  These functions used the result rowtype specified in the \texttt{FROM ... AS} clause without checking that it matched the actual rowtype of the supplied tuple value. If it didn’t, that would usually result in a crash, though disclosure of server memory contents seems possible as well. (CVE-2017-15098)

- Fix sample server-start scripts to become $\texttt{PGUSER}$ before opening $\texttt{PGLOG}$ (Noah Misch)

  Previously, the postmaster log file was opened while still running as root. The database owner could therefore mount an attack against another system user by making $\texttt{PGLOG}$ be a symbolic link to some other file, which would then become corrupted by appending log messages.

  By default, these scripts are not installed anywhere. Users who have made use of them will need to manually recopy them, or apply the same changes to their modified versions. If the existing $\texttt{PGLOG}$ file is root-owned, it will need to be removed or renamed out of the way before restarting the server with the corrected script. (CVE-2017-12172)

- Fix crash when logical decoding is invoked from a SPI-using function, in particular any function written in a PL language (Tom Lane)

- Fix \texttt{json\_build\_array()}, \texttt{json\_build\_object()}, and their \texttt{jsonb} equivalents to handle explicit \texttt{VARIADIC} arguments correctly (Michael Paquier)

- Properly reject attempts to convert infinite float values to type \texttt{numeric} (Tom Lane, KaiGai Kohei)
Previously the behavior was platform-dependent.

- Fix corner-case crashes when columns have been added to the end of a view (Tom Lane)
- Record proper dependencies when a view or rule contains `FieldSelect` or `FieldStore` expression nodes (Tom Lane)

Lack of these dependencies could allow a column or data type `DROP` to go through when it ought to fail, thereby causing later uses of the view or rule to get errors. This patch does not do anything to protect existing views/rules, only ones created in the future.

- Correctly detect hashability of range data types (Tom Lane)
  The planner mistakenly assumed that any range type could be hashed for use in hash joins or hash aggregation, but actually it must check whether the range’s subtype has hash support. This does not affect any of the built-in range types, since they’re all hashable anyway.

- Fix low-probability loss of `NOTIFY` messages due to XID wraparound (Marko Tiikkaja, Tom Lane)
  If a session executed no queries, but merely listened for notifications, for more than 2 billion transactions, it started to miss some notifications from concurrently-committing transactions.

- Avoid SIGBUS crash on Linux when a DSM memory request exceeds the space available in tmpfs (Thomas Munro)
- Prevent low-probability crash in processing of nested trigger firings (Tom Lane)
- Allow `COPY`’s `FREEZE` option to work when the transaction isolation level is `REPEATABLE READ` or higher (Noah Misch)
  This case was unintentionally broken by a previous bug fix.
- Correctly restore the umask setting when file creation fails in `COPY` or `lo_export()` (Peter Eisentraut)
- Give a better error message for duplicate column names in `ANALYZE` (Nathan Bossart)
- Fix mis-parsing of the last line in a non-newline-terminated `pg_hba.conf` file (Tom Lane)
- Fix libpq to not require user’s home directory to exist (Tom Lane)
  In v10, failure to find the home directory while trying to read `~/.pgpass` was treated as a hard error, but it should just cause that file to not be found. Both v10 and previous release branches made the same mistake when reading `~/.pg_service.conf`, though this was less obvious since that file is not sought unless a service name is specified.
- Fix libpq to guard against integer overflow in the row count of a `PGresult` (Michael Paquier)
- Fix ecpg’s handling of out-of-scope cursor declarations with pointer or array variables (Michael Meskes)
- In ecpglib, correctly handle backslashes in string literals depending on whether `standard_conforming_strings` is set (Tsunakawa Takayuki)
- Make ecpglib’s Informix-compatibility mode ignore fractional digits in integer input strings, as expected (Gao Zengqi, Michael Meskes)
- Sync our copy of the timezone library with IANA release tzcode2017c (Tom Lane)
  This fixes various issues; the only one likely to be user-visible is that the default DST rules for a POSIX-style zone name, if no `posixrules` file exists in the timezone data directory, now match current US law rather than what it was a dozen years ago.

- Update time zone data files to tzdata release 2017c for DST law changes in Fiji, Namibia, Northern Cyprus, Sudan, Tonga, and Turks & Caicos Islands, plus historical corrections for Alaska, Apia, Burma, Calcutta, Detroit, Ireland, Namibia, and Pago Pago.

Release date: 2017-08-31

This release contains a small number of fixes from 9.4.13. For information about new features in the 9.4 major release, see Section E.35.

E.21.1. Migration to Version 9.4.14

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.13, see Section E.22.

E.21.2. Changes

- Fix failure of walsender processes to respond to shutdown signals (Marco Nenciarini)
  A missed flag update resulted in walsenders continuing to run as long as they had a standby server connected, preventing primary-server shutdown unless immediate shutdown mode is used.

- Show foreign tables in `information_schema.table_privileges` view (Peter Eisentraut)
  All other relevant `information_schema` views include foreign tables, but this one ignored them.

Since this view definition is installed by `initdb`, merely upgrading will not fix the problem. If you need to fix this in an existing installation, you can, as a superuser, do this in `psql`:

```sql
SET search_path TO information_schema;
CREATE OR REPLACE VIEW table_privileges AS
SELECT CAST(u_grantor.rolname AS sql_identifier) AS grantor,
       CAST(grantee.rolname AS sql_identifier) AS grantee,
       CAST(current_database() AS sql_identifier) AS table_catalog,
       CAST(nc.nspname AS sql_identifier) AS table_schema,
       CAST(c.relname AS sql_identifier) AS table_name,
       CAST(c.prtype AS character_data) AS privilege_type,
       CAST(CASE WHEN c.prtype = 'SELECT' THEN 'YES' ELSE 'NO' END AS yes_or_no) AS with_hierarchy
FROM (SELECT oid, relname, relnamespace, relkind, relowner, (aclexplode(coalesce(relacl, acldefault('r', relowner)))).* FROM pg_class
       -- object owner always has grant options
       UNION
       SELECT 0::oid, 'PUBLIC') AS grantee
WHERE c.relnamespace = nc.oid
  AND c.relkind IN ('r', 'v', 'f')
```

2255
AND c.grantee = grantee.oid
AND c.grantor = u_grantor.oid
AND c.prtype IN ('INSERT', 'SELECT', 'UPDATE', 'DELETE', 'TRUNCATE', 'REFERENCES', 'TRIGGER')
AND (pg_has_role(u_grantor.oid, 'USAGE')
   OR pg_has_role(grantee.oid, 'USAGE')
   OR grantee.rolname = 'PUBLIC');

This must be repeated in each database to be fixed, including template0.

- Clean up handling of a fatal exit (e.g., due to receipt of SIGTERM) that occurs while trying to execute a ROLLBACK of a failed transaction (Tom Lane)
  This situation could result in an assertion failure. In production builds, the exit would still occur, but it would log an unexpected message about “cannot drop active portal”.

- Remove assertion that could trigger during a fatal exit (Tom Lane)

- Correctly identify columns that are of a range type or domain type over a composite type or domain type being searched for (Tom Lane)
  Certain ALTER commands that change the definition of a composite type or domain type are supposed to fail if there are any stored values of that type in the database, because they lack the infrastructure needed to update or check such values. Previously, these checks could miss relevant values that are wrapped inside range types or sub-domains, possibly allowing the database to become inconsistent.

- Fix crash in pg_restore when using parallel mode and using a list file to select a subset of items to restore (Fabrízio de Royes Mello)

- Change ecpg’s parser to allow RETURNING clauses without attached C variables (Michael Meskes)
  This allows ecpg programs to contain SQL constructs that use RETURNING internally (for example, inside a CTE) rather than using it to define values to be returned to the client.

- Improve selection of compiler flags for PL/Perl on Windows (Tom Lane)
  This fix avoids possible crashes of PL/Perl due to inconsistent assumptions about the width of time_t values. A side-effect that may be visible to extension developers is that _USE_32BIT_TIME_T is no longer defined globally in PostgreSQL Windows builds. This is not expected to cause problems, because type time_t is not used in any PostgreSQL API definitions.

E.22. Release 9.4.13

Release date: 2017-08-10

This release contains a variety of fixes from 9.4.12. For information about new features in the 9.4 major release, see Section E.35.

E.22.1. Migration to Version 9.4.13

A dump/restore is not required for those running 9.4.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.4.12, see Section E.23.
E.22.2. Changes

- Further restrict visibility of pg_user_mappings.umoptions, to protect passwords stored as user mapping options (Noah Misch)

The fix for CVE-2017-7486 was incorrect: it allowed a user to see the options in her own user mapping, even if she did not have USAGE permission on the associated foreign server. Such options might include a password that had been provided by the server owner rather than the user herself. Since information_schema.user_mapping_options does not show the options in such cases, pg_user_mappings should not either. (CVE-2017-7547)

By itself, this patch will only fix the behavior in newly initdb’ed databases. If you wish to apply this change in an existing database, you will need to do the following:

1. Restart the postmaster after adding allow_system_table_mods = true to postgresql.conf. (In versions supporting ALTER SYSTEM, you can use that to make the configuration change, but you’ll still need a restart.)

2. In each database of the cluster, run the following commands as superuser:

   ```sql
   SET search_path = pg_catalog;
   CREATE OR REPLACE VIEW pg_user_mappings AS
   SELECT
     U.oid AS umid,
     S.oid AS srvid,
     S.srvname AS srvname,
     U.umuser AS umuser,
     CASE WHEN U.umuser = 0 THEN
       'public'
     ELSE
       A.rolname
     END AS usename,
     CASE WHEN (U.umuser <> 0 AND A.rolname = current_user
               AND (pg_has_role(S.srvowner, 'USAGE')
                  OR has_server_privilege(S.oid, 'USAGE')))
          OR (U.umuser = 0 AND pg_has_role(S.srvowner, 'USAGE'))
          OR (SELECT rolsuper FROM pg_authid WHERE rolname = current_user)
            THEN U.umoptions
     ELSE NULL END AS umoptions
   FROM pg_user_mapping U
   LEFT JOIN pg_authid A ON (A.oid = U.umuser)
   JOIN pg_foreign_server S ON (U.umserver = S.oid);
   ```

3. Do not forget to include the template0 and template1 databases, or the vulnerability will still exist in databases you create later. To fix template0, you’ll need to temporarily make it accept connections. In PostgreSQL 9.5 and later, you can use

   ```sql
   ALTER DATABASE template0 WITH ALLOW_CONNECTIONS true;
   ```

   and then after fixing template0, undo that with

   ```sql
   ALTER DATABASE template0 WITH ALLOW_CONNECTIONS false;
   ```

   In prior versions, instead use

   ```sql
   UPDATE pg_database SET datallowconn = true WHERE datname = 'template0';
   UPDATE pg_database SET datallowconn = false WHERE datname = 'template0';
   ```

4. Finally, remove the allow_system_table_mods configuration setting, and again restart the postmaster.
Appendix E. Release Notes

- Disallow empty passwords in all password-based authentication methods (Heikki Linnakangas)
  libpq ignores empty password specifications, and does not transmit them to the server. So, if a user’s password has been set to the empty string, it’s impossible to log in with that password via psql or other libpq-based clients. An administrator might therefore believe that setting the password to empty is equivalent to disabling password login. However, with a modified or non-libpq-based client, logging in could be possible, depending on which authentication method is configured. In particular the most common method, md5, accepted empty passwords. Change the server to reject empty passwords in all cases. (CVE-2017-7546)

- Make lo_put() check for UPDATE privilege on the target large object (Tom Lane, Michael Paquier)
  lo_put() should surely require the same permissions as lowrite(), but the check was missing, allowing any user to change the data in a large object. (CVE-2017-7548)

- Fix concurrent locking of tuple update chains (Álvaro Herrera)
  If several sessions concurrently lock a tuple update chain with nonconflicting lock modes using an old snapshot, and they all succeed, it was possible for some of them to nonetheless fail (and conclude there is no live tuple version) due to a race condition. This had consequences such as foreign-key checks failing to see a tuple that definitely exists but is being updated concurrently.

- Fix potential data corruption when freezing a tuple whose XMAX is a multixact with exactly one still-interesting member (Teodor Sigaev)

- Avoid integer overflow and ensuing crash when sorting more than one billion tuples in-memory (Sergey Koposov)

- On Windows, retry process creation if we fail to reserve the address range for our shared memory in the new process (Tom Lane, Amit Kapila)
  This is expected to fix infrequent child-process-launch failures that are probably due to interference from antivirus products.

- Fix low-probability corruption of shared predicate-lock hash table in Windows builds (Thomas Munro, Tom Lane)

- Avoid logging clean closure of an SSL connection as though it were a connection reset (Michael Paquier)

- Prevent sending SSL session tickets to clients (Tom Lane)
  This fix prevents reconnection failures with ticket-aware client-side SSL code.

- Fix code for setting tcp_keepalives_idle on Solaris (Tom Lane)

- Fix statistics collector to honor inquiry messages issued just after a postmaster shutdown and immediate restart (Tom Lane)
  Statistics inquiries issued within half a second of the previous postmaster shutdown were effectively ignored.

- Ensure that the statistics collector’s receive buffer size is at least 100KB (Tom Lane)
  This reduces the risk of dropped statistics data on older platforms whose default receive buffer size is less than that.

- Fix possible creation of an invalid WAL segment when a standby is promoted just after it processes an XLOG_SWITCH WAL record (Andres Freund)

- Fix walsender to exit promptly when client requests shutdown (Tom Lane)
Appendix E. Release Notes

- Fix SIGHUP and SIGUSR1 handling in walsender processes (Petr Jelinek, Andres Freund)
- Prevent walsender-triggered panics during shutdown checkpoints (Andres Freund, Michael Paquier)
- Fix unnecessarily slow restarts of walreceiver processes due to race condition in postmaster (Tom Lane)
- Fix logical decoding failure with very wide tuples (Andres Freund)
  Logical decoding crashed on tuples that are wider than 64KB (after compression, but with all data in-line). The case arises only when \texttt{REPLICA IDENTITY FULL} is enabled for a table containing such tuples.
- Fix leakage of small subtransactions spilled to disk during logical decoding (Andres Freund)
  This resulted in temporary files consuming excessive disk space.
- Reduce the work needed to build snapshots during creation of logical-decoding slots (Andres Freund, Petr Jelinek)
  The previous algorithm was infeasibly expensive on a server with a lot of open transactions.
- Fix race condition that could indefinitely delay creation of logical-decoding slots (Andres Freund, Petr Jelinek)
- Reduce overhead in processing syscache invalidation events (Tom Lane)
  This is particularly helpful for logical decoding, which triggers frequent cache invalidation.
- Fix cases where an \texttt{INSERT} or \texttt{UPDATE} assigns to more than one element of a column that is of domain-over-array type (Tom Lane)
- Allow window functions to be used in \texttt{sub-selects} that are within the arguments of an aggregate function (Tom Lane)
- Move autogenerated array types out of the way during \texttt{ALTER ... RENAME} (Vik Fearing)
  Previously, we would rename a conflicting autogenerated array type out of the way during \texttt{CREATE}; this fix extends that behavior to renaming operations.
- Ensure that \texttt{ALTER USER ... SET} accepts all the syntax variants that \texttt{ALTER ROLE ... SET} does (Peter Eisentraut)
- Properly update dependency info when changing a datatype I/O function’s argument or return type from \texttt{opaque} to the correct type (Heikki Linnakangas)
  \texttt{CREATE TYPE} updates I/O functions declared in this long-obsolete style, but it forgot to record a dependency on the type, allowing a subsequent \texttt{DROP TYPE} to leave broken function definitions behind.
- Reduce memory usage when \texttt{ANALYZE} processes a \texttt{tsvector} column (Heikki Linnakangas)
- Fix unnecessary precision loss and sloppy rounding when multiplying or dividing \texttt{money} values by integers or floats (Tom Lane)
- Tighten checks for whitespace in functions that parse identifiers, such as \texttt{regprocedurein()} (Tom Lane)
  Depending on the prevailing locale, these functions could misinterpret fragments of multibyte characters as whitespace.
- Use relevant \texttt{#define} symbols from Perl while compiling PL/Perl (Ashutosh Sharma, Tom Lane)
  This avoids portability problems, typically manifesting as a “handshake” mismatch during library load, when working with recent Perl versions.
• In libpq, reset GSS/SASL and SSPI authentication state properly after a failed connection attempt (Michael Paquier)
  Failure to do this meant that when falling back from SSL to non-SSL connections, a GSS/SASL failure in the SSL attempt would always cause the non-SSL attempt to fail. SSPI did not fail, but it leaked memory.
• In psql, fix failure when `COPY FROM STDIN` is ended with a keyboard EOF signal and then another `COPY FROM STDIN` is attempted (Thomas Munro)
  This misbehavior was observed on BSD-derived platforms (including macOS), but not on most others.
• Fix `pg_dump` and `pg_restore` to emit `REFRESH MATERIALIZED VIEW` commands last (Tom Lane)
  This prevents errors during dump/restore when a materialized view refers to tables owned by a different user.
• Improve `pg_dump/pg_restore`’s reporting of error conditions originating in zlib (Vladimir Kunschikov, Álvaro Herrera)
• Fix `pg_dump` with the `--clean` option to drop event triggers as expected (Tom Lane)
  It also now correctly assigns ownership of event triggers; before, they were restored as being owned by the superuser running the restore script.
• Fix `pg_dump` to not emit invalid SQL for an empty operator class (Daniel Gustafsson)
• Fix `pg_dump` output to stdout on Windows (Kuntal Ghosh)
  A compressed plain-text dump written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.
• Fix `pg_get_ruledef()` to print correct output for the `ON SELECT` rule of a view whose columns have been renamed (Tom Lane)
  In some corner cases, `pg_dump` relies on `pg_get_ruledef()` to dump views, so that this error could result in dump/reload failures.
• Fix dumping of outer joins with empty constraints, such as the result of a `NATURAL LEFT JOIN` with no common columns (Tom Lane)
• Fix dumping of function expressions in the `FROM` clause in cases where the expression does not deparse into something that looks like a function call (Tom Lane)
• Fix `pg_basebackup` output to stdout on Windows (Haribabu Kommi)
  A backup written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.
• Fix `pg_upgrade` to ensure that the ending WAL record does not have `wal_level = minimum` (Bruce Momjian)
  This condition could prevent upgraded standby servers from reconnecting.
• In `postgres_fdw`, re-establish connections to remote servers after `ALTER SERVER` or `ALTER USER MAPPING` commands (Kyotaro Horiguchi)
  This ensures that option changes affecting connection parameters will be applied promptly.
• In `postgres_fdw`, allow cancellation of remote transaction control commands (Robert Haas, Rafia Sabih)
  This change allows us to quickly escape a wait for an unresponsive remote server in many more cases than previously.
Appendix E. Release Notes

- Increase MAX_SYSCACHE_CALLBACKS to provide more room for extensions (Tom Lane)
- Always use -fpIC, not -fpic, when building shared libraries with gcc (Tom Lane)
  This supports larger extension libraries on platforms where it makes a difference.
- Fix unescaped-braces issue in our build scripts for Microsoft MSVC, to avoid a warning or error from recent Perl versions (Andrew Dunstan)
- In MSVC builds, handle the case where the openssl library is not within a VC subdirectory (Andrew Dunstan)
- In MSVC builds, add proper include path for libxml2 header files (Andrew Dunstan)
  This fixes a former need to move things around in standard Windows installations of libxml2.
- In MSVC builds, recognize a Tcl library that is named tcl86.lib (Noah Misch)
- In MSVC builds, honor PROVE_FLAGS settings on vcregress.pl's command line (Andrew Dunstan)

Release date: 2017-05-11

This release contains a variety of fixes from 9.4.11. For information about new features in the 9.4 major release, see Section E.35.

E.23.1. Migration to Version 9.4.12

A dump/restore is not required for those running 9.4.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are using third-party replication tools that depend on “logical decoding”, see the fourth changelog entry below.

Also, if you are upgrading from a version earlier than 9.4.11, see Section E.24.

E.23.2. Changes

- Restrict visibility of pg_user_mappings.umoptions, to protect passwords stored as user mapping options (Michael Paquier, Feike Steenbergen)

  The previous coding allowed the owner of a foreign server object, or anyone he has granted server USAGE permission to, to see the options for all user mappings associated with that server. This might well include passwords for other users. Adjust the view definition to match the behavior of information_schema.user_mapping_options, namely that these options are visible to the user being mapped, or if the mapping is for PUBLIC and the current user is the server owner, or if the current user is a superuser. (CVE-2017-7486)

  By itself, this patch will only fix the behavior in newly initdb’d databases. If you wish to apply this change in an existing database, follow the corrected procedure shown in the changelog entry for CVE-2017-7547, in Section E.22.
Appendix E. Release Notes

• Prevent exposure of statistical information via leaky operators (Peter Eisentraut)

Some selectivity estimation functions in the planner will apply user-defined operators to values obtained from pg_statistic, such as most common values and histogram entries. This occurs before table permissions are checked, so a nefarious user could exploit the behavior to obtain these values for table columns he does not have permission to read. To fix, fall back to a default estimate if the operator’s implementation function is not certified leak-proof and the calling user does not have permission to read the table column whose statistics are needed. At least one of these criteria is satisfied in most cases in practice. (CVE-2017-7484)

• Restore libpq’s recognition of the PGREQUIRESSL environment variable (Daniel Gustafsson)

Processing of this environment variable was unintentionally dropped in PostgreSQL 9.3, but its documentation remained. This creates a security hazard, since users might be relying on the environment variable to force SSL-encrypted connections, but that would no longer be guaranteed. Restore handling of the variable, but give it lower priority than PGSSLMODE, to avoid breaking configurations that work correctly with post-9.3 code. (CVE-2017-7485)

• Fix possibly-invalid initial snapshot during logical decoding (Petr Jelinek, Andres Freund)

The initial snapshot created for a logical decoding replication slot was potentially incorrect. This could cause third-party tools that use logical decoding to copy incomplete/inconsistent initial data. This was more likely to happen if the source server was busy at the time of slot creation, or if another logical slot already existed.

If you are using a replication tool that depends on logical decoding, and it should have copied a nonempty data set at the start of replication, it is advisable to recreate the replica after installing this update, or to verify its contents against the source server.

• Fix possible corruption of “init forks” of unlogged indexes (Robert Haas, Michael Paquier)

This could result in an unlogged index being set to an invalid state after a crash and restart. Such a problem would persist until the index was dropped and rebuilt.

• Fix incorrect reconstruction of pg_subtrans entries when a standby server replays a prepared but uncommitted two-phase transaction (Tom Lane)

In most cases this turned out to have no visible ill effects, but in corner cases it could result in circular references in pg_subtrans, potentially causing infinite loops in queries that examine rows modified by the two-phase transaction.

• Avoid possible crash in walsender due to failure to initialize a string buffer (Stas Kelvich, Fujii Masao)

• Fix postmaster’s handling of fork() failure for a background worker process (Tom Lane)

Previously, the postmaster updated portions of its state as though the process had been launched successfully, resulting in subsequent confusion.

• Ensure parsing of queries in extension scripts sees the results of immediately-preceding DDL (Julien Rouhaud, Tom Lane)

Due to lack of a cache flush step between commands in an extension script file, non-utility queries might not see the effects of an immediately preceding catalog change, such as ALTER TABLE ... RENAME.

• Skip tablespace privilege checks when ALTER TABLE ... ALTER COLUMN TYPE rebuilds an existing index (Noah Misch)

The command failed if the calling user did not currently have CREATE privilege for the tablespace containing the index. That behavior seems unhelpful, so skip the check, allowing the index to be rebuilt where it is.
Appendix E. Release Notes

- **Fix** `ALTER TABLE ... VALIDATE CONSTRAINT` to not recurse to child tables when the constraint is marked `NO INHERIT` (Amit Langote)
  
  This fix prevents unwanted “constraint does not exist” failures when no matching constraint is present in the child tables.

- **Fix** `VACUUM` to account properly for pages that could not be scanned due to conflicting page pins (Andrew Gierth)
  
  This tended to lead to underestimation of the number of tuples in the table. In the worst case of a small heavily-contended table, `VACUUM` could incorrectly report that the table contained no tuples, leading to very bad planning choices.

- Ensure that bulk-tuple-transfer loops within a hash join are interruptible by query cancel requests (Tom Lane, Thomas Munro)

- **Fix** integer-overflow problems in `interval` comparison (Kyotaro Horiguchi, Tom Lane)
  
  The comparison operators for type `interval` could yield wrong answers for intervals larger than about 296000 years. Indexes on columns containing such large values should be reindexed, since they may be corrupt.

- **Fix** `cursor_to_xml()` to produce valid output with `tableforest = false` (Thomas Munro, Peter Eisentraut)
  
  Previously it failed to produce a wrapping `<table>` element.

- **Fix** roundoff problems in `float8_timestamptz()` and `make_interval()` (Tom Lane)
  
  These functions truncated, rather than rounded, when converting a floating-point value to integer microseconds; that could cause unexpectedly off-by-one results.

- Improve performance of `pg_timezone_names` view (Tom Lane, David Rowley)

- Reduce memory management overhead for contexts containing many large blocks (Tom Lane)

- **Fix** sloppy handling of corner-case errors from `lseek()` and `close()` (Tom Lane)
  
  Neither of these system calls are likely to fail in typical situations, but if they did, `fd.c` could get quite confused.

- **Fix** incorrect check for whether postmaster is running as a Windows service (Michael Paquier)
  
  This could result in attempting to write to the event log when that isn’t accessible, so that no logging happens at all.

- **Fix** `ecpg` to support `COMMIT PREPARED` and `ROLLBACK PREPARED` (Masahiko Sawada)

- **Fix** a double-free error when processing dollar-quoted string literals in `ecpg` (Michael Meskes)

- In `pg_dump`, fix incorrect schema and owner marking for comments and security labels of some types of database objects (Giuseppe Broccolo, Tom Lane)
  
  In simple cases this caused no ill effects; but for example, a schema-selective restore might omit comments it should include, because they were not marked as belonging to the schema of their associated object.

- Avoid emitting an invalid list file in `pg_restore -l` when SQL object names contain newlines (Tom Lane)
  
  Replace newlines by spaces, which is sufficient to make the output valid for `pg_restore -L`'s purposes.

- **Fix** `pg_upgrade` to transfer comments and security labels attached to “large objects” (blobs) (Stephen Frost)
Previously, blobs were correctly transferred to the new database, but any comments or security labels attached to them were lost.

- Improve error handling in contrib/adminpack\'s pg_file_write() function (Noah Misch)
  Notably, it failed to detect errors reported by fclose().
- In contrib/dblink, avoid leaking the previous unnamed connection when establishing a new unnamed connection (Joe Conway)
- Fix contrib/pg_trgm\'s extraction of trigrams from regular expressions (Tom Lane)
  In some cases it would produce a broken data structure that could never match anything, leading to GIN or GiST indexscans that use a trigram index not finding any matches to the regular expression.
- In contrib/postgres_fdw, transmit query cancellation requests to the remote server (Michael Paquier, Etsuro Fujita)
  Previously, a local query cancellation request did not cause an already-sent remote query to terminate early. This is a back-patch of work originally done for 9.6.
- Support OpenSSL 1.1.0 (Heikki Linnakangas, Andreas Karlsson, Tom Lane)
  This is a back-patch of work previously done in newer branches; it\'s needed since many platforms are adopting newer OpenSSL versions.
- Support Tcl 8.6 in MSVC builds (Álvaro Herrera)
- Sync our copy of the timezone library with IANA release tzcode2017b (Tom Lane)
  This fixes a bug affecting some DST transitions in January 2038.
- Update time zone data files to tzdata release 2017b for DST law changes in Chile, Haiti, and Mongolia, plus historical corrections for Ecuador, Kazakhstan, Liberia, and Spain. Switch to numeric abbreviations for numerous time zones in South America, the Pacific and Indian oceans, and some Asian and Middle Eastern countries.
  The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the pg_timezone_names view nor used for output.
- Use correct daylight-savings rules for POSIX-style time zone names in MSVC builds (David Rowley)
  The Microsoft MSVC build scripts neglected to install the posixrules file in the timezone directory tree. This resulted in the timezone code falling back to its built-in rule about what DST behavior to assume for a POSIX-style time zone name. For historical reasons that still corresponds to the DST rules the USA was using before 2007 (i.e., change on first Sunday in April and last Sunday in October). With this fix, a POSIX-style zone name will use the current and historical DST transition dates of the US/Eastern zone. If you don\’t want that, remove the posixrules file, or replace it with a copy of some other zone file (see Section 8.5.3). Note that due to caching, you may need to restart the server to get such changes to take effect.

E.24. Release 9.4.11

Release date: 2017-02-09
This release contains a variety of fixes from 9.4.10. For information about new features in the 9.4 major release, see Section E.35.

**E.24.1. Migration to Version 9.4.11**

A dump/restore is not required for those running 9.4.X. However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted indexes. Also, if you are upgrading from a version earlier than 9.4.10, see Section E.25.

**E.24.2. Changes**

- Fix a race condition that could cause indexes built with `CREATE INDEX CONCURRENTLY` to be corrupt (Pavan Deolasee, Tom Lane)

  If `CREATE INDEX CONCURRENTLY` was used to build an index that depends on a column not previously indexed, then rows updated by transactions that ran concurrently with the `CREATE INDEX` command could have received incorrect index entries. If you suspect this may have happened, the most reliable solution is to rebuild affected indexes after installing this update.

- Ensure that the special snapshot used for catalog scans is not invalidated by premature data pruning (Tom Lane)

  Backends failed to account for this snapshot when advertising their oldest xmin, potentially allowing concurrent vacuuming operations to remove data that was still needed. This led to transient failures along the lines of “cache lookup failed for relation 1255”.

- Unconditionally WAL-log creation of the “init fork” for an unlogged table (Michael Paquier)

  Previously, this was skipped when `wal_level = minimal`, but actually it’s necessary even in that case to ensure that the unlogged table is properly reset to empty after a crash.

- Reduce interlocking on standby servers during the replay of btree index vacuuming operations (Simon Riggs)

  This change avoids substantial replication delays that sometimes occurred while replaying such operations.

- If the stats collector dies during hot standby, restart it (Takayuki Tsunakawa)

- Ensure that hot standby feedback works correctly when it’s enabled at standby server start (Ants Aasma, Craig Ringer)

- Check for interrupts while hot standby is waiting for a conflicting query (Simon Riggs)

- Avoid constantly respawning the autovacuum launcher in a corner case (Amit Khandekar)

  This fix avoids problems when autovacuum is nominally off and there are some tables that require freezing, but all such tables are already being processed by autovacuum workers.

- Fix check for when an extension member object can be dropped (Tom Lane)

  Extension upgrade scripts should be able to drop member objects, but this was disallowed for serial-column sequences, and possibly other cases.

- Make sure `ALTER TABLE` preserves index tablespace assignments when rebuilding indexes (Tom Lane, Michael Paquier)
Previously, non-default settings of default_tablespace could result in broken indexes.

- Fix incorrect updating of trigger function properties when changing a foreign-key constraint’s deferrability properties with `ALTER TABLE ... ALTER CONSTRAINT` (Tom Lane)
  This led to odd failures during subsequent exercise of the foreign key, as the triggers were fired at the wrong times.

- Prevent dropping a foreign-key constraint if there are pending trigger events for the referenced relation (Tom Lane)
  This avoids “could not find trigger NNN” or “relation NNN has no triggers” errors.

- Fix processing of OID column when a table with OIDs is associated to a parent with OIDs via `ALTER TABLE ... INHERIT` (Amit Langote)
  The OID column should be treated the same as regular user columns in this case, but it wasn’t, leading to odd behavior in later inheritance changes.

- Fix `CREATE OR REPLACE VIEW` to update the view query before attempting to apply the new view options (Dean Rasheed)
  Previously the command would fail if the new options were inconsistent with the old view definition.

- Report correct object identity during `ALTER TEXT SEARCH CONFIGURATION` (Artur Zakirov)
  The wrong catalog OID was reported to extensions such as logical decoding.

- Check for serializability conflicts before reporting constraint-violation failures (Thomas Munro)
  When using serializable transaction isolation, it is desirable that any error due to concurrent transactions should manifest as a serialization failure, thereby cueing the application that a retry might succeed. Unfortunately, this does not reliably happen for duplicate-key failures caused by concurrent insertions. This change ensures that such an error will be reported as a serialization error if the application explicitly checked for the presence of a conflicting key (and did not find it) earlier in the transaction.

- Prevent multicolumn expansion of `foo.*` in an `UPDATE` source expression (Tom Lane)
  This led to “UPDATE target count mismatch --- internal error”. Now the syntax is understood as a whole-row variable, as it would be in other contexts.

- Ensure that column typmods are determined accurately for multi-row `VALUES` constructs (Tom Lane)
  This fixes problems occurring when the first value in a column has a determinable typmod (e.g., length for a `varchar` value) but later values don’t share the same limit.

- Throw error for an unfinished Unicode surrogate pair at the end of a Unicode string (Tom Lane)
  Normally, a Unicode surrogate leading character must be followed by a Unicode surrogate trailing character, but the check for this was missed if the leading character was the last character in a Unicode string literal (`U&'...'`) or Unicode identifier (`U&"..."`).

- Ensure that a purely negative text search query, such as `!foo`, matches empty `tsvector` (Tom Dunstan)
  Such matches were found by GIN index searches, but not by sequential scans or GiST index searches.

- Prevent crash when `ts_rewrite()` replaces a non-top-level subtree with an empty query (Artur Zakirov)

- Fix performance problems in `ts_rewrite()` (Tom Lane)
Appendix E. Release Notes

• Fix ts_rewrite()'s handling of nested NOT operators (Tom Lane)
• Fix array_fill() to handle empty arrays properly (Tom Lane)
• Fix one-byte buffer overrun in quote_literal_cstr() (Heikki Linnakangas)
  The overrun occurred only if the input consisted entirely of single quotes and/or backslashes.
• Prevent multiple calls of pg_start_backup() and pg_stop_backup() from running concurrently (Michael Paquier)
  This avoids an assertion failure, and possibly worse things, if someone tries to run these functions in parallel.
• Avoid discarding interval-to-interval casts that aren’t really no-ops (Tom Lane)
  In some cases, a cast that should result in zeroing out low-order interval fields was mistakenly deemed to be a no-op and discarded. An example is that casting from INTERVAL MONTH to INTERVAL YEAR failed to clear the months field.
• Ensure that cached plans are invalidated by changes in foreign-table options (Amit Langote, Etsuro Fujita, Ashutosh Bapat)
• Fix pg_dump to dump user-defined casts and transforms that use built-in functions (Stephen Frost)
• Fix pg_restore with --create --if-exists to behave more sanely if an archive contains unrecognized DROP commands (Tom Lane)
  This doesn’t fix any live bug, but it may improve the behavior in future if pg_restore is used with an archive generated by a later pg_dump version.
• Fix pg_basebackup’s rate limiting in the presence of slow I/O (Antonin Houska)
  If disk I/O was transiently much slower than the specified rate limit, the calculation overflowed, effectively disabling the rate limit for the rest of the run.
• Fix pg_basebackup’s handling of symlinked pg_stat_tmp and pg_replslot subdirectories (Magnus Hagander, Michael Paquier)
• Fix possible pg_basebackup failure on standby server when including WAL files (Amit Kapila, Robert Haas)
• Ensure that the Python exception objects we create for PL/Python are properly reference-counted (Rafa de la Torre, Tom Lane)
  This avoids failures if the objects are used after a Python garbage collection cycle has occurred.
• Fix PL/Tcl to support triggers on tables that have .tupno as a column name (Tom Lane)
  This matches the (previously undocumented) behavior of PL/Tcl’s spi_exec and spi_execp commands, namely that a magic .tupno column is inserted only if there isn’t a real column named that.
• Allow DOS-style line endings in ~/.pgpass files, even on Unix (Vik Fearing)
  This change simplifies use of the same password file across Unix and Windows machines.
• Fix one-byte buffer overrun if ecpg is given a file name that ends with a dot (Takayuki Tsunakawa)
• Fix psql’s tab completion for ALTER DEFAULT PRIVILEGES (Gilles Darold, Stephen Frost)
• In psql, treat an empty or all-blank setting of the PAGER environment variable as meaning “no pager” (Tom Lane)
  Previously, such a setting caused output intended for the pager to vanish entirely.
• Improve contrib/dblink’s reporting of low-level libpq errors, such as out-of-memory (Joe Con-...
Appendix E. Release Notes

• Teach `contrib/dblink` to ignore irrelevant server options when it uses a `contrib/postgres_fdw` foreign server as the source of connection options (Corey Huinker)

  Previously, if the foreign server object had options that were not also `libpq` connection options, an error occurred.

• On Windows, ensure that environment variable changes are propagated to DLLs built with debug options (Christian Ullrich)

• Sync our copy of the timezone library with IANA release `tzcode2016j` (Tom Lane)

  This fixes various issues, most notably that timezone data installation failed if the target directory didn’t support hard links.

• Update timezone data files to `tzdata` release `2016j` for DST law changes in northern Cyprus (adding a new zone `Asia/Famagusta`), Russia (adding a new zone `Europe/Saratov`), Tonga, and Antarctica/Casey. Historical corrections for Italy, Kazakhstan, Malta, and Palestine. Switch to preferring numeric zone abbreviations for Tonga.

E.25. Release 9.4.10

Release date: 2016-10-27

This release contains a variety of fixes from 9.4.9. For information about new features in the 9.4 major release, see Section E.35.

E.25.1. Migration to Version 9.4.10

A dump/restore is not required for those running 9.4.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted free space maps.

Also, if you are upgrading from a version earlier than 9.4.6, see Section E.29.

E.25.2. Changes

• Fix WAL-logging of truncation of relation free space maps and visibility maps (Pavan Deolasee, Heikki Linnakangas)

  It was possible for these files to not be correctly restored during crash recovery, or to be written incorrectly on a standby server. Bogus entries in a free space map could lead to attempts to access pages that have been truncated away from the relation itself, typically producing errors like “could not read block XXX: read only 0 of 8192 bytes”. Checksum failures in the visibility map are also possible, if checksumming is enabled.

  Procedures for determining whether there is a problem and repairing it if so are discussed at https://wiki.postgresql.org/wiki/Free_Space_Map_Problems.

• Fix incorrect creation of GIN index WAL records on big-endian machines (Tom Lane)

  The typical symptom was “unexpected GIN leaf action” errors during WAL replay.

• Fix `SELECT FOR UPDATE/SHARE` to correctly lock tuples that have been updated by a subsequently-aborted transaction (Álvaro Herrera)
Appendix E. Release Notes

In 9.5 and later, the \texttt{SELECT} would sometimes fail to return such tuples at all. A failure has not been proven to occur in earlier releases, but might be possible with concurrent updates.

- Fix EvalPlanQual rechecks involving CTE scans (Tom Lane)
  The recheck would always see the CTE as returning no rows, typically leading to failure to update rows that were recently updated.

- Fix improper repetition of previous results from hashed aggregation in a subquery (Andrew Gierth)
  The test to see if we can reuse a previously-computed hash table of the aggregate state values neglected the possibility of an outer query reference appearing in an aggregate argument expression. A change in the value of such a reference should lead to recalculating the hash table, but did not.

- Fix query-lifespan memory leak in a bulk \texttt{UPDATE} on a table with a \texttt{PRIMARY KEY} or \texttt{REPLICA IDENTITY} index (Tom Lane)

- Fix \texttt{EXPLAIN} to emit valid XML when track\_io\_timing is on (Markus Winand)
  Previously the XML output-format option produced syntactically invalid tags such as \texttt{<I/O-Read-Time>}. That is now rendered as \texttt{<I-O-Read-Time>}.

- Suppress printing of zeroes for unmeasured times in \texttt{EXPLAIN} (Maksim Milyutin)
  Certain option combinations resulted in printing zero values for times that actually aren’t ever measured in that combination. Our general policy in \texttt{EXPLAIN} is not to print such fields at all, so do that consistently in all cases.

- Fix timeout length when \texttt{VACUUM} is waiting for exclusive table lock so that it can truncate the table (Simon Riggs)
  The timeout was meant to be 50 milliseconds, but it was actually only 50 microseconds, causing \texttt{VACUUM} to give up on truncation much more easily than intended. Set it to the intended value.

- Fix bugs in merging inherited \texttt{CHECK} constraints while creating or altering a table (Tom Lane, Amit Langote)
  Allow identical \texttt{CHECK} constraints to be added to a parent and child table in either order. Prevent merging of a valid constraint from the parent table with a \texttt{NOT VALID} constraint on the child. Likewise, prevent merging of a \texttt{NO INHERIT} child constraint with an inherited constraint.

- Remove artificial restrictions on the values accepted by \texttt{numeric\_in()} and \texttt{numeric\_recv()} (Tom Lane)
  We allow numeric values up to the limit of the storage format (more than $1e100000$), so it seems fairly pointless that \texttt{numeric\_in()} rejected scientific-notation exponents above 1000. Likewise, it was silly for \texttt{numeric\_recv()} to reject more than 1000 digits in an input value.

- Avoid very-low-probability data corruption due to testing tuple visibility without holding buffer lock (Thomas Munro, Peter Geoghegan, Tom Lane)

- Fix logical WAL decoding to work properly when a subtransaction’s WAL output is large enough to spill to disk (Andres Freund)

- Fix buffer overread in logical WAL decoding (Tom Lane)
  Logical decoding of a tuple update record read 23 bytes too many, which was usually harmless but with very bad luck could result in a crash.

- Fix file descriptor leakage when truncating a temporary relation of more than 1GB (Andres Freund)

- Disallow starting a standalone backend with \texttt{standby\_mode} turned on (Michael Paquier)
  This can’t do anything useful, since there will be no WAL receiver process to fetch more WAL data; and it could result in misbehavior in code that wasn’t designed with this situation in mind.
Appendix E. Release Notes

- Properly initialize replication slot state when recycling a previously-used slot (Michael Paquier)
  This failure to reset all of the fields of the slot could prevent VACUUM from removing dead tuples.
- Round shared-memory allocation request to a multiple of the actual huge page size when attempting to use huge pages on Linux (Tom Lane)
  This avoids possible failures during munmap() on systems with atypical default huge page sizes. Except in crash-recovery cases, there were no ill effects other than a log message.
- Use a more random value for the dynamic shared memory control segment’s ID (Robert Haas, Tom Lane)
  Previously, the same value would be chosen every time, because it was derived from random() but srand() had not yet been called. While relatively harmless, this was not the intended behavior.
- On Windows, retry creation of the dynamic shared memory control segment after an access-denied error (Kyotaro Horiguchi, Amit Kapila)
  Windows sometimes returns ERROR_ACCESS_DENIED rather than ERROR_ALREADY_EXISTS when there is an existing segment. This led to postmaster startup failure due to believing that the former was an unrecoverable error.
- Don’t try to share SSL contexts across multiple connections in libpq (Heikki Linnakangas)
  This led to assorted corner-case bugs, particularly when trying to use different SSL parameters for different connections.
- Avoid corner-case memory leak in libpq (Tom Lane)
  The reported problem involved leaking an error report during PQreset(), but there might be related cases.
- Make ecpg’s --help and --version options work consistently with our other executables (Haribabu Kommi)
- Fix pgbench’s calculation of average latency (Fabien Coelho)
  The calculation was incorrect when there were \sleep commands in the script, or when the test duration was specified in number of transactions rather than total time.
- In pg_dump, never dump range constructor functions (Tom Lane)
  This oversight led to pg_upgrade failures with extensions containing range types, due to duplicate creation of the constructor functions.
- In pg_xlogdump, retry opening new WAL segments when using --follow option (Magnus Hagander)
  This allows for a possible delay in the server’s creation of the next segment.
- Fix pg_xlogdump to cope with a WAL file that begins with a continuation record spanning more than one page (Pavan Deolasee)
- Fix contrib/pg_buffercache to work when shared_buffers exceeds 256GB (KaiGai Kohei)
- Fix contrib/intarray/bench/bench.pl to print the results of the EXPLAIN it does when given the -e option (Daniel Gustafsson)
- Install TAP test infrastructure so that it’s available for extension testing (Craig Ringer)
  When PostgreSQL has been configured with --enable-tap-tests, “make install” will now install the Perl support files for TAP testing where PGXS can find them. This allows non-core extensions to use $(prove_check) without extra tests.
• In MSVC builds, include pg_recvlogical in a client-only installation (MauMau)
• Update Windows time zone mapping to recognize some time zone names added in recent Windows versions (Michael Paquier)
• Prevent failure of obsolete dynamic time zone abbreviations (Tom Lane)

If a dynamic time zone abbreviation does not match any entry in the referenced time zone, treat it as equivalent to the time zone name. This avoids unexpected failures when IANA removes abbreviations from their time zone database, as they did in tzdata release 2016f and seem likely to do again in the future. The consequences were not limited to not recognizing the individual abbreviation; any mismatch caused the `pg_timezone_abbr` view to fail altogether.

• Update time zone data files to tzdata release 2016h for DST law changes in Palestine and Turkey, plus historical corrections for Turkey and some regions of Russia. Switch to numeric abbreviations for some time zones in Antarctica, the former Soviet Union, and Sri Lanka.

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the `pg_timezone_names` view nor used for output.

In this update, AMT is no longer shown as being in use to mean Armenia Time. Therefore, we have changed the Default abbreviation set to interpret it as Amazon Time, thus UTC-4 not UTC+4.

E.26. Release 9.4.9

Release date: 2016-08-11

This release contains a variety of fixes from 9.4.8. For information about new features in the 9.4 major release, see Section E.35.

E.26.1. Migration to Version 9.4.9

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.6, see Section E.29.

E.26.2. Changes

• Fix possible mis-evaluation of nested `CASE-WHEN` expressions (Heikki Linnakangas, Michael Paquier, Tom Lane)

A `CASE` expression appearing within the test value subexpression of another `CASE` could become confused about whether its own test value was null or not. Also, inlining of a SQL function implementing the equality operator used by a `CASE` expression could result in passing the wrong test value to functions called within a `CASE` expression in the SQL function’s body. If the test values were of different data types, a crash might result; moreover such situations could be abused to allow disclosure of portions of server memory. (CVE-2016-5423)
• Fix client programs’ handling of special characters in database and role names (Noah Misch, Nathan Bossart, Michael Paquier)

Numerous places in vacuumdb and other client programs could become confused by database and role names containing double quotes or backslashes. Tighten up quoting rules to make that safe. Also, ensure that when a conninfo string is used as a database name parameter to these programs, it is correctly treated as such throughout.

Fix handling of paired double quotes in psql’s \connect and \password commands to match the documentation.

Introduce a new -reuse-previous option in psql’s \connect command to allow explicit control of whether to re-use connection parameters from a previous connection. (Without this, the choice is based on whether the database name looks like a conninfo string, as before.) This allows secure handling of database names containing special characters in pg_dumpall scripts.

pg_dumpall now refuses to deal with database and role names containing carriage returns or newlines, as it seems impractical to quote those characters safely on Windows. In future we may reject such names on the server side, but that step has not been taken yet.

These are considered security fixes because crafted object names containing special characters could have been used to execute commands with superuser privileges the next time a superuser executes pg_dumpall or other routine maintenance operations. (CVE-2016-5424)

• Fix corner-case misbehaviors for IS NULL/IS NOT NULL applied to nested composite values (Andrew Gierth, Tom Lane)

The SQL standard specifies that IS NULL should return TRUE for a row of all null values (thus ROW(NULL,NULL) IS NULL yields TRUE), but this is not meant to apply recursively (thus ROW(NULL, ROW(NULL,NULL)) IS NULL yields FALSE). The core executor got this right, but certain planner optimizations treated the test as recursive (thus producing TRUE in both cases), and contrib/postgres_fdw could produce remote queries that misbehaved similarly.

• Make the inet and cidr data types properly reject IPv6 addresses with too many colon-separated fields (Tom Lane)

• Prevent crash in close_ps() (the point ## lseg operator) for NaN input coordinates (Tom Lane)

Make it return NULL instead of crashing.

• Avoid possible crash in pg_get_expr() when inconsistent values are passed to it (Michael Paquier, Thomas Munro)

• Fix several one-byte buffer over-reads in to_number() (Peter Eisentraut)

In several cases the to_number() function would read one more character than it should from the input string. There is a small chance of a crash, if the input happens to be adjacent to the end of memory.

• Do not run the planner on the query contained in CREATE MATERIALIZED VIEW or CREATE TABLE AS when WITH NO DATA is specified (Michael Paquier, Tom Lane)

This avoids some unnecessary failure conditions, for example if a stable function invoked by the materialized view depends on a table that doesn’t exist yet.

• Avoid unsafe intermediate state during expensive paths through heap_update() (Masahiko Sawada, Andres Freund)

Previously, these cases locked the target tuple (by setting its XMAX) but did not WAL-log that action, thus risking data integrity problems if the page were spilled to disk and then a database crash occurred before the tuple update could be completed.
Appendix E. Release Notes

- Fix hint bit update during WAL replay of row locking operations (Andres Freund)
  The only known consequence of this problem is that row locks held by a prepared, but uncommitted, transaction might fail to be enforced after a crash and restart.

- Avoid unnecessary “could not serialize access” errors when acquiring FOR KEY SHARE row locks in serializable mode (Álvaro Herrera)

- Avoid crash in postgres -C when the specified variable has a null string value (Michael Paquier)

- Fix possible loss of large subtransactions in logical decoding (Petru-Florin Mihancea)

- Fix failure of logical decoding when a subtransaction contains no actual changes (Marko Tiikkaja, Andrew Gierth)

- Ensure that backends see up-to-date statistics for shared catalogs (Tom Lane)
  The statistics collector failed to update the statistics file for shared catalogs after a request from a regular backend. This problem was partially masked because the autovacuum launcher regularly makes requests that did cause such updates; however, it became obvious with autovacuum disabled.

- Avoid redundant writes of the statistics files when multiple backends request updates close together (Tom Lane, Tomas Vondra)

- Avoid consuming a transaction ID during VACUUM (Alexander Korotkov)
  Some cases in VACUUM unnecessarily caused an XID to be assigned to the current transaction. Normally this is negligible, but if one is up against the XID wraparound limit, consuming more XIDs during anti-wraparound vacuums is a very bad thing.

- Avoid canceling hot-standby queries during VACUUM FREEZE (Simon Riggs, Álvaro Herrera)
  VACUUM FREEZE on an otherwise-idle master server could result in unnecessary cancellations of queries on its standby servers.

- Prevent possible failure when vacuuming multixact IDs in an installation that has been pg_upgrade’d from pre-9.3 (Andrew Gierth, Álvaro Herrera)
  The usual symptom of this bug is errors like “MultiXactId NNN has not been created yet -- apparent wraparound”.

- When a manual ANALYZE specifies a column list, don’t reset the table’s changes_since_analyze counter (Tom Lane)
  If we’re only analyzing some columns, we should not prevent routine auto-analyze from happening for the other columns.

- Fix ANALYZE’s overestimation of n_distinct for a unique or nearly-unique column with many null entries (Tom Lane)
  The nulls could get counted as though they were themselves distinct values, leading to serious planner misestimates in some types of queries.

- Prevent autovacuum from starting multiple workers for the same shared catalog (Álvaro Herrera)
  Normally this isn’t much of a problem because the vacuum doesn’t take long anyway; but in the case of a severely bloated catalog, it could result in all but one worker uselessly waiting instead of doing useful work on other tables.

- Avoid duplicate buffer lock release when abandoning a b-tree index page deletion attempt (Tom Lane)
  This mistake prevented VACUUM from completing in some cases involving corrupt b-tree indexes.

- Prevent infinite loop in GiST index build for geometric columns containing NaN component values (Tom Lane)
Appendix E. Release Notes

• Fix contrib/btree_gin to handle the smallest possible bigint value correctly (Peter Eisen-traut)

• Teach libpq to correctly decode server version from future servers (Peter Eisentraut)

  It’s planned to switch to two-part instead of three-part server version numbers for releases after 9.6. Make sure that PQserverVersion() returns the correct value for such cases.

• Fix ecpg’s code for unsigned long long array elements (Michael Meskes)

• In pg_dump with both -c and -C options, avoid emitting an unwanted CREATE SCHEMA public command (David Johnston, Tom Lane)

• Improve handling of SIGTERM/control-C in parallel pg_dump and pg_restore (Tom Lane)

  Make sure that the worker processes will exit promptly, and also arrange to send query-cancel re- quests to the connected backends, in case they are doing something long-running such as a CREATE INDEX.

• Fix error reporting in parallel pg_dump and pg_restore (Tom Lane)

  Previously, errors reported by pg_dump or pg_restore worker processes might never make it to the user’s console, because the messages went through the master process, and there were various deadlock scenarios that would prevent the master process from passing on the messages. Instead, just print everything to stderr. In some cases this will result in duplicate messages (for instance, if all the workers report a server shutdown), but that seems better than no message.

• Ensure that parallel pg_dump or pg_restore on Windows will shut down properly after an error (Kyotaro Horiguchi)

  Previously, it would report the error, but then just sit until manually stopped by the user.

• Make pg_dump behave better when built without zlib support (Kyotaro Horiguchi)

  It didn’t work right for parallel dumps, and emitted some rather pointless warnings in other cases.

• Make pg_basebackup accept -Z 0 as specifying no compression (Fujii Masao)

• Fix makefiles’ rule for building AIX shared libraries to be safe for parallel make (Noah Misch)

• Fix TAP tests and MSVC scripts to work when build directory’s path name contains spaces (Michael Paquier, Kyotaro Horiguchi)

• Be more predictable about reporting “statement timeout” versus “lock timeout” (Tom Lane)

  On heavily loaded machines, the regression tests sometimes failed due to reporting “lock timeout” even though the statement timeout should have occurred first.

• Make regression tests safe for Danish and Welsh locales (Jeff Janes, Tom Lane)

  Change some test data that triggered the unusual sorting rules of these locales.

• Update our copy of the timezone code to match IANA’s tzcode release 2016c (Tom Lane)

  This is needed to cope with anticipated future changes in the time zone data files. It also fixes some corner-case bugs in coping with unusual time zones.

• Update time zone data files to tzdata release 2016f for DST law changes in Kemerovo and Novosibirsk, plus historical corrections for Azerbaijan, Belarus, and Morocco.

E.27. Release 9.4.8

  Release date: 2016-05-12
This release contains a variety of fixes from 9.4.7. For information about new features in the 9.4 major release, see Section E.35.

E.27.1. Migration to Version 9.4.8

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.6, see Section E.29.

E.27.2. Changes

- Clear the OpenSSL error queue before OpenSSL calls, rather than assuming it’s clear already; and make sure we leave it clear afterwards (Peter Geoghegan, Dave Vitek, Peter Eisentraut)

  This change prevents problems when there are multiple connections using OpenSSL within a single process and not all the code involved follows the same rules for when to clear the error queue. Failures have been reported specifically when a client application uses SSL connections in libpq concurrently with SSL connections using the PHP, Python, or Ruby wrappers for OpenSSL. It’s possible for similar problems to arise within the server as well, if an extension module establishes an outgoing SSL connection.

- Fix “failed to build any $i$-way joins” planner error with a full join enclosed in the right-hand side of a left join (Tom Lane)

- Fix incorrect handling of equivalence-class tests in multilevel nestloop plans (Tom Lane)

  Given a three-or-more-way equivalence class of variables, such as $X.X = Y.Y = Z.Z$, it was possible for the planner to omit some of the tests needed to enforce that all the variables are actually equal, leading to join rows being output that didn’t satisfy the WHERE clauses. For various reasons, erroneous plans were seldom selected in practice, so that this bug has gone undetected for a long time.

- Fix query-lifespan memory leak in GIN index scans (Julien Rouhaud)

- Fix query-lifespan memory leak and potential index corruption hazard in GIN index insertion (Tom Lane)

  The memory leak would typically not amount to much in simple queries, but it could be very substantial during a large GIN index build with high maintenance_work_mem.

- Fix possible misbehavior of TH, th, and Y,YYY format codes in to_timestamp() (Tom Lane)

  These could advance off the end of the input string, causing subsequent format codes to read garbage.

- Fix dumping of rules and views in which the array argument of a value operator ANY (array) construct is a sub-SELECT (Tom Lane)

- Disallow newlines in ALTER SYSTEM parameter values (Tom Lane)

  The configuration-file parser doesn’t support embedded newlines in string literals, so we mustn’t allow them in values to be inserted by ALTER SYSTEM.

- Fix ALTER TABLE ... REPLICA IDENTITY USING INDEX to work properly if an index on OID is selected (David Rowley)

- Fix crash in logical decoding on alignment-picky platforms (Tom Lane, Andres Freund)
The failure occurred only with a transaction large enough to spill to disk and a primary-key change within that transaction.

- Avoid repeated requests for feedback from receiver while shutting down walsender (Nick Cleaton)
- Make `pg_regress` use a startup timeout from the `PGCTLTIMEOUT` environment variable, if that’s set (Tom Lane)

  This is for consistency with a behavior recently added to `pg_ctl`; it eases automated testing on slow machines.

- Fix `pg_upgrade` to correctly restore extension membership for operator families containing only one operator class (Tom Lane)

  In such a case, the operator family was restored into the new database, but it was no longer marked as part of the extension. This had no immediate ill effects, but would cause later `pg_dump` runs to emit output that would cause (harmless) errors on restore.

- Fix `pg_upgrade` to not fail when new-cluster TOAST rules differ from old (Tom Lane)

  `pg_upgrade` had special-case code to handle the situation where the new PostgreSQL version thinks that a table should have a TOAST table while the old version did not. That code was broken, so remove it, and instead do nothing in such cases; there seems no reason to believe that we can’t get along fine without a TOAST table if that was okay according to the old version’s rules.

- Reduce the number of SysV semaphores used by a build configured with `--disable-spinlocks` (Tom Lane)

- Rename internal function `strtoi()` to `strtoint()` to avoid conflict with a NetBSD library function (Thomas Munro)

- Fix reporting of errors from `bind()` and `listen()` system calls on Windows (Tom Lane)

- Reduce verbosity of compiler output when building with Microsoft Visual Studio (Christian Ullrich)

- Fix `putenv()` to work properly with Visual Studio 2013 (Michael Paquier)

- Avoid possibly-unsafe use of Windows’ `FormatMessage()` function (Christian Ullrich)

  Use the `FORMAT_MESSAGE_IGNORE_INSERTS` flag where appropriate. No live bug is known to exist here, but it seems like a good idea to be careful.

- Update time zone data files to `tzdata` release 2016d for DST law changes in Russia and Venezuela. There are new zone names `Europe/Kirov` and `Asia/Tomsk` to reflect the fact that these regions now have different time zone histories from adjacent regions.

E.28. Release 9.4.7

**Release date:** 2016-03-31

This release contains a variety of fixes from 9.4.6. For information about new features in the 9.4 major release, see Section E.35.

E.28.1. Migration to Version 9.4.7

A dump/restore is not required for those running 9.4.X. However, if you are upgrading from a version earlier than 9.4.6, see Section E.29.
E.28.2. Changes

- Fix incorrect handling of NULL index entries in indexed \texttt{ROW()} comparisons (Tom Lane)
  
  An index search using a row comparison such as \texttt{ROW(a, b) > ROW(’x’, ’y’)} would stop upon reaching a NULL entry in the \texttt{b} column, ignoring the fact that there might be non-NULL \texttt{b} values associated with later values of \texttt{a}.

- Avoid unlikely data-loss scenarios due to renaming files without adequate \texttt{fsync()} calls before and after (Michael Paquier, Tomas Vondra, Andres Freund)

- Fix bug in \texttt{json_to_record()} when a field of its input object contains a sub-object with a field name matching one of the requested output column names (Tom Lane)

- Fix misformatting of negative time zone offsets by \texttt{to_char()}’s \texttt{OF} format code (Thomas Munro, Tom Lane)

- Ignore recovery\_min\_apply\_delay parameter until recovery has reached a consistent state (Michael Paquier)
  
  Previously, standby servers would delay application of WAL records in response to \texttt{recovery\_min\_apply\_delay} even while replaying the initial portion of WAL needed to make their database state valid. Since the standby is useless until it’s reached a consistent database state, this was deemed unhelpful.

- Correctly handle cases where \texttt{pg\_subtrans} is close to XID wraparound during server startup (Jeff Janes)

- Fix assorted bugs in logical decoding (Andres Freund)
  
  Trouble cases included tuples larger than one page when replica identity is \texttt{FULL}, \texttt{UPDATES} that change a primary key within a transaction large enough to be spooled to disk, incorrect reports of “subxact logged without previous toplevel record”, and incorrect reporting of a transaction’s commit time.

- Fix planner error with nested security barrier views when the outer view has a \texttt{WHERE} clause containing a correlated subquery (Dean Rasheed)

- Fix corner-case crash due to trying to free \texttt{localeconv()} output strings more than once (Tom Lane)

- Fix parsing of affix files for \texttt{ispell} dictionaries (Tom Lane)
  
  The code could go wrong if the affix file contained any characters whose byte length changes during case-folding, for example \texttt{I} in Turkish UTF8 locales.

- Avoid use of \texttt{sscanf()} to parse \texttt{ispell} dictionary files (Artur Zakirov)
  
  This dodges a portability problem on FreeBSD-derived platforms (including macOS).

- Avoid a crash on old Windows versions (before 7SP1/2008R2SP1) with an AVX2-capable CPU and a Postgres build done with Visual Studio 2013 (Christian Ullrich)
  
  This is a workaround for a bug in Visual Studio 2013’s runtime library, which Microsoft have stated they will not fix in that version.

- Fix psql’s tab completion logic to handle multibyte characters properly (Kyotaro Horiguchi, Robert Haas)

- Fix psql’s tab completion for \texttt{SECURITY LABEL} (Tom Lane)
  
  Pressing TAB after \texttt{SECURITY LABEL} might cause a crash or offering of inappropriate keywords.
Appendix E. Release Notes

- Make pg_ctl accept a wait timeout from the PGCTLTIMEOUT environment variable, if none is specified on the command line (Noah Misch)
  This eases testing of slower buildfarm members by allowing them to globally specify a longer-than-normal timeout for postmaster startup and shutdown.
- Fix incorrect test for Windows service status in pg_ctl (Manuel Mathar)
  The previous set of minor releases attempted to fix pg_ctl to properly determine whether to send log messages to Window’s Event Log, but got the test backwards.
- Fix pgbench to correctly handle the combination of -C and -M prepared options (Tom Lane)
- In pg_upgrade, skip creating a deletion script when the new data directory is inside the old data directory (Bruce Momjian)
  Blind application of the script in such cases would result in loss of the new data directory.
- In PL/Perl, properly translate empty Postgres arrays into empty Perl arrays (Alex Hunsaker)
- Make PL/Python cope with function names that aren’t valid Python identifiers (Jim Nasby)
- Fix multiple mistakes in the statistics returned by contrib/pgstattuple's pgstatindex() function (Tom Lane)
- Remove dependency on psed in MSVC builds, since it’s no longer provided by core Perl (Michael Paquier, Andrew Dunstan)
- Update time zone data files to tzdata release 2016c for DST law changes in Azerbaijan, Chile, Haiti, Palestine, and Russia (Altai, Astrakhan, Kirov, Sakhalin, Ulyanovsk regions), plus historical corrections for Lithuania, Moldova, and Russia (Kaliningrad, Samara, Volgograd).

E.29. Release 9.4.6

Release date: 2016-02-11
This release contains a variety of fixes from 9.4.5. For information about new features in the 9.4 major release, see Section E.35.

E.29.1. Migration to Version 9.4.6

A dump/restore is not required for those running 9.4.X.
However, if you are upgrading an installation that contains any GIN indexes that use the (non-default) jsonb_path_ops operator class, see the first changelog entry below.
Also, if you are upgrading from a version earlier than 9.4.4, see Section E.31.

E.29.2. Changes

- Fix inconsistent hash calculations in jsonb_path_ops GIN indexes (Tom Lane)
  When processing jsonb values that contain both scalars and sub-objects at the same nesting level, for example an array containing both scalars and sub-arrays, key hash values could be calculated differently than they would be for the same key in a different context. This could result in queries
not finding entries that they should find. Fixing this means that existing indexes may now be inconsistent with the new hash calculation code. Users should `REINDEX jsonb_path_ops GIN indexes` after installing this update to make sure that all searches work as expected.

- **Fix infinite loops and buffer-overrun problems in regular expressions (Tom Lane)**
  
  Very large character ranges in bracket expressions could cause infinite loops in some cases, and memory overwrites in other cases. (CVE-2016-0773)

- **Perform an immediate shutdown if the `postmaster.pid` file is removed (Tom Lane)**
  
  The postmaster now checks every minute or so that `postmaster.pid` is still there and still contains its own PID. If not, it performs an immediate shutdown, as though it had received SIGQUIT. The main motivation for this change is to ensure that failed buildfarm runs will get cleaned up without manual intervention; but it also serves to limit the bad effects if a DBA forcibly removes `postmaster.pid` and then starts a new postmaster.

- **In `SERIALIZABLE` transaction isolation mode, serialization anomalies could be missed due to race conditions during insertions (Kevin Grittner, Thomas Munro)**

- **Fix failure to emit appropriate WAL records when doing `ALTER TABLE ... SET TABLESPACE` for unlogged relations (Michael Paquier, Andres Freund)**
  
  Even though the relation’s data is unlogged, the move must be logged or the relation will be inaccessible after a standby is promoted to master.

- **Fix possible misinitialization of unlogged relations at the end of crash recovery (Andres Freund, Michael Paquier)**

- **Ensure walsender slots are fully re-initialized when being re-used (Magnus Hagander)**

- **Fix `ALTER COLUMN TYPE` to reconstruct inherited check constraints properly (Tom Lane)**

- **Fix `REASSIGN OWNED` to change ownership of composite types properly (Álvaro Herrera)**

- **Fix `REASSIGN OWNED` and `ALTER OWNER` to correctly update granted-permissions lists when changing owners of data types, foreign data wrappers, or foreign servers (Bruce Momjian, Álvaro Herrera)**

- **Fix `REASSIGN OWNED` to ignore foreign user mappings, rather than fail (Álvaro Herrera)**

- **Fix possible crash after doing query rewrite for an updatable view (Stephen Frost)**

- **Fix planner’s handling of `LATERAL` references (Tom Lane)**
  
  This fixes some corner cases that led to “failed to build any N-way joins” or “could not devise a query plan” planner failures.

- **Add more defenses against bad planner cost estimates for GIN index scans when the index’s internal statistics are very out-of-date (Tom Lane)**

- **Make planner cope with hypothetical GIN indexes suggested by an index advisor plug-in (Julien Rouhaud)**

- **Speed up generation of unique table aliases in `EXPLAIN` and rule dumping, and ensure that generated aliases do not exceed `NAMEDATALEN` (Tom Lane)**

- **Fix dumping of whole-row Vars in `ROW()` and `VALUES()` lists (Tom Lane)**

- **Translation of minus-infinity dates and timestamps to `json` or `jsonb` incorrectly rendered them as plus-infinity (Tom Lane)**

- **Fix possible internal overflow in `numeric` division (Dean Rasheed)**

- **Fix enforcement of restrictions inside parentheses within regular expression lookahead constraints (Tom Lane)**
Lookahead constraints aren’t allowed to contain backrefs, and parentheses within them are always considered non-capturing, according to the manual. However, the code failed to handle these cases properly inside a parenthesized subexpression, and would give unexpected results.

- Conversion of regular expressions to indexscan bounds could produce incorrect bounds from regexps containing lookahead constraints (Tom Lane)
- Fix regular-expression compiler to handle loops of constraint arcs (Tom Lane)

The code added for CVE-2007-4772 was both incomplete, in that it didn’t handle loops involving more than one state, and incorrect, in that it could cause assertion failures (though there seem to be no bad consequences of that in a non-assert build). Multi-state loops would cause the compiler to run until the query was canceled or it reached the too-many-states error condition.

- Improve memory-usage accounting in regular-expression compiler (Tom Lane)

This causes the code to emit “regular expression is too complex” errors in some cases that previously used unreasonable amounts of time and memory.

- Improve performance of regular-expression compiler (Tom Lane)
- Make %h and %r escapes in log_line_prefix work for messages emitted due to log_connections (Tom Lane)

Previously, %h/%r started to work just after a new session had emitted the “connection received” log message; now they work for that message too.

- On Windows, ensure the shared-memory mapping handle gets closed in child processes that don’t need it (Tom Lane, Amit Kapila)

This oversight resulted in failure to recover from crashes whenever logging_collector is turned on.

- Fix possible failure to detect socket EOF in non-blocking mode on Windows (Tom Lane)

It’s not entirely clear whether this problem can happen in pre-9.5 branches, but if it did, the symptom would be that a walsender process would wait indefinitely rather than noticing a loss of connection.

- Avoid leaking a token handle during SSPI authentication (Christian Ullrich)

- In psql, ensure that libreadline’s idea of the screen size is updated when the terminal window size changes (Merlin Moncure)

Previously, libreadline did not notice if the window was resized during query output, leading to strange behavior during later input of multiline queries.

- Fix psql’s \det command to interpret its pattern argument the same way as other \d commands with potentially schema-qualified patterns do (Reece Hart)

- Avoid possible crash in psql’s \c command when previous connection was via Unix socket and command specifies a new hostname and same username (Tom Lane)

- In pg_ctl start -w, test child process status directly rather than relying on heuristics (Tom Lane, Michael Paquier)

Previously, pg_ctl relied on an assumption that the new postmaster would always create postmaster.pid within five seconds. But that can fail on heavily-loaded systems, causing pg_ctl to report incorrectly that the postmaster failed to start.

Except on Windows, this change also means that a pg_ctl start -w done immediately after another such command will now reliably fail, whereas previously it would report success if done within two seconds of the first command.
Appendix E. Release Notes

• In `pg_ctl start -w`, don’t attempt to use a wildcard listen address to connect to the postmaster (Kondo Yuta)

  On Windows, `pg_ctl` would fail to detect postmaster startup if `listen_addresses` is set to `0.0.0.0` or `::`, because it would try to use that value verbatim as the address to connect to, which doesn’t work. Instead assume that `127.0.0.1` or `::1`, respectively, is the right thing to use.

• In `pg_ctl` on Windows, check service status to decide where to send output, rather than checking if standard output is a terminal (Michael Paquier)

• In `pg_dump` and `pg_basebackup`, adopt the GNU convention for handling tar-archive members exceeding 8GB (Tom Lane)

  The POSIX standard for `tar` file format does not allow archive member files to exceed 8GB, but most modern implementations of tar support an extension that fixes that. Adopt this extension so that `pg_dump` with `-Ft` no longer fails on tables with more than 8GB of data, and so that `pg_basebackup` can handle files larger than 8GB. In addition, fix some portability issues that could cause failures for members between 4GB and 8GB on some platforms. Potentially these problems could cause unrecoverable data loss due to unreadable backup files.

• Fix assorted corner-case bugs in `pg_dump`’s processing of extension member objects (Tom Lane)

• Make `pg_dump` mark a view’s triggers as needing to be processed after its rule, to prevent possible failure during parallel `pg_restore` (Tom Lane)

• Ensure that relation option values are properly quoted in `pg_dump` (Kouhei Sutou, Tom Lane)

  A reloption value that isn’t a simple identifier or number could lead to dump/reload failures due to syntax errors in CREATE statements issued by `pg_dump`. This is not an issue with any reloption currently supported by core PostgreSQL, but extensions could allow reloptions that cause the problem.

• Avoid repeated password prompts during parallel `pg_dump` (Zeus Kronion)

• Fix `pg_upgrade`’s file-copying code to handle errors properly on Windows (Bruce Momjian)

• Install guards in `pgbench` against corner-case overflow conditions during evaluation of script-specified division or modulo operators (Fabien Coelho, Michael Paquier)

• Fix failure to localize messages emitted by `pg_receivexlog` and `pg_recvlogical` (Ioseph Kim)

• Avoid dump/reload problems when using both `plpython2` and `plpython3` (Tom Lane)

  In principle, both versions of PL/Python can be used in the same database, though not in the same session (because the two versions of libpython cannot safely be used concurrently). However, `pg_restore` and `pg_upgrade` both do things that can fall foul of the same-session restriction. Work around that by changing the timing of the check.

• Fix PL/Python regression tests to pass with Python 3.5 (Peter Eisentraut)

• Fix premature clearing of libpq’s input buffer when socket EOF is seen (Tom Lane)

  This mistake caused libpq to sometimes not report the backend’s final error message before reporting “server closed the connection unexpectedly”.

• Prevent certain PL/Java parameters from being set by non-superusers (Noah Misch)

  This change mitigates a PL/Java security bug (CVE-2016-0766), which was fixed in PL/Java by marking these parameters as superuser-only. To fix the security hazard for sites that updated PostgreSQL more frequently than PL/Java, make the core code aware of them also.

• Improve libpq’s handling of out-of-memory situations (Michael Paquier, Amit Kapila, Heikki Linnakangas)
• Fix order of arguments in ecpg-generated typedef statements (Michael Meskes)
• Use %g not %f format in ecpg's PGTYPESnumeric_from_double() (Tom Lane)
• Fix ecpg-supplied header files to not contain comments continued from a preprocessor directive line onto the next line (Michael Meskes)

  Such a comment is rejected by ecpg. It’s not yet clear whether ecpg itself should be changed.
• Fix hstore_to_json_loose()'s test for whether an hstore value can be converted to a JSON number (Tom Lane)

  Previously this function could be fooled by non-alphanumeric trailing characters, leading to emitting syntactically-invalid JSON.
• Ensure that contrib/pgcrypto's crypt() function can be interrupted by query cancel (Andreas Karlsson)
• In contrib/postgres_fdw, fix bugs triggered by use of tableoid in data-modifying commands (Etsuro Fujita, Robert Haas)
• Accept flex versions later than 2.5.x (Tom Lane, Michael Paquier)

  Now that flex 2.6.0 has been released, the version checks in our build scripts needed to be adjusted.
• Improve reproducibility of build output by ensuring filenames are given to the linker in a fixed order (Christoph Berg)

  This avoids possible bitwise differences in the produced executable files from one build to the next.
• Install our missing script where PGXS builds can find it (Jim Nasby)

  This allows sane behavior in a PGXS build done on a machine where build tools such as bison are missing.
• Ensure that dynloader.h is included in the installed header files in MSVC builds (Bruce Momjian, Michael Paquier)
• Add variant regression test expected-output file to match behavior of current libxml2 (Tom Lane)

  The fix for libxml2’s CVE-2015-7499 causes it not to output error context reports in some cases where it used to do so. This seems to be a bug, but we’ll probably have to live with it for some time, so work around it.
• Update time zone data files to tzdata release 2016a for DST law changes in Cayman Islands, Metlakatla, and Trans-Baikal Territory (Zabaykalsky Krai), plus historical corrections for Pakistan.

E.30. Release 9.4.5

Release date: 2015-10-08

This release contains a variety of fixes from 9.4.4. For information about new features in the 9.4 major release, see Section E.35.

E.30.1. Migration to Version 9.4.5

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.4, see Section E.31.
E.30.2. Changes

- Guard against stack overflows in `json` parsing (Oskari Saarenmaa)
  If an application constructs PostgreSQL `json` or `jsonb` values from arbitrary user input, the application’s users can reliably crash the PostgreSQL server, causing momentary denial of service. (CVE-2015-5289)

- Fix `contrib/pgcrypto` to detect and report too-short `crypt()` salts (Josh Kupershmidt)
  Certain invalid salt arguments crashed the server or disclosed a few bytes of server memory. We have not ruled out the viability of attacks that arrange for presence of confidential information in the disclosed bytes, but they seem unlikely. (CVE-2015-5288)

- Fix subtransaction cleanup after a portal (cursor) belonging to an outer subtransaction fails (Tom Lane, Michael Paquier)
  A function executed in an outer-subtransaction cursor could cause an assertion failure or crash by referencing a relation created within an inner subtransaction.

- Fix possible deadlock during WAL insertion when `commit_delay` is set (Heikki Linnakangas)

- Ensure all relations referred to by an updatable view are properly locked during an update statement (Dean Rasheed)

- Fix insertion of relations into the relation cache “init file” (Tom Lane)
  An oversight in a patch in the most recent minor releases caused `pg_trigger_tgrelid_tgname_index` to be omitted from the init file. Subsequent sessions detected this, then deemed the init file to be broken and silently ignored it, resulting in a significant degradation in session startup time. In addition to fixing the bug, install some guards so that any similar future mistake will be more obvious.

- Avoid O(N^2) behavior when inserting many tuples into a SPI query result (Neil Conway)

- Improve `LISTEN` startup time when there are many unread notifications (Matt Newell)

- Fix performance problem when a session alters large numbers of foreign key constraints (Jan Wieck, Tom Lane)
  This was seen primarily when restoring `pg_dump` output for databases with many thousands of tables.

- Disable SSL renegotiation by default (Michael Paquier, Andres Freund)
  While use of SSL renegotiation is a good idea in theory, we have seen too many bugs in practice, both in the underlying OpenSSL library and in our usage of it. Renegotiation will be removed entirely in 9.5 and later. In the older branches, just change the default value of `ssl_renegotiation_limit` to zero (disabled).

- Lower the minimum values of the `_freeze_max_age` parameters (Andres Freund)
  This is mainly to make tests of related behavior less time-consuming, but it may also be of value for installations with limited disk space.

- Limit the maximum value of `wal_buffers` to 2GB to avoid server crashes (Josh Berkus)

- Avoid logging complaints when a parameter that can only be set at server start appears multiple times in `postgresql.conf`, and fix counting of line numbers after an `include_dir` directive (Tom Lane)

- Fix rare internal overflow in multiplication of `numeric` values (Dean Rasheed)
Appendix E. Release Notes

- Guard against hard-to-reach stack overflows involving record types, range types, json, jsonb, tsquery, ltxtquery and query_int (Noah Misch)
- Fix handling of DOW and DOY in datetime input (Greg Stark)
  These tokens aren’t meant to be used in datetime values, but previously they resulted in opaque internal error messages rather than “invalid input syntax”.
- Add more query-cancel checks to regular expression matching (Tom Lane)
- Add recursion depth protections to regular expression, SIMILAR TO, and LIKE matching (Tom Lane)
  Suitable search patterns and a low stack depth limit could lead to stack-overrun crashes.
- Fix potential infinite loop in regular expression execution (Tom Lane)
  A search pattern that can apparently match a zero-length string, but actually doesn’t match because of a back reference, could lead to an infinite loop.
- In regular expression execution, correctly record match data for capturing parentheses within a quantifier even when the match is zero-length (Tom Lane)
- Fix low-memory failures in regular expression compilation (Andreas Seltenreich)
- Fix low-probability memory leak during regular expression execution (Tom Lane)
- Fix rare low-memory failure in lock cleanup during transaction abort (Tom Lane)
- Fix “unexpected out-of-memory situation during sort” errors when using tuplestores with small work_mem settings (Tom Lane)
- Fix very-low-probability stack overrun in qsort (Tom Lane)
- Fix “invalid memory alloc request size” failure in hash joins with large work_mem settings (Tomas Vondra, Tom Lane)
- Fix assorted planner bugs (Tom Lane)
  These mistakes could lead to incorrect query plans that would give wrong answers, or to assertion failures in assert-enabled builds, or to odd planner errors such as “could not devise a query plan for the given query”, “could not find pathkey item to sort”, “plan should not reference subplan’s variable”, or “failed to assign all NestLoopParams to plan nodes”. Thanks are due to Andreas Seltenreich and Piotr Stefaniak for fuzz testing that exposed these problems.
- Improve planner’s performance for UPDATE/DELETE on large inheritance sets (Tom Lane, Dean Rasheed)
- Ensure standby promotion trigger files are removed at postmaster startup (Michael Paquier, Fujii Masao)
  This prevents unwanted promotion from occurring if these files appear in a database backup that is used to initialize a new standby server.
- During postmaster shutdown, ensure that per-socket lock files are removed and listen sockets are closed before we remove the postmaster.pid file (Tom Lane)
  This avoids race-condition failures if an external script attempts to start a new postmaster as soon as pg_ctl stop returns.
- Ensure that the postmaster does not exit until all its child processes are gone, even in an immediate shutdown (Tom Lane)
  Like the previous item, this avoids possible race conditions against a subsequently-started postmaster.
Appendix E. Release Notes

- Fix postmaster’s handling of a startup-process crash during crash recovery (Tom Lane)

  If, during a crash recovery cycle, the startup process crashes without having restored database consistency, we’d try to launch a new startup process, which typically would just crash again, leading to an infinite loop.

- Make emergency autovacuuming for multixact wraparound more robust (Andres Freund)

- Do not print a WARNING when an autovacuum worker is already gone when we attempt to signal it, and reduce log verbosity for such signals (Tom Lane)

- Prevent autovacuum launcher from sleeping unduly long if the server clock is moved backwards a large amount (Álvaro Herrera)

- Ensure that cleanup of a GIN index’s pending-insertions list is interruptable by cancel requests (Jeff Janes)

- Allow all-zeroes pages in GIN indexes to be reused (Heikki Linnakangas)

  Such a page might be left behind after a crash.

- Fix handling of all-zeroes pages in SP-GiST indexes (Heikki Linnakangas)

  VACUUM attempted to recycle such pages, but did so in a way that wasn’t crash-safe.

- Fix off-by-one error that led to otherwise-harmless warnings about “apparent wraparound” in subtrans/multixact truncation (Thomas Munro)

- Fix misreporting of CONTINUE and MOVE statement types in PL/pgSQL’s error context messages (Pavel Stehule, Tom Lane)

- Fix PL/Perl to handle non-ASCII error message texts correctly (Alex Hunsaker)

- Fix PL/Python crash when returning the string representation of a record result (Tom Lane)

- Fix some places in PL/Tcl that neglected to check for failure of malloc() calls (Michael Paquier, Álvaro Herrera)

- In contrib/isn, fix output of ISBN-13 numbers that begin with 979 (Fabien Coelho)

  EANs beginning with 979 (but not 9790) are considered ISBNs, but they must be printed in the new 13-digit format, not the 10-digit format.

- Improve contrib/pg_stat_statements’ handling of query-text garbage collection (Peter Geoghegan)

  The external file containing query texts could bloat to very large sizes; once it got past 1GB attempts to trim it would fail, soon leading to situations where the file could not be read at all.

- Improve contrib/postgres_fdw’s handling of collation-related decisions (Tom Lane)

  The main user-visible effect is expected to be that comparisons involving varchar columns will be sent to the remote server for execution in more cases than before.

- Improve libpq’s handling of out-of-memory conditions (Michael Paquier, Heikki Linnakangas)

- Fix memory leaks and missing out-of-memory checks in ecpg (Michael Paquier)

- Fix psql’s code for locale-aware formatting of numeric output (Tom Lane)

  The formatting code invoked by \pset numericlocale on did the wrong thing for some uncommon cases such as numbers with an exponent but no decimal point. It could also mangle already-localized output from the money data type.

- Prevent crash in psql’s \c command when there is no current connection (Noah Misch)

- Make pg_dump handle inherited NOT VALID check constraints correctly (Tom Lane)
• Fix selection of default zlib compression level in pg_dump’s directory output format (Andrew Dunstan)

• Ensure that temporary files created during a pg_dump run with tar-format output are not world-readable (Michael Paquier)

• Fix pg_dump and pg_upgrade to support cases where the postgres or template1 database is in a non-default tablespace (Marti Raudsepp, Bruce Momjian)

• Fix pg_dump to handle object privileges sanely when dumping from a server too old to have a particular privilege type (Tom Lane)

When dumping data types from pre-9.2 servers, and when dumping functions or procedural languages from pre-7.3 servers, pg_dump would produce GRANT/REVOKE commands that revoked the owner’s grantable privileges and instead granted all privileges to PUBLIC. Since the privileges involved are just USAGE and EXECUTE, this isn’t a security problem, but it’s certainly a surprising representation of the older systems’ behavior. Fix it to leave the default privilege state alone in these cases.

• Fix pg_dump to dump shell types (Tom Lane)

Shell types (that is, not-yet-fully-defined types) aren’t useful for much, but nonetheless pg_dump should dump them.

• Fix assorted minor memory leaks in pg_dump and other client-side programs (Michael Paquier)

• Fix pgbench’s progress-report behavior when a query, or pgbench itself, gets stuck (Fabien Coelho)

• Fix spinlock assembly code for Alpha hardware (Tom Lane)

• Fix spinlock assembly code for PPC hardware to be compatible with AIX’s native assembler (Tom Lane)

Building with gcc didn’t work if gcc had been configured to use the native assembler, which is becoming more common.

• On AIX, test the -qlonglong compiler option rather than just assuming it’s safe to use (Noah Misch)

• On AIX, use -Wl,-brtllib link option to allow symbols to be resolved at runtime (Noah Misch)

Perl relies on this ability in 5.8.0 and later.

• Avoid use of inline functions when compiling with 32-bit xlc, due to compiler bugs (Noah Misch)

• Use librt for sched_yield() when necessary, which it is on some Solaris versions (Oskari Saarenmaa)

• Translate encoding UHC as Windows code page 949 (Noah Misch)

This fixes presentation of non-ASCII log messages from processes that are not attached to any particular database, such as the postmaster.

• On Windows, avoid failure when doing encoding conversion to UTF16 outside a transaction, such as for log messages (Noah Misch)

• Fix postmaster startup failure due to not copying setlocale()’s return value (Noah Misch)

This has been reported on Windows systems with the ANSI code page set to CP936 (“Chinese (Simplified, PRC)”), and may occur with other multibyte code pages.

• Fix Windows install.bat script to handle target directory names that contain spaces (Heikki Linnakangas)

• Make the numeric form of the PostgreSQL version number (e.g., 90405) readily available to extension Makefiles, as a variable named VERSION_NUM (Michael Paquier)
• Update time zone data files to tzdata release 2015g for DST law changes in Cayman Islands, Fiji, Moldova, Morocco, Norfolk Island, North Korea, Turkey, and Uruguay. There is a new zone name America/Fort_Nelson for the Canadian Northern Rockies.

E.31. Release 9.4.4

Release date: 2015-06-12

This release contains a small number of fixes from 9.4.3. For information about new features in the 9.4 major release, see Section E.35.

E.31.1. Migration to Version 9.4.4

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading an installation that was previously upgraded using a pg_upgrade version between 9.3.0 and 9.3.4 inclusive, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.4.2, see Section E.33.

E.31.2. Changes

• Fix possible failure to recover from an inconsistent database state (Robert Haas)

Recent PostgreSQL releases introduced mechanisms to protect against multi-xact wraparound, but some of that code did not account for the possibility that it would need to run during crash recovery, when the database may not be in a consistent state. This could result in failure to restart after a crash, or failure to start up a secondary server. The lingering effects of a previously-fixed bug in pg_upgrade could also cause such a failure, in installations that had used pg_upgrade versions between 9.3.0 and 9.3.4.

The pg_upgrade bug in question was that it would set oldestMultiXid to 1 in pg_control even if the true value should be higher. With the fixes introduced in this release, such a situation will result in immediate emergency autovacuuming until a correct oldestMultiXid value can be determined. If that would pose a hardship, users can avoid it by doing manual vacuuming before upgrading to this release. In detail:

1. Check whether pg_controldata reports “Latest checkpoint’s oldestMultiXid” to be 1. If not, there’s nothing to do.

2. Look in PGDATA/pg_multixact/offsets to see if there’s a file named 0000. If there is, there’s nothing to do.

3. Otherwise, for each table that has pg_class.relminmxid equal to 1, VACUUM that table with both vacuum_multixact_freeze_min_age and vacuum_multixact_freeze_table_age set to zero. (You can use the vacuum cost delay parameters described in Section 18.4.4 to reduce the performance consequences for concurrent sessions.)

• Fix rare failure to invalidate relation cache init file (Tom Lane)
With just the wrong timing of concurrent activity, a `VACUUM FULL` on a system catalog might fail to update the "init file" that’s used to avoid cache-loading work for new sessions. This would result in later sessions being unable to access that catalog at all. This is a very ancient bug, but it’s so hard to trigger that no reproducible case had been seen until recently.

- **Avoid deadlock between incoming sessions and `CREATE/DROP DATABASE`** (Tom Lane)
  
  A new session starting in a database that is the target of a `DROP DATABASE` command, or is the template for a `CREATE DATABASE` command, could cause the command to wait for five seconds and then fail, even if the new session would have exited before that.

- **Improve planner’s cost estimates for semi-joins and anti-joins with inner indexscans** (Tom Lane, Tomas Vondra)
  
  This type of plan is quite cheap when all the join clauses are used as index scan conditions, even if the inner scan would nominally fetch many rows, because the executor will stop after obtaining one row. The planner only partially accounted for that effect, and would therefore overestimate the cost, leading it to possibly choose some other much less efficient plan type.

---

### E.32. Release 9.4.3

**Release date:** 2015-06-04

This release contains a small number of fixes from 9.4.2. For information about new features in the 9.4 major release, see Section E.35.

### E.32.1. Migration to Version 9.4.3

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.2, see Section E.33.

### E.32.2. Changes

- **Avoid failures while `fsync`ing data directory during crash restart** (Abhijit Menon-Sen, Tom Lane)
  
  In the previous minor releases we added a patch to `fsync` everything in the data directory after a crash. Unfortunately its response to any error condition was to fail, thereby preventing the server from starting up, even when the problem was quite harmless. An example is that an unwritable file in the data directory would prevent restart on some platforms; but it is common to make SSL certificate files unwritable by the server. Revise this behavior so that permissions failures are ignored altogether, and other types of failures are logged but do not prevent continuing.

  Also apply the same rules in `initdb --sync-only`. This case is less critical but it should act similarly.

- **Fix `pg_get_functiondef()` to show functions’ LEAKPROOF property, if set** (Jeevan Chalke)

- **Fix `pushJsonbValue()` to unpack `jbvBinary` objects** (Andrew Dunstan)
  
  This change does not affect any behavior in the core code as of 9.4, but it avoids a corner case for possible third-party callers.

- **Remove configure’s check prohibiting linking to a threaded libpython on OpenBSD** (Tom Lane)
Appendix E. Release Notes

The failure this restriction was meant to prevent seems to not be a problem anymore on current OpenBSD versions.

E.33. Release 9.4.2

Release date: 2015-05-22

This release contains a variety of fixes from 9.4.1. For information about new features in the 9.4 major release, see Section E.35.

E.33.1. Migration to Version 9.4.2

A dump/restore is not required for those running 9.4.X.

However, if you use contrib/citext’s regexp_matches() functions, see the changelog entry below about that.

Also, if you are upgrading from a version earlier than 9.4.1, see Section E.34.

E.33.2. Changes

- Avoid possible crash when client disconnects just before the authentication timeout expires (Benkocs Norbert Attila)
  If the timeout interrupt fired partway through the session shutdown sequence, SSL-related state would be freed twice, typically causing a crash and hence denial of service to other sessions. Experimentation shows that an unauthenticated remote attacker could trigger the bug somewhat consistently, hence treat as security issue. (CVE-2015-3165)

- Improve detection of system-call failures (Noah Misch)
  Our replacement implementation of snprintf() failed to check for errors reported by the underlying system library calls; the main case that might be missed is out-of-memory situations. In the worst case this might lead to information exposure, due to our code assuming that a buffer had been overwritten when it hadn’t been. Also, there were a few places in which security-relevant calls of other system library functions did not check for failure.
  It remains possible that some calls of the *printf() family of functions are vulnerable to information disclosure if an out-of-memory error occurs at just the wrong time. We judge the risk to not be large, but will continue analysis in this area. (CVE-2015-3166)

- In contrib/pgcrypto, uniformly report decryption failures as “Wrong key or corrupt data” (Noah Misch)
  Previously, some cases of decryption with an incorrect key could report other error message texts. It has been shown that such variance in error reports can aid attackers in recovering keys from other systems. While it’s unknown whether pgcrypto’s specific behaviors are likewise exploitable, it seems better to avoid the risk by using a one-size-fits-all message. (CVE-2015-3167)

- Protect against wraparound of multixact member IDs (Álvaro Herrera, Robert Haas, Thomas Munro)
Under certain usage patterns, the existing defenses against this might be insufficient, allowing `pg_multixact/members` files to be removed too early, resulting in data loss. The fix for this includes modifying the server to fail transactions that would result in overwriting old multixact member ID data, and improving autovacuum to ensure it will act proactively to prevent multixact member ID wraparound, as it does for transaction ID wraparound.

- **Fix incorrect declaration of contrib/citext’s `regexp_matches()` functions (Tom Lane)**

  These functions should return `setof text[]`, like the core functions they are wrappers for; but they were incorrectly declared as returning just `text[]`. This mistake had two results: first, if there was no match you got a scalar null result, whereas what you should get is an empty set (zero rows). Second, the `g` flag was effectively ignored, since you would get only one result array even if there were multiple matches.

  While the latter behavior is clearly a bug, there might be applications depending on the former behavior; therefore the function declarations will not be changed by default until PostgreSQL 9.5. In pre-9.5 branches, the old behavior exists in version 1.0 of the citext extension, while we have provided corrected declarations in version 1.1 (which is not installed by default). To adopt the fix in pre-9.5 branches, execute `ALTER EXTENSION citext UPDATE TO '1.1'` in each database in which citext is installed. (You can also “update” back to 1.0 if you need to undo that.) Be aware that either update direction will require dropping and recreating any views or rules that use citext’s `regexp_matches()` functions.

- **Render infinite dates and timestamps as `infinity` when converting to json, rather than throwing an error (Andrew Dunstan)**

- **Fix json/jsonb’s `populate_record()` and `to_record()` functions to handle empty input properly (Andrew Dunstan)**

- **Fix incorrect checking of deferred exclusion constraints after a HOT update (Tom Lane)**

  If a new row that potentially violates a deferred exclusion constraint is HOT-updated (that is, no indexed columns change and the row can be stored back onto the same table page) later in the same transaction, the exclusion constraint would be reported as violated when the check finally occurred, even if the row(s) the new row originally conflicted with had been deleted.

- **Fix behavior when changing foreign key constraint deferrability status with `ALTER TABLE ... ALTER CONSTRAINT` (Tom Lane)**

  Operations later in the same session or concurrent sessions might not honor the status change promptly.

- **Fix planning of star-schema-style queries (Tom Lane)**

  Sometimes, efficient scanning of a large table requires that index parameters be provided from more than one other table (commonly, dimension tables whose keys are needed to index a large fact table). The planner should be able to find such plans, but an overly restrictive search heuristic prevented it.

- **Prevent improper reordering of antijoins (NOT EXISTS joins) versus other outer joins (Tom Lane)**

  This oversight in the planner has been observed to cause “could not find RelOptInfo for given relids” errors, but it seems possible that sometimes an incorrect query plan might get past that consistency check and result in silently-wrong query output.

- **Fix incorrect matching of subexpressions in outer-join plan nodes (Tom Lane)**

  Previously, if textually identical non-strict subexpressions were used both above and below an outer join, the planner might try to re-use the value computed below the join, which would be incorrect because the executor would force the value to NULL in case of an unmatched outer row.
• Fix GEQO planner to cope with failure of its join order heuristic (Tom Lane)
  This oversight has been seen to lead to “failed to join all relations together” errors in queries involving LATERAL, and that might happen in other cases as well.

• Ensure that row locking occurs properly when the target of an UPDATE or DELETE is a security-barrier view (Stephen Frost)

• Use a file opened for read/write when syncing replication slot data during database startup (Andres Freund)
  On some platforms, the previous coding could result in errors like “could not fsync file ”pg_replslot/...”: Bad file descriptor”.

• Fix possible deadlock at startup when max_prepared_transactions is too small (Heikki Linnakangas)

• Don’t archive useless preallocated WAL files after a timeline switch (Heikki Linnakangas)

• Recursively fsync() the data directory after a crash (Abhijit Menon-Sen, Robert Haas)
  This ensures consistency if another crash occurs shortly later. (The second crash would have to be a system-level crash, not just a database crash, for there to be a problem.)

• Fix autovacuum launcher’s possible failure to shut down, if an error occurs after it receives SIGTERM (Álvaro Herrera)

• Fix failure to handle invalidation messages for system catalogs early in session startup (Tom Lane)
  This oversight could result in failures in sessions that start concurrently with a VACUUM FULL on a system catalog.

• Fix crash in BackendIdGetTransactionIds() when trying to get status for a backend process that just exited (Tom Lane)

• Cope with unexpected signals in LockBufferForCleanup() (Andres Freund)
  This oversight could result in spurious errors about “multiple backends attempting to wait for pin-count 1”.

• Fix crash when doing COPY IN to a table with check constraints that contain whole-row references (Tom Lane)
  The known failure case only crashes in 9.4 and up, but there is very similar code in 9.3 and 9.2, so back-patch those branches as well.

• Avoid waiting for WAL flush or synchronous replication during commit of a transaction that was read-only so far as the user is concerned (Andres Freund)
  Previously, a delay could occur at commit in transactions that had written WAL due to HOT page pruning, leading to undesirable effects such as sessions getting stuck at startup if all synchronous replicas are down. Sessions have also been observed to get stuck in catchup interrupt processing when using synchronous replication; this will fix that problem as well.

• Avoid busy-waiting with short recovery_min_apply_delay values (Andres Freund)

• Fix crash when manipulating hash indexes on temporary tables (Heikki Linnakangas)

• Fix possible failure during hash index bucket split, if other processes are modifying the index concurrently (Tom Lane)

• Fix memory leaks in GIN index vacuum (Heikki Linnakangas)

• Check for interrupts while analyzing index expressions (Jeff Janes)
ANALYZE executes index expressions many times; if there are slow functions in such an expression, it’s desirable to be able to cancel the `ANALYZE` before that loop finishes.

- Ensure `tableoid` of a foreign table is reported correctly when a `READ COMMITTED` recheck occurs after locking rows in `SELECT FOR UPDATE`, `UPDATE`, or `DELETE` (Etsuro Fujita)

- Add the name of the target server to object description strings for foreign-server user mappings (Álvaro Herrera)

- Include the schema name in object identity strings for conversions (Álvaro Herrera)

- Recommend setting `include_realm` to 1 when using Kerberos/GSSAPI/SSPI authentication (Stephen Frost)

  Without this, identically-named users from different realms cannot be distinguished. For the moment this is only a documentation change, but it will become the default setting in PostgreSQL 9.5.

- Remove code for matching IPv4 `pg_hba.conf` entries to IPv4-in-IPv6 addresses (Tom Lane)

  This hack was added in 2003 in response to a report that some Linux kernels of the time would report IPv4 connections as having IPv4-in-IPv6 addresses. However, the logic was accidentally broken in 9.0. The lack of any field complaints since then shows that it’s not needed anymore. Now we have reports that the broken code causes crashes on some systems, so let’s just remove it rather than fix it. (Had we chosen to fix it, that would make for a subtle and potentially security-sensitive change in the effective meaning of IPv4 `pg_hba.conf` entries, which does not seem like a good thing to do in minor releases.)

- Fix status reporting for terminated background workers that were never actually started (Robert Haas)

- After a database crash, don’t restart background workers that are marked `BGW_NEVER_RESTART` (Amit Khandekar)

- Report WAL flush, not insert, position in `IDENTIFY_SYSTEM` replication command (Heikki Linnakangas)

  This avoids a possible startup failure in `pg_receivexlog`.

- While shutting down service on Windows, periodically send status updates to the Service Control Manager to prevent it from killing the service too soon; and ensure that `pg_ctl` will wait for shutdown (Krystian Bigaj)

- Reduce risk of network deadlock when using libpq’s non-blocking mode (Heikki Linnakangas)

  When sending large volumes of data, it’s important to drain the input buffer every so often, in case the server has sent enough response data to cause it to block on output. (A typical scenario is that the server is sending a stream of NOTICE messages during `COPY FROM STDIN`.) This worked properly in the normal blocking mode, but not so much in non-blocking mode. We’ve modified libpq to opportunistically drain input when it can, but a full defense against this problem requires application cooperation: the application should watch for socket read-ready as well as write-ready conditions, and be sure to call `PQconsumeInput()` upon read-ready.

- In libpq, fix misparsing of empty values in URI connection strings (Thomas Fanghaenel)

- Fix array handling in `ecpg` (Michael Meskes)

- Fix `psql` to sanely handle URIs and `conninfo` strings as the first parameter to `\connect` (David Fetter, Andrew Dunstan, Álvaro Herrera)

  This syntax has been accepted (but undocumented) for a long time, but previously some parameters might be taken from the old connection instead of the given string, which was agreed to be undesirable.
• Suppress incorrect complaints from psql on some platforms that it failed to write ~/.psql_history at exit (Tom Lane)
  
  This misbehavior was caused by a workaround for a bug in very old (pre-2006) versions of libedit. We fixed it by removing the workaround, which will cause a similar failure to appear for anyone still using such versions of libedit. Recommendation: upgrade that library, or use libreadline.

• Fix pg_dump’s rule for deciding which casts are system-provided casts that should not be dumped (Tom Lane)

• In pg_dump, fix failure to honor -z compression level option together with -Fd (Michael Paquier)

• Make pg_dump consider foreign key relationships between extension configuration tables while choosing dump order (Gilles Darold, Michael Paquier, Stephen Frost)
  
  This oversight could result in producing dumps that fail to reload because foreign key constraints are transiently violated.

• Avoid possible pg_dump failure when concurrent sessions are creating and dropping temporary functions (Tom Lane)

• Fix dumping of views that are just VALUES(...) but have column aliases (Tom Lane)

• Ensure that a view’s replication identity is correctly set to nothing during dump/restore (Marko Tiikkaja)
  
  Previously, if the view was involved in a circular dependency, it might wind up with an incorrect replication identity property.

• In pg_upgrade, force timeline 1 in the new cluster (Bruce Momjian)
  
  This change prevents upgrade failures caused by bogus complaints about missing WAL history files.

• In pg_upgrade, check for improperly non-connectable databases before proceeding (Bruce Momjian)

• In pg_upgrade, quote directory paths properly in the generated delete_old_cluster script (Bruce Momjian)

• In pg_upgrade, preserve database-level freezing info properly (Bruce Momjian)
  
  This oversight could cause missing-clog-file errors for tables within the postgres and template1 databases.

• Run pg_upgrade and pg_resetxlog with restricted privileges on Windows, so that they don’t fail when run by an administrator (Muhammad Asif Naeem)

• Improve handling of readdir() failures when scanning directories in initdb and pg_basebackup (Marco Nenciarini)

• Fix slow sorting algorithm in contrib/intarray (Tom Lane)

• Fix compile failure on Sparc V8 machines (Rob Rowan)

• Silence some build warnings on macOS (Tom Lane)

• Update time zone data files to tzdata release 2015d for DST law changes in Egypt, Mongolia, and Palestine, plus historical changes in Canada and Chile. Also adopt revised zone abbreviations for the America/Adak zone (HST/HDT not HAST/HADT).
E.34. Release 9.4.1

Release date: 2015-02-05

This release contains a variety of fixes from 9.4.0. For information about new features in the 9.4 major release, see Section E.35.

E.34.1. Migration to Version 9.4.1

A dump/restore is not required for those running 9.4.X.

However, if you are a Windows user and are using the “Norwegian (Bokmål)” locale, manual action is needed after the upgrade to replace any “Norwegian (Bokmål)_Norway” or “norwegian-bokmål” locale names stored in PostgreSQL system catalogs with the plain-ASCII alias “Norwegian_Norway”. For details see http://wiki.postgresql.org/wiki/Changes_To_Norwegian_Locale

E.34.2. Changes

- Fix buffer overruns in `to_char()` (Bruce Momjian)
  
  When `to_char()` processes a numeric formatting template calling for a large number of digits, PostgreSQL would read past the end of a buffer. When processing a crafted timestamp formatting template, PostgreSQL would write past the end of a buffer. Either case could crash the server. We have not ruled out the possibility of attacks that lead to privilege escalation, though they seem unlikely. (CVE-2015-0241)

- Fix buffer overrun in replacement `*printf()` functions (Tom Lane)
  
  PostgreSQL includes a replacement implementation of `printf` and related functions. This code will overrun a stack buffer when formatting a floating point number (conversion specifiers e, E, f, F, g or G) with requested precision greater than about 500. This will crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. A database user can trigger such a buffer overrun through the `to_char()` SQL function. While that is the only affected core PostgreSQL functionality, extension modules that use printf-family functions may be at risk as well.
  
  This issue primarily affects PostgreSQL on Windows. PostgreSQL uses the system implementation of these functions where adequate, which it is on other modern platforms. (CVE-2015-0242)

- Fix buffer overruns in `contrib/pgcrypto` (Marko Tiikkaja, Noah Misch)
  
  Errors in memory size tracking within the `pgcrypto` module permitted stack buffer overruns and improper dependence on the contents of uninitialized memory. The buffer overrun cases can crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. (CVE-2015-0243)

- Fix possible loss of frontend/backend protocol synchronization after an error (Heikki Linnakangas)
  
  If any error occurred while the server was in the middle of reading a protocol message from the client, it could lose synchronization and incorrectly try to interpret part of the message’s data as a new protocol message. An attacker able to submit crafted binary data within a command parameter might succeed in injecting his own SQL commands this way. Statement timeout and query cancellation are the most likely sources of errors triggering this scenario. Particularly vulnerable are applications that use a timeout and also submit arbitrary user-crafted data as binary query param-
etters. Disabling statement timeout will reduce, but not eliminate, the risk of exploit. Our thanks to Emil Lenngren for reporting this issue. (CVE-2015-0244)

- Fix information leak via constraint-violation error messages (Stephen Frost)
  Some server error messages show the values of columns that violate a constraint, such as a unique constraint. If the user does not have SELECT privilege on all columns of the table, this could mean exposing values that the user should not be able to see. Adjust the code so that values are displayed only when they came from the SQL command or could be selected by the user. (CVE-2014-8161)

- Lock down regression testing’s temporary installations on Windows (Noah Misch)
  Use SSPI authentication to allow connections only from the OS user who launched the test suite. This closes on Windows the same vulnerability previously closed on other platforms, namely that other users might be able to connect to the test postmaster. (CVE-2014-0067)

- Cope with the Windows locale named “Norwegian (Bokmål)” (Heikki Linnakangas)
  Non-ASCII locale names are problematic since it’s not clear what encoding they should be represented in. Map the troublesome locale name to a plain-ASCII alias, “Norwegian_Norway”.
  9.4.0 mapped the troublesome name to “norwegian-bokmal”, but that turns out not to work on all Windows configurations. “Norwegian_Norway” is now recommended instead.

- Fix use-of-already-freed-memory problem in EvalPlanQual processing (Tom Lane)
  In READ COMMITTED mode, queries that lock or update recently-updated rows could crash as a result of this bug.

- Avoid possible deadlock while trying to acquire tuple locks in EvalPlanQual processing (Álvaro Herrera, Mark Kirkwood)

- Fix failure to wait when a transaction tries to acquire a FOR NO KEY EXCLUSIVE tuple lock, while multiple other transactions currently hold FOR SHARE locks (Álvaro Herrera)

- Improve performance of EXPLAIN with large range tables (Tom Lane)

- Fix jsonb Unicode escape processing, and in consequence disallow \u0000 (Tom Lane)
  Previously, the JSON Unicode escape \u0000 was accepted and was stored as those six characters; but that is indistinguishable from what is stored for the input \u0000, resulting in ambiguity.
  Moreover, in cases where de-escaped textual output is expected, such as the -> operator, the sequence was printed as \u0000, which does not meet the expectation that JSON escaping would be removed. (Consistent behavior would require emitting a zero byte, but PostgreSQL does not support zero bytes embedded in text strings.) 9.4.0 included an ill-advised attempt to improve this situation by adjusting JSON output conversion rules; but of course that could not fix the fundamental ambiguity, and it turned out to break other usages of Unicode escape sequences. Revert that, and to avoid the core problem, reject \u0000 in jsonb input.
  If a jsonb column contains a \u0000 value stored with 9.4.0, it will henceforth read out as though it were \u0000, which is the other valid interpretation of the data stored by 9.4.0 for this case.

  The json type did not have the storage-ambiguity problem, but it did have the problem of inconsistent de-escaped textual output. Therefore \u0000 will now also be rejected in json values when conversion to de-escaped form is required. This change does not break the ability to store \u0000 in json columns so long as no processing is done on the values. This is exactly parallel to the cases in which non-ASCII Unicode escapes are allowed when the database encoding is not UTF8.

- Fix namespace handling in xpath() (Ali Akbar)
  Previously, the xml value resulting from an xpath() call would not have namespace declarations if the namespace declarations were attached to an ancestor element in the input xml value, rather
than to the specific element being returned. Propagate the ancestral declaration so that the result is correct when considered in isolation.

- Fix assorted oversights in range-operator selectivity estimation (Emre Hasegeli)
  This patch fixes corner-case "unexpected operator NNNN" planner errors, and improves the selectivity estimates for some other cases.

- Revert unintended reduction in maximum size of a GIN index item (Heikki Linnakangas)
  9.4.0 could fail with "index row size exceeds maximum" errors for data that previous versions would accept.

- Fix query-duration memory leak during repeated GIN index rescans (Heikki Linnakangas)

- Fix possible crash when using nonzero gin_fuzzy_search_limit (Heikki Linnakangas)

- Assorted fixes for logical decoding (Andres Freund)

- Fix incorrect replay of WAL parameter change records that report changes in the wal_log_hints setting (Petr Jelinek)

- Change "pgstat wait timeout" warning message to be LOG level, and rephrase it to be more understandable (Tom Lane)
  This message was originally thought to be essentially a can’t-happen case, but it occurs often enough on our slower buildfarm members to be a nuisance. Reduce it to LOG level, and expend a bit more effort on the wording: it now reads “using stale statistics instead of current ones because stats collector is not responding”.

- Warn if macOS’s setlocale() starts an unwanted extra thread inside the postmaster (Noah Misch)

- Fix libpq’s behavior when /etc/passwd isn’t readable (Tom Lane)
  While doing PQsetdbLogin(), libpq attempts to ascertain the user’s operating system name, which on most Unix platforms involves reading /etc/passwd. As of 9.4, failure to do that was treated as a hard error. Restore the previous behavior, which was to fail only if the application does not provide a database role name to connect as. This supports operation in chroot environments that lack an /etc/passwd file.

- Improve consistency of parsing of psql’s special variables (Tom Lane)
  Allow variant spellings of on and off (such as 1/0) for ECHO_HIDDEN and ON_ERROR_ROLLBACK. Report a warning for unrecognized values for COMP_KEYWORD_CASE, ECHO, ECHO_HIDDEN, HISTCONTROL, ON_ERROR_ROLLBACK, and VERBOSITY. Recognize all values for all these variables case-insensitively; previously there was a mishmash of case-sensitive and case-insensitive behaviors.

- Fix pg_dump to handle comments on event triggers without failing (Tom Lane)

- Allow parallel pg_dump to use --serializable-deferrable (Kevin Grittner)

- Prevent WAL files created by pg_basebackup -x/-X from being archived again when the standby is promoted (Andres Freund)

- Handle unexpected query results, especially NULLs, safely in contrib/tablefunc’s connectby() (Michael Paquier)
  connectby() previously crashed if it encountered a NULL key value. It now prints that row but doesn’t recurse further.

- Numerous cleanups of warnings from Coverity static code analyzer (Andres Freund, Tatsuo Ishii, Marko Kreen, Tom Lane, Michael Paquier)
These changes are mostly cosmetic but in some cases fix corner-case bugs, for example a crash rather than a proper error report after an out-of-memory failure. None are believed to represent security issues.

- Allow CFLAGS from configure’s environment to override automatically-supplied CFLAGS (Tom Lane)
  
  Previously, configure would add any switches that it chose of its own accord to the end of the user-specified CFLAGS string. Since most compilers process switches left-to-right, this meant that configure’s choices would override the user-specified flags in case of conflicts. That should work the other way around, so adjust the logic to put the user’s string at the end not the beginning.

- Make pg_regress remove any temporary installation it created upon successful exit (Tom Lane)
  
  This results in a very substantial reduction in disk space usage during make check-world, since that sequence involves creation of numerous temporary installations.

- Add CST (China Standard Time) to our lists of timezone abbreviations (Tom Lane)

- Update time zone data files to tzdata release 2015a for DST law changes in Chile and Mexico, plus historical changes in Iceland.

## E.35. Release 9.4

**Release date:** 2014-12-18

### E.35.1. Overview

Major enhancements in PostgreSQL 9.4 include:

- Add jsonb, a more capable and efficient data type for storing JSON data
- Add new SQL command ALTER SYSTEM for changing postgresql.conf configuration file entries
- Reduce lock strength for some ALTER TABLE commands
- Allow materialized views to be refreshed without blocking concurrent reads
- Add support for logical decoding of WAL data, to allow database changes to be streamed out in a customizable format
- Allow background worker processes to be dynamically registered, started and terminated

The above items are explained in more detail in the sections below.

### E.35.2. Migration to Version 9.4

A dump/restore using pg_dumpall, or use of pg_upgrade, is required for those wishing to migrate data from any previous release.

Version 9.4 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- Tighten checks for multidimensional array input (Bruce Momjian)
Previously, an input array string that started with a single-element sub-array could later contain multi-element sub-arrays, e.g. `{{1}, {2,3}}>::int[]` would be accepted.

- When converting values of type `date`, `timestamp` or `timestamptz` to JSON, render the values in a format compliant with ISO 8601 (Andrew Dunstan)

Previously such values were rendered according to the current DateStyle setting; but many JSON processors require timestamps to be in ISO 8601 format. If necessary, the previous behavior can be obtained by explicitly casting the datetime value to `text` before passing it to the JSON conversion function.

- The `json #> text[]` path extraction operator now returns its lefthand input, not NULL, if the array is empty (Tom Lane)

This is consistent with the notion that this represents zero applications of the simple field/element extraction operator `->`. Similarly, `json #>> text[]` with an empty array merely coerces its lefthand input to `text`.

- Corner cases in the JSON field/element/path extraction operators now return NULL rather than raising an error (Tom Lane)

For example, applying field extraction to a JSON array now yields NULL not an error. This is more consistent (since some comparable cases such as no-such-field already returned NULL), and it makes it safe to create expression indexes that use these operators, since they will now not throw errors for any valid JSON input.

- Cause consecutive whitespace in `to_timestamp()` and `to_date()` format strings to consume a corresponding number of characters in the input string (whitespace or not), then conditionally consume adjacent whitespace, if not in FX mode (Jeevan Chalke)

Previously, consecutive whitespace characters in a non-FX format string behaved like a single whitespace character and consumed all adjacent whitespace in the input string. For example, previously a format string of three spaces would consume only the first space in ‘ 12’, but it will now consume all three characters.

- Fix `ts_rank_cd()` to ignore stripped lexemes (Alex Hill)

Previously, stripped lexemes were treated as if they had a default location, producing a rank of dubious usefulness.

- For functions declared to take VARIADIC "any", an actual parameter marked as VARIADIC must be of a determinable array type (Pavel Stehule)

Such parameters can no longer be written as an undecorated string literal or NULL; a cast to an appropriate array data type will now be required. Note that this does not affect parameters not marked VARIADIC.

- Ensure that whole-row variables expose the expected column names to functions that pay attention to column names within composite arguments (Tom Lane)

Constructs like `row_to_json(tab.*)` now always emit column names that match the column aliases visible for table `tab` at the point of the call. In previous releases the emitted column names would sometimes be the table’s actual column names regardless of any aliases assigned in the query.

- DISCARD now also discards sequence-related state (Fabrízio de Royes Mello, Robert Haas)

- Rename EXPLAIN ANALYZE’s “total runtime” output to “execution time” (Tom Lane)

Now that planning time is also reported, the previous name was confusing.

- SHOW TIME ZONE now outputs simple numeric UTC offsets in POSIX timezone format (Tom Lane)
Previously, such timezone settings were displayed as *interval* values. The new output is properly interpreted by `SET TIME ZONE` when passed as a simple string, whereas the old output required special treatment to be re-parsed correctly.

- **Foreign data wrappers that support updating foreign tables must consider the possible presence of *AFTER ROW* triggers (Noah Misch)**

  When an *AFTER ROW* trigger is present, all columns of the table must be returned by updating actions, since the trigger might inspect any or all of them. Previously, foreign tables never had triggers, so the FDW might optimize away fetching columns not mentioned in the *RETURNING* clause (if any).

- **Prevent *CHECK* constraints from referencing system columns, except *tableoid (Amit Kapila)**

  Previously such check constraints were allowed, but they would often cause errors during restores.

- **Use the last specified recovery target parameter if multiple target parameters are specified (Heikki Linnakangas)**

  Previously, there was an undocumented precedence order among the *recovery_target_***xxx*** parameters.

- **On Windows, automatically preserve quotes in command strings supplied by the user (Heikki Linnakangas)**

  User commands that did their own quote preservation might need adjustment. This is likely to be an issue for commands used in *archive_command*, *restore_command*, and *COPY TO/FROM PROGRAM*.

- **Remove catalog column *pg_class.reltoastidxid (Michael Paquier)**

- **Remove catalog column *pg_rewrite.ev_attr (Kevin Grittner)**

  Per-column rules have not been supported since PostgreSQL 7.3.

- **Remove native support for Kerberos authentication (*--with-krb5, etc (Magnus Hagander)**

  The supported way to use Kerberos authentication is with GSSAPI. The native code has been deprecated since PostgreSQL 8.3.

- **In PL/Python, handle domains over arrays like the underlying array type (Rodolfo Campero)**

  Previously such values were treated as strings.

- **Make *libpq*s *PQconnectdbParams() and PQpingParams() functions process zero-length strings as defaults (Adrian Vondendriesch)**

  Previously, these functions treated zero-length string values as selecting the default in only some cases.

- **Change empty arrays returned by the intarray module to be zero-dimensional arrays (Bruce Momjian)**

  Previously, empty arrays were returned as zero-length one-dimensional arrays, whose text representation looked the same as zero-dimensional arrays ({ }), but they acted differently in array operations. intarray’s behavior in this area now matches the built-in array operators.

- **pg_upgrade now uses *--username* to specify the user name (Bruce Momjian)**

  Previously this option was spelled *--user*, but that was inconsistent with other tools.

**E.35.3. Changes**

Below you will find a detailed account of the changes between PostgreSQL 9.4 and the previous major release.
Appendix E. Release Notes

E.35.3.1. Server

- Allow background worker processes to be dynamically registered, started and terminated (Robert Haas)
  The new worker_spi module shows an example of use of this feature.
- Allow dynamic allocation of shared memory segments (Robert Haas, Amit Kapila)
  This feature is illustrated in the test_shm_mq module.
- During crash recovery or immediate shutdown, send uncatchable termination signals (SIGKILL) to child processes that do not shut down promptly (MauMau, Álvaro Herrera)
  This reduces the likelihood of leaving orphaned child processes behind after postmaster shutdown, as well as ensuring that crash recovery can proceed if some child processes have become “stuck”.
- Improve randomness of the database system identifier (Tom Lane)
- Make VACUUM properly report dead but not-yet-removable rows to the statistics collector (Hari Babu)
  Previously these were reported as live rows.

E.35.3.1.1. Indexes

- Reduce GIN index size (Alexander Korotkov, Heikki Linnakangas)
  Indexes upgraded via pg_upgrade will work fine but will still be in the old, larger GIN format. Use REINDEX to recreate old GIN indexes in the new format.
- Improve speed of multi-key GIN lookups (Alexander Korotkov, Heikki Linnakangas)
- Add GiST index support for inet and cidr data types (Emre Hasegeli)
  Such indexes improve subnet and supernet lookups and ordering comparisons.
- Fix rare race condition in B-tree page deletion (Heikki Linnakangas)
- Make the handling of interrupted B-tree page splits more robust (Heikki Linnakangas)

E.35.3.1.2. General Performance

- Allow multiple backends to insert into WAL buffers concurrently (Heikki Linnakangas)
  This improves parallel write performance.
- Conditionally write only the modified portion of updated rows to WAL (Amit Kapila)
- Improve performance of aggregate functions used as window functions (David Rowley, Florian Pflug, Tom Lane)
- Improve speed of aggregates that use numeric state values (Hadi Moshayedi)
- Attempt to freeze tuples when tables are rewritten with CLUSTER or VACUUM FULL (Robert Haas, Andres Freund)
  This can avoid the need to freeze the tuples in the future.
- Improve speed of COPY with default nextval() columns (Simon Riggs)
- Improve speed of accessing many different sequences in the same session (David Rowley)
• Raise hard limit on the number of tuples held in memory during sorting and B-tree index builds (Noah Misch)
• Reduce memory allocated by PL/pgSQL DO blocks (Tom Lane)
• Make the planner more aggressive about extracting restriction clauses from mixed AND/OR clauses (Tom Lane)
• Disallow pushing volatile WHERE clauses down into DISTINCT subqueries (Tom Lane)
  Pushing down a WHERE clause can produce a more efficient plan overall, but at the cost of evaluating the clause more often than is implied by the text of the query; so don’t do it if the clause contains any volatile functions.
• Auto-resize the catalog caches (Heikki Linnakangas)
  This reduces memory consumption for sessions accessing only a few tables, and improves performance for sessions accessing many tables.

E.35.3.1.3. Monitoring

• Add pg_stat_archiver system view to report WAL archiver activity (Gabriele Bartolini)
• Add n_mod_since_analyze columns to pg_stat_all_tables and related system views (Mark Kirkwood)
  These columns expose the system’s estimate of the number of changed tuples since the table’s last ANALYZE. This estimate drives decisions about when to auto-analyze.
• Add backend_xid and backend_xmin columns to the system view pg_stat_activity, and a backend_xmin column to pg_stat_replication (Christian Kruse)

E.35.3.1.4. SSL

• Add support for SSL ECDH key exchange (Marko Kreen)
  This allows use of Elliptic Curve keys for server authentication. Such keys are faster and have better security than RSA keys. The new configuration parameter ssl_ecdh_curve controls which curve is used for ECDH.
• Improve the default ssl_ciphers setting (Marko Kreen)
  By default, the server not the client now controls the preference order of SSL ciphers (Marko Kreen)
  Previously, the order specified by ssl_ciphers was usually ignored in favor of client-side defaults, which are not configurable in most PostgreSQL clients. If desired, the old behavior can be restored via the new configuration parameter ssl_prefer_server_ciphers.
• Make log_connections show SSL encryption information (Andreas Kunert)
• Improve SSL renegotiation handling (Álvaro Herrera)

E.35.3.1.5. Server Settings

• Add new SQL command ALTER SYSTEM for changing postgresql.conf configuration file entries (Amit Kapila)
Previously such settings could only be changed by manually editing `postgresql.conf`.

- Add `autovacuum_work_mem` configuration parameter to control the amount of memory used by autovacuum workers (Peter Geoghegan)

- Add `huge_pages` parameter to allow using huge memory pages on Linux (Christian Kruse, Richard Poole, Abhijit Menon-Sen)
  
  This can improve performance on large-memory systems.

- Add `max_worker_processes` parameter to limit the number of background workers (Robert Haas)
  
  This is helpful in configuring a standby server to have the required number of worker processes (the same as the primary).

- Add `superuser-only session_preload_libraries` parameter to load libraries at session start (Peter Eisentraut)
  
  In contrast to `local_preload_libraries`, this parameter can load any shared library, not just those in the `$libdir/plugins` directory.

- Add `wal_log_hints` parameter to enable WAL logging of hint-bit changes (Sawada Masahiko)
  
  Hint bit changes are not normally logged, except when checksums are enabled. This is useful for external tools like `pg_rewind`.

- Increase the default settings of `work_mem` and `maintenance_work_mem` by four times (Bruce Momjian)
  
  The new defaults are 4MB and 64MB respectively.

- Increase the default setting of `effective_cache_size` to 4GB (Bruce Momjian, Tom Lane)

- Allow `printf`-style space padding to be specified in `log_line_prefix` (David Rowley)

- Allow terabyte units (`TB`) to be used when specifying configuration variable values (Simon Riggs)

- Show PIDs of lock holders and waiters and improve information about relations in `log_lock_waits` log messages (Christian Kruse)

- Reduce server logging level when loading shared libraries (Peter Geoghegan)
  
  The previous level was `LOG`, which was too verbose for libraries loaded per-session.

- On Windows, make `SQL_ASCII`-encoded databases and server processes (e.g., `postmaster`) emit messages in the character encoding of the server’s Windows user locale (Alexander Law, Noah Misch)
  
  Previously these messages were output in the Windows ANSI code page.

**E.35.3.2. Replication and Recovery**

- Add replication slots to coordinate activity on streaming standbys with the node they are streaming from (Andres Freund, Robert Haas)
  
  Replication slots allow preservation of resources like WAL files on the primary until they are no longer needed by standby servers.

- Add recovery parameter `recovery_min_apply_delay` to delay replication (Robert Haas, Fabrício de Royes Mello, Simon Riggs)
  
  Delaying replay on standby servers can be useful for recovering from user errors.
• Add recovery_target option immediate to stop WAL recovery as soon as a consistent state is reached (MauMau, Heikki Linnakangas)

• Improve recovery target processing (Heikki Linnakangas)
  The timestamp reported by `pg_last_xact_replay_timestamp()` now reflects already-committed records, not transactions about to be committed. Recovering to a restore point now replays the restore point, rather than stopping just before the restore point.

• `pg_switch_xlog()` now clears any unused trailing space in the old WAL file (Heikki Linnakangas)
  This improves the compression ratio for WAL files.

• Report failure return codes from external recovery commands (Peter Eisentraut)

• Reduce spinlock contention during WAL replay (Heikki Linnakangas)

• Write WAL records of running transactions more frequently (Andres Freund)
  This allows standby servers to start faster and clean up resources more aggressively.

E.35.3.2.1. Logical Decoding

Logical decoding allows database changes to be streamed in a configurable format. The data is read from the WAL and transformed into the desired target format. To implement this feature, the following changes were made:

• Add support for logical decoding of WAL data, to allow database changes to be streamed out in a customizable format (Andres Freund)

• Add new wal_level setting `logical` to enable logical change-set encoding in WAL (Andres Freund)

• Add table-level parameter `REPLICA IDENTITY` to control logical replication (Andres Freund)

• Add relation option `user_catalog_table` to identify user-created tables involved in logical change-set encoding (Andres Freund)

• Add `pg_recvlogical` application to receive logical-decoding data (Andres Freund)

• Add `test_decoding` module to illustrate logical decoding at the SQL level (Andres Freund)

E.35.3.3. Queries

• Add `WITH ORDINALITY` syntax to number the rows returned from a set-returning function in the `FROM` clause (Andrew Gierth, David Fetter)
  This is particularly useful for functions like `unnest()`.

• Add `ROWS FROM()` syntax to allow horizontal concatenation of set-returning functions in the `FROM` clause (Andrew Gierth)

• Allow `SELECT` to have an empty target list (Tom Lane)
  This was added so that views that select from a table with zero columns can be dumped and restored correctly.

• Ensure that `SELECT ... FOR UPDATE NOWAIT` does not wait in corner cases involving already-concurrently-updated tuples (Craig Ringer and Thomas Munro)
E.35.3.4. Utility Commands

- **Add** DISCARD SEQUENCES **command** to discard cached sequence-related state (Fabrízio de Royes Mello, Robert Haas)
  
  DISCARD ALL will now also discard such information.

- **Add** FORCE NULL option to COPY FROM, which causes quoted strings matching the specified null string to be converted to NULLs in CSV mode (Ian Barwick, Michael Paquier)
  
  Without this option, only unquoted matching strings will be imported as null values.

- Issue warnings for commands used outside of transaction blocks when they can have no effect (Bruce Momjian)
  
  New warnings are issued for SET LOCAL, SET CONSTRAINTS, SET TRANSACTION and ABORT when used outside a transaction block.

E.35.3.4.1. EXPLAIN

- Make EXPLAIN ANALYZE show planning time (Andreas Karlsson)

- Make EXPLAIN show the grouping columns in Agg and Group nodes (Tom Lane)

- Make EXPLAIN ANALYZE show exact and lossy block counts in bitmap heap scans (Etsuro Fujita)

E.35.3.4.2. Views

- Allow a materialized view to be refreshed without blocking other sessions from reading the view meanwhile (Kevin Grittner)
  
  This is done with REFRESH MATERIALIZED VIEW CONCURRENTLY.

- Allow views to be automatically updated even if they contain some non-updatable columns (Dean Rasheed)
  
  Previously the presence of non-updatable output columns such as expressions, literals, and function calls prevented automatic updates. Now INSERTS, UPDATES and DELETES are supported, provided that they do not attempt to assign new values to any of the non-updatable columns.

- Allow control over whether INSERTS and UPDATES can add rows to an auto-updatable view that would not appear in the view (Dean Rasheed)
  
  This is controlled with the new CREATE VIEW clause WITH CHECK OPTION.

- Allow security barrier views to be automatically updatable (Dean Rasheed)

E.35.3.5. Object Manipulation

- Support triggers on foreign tables (Ronan Dunklau)

- Allow moving groups of objects from one tablespace to another using the ALL IN TABLESPACE ... SET TABLESPACE form of ALTER TABLE, ALTER INDEX, or ALTER MATERIALIZED VIEW (Stephen Frost)

- Allow changing foreign key constraint deferrability via ALTER TABLE ... ALTER CONSTRAINT (Simon Riggs)
• Reduce lock strength for some ALTER TABLE commands (Simon Riggs, Noah Misch, Robert Haas)

Specifically, VALIDATE CONSTRAINT, CLUSTER ON, SET WITHOUT CLUSTER, ALTER COLUMN SET STATISTICS, ALTER COLUMN SET (attribute_option), ALTER COLUMN RESET (attribute_option) no longer require ACCESS EXCLUSIVE locks.

• Allow tablespace options to be set in CREATE TABLESPACE (Vik Fearing)

Formerly these options could only be set via ALTER TABLESPACE.

• Allow CREATE AGGREGATE to define the estimated size of the aggregate’s transition state data (Hadi Moshayedi)

Proper use of this feature allows the planner to better estimate how much memory will be used by aggregates.

• Fix DROP IF EXISTS to avoid errors for non-existent objects in more cases (Pavel Stehule, Dean Rasheed)

• Improve how system relations are identified (Andres Freund, Robert Haas)

Previously, relations once moved into the pg_catalog schema could no longer be modified or dropped.

E.35.3.6. Data Types

• Fully implement the line data type (Peter Eisentraut)

The line segment data type (lseg) has always been fully supported. The previous line data type (which was enabled only via a compile-time option) is not binary or dump-compatible with the new implementation.

• Add pg_lsn data type to represent a WAL log sequence number (LSN) (Robert Haas, Michael Paquier)

• Allow single-point polygons to be converted to circles (Bruce Momjian)

• Support time zone abbreviations that change UTC offset from time to time (Tom Lane)

Previously, PostgreSQL assumed that the UTC offset associated with a time zone abbreviation (such as EST) never changes in the usage of any particular locale. However this assumption fails in the real world, so introduce the ability for a zone abbreviation to represent a UTC offset that sometimes changes. Update the zone abbreviation definition files to make use of this feature in timezone locales that have changed the UTC offset of their abbreviations since 1970 (according to the IANA timezone database). In such timezones, PostgreSQL will now associate the correct UTC offset with the abbreviation depending on the given date.

• Allow 5+ digit years for non-ISO timestamp and date strings, where appropriate (Bruce Momjian)

• Add checks for overflow/underflow of interval values (Bruce Momjian)

E.35.3.6.1. JSON

• Add jsonb, a more capable and efficient data type for storing JSON data (Oleg Bartunov, Teodor Sigaev, Alexander Korotkov, Peter Geoghegan, Andrew Dunstan)
Appendix E. Release Notes

This new type allows faster access to values within a JSON document, and faster and more useful
indexing of JSON columns. Scalar values in \texttt{jsonb} documents are stored as appropriate scalar
SQL types, and the JSON document structure is pre-parsed rather than being stored as text as in the
original \texttt{json} data type.

• Add new JSON functions to allow for the construction of arbitrarily complex JSON trees (Andrew
Dunstan, Laurence Rowe)

  New functions include \texttt{json_array_elements_text()}, \texttt{json_build_array()},
\texttt{json_object()}, \texttt{json_object_agg()}, \texttt{json_to_record()}, and \texttt{json_to_recordset()}.

• Add \texttt{json_typeof()} to return the data type of a \texttt{json} value (Andrew Tipton)

E.35.3.7. Functions

• Add \texttt{pg\_sleep\_for(interval)} and \texttt{pg\_sleep\_until(timestamp)} to specify delays more
flexibly (Vik Fearing, Julien Rouhaud)

  The existing \texttt{pg\_sleep()} function only supports delays specified in seconds.

• Add \texttt{cardinality()} function for arrays (Marko Tiikkaja)

  This returns the total number of elements in the array, or zero for an array with no elements.

• Add SQL functions to allow large object reads/writes at arbitrary offsets (Pavel Stehule)

• Allow \texttt{unnest()} to take multiple arguments, which are individually unnested then horizontally
concatenated (Andrew Gierth)

• Add functions to construct \texttt{times}, \texttt{dates}, \texttt{timestamps}, \texttt{timestamptz}s, and \texttt{intervals} from
individual values, rather than strings (Pavel Stehule)

  These functions’ names are prefixed with \texttt{make\_}, e.g. \texttt{make\_date()}.

• Make \texttt{to\_char()}’s \texttt{TZ} format specifier return a useful value for simple numeric time zone offsets
(Tom Lane)

  Previously, \texttt{to\_char(CURRENT\_TIMESTAMP, ’TZ’)} returned an empty string if the \texttt{timezone}
was set to a constant like \texttt{-4}.

• Add timezone offset format specifier \texttt{OF} to \texttt{to\_char()} (Bruce Momjian)

• Improve the random seed used for \texttt{random()} (Honza Horak)

• Tighten validity checking for Unicode code points in \texttt{chr(int)} (Tom Lane)

  This function now only accepts values that are valid UTF8 characters according to RFC 3629.

E.35.3.7.1. System Information Functions

• Add functions for looking up objects in \texttt{pg\_class}, \texttt{pg\_proc}, \texttt{pg\_type}, and \texttt{pg\_operator} that
do not generate errors for non-existent objects (Yugo Nagata, Nozomi Anzai, Robert Haas)

  For example, \texttt{to\_regclass()} does a lookup in \texttt{pg\_class} similarly to the \texttt{regclass} input func-
tion, but it returns NULL for a non-existent object instead of failing.

• Add function \texttt{pg\_filenode\_relation()} to allow for more efficient lookup of relation names
from filenodes (Andres Freund)
Appendix E. Release Notes

- Add parameter_default column to information_schema.parameters view (Peter Eisen-}
  traut)
- Make information_schema.schemata show all accessible schemas (Peter Eisentraut)
  Previously it only showed schemas owned by the current user.

**E.35.3.7.2. Aggregates**

- Add control over which rows are passed into aggregate functions via the FILTER clause (David}
  Fetter)
- Support ordered-set (WITHIN GROUP) aggregates (Atri Sharma, Andrew Gierth, Tom Lane)
- Add standard ordered-set aggregates percentile_cont(), percentile_disc(), mode(),
  rank(), dense_rank(), percent_rank(), and cume_dist() (Atri Sharma, Andrew Gierth)
- Support VARIADIC aggregate functions (Tom Lane)
- Allow polymorphic aggregates to have non-polymorphic state data types (Tom Lane)
  This allows proper declaration in SQL of aggregates like the built-in aggregate array_agg().

**E.35.3.8. Server-Side Languages**

- Add event trigger support to PL/Perl and PL/Tcl (Dimitri Fontaine)
- Convert numeric values to decimal in PL/Python (Szymon Guz, Ronan Dunklau)
  Previously such values were converted to Python float values, risking loss of precision.

**E.35.3.8.1. PL/pgSQL Server-Side Language**

- Add ability to retrieve the current PL/pgSQL call stack using GET DIAGNOSTICS (Pavel Stehule,
  Stephen Frost)
- Add option print_strict_params to display the parameters passed to a query that violated a
  STRICT constraint (Marko Tiikkaja)
- Add variables plpgsql.extra_warnings and plpgsql.extra_errors to enable additional
  PL/pgSQL warnings and errors (Marko Tiikkaja, Petr Jelinek)
  Currently only warnings/errors about shadowed variables are available.

**E.35.3.9. libpq**

- Make libpq’s PQconndefaults() function ignore invalid service files (Steve Singer, Bruce}
  Momjian)
  Previously it returned NULL if an incorrect service file was encountered.
- Accept TLS protocol versions beyond TLSv1 in libpq (Marko Kreen)
Appendix E. Release Notes

E.35.3.10. Client Applications

- Add createuser option -g to specify role membership (Christopher Browne)
- Add vacuumdb option --analyze-in-stages to analyze in stages of increasing granularity (Peter Eisentraut)
  
  This allows minimal statistics to be created quickly.
- Make pg_resetxlog with option -n output current and potentially changed values (Rajeev Rastogi)
- Make initdb throw error for incorrect locale settings, rather than silently falling back to a default choice (Tom Lane)
- Make pg_ctl return exit code 4 for an inaccessible data directory (Amit Kapila, Bruce Momjian)
  
  This behavior more closely matches the Linux Standard Base (LSB) Core Specification.
- On Windows, ensure that a non-absolute -D path specification is interpreted relative to pg_ctl’s current directory (Kumar Rajeev Rastogi)
  
  Previously it would be interpreted relative to whichever directory the underlying Windows service was started in.
- Allow sizeof() in ECPG C array definitions (Michael Meskes)
- Make ECPG properly handle nesting of C-style comments in both C and SQL text (Michael Meskes)

E.35.3.10.1. psql

- Suppress “No rows” output in psql expanded mode when the footer is disabled (Bruce Momjian)
- Allow Control-C to abort psql when it’s hung at connection startup (Peter Eisentraut)

E.35.3.10.1.1. Backslash Commands

- Make psql’s \db+ show tablespace options (Magnus Hagander)
- Make \do+ display the functions that implement the operators (Marko Tiikkaja)
- Make \d+ output an OID line only if an oid column exists in the table (Bruce Momjian)
  
  Previously, the presence or absence of an oid column was always reported.
- Make \d show disabled system triggers (Bruce Momjian)
  
  Previously, if you disabled all triggers, only user triggers would show as disabled.
- Fix \copy to no longer require a space between stdin and a semicolon (Etsuro Fujita)
- Output the row count at the end of \copy, just like COPY already did (Kumar Rajeev Rastogi)
- Fix \conninfo to display the server’s IP address for connections using hostaddr (Fujii Masao)
  
  Previously \conninfo could not display the server’s IP address in such cases.
- Show the SSL protocol version in \conninfo (Marko Kreen)
- Add tab completion for \pset (Pavel Stehule)
- Allow \pset with no arguments to show all settings (Gilles Darold)
- Make \a display the name of the history file it wrote without converting it to an absolute path (Tom Lane)
The code previously attempted to convert a relative file name to an absolute path for display, but frequently got it wrong.

**E.35.3.10.2. pg_dump**

- Allow `pg_restore` options `-I`, `-P`, `-T` and `-n` to be specified multiple times (Heikki Linnakangas)
  
  This allows multiple objects to be restored in one operation.

- Optionally add `IF EXISTS` clauses to the `DROP` commands emitted when removing old objects during a restore (Pavel Stehule)
  
  This change prevents unnecessary errors when removing old objects. The new `--if-exists` option for `pg_dump`, `pg_dumpall`, and `pg_restore` is only available when `--clean` is also specified.

**E.35.3.10.3. pg_basebackup**

- Add `pg_basebackup` option `--xlogdir` to specify the `pg_xlog` directory location (Haribabu Kommi)

- Allow `pg_basebackup` to relocate tablespaces in the backup copy (Steeve Lennmark)
  
  This is particularly useful for using `pg_basebackup` on the same machine as the primary.

- Allow network-stream base backups to be throttled (Antonin Houska)
  
  This can be controlled with the `pg_basebackup --max-rate` parameter.

**E.35.3.11. Source Code**

- Improve the way tuples are frozen to preserve forensic information (Robert Haas, Andres Freund)
  
  This change removes the main objection to freezing tuples as soon as possible. Code that inspects tuple flag bits will need to be modified.

- No longer require function prototypes for functions marked with the `PG_FUNCTION_INFO_V1` macro (Peter Eisentraut)
  
  This change eliminates the need to write boilerplate prototypes. Note that the `PG_FUNCTION_INFO_V1` macro must appear before the corresponding function definition to avoid compiler warnings.

- Remove `SnapshotNow` and `HeapTupleSatisfiesNow()` (Robert Haas)
  
  All existing uses have been switched to more appropriate snapshot types. Catalog scans now use MVCC snapshots.

- Add an API to allow memory allocations over one gigabyte (Noah Misch)

- Add `psprintf()` to simplify memory allocation during string composition (Peter Eisentraut, Tom Lane)

- Support `printf()` size modifier `z` to print `size_t` values (Andres Freund)

- Change API of `appendStringInfoVA()` to better use `vsnprintf()` (David Rowley, Tom Lane)

- Allow new types of external toast datums to be created (Andres Freund)
• Add single-reader, single-writer, lightweight shared message queue (Robert Haas)
• Improve spinlock speed on x86_64 CPUs (Heikki Linnakangas)
• Remove spinlock support for unsupported platforms SINIX, Sun3, and NS32K (Robert Haas)
• Remove IRIX port (Robert Haas)
• Reduce the number of semaphores required by --disable-spinlocks builds (Robert Haas)
• Rewrite duplicate_oids Unix shell script in Perl (Andrew Dunstan)
• Add Test Anything Protocol (TAP) tests for client programs (Peter Eisentraut)
  Currently, these tests are run by make check-world only if the --enable-tap-tests option was given to configure. This might become the default behavior in some future release.
• Add make targets check-tests and installcheck-tests, which allow selection of individual tests to be run (Andrew Dunstan)
• Remove maintainer-check makefile rule (Peter Eisentraut)
  The default build rules now include all the formerly-optional tests.
• Improve support for VPATH builds of PGXS modules (Cédric Villemain, Andrew Dunstan, Peter Eisentraut)
• Upgrade to Autoconf 2.69 (Peter Eisentraut)
• Add a configure flag that appends custom text to the PG_VERSION string (Oskari Saarenmaa)
  This is useful for packagers building custom binaries.
• Improve DocBook XML validity (Peter Eisentraut)
• Fix various minor security and sanity issues reported by the Coverity scanner (Stephen Frost)
• Improve detection of invalid memory usage when testing PostgreSQL with Valgrind (Noah Misch)
• Improve sample Emacs configuration file emacs.samples (Peter Eisentraut)
  Also add .dir-locals.el to the top of the source tree.
• Allow pgindent to accept a command-line list of typedefs (Bruce Momjian)
• Make pgindent smarter about blank lines around preprocessor conditionals (Bruce Momjian)
• Avoid most uses of dlltool in Cygwin and Mingw builds (Marco Atzeri, Hiroshi Inoue)
• Support client-only installs in MSVC (Windows) builds (MauMau)

E.35.3.12. Additional Modules

• Add pg_prewarm extension to preload relation data into the shared buffer cache at server start (Robert Haas)
  This allows reaching full operating performance more quickly.
• Add UUID random number generator gen_random_uuid() to pgcrypto (Oskari Saarenmaa)
  This allows creation of version 4 UUIDs without requiring installation of uuid-ossp.
• Allow uuid-ossp to work with the BSD or e2fsprogs UUID libraries, not only the OSSP UUID library (Matteo Beccati)
  This improves the uuid-ossp module’s portability since it no longer has to have the increasingly-obsolete OSSP library. The module’s name is now rather a misnomer, but we won’t change it.
• Add option to auto_explain to include trigger execution time (Horiguchi Kyotaro)
• Fix pgstattuple to not report rows from uncommitted transactions as dead (Robert Haas)
• Make pgstattuple functions use regclass-type arguments (Satoshi Nagayasu)
  While text-type arguments are still supported, they may be removed in a future major release.
• Improve consistency of pgrowlocks output to honor snapshot rules more consistently (Robert Haas)
• Improve pg_trgm’s choice of trigrams for indexed regular expression searches (Alexander Kotorov)
  This change discourages use of trigrams containing whitespace, which are usually less selective.
• Allow pg_xlogdump to report a live log stream with --follow (Heikki Linnakangas)
• Store cube data more compactly (Stas Kelvich)
  Existing data must be dumped/ restored to use the new format. The old format can still be read.
• Reduce vacuumlo client-side memory usage by using a cursor (Andrew Dunstan)
• Dramatically reduce memory consumption in pg_upgrade (Bruce Momjian)
• Pass pg_upgrade’s user name (-U) option to generated analyze scripts (Bruce Momjian)

E.35.3.12.1. pgbench

• Remove line length limit for pgbench scripts (Sawada Masahiko)
  The previous line limit was BUFSIZ.
• Add long option names to pgbench (Fabien Coelho)
• Add pgbench option --rate to control the transaction rate (Fabien Coelho)
• Add pgbench option --progress to print periodic progress reports (Fabien Coelho)

E.35.3.12.2. pg_stat_statements

• Make pg_stat_statements use a file, rather than shared memory, for query text storage (Peter Geoghegan)
  This removes the previous limitation on query text length, and allows a higher number of unique
  statements to be tracked by default.
• Allow reporting of pg_stat_statements’s internal query hash identifier (Daniel Farina, Sameer
  Thakur, Peter Geoghegan)
• Add the ability to retrieve all pg_stat_statements information except the query text (Peter Geoghegan)
  This allows monitoring tools to fetch query text only for just-created entries, improving performance
  during repeated querying of the statistics.
• Make pg_stat_statements ignore DEALLOCATE commands (Fabien Coelho)
  It already ignored PREPARE, as well as planning time in general, so this seems more consistent.
• Save the statistics file into $PGDATA/pg_stat at server shutdown, rather than $PGDATA/global
  (Fujii Masao)
E.36. Release 9.3.24

Release date: 2018-08-09

This release contains a variety of fixes from 9.3.23. For information about new features in the 9.3 major release, see Section E.60.

The PostgreSQL community will stop releasing updates for the 9.3.X release series shortly after September 2018. Users are encouraged to update to a newer release branch soon.

E.36.1. Migration to Version 9.3.24

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.23, see Section E.37.

E.36.2. Changes

- Fix failure to reset libpq’s state fully between connection attempts (Tom Lane)

  An unprivileged user of dblink or postgres_fdw could bypass the checks intended to prevent use of server-side credentials, such as a ~/.pgpass file owned by the operating-system user running the server. Servers allowing peer authentication on local connections are particularly vulnerable. Other attacks such as SQL injection into a postgres_fdw session are also possible. Attacking postgres_fdw in this way requires the ability to create a foreign server object with selected connection parameters, but any user with access to dblink could exploit the problem. In general, an attacker with the ability to select the connection parameters for a libpq-using application could cause mischief, though other plausible attack scenarios are harder to think of. Our thanks to Andrew Krasichkov for reporting this issue. (CVE-2018-10915)

- Ensure that updates to the relfrozenxid and relminxid values for “nailed” system catalogs are processed in a timely fashion (Andres Freund)

  Overoptimistic caching rules could prevent these updates from being seen by other sessions, leading to spurious errors and/or data corruption. The problem was significantly worse for shared catalogs, such as pg_authid, because the stale cache data could persist into new sessions as well as existing ones.

- Fix case where a freshly-promoted standby crashes before having completed its first post-recovery checkpoint (Michael Paquier, Kyotaro Horiguchi, Pavan Deolasee, Álvaro Herrera)

  This led to a situation where the server did not think it had reached a consistent database state during subsequent WAL replay, preventing restart.

- Avoid emitting a bogus WAL record when recycling an all-zero btree page (Amit Kapila)

  This mistake has been seen to cause assertion failures, and potentially it could result in unnecessary query cancellations on hot standby servers.

- Improve performance of WAL replay for transactions that drop many relations (Fujii Masao)

  This change reduces the number of times that shared buffers are scanned, so that it is of most benefit when that setting is large.

- Improve performance of lock releasing in standby server WAL replay (Thomas Munro)

- Ensure a table’s cached index list is correctly rebuilt after an index creation fails partway through (Peter Geoghegan)
Previously, the failed index’s OID could remain in the list, causing problems later in the same session.

- Fix misoptimization of equivalence classes involving composite-type columns (Tom Lane)
  This resulted in failure to recognize that an index on a composite column could provide the sort order needed for a merge join on that column.

- Fix SQL-standard `FETCH FIRST` syntax to allow parameters ($n), as the standard expects (Andrew Gierth)

- Fix failure to schema-qualify some object names in `getObjectDescription` output (Kyotaro Horiguchi, Tom Lane)
  Names of collations, conversions, and text search objects were not schema-qualified when they should be.

- Widen `COPY FROM`’s current-line-number counter from 32 to 64 bits (David Rowley)
  This avoids two problems with input exceeding 4G lines: `COPY FROM WITH HEADER` would drop a line every 4G lines, not only the first line, and error reports could show a wrong line number.

- Add a string freeing function to `ecpg`’s `pgtypes` library, so that cross-module memory management problems can be avoided on Windows (Takayuki Tsunakawa)
  On Windows, crashes can ensue if the `free` call for a given chunk of memory is not made from the same DLL that `malloc`’ed the memory. The `pgtypes` library sometimes returns strings that it expects the caller to free, making it impossible to follow this rule. Add a `PGTYPESchar_free()` function that just wraps `free`, allowing applications to follow this rule.

- Fix `ecpg`’s support for `long long` variables on Windows, as well as other platforms that declare `strtoll/strtoull` nonstandardly or not at all (Dang Minh Huong, Tom Lane)

- Fix misidentification of SQL statement type in PL/pgSQL, when a rule change causes a change in the semantics of a statement intra-session (Tom Lane)
  This error led to assertion failures, or in rare cases, failure to enforce the `INTO STRICT` option as expected.

- Fix password prompting in client programs so that echo is properly disabled on Windows when `stdin` is not the terminal (Matthew Stickney)

- Further fix mis-quoting of values for list-valued GUC variables in dumps (Tom Lane)
  The previous fix for quoting of `search_path` and other list-valued variables in `pg_dump` output turned out to misbehave for empty-string list elements, and it risked truncation of long file paths.

- Make `pg_upgrade` check that the old server was shut down cleanly (Bruce Momjian)
  The previous check could be fooled by an immediate-mode shutdown.

- Fix crash in contrib/ltree’s `lca()` function when the input array is empty (Pierre Ducroquet)

- Fix various error-handling code paths in which an incorrect error code might be reported (Michael Paquier, Tom Lane, Magnus Hagander)

- Rearrange `makefiles` to ensure that programs link to freshly-built libraries (such as `libpq.so`) rather than ones that might exist in the system library directories (Tom Lane)
  This avoids problems when building on platforms that supply old copies of PostgreSQL libraries.

- Update time zone data files to tzdata release 2018e for DST law changes in North Korea, plus historical corrections for Czechoslovakia.
  This update includes a redefinition of “daylight savings” in Ireland, as well as for some past years in Namibia and Czechoslovakia. In those jurisdictions, legally standard time is observed in summer,
and daylight savings time in winter, so that the daylight savings offset is one hour behind standard
time not one hour ahead. This does not affect either the actual UTC offset or the timezone abbrevi-
atations in use; the only known effect is that the is_dst column in the pg_timezone_names view
will now be true in winter and false in summer in these cases.

E.37. Release 9.3.23

Release date: 2018-05-10

This release contains a variety of fixes from 9.3.22. For information about new features in the 9.3
major release, see Section E.60.

E.37.1. Migration to Version 9.3.23

A dump/restore is not required for those running 9.3.X.

However, if the function marking mistakes mentioned in the first changelog entry below affect you,
you will want to take steps to correct your database catalogs.

Also, if you are upgrading from a version earlier than 9.3.22, see Section E.38.

E.37.2. Changes

• Fix incorrect volatility markings on a few built-in functions (Thomas Munro, Tom Lane)

   The functions query_to_xml, cursor_to_xml, cursor_to_xmlschema,
   query_to_xmlschema, and query_to_xml_and_xmlschema should be marked volatile
   because they execute user-supplied queries that might contain volatile operations. They were not,
   leading to a risk of incorrect query optimization. This has been repaired for new installations by
   correcting the initial catalog data, but existing installations will continue to contain the incorrect
   markings. Practical use of these functions seems to pose little hazard, but in case of trouble, it can
   be fixed by manually updating these functions’ pg_proc entries, for example ALTER FUNCTION
   pg_catalog.query_to_xml(text, boolean, boolean, text) VOLATILE. (Note that
   that will need to be done in each database of the installation.) Another option is to pg_upgrade the
   database to a version containing the corrected initial data.

• Avoid re-using TOAST value OIDs that match dead-but-not-yet-vacuumed TOAST entries (Pavan
   Deolasee)

   Once the OID counter has wrapped around, it’s possible to assign a TOAST value whose OID
   matches a previously deleted entry in the same TOAST table. If that entry were not yet vacuumed
   away, this resulted in “unexpected chunk number 0 (expected 1) for toast value nnnnn” errors,
   which would persist until the dead entry was removed by VACUUM. Fix by not selecting such OIDs
   when creating a new TOAST entry.

• Change ANALYZE’s algorithm for updating pg_class.relpages (David Gould)

   Previously, pages not actually scanned by ANALYZE were assumed to retain their old tuple density.
   In a large table where ANALYZE samples only a small fraction of the pages, this meant that the
   overall tuple density estimate could not change very much, so that reltuples would change nearly
   proportionally to changes in the table’s physical size (relpages) regardless of what was actually
happening in the table. This has been observed to result in reltuples becoming so much larger than reality as to effectively shut off autovacuuming. To fix, assume that ANALYZE's sample is a statistically unbiased sample of the table (as it should be), and just extrapolate the density observed within those pages to the whole table.

- Fix UPDATE/DELETE ... WHERE CURRENT OF to not fail when the referenced cursor uses an index-only-scan plan (Yugo Nagata, Tom Lane)
- Fix incorrect planning of join clauses pushed into parameterized paths (Andrew Gierth, Tom Lane)
  This error could result in misclassifying a condition as a "join filter" for an outer join when it should be a plain "filter" condition, leading to incorrect join output.
- Fix misoptimization of CHECK constraints having provably-NULL subclauses of top-level AND/OR conditions (Tom Lane, Dean Rasheed)
  This could, for example, allow constraint exclusion to exclude a child table that should not be excluded from a query.
- Avoid failure if a query-cancel or session-termination interrupt occurs while committing a prepared transaction (Stas Kelvich)
- Fix query-lifespan memory leakage in repeatedly executed hash joins (Tom Lane)
- Fix overly strict sanity check in heap_prepare_freeze_tuple (Álvaro Herrera)
  This could result in incorrect “cannot freeze committed xmax” failures in databases that have been pg_upgrade’d from 9.2 or earlier.
- Prevent dangling-pointer dereference when a C-coded before-update row trigger returns the “old” tuple (Rushabh Lathia)
- Reduce locking during autovacuum worker scheduling (Jeff Janes)
The previous behavior caused drastic loss of potential worker concurrency in databases with many tables.
- Ensure client hostname is copied while copying pg_stat_activity data to local memory (Edmund Horner)
  Previously the supposedly-local snapshot contained a pointer into shared memory, allowing the client hostname column to change unexpectedly if any existing session disconnected.
- Fix incorrect processing of multiple compound affixes in ispell dictionaries (Arthur Zakirov)
- Fix collation-aware searches (that is, indexscans using inequality operators) in SP-GiST indexes on text columns (Tom Lane)
  Such searches would return the wrong set of rows in most non-C locales.
- Count the number of index tuples correctly during initial build of an SP-GiST index (Tomas Vondra)
  Previously, the tuple count was reported to be the same as that of the underlying table, which is wrong if the index is partial.
- Count the number of index tuples correctly during vacuuming of a GiST index (Andrey Borodin)
  Previously it reported the estimated number of heap tuples, which might be inaccurate, and is certainly wrong if the index is partial.
- Allow scalarltsel and scalargtsel to be used on non-core datatypes (Tomas Vondra)
- Reduce libpq’s memory consumption when a server error is reported after a large amount of query output has been collected (Tom Lane)
Appendix E. Release Notes

Discard the previous output before, not after, processing the error message. On some platforms, notably Linux, this can make a difference in the application’s subsequent memory footprint.

- Fix double-free crashes in ecpg (Patrick Krecker, Jeevan Ladhe)
- Fix ecpg to handle `long long int` variables correctly in MSVC builds (Michael Meskes, Andrew Gierth)
- Fix mis-quoting of values for list-valued GUC variables in dumps (Michael Paquier, Tom Lane)

  The `local_preload_libraries`, `session_preload_libraries`, `shared_preload_libraries`, and `temp_tablespaces` variables were not correctly quoted in `pg_dump` output. This would cause problems if settings for these variables appeared in `CREATE FUNCTION ... SET or ALTER DATABASE/ROLE ... SET` clauses.

- Fix overflow handling in PL/pgSQL integer `FOR` loops (Tom Lane)

  The previous coding failed to detect overflow of the loop variable on some non-gcc compilers, leading to an infinite loop.

- Adjust PL/Python regression tests to pass under Python 3.7 (Peter Eisentraut)
- Support testing PL/Python and related modules when building with Python 3 and MSVC (Andrew Dunstan)
- Rename internal `b64_encode` and `b64_decode` functions to avoid conflict with Solaris 11.4 built-in functions (Rainer Orth)
- Sync our copy of the timezone library with IANA tzcode release 2018e (Tom Lane)

  This fixes the zic timezone data compiler to cope with negative daylight-savings offsets. While the PostgreSQL project will not immediately ship such timezone data, zic might be used with timezone data obtained directly from IANA, so it seems prudent to update zic now.

- Update time zone data files to tzdata release 2018d for DST law changes in Palestine and Antarctica (Casey Station), plus historical corrections for Portugal and its colonies, as well as Enderbury, Jamaica, Turks & Caicos Islands, and Uruguay.

E.38. Release 9.3.22

Release date: 2018-03-01

This release contains a variety of fixes from 9.3.21. For information about new features in the 9.3 major release, see Section E.60.

E.38.1. Migration to Version 9.3.22

A dump/restore is not required for those running 9.3.X.

However, if you run an installation in which not all users are mutually trusting, or if you maintain an application or extension that is intended for use in arbitrary situations, it is strongly recommended that you read the documentation changes described in the first changelog entry below, and take suitable steps to ensure that your installation or code is secure.

Also, the changes described in the second changelog entry below may cause functions used in index expressions or materialized views to fail during auto-analyze, or when reloading from a dump. After upgrading, monitor the server logs for such problems, and fix affected functions.

Also, if you are upgrading from a version earlier than 9.3.18, see Section E.42.
E.38.2. Changes

- Document how to configure installations and applications to guard against search-path-dependent trojan-horse attacks from other users (Noah Misch)

  Using a `search_path` setting that includes any schemas writable by a hostile user enables that user to capture control of queries and then run arbitrary SQL code with the permissions of the attacked user. While it is possible to write queries that are proof against such hijacking, it is notationally tedious, and it’s very easy to overlook holes. Therefore, we now recommend configurations in which no untrusted schemas appear in one’s search path. Relevant documentation appears in Section 5.8.6 (for database administrators and users), Section 31.1 (for application authors), Section 35.15.1 (for extension authors), and CREATE FUNCTION (for authors of `SECURITY DEFINER` functions). (CVE-2018-1058)

- Avoid use of insecure `search_path` settings in `pg_dump` and other client programs (Noah Misch, Tom Lane)

  `pg_dump`, `pg_upgrade`, `vacuumdb` and other PostgreSQL-provided applications were themselves vulnerable to the type of hijacking described in the previous changelog entry; since these applications are commonly run by superusers, they present particularly attractive targets. To make them secure whether or not the installation as a whole has been secured, modify them to include only the `pg_catalog` schema in their `search_path` settings. Autovacuum worker processes now do the same, as well.

  In cases where user-provided functions are indirectly executed by these programs — for example, user-provided functions in index expressions — the tighter `search_path` may result in errors, which will need to be corrected by adjusting those user-provided functions to not assume anything about what search path they are invoked under. That has always been good practice, but now it will be necessary for correct behavior. (CVE-2018-1058)

- Fix misbehavior of concurrent-update rechecks with CTE references appearing in subplans (Tom Lane)

  If a CTE (`WITH` clause reference) is used in an InitPlan or SubPlan, and the query requires a recheck due to trying to update or lock a concurrently-updated row, incorrect results could be obtained.

- Fix planner failures with overlapping mergejoin clauses in an outer join (Tom Lane)

  These mistakes led to “left and right pathkeys do not match in mergejoin” or “outer pathkeys do not match mergeclauses” planner errors in corner cases.

- Repair `pg_upgrade`’s failure to preserve `relfrozenxid` for materialized views (Tom Lane, Andres Freund)

  This oversight could lead to data corruption in materialized views after an upgrade, manifesting as “could not access status of transaction” or “found xmin from before relfrozenxid” errors. The problem would be more likely to occur in seldom-refreshed materialized views, or ones that were maintained only with `REFRESH MATERIALIZED VIEW CONCURRENTLY`.

  If such corruption is observed, it can be repaired by refreshing the materialized view (without `CONCURRENTLY`).

- Fix incorrect reporting of PL/Python function names in error `CONTEXT` stacks (Tom Lane)

  An error occurring within a nested PL/Python function call (that is, one reached via a SPI query from another PL/Python function) would result in a stack trace showing the inner function’s name twice, rather than the expected results. Also, an error in a nested PL/Python `DO` block could result in a null pointer dereference crash on some platforms.
• Allow contrib/auto_explain’s log_min_duration setting to range up to INT_MAX, or about 24 days instead of 35 minutes (Tom Lane)

E.39. Release 9.3.21

Release date: 2018-02-08

This release contains a variety of fixes from 9.3.20. For information about new features in the 9.3 major release, see Section E.60.

E.39.1. Migration to Version 9.3.21

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.18, see Section E.42.

E.39.2. Changes

• Ensure that all temporary files made by pg_upgrade are non-world-readable (Tom Lane, Noah Misch)

pg_upgrade normally restricts its temporary files to be readable and writable only by the calling user. But the temporary file containing pg_dumpall -g output would be group- or world-readable, or even writable, if the user’s umask setting allows. In typical usage on multi-user machines, the umask and/or the working directory’s permissions would be tight enough to prevent problems; but there may be people using pg_upgrade in scenarios where this oversight would permit disclosure of database passwords to unfriendly eyes. (CVE-2018-1053)

• Fix vacuuming of tuples that were updated while key-share locked (Andres Freund, Álvaro Herrera)

In some cases VACUUM would fail to remove such tuples even though they are now dead, leading to assorted data corruption scenarios.

• Fix inadequate buffer locking in some LSN fetches (Jacob Champion, Asim Praveen, Ashwin Agrawal)

These errors could result in misbehavior under concurrent load. The potential consequences have not been characterized fully.

• Avoid unnecessary failure in a query on an inheritance tree that occurs concurrently with some child table being removed from the tree by ALTER TABLE NO INHERIT (Tom Lane)

• Repair failure with correlated sub-SELECT inside VALUES inside a LATERAL subquery (Tom Lane)

• Fix “could not devise a query plan for the given query” planner failure for some cases involving nested UNION ALL inside a lateral subquery (Tom Lane)

• Fix has_sequence_privilege() to support WITH GRANT OPTION tests, as other privilege-testing functions do (Joe Conway)

• In databases using UTF8 encoding, ignore any XML declaration that asserts a different encoding (Pavel Stehule, Noah Misch)

We always store XML strings in the database encoding, so allowing libxml to act on a declaration of another encoding gave wrong results. In encodings other than UTF8, we don’t promise to support
non-ASCII XML data anyway, so retain the previous behavior for bug compatibility. This change affects only `xpath()` and related functions; other XML code paths already acted this way.

- Provide for forward compatibility with future minor protocol versions (Robert Haas, Badrul Chowdhury)
  
  Up to now, PostgreSQL servers simply rejected requests to use protocol versions newer than 3.0, so that there was no functional difference between the major and minor parts of the protocol version number. Allow clients to request versions 3.x without failing, sending back a message showing that the server only understands 3.0. This makes no difference at the moment, but back-patching this change should allow speedier introduction of future minor protocol upgrades.

- Prevent stack-overflow crashes when planning extremely deeply nested set operations (`UNION/INTERSECT/EXCEPT`) (Tom Lane)

- Fix null-pointer crashes for some types of LDAP URLs appearing in `pg_hba.conf` (Thomas Munro)

- Fix sample `INSTR()` functions in the PL/pgSQL documentation (Yugo Nagata, Tom Lane)
  
  These functions are stated to be Oracle® compatible, but they weren’t exactly. In particular, there was a discrepancy in the interpretation of a negative third parameter: Oracle thinks that a negative value indicates the last place where the target substring can begin, whereas our functions took it as the last place where the target can end. Also, Oracle throws an error for a zero or negative fourth parameter, whereas our functions returned zero.
  
  The sample code has been adjusted to match Oracle’s behavior more precisely. Users who have copied this code into their applications may wish to update their copies.

- Fix `pg_dump` to make ACL (permissions), comment, and security label entries reliably identifiable in archive output formats (Tom Lane)
  
  The “tag” portion of an ACL archive entry was usually just the name of the associated object. Make it start with the object type instead, bringing ACLs into line with the convention already used for comment and security label archive entries. Also, fix the comment and security label entries for the whole database, if present, to make their tags start with `DATABASE` so that they also follow this convention. This prevents false matches in code that tries to identify large-object-related entries by seeing if the tag starts with `LARGE OBJECT`. That could have resulted in misclassifying entries as data rather than schema, with undesirable results in a schema-only or data-only dump.
  
  Note that this change has user-visible results in the output of `pg_restore --list`.

- In `ecpg`, detect indicator arrays that do not have the correct length and report an error (David Rader)

- Avoid triggering a libc assertion in `contrib/hstore`, due to use of `memcpy()` with equal source and destination pointers (Tomas Vondra)

- Provide modern examples of how to auto-start Postgres on macOS (Tom Lane)
  
  The scripts in `contrib/start-scripts/osx` use infrastructure that’s been deprecated for over a decade, and which no longer works at all in macOS releases of the last couple of years. Add a new subdirectory `contrib/start-scripts/macos` containing scripts that use the newer launchd infrastructure.

- Fix incorrect selection of configuration-specific libraries for OpenSSL on Windows (Andrew Dunstan)

- Support linking to MinGW-built versions of `libperl` (Noah Misch)
  
  This allows building PL/Perl with some common Perl distributions for Windows.

- Fix MSVC build to test whether 32-bit `libperl` needs `--D_USE_32BIT_TIME_T` (Noah Misch)
Available Perl distributions are inconsistent about what they expect, and lack any reliable means of reporting it, so resort to a build-time test on what the library being used actually does.

- On Windows, install the crash dump handler earlier in postmaster startup (Takayuki Tsunakawa)
  This may allow collection of a core dump for some early-startup failures that did not produce a dump before.
- On Windows, avoid encoding-conversion-related crashes when emitting messages very early in postmaster startup (Takayuki Tsunakawa)
- Use our existing Motorola 68K spinlock code on OpenBSD as well as NetBSD (David Carlier)
- Add support for spinlocks on Motorola 88K (David Carlier)
- Update time zone data files to tzdata release 2018c for DST law changes in Brazil, Sao Tome and Principe, plus historical corrections for Bolivia, Japan, and South Sudan. The US/Pacific-New zone has been removed (it was only an alias for America/Los_Angeles anyway).

E.40. Release 9.3.20

Release date: 2017-11-09
This release contains a variety of fixes from 9.3.19. For information about new features in the 9.3 major release, see Section E.60.

E.40.1. Migration to Version 9.3.20
A dump/restore is not required for those running 9.3.X.
However, if you are upgrading from a version earlier than 9.3.18, see Section E.42.

E.40.2. Changes

- Fix crash due to rowtype mismatch in json{b}_populate_recordset() (Michael Paquier, Tom Lane)
  These functions used the result rowtype specified in the FROM ... AS clause without checking that it matched the actual rowtype of the supplied tuple value. If it didn’t, that would usually result in a crash, though disclosure of server memory contents seems possible as well. (CVE-2017-15098)
- Fix sample server-start scripts to become $PGUSER before opening $PGLOG (Noah Misch)
  Previously, the postmaster log file was opened while still running as root. The database owner could therefore mount an attack against another system user by making $PGLOG be a symbolic link to some other file, which would then become corrupted by appending log messages.
  By default, these scripts are not installed anywhere. Users who have made use of them will need to manually recopy them, or apply the same changes to their modified versions. If the existing $PGLOG file is root-owned, it will need to be removed or renamed out of the way before restarting the server with the corrected script. (CVE-2017-12172)
- Properly reject attempts to convert infinite float values to type numeric (Tom Lane, KaiGai Kohei)
  Previously the behavior was platform-dependent.
• Fix corner-case crashes when columns have been added to the end of a view (Tom Lane)
• Record proper dependencies when a view or rule contains FieldSelect or FieldStore expression nodes (Tom Lane)

Lack of these dependencies could allow a column or data type DROP to go through when it ought to fail, thereby causing later uses of the view or rule to get errors. This patch does not do anything to protect existing views/rules, only ones created in the future.

• Correctly detect hashability of range data types (Tom Lane)

The planner mistakenly assumed that any range type could be hashed for use in hash joins or hash aggregation, but actually it must check whether the range’s subtype has hash support. This does not affect any of the built-in range types, since they’re all hashable anyway.

• Fix low-probability loss of NOTIFY messages due to XID wraparound (Marko Tiikkaja, Tom Lane)

If a session executed no queries, but merely listened for notifications, for more than 2 billion transactions, it started to miss some notifications from concurrently-committing transactions.

• Prevent low-probability crash in processing of nested trigger firings (Tom Lane)
• Correctly restore the umask setting when file creation fails in COPY or lo_export() (Peter Eisentraut)
• Give a better error message for duplicate column names in ANALYZE (Nathan Bossart)
• Fix mis-parsing of the last line in a non-newline-terminated pg_hba.conf file (Tom Lane)
• Fix libpq to not require user’s home directory to exist (Tom Lane)

In v10, failure to find the home directory while trying to read ~/.pgpass was treated as a hard error, but it should just cause that file to not be found. Both v10 and previous release branches made the same mistake when reading ~/.pg_service.conf, though this was less obvious since that file is not sought unless a service name is specified.

• Fix libpq to guard against integer overflow in the row count of a PGresult (Michael Paquier)
• Fix ecpg’s handling of out-of-scope cursor declarations with pointer or array variables (Michael Meskes)
• Make ecpglib’s Informix-compatibility mode ignore fractional digits in integer input strings, as expected (Gao Zengqi, Michael Meskes)
• Sync our copy of the timezone library with IANA release tzcode2017c (Tom Lane)

This fixes various issues; the only one likely to be user-visible is that the default DST rules for a POSIX-style zone name, if no posixrules file exists in the timezone data directory, now match current US law rather than what it was a dozen years ago.

• Update time zone data files to tzdata release 2017c for DST law changes in Fiji, Namibia, Northern Cyprus, Sudan, Tonga, and Turks & Caicos Islands, plus historical corrections for Alaska, Apia, Burma, Calcutta, Detroit, Ireland, Namibia, and Pago Pago.

E.41. Release 9.3.19

Release date: 2017-08-31

This release contains a small number of fixes from 9.3.18. For information about new features in the 9.3 major release, see Section E.60.
E.41.1. Migration to Version 9.3.19

A dump/restore is not required for those running 9.3.X.
However, if you are upgrading from a version earlier than 9.3.18, see Section E.42.

E.41.2. Changes

- Show foreign tables in `information_schema.table_privileges` view (Peter Eisentraut)
  All other relevant `information_schema` views include foreign tables, but this one ignored them.
  Since this view definition is installed by initdb, merely upgrading will not fix the problem. If you need to fix this in an existing installation, you can, as a superuser, do this in psql:

  ```sql
  SET search_path TO information_schema;
  CREATE OR REPLACE VIEW table_privileges AS
  SELECT CAST(u_grantor.rolname AS sql_identifier) AS grantor,
          CAST(grantee.rolname AS sql_identifier) AS grantee,
          CAST(current_database() AS sql_identifier) AS table_catalog,
          CAST(nc.nspname AS sql_identifier) AS table_schema,
          CAST(c.relname AS sql_identifier) AS table_name,
          CAST(c.prtype AS character_data) AS privilege_type,
          CAST(
                CASE WHEN
                  -- object owner always has grant options
                  pg_has_role(grantee.oid, c.relowner, 'USAGE')
                  OR c.grantable
                THEN 'YES' ELSE 'NO' END AS yes_or_no) AS is_grantable,
          CAST(CASE WHEN c.prtype = 'SELECT' THEN 'YES' ELSE 'NO' END AS yes_or_no) AS with_hierarchy
  FROM (SELECT oid, relname, relnamespace, relkind, relowner, (aclexplode(coalesce(relacl, acldefault('r', relowner)))).* FROM pg_class ) AS c (oid, relname, relnamespace, relkind, relowner, grantor, grantee, prtype, grantable),
          pg_namespace nc,
          pg_authid u_grantor,
          (SELECT oid, rolname FROM pg_authid
          UNION ALL
          SELECT 0::oid, 'PUBLIC') AS grantee
  WHERE c.relnamespace = nc.oid
  AND c.relkind IN ('r', 'v', 'f')
  AND c.grantee = grantee.oid
  AND c.grantor = u_grantor.oid
  AND c.prtype IN ('INSERT', 'SELECT', 'UPDATE', 'DELETE', 'TRUNCATE', 'REFERENCES', 'TRIGGER')
  AND (pg_has_role(u_grantor.oid, 'USAGE')
       OR pg_has_role(grantee.oid, 'USAGE')
       OR grantee.rolname = 'PUBLIC');
  ```

  This must be repeated in each database to be fixed, including `template0`.

- Clean up handling of a fatal exit (e.g., due to receipt of SIGTERM) that occurs while trying to execute a `ROLLBACK` of a failed transaction (Tom Lane)
  This situation could result in an assertion failure. In production builds, the exit would still occur, but it would log an unexpected message about “cannot drop active portal”.

2322
• Remove assertion that could trigger during a fatal exit (Tom Lane)

• Correctly identify columns that are of a range type or domain type over a composite type or domain type being searched for (Tom Lane)

Certain `ALTER` commands that change the definition of a composite type or domain type are supposed to fail if there are any stored values of that type in the database, because they lack the infrastructure needed to update or check such values. Previously, these checks could miss relevant values that are wrapped inside range types or sub-domains, possibly allowing the database to become inconsistent.

• Fix crash in `pg_restore` when using parallel mode and using a list file to select a subset of items to restore (Fabrizio de Royes Mello)

• Change `ecpg`'s parser to allow `RETURNING` clauses without attached C variables (Michael Meskes)

This allows `ecpg` programs to contain SQL constructs that use `RETURNING` internally (for example, inside a CTE) rather than using it to define values to be returned to the client.

• Improve selection of compiler flags for PL/Perl on Windows (Tom Lane)

This fix avoids possible crashes of PL/Perl due to inconsistent assumptions about the width of `time_t` values. A side-effect that may be visible to extension developers is that `_USE_32BIT_TIME_T` is no longer defined globally in PostgreSQL Windows builds. This is not expected to cause problems, because type `time_t` is not used in any PostgreSQL API definitions.

---

**E.42. Release 9.3.18**

**Release date:** 2017-08-10

This release contains a variety of fixes from 9.3.17. For information about new features in the 9.3 major release, see Section E.60.

### E.42.1. Migration to Version 9.3.18

A dump/restore is not required for those running 9.3.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.3.16, see Section E.44.

### E.42.2. Changes

• Further restrict visibility of `pg_user_mappings.umoptions`, to protect passwords stored as user mapping options (Noah Misch)

The fix for CVE-2017-7486 was incorrect: it allowed a user to see the options in her own user mapping, even if she did not have `USAGE` permission on the associated foreign server. Such options might include a password that had been provided by the server owner rather than the user herself. Since `information_schema.user_mapping_options` does not show the options in such cases, `pg_user_mappings` should not either. (CVE-2017-7547)
Appendix E. Release Notes

By itself, this patch will only fix the behavior in newly initdb’d databases. If you wish to apply this change in an existing database, you will need to do the following:

1. **Restart the postmaster after adding** `allow_system_table_mods = true` **to postgreSQL.conf**. (In versions supporting **ALTER SYSTEM**, you can use that to make the configuration change, but you’ll still need a restart.)

2. **In each database of the cluster**, run the following commands as superuser:

   ```sql
   SET search_path = pg_catalog;
   CREATE OR REPLACE VIEW pg_user_mappings AS
   SELECT
       U.oid AS umid,
       S.oid AS srvid,
       S.srvname AS srvname,
       U.umuser AS umuser,
       CASE WHEN U.umuser = 0 THEN 'public' ELSE A.rolname END AS usename,
       CASE WHEN (U.umuser <> 0 AND A.rolname = current_user
                  AND (pg_has_role(S.srvowner, 'USAGE')
                       OR has_server_privilege(S.oid, 'USAGE')))
          OR (U.umuser = 0 AND pg_has_role(S.srvowner, 'USAGE'))
          OR (SELECT rolsuper FROM pg_authid WHERE rolname = current_user)
          THEN U.umoptions
          ELSE NULL END AS umoptions
   FROM pg_user_mapping U
   LEFT JOIN pg_authid A ON (A.oid = U.umuser) JOIN
   pg_foreign_server S ON (U.umserver = S.oid);
   ```

3. Do not forget to include the **template0** and **template1** databases, or the vulnerability will still exist in databases you create later. To fix **template0**, you’ll need to temporarily make it accept connections. In PostgreSQL 9.5 and later, you can use

   ```sql
   ALTER DATABASE template0 WITH ALLOW_CONNECTIONS true;
   and then after fixing template0, **undo that with**
   ```

   ```sql
   ALTER DATABASE template0 WITH ALLOW_CONNECTIONS false;
   ```

   In prior versions, instead use

   ```sql
   UPDATE pg_database SET datallowconn = true WHERE datname = 'template0';
   UPDATE pg_database SET datallowconn = false WHERE datname = 'template0';
   ```

4. Finally, remove the `allow_system_table_mods` configuration setting, and again restart the postmaster.

- **Disallow empty passwords in all password-based authentication methods** (Heikki Linnakangas)

  libpq ignores empty password specifications, and does not transmit them to the server. So, if a user’s password has been set to the empty string, it’s impossible to log in with that password via `psql` or other libpq-based clients. An administrator might therefore believe that setting the password to empty is equivalent to disabling password login. However, with a modified or non-libpq-based client, logging in could be possible, depending on which authentication method is configured. In particular the most common method, md5, accepted empty passwords. Change the server to reject empty passwords in all cases. (CVE-2017-7546)
Appendix E. Release Notes

• Fix concurrent locking of tuple update chains (Álvaro Herrera)

If several sessions concurrently lock a tuple update chain with nonconflicting lock modes using an old snapshot, and they all succeed, it was possible for some of them to nonetheless fail (and conclude there is no live tuple version) due to a race condition. This had consequences such as foreign-key checks failing to see a tuple that definitely exists but is being updated concurrently.

• Fix potential data corruption when freezing a tuple whose XMAX is a multixact with exactly one still-interesting member (Teodor Sigaev)

• On Windows, retry process creation if we fail to reserve the address range for our shared memory in the new process (Tom Lane, Amit Kapila)

This is expected to fix infrequent child-process-launch failures that are probably due to interference from antivirus products.

• Fix low-probability corruption of shared predicate-lock hash table in Windows builds (Thomas Munro, Tom Lane)

• Avoid logging clean closure of an SSL connection as though it were a connection reset (Michael Paquier)

• Prevent sending SSL session tickets to clients (Tom Lane)

This fix prevents reconnection failures with ticket-aware client-side SSL code.

• Fix code for setting tcp_keepalives_idle on Solaris (Tom Lane)

• Fix statistics collector to honor inquiry messages issued just after a postmaster shutdown and immediate restart (Tom Lane)

Statistics inquiries issued within half a second of the previous postmaster shutdown were effectively ignored.

• Ensure that the statistics collector’s receive buffer size is at least 100KB (Tom Lane)

This reduces the risk of dropped statistics data on older platforms whose default receive buffer size is less than that.

• Fix possible creation of an invalid WAL segment when a standby is promoted just after it processes an XLOG_SWITCH WAL record (Andres Freund)

• Fix SIGHUP and SIGUSR1 handling in walsender processes (Petr Jelinek, Andres Freund)

• Fix unnecessarily slow restarts of walreceiver processes due to race condition in postmaster (Tom Lane)

• Fix cases where an INSERT or UPDATE assigns to more than one element of a column that is of domain-over-array type (Tom Lane)

• Allow window functions to be used in sub-SELECTs that are within the arguments of an aggregate function (Tom Lane)

• Move autogenerated array types out of the way during ALTER ... RENAME (Vik Fearing)

Previously, we would rename a conflicting autogenerated array type out of the way during CREATE; this fix extends that behavior to renaming operations.

• Ensure that ALTER USER ... SET accepts all the syntax variants that ALTER ROLE ... SET does (Peter Eisentraut)

• Properly update dependency info when changing a datatype I/O function’s argument or return type from opaque to the correct type (Heikki Linnakangas)
**CREATE TYPE** updates I/O functions declared in this long-obsolete style, but it forgot to record a dependency on the type, allowing a subsequent **DROP TYPE** to leave broken function definitions behind.

- Reduce memory usage when **ANALYZE** processes **tsvector** column (Heikki Linnakangas)

- Fix unnecessary precision loss and sloppy rounding when multiplying or dividing **money** values by integers or floats (Tom Lane)

- Tighten checks for whitespace in functions that parse identifiers, such as **regprocedurein()** (Tom Lane)

  Depending on the prevailing locale, these functions could misinterpret fragments of multibyte characters as whitespace.

- Use relevant **#define** symbols from Perl while compiling PL/Perl (Ashutosh Sharma, Tom Lane)

  This avoids portability problems, typically manifesting as a “handshake” mismatch during library load, when working with recent Perl versions.

- In **libpq**, reset GSS/SASL and SSPI authentication state properly after a failed connection attempt (Michael Paquier)

  Failure to do this meant that when falling back from SSL to non-SSL connections, a GSS/SASL failure in the SSL attempt would always cause the non-SSL attempt to fail. SSPI did not fail, but it leaked memory.

- In **psql**, fix failure when **COPY FROM STDIN** is ended with a keyboard EOF signal and then another **COPY FROM STDIN** is attempted (Thomas Munro)

  This misbehavior was observed on BSD-derived platforms (including macOS), but not on most others.

- Fix **pg_dump** and **pg_restore** to emit **REFRESH MATERIALIZED VIEW** commands last (Tom Lane)

  This prevents errors during dump/restore when a materialized view refers to tables owned by a different user.

- Fix **pg_dump** with the **--clean** option to drop event triggers as expected (Tom Lane)

  It also now correctly assigns ownership of event triggers; before, they were restored as being owned by the superuser running the restore script.

- Fix **pg_dump** to not emit invalid SQL for an empty operator class (Daniel Gustafsson)

- Fix **pg_dump** output to stdout on Windows (Kuntal Ghosh)

  A compressed plain-text dump written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

- Fix **pg_get_ruledef()** to print correct output for the **ON SELECT** rule of a view whose columns have been renamed (Tom Lane)

  In some corner cases, **pg_dump** relies on **pg_get_ruledef()** to dump views, so that this error could result in dump/reload failures.

- Fix dumping of outer joins with empty constraints, such as the result of a **NATURAL LEFT JOIN** with no common columns (Tom Lane)

- Fix dumping of function expressions in the **FROM** clause in cases where the expression does not deparse into something that looks like a function call (Tom Lane)

- Fix **pg_basebackup** output to stdout on Windows (Haribabu Kommi)

  A backup written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.
• Fix pg_upgrade to ensure that the ending WAL record does not have wal_level = minimum (Bruce Momjian)
  This condition could prevent upgraded standby servers from reconnecting.
• In postgres_fdw, re-establish connections to remote servers after ALTER SERVER or ALTER USER MAPPING commands (Kyotaro Horiguchi)
  This ensures that option changes affecting connection parameters will be applied promptly.
• In postgres_fdw, allow cancellation of remote transaction control commands (Robert Haas, Rafia Sabih)
  This change allows us to quickly escape a wait for an unresponsive remote server in many more cases than previously.
• Always use -fPIC, not -fpic, when building shared libraries with gcc (Tom Lane)
  This supports larger extension libraries on platforms where it makes a difference.
• Fix unescaped-braces issue in our build scripts for Microsoft MSVC, to avoid a warning or error from recent Perl versions (Andrew Dunstan)
• In MSVC builds, handle the case where the openssl library is not within a VC subdirectory (Andrew Dunstan)
• In MSVC builds, add proper include path for libxml2 header files (Andrew Dunstan)
  This fixes a former need to move things around in standard Windows installations of libxml2.
• In MSVC builds, recognize a Tcl library that is named tcl86.lib (Noah Misch)

E.43. Release 9.3.17

Release date: 2017-05-11

This release contains a variety of fixes from 9.3.16. For information about new features in the 9.3 major release, see Section E.60.

E.43.1. Migration to Version 9.3.17

A dump/restore is not required for those running 9.3.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.3.16, see Section E.44.

E.43.2. Changes

• Restrict visibility of pg_user_mappings.umoptions, to protect passwords stored as user mapping options (Michael Paquier, Feike Steenbergen)
  The previous coding allowed the owner of a foreign server object, or anyone he has granted server USAGE permission to, to see the options for all user mappings associated with that server. This might well include passwords for other users. Adjust the view definition to match the behavior of
Appendix E. Release Notes

information_schema.user_mapping_options, namely that these options are visible to the
user being mapped, or if the mapping is for PUBLIC and the current user is the server owner, or if
the current user is a superuser. (CVE-2017-7486)

By itself, this patch will only fix the behavior in newly initdb’d databases. If you wish to apply this
change in an existing database, follow the corrected procedure shown in the changelog entry for
CVE-2017-7547, in Section E.42.

• Prevent exposure of statistical information via leaky operators (Peter Eisentraut)

Some selectivity estimation functions in the planner will apply user-defined operators to values
obtained from pg_statistic, such as most common values and histogram entries. This occurs
before table permissions are checked, so a nefarious user could exploit the behavior to obtain these
values for table columns he does not have permission to read. To fix, fall back to a default estimate
if the operator’s implementation function is not certified leak-proof and the calling user does not
have permission to read the table column whose statistics are needed. At least one of these criteria
is satisfied in most cases in practice. (CVE-2017-7484)

• Restore libpq’s recognition of the PGREQUIRESSL environment variable (Daniel Gustafsson)

Processing of this environment variable was unintentionally dropped in PostgreSQL 9.3, but its
documentation remained. This creates a security hazard, since users might be relying on the en-
vironment variable to force SSL-encrypted connections, but that would no longer be guaranteed.
Restore handling of the variable, but give it lower priority than PGSSLMODE, to avoid breaking
configurations that work correctly with post-9.3 code. (CVE-2017-7485)

• Fix possible corruption of “init forks” of unlogged indexes (Robert Haas, Michael Paquier)

This could result in an unlogged index being set to an invalid state after a crash and restart. Such a
problem would persist until the index was dropped and rebuilt.

• Fix incorrect reconstruction of pg_subtrans entries when a standby server replays a prepared but
uncommitted two-phase transaction (Tom Lane)

In most cases this turned out to have no visible ill effects, but in corner cases it could result in
circular references in pg_subtrans, potentially causing infinite loops in queries that examine
rows modified by the two-phase transaction.

• Ensure parsing of queries in extension scripts sees the results of immediately-preceding DDL
(Julien Rouhaud, Tom Lane)

Due to lack of a cache flush step between commands in an extension script file, non-utility queries
might not see the effects of an immediately preceding catalog change, such as ALTER TABLE ...
RENAME.

• Skip tablespace privilege checks when ALTER TABLE ... ALTER COLUMN TYPE rebuilds an ex-
isting index (Noah Misch)

The command failed if the calling user did not currently have CREATE privilege for the tablespace
containing the index. That behavior seems unhelpful, so skip the check, allowing the index to be
rebuilt where it is.

• Fix ALTER TABLE ... VALIDATE CONSTRAINT to not recurse to child tables when the con-
straint is marked NO INHERIT (Amit Langote)

This fix prevents unwanted “constraint does not exist” failures when no matching constraint is
present in the child tables.

• Fix VACUUM to account properly for pages that could not be scanned due to conflicting page pins
(Andrew Gierth)
This tended to lead to underestimation of the number of tuples in the table. In the worst case of a small heavily-contended table, VACUUM could incorrectly report that the table contained no tuples, leading to very bad planning choices.

- Ensure that bulk-tuple-transfer loops within a hash join are interruptible by query cancel requests (Tom Lane, Thomas Munro)
- Fix cursor_to_xml() to produce valid output with tableforest = false (Thomas Munro, Peter Eisentraut)

Previously it failed to produce a wrapping <table> element.

- Improve performance of pg_timezone_names view (Tom Lane, David Rowley)
- Fix sloppy handling of corner-case errors from lseek() and close() (Tom Lane)

Neither of these system calls are likely to fail in typical situations, but if they did, fd.c could get quite confused.

- Fix incorrect check for whether postmaster is running as a Windows service (Michael Paquier)

This could result in attempting to write to the event log when that isn’t accessible, so that no logging happens at all.

- Fix ecpg to support COMMIT PREPARED and ROLLBACK PREPARED (Masahiko Sawada)
- Fix a double-free error when processing dollar-quoted string literals in ecpg (Michael Meskes)
- In pg_dump, fix incorrect schema and owner marking for comments and security labels of some types of database objects (Giuseppe Broccolo, Tom Lane)

In simple cases this caused no ill effects; but for example, a schema-selective restore might omit comments it should include, because they were not marked as belonging to the schema of their associated object.

- Avoid emitting an invalid list file in pg_restore -l when SQL object names contain newlines (Tom Lane)

Replace newlines by spaces, which is sufficient to make the output valid for pg_restore -L’s purposes.

- Fix pg_upgrade to transfer comments and security labels attached to “large objects” (blobs) (Stephen Frost)

Previously, blobs were correctly transferred to the new database, but any comments or security labels attached to them were lost.

- Improve error handling in contrib/adminpack’s pg_file_write() function (Noah Misch)

Notably, it failed to detect errors reported by fclose().

- In contrib/dblink, avoid leaking the previous unnamed connection when establishing a new unnamed connection (Joe Conway)
- Fix contrib/pg_trgm’s extraction of trigrams from regular expressions (Tom Lane)

In some cases it would produce a broken data structure that could never match anything, leading to GIN or GiST indexscans that use a trigram index not finding any matches to the regular expression.

- In contrib/postgres_fdw, transmit query cancellation requests to the remote server (Michael Paquier, Etsuro Fujita)

Previously, a local query cancellation request did not cause an already-sent remote query to terminate early. This is a back-patch of work originally done for 9.6.

- Support OpenSSL 1.1.0 (Heikki Linnakangas, Andreas Karlsson, Tom Lane)
This is a back-patch of work previously done in newer branches; it’s needed since many platforms are adopting newer OpenSSL versions.

- Support Tcl 8.6 in MSVC builds (Álvaro Herrera)
- Sync our copy of the timezone library with IANA release tzcode2017b (Tom Lane)
  This fixes a bug affecting some DST transitions in January 2038.
- Update time zone data files to tzdata release 2017b for DST law changes in Chile, Haiti, and Mongolia, plus historical corrections for Ecuador, Kazakhstan, Liberia, and Spain. Switch to numeric abbreviations for numerous time zones in South America, the Pacific and Indian oceans, and some Asian and Middle Eastern countries.

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the `pg_timezone_names` view nor used for output.

- Use correct daylight-savings rules for POSIX-style time zone names in MSVC builds (David Rowley)

The Microsoft MSVC build scripts neglected to install the `posixrules` file in the timezone directory tree. This resulted in the timezone code falling back to its built-in rule about what DST behavior to assume for a POSIX-style time zone name. For historical reasons that still corresponds to the DST rules the USA was using before 2007 (i.e., change on first Sunday in April and last Sunday in October). With this fix, a POSIX-style zone name will use the current and historical DST transition dates of the `US/Eastern` zone. If you don’t want that, remove the `posixrules` file, or replace it with a copy of some other zone file (see Section 8.5.3). Note that due to caching, you may need to restart the server to get such changes to take effect.

**E.44. Release 9.3.16**

**Release date:** 2017-02-09

This release contains a variety of fixes from 9.3.15. For information about new features in the 9.3 major release, see Section E.60.

**E.44.1. Migration to Version 9.3.16**

A dump/restore is not required for those running 9.3.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted indexes.

Also, if you are upgrading from a version earlier than 9.3.15, see Section E.45.

**E.44.2. Changes**

- Fix a race condition that could cause indexes built with `CREATE INDEX CONCURRENTLY` to be corrupt (Pavan Deolasee, Tom Lane)
Appendix E. Release Notes

If `CREATE INDEX CONCURRENTLY` was used to build an index that depends on a column not previously indexed, then rows updated by transactions that ran concurrently with the `CREATE INDEX` command could have received incorrect index entries. If you suspect this may have happened, the most reliable solution is to rebuild affected indexes after installing this update.

- Unconditionally WAL-log creation of the “init fork” for an unlogged table (Michael Paquier)
  
  Previously, this was skipped when `wal_level = minimal`, but actually it’s necessary even in that case to ensure that the unlogged table is properly reset to empty after a crash.

- If the stats collector dies during hot standby, restart it (Takayuki Tsunakawa)

- Ensure that hot standby feedback works correctly when it’s enabled at standby server start (Ants Aasma, Craig Ringer)

- Check for interrupts while hot standby is waiting for a conflicting query (Simon Riggs)

- Avoid constantly respawning the autovacuum launcher in a corner case (Amit Khandekar)
  
  This fix avoids problems when autovacuum is nominally off and there are some tables that require freezing, but all such tables are already being processed by autovacuum workers.

- Fix check for when an extension member object can be dropped (Tom Lane)

  Extension upgrade scripts should be able to drop member objects, but this was disallowed for serial-column sequences, and possibly other cases.

- Make sure `ALTER TABLE` preserves index tablespace assignments when rebuilding indexes (Tom Lane, Michael Paquier)

  Previously, non-default settings of `default_tablespace` could result in broken indexes.

- Prevent dropping a foreign-key constraint if there are pending trigger events for the referenced relation (Tom Lane)

  This avoids “could not find trigger NNN” or “relation NNN has no triggers” errors.

- Fix processing of OID column when a table with OIDs is associated to a parent with OIDs via `ALTER TABLE ... INHERIT` (Amit Langote)

  The OID column should be treated the same as regular user columns in this case, but it wasn’t, leading to odd behavior in later inheritance changes.

- Report correct object identity during `ALTER TEXT SEARCH CONFIGURATION` (Artur Zakirov)

  The wrong catalog OID was reported to extensions such as logical decoding.

- Check for serializability conflicts before reporting constraint-violation failures (Thomas Munro)

  When using serializable transaction isolation, it is desirable that any error due to concurrent transactions should manifest as a serialization failure, thereby cueing the application that a retry might succeed. Unfortunately, this does not reliably happen for duplicate-key failures caused by concurrent insertions. This change ensures that such an error will be reported as a serialization error if the application explicitly checked for the presence of a conflicting key (and did not find it) earlier in the transaction.

- Prevent multicolunm expansion of `foo.*` in an `UPDATE` source expression (Tom Lane)

  This led to “UPDATE target count mismatch --- internal error”. Now the syntax is understood as a whole-row variable, as it would be in other contexts.

- Ensure that column typmods are determined accurately for multi-row `VALUES` constructs (Tom Lane)

  This fixes problems occurring when the first value in a column has a determinable typmod (e.g., length for a `varchar` value) but later values don’t share the same limit.
Appendix E. Release Notes

- Throw error for an unfinished Unicode surrogate pair at the end of a Unicode string (Tom Lane)
  Normally, a Unicode surrogate leading character must be followed by a Unicode surrogate trailing
  character, but the check for this was missed if the leading character was the last character in a
  Unicode string literal (U"..."), or Unicode identifier (U"...").
- Ensure that a purely negative text search query, such as !foo, matches empty tsvectors (Tom Dunstan)
  Such matches were found by GIN index searches, but not by sequential scans or GiST index
  searches.
- Prevent crash when ts_rewrite() replaces a non-top-level subtree with an empty query (Artur Zakirov)
- Fix performance problems in ts_rewrite() (Tom Lane)
- Fix ts_rewrite()'s handling of nested NOT operators (Tom Lane)
- Fix array_fill() to handle empty arrays properly (Tom Lane)
- Fix one-byte buffer overrun in quote_literal_cstr() (Heikki Linnakangas)
  The overrun occurred only if the input consisted entirely of single quotes and/or backslashes.
- Prevent multiple calls of pg_start_backup() and pg_stop_backup() from running concurrently (Michael Paquier)
  This avoids an assertion failure, and possibly worse things, if someone tries to run these functions
  in parallel.
- Avoid discarding interval-to-interval casts that aren’t really no-ops (Tom Lane)
  In some cases, a cast that should result in zeroing out low-order interval fields was mistakenly
  deemed to be a no-op and discarded. An example is that casting from INTERVAL MONTH to
  INTERVAL YEAR failed to clear the months field.
- Ensure that cached plans are invalidated by changes in foreign-table options (Amit Langote, Etsuro
  Fujita, Ashutosh Bapat)
- Fix pg_dump to dump user-defined casts and transforms that use built-in functions (Stephen Frost)
- Fix possible pg_basebackup failure on standby server when including WAL files (Amit Kapila,
  Robert Haas)
- Ensure that the Python exception objects we create for PL/Python are properly reference-counted
  (Rafa de la Torre, Tom Lane)
  This avoids failures if the objects are used after a Python garbage collection cycle has occurred.
- Fix PL/Tcl to support triggers on tables that have .tupno as a column name (Tom Lane)
  This matches the (previously undocumented) behavior of PL/Tcl’s spi_exec and spi_execp
  commands, namely that a magic .tupno column is inserted only if there isn’t a real column named
  that.
- Allow DOS-style line endings in ~/.pgpass files, even on Unix (Vik Fearing)
  This change simplifies use of the same password file across Unix and Windows machines.
- Fix one-byte buffer overrun if ecpg is given a file name that ends with a dot (Takayuki Tsunakawa)
- Fix psql’s tab completion for ALTER DEFAULT PRIVILEGES (Gilles Darold, Stephen Frost)
- In psql, treat an empty or all-blank setting of the PAGER environment variable as meaning “no
  pager” (Tom Lane)
  Previously, such a setting caused output intended for the pager to vanish entirely.
Appendix E. Release Notes

- Improve contrib/dblink’s reporting of low-level libpq errors, such as out-of-memory (Joe Conway)

- Teach contrib/dblink to ignore irrelevant server options when it uses a contrib/postgres_fdw foreign server as the source of connection options (Corey Huinker)
  
  Previously, if the foreign server object had options that were not also libpq connection options, an error occurred.

- On Windows, ensure that environment variable changes are propagated to DLLs built with debug options (Christian Ullrich)

- Sync our copy of the timezone library with IANA release tzcode2016j (Tom Lane)
  
  This fixes various issues, most notably that timezone data installation failed if the target directory didn’t support hard links.

- Update time zone data files to tzdata release 2016j for DST law changes in northern Cyprus (adding a new zone Asia/Famagusta), Russia (adding a new zone Europe/Saratov), Tonga, and Antarctica/Ceay. Historical corrections for Italy, Kazakhstan, Malta, and Palestine. Switch to preferring numeric zone abbreviations for Tonga.

E.45. Release 9.3.15

Release date: 2016-10-27

This release contains a variety of fixes from 9.3.14. For information about new features in the 9.3 major release, see Section E.60.

E.45.1. Migration to Version 9.3.15

A dump/restore is not required for those running 9.3.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted free space maps.

Also, if you are upgrading from a version earlier than 9.3.9, see Section E.51.

E.45.2. Changes

- Fix WAL-logging of truncation of relation free space maps and visibility maps (Pavan Deolasee, Heikki Linnakangas)

  It was possible for these files to not be correctly restored during crash recovery, or to be written incorrectly on a standby server. Bogus entries in a free space map could lead to attempts to access pages that have been truncated away from the relation itself, typically producing errors like “could not read block XXX: read only 0 of 8192 bytes”. Checksum failures in the visibility map are also possible, if checksumming is enabled.

  Procedures for determining whether there is a problem and repairing it if so are discussed at https://wiki.postgresql.org/wiki/Free_Space_Map_Problems.

- Fix SELECT FOR UPDATE/SHARE to correctly lock tuples that have been updated by a subsequently-aborted transaction (Álvaro Herrera)
In 9.5 and later, the `SELECT` would sometimes fail to return such tuples at all. A failure has not been proven to occur in earlier releases, but might be possible with concurrent updates.

- **Fix EvalPlanQual rechecks involving CTE scans (Tom Lane)**
  The recheck would always see the CTE as returning no rows, typically leading to failure to update rows that were recently updated.

- **Fix improper repetition of previous results from hashed aggregation in a subquery (Andrew Gierth)**
  The test to see if we can reuse a previously-computed hash table of the aggregate state values neglected the possibility of an outer query reference appearing in an aggregate argument expression. A change in the value of such a reference should lead to recalculating the hash table, but did not.

- **Fix `EXPLAIN` to emit valid XML when track_io_timing is on (Markus Winand)**
  Previously the XML output-format option produced syntactically invalid tags such as `<I/O-Read-Time>`. That is now rendered as `<I-O-Read-Time>`.

- **Suppress printing of zeroes for unmeasured times in `EXPLAIN` (Maksim Milyutin)**
  Certain option combinations resulted in printing zero values for times that actually aren’t ever measured in that combination. Our general policy in `EXPLAIN` is not to print such fields at all, so do that consistently in all cases.

- **Fix timeout length when `VACUUM` is waiting for exclusive table lock so that it can truncate the table (Simon Riggs)**
  The timeout was meant to be 50 milliseconds, but it was actually only 50 microseconds, causing `VACUUM` to give up on truncation much more easily than intended. Set it to the intended value.

- **Fix bugs in merging inherited `CHECK` constraints while creating or altering a table (Tom Lane, Amit Langote)**
  Allow identical `CHECK` constraints to be added to a parent and child table in either order. Prevent merging of a valid constraint from the parent table with a `NOT VALID` constraint on the child. Likewise, prevent merging of a `NO INHERIT` child constraint with an inherited constraint.

- **Remove artificial restrictions on the values accepted by `numeric_in()` and `numeric_recv()` (Tom Lane)**
  We allow numeric values up to the limit of the storage format (more than `1e100000`), so it seems fairly pointless that `numeric_in()` rejected scientific-notation exponents above 1000. Likewise, it was silly for `numeric_recv()` to reject more than 1000 digits in an input value.

- **Avoid very-low-probability data corruption due to testing tuple visibility without holding buffer lock (Thomas Munro, Peter Geoghegan, Tom Lane)**

- **Fix file descriptor leakage when truncating a temporary relation of more than 1GB (Andres Freund)**

- **Disallow starting a standalone backend with `standby_mode` turned on (Michael Paquier)**
  This can’t do anything useful, since there will be no WAL receiver process to fetch more WAL data; and it could result in misbehavior in code that wasn’t designed with this situation in mind.

- **Don’t try to share SSL contexts across multiple connections in libpq (Heikki Linnakangas)**
  This led to assorted corner-case bugs, particularly when trying to use different SSL parameters for different connections.

- **Avoid corner-case memory leak in libpq (Tom Lane)**
  The reported problem involved leaking an error report during `PQreset()`, but there might be related cases.
• Make ecpg’s `--help` and `--version` options work consistently with our other executables (Haribabu Kommi)

• In `pg_dump`, never dump range constructor functions (Tom Lane)
  This oversight led to `pg_upgrade` failures with extensions containing range types, due to duplicate creation of the constructor functions.

• In `pg_xlogdump`, retry opening new WAL segments when using `--follow` option (Magnus Hagander)
  This allows for a possible delay in the server’s creation of the next segment.

• Fix `pg_xlogdump` to cope with a WAL file that begins with a continuation record spanning more than one page (Pavan Deolasee)

• Fix `contrib/intarray/bench/bench.pl` to print the results of the `EXPLAIN` it does when given the `-e` option (Daniel Gustafsson)

• Update Windows time zone mapping to recognize some time zone names added in recent Windows versions (Michael Paquier)

• Prevent failure of obsolete dynamic time zone abbreviations (Tom Lane)
  If a dynamic time zone abbreviation does not match any entry in the referenced time zone, treat it as equivalent to the time zone name. This avoids unexpected failures when IANA removes abbreviations from their time zone database, as they did in tzdata release 2016f and seem likely to do again in the future. The consequences were not limited to not recognizing the individual abbreviation; any mismatch caused the `pg_timezone_abbrevs` view to fail altogether.

• Update time zone data files to tzdata release 2016h for DST law changes in Palestine and Turkey, plus historical corrections for Turkey and some regions of Russia. Switch to numeric abbreviations for some time zones in Antarctica, the former Soviet Union, and Sri Lanka.

  The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the `pg_timezone_names` view nor used for output.

  In this update, AMT is no longer shown as being in use to mean Armenia Time. Therefore, we have changed the Default abbreviation set to interpret it as Amazon Time, thus UTC-4 not UTC+4.

---

E.46. Release 9.3.14

Release date: 2016-08-11

This release contains a variety of fixes from 9.3.13. For information about new features in the 9.3 major release, see Section E.60.

E.46.1. Migration to Version 9.3.14

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.9, see Section E.51.
E.46.2. Changes

- Fix possible mis-evaluation of nested `CASE-WHEN` expressions (Heikki Linnakangas, Michael Paquier, Tom Lane)

  A `CASE` expression appearing within the test value subexpression of another `CASE` could become confused about whether its own test value was null or not. Also, inlining of a SQL function implementing the equality operator used by a `CASE` expression could result in passing the wrong test value to functions called within a `CASE` expression in the SQL function’s body. If the test values were of different data types, a crash might result; moreover such situations could be abused to allow disclosure of portions of server memory. (CVE-2016-5423)

- Fix client programs’ handling of special characters in database and role names (Noah Misch, Nathan Bossart, Michael Paquier)

  Numerous places in vacuumdb and other client programs could become confused by database and role names containing double quotes or backslashes. Tighten up quoting rules to make that safe. Also, ensure that when a conninfo string is used as a database name parameter to these programs, it is correctly treated as such throughout.

  Fix handling of paired double quotes in `psql`’s `\connect` and `\password` commands to match the documentation.

  Introduce a new `-reuse-previous` option in `psql`’s `\connect` command to allow explicit control of whether to re-use connection parameters from a previous connection. (Without this, the choice is based on whether the database name looks like a conninfo string, as before.) This allows secure handling of database names containing special characters in `pg_dumpall` scripts.

  `pg_dumpall` now refuses to deal with database and role names containing carriage returns or newlines, as it seems impractical to quote those characters safely on Windows. In future we may reject such names on the server side, but that step has not been taken yet.

  These are considered security fixes because crafted object names containing special characters could have been used to execute commands with superuser privileges the next time a superuser executes `pg_dumpall` or other routine maintenance operations. (CVE-2016-5424)

- Fix corner-case misbehaviors for `IS NULL/IS NOT NULL` applied to nested composite values (Andrew Gierth, Tom Lane)

  The SQL standard specifies that `IS NULL` should return TRUE for a row of all null values (thus `ROW(NULL,NULL) IS NULL` yields TRUE), but this is not meant to apply recursively (thus `ROW(NULL, ROW(NULL,NULL)) IS NULL` yields FALSE). The core executor got this right, but certain planner optimizations treated the test as recursive (thus producing TRUE in both cases), and `contrib/postgres_fdw` could produce remote queries that misbehaved similarly.

- Make the `inet` and `cidr` data types properly reject IPv6 addresses with too many colon-separated fields (Tom Lane)

- Prevent crash in `close_ps()` (the `## lseg` operator) for NaN input coordinates (Tom Lane)

  Make it return NULL instead of crashing.

- Avoid possible crash in `pg_get_expr()` when inconsistent values are passed to it (Michael Paquier, Thomas Munro)

- Fix several one-byte buffer over-reads in `to_number()` (Peter Eisentraut)
In several cases the `to_number()` function would read one more character than it should from the input string. There is a small chance of a crash, if the input happens to be adjacent to the end of memory.

- Do not run the planner on the query contained in `CREATE MATERIALIZED VIEW` or `CREATE TABLE AS` when `WITH NO DATA` is specified (Michael Paquier, Tom Lane)

  This avoids some unnecessary failure conditions, for example if a stable function invoked by the materialized view depends on a table that doesn’t exist yet.

- Avoid unsafe intermediate state during expensive paths through `heap_update()` (Masahiko Sawada, Andres Freund)

  Previously, these cases locked the target tuple (by setting its XMAX) but did not WAL-log that action, thus risking data integrity problems if the page were spilled to disk and then a database crash occurred before the tuple update could be completed.

- Fix bit update during WAL replay of row locking operations (Andres Freund)

  The only known consequence of this problem is that row locks held by a prepared, but uncommitted, transaction might fail to be enforced after a crash and restart.

- Avoid unnecessary “could not serialize access” errors when acquiring `FOR KEY SHARE` row locks in serializable mode (Álvaro Herrera)

- Avoid crash in `postgres -C` when the specified variable has a null string value (Michael Paquier)

- Ensure that backends see up-to-date statistics for shared catalogs (Tom Lane)

  The statistics collector failed to update the statistics file for shared catalogs after a request from a regular backend. This problem was partially masked because the autovacuum launcher regularly makes requests that did cause such updates; however, it became obvious with autovacuum disabled.

- Avoid redundant writes of the statistics files when multiple backends request updates close together (Tom Lane, Tomas Vondra)

- Avoid consuming a transaction ID during `VACUUM` (Alexander Korotkov)

  Some cases in `VACUUM` unnecessarily caused an XID to be assigned to the current transaction. Normally this is negligible, but if one is up against the XID wraparound limit, consuming more XIDs during anti-wraparound vacuums is a very bad thing.

- Avoid canceling hot-standby queries during `VACUUM FREEZE` (Simon Riggs, Álvaro Herrera)

  `VACUUM FREEZE` on an otherwise-idle master server could result in unnecessary cancellations of queries on its standby servers.

- Prevent possible failure when vacuuming multixact IDs in an installation that has been `pg_upgrade`d from pre-9.3 (Andrew Gierth, Álvaro Herrera)

  The usual symptom of this bug is errors like “MultiXactId NNN has not been created yet -- apparent wraparound”.

- When a manual `ANALYZE` specifies a column list, don’t reset the table’s `changes_since_analyze` counter (Tom Lane)

  If we’re only analyzing some columns, we should not prevent routine auto-analyze from happening for the other columns.

- Fix `ANALYZE`’s overestimation of `n_distinct` for a unique or nearly-unique column with many null entries (Tom Lane)

  The nulls could get counted as though they were themselves distinct values, leading to serious planner misestimates in some types of queries.
Appendix E. Release Notes

- Prevent autovacuum from starting multiple workers for the same shared catalog (Álvaro Herrera)
  Normally this isn’t much of a problem because the vacuum doesn’t take long anyway; but in the case of a severely bloated catalog, it could result in all but one worker uselessly waiting instead of doing useful work on other tables.

- Prevent infinite loop in GiST index build for geometric columns containing NaN component values (Tom Lane)

- Fix contrib/btree_gin to handle the smallest possible bigint value correctly (Peter Eisentraut)

- Teach libpq to correctly decode server version from future servers (Peter Eisentraut)
  It’s planned to switch to two-part instead of three-part server version numbers for releases after 9.6. Make sure that PQserverVersion() returns the correct value for such cases.

- Fix ecpg’s code for unsigned long long array elements (Michael Meskes)

- In pg_dump with both -c and -C options, avoid emitting an unwanted CREATE SCHEMA public command (David Johnston, Tom Lane)

- Improve handling of SIGTERM/control-C in parallel pg_dump and pg_restore (Tom Lane)
  Make sure that the worker processes will exit promptly, and also arrange to send query-cancel requests to the connected backends, in case they are doing something long-running such as a CREATE INDEX.

- Fix error reporting in parallel pg_dump and pg_restore (Tom Lane)
  Previously, errors reported by pg_dump or pg_restore worker processes might never make it to the user’s console, because the messages went through the master process, and there were various deadlock scenarios that would prevent the master process from passing on the messages. Instead, just print everything to stderr. In some cases this will result in duplicate messages (for instance, if all the workers report a server shutdown), but that seems better than no message.

- Ensure that parallel pg_dump or pg_restore on Windows will shut down properly after an error (Kyotaro Horiguchi)
  Previously, it would report the error, but then just sit until manually stopped by the user.

- Make pg_dump behave better when built without zlib support (Kyotaro Horiguchi)
  It didn’t work right for parallel dumps, and emitted some rather pointless warnings in other cases.

- Make pg_basebackup accept -Z 0 as specifying no compression (Fujii Masao)

- Fix makefiles’ rule for building AIX shared libraries to be safe for parallel make (Noah Misch)

- Fix TAP tests and MSVC scripts to work when build directory’s path name contains spaces (Michael Paquier, Kyotaro Horiguchi)

- Be more predictable about reporting “statement timeout” versus “lock timeout” (Tom Lane)
  On heavily loaded machines, the regression tests sometimes failed due to reporting “lock timeout” even though the statement timeout should have occurred first.

- Make regression tests safe for Danish and Welsh locales (Jeff Janes, Tom Lane)
  Change some test data that triggered the unusual sorting rules of these locales.

- Update our copy of the timezone code to match IANA’s tzcode release 2016c (Tom Lane)
  This is needed to cope with anticipated future changes in the time zone data files. It also fixes some corner-case bugs in coping with unusual time zones.
Appendix E. Release Notes

- Update time zone data files to tzdata release 2016f for DST law changes in Kemerovo and Novosibirsk, plus historical corrections for Azerbaijan, Belarus, and Morocco.

E.47. Release 9.3.13

Release date: 2016-05-12

This release contains a variety of fixes from 9.3.12. For information about new features in the 9.3 major release, see Section E.60.

E.47.1. Migration to Version 9.3.13

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.9, see Section E.51.

E.47.2. Changes

- Clear the OpenSSL error queue before OpenSSL calls, rather than assuming it’s clear already; and make sure we leave it clear afterwards (Peter Geoghegan, Dave Vitek, Peter Eisentraut)

This change prevents problems when there are multiple connections using OpenSSL within a single process and not all the code involved follows the same rules for when to clear the error queue. Failures have been reported specifically when a client application uses SSL connections in libpq concurrently with SSL connections using the PHP, Python, or Ruby wrappers for OpenSSL. It’s possible for similar problems to arise within the server as well, if an extension module establishes an outgoing SSL connection.

- Fix “failed to build any n-way joins” planner error with a full join enclosed in the right-hand side of a left join (Tom Lane)

- Fix incorrect handling of equivalence-class tests in multilevel nestloop plans (Tom Lane)

Given a three-or-more-way equivalence class of variables, such as \(x.x = y.y = z.z\), it was possible for the planner to omit some of the tests needed to enforce that all the variables are actually equal, leading to join rows being output that didn’t satisfy the \(\text{WHERE}\) clauses. For various reasons, erroneous plans were seldom selected in practice, so that this bug has gone undetected for a long time.

- Fix possible misbehavior of \(\text{TH}, \text{th}, \text{and} Y, Y Y Y\) format codes in \(\text{to_timestamp()}\) (Tom Lane)

These could advance off the end of the input string, causing subsequent format codes to read garbage.

- Fix dumping of rules and views in which the \(\text{array}\) argument of a \(\text{value operator ANY (array)}\) construct is a sub-SELECT (Tom Lane)

- Make \(\text{pg_regress}\) use a startup timeout from the \(\text{PGCTLTIMEOUT}\) environment variable, if that’s set (Tom Lane)

This is for consistency with a behavior recently added to \(\text{pg_ctl}\); it eases automated testing on slow machines.
Appendix E. Release Notes

- Fix `pg_upgrade` to correctly restore extension membership for operator families containing only
  one operator class (Tom Lane)

  In such a case, the operator family was restored into the new database, but it was no longer marked
  as part of the extension. This had no immediate ill effects, but would cause later `pg_dump` runs to
  emit output that would cause (harmless) errors on restore.

- Fix `pg_upgrade` to not fail when new-cluster TOAST rules differ from old (Tom Lane)

  `pg_upgrade` had special-case code to handle the situation where the new PostgreSQL version thinks
  that a table should have a TOAST table while the old version did not. That code was broken, so
  remove it, and instead do nothing in such cases; there seems no reason to believe that we can’t get
  along fine without a TOAST table if that was okay according to the old version’s rules.

- Back-port 9.4-era memory-barrier code changes into 9.2 and 9.3 (Tom Lane)

  These changes were not originally needed in pre-9.4 branches, but we recently back-patched a fix
  that expected the barrier code to work properly. Only IA64 (when using `icc`), HPPA, and Alpha
  platforms are affected.

- Reduce the number of SysV semaphores used by a build configured with `--disable-spinlocks`
  (Tom Lane)

- Rename internal function `strtoi()` to `strtoint()` to avoid conflict with a NetBSD library func-
  tion (Thomas Munro)

- Fix reporting of errors from `bind()` and `listen()` system calls on Windows (Tom Lane)

- Reduce verbosity of compiler output when building with Microsoft Visual Studio (Christian Ull-
  rich)

- Fix `putenv()` to work properly with Visual Studio 2013 (Michael Paquier)

- Avoid possibly-unsafe use of Windows’ `FormatMessage()` function (Christian Ullrich)

  Use the `FORMAT_MESSAGE_IGNORE_INSERTS` flag where appropriate. No live bug is known to
  exist here, but it seems like a good idea to be careful.

- Update time zone data files to tzdata release 2016d for DST law changes in Russia and Venezuela.

  There are new zone names `Europe/Kirov` and `Asia/Tomsk` to reflect the fact that these regions
  now have different time zone histories from adjacent regions.

Release date: 2016-03-31

This release contains a variety of fixes from 9.3.11. For information about new features in the 9.3
major release, see Section E.60.

E.48.1. Migration to Version 9.3.12

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.9, see Section E.51.
E.48.2. Changes

- Fix incorrect handling of NULL index entries in indexed \texttt{ROW()} comparisons (Tom Lane)
  
  An index search using a row comparison such as \texttt{ROW(a, b) > ROW('x', 'y')} would stop upon reaching a NULL entry in the \texttt{b} column, ignoring the fact that there might be non-NULL \texttt{b} values associated with later values of \texttt{a}.

- Avoid unlikely data-loss scenarios due to renaming files without adequate \texttt{fsync()} calls before and after (Michael Paquier, Tomas Vondra, Andres Freund)

- Correctly handle cases where \texttt{pg_subtrans} is close to XID wraparound during server startup (Jeff Janes)

- Fix corner-case crash due to trying to free \texttt{localeconv()} output strings more than once (Tom Lane)

- Fix parsing of affix files for \texttt{ispell} dictionaries (Tom Lane)
  
  The code could go wrong if the affix file contained any characters whose byte length changes during case-folding, for example \texttt{I} in Turkish UTF8 locales.

- Avoid use of \texttt{sscanf()} to parse \texttt{ispell} dictionary files (Artur Zakirov)
  
  This dodges a portability problem on FreeBSD-derived platforms (including macOS).

- Avoid a crash on old Windows versions (before 7SP1/2008R2SP1) with an AVX2-capable CPU and a Postgres build done with Visual Studio 2013 (Christian Ullrich)
  This is a workaround for a bug in Visual Studio 2013’s runtime library, which Microsoft have stated they will not fix in that version.

- Fix psql’s tab completion logic to handle multibyte characters properly (Kyotaro Horiguchi, Robert Haas)

- Fix psql’s tab completion for \texttt{SECURITY LABEL} (Tom Lane)
  
  Pressing TAB after \texttt{SECURITY LABEL} might cause a crash or offering of inappropriate keywords.

- Make \texttt{pg_ctl} accept a wait timeout from the \texttt{PGCTLTIMEOUT} environment variable, if none is specified on the command line (Noah Misch)
  
  This eases testing of slower buildfarm members by allowing them to globally specify a longer-than-normal timeout for postmaster startup and shutdown.

- Fix incorrect test for Windows service status in \texttt{pg_ctl} (Manuel Mathar)
  
  The previous set of minor releases attempted to fix \texttt{pg_ctl} to properly determine whether to send log messages to Window’s Event Log, but got the test backwards.

- Fix \texttt{pgbench} to correctly handle the combination of \texttt{-C} and \texttt{-M} prepared options (Tom Lane)

- In \texttt{pg_upgrade}, skip creating a deletion script when the new data directory is inside the old data directory (Bruce Momjian)
  
  Blind application of the script in such cases would result in loss of the new data directory.

- In PL/Perl, properly translate empty Postgres arrays into empty Perl arrays (Alex Hunsaker)

- Make PL/Python cope with function names that aren’t valid Python identifiers (Jim Nasby)

- Fix multiple mistakes in the statistics returned by \texttt{contrib/pgstattriple\_s pgstatindex()} function (Tom Lane)

- Remove dependency on \texttt{psed} in MSVC builds, since it’s no longer provided by core Perl (Michael Paquier, Andrew Dunstan)
• Update time zone data files to tzdata release 2016c for DST law changes in Azerbaijan, Chile, Haiti, Palestine, and Russia (Altai, Astrakhan, Kirov, Sakhalin, Ulyanovsk regions), plus historical corrections for Lithuania, Moldova, and Russia (Kaliningrad, Samara, Volgograd).

E.49. Release 9.3.11

Release date: 2016-02-11

This release contains a variety of fixes from 9.3.10. For information about new features in the 9.3 major release, see Section E.60.

E.49.1. Migration to Version 9.3.11

A dump/restore is not required for those running 9.3.X. However, if you are upgrading from a version earlier than 9.3.9, see Section E.51.

E.49.2. Changes

• Fix infinite loops and buffer-overrun problems in regular expressions (Tom Lane)
  Very large character ranges in bracket expressions could cause infinite loops in some cases, and memory overwrites in other cases. (CVE-2016-0773)

• Perform an immediate shutdown if the postmaster.pid file is removed (Tom Lane)
  The postmaster now checks every minute or so that postmaster.pid is still there and still contains its own PID. If not, it performs an immediate shutdown, as though it had received SIGQUIT. The main motivation for this change is to ensure that failed buildfarm runs will get cleaned up without manual intervention; but it also serves to limit the bad effects if a DBA forcibly removes postmaster.pid and then starts a new postmaster.

• In SERIALIZABLE transaction isolation mode, serialization anomalies could be missed due to race conditions during insertions (Kevin Grittner, Thomas Munro)

• Fix failure to emit appropriate WAL records when doing ALTER TABLE ... SET TABLESPACE for unlogged relations (Michael Paquier, Andres Freund)
  Even though the relation’s data is unlogged, the move must be logged or the relation will be inaccessible after a standby is promoted to master.

• Fix possible misinitialization of unlogged relations at the end of crash recovery (Andres Freund, Michael Paquier)

• Ensure walsender slots are fully re-initialized when being re-used (Magnus Hagander)

• Fix ALTER COLUMN TYPE to reconstruct inherited check constraints properly (Tom Lane)

• Fix REASSIGN OWNED to change ownership of composite types properly (Álvaro Herrera)

• Fix REASSIGN OWNED and ALTER OWNER to correctly update granted-permissions lists when changing owners of data types, foreign data wrappers, or foreign servers (Bruce Momjian, Álvaro Herrera)

• Fix REASSIGN OWNED to ignore foreign user mappings, rather than fail (Álvaro Herrera)
Appendix E. Release Notes

• Fix possible crash after doing query rewrite for an updatable view (Stephen Frost)
• Fix planner’s handling of LATERAL references (Tom Lane)
  This fixes some corner cases that led to “failed to build any N-way joins” or “could not devise a query plan” planner failures.
• Add more defenses against bad planner cost estimates for GIN index scans when the index’s internal statistics are very out-of-date (Tom Lane)
• Make planner cope with hypothetical GIN indexes suggested by an index advisor plug-in (Julien Rouhaud)
• Speed up generation of unique table aliases in EXPLAIN and rule dumping, and ensure that generated aliases do not exceed NAMEDATALEN (Tom Lane)
• Fix dumping of whole-row Vars in ROW() and VALUES() lists (Tom Lane)
• Fix possible internal overflow in numeric division (Dean Rasheed)
• Fix enforcement of restrictions inside parentheses within regular expression lookahead constraints (Tom Lane)
  Lookahead constraints aren’t allowed to contain backrefs, and parentheses within them are always considered non-capturing, according to the manual. However, the code failed to handle these cases properly inside a parenthesized subexpression, and would give unexpected results.
• Conversion of regular expressions to indexscan bounds could produce incorrect bounds from reg-exps containing lookahead constraints (Tom Lane)
• Fix regular-expression compiler to handle loops of constraint arcs (Tom Lane)
  The code added for CVE-2007-4772 was both incomplete, in that it didn’t handle loops involving more than one state, and incorrect, in that it could cause assertion failures (though there seem to be no bad consequences of that in a non-assert build). Multi-state loops would cause the compiler to run until the query was canceled or it reached the too-many-states error condition.
• Improve memory-usage accounting in regular-expression compiler (Tom Lane)
  This causes the code to emit “regular expression is too complex” errors in some cases that previously used unreasonable amounts of time and memory.
• Improve performance of regular-expression compiler (Tom Lane)
• Make %h and %r escapes in log_line_prefix work for messages emitted due to log_connections (Tom Lane)
  Previously, %h/%r started to work just after a new session had emitted the “connection received” log message; now they work for that message too.
• On Windows, ensure the shared-memory mapping handle gets closed in child processes that don’t need it (Tom Lane, Amit Kapila)
  This oversight resulted in failure to recover from crashes whenever logging_collector is turned on.
• Fix possible failure to detect socket EOF in non-blocking mode on Windows (Tom Lane)
  It’s not entirely clear whether this problem can happen in pre-9.5 branches, but if it did, the symptom would be that a walsender process would wait indefinitely rather than noticing a loss of connection.
• Avoid leaking a token handle during SSPI authentication (Christian Ullrich)
• In psql, ensure that libreadline’s idea of the screen size is updated when the terminal window size changes (Merlin Moncure)
Previously, libreadline did not notice if the window was resized during query output, leading to strange behavior during later input of multiline queries.

- Fix psql’s `\det` command to interpret its pattern argument the same way as other `\d` commands with potentially schema-qualified patterns do (Reece Hart)
- Avoid possible crash in psql’s `\c` command when previous connection was via Unix socket and command specifies a new hostname and same username (Tom Lane)
- In `pg_ctl start -w`, test child process status directly rather than relying on heuristics (Tom Lane, Michael Paquier)

  Previously, `pg_ctl` relied on an assumption that the new postmaster would always create `postmaster.pid` within five seconds. But that can fail on heavily-loaded systems, causing `pg_ctl` to report incorrectly that the postmaster failed to start.

  Except on Windows, this change also means that a `pg_ctl start -w` done immediately after another such command will now reliably fail, whereas previously it would report success if done within two seconds of the first command.

- In `pg_ctl start -w`, don’t attempt to use a wildcard listen address to connect to the postmaster (Kondo Yuta)

  On Windows, `pg_ctl` would fail to detect postmaster startup if `listen_addresses` is set to `0.0.0.0` or `::`, because it would try to use that value verbatim as the address to connect to, which doesn’t work. Instead assume that `127.0.0.1` or `::1`, respectively, is the right thing to use.

- In `pg_ctl` on Windows, check service status to decide where to send output, rather than checking if standard output is a terminal (Michael Paquier)

- In `pg_dump` and `pg_basebackup`, adopt the GNU convention for handling tar-archive members exceeding 8GB (Tom Lane)

  The POSIX standard for `tar` file format does not allow archive member files to exceed 8GB, but most modern implementations of `tar` support an extension that fixes that. Adopt this extension so that `pg_dump` with `--f` no longer fails on tables with more than 8GB of data, and so that `pg_basebackup` can handle files larger than 8GB. In addition, fix some portability issues that could cause failures for members between 4GB and 8GB on some platforms. Potentially these problems could cause unrecoverable data loss due to unreadable backup files.

- Fix assorted corner-case bugs in `pg_dump`’s processing of extension member objects (Tom Lane)

- Make `pg_dump` mark a view’s triggers as needing to be processed after its rule, to prevent possible failure during parallel `pg_restore` (Tom Lane)

- Ensure that relation option values are properly quoted in `pg_dump` (Kouhei Sutou, Tom Lane)

  A relation option that isn’t a simple identifier or number could lead to dump/reload failures due to syntax errors in CREATE statements issued by `pg_dump`. This is not an issue with any reloption currently supported by core PostgreSQL, but extensions could allow reloptions that cause the problem.

- Avoid repeated password prompts during parallel `pg_dump` (Zeus Kronion)

- Fix `pg_upgrade`’s file-copying code to handle errors properly on Windows (Bruce Momjian)

- Install guards in `pgbench` against corner-case overflow conditions during evaluation of script-specified division or modulo operators (Fabien Coelho, Michael Paquier)

- Fix failure to localize messages emitted by `pg_receivexlog` and `pg_recvlogical` (Joseph Kim)

- Avoid dump/reload problems when using both `plpython2` and `plpython3` (Tom Lane)
In principle, both versions of PL/Python can be used in the same database, though not in the same session (because the two versions of libpython cannot safely be used concurrently). However, pg_restore and pg_upgrade both do things that can fall foul of the same-session restriction. Work around that by changing the timing of the check.

- Fix PL/Python regression tests to pass with Python 3.5 (Peter Eisentraut)
- Fix premature clearing of libpq’s input buffer when socket EOF is seen (Tom Lane)
  This mistake caused libpq to sometimes not report the backend’s final error message before reporting “server closed the connection unexpectedly”.
- Prevent certain PL/Java parameters from being set by non-superusers (Noah Misch)
  This change mitigates a PL/Java security bug (CVE-2016-0766), which was fixed in PL/Java by marking these parameters as superuser-only. To fix the security hazard for sites that update PostgreSQL more frequently than PL/Java, make the core code aware of them also.
- Improve libpq’s handling of out-of-memory situations (Michael Paquier, Amit Kapila, Heikki Linnakangas)
- Fix order of arguments in ecpg-generated typedef statements (Michael Meskes)
- Use %g not %f format in ecpg’s PGTYPESnumeric_from_double() (Tom Lane)
- Fix ecpg-supplied header files to not contain comments continued from a preprocessor directive line onto the next line (Michael Meskes)
  Such a comment is rejected by ecpg. It’s not yet clear whether ecpg itself should be changed.
- Fix hstore_to_json_loose()’s test for whether an hstore value can be converted to a JSON number (Tom Lane)
  Previously this function could be fooled by non-alphanumeric trailing characters, leading to emitting syntactically-invalid JSON.
- Ensure that contrib/pgcrypto’s crypt() function can be interrupted by query cancel (Andreas Karlsson)
- Accept flex versions later than 2.5.x (Tom Lane, Michael Paquier)
  Now that flex 2.6.0 has been released, the version checks in our build scripts needed to be adjusted.
- Improve reproducibility of build output by ensuring filenames are given to the linker in a fixed order (Christoph Berg)
  This avoids possible bitwise differences in the produced executable files from one build to the next.
- Install our missing script where PGXS builds can find it (Jim Nasby)
  This allows sane behavior in a PGXS build done on a machine where build tools such as bison are missing.
- Ensure that dynloader.h is included in the installed header files in MSVC builds (Bruce Momjian, Michael Paquier)
- Add variant regression test expected-output file to match behavior of current libxml2 (Tom Lane)
  The fix for libxml2’s CVE-2015-7499 causes it not to output error context reports in some cases where it used to do so. This seems to be a bug, but we’ll probably have to live with it for some time, so work around it.
- Update time zone data files to tzdata release 2016a for DST law changes in Cayman Islands, Metlakatla, and Trans-Baikal Territory (Zabaykalsky Krai), plus historical corrections for Pakistan.
Appendix E. Release Notes

E.50. Release 9.3.10

Release date: 2015-10-08

This release contains a variety of fixes from 9.3.9. For information about new features in the 9.3 major release, see Section E.60.

E.50.1. Migration to Version 9.3.10

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.9, see Section E.51.

E.50.2. Changes

- Guard against stack overflows in json parsing (Oskari Saarenmaa)
  
  If an application constructs PostgreSQL json or jsonb values from arbitrary user input, the application’s users can reliably crash the PostgreSQL server, causing momentary denial of service. (CVE-2015-5289)

- Fix contrib/pgcrypto to detect and report too-short crypt() salts (Josh Kupershmidt)
  
  Certain invalid salt arguments crashed the server or disclosed a few bytes of server memory. We have not ruled out the viability of attacks that arrange for presence of confidential information in the disclosed bytes, but they seem unlikely. (CVE-2015-5288)

- Fix subtransaction cleanup after a portal (cursor) belonging to an outer subtransaction fails (Tom Lane, Michael Paquier)
  
  A function executed in an outer-subtransaction cursor could cause an assertion failure or crash by referencing a relation created within an inner subtransaction.

- Ensure all relations referred to by an updatable view are properly locked during an update statement (Dean Rasheed)

- Fix insertion of relations into the relation cache “init file” (Tom Lane)

  An oversight in a patch in the most recent minor releases caused pg_trigger_tgrelid_tgname_index to be omitted from the init file. Subsequent sessions detected this, then deemed the init file to be broken and silently ignored it, resulting in a significant degradation in session startup time. In addition to fixing the bug, install some guards so that any similar future mistake will be more obvious.

- Avoid O(N^2) behavior when inserting many tuples into a SPI query result (Neil Conway)

- Improve LISTEN startup time when there are many unread notifications (Matt Newell)

- Fix performance problem when a session alters large numbers of foreign key constraints (Jan Wieck, Tom Lane)

  This was seen primarily when restoring pg_dump output for databases with many thousands of tables.

- Disable SSL renegotiation by default (Michael Paquier, Andres Freund)

  While use of SSL renegotiation is a good idea in theory, we have seen too many bugs in practice, both in the underlying OpenSSL library and in our usage of it. Renegotiation will
Appendix E. Release Notes

be removed entirely in 9.5 and later. In the older branches, just change the default value of
ssl_renegotiation_limit to zero (disabled).

- Lower the minimum values of the *_freeze_max_age parameters (Andres Freund)
  This is mainly to make tests of related behavior less time-consuming, but it may also be of value
  for installations with limited disk space.

- Limit the maximum value of wal_buffers to 2GB to avoid server crashes (Josh Berkus)

- Avoid logging complaints when a parameter that can only be set at server start appears multiple
times in postgresql.conf, and fix counting of line numbers after an include_dir directive
  (Tom Lane)

- Fix rare internal overflow in multiplication of numeric values (Dean Rasheed)

- Guard against hard-to-reach stack overflows involving record types, range types, json, jsonb,
tsquery, ltxtquery and query_int (Noah Misch)

- Fix handling of DOW and DOY in datetime input (Greg Stark)
  These tokens aren’t meant to be used in datetime values, but previously they resulted in opaque
  internal error messages rather than “invalid input syntax”.

- Add more query-cancel checks to regular expression matching (Tom Lane)

- Add recursion depth protections to regular expression, SIMILAR TO, and LIKE matching (Tom
  Lane)
  Suitable search patterns and a low stack depth limit could lead to stack-overrun crashes.

- Fix potential infinite loop in regular expression execution (Tom Lane)
  A search pattern that can apparently match a zero-length string, but actually doesn’t match because
  of a back reference, could lead to an infinite loop.

- In regular expression execution, correctly record match data for capturing parentheses within a
  quantifier even when the match is zero-length (Tom Lane)

- Fix low-memory failures in regular expression compilation (Andreas Seltenreich)

- Fix low-probability memory leak during regular expression execution (Tom Lane)

- Fix rare low-memory failure in lock cleanup during transaction abort (Tom Lane)

- Fix “unexpected out-of-memory situation during sort” errors when using tuplestores with small
  work_mem settings (Tom Lane)

- Fix very-low-probability stack overrun in qsort (Tom Lane)

- Fix “invalid memory alloc request size” failure in hash joins with large work_mem settings (Tomas
  Vondra, Tom Lane)

- Fix assorted planner bugs (Tom Lane)
  These mistakes could lead to incorrect query plans that would give wrong answers, or to assertion
  failures in assert-enabled builds, or to odd planner errors such as “could not devise a query plan
  for the given query”, “could not find pathkey item to sort”, “plan should not reference subplan’s
  variable”, or “failed to assign all NestLoopParams to plan nodes”. Thanks are due to Andreas
  Seltenreich and Piotr Stefaniak for fuzz testing that exposed these problems.

- Improve planner’s performance for UPDATE/DELETE on large inheritance sets (Tom Lane, Dean
  Rasheed)

- Ensure standby promotion trigger files are removed at postmaster startup (Michael Paquier, Fujii
  Masao)
This prevents unwanted promotion from occurring if these files appear in a database backup that is used to initialize a new standby server.

- During postmaster shutdown, ensure that per-socket lock files are removed and listen sockets are closed before we remove the postmaster.pid file (Tom Lane)
  This avoids race-condition failures if an external script attempts to start a new postmaster as soon as pg_ctl stop returns.
- Fix postmaster’s handling of a startup-process crash during crash recovery (Tom Lane)
  If, during a crash recovery cycle, the startup process crashes without having restored database consistency, we’d try to launch a new startup process, which typically would just crash again, leading to an infinite loop.
- Make emergency autovacuuming for multixact wraparound more robust (Andres Freund)
- Do not print a WARNING when an autovacuum worker is already gone when we attempt to signal it, and reduce log verbosity for such signals (Tom Lane)
- Prevent autovacuum launcher from sleeping unduly long if the server clock is moved backwards a large amount (Álvaro Herrera)
- Ensure that cleanup of a GIN index’s pending-insertions list is interruptable by cancel requests (Jeff Janes)
- Allow all-zeroes pages in GIN indexes to be reused (Heikki Linnakangas)
  Such a page might be left behind after a crash.
- Fix handling of all-zeroes pages in SP-GiST indexes (Heikki Linnakangas)
  VACUUM attempted to recycle such pages, but did so in a way that wasn’t crash-safe.
- Fix off-by-one error that led to otherwise-harmless warnings about “apparent wraparound” in sub-trans/multixact truncation (Thomas Munro)
- Fix misreporting of CONTINUE and MOVE statement types in PL/pgSQL’s error context messages (Pavel Stehule, Tom Lane)
- Fix PL/Perl to handle non-ASCII error message texts correctly (Alex Hunsaker)
- Fix PL/Python crash when returning the string representation of a record result (Tom Lane)
- Fix some places in PL/Tcl that neglected to check for failure of malloc() calls (Michael Paquier, Álvaro Herrera)
- In contrib/isn, fix output of ISBN-13 numbers that begin with 979 (Fabien Coelho)
  EANs beginning with 979 (but not 9790) are considered ISBNs, but they must be printed in the new 13-digit format, not the 10-digit format.
- Improve contrib/postgres_fdw’s handling of collation-related decisions (Tom Lane)
  The main user-visible effect is expected to be that comparisons involving varchar columns will be sent to the remote server for execution in more cases than before.
- Improve libpq’s handling of out-of-memory conditions (Michael Paquier, Heikki Linnakangas)
- Fix memory leaks and missing out-of-memory checks in ecpg (Michael Paquier)
- Fix psqi’s code for locale-aware formatting of numeric output (Tom Lane)
  The formatting code invoked by \pset numericlocale on did the wrong thing for some uncommon cases such as numbers with an exponent but no decimal point. It could also mangle already-localized output from the money data type.
- Prevent crash in psqi’s \c command when there is no current connection (Noah Misch)
Appendix E. Release Notes

- Make pg_dump handle inherited NOT VALID check constraints correctly (Tom Lane)
- Fix selection of default zlib compression level in pg_dump's directory output format (Andrew Dunstan)
- Ensure that temporary files created during a pg_dump run with tar-format output are not world-readable (Michael Paquier)
- Fix pg_dump and pg_upgrade to support cases where the postgres or template1 database is in a non-default tablespace (Marti Raudsepp, Bruce Momjian)
- Fix pg_dump to handle object privileges sanely when dumping from a server too old to have a particular privilege type (Tom Lane)

  When dumping data types from pre-9.2 servers, and when dumping functions or procedural languages from pre-7.3 servers, pg_dump would produce GRANT/REVOKE commands that revoked the owner's grantable privileges and instead granted all privileges to PUBLIC. Since the privileges involved are just USAGE and EXECUTE, this isn't a security problem, but it's certainly a surprising representation of the older systems' behavior. Fix it to leave the default privilege state alone in these cases.

- Fix pg_dump to dump shell types (Tom Lane)

  Shell types (that is, not-yet-fully-defined types) aren't useful for much, but nonetheless pg_dump should dump them.

- Fix assorted minor memory leaks in pg_dump and other client-side programs (Michael Paquier)
- Fix spinlock assembly code for PPC hardware to be compatible with AIX's native assembler (Tom Lane)

  Building with gcc didn't work if gcc had been configured to use the native assembler, which is becoming more common.

- On AIX, test the -qlonglong compiler option rather than just assuming it's safe to use (Noah Misch)
- On AIX, use -Wl,-brtllib link option to allow symbols to be resolved at runtime (Noah Misch)

  Perl relies on this ability in 5.8.0 and later.

- Avoid use of inline functions when compiling with 32-bit xlc, due to compiler bugs (Noah Misch)
- Use librt for sched_yield() when necessary, which it is on some Solaris versions (Oskari Saarenmaa)
- Fix Windows install.bat script to handle target directory names that contain spaces (Heikki Linnakangas)
- Make the numeric form of the PostgreSQL version number (e.g., 90405) readily available to extension Makefiles, as a variable named VERSION_NUM (Michael Paquier)
- Update time zone data files to tzdata release 2015g for DST law changes in Cayman Islands, Fiji, Moldova, Morocco, Norfolk Island, North Korea, Turkey, and Uruguay. There is a new zone name America/Fort_Nelson for the Canadian Northern Rockies.

E.51. Release 9.3.9

Release date: 2015-06-12
Appendix E. Release Notes

This release contains a small number of fixes from 9.3.8. For information about new features in the 9.3 major release, see Section E.60.

E.51.1. Migration to Version 9.3.9

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading an installation that was previously upgraded using a pg_upgrade version between 9.3.0 and 9.3.4 inclusive, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.3.7, see Section E.53.

E.51.2. Changes

• Fix possible failure to recover from an inconsistent database state (Robert Haas)

Recent PostgreSQL releases introduced mechanisms to protect against multixact wraparound, but some of that code did not account for the possibility that it would need to run during crash recovery, when the database may not be in a consistent state. This could result in failure to restart after a crash, or failure to start up a secondary server. The lingering effects of a previously-fixed bug in pg_upgrade could also cause such a failure, in installations that had used pg_upgrade versions between 9.3.0 and 9.3.4.

The pg_upgrade bug in question was that it would set oldestMultiXid to 1 in pg_control even if the true value should be higher. With the fixes introduced in this release, such a situation will result in immediate emergency autovacuuming until a correct oldestMultiXid value can be determined. If that would pose a hardship, users can avoid it by doing manual vacuuming before upgrading to this release. In detail:

1. Check whether pg_controldata reports “Latest checkpoint’s oldestMultiXid” to be 1. If not, there’s nothing to do.

2. Look in PGDATA/pg_multixact/offsets to see if there’s a file named 0000. If there is, there’s nothing to do.

3. Otherwise, for each table that has pg_class.relminmxid equal to 1, VACUUM that table with both vacuum_multixact_freeze_min_age and vacuum_multixact_freeze_table_age set to zero. (You can use the vacuum cost delay parameters described in Section 18.4.4 to reduce the performance consequences for concurrent sessions.) You must use PostgreSQL 9.3.5 or later to perform this step.

• Fix rare failure to invalidate relation cache init file (Tom Lane)

With just the wrong timing of concurrent activity, a VACUUM FULL on a system catalog might fail to update the “init file” that’s used to avoid cache-loading work for new sessions. This would result in later sessions being unable to access that catalog at all. This is a very ancient bug, but it’s so hard to trigger that no reproducible case had been seen until recently.

• Avoid deadlock between incoming sessions and CREATE/DROP DATABASE (Tom Lane)

A new session starting in a database that is the target of a DROP DATABASE command, or is the template for a CREATE DATABASE command, could cause the command to wait for five seconds and then fail, even if the new session would have exited before that.
Appendix E. Release Notes

- Improve planner’s cost estimates for semi-joins and anti-joins with inner indexscans (Tom Lane, Tomas Vondra)

This type of plan is quite cheap when all the join clauses are used as index scan conditions, even if the inner scan would nominally fetch many rows, because the executor will stop after obtaining one row. The planner only partially accounted for that effect, and would therefore overestimate the cost, leading it to possibly choose some other much less efficient plan type.

E.52. Release 9.3.8

Release date: 2015-06-04

This release contains a small number of fixes from 9.3.7. For information about new features in the 9.3 major release, see Section E.60.

E.52.1. Migration to Version 9.3.8

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.7, see Section E.53.

E.52.2. Changes

- Avoid failures while fsync’ing data directory during crash restart (Abhijit Menon-Sen, Tom Lane)

In the previous minor releases we added a patch to fsync everything in the data directory after a crash. Unfortunately its response to any error condition was to fail, thereby preventing the server from starting up, even when the problem was quite harmless. An example is that an unwritable file in the data directory would prevent restart on some platforms; but it is common to make SSL certificate files unwritable by the server. Revise this behavior so that permissions failures are ignored altogether, and other types of failures are logged but do not prevent continuing.

Also apply the same rules in initdb --sync-only. This case is less critical but it should act similarly.

- Fix pg_get_functiondef() to show functions’ LEAKPROOF property, if set (Jeevan Chalke)

- Remove configure’s check prohibiting linking to a threaded libpython on OpenBSD (Tom Lane)

The failure this restriction was meant to prevent seems to not be a problem anymore on current OpenBSD versions.

- Allow libpq to use TLS protocol versions beyond v1 (Noah Misch)

For a long time, libpq was coded so that the only SSL protocol it would allow was TLS v1. Now that newer TLS versions are becoming popular, allow it to negotiate the highest commonly-supported TLS version with the server. (PostgreSQL servers were already capable of such negotiation, so no change is needed on the server side.) This is a back-patch of a change already released in 9.4.0.
E.53. Release 9.3.7

Release date: 2015-05-22

This release contains a variety of fixes from 9.3.6. For information about new features in the 9.3 major release, see Section E.60.

E.53.1. Migration to Version 9.3.7

A dump/restore is not required for those running 9.3.X. However, if you use contrib/citext's regexp_matches() functions, see the changelog entry below about that. Also, if you are upgrading from a version earlier than 9.3.6, see Section E.54.

E.53.2. Changes

• Avoid possible crash when client disconnects just before the authentication timeout expires (Benkocs Norbert Attila)

If the timeout interrupt fired partway through the session shutdown sequence, SSL-related state would be freed twice, typically causing a crash and hence denial of service to other sessions. Experimentation shows that an unauthenticated remote attacker could trigger the bug somewhat consistently, hence treat as security issue. (CVE-2015-3165)

• Improve detection of system-call failures (Noah Misch)

Our replacement implementation of snprintf() failed to check for errors reported by the underlying system library calls; the main case that might be missed is out-of-memory situations. In the worst case this might lead to information exposure, due to our code assuming that a buffer had been overwritten when it hadn’t been. Also, there were a few places in which security-relevant calls of other system library functions did not check for failure.

It remains possible that some calls of the *printf() family of functions are vulnerable to information disclosure if an out-of-memory error occurs at just the wrong time. We judge the risk to not be large, but will continue analysis in this area. (CVE-2015-3166)

• In contrib/pgcrypto, uniformly report decryption failures as “Wrong key or corrupt data” (Noah Misch)

Previously, some cases of decryption with an incorrect key could report other error message texts. It has been shown that such variance in error reports can aid attackers in recovering keys from other systems. While it’s unknown whether pgcrypto’s specific behaviors are likewise exploitable, it seems better to avoid the risk by using a one-size-fits-all message. (CVE-2015-3167)

• Protect against wraparound of multixact member IDs (Álvaro Herrera, Robert Haas, Thomas Munro)

Under certain usage patterns, the existing defenses against this might be insufficient, allowing pg_multixact/members files to be removed too early, resulting in data loss. The fix for this includes modifying the server to fail transactions that would result in overwriting old multixact member ID data, and improving autovacuum to ensure it will act proactively to prevent multixact member ID wraparound, as it does for transaction ID wraparound.

• Fix incorrect declaration of contrib/citext's regexp_matches() functions (Tom Lane)
These functions should return *setof text[]*, like the core functions they are wrappers for; but they were incorrectly declared as returning *just text[]*. This mistake had two results: first, if there was no match you got a scalar null result, whereas what you should get is an empty set (zero rows). Second, the *g* flag was effectively ignored, since you would get only one result array even if there were multiple matches.

While the latter behavior is clearly a bug, there might be applications depending on the former behavior; therefore the function declarations will not be changed by default until PostgreSQL 9.5. In pre-9.5 branches, the old behavior exists in version 1.0 of the *citext* extension, while we have provided corrected declarations in version 1.1 (which is *not* installed by default). To adopt the fix in pre-9.5 branches, execute `ALTER EXTENSION citext UPDATE TO '1.1'` in each database in which *citext* is installed. (You can also “update” back to 1.0 if you need to undo that.) Be aware that either update direction will require dropping and recreating any views or rules that use *citext’s regexp_matches()* functions.

- **Fix incorrect checking of deferred exclusion constraints after a HOT update (Tom Lane)**
  
  If a new row that potentially violates a deferred exclusion constraint is HOT-updated (that is, no indexed columns change and the row can be stored back onto the same table page) later in the same transaction, the exclusion constraint would be reported as violated when the check finally occurred, even if the row(s) the new row originally conflicted with had been deleted.

- **Fix planning of star-schema-style queries (Tom Lane)**
  
  Sometimes, efficient scanning of a large table requires that index parameters be provided from more than one other table (commonly, dimension tables whose keys are needed to index a large fact table). The planner should be able to find such plans, but an overly restrictive search heuristic prevented it.

- **Prevent improper reordering of antijoins (NOT EXISTS joins) versus other outer joins (Tom Lane)**
  
  This oversight in the planner has been observed to cause “could not find RelOptInfo for given relids” errors, but it seems possible that sometimes an incorrect query plan might get past that consistency check and result in silently-wrong query output.

- **Fix incorrect matching of subexpressions in outer-join plan nodes (Tom Lane)**
  
  Previously, if textually identical non-strict subexpressions were used both above and below an outer join, the planner might try to re-use the value computed below the join, which would be incorrect because the executor would force the value to NULL in case of an unmatched outer row.

- **Fix GEGO planner to cope with failure of its join order heuristic (Tom Lane)**
  
  This oversight has been seen to lead to “failed to join all relations together” errors in queries involving *LATERAL*, and that might happen in other cases as well.

- **Fix possible deadlock at startup when *max_prepared_transactions* is too small (Heikki Linnakangas)**

- **Don’t archive useless preallocated WAL files after a timeline switch (Heikki Linnakangas)**

- **Recursively *fsync()* the data directory after a crash (Abhijit Menon-Sen, Robert Haas)**

  This ensures consistency if another crash occurs shortly later. (The second crash would have to be a system-level crash, not just a database crash, for there to be a problem.)

- **Fix autovacuum launcher’s possible failure to shut down, if an error occurs after it receives SIGTERM (Álvaro Herrera)**

- **Cope with unexpected signals in *LockBufferForCleanup()* (Andres Freund)**

  This oversight could result in spurious errors about “multiple backends attempting to wait for pincount 1”. 
Appendix E. Release Notes

- Fix crash when doing COPY IN to a table with check constraints that contain whole-row references (Tom Lane)

The known failure case only crashes in 9.4 and up, but there is very similar code in 9.3 and 9.2, so back-patch those branches as well.

- Avoid waiting for WAL flush or synchronous replication during commit of a transaction that was read-only so far as the user is concerned (Andres Freund)

Previously, a delay could occur at commit in transactions that had written WAL due to HOT page pruning, leading to undesirable effects such as sessions getting stuck at startup if all synchronous replicas are down. Sessions have also been observed to get stuck in catchup interrupt processing when using synchronous replication; this will fix that problem as well.

- Fix crash when manipulating hash indexes on temporary tables (Heikki Linnakangas)

- Fix possible failure during hash index bucket split, if other processes are modifying the index concurrently (Tom Lane)

- Check for interrupts while analyzing index expressions (Jeff Janes)

`ANALYZE` executes index expressions many times; if there are slow functions in such an expression, it’s desirable to be able to cancel the `ANALYZE` before that loop finishes.

- Ensure tableoid of a foreign table is reported correctly when a READ COMMITTED recheck occurs after locking rows in SELECT FOR UPDATE, UPDATE, or DELETE (Etsuro Fujita)

- Add the name of the target server to object description strings for foreign-server user mappings (Álvaro Herrera)

- Include the schema name in object identity strings for conversions (Álvaro Herrera)

- Recommend setting `include_realm` to 1 when using Kerberos/GSSAPI/SSPI authentication (Stephen Frost)

Without this, identically-named users from different realms cannot be distinguished. For the moment this is only a documentation change, but it will become the default setting in PostgreSQL 9.5.

- Remove code for matching IPv4 `pg_hba.conf` entries to IPv4-in-IPv6 addresses (Tom Lane)

This hack was added in 2003 in response to a report that some Linux kernels of the time would report IPv4 connections as having IPv4-in-IPv6 addresses. However, the logic was accidentally broken in 9.0. The lack of any field complaints since then shows that it’s not needed anymore. Now we have reports that the broken code causes crashes on some systems, so let’s just remove it rather than fix it. (Had we chosen to fix it, that would make for a subtle and potentially security-sensitive change in the effective meaning of IPv4 `pg_hba.conf` entries, which does not seem like a good thing to do in minor releases.)

- Report WAL flush, not insert, position in IDENTIFY_SYSTEM replication command (Heikki Linnakangas)

This avoids a possible startup failure in `pg_receivexlog`.

- While shutting down service on Windows, periodically send status updates to the Service Control Manager to prevent it from killing the service too soon; and ensure that `pg_ctl` will wait for shutdown (Krystian Bigaj)

- Reduce risk of network deadlock when using libpq’s non-blocking mode (Heikki Linnakangas)

When sending large volumes of data, it’s important to drain the input buffer every so often, in case the server has sent enough response data to cause it to block on output. (A typical scenario is that the server is sending a stream of NOTICE messages during `COPY FROM STDIN`.)
Appendix E. Release Notes

properly in the normal blocking mode, but not so much in non-blocking mode. We’ve modified libpq to opportunistically drain input when it can, but a full defense against this problem requires application cooperation: the application should watch for socket read-ready as well as write-ready conditions, and be sure to call PQconsumeInput() upon read-ready.

• In libpq, fix misparsing of empty values in URI connection strings (Thomas Fanghaenel)

• Fix array handling in ecpg (Michael Meskes)

• Fix psql to sanely handle URIs and conninfo strings as the first parameter to \connect (David Fetter, Andrew Dunstan, Álvaro Herrera)

This syntax has been accepted (but undocumented) for a long time, but previously some parameters might be taken from the old connection instead of the given string, which was agreed to be undesirable.

• Suppress incorrect complaints from psql on some platforms that it failed to write ~/.psql_history at exit (Tom Lane)

This misbehavior was caused by a workaround for a bug in very old (pre-2006) versions of libedit. We fixed it by removing the workaround, which will cause a similar failure to appear for anyone still using such versions of libedit. Recommendation: upgrade that library, or use libreadline.

• Fix pg_dump’s rule for deciding which casts are system-provided casts that should not be dumped (Tom Lane)

• In pg_dump, fix failure to honor -Z compression level option together with -Fd (Michael Paquier)

• Make pg_dump consider foreign key relationships between extension configuration tables while choosing dump order (Gilles Darold, Michael Paquier, Stephen Frost)

This oversight could result in producing dumps that fail to reload because foreign key constraints are transiently violated.

• Avoid possible pg_dump failure when concurrent sessions are creating and dropping temporary functions (Tom Lane)

• Fix dumping of views that are just VALUES(...) but have column aliases (Tom Lane)

• In pg_upgrade, force timeline 1 in the new cluster (Bruce Momjian)

This change prevents upgrade failures caused by bogus complaints about missing WAL history files.

• In pg_upgrade, check for improperly non-connectable databases before proceeding (Bruce Momjian)

• In pg_upgrade, quote directory paths properly in the generated delete_old_cluster script (Bruce Momjian)

• In pg_upgrade, preserve database-level freezing info properly (Bruce Momjian)

This oversight could cause missing-clog-file errors for tables within the postgres and template1 databases.

• Run pg_upgrade and pg_resetxlog with restricted privileges on Windows, so that they don’t fail when run by an administrator (Muhammad Asif Naeem)

• Improve handling of readdir() failures when scanning directories in initdb and pg_basebackup (Marco Nenciarini)

• Fix slow sorting algorithm in contrib/intarray (Tom Lane)

• Fix compile failure on Sparc V8 machines (Rob Rowan)

• Silence some build warnings on macOS (Tom Lane)

2355
• Update time zone data files to tzdata release 2015d for DST law changes in Egypt, Mongolia, and Palestine, plus historical changes in Canada and Chile. Also adopt revised zone abbreviations for the America/Adak zone (HST/HDT not HAST/HADT).

E.54. Release 9.3.6

Release date: 2015-02-05

This release contains a variety of fixes from 9.3.5. For information about new features in the 9.3 major release, see Section E.60.

E.54.1. Migration to Version 9.3.6

A dump/restore is not required for those running 9.3.X.

However, if you are a Windows user and are using the “Norwegian (Bokmål)” locale, manual action is needed after the upgrade to replace any “Norwegian (Bokmål)_Norway” locale names stored in PostgreSQL system catalogs with the plain-ASCII alias “Norwegian_Norway”. For details see http://wiki.postgresql.org/wiki/Changes_To_Norwegian_Locale

Also, if you are upgrading from a version earlier than 9.3.5, see Section E.55.

E.54.2. Changes

• Fix buffer overruns in to_char() (Bruce Momjian)

When to_char() processes a numeric formatting template calling for a large number of digits, PostgreSQL would read past the end of a buffer. When processing a crafted timestamp formatting template, PostgreSQL would write past the end of a buffer. Either case could crash the server. We have not ruled out the possibility of attacks that lead to privilege escalation, though they seem unlikely. (CVE-2015-0241)

• Fix buffer overrun in replacement *printf() functions (Tom Lane)

PostgreSQL includes a replacement implementation of printf and related functions. This code will overrun a stack buffer when formatting a floating point number (conversion specifiers e, E, f, F, g or G) with requested precision greater than about 500. This will crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. A database user can trigger such a buffer overrun through the to_char() SQL function. While that is the only affected core PostgreSQL functionality, extension modules that use printf-family functions may be at risk as well.

This issue primarily affects PostgreSQL on Windows. PostgreSQL uses the system implementation of these functions where adequate, which it is on other modern platforms. (CVE-2015-0242)

• Fix buffer overruns in contrib/pgcrypto (Marko Tiikkaja, Noah Misch)

Errors in memory size tracking within the pgcrypto module permitted stack buffer overruns and improper dependence on the contents of uninitialized memory. The buffer overrun cases can crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. (CVE-2015-0243)

• Fix possible loss of frontend/backend protocol synchronization after an error (Heikki Linnakangas)
If any error occurred while the server was in the middle of reading a protocol message from the client, it could lose synchronization and incorrectly try to interpret part of the message’s data as a new protocol message. An attacker able to submit crafted binary data within a command parameter might succeed in injecting his own SQL commands this way. Statement timeout and query cancellation are the most likely sources of errors triggering this scenario. Particularly vulnerable are applications that use a timeout and also submit arbitrary user-crafted data as binary query parameters. Disabling statement timeout will reduce, but not eliminate, the risk of exploit. Our thanks to Emil Lenngren for reporting this issue. (CVE-2015-0244)

• Fix information leak via constraint-violation error messages (Stephen Frost)
  Some server error messages show the values of columns that violate a constraint, such as a unique constraint. If the user does not have SELECT privilege on all columns of the table, this could mean exposing values that the user should not be able to see. Adjust the code so that values are displayed only when they came from the SQL command or could be selected by the user. (CVE-2014-8161)

• Lock down regression testing’s temporary installations on Windows (Noah Misch)
  Use SSPI authentication to allow connections only from the OS user who launched the test suite. This closes on Windows the same vulnerability previously closed on other platforms, namely that other users might be able to connect to the test postmaster. (CVE-2014-0067)

• Cope with the Windows locale named “Norwegian (Bokmål)” (Heikki Linnakangas)
  Non-ASCII locale names are problematic since it’s not clear what encoding they should be represented in. Map the troublesome locale name to a plain-ASCII alias, “Norwegian_Norway”.

• Avoid possible data corruption if ALTER DATABASE SET TABLESPACE is used to move a database to a new tablescape and then shortly later move it back to its original tablespace (Tom Lane)

• Avoid corrupting tables when ANALYZE inside a transaction is rolled back (Andres Freund, Tom Lane, Michael Paquier)
  If the failing transaction had earlier removed the last index, rule, or trigger from the table, the table would be left in a corrupted state with the relevant pg_class flags not set though they should be.

• Ensure that unlogged tables are copied correctly during CREATE DATABASE or ALTER DATABASE SET TABLESPACE (Pavan Deolasee, Andres Freund)

• Fix incorrect processing of CreateEventTrigStmt.eventname (Petr Jelinek)
  This could result in misbehavior if CREATE EVENT TRIGGER were executed as a prepared query, or via extended query protocol.

• Fix DROP’s dependency searching to correctly handle the case where a table column is recursively visited before its table (Petr Jelinek, Tom Lane)
  This case is only known to arise when an extension creates both a datatype and a table using that datatype. The faulty code might refuse a DROP EXTENSION unless CASCADE is specified, which should not be required.

• Fix use-of-already-freed-memory problem in EvalPlanQual processing (Tom Lane)
  In READ COMMITTED mode, queries that lock or update recently-updated rows could crash as a result of this bug.

• Avoid possible deadlock while trying to acquire tuple locks in EvalPlanQual processing (Álvaro Herrera, Mark Kirkwood)

• Fix failure to wait when a transaction tries to acquire a FOR NO KEY EXCLUSIVE tuple lock, while multiple other transactions currently hold FOR SHARE locks (Álvaro Herrera)
• Fix planning of `SELECT FOR UPDATE` when using a partial index on a child table (Kyotaro Horiguchi)

In `READ COMMITTED` mode, `SELECT FOR UPDATE` must also recheck the partial index’s `WHERE` condition when rechecking a recently-updated row to see if it still satisfies the query’s `WHERE` condition. This requirement was missed if the index belonged to an inheritance child table, so that it was possible to incorrectly return rows that no longer satisfy the query condition.

• Fix corner case wherein `SELECT FOR UPDATE` could return a row twice, and possibly miss returning other rows (Tom Lane)

In `READ COMMITTED` mode, a `SELECT FOR UPDATE` that is scanning an inheritance tree could incorrectly return a row from a prior child table instead of the one it should return from a later child table.

• Improve performance of `EXPLAIN` with large range tables (Tom Lane)

• Reject duplicate column names in the referenced-columns list of a `FOREIGN KEY` declaration (David Rowley)

This restriction is per SQL standard. Previously we did not reject the case explicitly, but later on the code would fail with bizarre-looking errors.

• Re-enable error for `SELECT ... OFFSET -1` (Tom Lane)

A negative offset value has been an error since 8.4, but an optimization added in 9.3 accidentally turned the case into a no-op. Restore the expected behavior.

• Restore previous behavior of conversion of domains to JSON (Tom Lane)

This change causes domains over numeric and boolean to be treated like their base types for purposes of conversion to JSON. It worked like that before 9.3.5 and 9.2.9, but was unintentionally changed while fixing a related problem.

• Fix `json_agg()` to not return extra trailing right brackets in its result (Tom Lane)

• Fix bugs in raising a numeric value to a large integral power (Tom Lane)

The previous code could get a wrong answer, or consume excessive amounts of time and memory before realizing that the answer must overflow.

• In `numeric_recv()`, truncate away any fractional digits that would be hidden according to the value’s `dscale` field (Tom Lane)

A numeric value’s display scale (`dscale`) should never be less than the number of nonzero fractional digits; but apparently there’s at least one broken client application that transmits binary numeric values in which that’s true. This leads to strange behavior since the extra digits are taken into account by arithmetic operations even though they aren’t printed. The least risky fix seems to be to truncate away such “hidden” digits on receipt, so that the value is indeed what it prints as.

• Fix incorrect search for shortest-first regular expression matches (Tom Lane)

Matching would often fail when the number of allowed iterations is limited by a `?` quantifier or a bound expression.

• Reject out-of-range numeric timezone specifications (Tom Lane)

Simple numeric timezone specifications exceeding +/- 168 hours (one week) would be accepted, but could then cause null-pointer dereference crashes in certain operations. There’s no use-case for such large UTC offsets, so reject them.

• Fix bugs in `tsquery @> tsquery` operator (Heikki Linnakangas)
Two different terms would be considered to match if they had the same CRC. Also, if the second operand had more terms than the first, it would be assumed not to be contained in the first; which is wrong since it might contain duplicate terms.

- Improve ispell dictionary’s defenses against bad affix files (Tom Lane)
- Allow more than 64K phrases in a thesaurus dictionary (David Boutin)

The previous coding could crash on an oversize dictionary, so this was deemed a back-patchable bug fix rather than a feature addition.

- Fix namespace handling in xpath() (Ali Akbar)

Previously, the xml value resulting from an xpath() call would not have namespace declarations if the namespace declarations were attached to an ancestor element in the input xml value, rather than to the specific element being returned. Propagate the ancestral declaration so that the result is correct when considered in isolation.

- Ensure that whole-row variables expose nonempty column names to functions that pay attention to column names within composite arguments (Tom Lane)

In some contexts, constructs like row_to_json(tab.*) may not produce the expected column names. This is fixed properly as of 9.4; in older branches, just ensure that we produce some nonempty name. (In some cases this will be the underlying table’s column name rather than the query-assigned alias that should theoretically be visible.)

- Fix mishandling of system columns, particularly tableoid, in FDW queries (Etsuro Fujita)

- Fix assorted oversights in range-operator selectivity estimation (Emre Hasegeli)

This patch fixes corner-case “unexpected operator NNNN” planner errors, and improves the selectivity estimates for some other cases.

- Avoid doing indexed_column = ANY (array) as an index qualifier if that leads to an inferior plan (Andrew Gierth)

In some cases, = ANY conditions applied to non-first index columns would be done as index conditions even though it would be better to use them as simple filter conditions.

- Fix “variable not found in subplan target list” planner failure when an inline-able SQL function taking a composite argument is used in a LATERAL subselect and the composite argument is a lateral reference (Tom Lane)

- Fix planner problems with nested append relations, such as inherited tables within UNION ALL subqueries (Tom Lane)

- Fail cleanly when a GiST index tuple doesn’t fit on a page, rather than going into infinite recursion (Andrew Gierth)

- Exempt tables that have per-table cost_limit and/or cost_delay settings from autovacuum’s global cost balancing rules (Álvaro Herrera)

The previous behavior resulted in basically ignoring these per-table settings, which was unintended. Now, a table having such settings will be vacuumed using those settings, independently of what is going on in other autovacuum workers. This may result in heavier total I/O load than before, so such settings should be re-examined for sanity.

- Avoid wholesale autovacuuming when autovacuum is nominally off (Tom Lane)

Even when autovacuum is nominally off, we will still launch autovacuum worker processes to vacuum tables that are at risk of XID wraparound. However, such a worker process then proceeded to vacuum all tables in the target database, if they met the usual thresholds for autovacuuming. This
Appendix E. Release Notes

is at best pretty unexpected; at worst it delays response to the wraparound threat. Fix it so that if autovacuum is turned off, workers only do anti-wraparound vacuums and not any other work.

- During crash recovery, ensure that unlogged relations are rewritten as empty and are synced to disk before recovery is considered complete (Abhijit Menon-Sen, Andres Freund)
  This prevents scenarios in which unlogged relations might contain garbage data following database crash recovery.

- Fix race condition between hot standby queries and replaying a full-page image (Heikki Linnakangas)
  This mistake could result in transient errors in queries being executed in hot standby.

- Fix several cases where recovery logic improperly ignored WAL records for COMMIT/ABORT PREPARED (Heikki Linnakangas)
  The most notable oversight was that recovery_target_xid could not be used to stop at a two-phase commit.

- Prevent latest WAL file from being archived a second time at completion of crash recovery (Fujii Masao)

- Avoid creating unnecessary .ready marker files for timeline history files (Fujii Masao)

- Fix possible null pointer dereference when an empty prepared statement is used and the log_statement setting is mod or ddl (Fujii Masao)

- Change “pgstat wait timeout” warning message to be LOG level, and rephrase it to be more understandable (Tom Lane)
  This message was originally thought to be essentially a can’t-happen case, but it occurs often enough on our slower buildfarm members to be a nuisance. Reduce it to LOG level, and expend a bit more effort on the wording: it now reads “using stale statistics instead of current ones because stats collector is not responding”.

- Fix possible corruption of postmaster’s list of dynamic background workers (Andres Freund)

- Fix SPARC spinlock implementation to ensure correctness if the CPU is being run in a non-TSO coherency mode, as some non-Solaris kernels do (Andres Freund)

- Warn if macOS’s setlocale() starts an unwanted extra thread inside the postmaster (Noah Misch)

- Fix processing of repeated dbname parameters in PQconnectdbParams() (Alex Shulgin)
  Unexpected behavior ensued if the first occurrence of dbname contained a connection string or URI to be expanded.

- Ensure that libpq reports a suitable error message on unexpected socket EOF (Marko Tiikkaja, Tom Lane)
  Depending on kernel behavior, libpq might return an empty error string rather than something useful when the server unexpectedly closed the socket.

- Clear any old error message during PQreset() (Heikki Linnakangas)
  If PQreset() is called repeatedly, and the connection cannot be re-established, error messages from the failed connection attempts kept accumulating in the PGconn’s error string.

- Properly handle out-of-memory conditions while parsing connection options in libpq (Alex Shulgin, Heikki Linnakangas)

- Fix array overrun in ecpg’s version of ParseDateTime() (Michael Paquier)
Appendix E. Release Notes

- In initdb, give a clearer error message if a password file is specified but is empty (Mats Erik Andersson)

- Fix psql’s \s command to work nicely with libedit, and add pager support (Stepan Rutz, Tom Lane)

  When using libedit rather than readline, \s printed the command history in a fairly unreadable encoded format, and on recent libedit versions might fail altogether. Fix that by printing the history ourselves rather than having the library do it. A pleasant side-effect is that the pager is used if appropriate.

  This patch also fixes a bug that caused newline encoding to be applied inconsistently when saving the command history with libedit. Multiline history entries written by older psql versions will be read cleanly with this patch, but perhaps not vice versa, depending on the exact libedit versions involved.

- Improve consistency of parsing of psql’s special variables (Tom Lane)

  Allow variant spellings of on and off (such as 1/0) for ECHO_HIDDEN and ON_ERROR_ROLLBACK.

  Report a warning for unrecognized values for COMP_KEYWORD_CASE, ECHO, ECHO_HIDDEN, HISTCONTROL, ON_ERROR_ROLLBACK, and VERBOSITY. Recognize all values for all these variables case-insensitively; previously there was a mishmash of case-sensitive and case-insensitive behaviors.

- Make psql’s \watch command display nulls as specified by \pset null (Fujii Masao)

- Fix psql’s expanded-mode display to work consistently when using border = 3 and linestyle = ascii or unicode (Stephen Frost)

- Fix pg_dump to handle comments on event triggers without failing (Tom Lane)

- Allow parallel pg_dump to use --serializable-deferrable (Kevin Grittner)

- Improve performance of pg_dump when the database contains many instances of multiple dependency paths between the same two objects (Tom Lane)

- Fix pg_dumpall to restore its ability to dump from pre-8.1 servers (Gilles Darold)

- Fix possible deadlock during parallel restore of a schema-only dump (Robert Haas, Tom Lane)

- Fix core dump in pg_dump --binary-upgrade on zero-column composite type (Rushabh Lathia)

- Fix failure to fsync tables in nondefault tablespaces during pg_upgrade (Abhijit Menon-Sen, Andres Freund)

  With an operating system crash and some bad luck, this could result in data loss during an upgrade.

- In pg_upgrade, cope with cases where the new cluster creates a TOAST table for a table that didn’t previously have one (Bruce Momjian)

  Previously this could result in failures due to OID conflicts.

- In pg_upgrade, don’t try to set autovacuum_multixact_freeze_max_age for the old cluster (Bruce Momjian)

  This could result in failure because not all 9.3.X versions have that parameter. Fortunately, we don’t actually need to set it at all.

- In pg_upgrade, preserve the transaction ID epoch (Bruce Momjian)

  This oversight did not bother PostgreSQL proper, but could confuse some external replication tools.

- Prevent WAL files created by pg_basebackup -x/-X from being archived again when the standby is promoted (Andres Freund)

- Fix memory leak in pg_receivexlog (Fujii Masao)
Appendix E. Release Notes

- Fix unintended suppression of pg_recv Bainxlog verbose messages (Fujii Masao)
- Fix failure of contrib/auto_explain to print per-node timing information when doing EXPLAIN ANALYZE (Tom Lane)
- Fix upgrade-from-unpackaged script for contrib/citext (Tom Lane)
- Avoid integer overflow and buffer overrun in contrib/hstore's hstore_to_json() (Heikki Linnakangas)
- Fix recognition of numbers in hstore_to_json_loose(), so that JSON numbers and strings are correctly distinguished (Andrew Dunstan)
- Fix block number checking in contrib/pageinspect's get_raw_page() (Tom Lane)
  The incorrect checking logic could prevent access to some pages in non-main relation forks.
- Fix contrib/pgcrypto's pgp_sym_decrypt() to not fail on messages whose length is 6 less than a power of 2 (Marko Tiikkaja)
- Fix file descriptor leak in contrib/pg_test_fsync (Jeff Janes)
  This could cause failure to remove temporary files on Windows.
- Handle unexpected query results, especially NULLs, safely in contrib/tablefunc's connectby() (Michael Paquier)
  connectby() previously crashed if it encountered a NULL key value. It now prints that row but doesn't recurse further.
- Avoid a possible crash in contrib/xml2's xslt_process() (Mark Simonetti)
  libxslt seems to have an undocumented dependency on the order in which resources are freed; reorder our calls to avoid a crash.
- Mark some contrib I/O functions with correct volatility properties (Tom Lane)
  The previous over-conservative marking was immaterial in normal use, but could cause optimization problems or rejection of valid index expression definitions. Since the consequences are not large, we've just adjusted the function definitions in the extension modules' scripts, without changing version numbers.
- Numerous cleanups of warnings from Coverity static code analyzer (Andres Freund, Tatsuo Ishii, Marko Kreen, Tom Lane, Michael Paquier)
  These changes are mostly cosmetic but in some cases fix corner-case bugs, for example a crash rather than a proper error report after an out-of-memory failure. None are believed to represent security issues.
- Fix setup of background workers in EXEC_BACKEND builds, eg Windows (Robert Haas)
- Detect incompatible OpenLDAP versions during build (Noah Misch)
  With OpenLDAP versions 2.4.24 through 2.4.31, inclusive, PostgreSQL backends can crash at exit. Raise a warning during configure based on the compile-time OpenLDAP version number, and test the crashing scenario in the contrib/dblink regression test.
- In non-MSVC Windows builds, ensure libpq.dll is installed with execute permissions (Noah Misch)
- Make pg_regress remove any temporary installation it created upon successful exit (Tom Lane)
  This results in a very substantial reduction in disk space usage during make check-world, since that sequence involves creation of numerous temporary installations.
- Support time zone abbreviations that change UTC offset from time to time (Tom Lane)
Previously, PostgreSQL assumed that the UTC offset associated with a time zone abbreviation (such as EST) never changes in the usage of any particular locale. However this assumption fails in the real world, so introduce the ability for a zone abbreviation to represent a UTC offset that sometimes changes. Update the zone abbreviation definition files to make use of this feature in timezone locales that have changed the UTC offset of their abbreviations since 1970 (according to the IANA timezone database). In such timezones, PostgreSQL will now associate the correct UTC offset with the abbreviation depending on the given date.

- Update time zone abbreviations lists (Tom Lane)
  Add CST (China Standard Time) to our lists. Remove references to ADT as “Arabia Daylight Time”, an abbreviation that’s been out of use since 2007; therefore, claiming there is a conflict with “Atlantic Daylight Time” doesn’t seem especially helpful. Fix entirely incorrect GMT offsets for CKT (Cook Islands), FJT, and FJST (Fiji); we didn’t even have them on the proper side of the date line.

- Update time zone data files to tzdata release 2015a.
  The IANA timezone database has adopted abbreviations of the form A\times ST/A\times DT for all Australian time zones, reflecting what they believe to be current majority practice Down Under. These names do not conflict with usage elsewhere (other than ACST for Acre Summer Time, which has been in disuse since 1994). Accordingly, adopt these names into our “Default” timezone abbreviation set. The “Australia” abbreviation set now contains only CST, EAST, EST, SAST, SAT, and WST, all of which are thought to be mostly historical usage. Note that SAST has also been changed to be South Africa Standard Time in the “Default” abbreviation set.
  Also, add zone abbreviations SRET (Asia/Srednekolymsk) and XJT (Asia/Urumqi), and use WSST/WSDT for western Samoa. Also, there were DST law changes in Chile, Mexico, the Turks & Caicos Islands (America/Grand_Turk), and Fiji. There is a new zone Pacific/Bougainville for portions of Papua New Guinea. Also, numerous corrections for historical (pre-1970) time zone data.

E.55. Release 9.3.5

Release date: 2014-07-24

This release contains a variety of fixes from 9.3.4. For information about new features in the 9.3 major release, see Section E.60.

E.55.1. Migration to Version 9.3.5

A dump/restore is not required for those running 9.3.X.

However, this release corrects a logic error in pg_upgrade, as well as an index corruption problem in some GiST indexes. See the first two changelog entries below to find out whether your installation has been affected and what steps you should take if so.

Also, if you are upgrading from a version earlier than 9.3.4, see Section E.56.
E.55.2. Changes

• In pg_upgrade, remove pg_multixact files left behind by initdb (Bruce Momjian)

If you used a pre-9.3.5 version of pg_upgrade to upgrade a database cluster to 9.3, it might have left behind a file $PGDATA/pg_multixact/offsets/0000 that should not be there and will eventually cause problems in VACUUM. However, in common cases this file is actually valid and must not be removed. To determine whether your installation has this problem, run this query as superuser, in any database of the cluster:

```sql
WITH list(file) AS (SELECT * FROM pg_ls_dir('pg_multixact/offsets'))
SELECT EXISTS (SELECT * FROM list WHERE file = '0000') AND
   NOT EXISTS (SELECT * FROM list WHERE file = '0001') AND
   NOT EXISTS (SELECT * FROM list WHERE file = 'FFFF') AND
   EXISTS (SELECT * FROM list WHERE file != '0000')
AS file_0000_removal_required;
```

If this query returns t, manually remove the file $PGDATA/pg_multixact/offsets/0000. Do nothing if the query returns f.

• Correctly initialize padding bytes in contrib/btree_gist indexes on bit columns (Heikki Linnakangas)

This error could result in incorrect query results due to values that should compare equal not being seen as equal. Users with GiST indexes on bit or bit varying columns should REINDEX those indexes after installing this update.

• Protect against torn pages when deleting GIN list pages (Heikki Linnakangas)

This fix prevents possible index corruption if a system crash occurs while the page update is being written to disk.

• Don’t clear the right-link of a GiST index page while replaying updates from WAL (Heikki Linnakangas)

This error could lead to transiently wrong answers from GiST index scans performed in Hot Standby.

• Fix corner-case infinite loop during insertion into an SP-GiST text index (Tom Lane)

• Fix incorrect answers from SP-GiST index searches with `-|-` (range adjacency) operator (Heikki Linnakangas)

• Fix wraparound handling for pg_multixact/members (Álvaro Herrera)

• Truncate pg_multixact during checkpoints, not during VACUUM (Álvaro Herrera)

This change ensures that pg_multixact segments can’t be removed if they’d still be needed during WAL replay after a crash.

• Fix possible inconsistency of all-visible flags after WAL recovery (Heikki Linnakangas)

• Fix possibly-incorrect cache invalidation during nested calls to ReceiveSharedInvalidMessages (Andres Freund)

• Fix race condition when updating a tuple concurrently locked by another process (Andres Freund, Álvaro Herrera)

• Fix “could not find pathkey item to sort” planner failures with UNION ALL over subqueries reading from tables with inheritance children (Tom Lane)

• Don’t assume a subquery’s output is unique if there’s a set-returning function in its targetlist (David Rowley)
Appendix E. Release Notes

This oversight could lead to misoptimization of constructs like
\[
\text{WHERE } x \text{ IN (SELECT } y, \text{ generate_series(1,10) FROM } t \text{ GROUP BY } y)\]

- Improve planner to drop constant-NULL inputs of AND/OR when possible (Tom Lane)
  
  This change fixes some cases where the more aggressive parameter substitution done by 9.2 and later can lead to a worse plan than older versions produced.

- Ensure that the planner sees equivalent VARIADIC and non-VARIADIC function calls as equivalent (Tom Lane)
  
  This bug could for example result in failure to use expression indexes involving variadic functions. It might be necessary to re-create such indexes, and/or re-create views including variadic function calls that should match the indexes, for the fix to be effective for existing 9.3 installations.

- Fix handling of nested JSON objects in \text{json_populate_recordset()} and friends (Michael Paquier, Tom Lane)
  
  A nested JSON object could result in previous fields of the parent object not being shown in the output.

- Fix identification of input type category in \text{to_json()} and friends (Tom Lane)
  
  This is known to have led to inadequate quoting of money fields in the JSON result, and there may have been wrong results for other data types as well.

- Fix failure to detoast fields in composite elements of structured types (Tom Lane)
  
  This corrects cases where TOAST pointers could be copied into other tables without being dereferenced. If the original data is later deleted, it would lead to errors like “missing chunk number 0 for toast value ...” when the now-dangling pointer is used.

- Fix “record type has not been registered” failures with whole-row references to the output of Append plan nodes (Tom Lane)

- Fix possible crash when invoking a user-defined function while rewinding a cursor (Tom Lane)

- Fix query-lifespan memory leak while evaluating the arguments for a function in FROM (Tom Lane)

- Fix session-lifespan memory leaks in regular-expression processing (Tom Lane, Arthur O’Dwyer, Greg Stark)

- Fix data encoding error in \text{hungarian.stop} (Tom Lane)

- Prevent foreign tables from being created with OIDS when default_with_oids is true (Etsuro Fujita)

- Fix liveness checks for rows that were inserted in the current transaction and then deleted by a now-rolled-back subtransaction (Andres Freund)
  
  This could cause problems (at least spurious warnings, and at worst an infinite loop) if CREATE INDEX or CLUSTER were done later in the same transaction.

- Clear \text{pg_stat_activity.xact_start} during PREPARE TRANSACTION (Andres Freund)
  
  After the PREPARE, the originating session is no longer in a transaction, so it should not continue to display a transaction start time.

- Fix \text{REASSIGN OWNED} to not fail for text search objects (Álvaro Herrera)

- Prevent \text{pg_class.relminmxid} values from going backwards during VACUUM FULL (Álvaro Herrera)

- Reduce indentation in rule/view dumps to improve readability and avoid excessive whitespace (Greg Stark, Tom Lane)
This change reduces the amount of indentation applied to nested constructs, including some cases that the user probably doesn’t think of as nested, such as UNION lists. Previously, deeply nested constructs were printed with an amount of whitespace growing as $O(N^2)$, which created a performance problem and even risk of out-of-memory failures. Now the indentation is reduced modulo 40, which is initially odd to look at but seems to preserve readability better than simply limiting the indentation would do. Redundant parenthesization of UNION lists has been reduced as well.

- Fix dumping of rules/views when subsequent addition of a column has resulted in multiple input columns matching a `USING` specification (Tom Lane)
- Repair view printing for some cases involving functions in `FROM` that return a composite type containing dropped columns (Tom Lane)
- Block signals during postmaster startup (Tom Lane)
  
  This ensures that the postmaster will properly clean up after itself if, for example, it receives SIG-INT while still starting up.
- Fix client host name lookup when processing `pg_hba.conf` entries that specify host names instead of IP addresses (Tom Lane)
  
  Ensure that reverse-DNS lookup failures are reported, instead of just silently not matching such entries. Also ensure that we make only one reverse-DNS lookup attempt per connection, not one per host name entry, which is what previously happened if the lookup attempts failed.
- Allow the root user to use `postgres -C variable` and `postgres --describe-config` (MauMau)
  
  The prohibition on starting the server as root does not need to extend to these operations, and relaxing it prevents failure of `pg_ctl` in some scenarios.
- Secure Unix-domain sockets of temporary postmasters started during `make check` (Noah Misch)
  
  Any local user able to access the socket file could connect as the server’s bootstrap superuser, then proceed to execute arbitrary code as the operating-system user running the test, as we previously noted in CVE-2014-0067. This change defends against that risk by placing the server’s socket in a temporary, mode 0700 subdirectory of `/tmp`. The hazard remains however on platforms where Unix sockets are not supported, notably Windows, because then the temporary postmaster must accept local TCP connections.
  
  A useful side effect of this change is to simplify `make check` testing in builds that override `DEFAULT_PGSOCKET_DIR`. Popular non-default values like `/var/run/postgresql` are often not writable by the build user, requiring workarounds that will no longer be necessary.
- Fix tablespace creation WAL replay to work on Windows (MauMau)
- Fix detection of socket creation failures on Windows (Bruce Momjian)
- On Windows, allow new sessions to absorb values of `PGC_BACKEND` parameters (such as `log_connections`) from the configuration file (Amit Kapila)
  
  Previously, if such a parameter were changed in the file post-startup, the change would have no effect.
- Properly quote executable path names on Windows (Nikhil Deshpande)
  
  This oversight could cause `initdb` and `pg_upgrade` to fail on Windows, if the installation path contained both spaces and @ signs.
- Fix linking of `libpython` on macOS (Tom Lane)
  
  The method we previously used can fail with the Python library supplied by Xcode 5.0 and later.
• Avoid buffer bloat in libpq when the server consistently sends data faster than the client can absorb it (Shin-ichi Morita, Tom Lane)

libpq could be coerced into enlarging its input buffer until it runs out of memory (which would be reported misleadingly as “lost synchronization with server”). Under ordinary circumstances it’s quite far-fetched that data could be continuously transmitted more quickly than the recv() loop can absorb it, but this has been observed when the client is artificially slowed by scheduler constraints.

• Ensure that LDAP lookup attempts in libpq time out as intended (Laurenz Albe)

• Fix ecpg to do the right thing when an array of char * is the target for a FETCH statement returning more than one row, as well as some other array-handling fixes (Ashutosh Bapat)

• Fix pg_dump to cope with a materialized view that depends on a table’s primary key (Tom Lane)

This occurs if the view’s query relies on functional dependency to abbreviate a GROUP BY list. pg_dump got sufficiently confused that it dumped the materialized view as a regular view.

• Fix parsing of pg_dumpall’s -i switch (Tom Lane)

• Fix pg_restore’s processing of old-style large object comments (Tom Lane)

A direct-to-database restore from an archive file generated by a pre-9.0 version of pg_dump would usually fail if the archive contained more than a few comments for large objects.

• Fix pg_upgrade for cases where the new server creates a TOAST table but the old version did not (Bruce Momjian)

This rare situation would manifest as “relation OID mismatch” errors.

• In pg_upgrade, preserve pg_database.datminmxid and pg_class.relminmxid values from the old cluster, or insert reasonable values when upgrading from pre-9.3; also defend against unreasonable values in the core server (Bruce Momjian, Álvaro Herrera, Tom Lane)

These changes prevent scenarios in which autovacuum might insist on scanning the entire cluster’s contents immediately upon starting the new cluster, or in which tracking of unfrozen MXID values might be disabled completely.

• Prevent contrib/auto_explain from changing the output of a user’s EXPLAIN (Tom Lane)

If auto_explain is active, it could cause an EXPLAIN (ANALYZE, TIMING OFF) command to nonetheless print timing information.

• Fix query-lifespan memory leak in contrib/dblink (MauMau, Joe Conway)

• In contrib/pgcrypto functions, ensure sensitive information is cleared from stack variables before returning (Marko Kreen)

• Prevent use of already-freed memory in contrib/pgstattuple’s pgstat_heap() (Noah Misch)

• In contrib/uuid-ossp, cache the state of the OSSP UUID library across calls (Tom Lane)

This improves the efficiency of UUID generation and reduces the amount of entropy drawn from /dev/urandom, on platforms that have that.

• Update time zone data files to tzdata release 2014e for DST law changes in Crimea, Egypt, and Morocco.
Appendix E. Release Notes

E.56. Release 9.3.4

**Release date:** 2014-03-20

This release contains a variety of fixes from 9.3.3. For information about new features in the 9.3 major release, see Section E.60.

E.56.1. Migration to Version 9.3.4

A dump/restore is not required for those running 9.3.X.

However, the error fixed in the first changelog entry below could have resulted in corrupt data on standby servers. It may be prudent to reinitialize standby servers from fresh base backups after installing this update.

Also, if you are upgrading from a version earlier than 9.3.3, see Section E.57.

E.56.2. Changes

- **Fix WAL replay of locking an already-updated tuple (Andres Freund, Álvaro Herrera)**
  
  This error caused updated rows to not be found by index scans, resulting in inconsistent query results depending on whether an index scan was used. Subsequent processing could result in constraint violations, since the previously updated row would not be found by later index searches, thus possibly allowing conflicting rows to be inserted. Since this error is in WAL replay, it would only manifest during crash recovery or on standby servers. The improperly-replayed case most commonly arises when a table row that is referenced by a foreign-key constraint is updated concurrently with creation of a referencing row.

- **Restore GIN metapages unconditionally to avoid torn-page risk (Heikki Linnakangas)**
  
  Although this oversight could theoretically result in a corrupted index, it is unlikely to have caused any problems in practice, since the active part of a GIN metapage is smaller than a standard 512-byte disk sector.

- **Avoid race condition in checking transaction commit status during receipt of a NOTIFY message (Marko Tiikkaja)**
  
  This prevents a scenario wherein a sufficiently fast client might respond to a notification before database updates made by the notifier have become visible to the recipient.

- **Allow materialized views to be referenced in UPDATE and DELETE commands (Michael Paquier)**
  
  Previously such queries failed with a complaint about not being able to lock rows in the materialized view.

- **Allow regular-expression operators to be terminated early by query cancel requests (Tom Lane)**
  
  This prevents scenarios wherein a pathological regular expression could lock up a server process uninterruptibly for a long time.

- **Remove incorrect code that tried to allow OVERLAPS with single-element row arguments (Joshua Yanovski)**
  
  This code never worked correctly, and since the case is neither specified by the SQL standard nor documented, it seemed better to remove it than fix it.

- **Avoid getting more than AccessShareLock when de-parsing a rule or view (Dean Rasheed)**
This oversight resulted in `pg_dump` unexpectedly acquiring `RowExclusiveLock` locks on tables mentioned as the targets of `INSERT/UPDATE/DELETE` commands in rules. While usually harmless, that could interfere with concurrent transactions that tried to acquire, for example, `ShareLock` on those tables.

- Improve performance of index endpoint probes during planning (Tom Lane)
  This change fixes a significant performance problem that occurred when there were many not-yet-committed rows at the end of the index, which is a common situation for indexes on sequentially-assigned values such as timestamps or sequence-generated identifiers.
- Use non-default selectivity estimates for `value IN (list)` and `value operator ANY (array)` expressions when the righthand side is a stable expression (Tom Lane)
- Remove the correct per-database statistics file during `DROP DATABASE` (Tomas Vondra)
  This fix prevents a permanent leak of statistics file space. Users who have done many `DROP DATABASE` commands since upgrading to PostgreSQL 9.3 may wish to check their statistics directory and delete statistics files that do not correspond to any existing database. Please note that `db_0.stat` should not be removed.
- Fix `walsender` ping logic to avoid inappropriate disconnects under continuous load (Andres Freund, Heikki Linnakangas)
  `walsender` failed to send ping messages to the client if it was constantly busy sending WAL data; but it expected to see ping responses despite that, and would therefore disconnect once `wal_sender_timeout` elapsed.
- Fix `walsender`’s failure to shut down cleanly when client is `pg_receivexlog` (Fujii Masao)
- Check WAL level and hot standby parameters correctly when doing crash recovery that will be followed by archive recovery (Heikki Linnakangas)
- Fix test to see if hot standby connections can be allowed immediately after a crash (Heikki Linnakangas)
- Add read-only `data_checksums` parameter to display whether page checksums are enabled (Heikki Linnakangas)
  Without this parameter, determining the state of checksum processing was difficult.
- Prevent interrupts while reporting non-`ERROR` messages (Tom Lane)
  This guards against rare server-process freezeups due to recursive entry to `syslog()`, and perhaps other related problems.
- Fix memory leak in PL/Perl when returning a composite result, including multiple-OUT-parameter cases (Alex Hunsaker)
- Fix tracking of `psql` script line numbers during `\copy` from out-of-line data (Kumar Rajeev Rastogi, Amit Khandekar)
  `\copy ... from` incremented the script file line number for each data line, even if the data was not coming from the script file. This mistake resulted in wrong line numbers being reported for any errors occurring later in the same script file.
- Fix contrib/postgres_fdw to handle multiple join conditions properly (Tom Lane)
  This oversight could result in sending `WHERE` clauses to the remote server for execution even though the clauses are not known to have the same semantics on the remote server (for example, clauses that use non-built-in operators). The query might succeed anyway, but it could also fail with errors from the remote server, or worse give silently wrong answers.
• Prevent intermittent “could not reserve shared memory region” failures on recent Windows versions (MauMau)
• Update time zone data files to tzdata release 2014a for DST law changes in Fiji and Turkey, plus historical changes in Israel and Ukraine.

E.57. Release 9.3.3

Release date: 2014-02-20

This release contains a variety of fixes from 9.3.2. For information about new features in the 9.3 major release, see Section E.60.

E.57.1. Migration to Version 9.3.3

A dump/restore is not required for those running 9.3.X. However, several of the issues corrected in this release could have resulted in corruption of foreign-key constraints; that is, there might now be referencing rows for which there is no matching row in the referenced table. It may be worthwhile to recheck such constraints after installing this update. The simplest way to do that is to drop and recreate each suspect constraint; however, that will require taking an exclusive lock on both tables, so it is unlikely to be acceptable in production databases. Alternatively, you can do a manual join query between the two tables to look for unmatched rows.

Note also the requirement for replication standby servers to be upgraded before their master server is upgraded.

Also, if you are upgrading from a version earlier than 9.3.2, see Section E.58.

E.57.2. Changes

• Shore up GRANT ... WITH ADMIN OPTION restrictions (Noah Misch)

Granting a role without ADMIN OPTION is supposed to prevent the grantee from adding or removing members from the granted role, but this restriction was easily bypassed by doing SET ROLE first. The security impact is mostly that a role member can revoke the access of others, contrary to the wishes of his grantor. Unapproved role member additions are a lesser concern, since an uncooperative role member could provide most of his rights to others anyway by creating views or SECURITY DEFINER functions. (CVE-2014-0060)

• Prevent privilege escalation via manual calls to PL validator functions (Andres Freund)

The primary role of PL validator functions is to be called implicitly during CREATE FUNCTION, but they are also normal SQL functions that a user can call explicitly. Calling a validator on a function actually written in some other language was not checked for and could be exploited for privilege-escalation purposes. The fix involves adding a call to a privilege-checking function in each validator function. Non-core procedural languages will also need to make this change to their own validator functions, if any. (CVE-2014-0061)

• Avoid multiple name lookups during table and index DDL (Robert Haas, Andres Freund)

If the name lookups come to different conclusions due to concurrent activity, we might perform some parts of the DDL on a different table than other parts. At least in the case of CREATE INDEX,
Appendix E. Release Notes

this can be used to cause the permissions checks to be performed against a different table than the index creation, allowing for a privilege escalation attack. (CVE-2014-0062)

- Prevent buffer overrun with long datetime strings (Noah Misch)
  The **MAXDATELEN** constant was too small for the longest possible value of type interval, allowing a buffer overrun in **interval_out()**. Although the datetime input functions were more careful about avoiding buffer overrun, the limit was short enough to cause them to reject some valid inputs, such as input containing a very long timezone name. The ecpg library contained these vulnerabilities along with some of its own. (CVE-2014-0063)

- Prevent buffer overrun due to integer overflow in size calculations (Noah Misch, Heikki Linnakan-gas)
  Several functions, mostly type input functions, calculated an allocation size without checking for overflow. If overflow did occur, a too-small buffer would be allocated and then written past. (CVE-2014-0064)

- Prevent overruns of fixed-size buffers (Peter Eisentraut, Jozef Mlich)
  Use **strlcpy()** and related functions to provide a clear guarantee that fixed-size buffers are not overrun. Unlike the preceding items, it is unclear whether these cases really represent live issues, since in most cases there appear to be previous constraints on the size of the input string. Nonetheless it seems prudent to silence all Coverity warnings of this type. (CVE-2014-0065)

- Avoid crashing if **crypt()** returns **NULL** (Honza Horak, Bruce Momjian)
  There are relatively few scenarios in which **crypt()** could return **NULL**, but **contrib/chkpass** would crash if it did. One practical case in which this could be an issue is if libc is configured to refuse to execute unapproved hashing algorithms (e.g., “FIPS mode”). (CVE-2014-0066)

- Document risks of make check in the regression testing instructions (Noah Misch, Tom Lane)
  Since the temporary server started by **make check** uses “trust” authentication, another user on the same machine could connect to it as database superuser, and then potentially exploit the privileges of the operating-system user who started the tests. A future release will probably incorporate changes in the testing procedure to prevent this risk, but some public discussion is needed first. So for the moment, just warn people against using **make check** when there are untrusted users on the same machine. (CVE-2014-0067)

- Rework tuple freezing protocol (Álvaro Herrera, Andres Freund)
  The logic for tuple freezing was unable to handle some cases involving freezing of **multixact** IDs, with the practical effect that shared row-level locks might be forgotten once old enough.

  Fixing this required changing the WAL record format for tuple freezing. While this is no issue for standalone servers, when using replication it means that **standby servers must be upgraded to 9.3.3 or later before their masters are**. An older standby will be unable to interpret freeze records generated by a newer master, and will fail with a PANIC message. (In such a case, upgrading the standby should be sufficient to let it resume execution.)

- Create separate GUC parameters to control multixact freezing (Álvaro Herrera)
  9.3 requires multixact tuple labels to be frozen before they grow too old, in the same fashion as plain transaction ID labels have been frozen for some time. Previously, the transaction ID freezing parameters were used for multixact IDs too; but since the consumption rates of transaction IDs and multixact IDs can be quite different, this did not work very well. Introduce new settings **vacuum_multixact_freeze_min_age**, **vacuum_multixact_freeze_table_age**, and **autovacuum_multixact_freeze_max_age** to control when to freeze multixacts.

- Account for remote row locks propagated by local updates (Álvaro Herrera)
If a row was locked by transaction A, and transaction B updated it, the new version of the row created by B would be locked by A, yet visible only to B. If transaction B then again updated the row, A’s lock wouldn’t get checked, thus possibly allowing B to complete when it shouldn’t. This case is new in 9.3 since prior versions did not have any types of row locking that would permit another transaction to update the row at all.

This oversight could allow referential integrity checks to give false positives (for instance, allow deletes that should have been rejected). Applications using the new commands SELECT FOR KEY SHARE and SELECT FOR NO KEY UPDATE might also have suffered locking failures of this kind.

• Prevent “forgetting” valid row locks when one of several holders of a row lock aborts (Álvaro Herrera)

This was yet another mechanism by which a shared row lock could be lost, thus possibly allowing updates that should have been prevented by foreign-key constraints.

• Fix incorrect logic during update chain locking (Álvaro Herrera)

This mistake could result in spurious “could not serialize access due to concurrent update” errors in REPEATABLE READ and SERIALIZABLE transaction isolation modes.

• Handle wraparound correctly during extension or truncation of pg_multixact/members (Andres Freund, Álvaro Herrera)

• Fix handling of 5-digit filenames in pg_multixact/members (Álvaro Herrera)

As of 9.3, these names can be more than 4 digits, but the directory cleanup code ignored such files.

• Improve performance of multixact cache code (Álvaro Herrera)

• Optimize updating a row that’s already locked by the same transaction (Andres Freund, Álvaro Herrera)

This fixes a performance regression from pre-9.3 versions when doing SELECT FOR UPDATE followed by UPDATE/DELETE.

• During archive recovery, prefer highest timeline number when WAL segments with the same ID are present in both the archive and pg_xlog/ (Kyotaro Horiguchi)

Previously, not-yet-archived segments could get ignored during recovery. This reverts an undesirable behavioral change in 9.3.0 back to the way things worked pre-9.3.

• Fix possible mis-replay of WAL records when some segments of a relation aren’t full size (Greg Stark, Tom Lane)

The WAL update could be applied to the wrong page, potentially many pages past where it should have been. Aside from corrupting data, this error has been observed to result in significant “bloat” of standby servers compared to their masters, due to updates being applied far beyond where the end-of-file should have been. This failure mode does not appear to be a significant risk during crash recovery, only when initially synchronizing a standby created from a base backup taken from a quickly-changing master.

• Fix bug in determining when recovery has reached consistency (Tomonari Katsumata, Heikki Linnakangas)

In some cases WAL replay would mistakenly conclude that the database was already consistent at the start of replay, thus possibly allowing hot-standby queries before the database was really consistent. Other symptoms such as “PANIC: WAL contains references to invalid pages” were also possible.

• Fix WAL logging of visibility map changes (Heikki Linnakangas)
Appendix E. Release Notes

- Fix improper locking of btree index pages while replaying a VACUUM operation in hot-standby mode (Andres Freund, Heikki Linnakangas, Tom Lane)
  This error could result in “PANIC: WAL contains references to invalid pages” failures.
- Ensure that insertions into non-leaf GIN index pages write a full-page WAL record when appropriate (Heikki Linnakangas)
  The previous coding risked index corruption in the event of a partial-page write during a system crash.
- When pause_at_recovery_target and recovery_target_inclusive are both set, ensure the target record is applied before pausing, not after (Heikki Linnakangas)
- Ensure walreceiver sends hot-standby feedback messages on time even when there is a continuous stream of data (Andres Freund, Amit Kapila)
- Prevent timeout interrupts from taking control away from mainline code unless ImmediateInterruptOK is set (Andres Freund, Tom Lane)
  This is a serious issue for any application making use of statement timeouts, as it could cause all manner of strange failures after a timeout occurred. We have seen reports of “stuck” spinlocks, ERRORs being unexpectedly promoted to PANICs, unkillable backends, and other misbehaviors.
- Fix race conditions during server process exit (Robert Haas)
  Ensure that signal handlers don’t attempt to use the process’s MyProc pointer after it’s no longer valid.
- Fix race conditions in walsender shutdown logic and walreceiver SIGHUP signal handler (Tom Lane)
- Fix unsafe references to errno within error reporting logic (Christian Kruse)
  This would typically lead to odd behaviors such as missing or inappropriate HINT fields.
- Fix possible crashes from using ereport() too early during server startup (Tom Lane)
  The principal case we’ve seen in the field is a crash if the server is started in a directory it doesn’t have permission to read.
- Clear retry flags properly in OpenSSL socket write function (Alexander Kukushkin)
  This omission could result in a server lockup after unexpected loss of an SSL-encrypted connection.
- Fix length checking for Unicode identifiers (U"..." syntax) containing escapes (Tom Lane)
  A spurious truncation warning would be printed for such identifiers if the escaped form of the identifier was too long, but the identifier actually didn’t need truncation after de-escaping.
- Fix parsing of Unicode literals and identifiers just before the end of a command string or function body (Tom Lane)
- Allow keywords that are type names to be used in lists of roles (Stephen Frost)
  A previous patch allowed such keywords to be used without quoting in places such as role identifiers; but it missed cases where a list of role identifiers was permitted, such as DROP ROLE.
- Fix parser crash for EXISTS(SELECT * FROM zero_column_table) (Tom Lane)
- Fix possible crash due to invalid plan for nested sub-selects, such as WHERE (... x IN (SELECT ...) ...) IN (SELECT ...) (Tom Lane)
- Fix mishandling of WHERE conditions pulled up from a LATERAL subquery (Tom Lane)
  The typical symptom of this bug was a “JOIN qualification cannot refer to other relations” error, though subtle logic errors in created plans seem possible as well.
• Disallow LATERAL references to the target table of an UPDATE/DELETE (Tom Lane)
  While this might be allowed in some future release, it was unintentional in 9.3, and didn’t work quite right anyway.

• Fix UPDATE/DELETE of an inherited target table that has UNION ALL subqueries (Tom Lane)
  Without this fix, UNION ALL subqueries aren’t correctly inserted into the update plans for inheritance child tables after the first one, typically resulting in no update happening for those child table(s).

• Fix ANALYZE to not fail on a column that’s a domain over a range type (Tom Lane)

• Ensure that ANALYZE creates statistics for a table column even when all the values in it are “too wide” (Tom Lane)
  ANALYZE intentionally omits very wide values from its histogram and most-common-values calculations, but it neglected to do something sane in the case that all the sampled entries are too wide.

• In ALTER TABLE ... SET TABLESPACE, allow the database’s default tablespace to be used without a permissions check (Stephen Frost)
  CREATE TABLE has always allowed such usage, but ALTER TABLE didn’t get the memo.

• Fix support for extensions containing event triggers (Tom Lane)
• Fix “cannot accept a set” error when some arms of a CASE return a set and others don’t (Tom Lane)
• Fix memory leakage in JSON functions (Craig Ringer)
• Properly distinguish numbers from non-numbers when generating JSON output (Andrew Dunstan)
• Fix checks for all-zero client addresses in pgstat functions (Kevin Grittner)
• Fix possible misclassification of multibyte characters by the text search parser (Tom Lane)
  Non-ASCII characters could be misclassified when using C locale with a multibyte encoding. On Cygwin, non-C locales could fail as well.
• Fix possible misbehavior in plainto_tsquery() (Heikki Linnakangas)
  Use memmove() not memcpy() for copying overlapping memory regions. There have been no field reports of this actually causing trouble, but it’s certainly risky.
• Fix placement of permissions checks in pg_start_backup() and pg_stop_backup() (Andres Freund, Magnus Hagander)
  The previous coding might attempt to do catalog access when it shouldn’t.
• Accept SHIFT_JIS as an encoding name for locale checking purposes (Tatsuo Ishii)
• Fix -q-qualification of named parameters in SQL-language functions (Tom Lane)
  Given a composite-type parameter named foo, $1.* worked fine, but foo.* not so much.
• Fix misbehavior of PQhost() on Windows (Fujii Masao)
  It should return localhost if no host has been specified.
• Improve error handling in libpq and psql for failures during COPY TO STDOUT/FROM STDIN (Tom Lane)
  In particular this fixes an infinite loop that could occur in 9.2 and up if the server connection was lost during COPY FROM STDIN. Variants of that scenario might be possible in older versions, or with other client applications.
• Fix incorrect translation handling in some psql \d commands (Peter Eisentraut, Tom Lane)
Appendix E. Release Notes

- Ensure `pg_basebackup`'s background process is killed when exiting its foreground process (Magnus Hagander)
- Fix possible incorrect printing of filenames in `pg_basebackup`'s verbose mode (Magnus Hagander)
- Avoid including tablespaces inside `PGDATA` twice in base backups (Dimitri Fontaine, Magnus Hagander)
- Fix misaligned descriptors in `ecpg` (MauMau)
- In `ecpg`, handle lack of a hostname in the connection parameters properly (Michael Meskes)
- Fix performance regression in `contrib/dblink` connection startup (Joe Conway)
  Avoid an unnecessary round trip when client and server encodings match.
- In `contrib/isn`, fix incorrect calculation of the check digit for ISMN values (Fabien Coelho)
- Fix `contrib/pgbench`'s progress logging to avoid overflow when the scale factor is large (Tatsuo Ishii)
- Fix `contrib/pg_stat_statement`'s handling of `CURRENT_DATE` and related constructs (Kyotaro Horiguchi)
- Improve lost-connection error handling in `contrib/postgres_fdw` (Tom Lane)
- Ensure client-code-only installation procedure works as documented (Peter Eisentraut)
- In Mingw and Cygwin builds, install the libpq DLL in the `bin` directory (Andrew Dunstan)
  This duplicates what the MSVC build has long done. It should fix problems with programs like `psql` failing to start because they can’t find the DLL.
- Avoid using the deprecated `dllwrap` tool in Cygwin builds (Marco Atzeri)
- Enable building with Visual Studio 2013 (Brar Piening)
- Don’t generate plain-text `HISTORY` and `src/test/regress/README` files anymore (Tom Lane)
  These text files duplicated the main HTML and PDF documentation formats. The trouble involved in maintaining them greatly outweighs the likely audience for plain-text format. Distribution tarballs will still contain files by these names, but they’ll just be stubs directing the reader to consult the main documentation. The plain-text `INSTALL` file will still be maintained, as there is arguably a use-case for that.
- Update time zone data files to `tzdata` release 2013i for DST law changes in Jordan and historical changes in Cuba.
  In addition, the zones `Asia/Riyadh87`, `Asia/Riyadh88`, and `Asia/Riyadh89` have been removed, as they are no longer maintained by IANA, and never represented actual civil timekeeping practice.

E.58. Release 9.3.2

Release date: 2013-12-05

This release contains a variety of fixes from 9.3.1. For information about new features in the 9.3 major release, see Section E.60.
Appendix E. Release Notes

E.58.1. Migration to Version 9.3.2

A dump/restore is not required for those running 9.3.X.

However, this release corrects a number of potential data corruption issues. See the first three changelog entries below to find out whether your installation has been affected and what steps you can take if so.

Also, if you are upgrading from a version earlier than 9.3.1, see Section E.59.

E.58.2. Changes

• Fix VACUUM’s tests to see whether it can update relfrozenxid (Andres Freund)

  In some cases VACUUM (either manual or autovacuum) could incorrectly advance a table’s relfrozenxid value, allowing tuples to escape freezing, causing those rows to become invisible once 2^31 transactions have elapsed. The probability of data loss is fairly low since multiple incorrect advancements would need to happen before actual loss occurs, but it’s not zero. In 9.2.0 and later, the probability of loss is higher, and it’s also possible to get “could not access status of transaction” errors as a consequence of this bug. Users upgrading from releases 9.0.4 or 8.4.8 or earlier are not affected, but all later versions contain the bug.

  The issue can be ameliorated by, after upgrading, vacuuming all tables in all databases while having vacuum_freeze_table_age set to zero. This will fix any latent corruption but will not be able to fix all pre-existing data errors. However, an installation can be presumed safe after performing this vacuuming if it has executed fewer than 2^31 update transactions in its lifetime (check this with SELECT txid_current() < 2^31).

• Fix multiple bugs in MultiXactId freezing (Andres Freund, Álvaro Herrera)

  These bugs could lead to “could not access status of transaction” errors, or to duplicate or vanishing rows. Users upgrading from releases prior to 9.3.0 are not affected.

  The issue can be ameliorated by, after upgrading, vacuuming all tables in all databases while having vacuum_freeze_table_age set to zero. This will fix latent corruption but will not be able to fix all pre-existing data errors.

  As a separate issue, these bugs can also cause standby servers to get out of sync with the primary, thus exhibiting data errors that are not in the primary. Therefore, it’s recommended that 9.3.0 and 9.3.1 standby servers be re-cloned from the primary (e.g., with a new base backup) after upgrading.

• Fix initialization of pg_clog and pg_subtrans during hot standby startup (Andres Freund, Heikki Linnakangas)

  This bug can cause data loss on standby servers at the moment they start to accept hot-standby queries, by marking committed transactions as uncommitted. The likelihood of such corruption is small unless, at the time of standby startup, the primary server has executed many updating transactions since its last checkpoint. Symptoms include missing rows, rows that should have been deleted being still visible, and obsolete versions of updated rows being still visible alongside their newer versions.

  This bug was introduced in versions 9.3.0, 9.2.5, 9.1.10, and 9.0.14. Standby servers that have only been running earlier releases are not at risk. It’s recommended that standby servers that have ever run any of the buggy releases be re-cloned from the primary (e.g., with a new base backup) after upgrading.

• Fix multiple bugs in update chain traversal (Andres Freund, Álvaro Herrera)
Appendix E. Release Notes

These bugs could result in incorrect behavior, such as locking or even updating the wrong row, in the presence of concurrent updates. Spurious “unable to fetch updated version of tuple” errors were also possible.

- Fix dangling-pointer problem in fast-path locking (Tom Lane)
  This could lead to corruption of the lock data structures in shared memory, causing “lock already held” and other odd errors.

- Fix assorted race conditions in timeout management (Tom Lane)
  These errors could result in a server process becoming unresponsive because it had blocked SIGALRM and/or SIGINT.

- Truncate pg_multixact contents during WAL replay (Andres Freund)
  This avoids ever-increasing disk space consumption in standby servers.

- Ensure an anti-wraparound VACUUM counts a page as scanned when it’s only verified that no tuples need freezing (Sergey Burladyan, Jeff Janes)
  This bug could result in failing to advance relfrozenxid, so that the table would still be thought to need another anti-wraparound vacuum. In the worst case the database might even shut down to prevent wraparound.

- Fix full-table-vacuum request mechanism for MultiXactIds (Andres Freund)
  This bug could result in large amounts of useless autovacuum activity.

- Fix race condition in GIN index posting tree page deletion (Heikki Linnakangas)
  This could lead to transient wrong answers or query failures.

- Fix “unexpected spgdoinsert() failure” error during SP-GiST index creation (Teodor Sigaev)

- Fix assorted bugs in materialized views (Kevin Grittner, Andres Freund)

- Re-allow duplicate table aliases if they’re within aliased JOINs (Tom Lane)
  Historically PostgreSQL has accepted queries like
  
  SELECT ... FROM tab1 x CROSS JOIN (tab2 x CROSS JOIN tab3 y) z
  
  although a strict reading of the SQL standard would forbid the duplicate usage of table alias x. A misguided change in 9.3.0 caused it to reject some such cases that were formerly accepted. Restore the previous behavior.

- Avoid flattening a subquery whose SELECT list contains a volatile function wrapped inside a sub-SELECT (Tom Lane)
  This avoids unexpected results due to extra evaluations of the volatile function.

- Fix planner’s processing of non-simple-variable subquery outputs nested within outer joins (Tom Lane)
  This error could lead to incorrect plans for queries involving multiple levels of subqueries within JOIN syntax.

- Fix incorrect planning in cases where the same non-strict expression appears in multiple WHERE and outer JOIN equality clauses (Tom Lane)

- Fix planner crash with whole-row reference to a subquery (Tom Lane)

- Fix incorrect generation of optimized MIN()/MAX() plans for inheritance trees (Tom Lane)
  The planner could fail in cases where the MIN()/MAX() argument was an expression rather than a simple variable.

- Fix premature deletion of temporary files (Andres Freund)
Appendix E. Release Notes

- Prevent intra-transaction memory leak when printing range values (Tom Lane)
  
  This fix actually cures transient memory leaks in any datatype output function, but range types are the only ones known to have had a significant problem.

- Fix memory leaks when reloading configuration files (Heikki Linnakangas, Hari Babu)

- Prevent incorrect display of dropped columns in NOT NULL and CHECK constraint violation messages (Michael Paquier and Tom Lane)

- Allow default arguments and named-argument notation for window functions (Tom Lane)
  
  Previously, these cases were likely to crash.

- Suppress trailing whitespace on each line when pretty-printing rules and views (Tom Lane)
  
  9.3.0 generated such whitespace in many more cases than previous versions did. To reduce unexpected behavioral changes, suppress unnecessary whitespace in all cases.

- Fix possible read past end of memory in rule printing (Peter Eisentraut)

- Fix array slicing of int2vector and oidvector values (Tom Lane)
  
  Expressions of this kind are now implicitly promoted to regular int2 or oid arrays.

- Return a valid JSON value when converting an empty hstore value to json (Oskari Saarenmaa)

- Fix incorrect behaviors when using a SQL-standard, simple GMT offset timezone (Tom Lane)
  
  In some cases, the system would use the simple GMT offset value when it should have used the regular timezone setting that had prevailed before the simple offset was selected. This change also causes the timeofday function to honor the simple GMT offset zone.

- Prevent possible misbehavior when logging translations of Windows error codes (Tom Lane)

- Properly quote generated command lines in pg_ctl (Naoya Anzai and Tom Lane)
  
  This fix applies only to Windows.

- Fix pg_dumpall to work when a source database sets default_transaction_read_only via ALTER DATABASE SET (Kevin Grittner)

  Previously, the generated script would fail during restore.

- Fix pg_isready to handle its -d option properly (Fabrízio de Royes Mello and Fujii Masao)

- Fix parsing of WAL file names in pg_receivexlog (Heikki Linnakangas)
  
  This error made pg_receivexlog unable to restart streaming after stopping, once at least 4 GB of WAL had been written.

- Report out-of-disk-space failures properly in pg_upgrade (Peter Eisentraut)

- Make ecpg search for quoted cursor names case-sensitively (Zoltán Böszörményi)

- Fix ecpg’s processing of lists of variables declared varchar (Zoltán Böszörményi)

- Make contrib/lo defend against incorrect trigger definitions (Marc Cousin)

- Update time zone data files to tzdata release 2013h for DST law changes in Argentina, Brazil, Jordan, Libya, Liechtenstein, Morocco, and Palestine. Also, new timezone abbreviations WIB, WIT, WITA for Indonesia.
E.59. Release 9.3.1

Release date: 2013-10-10

This release contains a variety of fixes from 9.3.0. For information about new features in the 9.3 major release, see Section E.60.

E.59.1. Migration to Version 9.3.1

A dump/restore is not required for those running 9.3.X. However, if you use the hstore extension, see the first changelog entry.

E.59.2. Changes

- Ensure new-in-9.3 JSON functionality is added to the hstore extension during an update (Andrew Dunstan)

Users who upgraded a pre-9.3 database containing hstore should execute

\[ \text{ALTER EXTENSION hstore UPDATE;} \]

after installing 9.3.1, to add two new JSON functions and a cast. (If hstore is already up to date, this command does nothing.)

- Fix memory leak when creating B-tree indexes on range columns (Heikki Linnakangas)
- Fix memory leak caused by `lo_open()` failure (Heikki Linnakangas)
- Serializable snapshot fixes (Kevin Grittner, Heikki Linnakangas)
- Fix deadlock bug in libpq when using SSL (Stephen Frost)
- Fix timeline handling bugs in `pg_receivexlog` (Heikki Linnakangas, Andrew Gierth)
- Prevent `CREATE FUNCTION` from checking SET variables unless function body checking is enabled (Tom Lane)
- Remove rare inaccurate warning during vacuum of index-less tables (Heikki Linnakangas)

E.60. Release 9.3

Release date: 2013-09-09

E.60.1. Overview

Major enhancements in PostgreSQL 9.3 include:

- Add materialized views
- Make simple views auto-updatable
- Add many features for the JSON data type, including operators and functions to extract elements from JSON values
- Implement SQL-standard LATERAL option for FROM-clause subqueries and function calls
Appendix E. Release Notes

- Allow foreign data wrappers to support writes (inserts/updates/deletes) on foreign tables
- Add a Postgres foreign data wrapper to allow access to other Postgres servers
- Add support for event triggers
- Add optional ability to checksum data pages and report corruption
- Prevent non-key-field row updates from blocking foreign key checks
- Greatly reduce System V shared memory requirements

The above items are explained in more detail in the sections below.

E.60.2. Migration to Version 9.3

A dump/restore using pg_dumpall, or use of pg_upgrade, is required for those wishing to migrate data from any previous release.

Version 9.3 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

E.60.2.1. Server Settings

- Rename replication_timeout to wal_sender_timeout (Amit Kapila)
  This setting controls the WAL sender timeout.
- Require superuser privileges to set commit_delay because it can now potentially delay other sessions (Simon Riggs)
- Allow in-memory sorts to use their full memory allocation (Jeff Janes)
  Users who have set work_mem based on the previous behavior may need to revisit that setting.

E.60.2.2. Other

- Throw an error if a tuple to be updated or deleted has already been updated or deleted by a BEFORE trigger (Kevin Grittner)
  Formerly, the originally-intended update was silently skipped, resulting in logical inconsistency since the trigger might have propagated data to other places based on the intended update. Now an error is thrown to prevent the inconsistent results from being committed. If this change affects your application, the best solution is usually to move the data-propagation actions to an AFTER trigger.
  This error will also be thrown if a query invokes a volatile function that modifies rows that are later modified by the query itself. Such cases likewise previously resulted in silently skipping updates.
- Change multicolumn ON UPDATE SET NULL/SET DEFAULT foreign key actions to affect all columns of the constraint, not just those changed in the UPDATE (Tom Lane)
  Previously, we would set only those referencing columns that correspond to referenced columns that were changed by the UPDATE. This was what was required by SQL-92, but more recent editions of the SQL standard specify the new behavior.
- Force cached plans to be replanned if the search_path changes (Tom Lane)
Previously, cached plans already generated in the current session were not redone if the query was re-executed with a new search_path setting, resulting in surprising behavior.

- **Fix to_number() to properly handle a period used as a thousands separator (Tom Lane)**

  Previously, a period was considered to be a decimal point even when the locale says it isn’t and the D format code is used to specify use of the locale-specific decimal point. This resulted in wrong answers if FM format was also used.

- **Fix strict non-set-returning functions that have set-returning functions in their arguments to properly return null rows (Tom Lane)**

  A null value passed to the strict function should result in a null output, but instead, that output row was suppressed entirely.

- **Store WAL in a continuous stream, rather than skipping the last 16MB segment every 4GB (Heikki Linnakangas)**

  Previously, WAL files with names ending in FF were not used because of this skipping. If you have WAL backup or restore scripts that took this behavior into account, they will need to be adjusted.

- **In pg_constraint.confmatchtype, store the default foreign key match type (non-FULL, non-PARTIAL) as s for “simple” (Tom Lane)**

  Previously this case was represented by u for “unspecified”.

### E.60.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 9.3 and the previous major release.

#### E.60.3.1. Server

**E.60.3.1.1. Locking**

- **Prevent non-key-field row updates from blocking foreign key checks (Álvaro Herrera, Noah Misch, Andres Freund, Alexander Shulgin, Marti Raudsepp, Alexander Shulgin)**

  This change improves concurrency and reduces the probability of deadlocks when updating tables involved in a foreign-key constraint. Updates that do not change any columns referenced in a foreign key now take the new NO KEY UPDATE lock mode on the row, while foreign key checks use the new KEY SHARE lock mode, which does not conflict with NO KEY UPDATE. So there is no blocking unless a foreign-key column is changed.

- **Add configuration variable lock_timeout to allow limiting how long a session will wait to acquire any one lock (Zoltán Bőszörményi)**

**E.60.3.1.2. Indexes**

- **Add SP-GiST support for range data types (Alexander Korotkov)**

- **Allow GiST indexes to be unlogged (Jeevan Chalke)**

- **Improve performance of GiST index insertion by randomizing the choice of which page to descend to when there are multiple equally good alternatives (Heikki Linnakangas)**
Appendix E. Release Notes

- Improve concurrency of hash index operations (Robert Haas)

E.60.3.1.3. Optimizer

- Collect and use histograms of upper and lower bounds, as well as range lengths, for range types (Alexander Korotkov)
- Improve optimizer’s cost estimation for index access (Tom Lane)
- Improve optimizer’s hash table size estimate for doing DISTINCT via hash aggregation (Tom Lane)
- Suppress no-op Result and Limit plan nodes (Kyotaro Horiguchi, Amit Kapila, Tom Lane)
- Reduce optimizer overhead by not keeping plans on the basis of cheap startup cost when the optimizer only cares about total cost overall (Tom Lane)

E.60.3.1.4. General Performance

- Add COPY FREEZE option to avoid the overhead of marking tuples as frozen later (Simon Riggs, Jeff Davis)
- Improve performance of NUMERIC calculations (Kyotaro Horiguchi)
- Improve synchronization of sessions waiting for commit_delay (Peter Geoghegan)
  This greatly improves the usefulness of commit_delay.
- Improve performance of the CREATE TEMPORARY TABLE ... ON COMMIT DELETE ROWS option by not truncating such temporary tables in transactions that haven’t touched any temporary tables (Heikki Linnakangas)
- Make vacuum recheck visibility after it has removed expired tuples (Pavan Deolasee)
  This increases the chance of a page being marked as all-visible.
- Add per-resource-owner lock caches (Jeff Janes)
  This speeds up lock bookkeeping at statement completion in multi-statement transactions that hold many locks; it is particularly useful for pg_dump.
- Avoid scanning the entire relation cache at commit of a transaction that creates a new relation (Jeff Janes)
  This speeds up sessions that create many tables in successive small transactions, such as a pg_restore run.
- Improve performance of transactions that drop many relations (Tomas Vondra)

E.60.3.1.5. Monitoring

- Add optional ability to checksum data pages and report corruption (Simon Riggs, Jeff Davis, Greg Smith, Ants Aasma)
  The checksum option can be set during initdb.
- Split the statistics collector’s data file into separate global and per-database files (Tomas Vondra)
  This reduces the I/O required for statistics tracking.

2382
• Fix the statistics collector to operate properly in cases where the system clock goes backwards
  (Tom Lane)
  Previously, statistics collection would stop until the time again reached the latest time previously
  recorded.
• Emit an informative message to postmaster standard error when we are about to stop logging there
  (Tom Lane)
  This should help reduce user confusion about where to look for log output in common configura-
  tions that log to standard error only during postmaster startup.

E.60.3.1.6. Authentication

• When an authentication failure occurs, log the relevant pg_hba.conf line, to ease debugging of
  unintended failures (Magnus Hagander)
• Improve LDAP error reporting and documentation (Peter Eisentraut)
• Add support for specifying LDAP authentication parameters in URL format, per RFC 4516 (Peter
  Eisentraut)
• Change the ssl_ciphers parameter to start with DEFAULT, rather than ALL, then remove insecure
  ciphers (Magnus Hagander)
  This should yield a more appropriate SSL cipher set.
• Parse and load pg_ident.conf once, not during each connection (Amit Kapila)
  This is similar to how pg_hba.conf is processed.

E.60.3.1.7. Server Settings

• Greatly reduce System V shared memory requirements (Robert Haas)
  On Unix-like systems, mmap() is now used for most of PostgreSQL’s shared memory. For most
  users, this will eliminate any need to adjust kernel parameters for shared memory.
• Allow the postmaster to listen on multiple Unix-domain sockets (Honza Horák)
  The configuration parameter unix_socket_directory is replaced by
  unix_socket_directories, which accepts a list of directories.
• Allow a directory of configuration files to be processed (Magnus Hagander, Greg Smith, Selena
  Deckelmann)
  Such a directory is specified with include_dir in the server configuration file.
• Increase the maximum initdb-configured value for shared_buffers to 128MB (Robert Haas)
  This is the maximum value that initdb will attempt to set in postgresql.conf; the previous
  maximum was 32MB.
• Remove the external PID file, if any, on postmaster exit (Peter Eisentraut)

E.60.3.2. Replication and Recovery

• Allow a streaming replication standby to follow a timeline switch (Heikki Linnakangas)
This allows streaming standby servers to receive WAL data from a slave newly promoted to master status. Previously, other standbys would require a resync to begin following the new master.

- Add SQL functions `pg_is_in_backup()` and `pg_backup_start_time()` (Gilles Darold)
  These functions report the status of base backups.
- Improve performance of streaming log shipping with `synchronous_commit` disabled (Andres Freund)
- Allow much faster promotion of a streaming standby to primary (Simon Riggs, Kyotaro Horiguchi)
- Add the last checkpoint’s redo location to `pg_controldata`’s output (Fujii Masao)
  This information is useful for determining which WAL files are needed for restore.
- Allow tools like `pg_receivexlog` to run on computers with different architectures (Heikki Linnakangas)
  WAL files can still only be replayed on servers with the same architecture as the primary; but they can now be transmitted to and stored on machines of any architecture, since the streaming replication protocol is now machine-independent.
- Make `pg_basebackup --write-recovery-conf` output a minimal `recovery.conf` file (Zoltán Böszörményi, Magnus Hagander)
  This simplifies setting up a standby server.
- Allow `pg_receivexlog` and `pg_basebackup --xlog-method` to handle streaming timeline switches (Heikki Linnakangas)
- Add `wal_receiver_timeout` parameter to control the WAL receiver’s timeout (Amit Kapila)
  This allows more rapid detection of connection failure.
- Change the WAL record format to allow splitting the record header across pages (Heikki Linnakangas)
  The new format is slightly more compact, and is more efficient to write.

### E.60.3.3. Queries

- Implement SQL-standard `LATERAL` option for `FROM-clause` subqueries and function calls (Tom Lane)
  This feature allows subqueries and functions in `FROM` to reference columns from other tables in the `FROM` clause. The `LATERAL` keyword is optional for functions.
- Add support for piping `COPY` and `psql \copy` data to/from an external program (Etsuro Fujita)
- Allow a multirow `VALUES` clause in a rule to reference `OLD/NEW` (Tom Lane)

### E.60.3.4. Object Manipulation

- Add support for event triggers (Dimitri Fontaine, Robert Haas, Álvaro Herrera)
  This allows server-side functions written in event-enabled languages to be called when DDL commands are run.
- Allow foreign data wrappers to support writes (inserts/updates/deletes) on foreign tables (KaiGai Kohei)
Appendix E. Release Notes

- Add `CREATE SCHEMA ... IF NOT EXISTS` clause (Fabrízio de Royes Mello)
- Make `REASSIGN OWNED` also change ownership of shared objects (Álvaro Herrera)
- Make `CREATE AGGREGATE` complain if the given initial value string is not valid input for the transition datatype (Tom Lane)
- Suppress `CREATE TABLE`'s messages about implicit index and sequence creation (Robert Haas)
  These messages now appear at `DEBUG1` verbosity, so that they will not be shown by default.
- Allow `DROP TABLE IF EXISTS` to succeed when a non-existent schema is specified in the table name (Bruce Momjian)
  Previously, it threw an error if the schema did not exist.
- Provide clients with constraint violation details as separate fields (Pavel Stehule)
  This allows clients to retrieve table, column, data type, or constraint name error details. Previously such information had to be extracted from error strings. Client library support is required to access these fields.

**E.60.3.4.1. ALTER**

- Support `IF NOT EXISTS` option in `ALTER TYPE ... ADD VALUE` (Andrew Dunstan)
  This is useful for conditionally adding values to enumerated types.
- Add `ALTER ROLE ALL SET` to establish settings for all users (Peter Eisentraut)
  This allows settings to apply to all users in all databases. `ALTER DATABASE SET` already allowed addition of settings for all users in a single database. `postgresql.conf` has a similar effect.
- Add support for `ALTER RULE ... RENAME` (Ali Dar)

**E.60.3.4.2. VIEWS**

- Add materialized views (Kevin Grittner)
  Unlike ordinary views, where the base tables are read on every access, materialized views create physical tables at creation or refresh time. Access to the materialized view then reads from its physical table. There is not yet any facility for incrementally refreshing materialized views or auto-accessing them via base table access.
- Make simple views auto-updatable (Dean Rasheed)
  Simple views that reference some or all columns from a single base table are now updatable by default. More complex views can be made updatable using `INSTEAD OF` triggers or `INSTEAD` rules.
- Add `CREATE RECURSIVE VIEW` syntax (Peter Eisentraut)
  Internally this is translated into `CREATE VIEW ... WITH RECURSIVE ....`
- Improve view/rule printing code to handle cases where referenced tables are renamed, or columns are renamed, added, or dropped (Tom Lane)
  Table and column renamings can produce cases where, if we merely substitute the new name into the original text of a rule or view, the result is ambiguous. This change fixes the rule-dumping code to insert manufactured table and column aliases when needed to preserve the original semantics.
E.60.3.5. Data Types

- Increase the maximum size of large objects from 2GB to 4TB (Nozomi Anzai, Yugo Nagata)
  This change includes adding 64-bit-capable large object access functions, both in the server and in libpq.
- Allow text timezone designations, e.g. “America/Chicago”, in the “T” field of ISO-format \texttt{timestamptz} input (Bruce Momjian)

E.60.3.5.1. JSON

- Add operators and functions to extract elements from JSON values (Andrew Dunstan)
- Allow JSON values to be converted into records (Andrew Dunstan)
- Add functions to convert scalars, records, and \texttt{hstore} values to JSON (Andrew Dunstan)

E.60.3.6. Functions

- Add \texttt{array_remove()} and \texttt{array_replace()} functions (Marco Nenciarini, Gabriele Bartolini)
- Allow \texttt{concat()} and \texttt{format()} to properly expand \texttt{VARIADIC}-labeled arguments (Pavel Stehule)
- Improve \texttt{format()} to provide field width and left/right alignment options (Pavel Stehule)
- Make \texttt{to_char()}, \texttt{to_date()}, and \texttt{to_timestamp()} handle negative (BC) century values properly (Bruce Momjian)
  Previously the behavior was either wrong or inconsistent with positive/AD handling, e.g. with the format mask “IYYY-IW-DY”.
- Make \texttt{to_date()} and \texttt{to_timestamp()} return proper results when mixing ISO and Gregorian week/day designations (Bruce Momjian)
- Cause \texttt{pg_get_viewdef()} to start a new line by default after each \texttt{SELECT} target list entry and \texttt{FROM} entry (Marko Tiikkaja)
  This reduces line length in view printing, for instance in \texttt{pg_dump} output.
- Fix \texttt{map_sql_value_to_xml_value()} to print values of domain types the same way their base type would be printed (Pavel Stehule)
  There are special formatting rules for certain built-in types such as \texttt{boolean}; these rules now also apply to domains over these types.

E.60.3.7. Server-Side Languages

E.60.3.7.1. PL/pgSQL Server-Side Language

- Allow PL/pgSQL to use \texttt{RETURN} with a composite-type expression (Asif Rehman)
  Previously, in a function returning a composite type, \texttt{RETURN} could only reference a variable of that type.
- Allow PL/pgSQL to access constraint violation details as separate fields (Pavel Stehule)
Appendix E. Release Notes

- Allow PL/pgSQL to access the number of rows processed by COPY (Pavel Stehule)
  A COPY executed in a PL/pgSQL function now updates the value retrieved by GET DIAGNOSTICS
  \( x = \text{ROW\_COUNT} \).
- Allow unreserved keywords to be used as identifiers everywhere in PL/pgSQL (Tom Lane)
  In certain places in the PL/pgSQL grammar, keywords had to be quoted to be used as identifiers, even if they were nominally unreserved.

E.60.3.7.2. PL/Python Server-Side Language

- Add PL/Python result object string handler (Peter Eisentraut)
  This allows `plpy.debug(rv)` to output something reasonable.
- Make PL/Python convert OID values to a proper Python numeric type (Peter Eisentraut)
- Handle SPI errors raised explicitly (with PL/Python’s RAISE) the same as internal SPI errors (Oskari Saarenmaa and Jan Urbanski)

E.60.3.8. Server Programming Interface (SPI)

- Prevent leakage of SPI tuple tables during subtransaction abort (Tom Lane)
  At the end of any failed subtransaction, the core SPI code now releases any SPI tuple tables that were created during that subtransaction. This avoids the need for SPI-using code to keep track of such tuple tables and release them manually in error-recovery code. Failure to do so caused a number of transaction-lifespan memory leakage issues in PL/pgSQL and perhaps other SPI clients.
  \( \text{SPI\_freetuptable()} \) now protects itself against multiple freeing requests, so any existing code that did take care to clean up shouldn’t be broken by this change.
- Allow SPI functions to access the number of rows processed by COPY (Pavel Stehule)

E.60.3.9. Client Applications

- Add command-line utility `pg_isready` to check if the server is ready to accept connections (Phil Sorber)
- Support multiple `--table` arguments for `pg_restore`, `clusterdb`, `reindexdb`, and `vacuumdb` (Josh Kupershmidt)
  This is similar to the way `pg_dump`’s `--table` option works.
- Add `--dbname` option to `pg_dumpall`, `pg_basebackup`, and `pg_receivexlog` to allow specifying a connection string (Amit Kapila)
- Add `libpq` function `PQconninfo()` to return connection information (Zoltán Böszörményi, Magnus Hagander)

E.60.3.9.1. psql

- Adjust function cost settings so `psql` tab completion and pattern searching are more efficient (Tom Lane)
Appendix E. Release Notes

- Improve psql’s tab completion coverage (Jeff Janes, Dean Rasheed, Peter Eisentraut, Magnus Hagander)
- Allow the psql \--single-transaction mode to work when reading from standard input (Fabien Coelho, Robert Haas)
  Previously this option only worked when reading from a file.
- Remove psql warning when connecting to an older server (Peter Eisentraut)
  A warning is still issued when connecting to a server of a newer major version than psql’s.

E.60.3.9.1.1. Backslash Commands

- Add psql command \watch to repeatedly execute a SQL command (Will Leinweber)
- Add psql command \gset to store query results in psql variables (Pavel Stehule)
- Add SSL information to psql’s \conninfo command (Alastair Turner)
- Add “Security” column to psql’s \df+ output (Jon Erdman)
- Allow psql command \1 to accept a database name pattern (Peter Eisentraut)
- In psql, do not allow \connect to use defaults if there is no active connection (Bruce Momjian)
  This might be the case if the server had crashed.
- Properly reset state after failure of a SQL command executed with psql’s \g file (Tom Lane)
  Previously, the output from subsequent SQL commands would unexpectedly continue to go to the same file.

E.60.3.9.1.2. Output

- Add a \latex-longtable output format to psql (Bruce Momjian)
  This format allows tables to span multiple pages.
- Add a \border=3 output mode to the psql \latex format (Bruce Momjian)
- In psql’s tuples-only and expanded output modes, no longer emit “(No rows)” for zero rows (Peter Eisentraut)
- In psql’s unaligned, expanded output mode, no longer print an empty line for zero rows (Peter Eisentraut)

E.60.3.9.2. pg_dump

- Add pg_dump \--jobs option to dump tables in parallel (Joachim Wieland)
- Make pg_dump output functions in a more predictable order (Joel Jacobson)
- Fix tar files emitted by pg_dump to be POSIX conformant (Brian Weaver, Tom Lane)
- Add \--dbname option to pg_dump, for consistency with other client commands (Heikki Linnakan-gas)
  The database name could already be supplied last without a flag.
Appendix E. Release Notes

E.60.3.9.3. initdb

- Make initdb fsync the newly created data directory (Jeff Davis)
  This insures data integrity in event of a system crash shortly after initdb. This can be disabled by
  using --nosync.
- Add initdb --sync-only option to sync the data directory to durable storage (Bruce Momjian)
  This is used by pg_upgrade.
- Make initdb issue a warning about placing the data directory at the top of a file system mount point
  (Bruce Momjian)

E.60.3.10. Source Code

- Add infrastructure to allow plug-in background worker processes (Álvaro Herrera)
- Create a centralized timeout API (Zoltán Böszörményi)
- Create libpgcommon and move pg_malloc() and other functions there (Álvaro Herrera, Andres
  Freund)
  This allows libpqport to be used solely for portability-related code.
- Add support for list links embedded in larger structs (Andres Freund)
- Use SA_RESTART for all signals, including SIGALRM (Tom Lane)
- Ensure that the correct text domain is used when translating errcontext() messages (Heikki
  Linnakangas)
- Standardize naming of client-side memory allocation functions (Tom Lane)
- Provide support for “static assertions” that will fail at compile time if some compile-time-constant
  condition is not met (Andres Freund, Tom Lane)
- Support Assert() in client-side code (Andrew Dunstan)
- Add decoration to inform the C compiler that some ereport() and elog() calls do not return
  (Peter Eisentraut, Andres Freund, Tom Lane, Heikki Linnakangas)
- Allow options to be passed to the regression test output comparison utility via
  PG_REGRESS_DIFF_OPTS (Peter Eisentraut)
- Add isolation tests for CREATE INDEX CONCURRENTLY (Abhijit Menon-Sen)
- Remove typedefs for int2/int4 as they are better represented as int16/int32 (Peter Eisentraut)
- Fix install-strip on Mac OS X (Peter Eisentraut)
- Remove configure flag --disable-shared, as it is no longer supported (Bruce Momjian)
- Rewrite pgindent in Perl (Andrew Dunstan)
- Provide Emacs macro to set Perl formatting to match PostgreSQL’s perltidy settings (Peter Eisentraut)
- Run tool to check the keyword list whenever the backend grammar is changed (Tom Lane)
- Change the way UESCAPE is lexed, to significantly reduce the size of the lexer tables (Heikki
  Linnakangas)
- Centralize flex and bison make rules (Peter Eisentraut)
This is useful for pgxs authors.

- Change many internal backend functions to return object OIDs rather than void (Dimitri Fontaine)
  This is useful for event triggers.
- Invent pre-commit/pre-prepare/pre-subcommit events for transaction callbacks (Tom Lane)
  Loadable modules that use transaction callbacks might need modification to handle these new event types.
- Add function `pg_identify_object()` to produce a machine-readable description of a database object (Álvaro Herrera)
- Add post-ALTER-object server hooks (KaiGai Kohei)
- Implement a generic binary heap and use it for Merge-Append operations (Abhijit Menon-Sen)
- Provide a tool to help detect timezone abbreviation changes when updating the `src/timezone/data` files (Tom Lane)
- Add pkg-config support for libpq and ecpg libraries (Peter Eisentraut)
- Remove `src/tools/backend`, now that the content is on the PostgreSQL wiki (Bruce Momjian)
- Split out WAL reading as an independent facility (Heikki Linnakangas, Andres Freund)
- Use a 64-bit integer to represent WAL positions (`XLogRecPtr`) instead of two 32-bit integers (Heikki Linnakangas)
  Generally, tools that need to read the WAL format will need to be adjusted.
- Allow PL/Python to support platform-specific include directories (Peter Eisentraut)
- Allow PL/Python on OS X to build against custom versions of Python (Peter Eisentraut)

### E.60.3.11. Additional Modules

- Add a Postgres foreign data wrapper contrib module to allow access to other Postgres servers (Shigeru Hanada)
  This foreign data wrapper supports writes.
- Add `pg_xlogdump` contrib program (Andres Freund)
- Add support for indexing of regular-expression searches in `pg_trgm` (Alexander Korotkov)
- Improve `pg_trgm`’s handling of multibyte characters (Tom Lane)
  On a platform that does not have the `wcstombs()` or `tolower()` library functions, this could result in an incompatible change in the contents of `pg_trgm` indexes for non-ASCII data. In such cases, `REINDEX` those indexes to ensure correct search results.
- Add a `pgstattuple` function to report the size of the pending-insertions list of a GIN index (Fujii Masao)
- Make `oid2name`, `pgbench`, and `vacuumlo` set `fallback_application_name` (Amit Kapila)
- Improve output of `pg_test_timing` (Bruce Momjian)
- Improve output of `pg_test_fsync` (Peter Geoghegan)
- Create a dedicated foreign data wrapper, with its own option validator function, for `dblink` (Shigeru Hanada)
Appendix E. Release Notes

When using this FDW to define the target of a dblink connection, instead of using a hard-wired list of connection options, the underlying libpq library is consulted to see what connection options it supports.

E.60.3.11.1. pg_upgrade

- Allow pg_upgrade to do dumps and restores in parallel (Bruce Momjian, Andrew Dunstan)
  This allows parallel schema dump/restore of databases, as well as parallel copy/link of data files per tablespace. Use the --jobs option to specify the level of parallelism.
- Make pg_upgrade create Unix-domain sockets in the current directory (Bruce Momjian, Tom Lane)
  This reduces the possibility that someone will accidentally connect during the upgrade.
- Make pg_upgrade --check mode properly detect the location of non-default socket directories (Bruce Momjian, Tom Lane)
- Improve performance of pg_upgrade for databases with many tables (Bruce Momjian)
- Improve pg_upgrade’s logs by showing executed commands (Álvaro Herrera)
- Improve pg_upgrade’s status display during copy/link (Bruce Momjian)

E.60.3.11.2. pgbench

- Add --foreign-keys option to pgbench (Jeff Janes)
  This adds foreign key constraints to the standard tables created by pgbench, for use in foreign key performance testing.
- Allow pgbench to aggregate performance statistics and produce output every --aggregate-interval seconds (Tomas Vondra)
- Add pgbench --sampling-rate option to control the percentage of transactions logged (Tomas Vondra)
- Reduce and improve the status message output of pgbench’s initialization mode (Robert Haas, Peter Eisentraut)
- Add pgbench -q mode to print one output line every five seconds (Tomas Vondra)
- Output pgbench elapsed and estimated remaining time during initialization (Tomas Vondra)
- Allow pgbench to use much larger scale factors, by changing relevant columns from integer to bigint when the requested scale factor exceeds 20000 (Greg Smith)

E.60.3.12. Documentation

- Allow EPUB-format documentation to be created (Peter Eisentraut)
- Update FreeBSD kernel configuration documentation (Brad Davis)
- Improve WINDOW function documentation (Bruce Momjian, Florian Pflug)
- Add instructions for setting up the documentation tool chain on macOS (Peter Eisentraut)
- Improve commit_delay documentation (Peter Geoghegan)
E.61. Release 9.2.24

Release date: 2017-11-09

This release contains a variety of fixes from 9.2.23. For information about new features in the 9.2 major release, see Section E.85.

This is expected to be the last PostgreSQL release in the 9.2.X series. Users are encouraged to update to a newer release branch soon.

E.61.1. Migration to Version 9.2.24

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.22, see Section E.63.

E.61.2. Changes

- Fix sample server-start scripts to become \$PGUSER before opening \$PGLOG (Noah Misch)
  
  Previously, the postmaster log file was opened while still running as root. The database owner could therefore mount an attack against another system user by making \$PGLOG be a symbolic link to some other file, which would then become corrupted by appending log messages.

  By default, these scripts are not installed anywhere. Users who have made use of them will need to manually recopy them, or apply the same changes to their modified versions. If the existing \$PGLOG file is root-owned, it will need to be removed or renamed out of the way before restarting the server with the corrected script. (CVE-2017-12172)

- Properly reject attempts to convert infinite float values to type numeric (Tom Lane, KaiGai Kohei)
  
  Previously the behavior was platform-dependent.

- Fix corner-case crashes when columns have been added to the end of a view (Tom Lane)

- Record proper dependencies when a view or rule contains FieldSelect or FieldStore expression nodes (Tom Lane)
  
  Lack of these dependencies could allow a column or data type DROP to go through when it ought to fail, thereby causing later uses of the view or rule to get errors. This patch does not do anything to protect existing views/rules, only ones created in the future.

- Correctly detect hashability of range data types (Tom Lane)
  
  The planner mistakenly assumed that any range type could be hashed for use in hash joins or hash aggregation, but actually it must check whether the range’s subtype has hash support. This does not affect any of the built-in range types, since they’re all hashable anyway.

- Fix low-probability loss of NOTIFY messages due to XID wraparound (Marko Tiikkaja, Tom Lane)
  
  If a session executed no queries, but merely listened for notifications, for more than 2 billion transactions, it started to miss some notifications from concurrently-committing transactions.

- Prevent low-probability crash in processing of nested trigger firings (Tom Lane)

- Correctly restore the umask setting when file creation fails in COPY or lo_export() (Peter Eisentraut)

- Give a better error message for duplicate column names in ANALYZE (Nathan Bossart)
Appendix E. Release Notes

• Fix libpq to not require user’s home directory to exist (Tom Lane)
  In v10, failure to find the home directory while trying to read ~/.pgpass was treated as a hard error, but it should just cause that file to not be found. Both v10 and previous release branches made the same mistake when reading ~/.pg_service.conf, though this was less obvious since that file is not sought unless a service name is specified.

• Fix libpq to guard against integer overflow in the row count of a PGresult (Michael Paquier)

• Sync our copy of the timezone library with IANA release tzcode2017c (Tom Lane)
  This fixes various issues; the only one likely to be user-visible is that the default DST rules for a POSIX-style zone name, if no posixrules file exists in the timezone data directory, now match current US law rather than what it was a dozen years ago.

• Update time zone data files to tzdata release 2017c for DST law changes in Fiji, Namibia, Northern Cyprus, Sudan, Tonga, and Turks & Caicos Islands, plus historical corrections for Alaska, Apia, Burma, Calcutta, Detroit, Ireland, Namibia, and Pago Pago.

E.62. Release 9.2.23

Release date: 2017-08-31

This release contains a small number of fixes from 9.2.22. For information about new features in the 9.2 major release, see Section E.85.

The PostgreSQL community will stop releasing updates for the 9.2.X release series in September 2017. Users are encouraged to update to a newer release branch soon.

E.62.1. Migration to Version 9.2.23

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.22, see Section E.63.

E.62.2. Changes

• Show foreign tables in information_schema.table_privileges view (Peter Eisentraut)
  All other relevant information_schema views include foreign tables, but this one ignored them.
  Since this view definition is installed by initdb, merely upgrading will not fix the problem. If you need to fix this in an existing installation, you can, as a superuser, do this in psql:

```sql
SET search_path TO information_schema;
CREATE OR REPLACE VIEW table_privileges AS
SELECT CAST(u_grantor.rolname AS sql_identifier) AS grantor,
      CAST(grantee.rolname AS sql_identifier) AS grantee,
      CAST(current_database() AS sql_identifier) AS table_catalog,
      CAST(nc.nspname AS sql_identifier) AS table_schema,
      CAST(c.relname AS sql_identifier) AS table_name,
      CAST(c.prtype AS character_data) AS privilege_type,
      CAST(2393
```
Appendix E. Release Notes

-- object owner always has grant options
pg_has_role(grantee.oid, c.relowner, 'USAGE')
OR c.grantable
THEN 'YES' ELSE 'NO' END AS yes_or_no) AS is_grantable,
CAST(CASE WHEN c.prtype = 'SELECT' THEN 'YES' ELSE 'NO' END AS yes_or_no) AS with_hierarchy
FROM (
    SELECT oid, relname, relnamespace, relkind, relowner, (aclexplode(coalesce(relacl, acldefault('r', relowner)))).* FROM pg_class
    ) AS c (oid, relname, relnamespace, relkind, relowner, grantor, grantee, prtype, grantable)
    , pg_namespace nc,
    pg_authid u_grantor,
    (
    SELECT oid, rolname FROM pg_authid
    UNION ALL
    SELECT 0::oid, 'PUBLIC'
    ) AS grantee (oid, rolname)
WHERE c.relnamespace = nc.oid
AND c.relkind IN ('r', 'v', 'f')
AND c.grantee = grantee.oid
AND c.grantor = u_grantor.oid
AND c.prtype IN ('INSERT', 'SELECT', 'UPDATE', 'DELETE', 'TRUNCATE', 'REFERENCES', 'TRIGGER')
AND (pg_has_role(u_grantor.oid, 'USAGE')
OR pg_has_role(grantee.oid, 'USAGE')
OR grantee.rolname = 'PUBLIC');

This must be repeated in each database to be fixed, including template0.

- Clean up handling of a fatal exit (e.g., due to receipt of SIGTERM) that occurs while trying to execute a ROLLBACK of a failed transaction (Tom Lane)
  This situation could result in an assertion failure. In production builds, the exit would still occur, but it would log an unexpected message about "cannot drop active portal".

- Remove assertion that could trigger during a fatal exit (Tom Lane)

- Correctly identify columns that are of a range type or domain type over a composite type or domain type being searched for (Tom Lane)
  Certain ALTER commands that change the definition of a composite type or domain type are supposed to fail if there are any stored values of that type in the database, because they lack the infrastructure needed to update or check such values. Previously, these checks could miss relevant values that are wrapped inside range types or sub-domains, possibly allowing the database to become inconsistent.

- Change ecpg’s parser to allow RETURNING clauses without attached C variables (Michael Meskes)
  This allows ecpg programs to contain SQL constructs that use RETURNING internally (for example, inside a CTE) rather than using it to define values to be returned to the client.

- Improve selection of compiler flags for PL/Perl on Windows (Tom Lane)
  This fix avoids possible crashes of PL/Perl due to inconsistent assumptions about the width of time_t values. A side-effect that may be visible to extension developers is that _USE_32BIT_TIME_T is no longer defined globally in PostgreSQL Windows builds. This is not expected to cause problems, because type time_t is not used in any PostgreSQL API definitions.
E.63. Release 9.2.22

Release date: 2017-08-10

This release contains a variety of fixes from 9.2.21. For information about new features in the 9.2 major release, see Section E.85.

The PostgreSQL community will stop releasing updates for the 9.2.X release series in September 2017. Users are encouraged to update to a newer release branch soon.

E.63.1. Migration to Version 9.2.22

A dump/restore is not required for those running 9.2.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.2.20, see Section E.65.

E.63.2. Changes

- Further restrict visibility of `pg_user_mappings.umoptions`, to protect passwords stored as user mapping options (Noah Misch)

The fix for CVE-2017-7486 was incorrect: it allowed a user to see the options in her own user mapping, even if she did not have USAGE permission on the associated foreign server. Such options might include a password that had been provided by the server owner rather than the user herself. Since `information_schema.user_mapping_options` does not show the options in such cases, `pg_user_mappings` should not either. (CVE-2017-7547)

By itself, this patch will only fix the behavior in newly initdb’ed databases. If you wish to apply this change in an existing database, you will need to do the following:

1. Restart the postmaster after adding `allow_system_table_mods = true` to `postgresql.conf`. (In versions supporting `ALTER SYSTEM`, you can use that to make the configuration change, but you’ll still need a restart.)

2. In each database of the cluster, run the following commands as superuser:

```
SET search_path = pg_catalog;
CREATE OR REPLACE VIEW pg_user_mappings AS
SELECT
    U.oid AS umid,
    S.oid AS srvid,
    S.srvname AS srvname,
    U.umuser AS umuser,
    CASE WHEN U.umuser <> 0 AND A.rolname = current_user
        AND (pg_has_role(S.srvowner, 'USAGE')
            OR has_server_privilege(S.oid, 'USAGE'))
        OR (U.umuser = 0 AND pg_has_role(S.srvowner, 'USAGE'))
        OR (SELECT rolsuper FROM pg_authid WHERE rolname = current_user)
    END AS usename,
    'public'
FROM
    pg_user_mapping_options U
    LEFT OUTER JOIN pg_foreign_server S ON U.srvname = S.srvname;
```

...
Appendix E. Release Notes

3. Do not forget to include the template0 and template1 databases, or the vulnerability will still exist in databases you create later. To fix template0, you’ll need to temporarily make it accept connections. In PostgreSQL 9.5 and later, you can use

```
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS true;
```

and then after fixing template0, undo that with

```
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS false;
```

In prior versions, instead use

```
UPDATE pg_database SET datallowconn = true WHERE datname = 'template0';
UPDATE pg_database SET datallowconn = false WHERE datname = 'template0';
```

4. Finally, remove the allow_system_table_mods configuration setting, and again restart the postmaster.

- Disallow empty passwords in all password-based authentication methods (Heikki Linnakangas)
  libpq ignores empty password specifications, and does not transmit them to the server. So, if a user’s password has been set to the empty string, it’s impossible to log in with that password via psql or other libpq-based clients. An administrator might therefore believe that setting the password to empty is equivalent to disabling password login. However, with a modified or non-libpq-based client, logging in could be possible, depending on which authentication method is configured. In particular the most common method, md5, accepted empty passwords. Change the server to reject empty passwords in all cases. (CVE-2017-7546)
- On Windows, retry process creation if we fail to reserve the address range for our shared memory in the new process (Tom Lane, Amit Kapila)
  This is expected to fix infrequent child-process-launch failures that are probably due to interference from antivirus products.
- Fix low-probability corruption of shared predicate-lock hash table in Windows builds (Thomas Munro, Tom Lane)
- Avoid logging clean closure of an SSL connection as though it were a connection reset (Michael Paquier)
- Prevent sending SSL session tickets to clients (Tom Lane)
  This fix prevents reconnection failures with ticket-aware client-side SSL code.
- Fix code for setting tcp_keepalives_idle on Solaris (Tom Lane)
- Fix statistics collector to honor inquiry messages issued just after a postmaster shutdown and immediate restart (Tom Lane)
  Statistics inquiries issued within half a second of the previous postmaster shutdown were effectively ignored.
- Ensure that the statistics collector’s receive buffer size is at least 100KB (Tom Lane)
  This reduces the risk of dropped statistics data on older platforms whose default receive buffer size is less than that.
• Fix possible creation of an invalid WAL segment when a standby is promoted just after it processes an XLOG_SWITCH WAL record (Andres Freund)

• Fix SIGHUP and SIGUSR1 handling in walsender processes (Petr Jelinek, Andres Freund)

• Fix unnecessarily slow restarts of walreceiver processes due to race condition in postmaster (Tom Lane)

• Fix cases where an INSERT or UPDATE assigns to more than one element of a column that is of domain-over-array type (Tom Lane)

• Move autogenerated array types out of the way during ALTER ... RENAME (Vik Fearing)

  Previously, we would rename a conflicting autogenerated array type out of the way during CREATE; this fix extends that behavior to renaming operations.

• Ensure that ALTER USER ... SET accepts all the syntax variants that ALTER ROLE ... SET does (Peter Eisentraut)

• Properly update dependency info when changing a datatype I/O function’s argument or return type from opaque to the correct type (Heikki Linnakangas)

  CREATE TYPE updates I/O functions declared in this long-obsolete style, but it forgot to record a dependency on the type, allowing a subsequent DROP TYPE to leave broken function definitions behind.

• Reduce memory usage when ANALYZE processes a tsvector column (Heikki Linnakangas)

• Fix unnecessary precision loss and sloppy rounding when multiplying or dividing money values by integers or floats (Tom Lane)

• Tighten checks for whitespace in functions that parse identifiers, such as regprocedurein() (Tom Lane)

  Depending on the prevailing locale, these functions could misinterpret fragments of multibyte characters as whitespace.

• Use relevant #define symbols from Perl while compiling PL/Perl (Ashutosh Sharma, Tom Lane)

  This avoids portability problems, typically manifesting as a “handshake” mismatch during library load, when working with recent Perl versions.

• In psql, fix failure when COPY FROM STDIN is ended with a keyboard EOF signal and then another COPY FROM STDIN is attempted (Thomas Munro)

  This misbehavior was observed on BSD-derived platforms (including macOS), but not on most others.

• Fix pg_dump to not emit invalid SQL for an empty operator class (Daniel Gustafsson)

• Fix pg_dump output to stdout on Windows (Kuntal Ghosh)

  A compressed plain-text dump written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

• Fix pg_get_ruledef() to print correct output for the ON SELECT rule of a view whose columns have been renamed (Tom Lane)

  In some corner cases, pg_dump relies on pg_get_ruledef() to dump views, so that this error could result in dump/reload failures.

• Fix dumping of function expressions in the FROM clause in cases where the expression does not deparse into something that looks like a function call (Tom Lane)

• Fix pg_basebackup output to stdout on Windows (Haribabu Kommi)
Appendix E. Release Notes

A backup written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

- Fix pg_upgrade to ensure that the ending WAL record does not have wal_level = minimum (Bruce Momjian)

  This condition could prevent upgraded standby servers from reconnecting.

- Always use -fPIC, not -fpic, when building shared libraries with gcc (Tom Lane)

  This supports larger extension libraries on platforms where it makes a difference.

- Fix unescaped-braces issue in our build scripts for Microsoft MSVC, to avoid a warning or error from recent Perl versions (Andrew Dunstan)

- In MSVC builds, handle the case where the openssl library is not within a VC subdirectory (Andrew Dunstan)

- In MSVC builds, add proper include path for libxml2 header files (Andrew Dunstan)

  This fixes a former need to move things around in standard Windows installations of libxml2.

- In MSVC builds, recognize a Tcl library that is named tcl86.lib (Noah Misch)

E.64. Release 9.2.21

Release date: 2017-05-11

This release contains a variety of fixes from 9.2.20. For information about new features in the 9.2 major release, see Section E.85.

The PostgreSQL community will stop releasing updates for the 9.2.X release series in September 2017. Users are encouraged to update to a newer release branch soon.

E.64.1. Migration to Version 9.2.21

A dump/restore is not required for those running 9.2.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.2.20, see Section E.65.

E.64.2. Changes

- Restrict visibility of pg_user_mappings.umoptions, to protect passwords stored as user mapping options (Michael Paquier, Feike Steenbergen)

  The previous coding allowed the owner of a foreign server object, or anyone he has granted server USAGE permission to, to see the options for all user mappings associated with that server. This might well include passwords for other users. Adjust the view definition to match the behavior of information_schema.user_mapping_options, namely that these options are visible to the user being mapped, or if the mapping is for PUBLIC and the current user is the server owner, or if the current user is a superuser. (CVE-2017-7486)
By itself, this patch will only fix the behavior in newly initdb'd databases. If you wish to apply this change in an existing database, follow the corrected procedure shown in the changelog entry for CVE-2017-7547, in Section E.63.

• Prevent exposure of statistical information via leaky operators (Peter Eisentraut)

Some selectivity estimation functions in the planner will apply user-defined operators to values obtained from `pg_statistic`, such as most common values and histogram entries. This occurs before table permissions are checked, so a nefarious user could exploit the behavior to obtain these values for table columns he does not have permission to read. To fix, fall back to a default estimate if the operator’s implementation function is not certified leak-proof and the calling user does not have permission to read the table column whose statistics are needed. At least one of these criteria is satisfied in most cases in practice. (CVE-2017-7484)

• Fix possible corruption of “init forks” of unlogged indexes (Robert Haas, Michael Paquier)

This could result in an unlogged index being set to an invalid state after a crash and restart. Such a problem would persist until the index was dropped and rebuilt.

• Fix incorrect reconstruction of `pg_subtrans` entries when a standby server replays a prepared but uncommitted two-phase transaction (Tom Lane)

In most cases this turned out to have no visible ill effects, but in corner cases it could result in circular references in `pg_subtrans`, potentially causing infinite loops in queries that examine rows modified by the two-phase transaction.

• Ensure parsing of queries in extension scripts sees the results of immediately-preceding DDL (Julien Rouhaud, Tom Lane)

Due to lack of a cache flush step between commands in an extension script file, non-utility queries might not see the effects of an immediately preceding catalog change, such as `ALTER TABLE ... RENAME`.

• Skip tablespace privilege checks when `ALTER TABLE ... ALTER COLUMN TYPE` rebuilds an existing index (Noah Misch)

The command failed if the calling user did not currently have `CREATE` privilege for the tablespace containing the index. That behavior seems unhelpful, so skip the check, allowing the index to be rebuilt where it is.

• Fix `ALTER TABLE ... VALIDATE CONSTRAINT` to not recurse to child tables when the constraint is marked `NO INHERIT` (Amit Langote)

This fix prevents unwanted “constraint does not exist” failures when no matching constraint is present in the child tables.

• Fix `VACUUM` to account properly for pages that could not be scanned due to conflicting page pins (Andrew Gierth)

This tended to lead to underestimation of the number of tuples in the table. In the worst case of a small heavily-contended table, `VACUUM` could incorrectly report that the table contained no tuples, leading to very bad planning choices.

• Ensure that bulk-tuple-transfer loops within a hash join are interruptible by query cancel requests (Tom Lane, Thomas Munro)

• Fix `cursor_to_xml()` to produce valid output with `tableforest = false` (Thomas Munro, Peter Eisentraut)

Previously it failed to produce a wrapping `<table>` element.

• Improve performance of `pg_timezone_names` view (Tom Lane, David Rowley)
Appendix E. Release Notes

- Fix sloppy handling of corner-case errors from lseek() and close() (Tom Lane)
  Neither of these system calls are likely to fail in typical situations, but if they did, fd.c could get quite confused.
- Fix incorrect check for whether postmaster is running as a Windows service (Michael Paquier)
  This could result in attempting to write to the event log when that isn’t accessible, so that no logging happens at all.
- Fix ecpg to support COMMIT PREPARED and ROLLBACK PREPARED (Masahiko Sawada)
- Fix a double-free error when processing dollar-quoted string literals in ecpg (Michael Meskes)
- In pg_dump, fix incorrect schema and owner marking for comments and security labels of some types of database objects (Giuseppe Broccolo, Tom Lane)
  In simple cases this caused no ill effects; but for example, a schema-selective restore might omit comments it should include, because they were not marked as belonging to the schema of their associated object.
- Avoid emitting an invalid list file in pg_restore -l when SQL object names contain newlines (Tom Lane)
  Replace newlines by spaces, which is sufficient to make the output valid for pg_restore -l’s purposes.
- Fix pg_upgrade to transfer comments and security labels attached to “large objects” (blobs) (Stephen Frost)
  Previously, blobs were correctly transferred to the new database, but any comments or security labels attached to them were lost.
- Improve error handling in contrib/adminpack’s pg_file_write() function (Noah Misch)
  Notably, it failed to detect errors reported by fclose().
- In contrib/dblink, avoid leaking the previous unnamed connection when establishing a new unnamed connection (Joe Conway)
- Support OpenSSL 1.1.0 (Heikki Linnakangas, Andreas Karlsson, Tom Lane)
  This is a back-patch of work previously done in newer branches; it’s needed since many platforms are adopting newer OpenSSL versions.
- Support Tcl 8.6 in MSVC builds (Álvaro Herrera)
- Sync our copy of the timezone library with IANA release tzcode2017b (Tom Lane)
  This fixes a bug affecting some DST transitions in January 2038.
- Update time zone data files to tzdata release 2017b for DST law changes in Chile, Haiti, and Mongolia, plus historical corrections for Ecuador, Kazakhstan, Liberia, and Spain. Switch to numeric abbreviations for numerous time zones in South America, the Pacific and Indian oceans, and some Asian and Middle Eastern countries.
  The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the pg_timezone_names view nor used for output.
- Use correct daylight-savings rules for POSIX-style time zone names in MSVC builds (David Rowley)
Appendix E. Release Notes

The Microsoft MSVC build scripts neglected to install the *posixrules* file in the timezone directory tree. This resulted in the timezone code falling back to its built-in rule about what DST behavior to assume for a POSIX-style time zone name. For historical reasons that still corresponds to the DST rules the USA was using before 2007 (i.e., change on first Sunday in April and last Sunday in October). With this fix, a POSIX-style zone name will use the current and historical DST transition dates of the US/Eastern zone. If you don’t want that, remove the *posixrules* file, or replace it with a copy of some other zone file (see Section 8.5.3). Note that due to caching, you may need to restart the server to get such changes to take effect.

E.65. Release 9.2.20

**Release date:** 2017-02-09

This release contains a variety of fixes from 9.2.19. For information about new features in the 9.2 major release, see Section E.85.

E.65.1. Migration to Version 9.2.20

A dump/restore is not required for those running 9.2.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted indexes.

Also, if you are upgrading from a version earlier than 9.2.11, see Section E.74.

E.65.2. Changes

- Fix a race condition that could cause indexes built with `CREATE INDEX CONCURRENTLY` to be corrupt (Pavan Deolasee, Tom Lane)
  
  If `CREATE INDEX CONCURRENTLY` was used to build an index that depends on a column not previously indexed, then rows updated by transactions that ran concurrently with the `CREATE INDEX` command could have received incorrect index entries. If you suspect this may have happened, the most reliable solution is to rebuild affected indexes after installing this update.

- Unconditionally WAL-log creation of the “init fork” for an unlogged table (Michael Paquier)
  
  Previously, this was skipped when `wal_level = minimal`, but actually it’s necessary even in that case to ensure that the unlogged table is properly reset to empty after a crash.

- Fix WAL page header validation when re-reading segments (Takayuki Tsunakawa, Amit Kapila)
  
  In corner cases, a spurious “out-of-sequence TLI” error could be reported during recovery.

- If the stats collector dies during hot standby, restart it (Takayuki Tsunakawa)

- Check for interrupts while hot standby is waiting for a conflicting query (Simon Riggs)

- Avoid constantly respawning the autovacuum launcher in a corner case (Amit Khandekar)
  
  This fix avoids problems when autovacuum is nominally off and there are some tables that require freezing, but all such tables are already being processed by autovacuum workers.

- Fix check for when an extension member object can be dropped (Tom Lane)
Extension upgrade scripts should be able to drop member objects, but this was disallowed for serial-column sequences, and possibly other cases.

- Make sure `ALTER TABLE` preserves index tablespace assignments when rebuilding indexes (Tom Lane, Michael Paquier)
  Previously, non-default settings of `default_tablespace` could result in broken indexes.

- Prevent dropping a foreign-key constraint if there are pending trigger events for the referenced relation (Tom Lane)
  This avoids “could not find trigger NNN” or “relation NNN has no triggers” errors.

- Fix processing of OID column when a table with OIDs is associated to a parent with OIDs via `ALTER TABLE ... INHERIT` (Amit Langote)
  The OID column should be treated the same as regular user columns in this case, but it wasn’t, leading to odd behavior in later inheritance changes.

- Check for serializability conflicts before reporting constraint-violation failures (Thomas Munro)
  When using serializable transaction isolation, it is desirable that any error due to concurrent transactions should manifest as a serialization failure, thereby cueing the application that a retry might succeed. Unfortunately, this does not reliably happen for duplicate-key failures caused by concurrent insertions. This change ensures that such an error will be reported as a serialization error if the application explicitly checked for the presence of a conflicting key (and did not find it) earlier in the transaction.

- Ensure that column typmods are determined accurately for multi-row `VALUES` constructs (Tom Lane)
  This fixes problems occurring when the first value in a column has a determinable typmod (e.g., length for a `varchar` value) but later values don’t share the same limit.

- Throw error for an unfinished Unicode surrogate pair at the end of a Unicode string (Tom Lane)
  Normally, a Unicode surrogate leading character must be followed by a Unicode surrogate trailing character, but the check for this was missed if the leading character was the last character in a Unicode string literal (`U&'...'`) or Unicode identifier (`U&"..."`).

- Ensure that a purely negative text search query, such as `!foo`, matches empty `tsvector`s (Tom Dunstan)
  Such matches were found by GIN index searches, but not by sequential scans or GiST index searches.

- Prevent crash when `ts_rewrite()` replaces a non-top-level subtree with an empty query (Artur Zakirov)

- Fix performance problems in `ts_rewrite()` (Tom Lane)

- Fix `ts_rewrite()`’s handling of nested NOT operators (Tom Lane)

- Fix `array_fill()` to handle empty arrays properly (Tom Lane)

- Fix one-byte buffer overrun in `quote_literal_cstr()` (Heikki Linnakangas)
  The overrun occurred only if the input consisted entirely of single quotes and/or backslashes.

- Prevent multiple calls of `pg_start_backup()` and `pg_stop_backup()` from running concurrently (Michael Paquier)
  This avoids an assertion failure, and possibly worse things, if someone tries to run these functions in parallel.

- Avoid discarding `interval-to-interval` casts that aren’t really no-ops (Tom Lane)
In some cases, a cast that should result in zeroing out low-order interval fields was mistakenly deemed to be a no-op and discarded. An example is that casting from `INTERVAL MONTH` to `INTERVAL YEAR` failed to clear the months field.

- Fix `pg_dump` to dump user-defined casts and transforms that use built-in functions (Stephen Frost)
- Fix possible `pg_basebackup` failure on standby server when including WAL files (Amit Kapila, Robert Haas)
- Ensure that the Python exception objects we create for PL/Python are properly reference-counted (Rafa de la Torre, Tom Lane)

This avoids failures if the objects are used after a Python garbage collection cycle has occurred.

- Fix PL/Tcl to support triggers on tables that have `.tupno` as a column name (Tom Lane)

  This matches the (previously undocumented) behavior of PL/Tcl's `spi_exec` and `spi_execp` commands, namely that a magic `.tupno` column is inserted only if there isn't a real column named that.

- Allow DOS-style line endings in `~/.pgpass` files, even on Unix (Vik Fearing)

  This change simplifies use of the same password file across Unix and Windows machines.

- Fix one-byte buffer overrun if `ecpg` is given a file name that ends with a dot (Takayuki Tsunakawa)

- Fix `psql`'s tab completion for `ALTER DEFAULT PRIVILEGES` (Gilles Darold, Stephen Frost)

- In `psql`, treat an empty or all-blank setting of the `PAGER` environment variable as meaning "no pager" (Tom Lane)

  Previously, such a setting caused output intended for the pager to vanish entirely.

- Improve `contrib/dblink`'s reporting of low-level `libpq` errors, such as out-of-memory (Joe Con- way)

- On Windows, ensure that environment variable changes are propagated to DLLs built with debug options (Christian Ullrich)

- Sync our copy of the timezone library with IANA release tzcode2016j (Tom Lane)

  This fixes various issues, most notably that timezone data installation failed if the target directory didn’t support hard links.

- Update time zone data files to `tzdata` release 2016j for DST law changes in northern Cyprus (adding a new zone Asia/Famagusta), Russia (adding a new zone Europe/Saratov), Tonga, and Antarctica/Ca- sey. Historical corrections for Italy, Kazakhstan, Malta, and Palestine. Switch to preferring numeric zone abbreviations for Tonga.

### E.66. Release 9.2.19

**Release date:** 2016-10-27

This release contains a variety of fixes from 9.2.18. For information about new features in the 9.2 major release, see Section E.85.

### E.66.1. Migration to Version 9.2.19

A dump/restore is not required for those running 9.2.X.
Appendix E. Release Notes

However, if you are upgrading from a version earlier than 9.2.11, see Section E.74.

E.66.2. Changes

- Fix EvalPlanQual rechecks involving CTE scans (Tom Lane)
  The recheck would always see the CTE as returning no rows, typically leading to failure to update rows that were recently updated.

- Fix improper repetition of previous results from hashed aggregation in a subquery (Andrew Gierth)
  The test to see if we can reuse a previously-computed hash table of the aggregate state values neglected the possibility of an outer query reference appearing in an aggregate argument expression. A change in the value of such a reference should lead to recalculating the hash table, but did not.

- Fix EXPLAIN to emit valid XML when track_io_timing is on (Markus Winand)
  Previously the XML output-format option produced syntactically invalid tags such as \(<I/O-Read-Time>\). That is now rendered as \(<I-O-Read-Time>\).

- Suppress printing of zeroes for unmeasured times in EXPLAIN (Maksim Milyutin)
  Certain option combinations resulted in printing zero values for times that actually aren’t ever measured in that combination. Our general policy in EXPLAIN is not to print such fields at all, so do that consistently in all cases.

- Fix timeout length when VACUUM is waiting for exclusive table lock so that it can truncate the table (Simon Riggs)
  The timeout was meant to be 50 milliseconds, but it was actually only 50 microseconds, causing VACUUM to give up on truncation much more easily than intended. Set it to the intended value.

- Fix bugs in merging inherited CHECK constraints while creating or altering a table (Tom Lane, Amit Langote)
  Allow identical CHECK constraints to be added to a parent and child table in either order. Prevent merging of a valid constraint from the parent table with a NOT VALID constraint on the child. Likewise, prevent merging of a NO INHERIT child constraint with an inherited constraint.

- Remove artificial restrictions on the values accepted by numeric_in() and numeric_recv() (Tom Lane)
  We allow numeric values up to the limit of the storage format (more than 1e100000), so it seems fairly pointless that numeric_in() rejected scientific-notation exponents above 1000. Likewise, it was silly for numeric_recv() to reject more than 1000 digits in an input value.

- Avoid very-low-probability data corruption due to testing tuple visibility without holding buffer lock (Thomas Munro, Peter Geoghegan, Tom Lane)

- Fix file descriptor leakage when truncating a temporary relation of more than 1GB (Andres Freund)

- Disallow starting a standalone backend with standby_mode turned on (Michael Paquier)
  This can’t do anything useful, since there will be no WAL receiver process to fetch more WAL data; and it could result in misbehavior in code that wasn’t designed with this situation in mind.

- Don’t try to share SSL contexts across multiple connections in libpq (Heikki Linnakangas)
  This led to assorted corner-case bugs, particularly when trying to use different SSL parameters for different connections.

- Avoid corner-case memory leak in libpq (Tom Lane)
The reported problem involved leaking an error report during PQreset(), but there might be related cases.

- **Make ecpg's --help and --version options work consistently with our other executables (Haribabu Kommi)**

- **In pg_dump, never dump range constructor functions (Tom Lane)**
  
  This oversight led to pg_upgrade failures with extensions containing range types, due to duplicate creation of the constructor functions.

- **Fix contrib/intarray/bench/bench.pl to print the results of the EXPLAIN it does when given the -e option (Daniel Gustafsson)**

- **Update Windows time zone mapping to recognize some time zone names added in recent Windows versions (Michael Paquier)**

- **Prevent failure of obsolete dynamic time zone abbreviations (Tom Lane)**
  
  If a dynamic time zone abbreviation does not match any entry in the referenced time zone, treat it as equivalent to the time zone name. This avoids unexpected failures when IANA removes abbreviations from their time zone database, as they did in tzdata release 2016f and seem likely to do again in the future. The consequences were not limited to not recognizing the individual abbreviation; any mismatch caused the pg_timezone_abbrevs view to fail altogether.

- **Update time zone data files to tzdata release 2016h for DST law changes in Palestine and Turkey, plus historical corrections for Turkey and some regions of Russia. Switch to numeric abbreviations for some time zones in Antarctica, the former Soviet Union, and Sri Lanka.**

  The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the pg_timezone_names view nor used for output.

  In this update, AMT is no longer shown as being in use to mean Armenia Time. Therefore, we have changed the Default abbreviation set to interpret it as Amazon Time, thus UTC-4 not UTC+4.

**E.67. Release 9.2.18**

**Release date:** 2016-08-11

This release contains a variety of fixes from 9.2.17. For information about new features in the 9.2 major release, see Section E.85.

**E.67.1. Migration to Version 9.2.18**

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.74.
E.67.2. Changes

• Fix possible mis-evaluation of nested CASE-WHEN expressions (Heikki Linnakangas, Michael Paquier, Tom Lane)

A CASE expression appearing within the test value subexpression of another CASE could become confused about whether its own test value was null or not. Also, inlining of a SQL function implementing the equality operator used by a CASE expression could result in passing the wrong test value to functions called within a CASE expression in the SQL function’s body. If the test values were of different data types, a crash might result; moreover such situations could be abused to allow disclosure of portions of server memory. (CVE-2016-5423)

• Fix client programs’ handling of special characters in database and role names (Noah Misch, Nathan Bossart, Michael Paquier)

Numerous places in vacuumdb and other client programs could become confused by database and role names containing double quotes or backslashes. Tighten up quoting rules to make that safe. Also, ensure that when a conninfo string is used as a database name parameter to these programs, it is correctly treated as such throughout.

Fix handling of paired double quotes in psql’s \connect and \password commands to match the documentation.

Introduce a new -reuse-previous option in psql’s \connect command to allow explicit control of whether to re-use connection parameters from a previous connection. (Without this, the choice is based on whether the database name looks like a conninfo string, as before.) This allows secure handling of database names containing special characters in pg_dumpall scripts.

pg_dumpall now refuses to deal with database and role names containing carriage returns or newlines, as it seems impractical to quote those characters safely on Windows. In future we may reject such names on the server side, but that step has not been taken yet.

These are considered security fixes because crafted object names containing special characters could have been used to execute commands with superuser privileges the next time a superuser executes pg_dumpall or other routine maintenance operations. (CVE-2016-5424)

• Fix corner-case misbehaviors for IS NULL/IS NOT NULL applied to nested composite values (Andrew Gierth, Tom Lane)

The SQL standard specifies that IS NULL should return TRUE for a row of all null values (thus ROW(NULL, NULL) IS NULL yields TRUE), but this is not meant to apply recursively (thus ROW(NULL, ROW(NULL, NULL)) IS NULL yields FALSE). The core executor got this right, but certain planner optimizations treated the test as recursive (thus producing TRUE in both cases), and contrib/postgres_fdw could produce remote queries that misbehaved similarly.

• Make the inet and cidr data types properly reject IPv6 addresses with too many colon-separated fields (Tom Lane)

• Prevent crash in close_ps() (the point ## lseg operator) for NaN input coordinates (Tom Lane)

Make it return NULL instead of crashing.

• Fix several one-byte buffer over-reads in to_number() (Peter Eisentraut)

In several cases the to_number() function would read one more character than it should from the input string. There is a small chance of a crash, if the input happens to be adjacent to the end of memory.
Appendix E. Release Notes

- Avoid unsafe intermediate state during expensive paths through heap_update() (Masahiko Sawada, Andres Freund)
  Previously, these cases locked the target tuple (by setting its XMAX) but did not WAL-log that action, thus risking data integrity problems if the page were spilled to disk and then a database crash occurred before the tuple update could be completed.

- Avoid crash in postgres -C when the specified variable has a null string value (Michael Paquier)

- Avoid consuming a transaction ID during VACUUM (Alexander Korotkov)
  Some cases in VACUUM unnecessarily caused an XID to be assigned to the current transaction. Normally this is negligible, but if one is up against the XID wraparound limit, consuming more XIDs during anti-wraparound vacuums is a very bad thing.

- Avoid canceling hot-standby queries during VACUUM FREEZE (Simon Riggs, Álvaro Herrera)
  VACUUM FREEZE on an otherwise-idle master server could result in unnecessary cancellations of queries on its standby servers.

- When a manual ANALYZE specifies a column list, don’t reset the table’s changes_since_analyze counter (Tom Lane)
  If we’re only analyzing some columns, we should not prevent routine auto-analyze from happening for the other columns.

- Fix ANALYZE’s overestimation of n_distinct for a unique or nearly-unique column with many null entries (Tom Lane)
  The nulls could get counted as though they were themselves distinct values, leading to serious planner misestimates in some types of queries.

- Prevent autovacuum from starting multiple workers for the same shared catalog (Álvaro Herrera)
  Normally this isn’t much of a problem because the vacuum doesn’t take long anyway; but in the case of a severely bloated catalog, it could result in all but one worker uselessly waiting instead of doing useful work on other tables.

- Prevent infinite loop in GiST index build for geometric columns containing NaN component values (Tom Lane)

- Fix contrib/btree_gin to handle the smallest possible bigint value correctly (Peter Eisentraut)

- Teach libpq to correctly decode server version from future servers (Peter Eisentraut)
  It’s planned to switch to two-part instead of three-part server version numbers for releases after 9.6. Make sure that PQserverVersion() returns the correct value for such cases.

- Fix ecpg’s code for unsigned long long array elements (Michael Meskes)

- In pg_dump with both -c and -C options, avoid emitting an unwanted CREATE SCHEMA public command (David Johnston, Tom Lane)

- Make pg_basebackup accept -Z 0 as specifying no compression (Fujii Masao)

- Fix makefiles’ rule for building AIX shared libraries to be safe for parallel make (Noah Misch)

- Fix TAP tests and MSVC scripts to work when build directory’s path name contains spaces (Michael Paquier, Kyotaro Horiguchi)

- Make regression tests safe for Danish and Welsh locales (Jeff Janes, Tom Lane)
  Change some test data that triggered the unusual sorting rules of these locales.

- Update our copy of the timezone code to match IANA’s tzcode release 2016c (Tom Lane)
This is needed to cope with anticipated future changes in the time zone data files. It also fixes some corner-case bugs in coping with unusual time zones.

- Update time zone data files to tzdata release 2016f for DST law changes in Kemerovo and Novosibirsk, plus historical corrections for Azerbaijan, Belarus, and Morocco.

E.68. Release 9.2.17

Release date: 2016-05-12

This release contains a variety of fixes from 9.2.16. For information about new features in the 9.2 major release, see Section E.85.

E.68.1. Migration to Version 9.2.17

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.74.

E.68.2. Changes

- Clear the OpenSSL error queue before OpenSSL calls, rather than assuming it’s clear already; and make sure we leave it clear afterwards (Peter Geoghegan, Dave Vitek, Peter Eisentraut)

  This change prevents problems when there are multiple connections using OpenSSL within a single process and not all the code involved follows the same rules for when to clear the error queue. Failures have been reported specifically when a client application uses SSL connections in libpq concurrently with SSL connections using the PHP, Python, or Ruby wrappers for OpenSSL. It’s possible for similar problems to arise within the server as well, if an extension module establishes an outgoing SSL connection.

- Fix “failed to build any *n*-way joins” planner error with a full join enclosed in the right-hand side of a left join (Tom Lane)

- Fix incorrect handling of equivalence-class tests in multilevel nestloop plans (Tom Lane)

  Given a three-or-more-way equivalence class of variables, such as X.X = Y.Y = Z.Z, it was possible for the planner to omit some of the tests needed to enforce that all the variables are actually equal, leading to join rows being output that didn’t satisfy the \texttt{WHERE} clauses. For various reasons, erroneous plans were seldom selected in practice, so that this bug has gone undetected for a long time.

- Fix possible misbehavior of \texttt{TH}, \texttt{th}, and \texttt{Y,YYY} format codes in \texttt{to_timestamp()} (Tom Lane)

  These could advance off the end of the input string, causing subsequent format codes to read garbage.

- Fix dumping of rules and views in which the \texttt{array} argument of a \texttt{value} operator \texttt{ANY (array)} construct is a sub-SELECT (Tom Lane)

- Make \texttt{pg_regress} use a startup timeout from the \texttt{PGCTLTIMEOUT} environment variable, if that’s set (Tom Lane)
This is for consistency with a behavior recently added to pg_ctl; it eases automated testing on slow machines.

- Fix pg_upgrade to correctly restore extension membership for operator families containing only one operator class (Tom Lane)

  In such a case, the operator family was restored into the new database, but it was no longer marked as part of the extension. This had no immediate ill effects, but would cause later pg_dump runs to emit output that would cause (harmless) errors on restore.

- Back-port 9.4-era memory-barrier code changes into 9.2 and 9.3 (Tom Lane)

  These changes were not originally needed in pre-9.4 branches, but we recently back-patched a fix that expected the barrier code to work properly. Only IA64 (when using icc), HPPA, and Alpha platforms are affected.

- Reduce the number of SysV semaphores used by a build configured with --disable-spinlocks (Tom Lane)

- Rename internal function strtoi() to strtoint() to avoid conflict with a NetBSD library function (Thomas Munro)

- Fix reporting of errors from bind() and listen() system calls on Windows (Tom Lane)

- Reduce verbosity of compiler output when building with Microsoft Visual Studio (Christian Ullrich)

- Avoid possibly-unsafe use of Windows’ FormatMessage() function (Christian Ullrich)

  Use the FORMAT_MESSAGE_IGNORE_INSERTS flag where appropriate. No live bug is known to exist here, but it seems like a good idea to be careful.

- Update time zone data files to tzdata release 2016d for DST law changes in Russia and Venezuela. There are new zone names Europe/Kirov and Asia/Tomsk to reflect the fact that these regions now have different time zone histories from adjacent regions.

---

**E.69. Release 9.2.16**

**Release date:** 2016-03-31

This release contains a variety of fixes from 9.2.15. For information about new features in the 9.2 major release, see Section E.85.

**E.69.1. Migration to Version 9.2.16**

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.74.

**E.69.2. Changes**

- Fix incorrect handling of NULL index entries in indexed ROW() comparisons (Tom Lane)
An index search using a row comparison such as \( \text{ROW}(a, b) > \text{ROW}('x', 'y') \) would stop upon reaching a NULL entry in the \( b \) column, ignoring the fact that there might be non-NULL \( b \) values associated with later values of \( a \).

- Avoid unlikely data-loss scenarios due to renaming files without adequate \text{fsync()} \) calls before and after (Michael Paquier, Tomas Vondra, Andres Freund)
- Correctly handle cases where pg_subtrans is close to XID wraparound during server startup (Jeff Janes)
- Fix corner-case crash due to trying to free localeconv() output strings more than once (Tom Lane)
- Fix parsing of affix files for ispell dictionaries (Tom Lane)
  The code could go wrong if the affix file contained any characters whose byte length changes during case-folding, for example \( I \) in Turkish UTF8 locales.
- Avoid use of sscanf() to parse ispell dictionary files (Artur Zakirov)
  This dodges a portability problem on FreeBSD-derived platforms (including macOS).
- Avoid a crash on old Windows versions (before 7SP1/2008R2SP1) with an AVX2-capable CPU and a Postgres build done with Visual Studio 2013 (Christian Ullrich)
  This is a workaround for a bug in Visual Studio 2013’s runtime library, which Microsoft have stated they will not fix in that version.
- Fix psql’s tab completion logic to handle multibyte characters properly (Kyotaro Horiguchi, Robert Haas)
- Fix psql’s tab completion for \texttt{SECURITY LABEL} (Tom Lane)
  Pressing TAB after \texttt{SECURITY LABEL} might cause a crash or offering of inappropriate keywords.
- Make pg_ctl accept a wait timeout from the PGCTLTIMEOUT environment variable, if none is specified on the command line (Noah Misch)
  This eases testing of slower buildfarm members by allowing them to globally specify a longer-than-normal timeout for postmaster startup and shutdown.
- Fix incorrect test for Windows service status in pg_ctl (Manuel Mathar)
  The previous set of minor releases attempted to fix pg_ctl to properly determine whether to send log messages to Window’s Event Log, but got the test backwards.
- Fix pgbench to correctly handle the combination of -C and -M prepared options (Tom Lane)
- In PL/Perl, properly translate empty Postgres arrays into empty Perl arrays (Alex Hunsaker)
- Make PL/Python cope with function names that aren’t valid Python identifiers (Jim Nasby)
- Fix multiple mistakes in the statistics returned by contrib/pgstattuple’s pgstatindex() function (Tom Lane)
- Remove dependency on psed in MSVC builds, since it’s no longer provided by core Perl (Michael Paquier, Andrew Dunstan)
- Update time zone data files to tzdata release 2016c for DST law changes in Azerbaijan, Chile, Haiti, Palestine, and Russia (Altai, Astrakhan, Kirov, Sakhalin, Ulyanovsk regions), plus historical corrections for Lithuania, Moldova, and Russia (Kaliningrad, Samara, Volgograd).
E.70. Release 9.2.15

Release date: 2016-02-11

This release contains a variety of fixes from 9.2.14. For information about new features in the 9.2 major release, see Section E.85.

E.70.1. Migration to Version 9.2.15

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.74.

E.70.2. Changes

- Fix infinite loops and buffer-overrun problems in regular expressions (Tom Lane)
  Very large character ranges in bracket expressions could cause infinite loops in some cases, and memory overwrites in other cases. (CVE-2016-0773)
- Perform an immediate shutdown if the postmaster.pid file is removed (Tom Lane)
  The postmaster now checks every minute or so that postmaster.pid is still there and still contains its own PID. If not, it performs an immediate shutdown, as though it had received SIGQUIT. The main motivation for this change is to ensure that failed buildfarm runs will get cleaned up without manual intervention; but it also serves to limit the bad effects if a DBA forcibly removes postmaster.pid and then starts a new postmaster.
- In SERIALIZABLE transaction isolation mode, serialization anomalies could be missed due to race conditions during insertions (Kevin Grittner, Thomas Munro)
- Fix failure to emit appropriate WAL records when doing ALTER TABLE ... SET TABLESPACE for unlogged relations (Michael Paquier, Andres Freund)
  Even though the relation’s data is unlogged, the move must be logged or the relation will be inaccessible after a standby is promoted to master.
- Fix possible misinitialization of unlogged relations at the end of crash recovery (Andres Freund, Michael Paquier)
- Fix ALTER COLUMN TYPE to reconstruct inherited check constraints properly (Tom Lane)
- Fix REASSIGN OWNED to change ownership of composite types properly (Álvaro Herrera)
- Fix REASSIGN OWNED and ALTER OWNER to correctly update granted-permissions lists when changing owners of data types, foreign data wrappers, or foreign servers (Bruce Momjian, Álvaro Herrera)
- Fix REASSIGN OWNED to ignore foreign user mappings, rather than fail (Álvaro Herrera)
- Add more defenses against bad planner cost estimates for GIN index scans when the index’s internal statistics are very out-of-date (Tom Lane)
- Make planner cope with hypothetical GIN indexes suggested by an index advisor plug-in (Julien Rouhaud)
- Fix dumping of whole-row Vars in ROW() and VALUES() lists (Tom Lane)
- Fix possible internal overflow in numeric division (Dean Rasheed)
• Fix enforcement of restrictions inside parentheses within regular expression lookahead constraints (Tom Lane)
  Lookahead constraints aren’t allowed to contain backrefs, and parentheses within them are always considered non-capturing, according to the manual. However, the code failed to handle these cases properly inside a parenthesized subexpression, and would give unexpected results.

• Conversion of regular expressions to indexscan bounds could produce incorrect bounds from regexps containing lookahead constraints (Tom Lane)

• Fix regular-expression compiler to handle loops of constraint arcs (Tom Lane)
  The code added for CVE-2007-4772 was both incomplete, in that it didn’t handle loops involving more than one state, and incorrect, in that it could cause assertion failures (though there seem to be no bad consequences of that in a non-assert build). Multi-state loops would cause the compiler to run until the query was canceled or it reached the too-many-states error condition.

• Improve memory-usage accounting in regular-expression compiler (Tom Lane)
  This causes the code to emit “regular expression is too complex” errors in some cases that previously used unreasonable amounts of time and memory.

• Improve performance of regular-expression compiler (Tom Lane)

• Make %h and %r escapes in log_line_prefix work for messages emitted due to log_connections (Tom Lane)
  Previously, %h/%r started to work just after a new session had emitted the “connection received” log message; now they work for that message too.

• On Windows, ensure the shared-memory mapping handle gets closed in child processes that don’t need it (Tom Lane, Amit Kapila)
  This oversight resulted in failure to recover from crashes whenever logging_collector is turned on.

• Fix possible failure to detect socket EOF in non-blocking mode on Windows (Tom Lane)
  It’s not entirely clear whether this problem can happen in pre-9.5 branches, but if it did, the symptom would be that a walsender process would wait indefinitely rather than noticing a loss of connection.

• Avoid leaking a token handle during SSPI authentication (Christian Ullrich)

• In psql, ensure that libreadline’s idea of the screen size is updated when the terminal window size changes (Merlin Moncure)
  Previously, libreadline did not notice if the window was resized during query output, leading to strange behavior during later input of multiline queries.

• Fix psql’s \det command to interpret its pattern argument the same way as other \d commands with potentially schema-qualified patterns do (Reece Hart)

• Avoid possible crash in psql’s \c command when previous connection was via Unix socket and command specifies a new hostname and same username (Tom Lane)

• In pg_ctl start -w, test child process status directly rather than relying on heuristics (Tom Lane, Michael Paquier)
  Previously, pg_ctl relied on an assumption that the new postmaster would always create postmaster.pid within five seconds. But that can fail on heavily-loaded systems, causing pg_ctl to report incorrectly that the postmaster failed to start.
Except on Windows, this change also means that a `pg_ctl start -w` done immediately after another such command will now reliably fail, whereas previously it would report success if done within two seconds of the first command.

- In `pg_ctl start -w`, don’t attempt to use a wildcard listen address to connect to the postmaster (Kondo Yuta)

On Windows, `pg_ctl` would fail to detect postmaster startup if `listen_addresses` is set to `0.0.0.0` or `::`, because it would try to use that value verbatim as the address to connect to, which doesn’t work. Instead assume that `127.0.0.1` or `::1`, respectively, is the right thing to use.

- In `pg_ctl` on Windows, check service status to decide where to send output, rather than checking if standard output is a terminal (Michael Paquier)

- In `pg_dump` and `pg_basebackup`, adopt the GNU convention for handling tar-archive members exceeding 8GB (Tom Lane)

The POSIX standard for `tar` file format does not allow archive member files to exceed 8GB, but most modern implementations of tar support an extension that fixes that. Adopt this extension so that `pg_dump` with `-Ft` no longer fails on tables with more than 8GB of data, and so that `pg_basebackup` can handle files larger than 8GB. In addition, fix some portability issues that could cause failures for members between 4GB and 8GB on some platforms. Potentially these problems could cause unrecoverable data loss due to unreadable backup files.

- Fix assorted corner-case bugs in `pg_dump`’s processing of extension member objects (Tom Lane)

- Make `pg_dump` mark a view’s triggers as needing to be processed after its rule, to prevent possible failure during parallel `pg_restore` (Tom Lane)

- Ensure that relation option values are properly quoted in `pg_dump` (Kouhei Sutou, Tom Lane)

A reloption value that isn’t a simple identifier or number could lead to dump/reload failures due to syntax errors in CREATE statements issued by `pg_dump`. This is not an issue with any reloption currently supported by core PostgreSQL, but extensions could allow options that cause the problem.

- Fix `pg_upgrade`’s file-copying code to handle errors properly on Windows (Bruce Momjian)

- Install guards in `pgbench` against corner-case overflow conditions during evaluation of script-specified division or modulo operators (Fabien Coelho, Michael Paquier)

- Fix failure to localize messages emitted by `pg_receivexlog` and `pg_recvlogical` (Ioseph Kim)

- Avoid dump/reload problems when using both plpython2 and plpython3 (Tom Lane)

In principle, both versions of PL/Python can be used in the same database, though not in the same session (because the two versions of libpython cannot safely be used concurrently). However, `pg_restore` and `pg_upgrade` both do things that can fall foul of the same-session restriction. Work around that by changing the timing of the check.

- Fix PL/Python regression tests to pass with Python 3.5 (Peter Eisentraut)

- Prevent certain PL/Java parameters from being set by non-superusers (Noah Misch)

This change mitigates a PL/Java security bug (CVE-2016-0766), which was fixed in PL/Java by marking these parameters as superuser-only. To fix the security hazard for sites that update PostgreSQL more frequently than PL/Java, make the core code aware of them also.

- Improve libpq’s handling of out-of-memory situations (Michael Paquier, Amit Kapila, Heikki Linnakangas)

- Fix order of arguments in `ecpg`-generated `typedef` statements (Michael Meskes)

- Use `%g` not `%f` format in `ecpg`’s `PGTYPESnumeric_from_double()` (Tom Lane)
• Fix ecpg-supplied header files to not contain comments continued from a preprocessor directive line onto the next line (Michael Meskes)
  Such a comment is rejected by ecpg. It’s not yet clear whether ecpg itself should be changed.
• Ensure that contrib/pgcrypto’s crypt() function can be interrupted by query cancel (Andreas Karlsson)
• Accept flex versions later than 2.5.x (Tom Lane, Michael Paquier)
  Now that flex 2.6.0 has been released, the version checks in our build scripts needed to be adjusted.
• Install our missing script where PGXS builds can find it (Jim Nasby)
  This allows sane behavior in a PGXS build done on a machine where build tools such as bison are missing.
• Ensure that dynloader.h is included in the installed header files in MSVC builds (Bruce Momjian, Michael Paquier)
• Add variant regression test expected-output file to match behavior of current libxml2 (Tom Lane)
  The fix for libxml2’s CVE-2015-7499 causes it not to output error context reports in some cases where it used to do so. This seems to be a bug, but we’ll probably have to live with it for some time, so work around it.
• Update time zone data files to tzdata release 2016a for DST law changes in Cayman Islands, Metlakatla, and Trans-Baikal Territory (Zabaykalsky Krai), plus historical corrections for Pakistan.

E.71. Release 9.2.14

Release date: 2015-10-08
This release contains a variety of fixes from 9.2.13. For information about new features in the 9.2 major release, see Section E.85.

E.71.1. Migration to Version 9.2.14
A dump/restore is not required for those running 9.2.X.
However, if you are upgrading from a version earlier than 9.2.11, see Section E.74.

E.71.2. Changes

• Fix contrib/pgcrypto to detect and report too-short crypt() salts (Josh Kupershmidt)
  Certain invalid salt arguments crashed the server or disclosed a few bytes of server memory. We have not ruled out the viability of attacks that arrange for presence of confidential information in the disclosed bytes, but they seem unlikely. (CVE-2015-5288)
• Fix subtransaction cleanup after a portal (cursor) belonging to an outer subtransaction fails (Tom Lane, Michael Paquier)
  A function executed in an outer-subtransaction cursor could cause an assertion failure or crash by referencing a relation created within an inner subtransaction.
Appendix E. Release Notes

• Fix insertion of relations into the relation cache “init file” (Tom Lane)

An oversight in a patch in the most recent minor releases caused `pg_trigger_tgrelid_tgname_index` to be omitted from the init file. Subsequent sessions detected this, then deemed the init file to be broken and silently ignored it, resulting in a significant degradation in session startup time. In addition to fixing the bug, install some guards so that any similar future mistake will be more obvious.

• Avoid O(N^2) behavior when inserting many tuples into a SPI query result (Neil Conway)

• Improve `LISTEN` startup time when there are many unread notifications (Matt Newell)

• Back-patch 9.3-era addition of per-resource-owner lock caches (Jeff Janes)

This substantially improves performance when `pg_dump` tries to dump a large number of tables.

• Disable SSL renegotiation by default (Michael Paquier, Andres Freund)

While use of SSL renegotiation is a good idea in theory, we have seen too many bugs in practice, both in the underlying OpenSSL library and in our usage of it. Renegotiation will be removed entirely in 9.5 and later. In the older branches, just change the default value of `ssl_renegotiation_limit` to zero (disabled).

• Lower the minimum values of the `_freeze_max_age` parameters (Andres Freund)

This is mainly to make tests of related behavior less time-consuming, but it may also be of value for installations with limited disk space.

• Limit the maximum value of `wal_buffers` to 2GB to avoid server crashes (Josh Berkus)

• Fix rare internal overflow in multiplication of numeric values (Dean Rasheed)

• Guard against hard-to-reach stack overflows involving record types, range types, `json`, `jsonb`, `tsquery`, `ltxtquery` and `query_int` (Noah Misch)

• Fix handling of `DOW` and `DOY` in datetime input (Greg Stark)

These tokens aren’t meant to be used in datetime values, but previously they resulted in opaque internal error messages rather than “invalid input syntax”.

• Add more query-cancel checks to regular expression matching (Tom Lane)

• Add recursion depth protections to regular expression, `SIMILAR TO`, and `LIKE` matching (Tom Lane)

Suitable search patterns and a low stack depth limit could lead to stack-overrun crashes.

• Fix potential infinite loop in regular expression execution (Tom Lane)

A search pattern that can apparently match a zero-length string, but actually doesn’t match because of a back reference, could lead to an infinite loop.

• In regular expression execution, correctly record match data for capturing parentheses within a quantifier even when the match is zero-length (Tom Lane)

• Fix low-memory failures in regular expression compilation (Andreas Seltenreich)

• Fix low-probability memory leak during regular expression execution (Tom Lane)

• Fix rare low-memory failure in lock cleanup during transaction abort (Tom Lane)

• Fix “unexpected out-of-memory situation during sort” errors when using tuplestores with small `work_mem` settings (Tom Lane)

• Fix very-low-probability stack overrun in `qsort` (Tom Lane)

• Fix “invalid memory alloc request size” failure in hash joins with large `work_mem` settings (Tomas Vondra, Tom Lane)
• Fix assorted planner bugs (Tom Lane)
  These mistakes could lead to incorrect query plans that would give wrong answers, or to assertion failures in assert-enabled builds, or to odd planner errors such as “could not devise a query plan for the given query”, “could not find pathkey item to sort”, “plan should not reference subplan’s variable”, or “failed to assign all NestLoopParams to plan nodes”. Thanks are due to Andreas Seltenreich and Piotr Stefaniak for fuzz testing that exposed these problems.

• Improve planner’s performance for UPDATE/DELETE on large inheritance sets (Tom Lane, Dean Rasheed)

• Ensure standby promotion trigger files are removed at postmaster startup (Michael Paquier, Fujii Masao)
  This prevents unwanted promotion from occurring if these files appear in a database backup that is used to initialize a new standby server.

• During postmaster shutdown, ensure that per-socket lock files are removed and listen sockets are closed before we remove the postmaster.pid file (Tom Lane)
  This avoids race-condition failures if an external script attempts to start a new postmaster as soon as pg_ctl stop returns.

• Fix postmaster’s handling of a startup-process crash during crash recovery (Tom Lane)
  If, during a crash recovery cycle, the startup process crashes without having restored database consistency, we’d try to launch a new startup process, which typically would just crash again, leading to an infinite loop.

• Do not print a WARNING when an autovacuum worker is already gone when we attempt to signal it, and reduce log verbosity for such signals (Tom Lane)

• Prevent autovacuum launcher from sleeping unduly long if the server clock is moved backwards a large amount (Álvaro Herrera)

• Ensure that cleanup of a GIN index’s pending-insertions list is interruptable by cancel requests (Jeff Janes)

• Allow all-zeroes pages in GIN indexes to be reused (Heikki Linnakangas)
  Such a page might be left behind after a crash.

• Fix handling of all-zeroes pages in SP-GiST indexes (Heikki Linnakangas)
  VACUUM attempted to recycle such pages, but did so in a way that wasn’t crash-safe.

• Fix off-by-one error that led to otherwise-harmless warnings about “apparent wraparound” in sub-trans/multixact truncation (Thomas Munro)

• Fix misreporting of CONTINUE and MOVE statement types in PL/pgSQL’s error context messages (Pavel Stehule, Tom Lane)

• Fix PL/Perl to handle non-ASCII error message texts correctly (Alex Hunsaker)

• Fix PL/Python crash when returning the string representation of a record result (Tom Lane)

• Fix some places in PL/Tcl that neglected to check for failure of malloc() calls (Michael Paquier, Álvaro Herrera)

• In contrib/isn, fix output of ISBN-13 numbers that begin with 979 (Fabien Coelho)
  EANs beginning with 979 (but not 9790) are considered ISBNs, but they must be printed in the new 13-digit format, not the 10-digit format.

• Fix contrib/sepgsql’s handling of SELECT INTO statements (Kohei KaiGai)
Appendix E. Release Notes

- Improve libpq’s handling of out-of-memory conditions (Michael Paquier, Heikki Linnakangas)
- Fix memory leaks and missing out-of-memory checks in ecpg (Michael Paquier)
- Fix psql’s code for locale-aware formatting of numeric output (Tom Lane)
  The formatting code invoked by \pset numericlocale on did the wrong thing for some uncommon cases such as numbers with an exponent but no decimal point. It could also mangle already-localized output from the money data type.
- Prevent crash in psql’s \c command when there is no current connection (Noah Misch)
- Make pg_dump handle inherited NOT VALID check constraints correctly (Tom Lane)
- Fix selection of default zlib compression level in pg_dump’s directory output format (Andrew Dunstan)
- Ensure that temporary files created during a pg_dump run with tar-format output are not world-readable (Michael Paquier)
- Fix pg_dump and pg_upgrade to support cases where the postgres or template1 database is in a non-default tablespace (Marti Raudsepp, Bruce Momjian)
- Fix pg_dump to handle object privileges sanely when dumping from a server too old to have a particular privilege type (Tom Lane)
  When dumping data types from pre-9.2 servers, and when dumping functions or procedural languages from pre-7.3 servers, pg_dump would produce GRANT/REVOKE commands that revoked the owner’s grantable privileges and instead granted all privileges to PUBLIC. Since the privileges involved are just USAGE and EXECUTE, this isn’t a security problem, but it’s certainly a surprising representation of the older systems’ behavior. Fix it to leave the default privilege state alone in these cases.
- Fix pg_dump to dump shell types (Tom Lane)
  Shell types (that is, not-yet-fully-defined types) aren’t useful for much, but nonetheless pg_dump should dump them.
- Fix assorted minor memory leaks in pg_dump and other client-side programs (Michael Paquier)
- Fix spinlock assembly code for PPC hardware to be compatible with AIX’s native assembler (Tom Lane)
  Building with gcc didn’t work if gcc had been configured to use the native assembler, which is becoming more common.
- On AIX, test the -qlonglong compiler option rather than just assuming it’s safe to use (Noah Misch)
- On AIX, use -Wl,-brtllib link option to allow symbols to be resolved at runtime (Noah Misch)
  Perl relies on this ability in 5.8.0 and later.
- Avoid use of inline functions when compiling with 32-bit xlc, due to compiler bugs (Noah Misch)
- Use librt for sched_yield() when necessary, which it is on some Solaris versions (Oskari Saarenmaa)
- Fix Windows install.bat script to handle target directory names that contain spaces (Heikki Linnakangas)
- Make the numeric form of the PostgreSQL version number (e.g., 90405) readily available to extension Makefiles, as a variable named VERSION_NUM (Michael Paquier)
• Update time zone data files to tzdata release 2015g for DST law changes in Cayman Islands, Fiji, Moldova, Morocco, Norfolk Island, North Korea, Turkey, and Uruguay. There is a new zone name America/Fort_Nelson for the Canadian Northern Rockies.

E.72. Release 9.2.13

Release date: 2015-06-12

This release contains a small number of fixes from 9.2.12. For information about new features in the 9.2 major release, see Section E.85.

E.72.1. Migration to Version 9.2.13

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.74.

E.72.2. Changes

• Fix rare failure to invalidate relation cache init file (Tom Lane)

With just the wrong timing of concurrent activity, a VACUUM FULL on a system catalog might fail to update the “init file” that’s used to avoid cache-loading work for new sessions. This would result in later sessions being unable to access that catalog at all. This is a very ancient bug, but it’s so hard to trigger that no reproducible case had been seen until recently.

• Avoid deadlock between incoming sessions and CREATE/DROP DATABASE (Tom Lane)

A new session starting in a database that is the target of a DROP DATABASE command, or is the template for a CREATE DATABASE command, could cause the command to wait for five seconds and then fail, even if the new session would have exited before that.

E.73. Release 9.2.12

Release date: 2015-06-04

This release contains a small number of fixes from 9.2.11. For information about new features in the 9.2 major release, see Section E.85.

E.73.1. Migration to Version 9.2.12

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.74.
E.73.2. Changes

- Avoid failures while `fsync`ing data directory during crash restart (Abhijit Menon-Sen, Tom Lane)
  In the previous minor releases we added a patch to `fsync` everything in the data directory after a crash. Unfortunately its response to any error condition was to fail, thereby preventing the server from starting up, even when the problem was quite harmless. An example is that an unwritable file in the data directory would prevent restart on some platforms; but it is common to make SSL certificate files unwritable by the server. Revise this behavior so that permissions failures are ignored altogether, and other types of failures are logged but do not prevent continuing.
- Fix `pg_get_functiondef()` to show functions’ `LEAKPROOF` property, if set (Jeevan Chalke)
- Remove configure’s check prohibiting linking to a threaded `libpython` on OpenBSD (Tom Lane)
  The failure this restriction was meant to prevent seems to not be a problem anymore on current OpenBSD versions.
- Allow `libpq` to use TLS protocol versions beyond v1 (Noah Misch)
  For a long time, `libpq` was coded so that the only SSL protocol it would allow was TLS v1. Now that newer TLS versions are becoming popular, allow it to negotiate the highest commonly-supported TLS version with the server. (PostgreSQL servers were already capable of such negotiation, so no change is needed on the server side.) This is a back-patch of a change already released in 9.4.0.

E.74. Release 9.2.11

Release date: 2015-05-22

This release contains a variety of fixes from 9.2.10. For information about new features in the 9.2 major release, see Section E.85.

E.74.1. Migration to Version 9.2.11

A dump/restore is not required for those running 9.2.X.

However, if you use `contrib/citext`'s `regexp_matches()` functions, see the changelog entry below about that.

Also, if you are upgrading from a version earlier than 9.2.10, see Section E.75.

E.74.2. Changes

- Avoid possible crash when client disconnects just before the authentication timeout expires (Benkocs Norbert Attila)
  If the timeout interrupt fired partway through the session shutdown sequence, SSL-related state would be freed twice, typically causing a crash and hence denial of service to other sessions. Experimentation shows that an unauthenticated remote attacker could trigger the bug somewhat consistently, hence treat as security issue. (CVE-2015-3165)
- Improve detection of system-call failures (Noah Misch)
Our replacement implementation of `snprintf()` failed to check for errors reported by the underlying system library calls; the main case that might be missed is out-of-memory situations. In the worst case this might lead to information exposure, due to our code assuming that a buffer had been overwritten when it hadn’t been. Also, there were a few places in which security-relevant calls of other system library functions did not check for failure.

It remains possible that some calls of the `printf()` family of functions are vulnerable to information disclosure if an out-of-memory error occurs at just the wrong time. We judge the risk to not be large, but will continue analysis in this area. (CVE-2015-3166)

- In `contrib/pgcrypto`, uniformly report decryption failures as “Wrong key or corrupt data” (Noah Misch)

  Previously, some cases of decryption with an incorrect key could report other error message texts. It has been shown that such variance in error reports can aid attackers in recovering keys from other systems. While it’s unknown whether `pgcrypto`’s specific behaviors are likewise exploitable, it seems better to avoid the risk by using a one-size-fits-all message. (CVE-2015-3167)

- Fix incorrect declaration of `contrib/citext`’s `regexp_matches()` functions (Tom Lane)

  These functions should return `setof text[]`, like the core functions they are wrappers for; but they were incorrectly declared as returning just `text[]`. This mistake had two results: first, if there was no match you got a scalar null result, whereas what you should get is an empty set (zero rows). Second, the `g` flag was effectively ignored, since you would get only one result array even if there were multiple matches.

  While the latter behavior is clearly a bug, there might be applications depending on the former behavior; therefore the function declarations will not be changed by default until PostgreSQL 9.5. In pre-9.5 branches, the old behavior exists in version 1.0 of the `citext` extension, while we have provided corrected declarations in version 1.1 (which is not installed by default). To adopt the fix in pre-9.5 branches, execute `ALTER EXTENSION citext UPDATE TO ’1.1’` in each database in which `citext` is installed. (You can also “update” back to 1.0 if you need to undo that.) Be aware that either update direction will require dropping and recreating any views or rules that use `citext`’s `regexp_matches()` functions.

- Fix incorrect checking of deferred exclusion constraints after a HOT update (Tom Lane)

  If a new row that potentially violates a deferred exclusion constraint is HOT-updated (that is, no indexed columns change and the row can be stored back onto the same table page) later in the same transaction, the exclusion constraint would be reported as violated when the check finally occurred, even if the row(s) the new row originally conflicted with had been deleted.

- Fix planning of star-schema-style queries (Tom Lane)

  Sometimes, efficient scanning of a large table requires that index parameters be provided from more than one other table (commonly, dimension tables whose keys are needed to index a large fact table). The planner should be able to find such plans, but an overly restrictive search heuristic prevented it.

- Prevent improper reordering of antijoins (NOT EXISTS joins) versus other outer joins (Tom Lane)

  This oversight in the planner has been observed to cause “could not find RelOptInfo for given relids” errors, but it seems possible that sometimes an incorrect query plan might get past that consistency check and result in silently-wrong query output.

- Fix incorrect matching of subexpressions in outer-join plan nodes (Tom Lane)

  Previously, if textually identical non-strict subexpressions were used both above and below an outer join, the planner might try to re-use the value computed below the join, which would be incorrect because the executor would force the value to NULL in case of an unmatched outer row.
• Fix GEQO planner to cope with failure of its join order heuristic (Tom Lane)
  This oversight has been seen to lead to “failed to join all relations together” errors in queries involving LATERAL, and that might happen in other cases as well.
• Fix possible deadlock at startup when max_prepared_transactions is too small (Heikki Linnakangas)
• Don’t archive useless preallocated WAL files after a timeline switch (Heikki Linnakangas)
• Avoid “cannot GetMultiXactIdMembers() during recovery” error (Álvaro Herrera)
• Recursively fsync() the data directory after a crash (Abhijit Menon-Sen, Robert Haas)
  This ensures consistency if another crash occurs shortly later. (The second crash would have to be a system-level crash, not just a database crash, for there to be a problem.)
• Fix autovacuum launcher’s possible failure to shut down, if an error occurs after it receives SIGTERM (Álvaro Herrera)
• Cope with unexpected signals in LockBufferForCleanup() (Andres Freund)
  This oversight could result in spurious errors about “multiple backends attempting to wait for pin-count 1”.
• Fix crash when doing COPY IN to a table with check constraints that contain whole-row references (Tom Lane)
  The known failure case only crashes in 9.4 and up, but there is very similar code in 9.3 and 9.2, so back-patch those branches as well.
• Avoid waiting for WAL flush or synchronous replication during commit of a transaction that was read-only so far as the user is concerned (Andres Freund)
  Previously, a delay could occur at commit in transactions that had written WAL due to HOT page pruning, leading to undesirable effects such as sessions getting stuck at startup if all synchronous replicas are down. Sessions have also been observed to get stuck in catchup interrupt processing when using synchronous replication; this will fix that problem as well.
• Fix crash when manipulating hash indexes on temporary tables (Heikki Linnakangas)
• Fix possible failure during hash index bucket split, if other processes are modifying the index concurrently (Tom Lane)
• Check for interrupts while analyzing index expressions (Jeff Janes)
  ANALYZE executes index expressions many times; if there are slow functions in such an expression, it’s desirable to be able to cancel the ANALYZE before that loop finishes.
• Ensure tableoid of a foreign table is reported correctly when a READ COMMITTED recheck occurs after locking rows in SELECT FOR UPDATE, UPDATE, or DELETE (Etsuro Fujita)
• Add the name of the target server to object description strings for foreign-server user mappings (Álvaro Herrera)
• Recommend setting include_realm to 1 when using Kerberos/GSSAPI/SSPI authentication (Stephen Frost)
  Without this, identically-named users from different realms cannot be distinguished. For the moment this is only a documentation change, but it will become the default setting in PostgreSQL 9.5.
• Remove code for matching IPv4 pg_hba.conf entries to IPv4-in-IPv6 addresses (Tom Lane)
  This hack was added in 2003 in response to a report that some Linux kernels of the time would report IPv4 connections as having IPv4-in-IPv6 addresses. However, the logic was accidentally
Appendix E. Release Notes

broken in 9.0. The lack of any field complaints since then shows that it’s not needed anymore. Now we have reports that the broken code causes crashes on some systems, so let’s just remove it rather than fix it. (Had we chosen to fix it, that would make for a subtle and potentially security-sensitive change in the effective meaning of IPv4 pg_hba.conf entries, which does not seem like a good thing to do in minor releases.)

- Report WAL flush, not insert, position in IDENTIFY_SYSTEM replication command (Heikki Linnakangas)
  This avoids a possible startup failure in pg_receivexlog.
- While shutting down service on Windows, periodically send status updates to the Service Control Manager to prevent it from killing the service too soon; and ensure that pg_ctl will wait for shutdown (Krystian Bigaj)
- Reduce risk of network deadlock when using libpq’s non-blocking mode (Heikki Linnakangas)
  When sending large volumes of data, it’s important to drain the input buffer every so often, in case the server has sent enough response data to cause it to block on output. (A typical scenario is that the server is sending a stream of NOTICE messages during COPY FROM STDIN.) This worked properly in the normal blocking mode, but not so much in non-blocking mode. We’ve modified libpq to opportunistically drain input when it can, but a full defense against this problem requires application cooperation: the application should watch for socket read-ready as well as write-ready conditions, and be sure to call PQconsumeInput() upon read-ready.
- In libpq, fix misparsing of empty values in URI connection strings (Thomas Fanghaenel)
- Fix array handling in ecpg (Michael Meskes)
- Fix psql to sanely handle URIs and conninfo strings as the first parameter to \connect (David Fetter, Andrew Dunstan, Álvaro Herrera)
  This syntax has been accepted (but undocumented) for a long time, but previously some parameters might be taken from the old connection instead of the given string, which was agreed to be undesirable.
- Suppress incorrect complaints from psql on some platforms that it failed to write ~/.psql_history at exit (Tom Lane)
  This misbehavior was caused by a workaround for a bug in very old (pre-2006) versions of libedit. We fixed it by removing the workaround, which will cause a similar failure to appear for anyone still using such versions of libedit. Recommendation: upgrade that library, or use libreadline.
- Fix pg_dump’s rule for deciding which casts are system-provided casts that should not be dumped (Tom Lane)
- In pg_dump, fix failure to honor -Z compression level option together with -Fd (Michael Paquier)
- Make pg_dump consider foreign key relationships between extension configuration tables while choosing dump order (Gilles Darold, Michael Paquier, Stephen Frost)
  This oversight could result in producing dumps that fail to reload because foreign key constraints are transiently violated.
- Fix dumping of views that are just VALUES(...) but have column aliases (Tom Lane)
- In pg_upgrade, force timeline 1 in the new cluster (Bruce Momjian)
  This change prevents upgrade failures caused by bogus complaints about missing WAL history files.
- In pg_upgrade, check for improperly non-connectable databases before proceeding (Bruce Momjian)
Appendix E. Release Notes

- In pg_upgrade, quote directory paths properly in the generated delete_old_cluster script (Bruce Momjian)
- In pg_upgrade, preserve database-level freezing info properly (Bruce Momjian)
  This oversight could cause missing-clog-file errors for tables within the postgres and template1 databases.
- Run pg_upgrade and pg_resetxlog with restricted privileges on Windows, so that they don’t fail when run by an administrator (Muhammad Asif Naeem)
- Improve handling of readdir() failures when scanning directories in initdb and pg_basebackup (Marco Nenciarini)
- Fix failure in pg_receivexlog (Andres Freund)
  A patch merge mistake in 9.2.10 led to “could not create archive status file” errors.
- Fix slow sorting algorithm in contrib/intarray (Tom Lane)
- Fix compile failure on Sparc V8 machines (Rob Rowan)
- Update time zone data files to tzdata release 2015d for DST law changes in Egypt, Mongolia, and Palestine, plus historical changes in Canada and Chile. Also adopt revised zone abbreviations for the America/Adak zone (HST/HDT not HAST/HADT).

E.75. Release 9.2.10

Release date: 2015-02-05

This release contains a variety of fixes from 9.2.9. For information about new features in the 9.2 major release, see Section E.85.

E.75.1. Migration to Version 9.2.10

A dump/restore is not required for those running 9.2.X.

However, if you are a Windows user and are using the “Norwegian (Bokmål)” locale, manual action is needed after the upgrade to replace any “Norwegian (Bokmål)_Norway” locale names stored in PostgreSQL system catalogs with the plain-ASCII alias “Norwegian_Norway”. For details see http://wiki.postgresql.org/wiki/Changes_To_Norwegian_Locale

Also, if you are upgrading from a version earlier than 9.2.9, see Section E.76.

E.75.2. Changes

- Fix buffer overruns in to_char() (Bruce Momjian)
  When to_char() processes a numeric formatting template calling for a large number of digits, PostgreSQL would read past the end of a buffer. When processing a crafted timestamp formatting template, PostgreSQL would write past the end of a buffer. Either case could crash the server. We have not ruled out the possibility of attacks that lead to privilege escalation, though they seem unlikely. (CVE-2015-0241)
- Fix buffer overrun in replacement *printf() functions (Tom Lane)
Appendix E. Release Notes

PostgreSQL includes a replacement implementation of `printf` and related functions. This code will overrun a stack buffer when formatting a floating point number (conversion specifiers `e`, `E`, `f`, `F`, `g` or `G`) with requested precision greater than about 500. This will crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. A database user can trigger such a buffer overrun through the `to_char()` SQL function. While that is the only affected core PostgreSQL functionality, extension modules that use printf-family functions may be at risk as well.

This issue primarily affects PostgreSQL on Windows. PostgreSQL uses the system implementation of these functions where adequate, which it is on other modern platforms. (CVE-2015-0242)

- Fix buffer overruns in `contrib/pgcrypto` (Marko Tiikkaja, Noah Misch)
  Errors in memory size tracking within the `pgcrypto` module permitted stack buffer overruns and improper dependence on the contents of uninitialized memory. The buffer overrun cases can crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. (CVE-2015-0243)

- Fix possible loss of frontend/backend protocol synchronization after an error (Heikki Linnakangas)
  If any error occurred while the server was in the middle of reading a protocol message from the client, it could lose synchronization and incorrectly try to interpret part of the message’s data as a new protocol message. An attacker able to submit crafted binary data within a command parameter might succeed in injecting his own SQL commands this way. Statement timeout and query cancellation are the most likely sources of errors triggering this scenario. Particularly vulnerable are applications that use a timeout and also submit arbitrary user-crafted data as binary query parameters. Disabling statement timeout will reduce, but not eliminate, the risk of exploit. Our thanks to Emil Lenngren for reporting this issue. (CVE-2015-0244)

- Fix information leak via constraint-violation error messages (Stephen Frost)
  Some server error messages show the values of columns that violate a constraint, such as a unique constraint. If the user does not have `SELECT` privilege on all columns of the table, this could mean exposing values that the user should not be able to see. Adjust the code so that values are displayed only when they came from the SQL command or could be selected by the user. (CVE-2014-8161)

- Lock down regression testing’s temporary installations on Windows (Noah Misch)
  Use SSPI authentication to allow connections only from the OS user who launched the test suite. This closes on Windows the same vulnerability previously closed on other platforms, namely that other users might be able to connect to the test postmaster. (CVE-2014-0067)

- Cope with the Windows locale named “Norwegian (Bokmål)” (Heikki Linnakangas)
  Non-ASCII locale names are problematic since it’s not clear what encoding they should be represented in. Map the troublesome locale name to a plain-ASCII alias, “Norwegian_Norway”.

- Avoid possible data corruption if `ALTER DATABASE SET TABLESPACE` is used to move a database to a new tablespace and then shortly later move it back to its original tablespace (Tom Lane)

- Avoid corrupting tables when `ANALYZE` inside a transaction is rolled back (Andres Freund, Tom Lane, Michael Paquier)
  If the failing transaction had earlier removed the last index, rule, or trigger from the table, the table would be left in a corrupted state with the relevant `pg_class` flags not set though they should be.

- Ensure that unlogged tables are copied correctly during `CREATE DATABASE` or `ALTER DATABASE SET TABLESPACE` (Pavan Deolasee, Andres Freund)

- Fix `DROP`’s dependency searching to correctly handle the case where a table column is recursively visited before its table (Petr Jelinek, Tom Lane)
Appendix E. Release Notes

This case is only known to arise when an extension creates both a datatype and a table using that datatype. The faulty code might refuse a `DROP EXTENSION` unless `CASCADE` is specified, which should not be required.

- Fix use-of-already-freed-memory problem in EvalPlanQual processing (Tom Lane)
  In `READ COMMITTED` mode, queries that lock or update recently-updated rows could crash as a result of this bug.

- Fix planning of `SELECT FOR UPDATE` when using a partial index on a child table (Kyotaro Horiguchi)
  In `READ COMMITTED` mode, `SELECT FOR UPDATE` must also recheck the partial index’s `WHERE` condition when rechecking a recently-updated row to see if it still satisfies the query’s `WHERE` condition. This requirement was missed if the index belonged to an inheritance child table, so that it was possible to incorrectly return rows that no longer satisfy the query condition.

- Fix corner case wherein `SELECT FOR UPDATE` could return a row twice, and possibly miss returning other rows (Tom Lane)
  In `READ COMMITTED` mode, a `SELECT FOR UPDATE` that is scanning an inheritance tree could incorrectly return a row from a prior child table instead of the one it should return from a later child table.

- Reject duplicate column names in the referenced-columns list of a `FOREIGN KEY` declaration (David Rowley)
  This restriction is per SQL standard. Previously we did not reject the case explicitly, but later on the code would fail with bizarre-looking errors.

- Restore previous behavior of conversion of domains to JSON (Tom Lane)
  This change causes domains over numeric and boolean to be treated like their base types for purposes of conversion to JSON. It worked like that before 9.3.5 and 9.2.9, but was unintentionally changed while fixing a related problem.

- Fix bugs in raising a `numeric` value to a large integral power (Tom Lane)
  The previous code could get a wrong answer, or consume excessive amounts of time and memory before realizing that the answer must overflow.

- In `numeric_recv()`, truncate away any fractional digits that would be hidden according to the value’s `dscale` field (Tom Lane)
  A `numeric` value’s display scale (`dscale`) should never be less than the number of nonzero fractional digits; but apparently there’s at least one broken client application that transmits binary `numeric` values in which that’s true. This leads to strange behavior since the extra digits are taken into account by arithmetic operations even though they aren’t printed. The least risky fix seems to be to truncate away such “hidden” digits on receipt, so that the value is indeed what it prints as.

- Fix incorrect search for shortest-first regular expression matches (Tom Lane)
  Matching would often fail when the number of allowed iterations is limited by a `?` quantifier or a bound expression.

- Reject out-of-range numeric timezone specifications (Tom Lane)
  Simple numeric timezone specifications exceeding +/- 168 hours (one week) would be accepted, but could then cause null-pointer dereference crashes in certain operations. There’s no use-case for such large UTC offsets, so reject them.

- Fix bugs in `tsquery @> tsquery` operator (Heikki Linnakangas)
Two different terms would be considered to match if they had the same CRC. Also, if the second operand had more terms than the first, it would be assumed not to be contained in the first; which is wrong since it might contain duplicate terms.

- Improve ispell dictionary’s defenses against bad affix files (Tom Lane)
- Allow more than 64K phrases in a thesaurus dictionary (David Boutin)

The previous coding could crash on an oversize dictionary, so this was deemed a back-patchable bug fix rather than a feature addition.

- Fix namespace handling in xpath() (Ali Akbar)

Previously, the xml value resulting from an xpath() call would not have namespace declarations if the namespace declarations were attached to an ancestor element in the input xml value, rather than to the specific element being returned. Propagate the ancestral declaration so that the result is correct when considered in isolation.

- Ensure that whole-row variables expose nonempty column names to functions that pay attention to column names within composite arguments (Tom Lane)

In some contexts, constructs like row_to_json(tab.*) may not produce the expected column names. This is fixed properly as of 9.4; in older branches, just ensure that we produce some nonempty name. (In some cases this will be the underlying table’s column name rather than the query-assigned alias that should theoretically be visible.)

- Fix mishandling of system columns, particularly tableoid, in FDW queries (Etsuro Fujita)

- Avoid doing indexed_column = ANY (array) as an index qualifier if that leads to an inferior plan (Andrew Gierth)

In some cases, = ANY conditions applied to non-first index columns would be done as index conditions even though it would be better to use them as simple filter conditions.

- Fix planner problems with nested append relations, such as inherited tables within UNION ALL subqueries (Tom Lane)

- Fail cleanly when a GiST index tuple doesn’t fit on a page, rather than going into infinite recursion (Andrew Gierth)

- Exempt tables that have per-table cost_limit and/or cost_delay settings from autovacuum’s global cost balancing rules (Álvaro Herrera)

The previous behavior resulted in basically ignoring these per-table settings, which was unintended. Now, a table having such settings will be vacuumed using those settings, independently of what is going on in other autovacuum workers. This may result in heavier total I/O load than before, so such settings should be re-examined for sanity.

- Avoid wholesale autovacuuming when autovacuum is nominally off (Tom Lane)

Even when autovacuum is nominally off, we will still launch autovacuum worker processes to vacuum tables that are at risk of XID wraparound. However, such a worker process then proceeded to vacuum all tables in the target database, if they met the usual thresholds for autovacuuming. This is at best pretty unexpected; at worst it delays response to the wraparound threat. Fix it so that if autovacuum is turned off, workers only do anti-wraparound vacuums and not any other work.

- During crash recovery, ensure that unlogged relations are rewritten as empty and are synced to disk before recovery is considered complete (Abhijit Menon-Sen, Andres Freund)

This prevents scenarios in which unlogged relations might contain garbage data following database crash recovery.
Appendix E. Release Notes

- Fix race condition between hot standby queries and replaying a full-page image (Heikki Linnakangas)
  
  This mistake could result in transient errors in queries being executed in hot standby.

- Fix several cases where recovery logic improperly ignored WAL records for COMMIT/ABORT PREPARED (Heikki Linnakangas)
  
  The most notable oversight was that `recovery_target_xid` could not be used to stop at a two-phase commit.

- Prevent latest WAL file from being archived a second time at completion of crash recovery (Fujii Masao)

- Avoid creating unnecessary `.ready` marker files for timeline history files (Fujii Masao)

- Fix possible null pointer dereference when an empty prepared statement is used and the `log_statement` setting is `mod` or `ddl` (Fujii Masao)

- Change “pgstat wait timeout” warning message to be LOG level, and rephrase it to be more understandable (Tom Lane)
  
  This message was originally thought to be essentially a can’t-happen case, but it occurs often enough on our slower buildfarm members to be a nuisance. Reduce it to LOG level, and expend a bit more effort on the wording: it now reads “using stale statistics instead of current ones because stats collector is not responding”.

- Fix SPARC spinlock implementation to ensure correctness if the CPU is being run in a non-TSO coherency mode, as some non-Solaris kernels do (Andres Freund)

- Warn if macOS’s `setlocale()` starts an unwanted extra thread inside the postmaster (Noah Misch)

- Fix processing of repeated `dbname` parameters in `PQconnectdbParams()` (Alex Shulgin)
  
  Unexpected behavior ensued if the first occurrence of `dbname` contained a connection string or URI to be expanded.

- Ensure that libpq reports a suitable error message on unexpected socket EOF (Marko Tiikkaja, Tom Lane)
  
  Depending on kernel behavior, libpq might return an empty error string rather than something useful when the server unexpectedly closed the socket.

- Clear any old error message during `PQreset()` (Heikki Linnakangas)
  
  If `PQreset()` is called repeatedly, and the connection cannot be re-established, error messages from the failed connection attempts kept accumulating in the `PGconn`’s error string.

- Properly handle out-of-memory conditions while parsing connection options in libpq (Alex Shulgin, Heikki Linnakangas)

- Fix array overrun in `ecpg`’s version of `ParseDateTime()` (Michael Paquier)

- In `initdb`, give a clearer error message if a password file is specified but is empty (Mats Erik Andersson)

- Fix `psql`’s `\s` command to work nicely with `libedit`, and add pager support (Stepan Rutz, Tom Lane)
  
  When using `libedit` rather than `readline`, `\s` printed the command history in a fairly unreadable encoded format, and on recent `libedit` versions might fail altogether. Fix that by printing the history ourselves rather than having the library do it. A pleasant side-effect is that the pager is used if appropriate.
Appendix E. Release Notes

This patch also fixes a bug that caused newline encoding to be applied inconsistently when saving
the command history with libedit. Multiline history entries written by older psql versions will be
read cleanly with this patch, but perhaps not vice versa, depending on the exact libedit versions
involved.

- Improve consistency of parsing of psql’s special variables (Tom Lane)
  Allow variant spellings of `on` and `off` (such as `1/0`) for `ECHO_HIDDEN` and `ON_ERROR_ROLLBACK`. Report a warning for unrecognized values for `COMP_KEYWORD_CASE`, `ECHO`, `ECHO_HIDDEN`, `HISTCONTROL`, `ON_ERROR_ROLLBACK`, and `VERBOSITY`. Recognize all values for all these variables case-insensitively; previously there was a mishmash of case-sensitive and case-insensitive behaviors.

- Fix psql’s expanded-mode display to work consistently when using `border = 3` and `linestyle = ascii` or `unicode` (Stephen Frost)

- Improve performance of `pg_dump` when the database contains many instances of multiple dependency paths between the same two objects (Tom Lane)

- Fix `pg_dumpall` to restore its ability to dump from pre-8.1 servers (Gilles Darold)

- Fix possible deadlock during parallel restore of a schema-only dump (Robert Haas, Tom Lane)

- Fix core dump in `pg_dump --binary-upgrade` on zero-column composite type (Rushabh Lathia)

- Prevent WAL files created by `pg_basebackup -x/-X` from being archived again when the standby is promoted (Andres Freund)

- Fix failure of `contrib/auto_explain` to print per-node timing information when doing `EXPLAIN ANALYZE` (Tom Lane)

- Fix upgrade-from-unpackaged script for `contrib/citext` (Tom Lane)

- Fix block number checking in `contrib/pageinspect`’s `get_raw_page()` (Tom Lane)

- Fix `contrib/pgcrypto`’s `pgp_sym_decrypt()` to not fail on messages whose length is 6 less than a power of 2 (Marko Tiikkaja)

- Fix file descriptor leak in `contrib/pg_test_fsync` (Jeff Janes)

  This could cause failure to remove temporary files on Windows.

- Handle unexpected query results, especially NULLs, safely in `contrib/tablefunc`’s `connectby()` (Michael Paquier)

  `connectby()` previously crashed if it encountered a NULL key value. It now prints that row but
doesn’t recurse further.

- Avoid a possible crash in `contrib/xml2`’s `xslt_process()` (Mark Simonetti)

  libxslt seems to have an undocumented dependency on the order in which resources are freed; reorder our calls to avoid a crash.

- Mark some `contrib` I/O functions with correct volatility properties (Tom Lane)

  The previous over-conservative marking was immaterial in normal use, but could cause optimization problems or rejection of valid index expression definitions. Since the consequences are not large, we’ve just adjusted the function definitions in the extension modules’ scripts, without changing version numbers.

- Numerous cleanups of warnings from Coverity static code analyzer (Andres Freund, Tatsuo Ishii, Marko Kreen, Tom Lane, Michael Paquier)
These changes are mostly cosmetic but in some cases fix corner-case bugs, for example a crash rather than a proper error report after an out-of-memory failure. None are believed to represent security issues.

• Detect incompatible OpenLDAP versions during build (Noah Misch)

  With OpenLDAP versions 2.4.24 through 2.4.31, inclusive, PostgreSQL backends can crash at exit. Raise a warning during configure based on the compile-time OpenLDAP version number, and test the crashing scenario in the `contrib/dblink` regression test.

• In non-MSVC Windows builds, ensure `libpq.dll` is installed with execute permissions (Noah Misch)

• Make `pg_regress` remove any temporary installation it created upon successful exit (Tom Lane)

  This results in a very substantial reduction in disk space usage during `make check-world`, since that sequence involves creation of numerous temporary installations.

• Support time zone abbreviations that change UTC offset from time to time (Tom Lane)

  Previously, PostgreSQL assumed that the UTC offset associated with a time zone abbreviation (such as `EST`) never changes in the usage of any particular locale. However this assumption fails in the real world, so introduce the ability for a zone abbreviation to represent a UTC offset that sometimes changes. Update the zone abbreviation definition files to make use of this feature in timezone locales that have changed the UTC offset of their abbreviations since 1970 (according to the IANA timezone database). In such timezones, PostgreSQL will now associate the correct UTC offset with the abbreviation depending on the given date.

• Update time zone abbreviations lists (Tom Lane)

  Add CST (China Standard Time) to our lists. Remove references to ADT as “Arabia Daylight Time”, an abbreviation that’s been out of use since 2007; therefore, claiming there is a conflict with “Atlantic Daylight Time” doesn’t seem especially helpful. Fix entirely incorrect GMT offsets for CKT (Cook Islands), FJT, and FJST (Fiji); we didn’t even have them on the proper side of the date line.

• Update time zone data files to tzdata release 2015a.

  The IANA timezone database has adopted abbreviations of the form `AaST/AaDT` for all Australian time zones, reflecting what they believe to be current majority practice Down Under. These names do not conflict with usage elsewhere (other than ACST for Acre Summer Time, which has been in disuse since 1994). Accordingly, adopt these names into our “Default” timezone abbreviation set. The “Australia” abbreviation set now contains only CST, EAST, EST, SAST, SAT, and WST, all of which are thought to be mostly historical usage. Note that SAST has also been changed to be South Africa Standard Time in the “Default” abbreviation set.

  Also, add zone abbreviations SRET (Asia/Srednekolymsk) and XJT (Asia/Urumqi), and use WSST/WSDT for western Samoa. Also, there were DST law changes in Chile, Mexico, the Turks & Caicos Islands (America/Grand_Turk), and Fiji. There is a new zone Pacific/Bougainville for portions of Papua New Guinea. Also, numerous corrections for historical (pre-1970) time zone data.

**E.76. Release 9.2.9**

*Release date: 2014-07-24*
This release contains a variety of fixes from 9.2.8. For information about new features in the 9.2 major release, see Section E.85.

E.76.1. Migration to Version 9.2.9

A dump/restore is not required for those running 9.2.X.

However, this release corrects an index corruption problem in some GiST indexes. See the first changelog entry below to find out whether your installation has been affected and what steps you should take if so.

Also, if you are upgrading from a version earlier than 9.2.6, see Section E.79.

E.76.2. Changes

- Correctly initialize padding bytes in contrib/btree_gist indexes on bit columns (Heikki Linnakangas)
  This error could result in incorrect query results due to values that should compare equal not being seen as equal. Users with GiST indexes on bit or bit varying columns should REINDEX those indexes after installing this update.
- Protect against torn pages when deleting GIN list pages (Heikki Linnakangas)
  This fix prevents possible index corruption if a system crash occurs while the page update is being written to disk.
- Don’t clear the right-link of a GiST index page while replaying updates from WAL (Heikki Linnakangas)
  This error could lead to transiently wrong answers from GiST index scans performed in Hot Standby.
- Fix corner-case infinite loop during insertion into an SP-GiST text index (Tom Lane)
- Fix feedback status when hot_standby_feedback is turned off on-the-fly (Simon Riggs)
- Fix possibly-incorrect cache invalidation during nested calls to ReceiveSharedInvalidMessages (Andres Freund)
- Fix planner’s mishandling of nested PlaceHolderVars generated in nested-nestloop plans (Tom Lane)
  This oversight could result in “variable not found in subplan target lists” errors, or in silently wrong query results.
- Fix “could not find pathkey item to sort” planner failures with UNION ALL over subqueries reading from tables with inheritance children (Tom Lane)
- Don’t assume a subquery’s output is unique if there’s a set-returning function in its targetlist (David Rowley)
  This oversight could lead to misoptimization of constructs like WHERE x IN (SELECT y, generate_series(1,10) FROM t GROUP BY y).
- Improve planner to drop constant-NULL inputs of AND/OR when possible (Tom Lane)
  This change fixes some cases where the more aggressive parameter substitution done by 9.2 and later can lead to a worse plan than older versions produced.
Appendix E. Release Notes

- Fix identification of input type category in `to_json()` and friends (Tom Lane)
  This is known to have led to inadequate quoting of `money` fields in the JSON result, and there may have been wrong results for other data types as well.
- Fix failure to detoast fields in composite elements of structured types (Tom Lane)
  This corrects cases where TOAST pointers could be copied into other tables without being dereferenced. If the original data is later deleted, it would lead to errors like “missing chunk number 0 for toast value ...” when the now-dangling pointer is used.
- Fix “record type has not been registered” failures with whole-row references to the output of Append plan nodes (Tom Lane)
- Fix possible crash when invoking a user-defined function while rewinding a cursor (Tom Lane)
- Fix query-lifespan memory leak while evaluating the arguments for a function in `FROM` (Tom Lane)
- Fix session-lifespan memory leaks in regular-expression processing (Tom Lane, Arthur O’Dwyer, Greg Stark)
- Fix data encoding error in `hungarian.stop` (Tom Lane)
- Prevent foreign tables from being created with OIDS when `default_with_oids` is true (Etsuro Fujita)
- Fix liveness checks for rows that were inserted in the current transaction and then deleted by a now-rolled-back subtransaction (Andres Freund)
  This could cause problems (at least spurious warnings, and at worst an infinite loop) if `CREATE INDEX` or `CLUSTER` were done later in the same transaction.
- Clear `pg_stat_activity.xact_start` during `PREPARE TRANSACTION` (Andres Freund)
  After the `PREPARE`, the originating session is no longer in a transaction, so it should not continue to display a transaction start time.
- Fix `REASSIGN OWNED` to not fail for text search objects (Álvaro Herrera)
- Block signals during postmaster startup (Tom Lane)
  This ensures that the postmaster will properly clean up after itself if, for example, it receives SIGINT while still starting up.
- Fix client host name lookup when processing `pg_hba.conf` entries that specify host names instead of IP addresses (Tom Lane)
  Ensure that reverse-DNS lookup failures are reported, instead of just silently not matching such entries. Also ensure that we make only one reverse-DNS lookup attempt per connection, not one per host name entry, which is what previously happened if the lookup attempts failed.
- Allow the root user to use `postgres -C variable` and `postgres --describe-config` (MauMau)
  The prohibition on starting the server as root does not need to extend to these operations, and relaxing it prevents failure of `pg_ctl` in some scenarios.
- Secure Unix-domain sockets of temporary postmasters started during `make check` (Noah Misch)
  Any local user able to access the socket file could connect as the server’s bootstrap superuser, then proceed to execute arbitrary code as the operating-system user running the test, as we previously noted in CVE-2014-0067. This change defends against that risk by placing the server’s socket in a temporary, mode 0700 subdirectory of `/tmp`. The hazard remains however on platforms where Unix sockets are not supported, notably Windows, because then the temporary postmaster must accept local TCP connections.
Appendix E. Release Notes

A useful side effect of this change is to simplify make check testing in builds that override DEFAULT_PGSOCKET_DIR. Popular non-default values like /var/run/postgresql are often not writable by the build user, requiring workarounds that will no longer be necessary.

- Fix tablespace creation WAL replay to work on Windows (MauMau)
- Fix detection of socket creation failures on Windows (Bruce Momjian)
- On Windows, allow new sessions to absorb values of PGC_BACKEND parameters (such as log_connections) from the configuration file (Amit Kapila)
  
  Previously, if such a parameter were changed in the file post-startup, the change would have no effect.

- Properly quote executable path names on Windows (Nikhil Deshpande)
  
  This oversight could cause initdb and pg_upgrade to fail on Windows, if the installation path contained both spaces and @ signs.

- Fix linking of libpython on macOS (Tom Lane)
  
  The method we previously used can fail with the Python library supplied by Xcode 5.0 and later.

- Avoid buffer bloat in libpq when the server consistently sends data faster than the client can absorb it (Shin-ichi Morita, Tom Lane)

  libpq could be coerced into enlarging its input buffer until it runs out of memory (which would be reported misleadingly as “lost synchronization with server”). Under ordinary circumstances it’s quite far-fetched that data could be continuously transmitted more quickly than the recv() loop can absorb it, but this has been observed when the client is artificially slowed by scheduler constraints.

- Ensure that LDAP lookup attempts in libpq time out as intended (Laurenz Albe)

- Fix ecpg to do the right thing when an array of char * is the target for a FETCH statement returning more than one row, as well as some other array-handling fixes (Ashutosh Bapat)

- Fix pg_restore’s processing of old-style large object comments (Tom Lane)

  A direct-to-database restore from an archive file generated by a pre-9.0 version of pg_dump would usually fail if the archive contained more than a few comments for large objects.

- Fix pg_upgrade for cases where the new server creates a TOAST table but the old version did not (Bruce Momjian)

  This rare situation would manifest as “relation OID mismatch” errors.

- Prevent contrib/auto_explain from changing the output of a user’s EXPLAIN (Tom Lane)

  If auto_explain is active, it could cause an EXPLAIN (ANALYZE, TIMING OFF) command to nonetheless print timing information.

- Fix query-lifespan memory leak in contrib/dblink (MauMau, Joe Conway)

- In contrib/pgcrypto functions, ensure sensitive information is cleared from stack variables before returning (Marko Kreen)

- Prevent use of already-freed memory in contrib/pgstattuple’s pgstat_heap() (Noah Misch)

- In contrib/uuid-ossp, cache the state of the OSSP UUID library across calls (Tom Lane)

  This improves the efficiency of UUID generation and reduces the amount of entropy drawn from /dev/urandom, on platforms that have that.
Appendix E. Release Notes

- Update time zone data files to tzdata release 2014e for DST law changes in Crimea, Egypt, and Morocco.

E.77. Release 9.2.8

Release date: 2014-03-20

This release contains a variety of fixes from 9.2.7. For information about new features in the 9.2 major release, see Section E.85.

E.77.1. Migration to Version 9.2.8

A dump/restore is not required for those running 9.2.X. However, if you are upgrading from a version earlier than 9.2.6, see Section E.79.

E.77.2. Changes

- Restore GIN metapages unconditionally to avoid torn-page risk (Heikki Linnakangas)
  Although this oversight could theoretically result in a corrupted index, it is unlikely to have caused any problems in practice, since the active part of a GIN metapage is smaller than a standard 512-byte disk sector.

- Avoid race condition in checking transaction commit status during receipt of a NOTIFY message (Marko Tiikkaja)
  This prevents a scenario wherein a sufficiently fast client might respond to a notification before database updates made by the notifier have become visible to the recipient.

- Allow regular-expression operators to be terminated early by query cancel requests (Tom Lane)
  This prevents scenarios wherein a pathological regular expression could lock up a server process uninterruptibly for a long time.

- Remove incorrect code that tried to allow OVERLAPS with single-element row arguments (Joshua Yanovski)
  This code never worked correctly, and since the case is neither specified by the SQL standard nor documented, it seemed better to remove it than fix it.

- Avoid getting more than AccessShareLock when de-parsing a rule or view (Dean Rasheed)
  This oversight resulted in pg_dump unexpectedly acquiring RowExclusiveLock locks on tables mentioned as the targets of INSERT/UPDATE/DELETE commands in rules. While usually harmless, that could interfere with concurrent transactions that tried to acquire, for example, ShareLock on those tables.

- Improve performance of index endpoint probes during planning (Tom Lane)
  This change fixes a significant performance problem that occurred when there were many not-yet-committed rows at the end of the index, which is a common situation for indexes on sequentially-assigned values such as timestamps or sequence-generated identifiers.

- Fix walsender’s failure to shut down cleanly when client is pg_receivexlog (Fujii Masao)
• Check WAL level and hot standby parameters correctly when doing crash recovery that will be followed by archive recovery (Heikki Linnakangas)
• Fix test to see if hot standby connections can be allowed immediately after a crash (Heikki Linnakangas)
• Prevent interrupts while reporting non-ERROR messages (Tom Lane)
  This guards against rare server-process freezeups due to recursive entry to syslog(), and perhaps other related problems.
• Fix memory leak in PL/Perl when returning a composite result, including multiple-OUT-parameter cases (Alex Hunsaker)
• Fix tracking of psql script line numbers during \copy from out-of-line data (Kumar Rajeev Rastogi, Amit Khandekar)
  \copy ... from incremented the script file line number for each data line, even if the data was not coming from the script file. This mistake resulted in wrong line numbers being reported for any errors occurring later in the same script file.
• Prevent intermittent “could not reserve shared memory region” failures on recent Windows versions (MauMau)
• Update time zone data files to tzdata release 2014a for DST law changes in Fiji and Turkey, plus historical changes in Israel and Ukraine.

E.78. Release 9.2.7

Release date: 2014-02-20
This release contains a variety of fixes from 9.2.6. For information about new features in the 9.2 major release, see Section E.85.

E.78.1. Migration to Version 9.2.7

A dump/restore is not required for those running 9.2.X.
However, if you are upgrading from a version earlier than 9.2.6, see Section E.79.

E.78.2. Changes

• Shore up GRANT ... WITH ADMIN OPTION restrictions (Noah Misch)
  Granting a role without ADMIN OPTION is supposed to prevent the grantee from adding or removing members from the granted role, but this restriction was easily bypassed by doing SET ROLE first. The security impact is mostly that a role member can revoke the access of others, contrary to the wishes of his grantor. Unapproved role member additions are a lesser concern, since an uncooperative role member could provide most of his rights to others anyway by creating views or SECURITY DEFINER functions. (CVE-2014-0060)
• Prevent privilege escalation via manual calls to PL validator functions (Andres Freund)
The primary role of PL validator functions is to be called implicitly during CREATE FUNCTION, but they are also normal SQL functions that a user can call explicitly. Calling a validator on a
function actually written in some other language was not checked for and could be exploited for privilege-escalation purposes. The fix involves adding a call to a privilege-checking function in each validator function. Non-core procedural languages will also need to make this change to their own validator functions, if any. (CVE-2014-0061)

• Avoid multiple name lookups during table and index DDL (Robert Haas, Andres Freund)
If the name lookups come to different conclusions due to concurrent activity, we might perform some parts of the DDL on a different table than other parts. At least in the case of CREATE INDEX, this can be used to cause the permissions checks to be performed against a different table than the index creation, allowing for a privilege escalation attack. (CVE-2014-0062)

• Prevent buffer overrun with long datetime strings (Noah Misch)
The MAXDATELEN constant was too small for the longest possible value of type interval, allowing a buffer overrun in interval_out(). Although the datetime input functions were more careful about avoiding buffer overrun, the limit was short enough to cause them to reject some valid inputs, such as input containing a very long timezone name. The ecpg library contained these vulnerabilities along with some of its own. (CVE-2014-0063)

• Prevent buffer overrun due to integer overflow in size calculations (Noah Misch, Heikki Linnakan-gas)
Several functions, mostly type input functions, calculated an allocation size without checking for overflow. If overflow did occur, a too-small buffer would be allocated and then written past. (CVE-2014-0064)

• Prevent overruns of fixed-size buffers (Peter Eisentraut, Jozef Mlich)
Use strlcpy() and related functions to provide a clear guarantee that fixed-size buffers are not overrun. Unlike the preceding items, it is unclear whether these cases really represent live issues, since in most cases there appear to be previous constraints on the size of the input string. Nonetheless it seems prudent to silence all Coverity warnings of this type. (CVE-2014-0065)

• Avoid crashing if crypt() returns NULL (Honza Horak, Bruce Momjian)
There are relatively few scenarios in which crypt() could return NULL, but contrib/chkpass would crash if it did. One practical case in which this could be an issue is if libc is configured to refuse to execute unapproved hashing algorithms (e.g., “FIPS mode”). (CVE-2014-0066)

• Document risks of make check in the regression testing instructions (Noah Misch, Tom Lane)
Since the temporary server started by make check uses “trust” authentication, another user on the same machine could connect to it as database superuser, and then potentially exploit the privileges of the operating-system user who started the tests. A future release will probably incorporate changes in the testing procedure to prevent this risk, but some public discussion is needed first. So for the moment, just warn people against using make check when there are untrusted users on the same machine. (CVE-2014-0067)

• Fix possible mis-replay of WAL records when some segments of a relation aren’t full size (Greg Stark, Tom Lane)
The WAL update could be applied to the wrong page, potentially many pages past where it should have been. Aside from corrupting data, this error has been observed to result in significant “bloat” of standby servers compared to their masters, due to updates being applied far beyond where the end-of-file should have been. This failure mode does not appear to be a significant risk during crash recovery, only when initially synchronizing a standby created from a base backup taken from a quickly-changing master.

• Fix bug in determining when recovery has reached consistency (Tomonari Katsumata, Heikki Lin-nakangas)
In some cases WAL replay would mistakenly conclude that the database was already consistent at the start of replay, thus possibly allowing hot-standby queries before the database was really consistent. Other symptoms such as “PANIC: WAL contains references to invalid pages” were also possible.

- Fix improper locking of btree index pages while replaying a VACUUM operation in hot-standby mode (Andres Freund, Heikki Linnakangas, Tom Lane)
  This error could result in “PANIC: WAL contains references to invalid pages” failures.

- Ensure that insertions into non-leaf GIN index pages write a full-page WAL record when appropriate (Heikki Linnakangas)
  The previous coding risked index corruption in the event of a partial-page write during a system crash.

- When pause_at_recovery_target and recovery_target_inclusive are both set, ensure the target record is applied before pausing, not after (Heikki Linnakangas)

- Fix race conditions during server process exit (Robert Haas)
  Ensure that signal handlers don’t attempt to use the process’s MyProc pointer after it’s no longer valid.

- Fix race conditions in walsender shutdown logic and walreceiver SIGHUP signal handler (Tom Lane)

- Fix unsafe references to errno within error reporting logic (Christian Kruse)
  This would typically lead to odd behaviors such as missing or inappropriate HINT fields.

- Fix possible crashes from using ereport() too early during server startup (Tom Lane)
  The principal case we’ve seen in the field is a crash if the server is started in a directory it doesn’t have permission to read.

- Clear retry flags properly in OpenSSL socket write function (Alexander Kukushkin)
  This omission could result in a server lockup after unexpected loss of an SSL-encrypted connection.

- Fix length checking for Unicode identifiers (U"..." syntax) containing escapes (Tom Lane)
  A spurious truncation warning would be printed for such identifiers if the escaped form of the identifier was too long, but the identifier actually didn’t need truncation after de-escaping.

- Allow keywords that are type names to be used in lists of roles (Stephen Frost)
  A previous patch allowed such keywords to be used without quoting in places such as role identifiers; but it missed cases where a list of role identifiers was permitted, such as DROP ROLE.

- Fix parser crash for EXISTS(SELECT * FROM zero_column_table) (Tom Lane)

- Fix possible crash due to invalid plan for nested sub-selects, such as WHERE (... x IN (SELECT ...) ...) IN (SELECT ...) (Tom Lane)

- Fix UPDATE/DELETE of an inherited target table that has UNION ALL subqueries (Tom Lane)
  Without this fix, UNION ALL subqueries aren’t correctly inserted into the update plans for inheritance child tables after the first one, typically resulting in no update happening for those child table(s).

- Ensure that ANALYZE creates statistics for a table column even when all the values in it are “too wide” (Tom Lane)
ANALYZE intentionally omits very wide values from its histogram and most-common-values calculations, but it neglected to do something sane in the case that all the sampled entries are too wide.

- In `ALTER TABLE ... SET TABLESPACE`, allow the database’s default tablespace to be used without a permissions check (Stephen Frost)

`CREATE TABLE` has always allowed such usage, but `ALTER TABLE` didn’t get the memo.

- Fix “cannot accept a set” error when some arms of a `CASE` return a set and others don’t (Tom Lane)
- Properly distinguish numbers from non-numbers when generating JSON output (Andrew Dunstan)
- Fix checks for all-zero client addresses in pgstat functions (Kevin Grittner)
- Fix possible misclassification of multibyte characters by the text search parser (Tom Lane)

Non-ASCII characters could be misclassified when using C locale with a multibyte encoding. On Cygwin, non-C locales could fail as well.

- Fix possible misbehavior in `plainto_tsquery()` (Heikki Linnakangas)

  Use `memmove()` not `memcpy()` for copying overlapping memory regions. There have been no field reports of this actually causing trouble, but it’s certainly risky.

- Fix placement of permissions checks in `pg_start_backup()` and `pg_stop_backup()` (Andres Freund, Magnus Hagander)

  The previous coding might attempt to do catalog access when it shouldn’t.

- Accept `SHIFT_JIS` as an encoding name for locale checking purposes (Tatsuo Ishii)
- Fix `- qualification of named parameters in SQL-language functions (Tom Lane)

  Given a composite-type parameter named `foo`, `$1.*` worked fine, but `foo.*` not so much.

- Fix misbehavior of `PQhost()` on Windows (Fujii Masao)

  It should return `localhost` if no host has been specified.

- Improve error handling in libpq and psql for failures during `COPY TO STDOUT/FROM STDIN` (Tom Lane)

  In particular this fixes an infinite loop that could occur in 9.2 and up if the server connection was lost during `COPY FROM STDIN`. Variants of that scenario might be possible in older versions, or with other client applications.

- Fix incorrect translation handling in some psql `\d` commands (Peter Eisentraut, Tom Lane)
- Ensure `pg_basebackup`’s background process is killed when exiting its foreground process (Magnus Hagander)
- Fix possible incorrect printing of filenames in `pg_basebackup`’s verbose mode (Magnus Hagander)
- Avoid including tablespaces inside `PGDATA` twice in base backups (Dimitri Fontaine, Magnus Hagander)
- Fix misaligned descriptors in `ecpg` (MauMau)
- In `ecpg`, handle lack of a hostname in the connection parameters properly (Michael Meskes)
- Fix performance regression in `contrib/dblink` connection startup (Joe Conway)

  Avoid an unnecessary round trip when client and server encodings match.

- In `contrib/isn`, fix incorrect calculation of the check digit for ISMN values (Fabien Coelho)
- Fix `contrib/pg_stat_statement`’s handling of `CURRENT_DATE` and related constructs (Kyo- otaro Horiguchi)
Appendix E. Release Notes

- Ensure client-code-only installation procedure works as documented (Peter Eisentraut)
- In Mingw and Cygwin builds, install the libpq DLL in the bin directory (Andrew Dunstan)
  This duplicates what the MSVC build has long done. It should fix problems with programs like
  psql failing to start because they can’t find the DLL.
- Avoid using the deprecated dllwrap tool in Cygwin builds (Marco Atzeri)
- Don’t generate plain-text HISTORY and src/test/regress/README files anymore (Tom Lane)
  These text files duplicated the main HTML and PDF documentation formats. The trouble involved
  in maintaining them greatly outweighs the likely audience for plain-text format. Distribution tar-
  balls will still contain files by these names, but they’ll just be stubs directing the reader to consult
  the main documentation. The plain-text INSTALL file will still be maintained, as there is arguably
  a use-case for that.
- Update time zone data files to tzdata release 2013i for DST law changes in Jordan and historical
  changes in Cuba.
  In addition, the zones Asia/Riyadh87, Asia/Riyadh88, and Asia/Riyadh89 have been re-
  moved, as they are no longer maintained by IANA, and never represented actual civil timekeeping
  practice.

E.79. Release 9.2.6

Release date: 2013-12-05

This release contains a variety of fixes from 9.2.5. For information about new features in the 9.2 major
release, see Section E.85.

E.79.1. Migration to Version 9.2.6

A dump/restore is not required for those running 9.2.X.

However, this release corrects a number of potential data corruption issues. See the first two changelog
entries below to find out whether your installation has been affected and what steps you can take if so.

Also, if you are upgrading from a version earlier than 9.2.4, see Section E.81.

E.79.2. Changes

- Fix VACUUM’s tests to see whether it can update relfrozenxid (Andres Freund)

  In some cases VACUUM (either manual or autovacuum) could incorrectly advance a table’s
  relfrozenxid value, allowing tuples to escape freezing, causing those rows to become invisible
  once 2^31 transactions have elapsed. The probability of data loss is fairly low since multiple
  incorrect advancements would need to happen before actual loss occurs, but it’s not zero. In 9.2.0
  and later, the probability of loss is higher, and it’s also possible to get “could not access status of
  transaction” errors as a consequence of this bug. Users upgrading from releases 9.0.4 or 8.4.8 or
  earlier are not affected, but all later versions contain the bug.

  The issue can be ameliorated by, after upgrading, vacuuming all tables in all databases while having
  vacuum_freeze_table_age set to zero. This will fix any latent corruption but will not be able to
Appendix E. Release Notes

fix all pre-existing data errors. However, an installation can be presumed safe after performing this vacuuming if it has executed fewer than $2^{31}$ update transactions in its lifetime (check this with `SELECT txid_current() < 2^{31}`).

- Fix initialization of `pg_clog` and `pg_subtrans` during hot standby startup (Andres Freund, Heikki Linnakangas)
  This bug can cause data loss on standby servers at the moment they start to accept hot-standby queries, by marking committed transactions as uncommitted. The likelihood of such corruption is small unless, at the time of standby startup, the primary server has executed many updating transactions since its last checkpoint. Symptoms include missing rows, rows that should have been deleted being still visible, and obsolete versions of updated rows being still visible alongside their newer versions.

- This bug was introduced in versions 9.3.0, 9.2.5, 9.1.10, and 9.0.14. Standby servers that have only been running earlier releases are not at risk. It’s recommended that standby servers that have ever run any of the buggy releases be re-cloned from the primary (e.g., with a new base backup) after upgrading.

- Fix dangling-pointer problem in fast-path locking (Tom Lane)
  This could lead to corruption of the lock data structures in shared memory, causing “lock already held” and other odd errors.

- Truncate `pg_multixact` contents during WAL replay (Andres Freund)
  This avoids ever-increasing disk space consumption in standby servers.

- Ensure an anti-wraparound `VACUUM` counts a page as scanned when it’s only verified that no tuples need freezing (Sergey Burladyan, Jeff Janes)
  This bug could result in failing to advance `relefrozenxid`, so that the table would still be thought to need another anti-wraparound vacuum. In the worst case the database might even shut down to prevent wraparound.

- Fix race condition in GIN index posting tree page deletion (Heikki Linnakangas)
  This could lead to transient wrong answers or query failures.

- Fix “unexpected spgdoinsert() failure” error during SP-GiST index creation (Teodor Sigaev)

- Avoid flattening a subquery whose `SELECT` list contains a volatile function wrapped inside a sub-`SELECT` (Tom Lane)
  This avoids unexpected results due to extra evaluations of the volatile function.

- Fix planner’s processing of non-simple-variable subquery outputs nested within outer joins (Tom Lane)
  This error could lead to incorrect plans for queries involving multiple levels of subqueries within `JOIN` syntax.

- Fix incorrect planning in cases where the same non-strict expression appears in multiple `WHERE` and outer `JOIN` equality clauses (Tom Lane)

- Fix planner crash with whole-row reference to a subquery (Tom Lane)

- Fix incorrect generation of optimized `MIN()`/`MAX()` plans for inheritance trees (Tom Lane)
  The planner could fail in cases where the `MIN()`/`MAX()` argument was an expression rather than a simple variable.

- Fix premature deletion of temporary files (Andres Freund)

- Prevent intra-transaction memory leak when printing range values (Tom Lane)
This fix actually cures transient memory leaks in any datatype output function, but range types are the only ones known to have had a significant problem.

- Prevent incorrect display of dropped columns in NOT NULL and CHECK constraint violation messages (Michael Paquier and Tom Lane)
- Allow default arguments and named-argument notation for window functions (Tom Lane)
  
  Previously, these cases were likely to crash.
- Fix possible read past end of memory in rule printing (Peter Eisentraut)
- Fix array slicing of int2vector and oidvector values (Tom Lane)
  
  Expressions of this kind are now implicitly promoted to regular int2 or oid arrays.
- Fix incorrect behaviors when using a SQL-standard, simple GMT offset timezone (Tom Lane)
  
  In some cases, the system would use the simple GMT offset value when it should have used the regular timezone setting that had prevailed before the simple offset was selected. This change also causes the timeofday function to honor the simple GMT offset zone.
- Prevent possible misbehavior when logging translations of Windows error codes (Tom Lane)
- Properly quote generated command lines in pg_ctl (Naoya Anzai and Tom Lane)
  
  This fix applies only to Windows.
- Fix pg_dumpall to work when a source database sets default_transaction_read_only via ALTER DATABASE SET (Kevin Grittner)
  
  Previously, the generated script would fail during restore.
- Make ecpg search for quoted cursor names case-sensitively (Zoltán Böszörményi)
- Fix ecpg’s processing of lists of variables declared varchar (Zoltán Böszörményi)
- Make contrib/lo defend against incorrect trigger definitions (Marc Cousin)
- Update time zone data files to tzdata release 2013h for DST law changes in Argentina, Brazil, Jordan, Libya, Liechtenstein, Morocco, and Palestine. Also, new timezone abbreviations WIB, WIT, WITA for Indonesia.

### E.80. Release 9.2.5

**Release date:** 2013-10-10

This release contains a variety of fixes from 9.2.4. For information about new features in the 9.2 major release, see Section E.85.

### E.80.1. Migration to Version 9.2.5

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.4, see Section E.81.
E.80.2. Changes

- Prevent corruption of multi-byte characters when attempting to case-fold identifiers (Andrew Dunstan)
  PostgreSQL case-folds non-ASCII characters only when using a single-byte server encoding.
- Fix memory leak when creating B-tree indexes on range columns (Heikki Linnakangas)
- Fix checkpoint memory leak in background writer when `wal_level = hot_standby` (Naoya Anzai)
- Fix memory leak caused by `lo_open()` failure (Heikki Linnakangas)
- Fix memory overcommit bug when `work_mem` is using more than 24GB of memory (Stephen Frost)
- Serializable snapshot fixes (Kevin Grittner, Heikki Linnakangas)
- Fix deadlock bug in `libpq` when using SSL (Stephen Frost)
- Fix possible SSL state corruption in threaded `libpq` applications (Nick Phillips, Stephen Frost)
- Improve estimate of planner cost when choosing between generic and custom plans (Tom Lane)
  This change will favor generic plans when planning cost is high.
- Properly compute row estimates for boolean columns containing many NULL values (Andrew Gierth)
  Previously tests like `col IS NOT TRUE` and `col IS NOT FALSE` did not properly factor in NULL values when estimating plan costs.
- Fix accounting for qualifier evaluation costs in `UNION ALL` and inheritance queries (Tom Lane)
  This fixes cases where suboptimal query plans could be chosen if some `WHERE` clauses are expensive to calculate.
- Prevent pushing down `WHERE` clauses into unsafe `UNION/INTERSECT` subqueries (Tom Lane)
  Subqueries of a `UNION` or `INTERSECT` that contain set-returning functions or volatile functions in their `SELECT` lists could be improperly optimized, leading to run-time errors or incorrect query results.
- Fix rare case of “failed to locate grouping columns” planner failure (Tom Lane)
- Fix `pg_dump` of foreign tables with dropped columns (Andrew Dunstan)
  Previously such cases could cause a `pg_upgrade` error.
- Reorder `pg_dump` processing of extension-related rules and event triggers (Joe Conway)
- Force dumping of extension tables if specified by `pg_dump -t` or `-n` (Joe Conway)
- Improve view dumping code’s handling of dropped columns in referenced tables (Tom Lane)
- Fix `pg_restore -l` with the directory archive to display the correct format name (Fujii Masao)
- Properly record index comments created using `UNIQUE` and `PRIMARY KEY` syntax (Andres Freund)
  This fixes a parallel `pg_restore` failure.
- Cause `pg_basebackup -x` with an empty xlog directory to throw an error rather than crashing (Magnus Hagander, Haruka Takatsuka)
- Properly guarantee transmission of WAL files before clean switchover (Fujii Masao)
  Previously, the streaming replication connection might close before all WAL files had been replayed on the standby.
Appendix E. Release Notes

- Fix WAL segment timeline handling during recovery (Mitsumasa Kondo, Heikki Linnakangas)
  WAL file recycling during standby recovery could lead to premature recovery completion, resulting in data loss.
- Prevent errors in WAL replay due to references to uninitialized empty pages (Andres Freund)
- Fix REINDEX TABLE and REINDEX DATABASE to properly revalidate constraints and mark invalidated indexes as valid (Noah Misch)
  REINDEX INDEX has always worked properly.
- Avoid deadlocks during insertion into SP-GiST indexes (Teodor Sigaev)
- Fix possible deadlock during concurrent CREATE INDEX CONCURRENTLY operations (Tom Lane)
- Fix GiST index lookup crash (Tom Lane)
- Fix regexp_matches() handling of zero-length matches (Jeevan Chalke)
  Previously, zero-length matches like "^" could return too many matches.
- Fix crash for overly-complex regular expressions (Heikki Linnakangas)
- Fix regular expression match failures for back references combined with non-greedy quantifiers (Jeevan Chalke)
- Prevent CREATE FUNCTION from checking SET variables unless function body checking is enabled (Tom Lane)
- Allow ALTER DEFAULT PRIVILEGES to operate on schemas without requiring CREATE permission (Tom Lane)
- Loosen restriction on keywords used in queries (Tom Lane)
  Specifically, lessen keyword restrictions for role names, language names, EXPLAIN and COPY options, and SET values. This allows COPY ... (FORMAT BINARY) to work as expected; previously BINARY needed to be quoted.
- Print proper line number during COPY failure (Heikki Linnakangas)
- Fix pgp_pub_decrypt() so it works for secret keys with passwords (Marko Kreen)
- Make pg_upgrade use pg_dump --quote-all-identifiers to avoid problems with keyword changes between releases (Tom Lane)
- Remove rare inaccurate warning during vacuum of index-less tables (Heikki Linnakangas)
- Ensure that VACUUM ANALYZE still runs the ANALYZE phase if its attempt to truncate the file is cancelled due to lock conflicts (Kevin Grittner)
- Avoid possible failure when performing transaction control commands (e.g ROLLBACK) in prepared queries (Tom Lane)
- Ensure that floating-point data input accepts standard spellings of “infinity” on all platforms (Tom Lane)
  The C99 standard says that allowable spellings are inf, +inf, -inf, infinity, +infinity, and -infinity. Make sure we recognize these even if the platform's strtod function doesn’t.
- Avoid unnecessary reporting when track_activities is off (Tom Lane)
- Expand ability to compare rows to records and arrays (Rafal Rzepecki, Tom Lane)
- Prevent crash when psql's PSQLRC variable contains a tilde (Bruce Momjian)
- Add spinlock support for ARM64 (Mark Salter)
• Update time zone data files to tzdata release 2013d for DST law changes in Israel, Morocco, Palestine, and Paraguay. Also, historical zone data corrections for Macquarie Island.

E.81. Release 9.2.4

Release date: 2013-04-04

This release contains a variety of fixes from 9.2.3. For information about new features in the 9.2 major release, see Section E.85.

E.81.1. Migration to Version 9.2.4

A dump/restore is not required for those running 9.2.X.

However, this release corrects several errors in management of GiST indexes. After installing this update, it is advisable to REINDEX any GiST indexes that meet one or more of the conditions described below.

Also, if you are upgrading from a version earlier than 9.2.2, see Section E.83.

E.81.2. Changes

• Fix insecure parsing of server command-line switches (Mitsumasa Kondo, Kyotaro Horiguchi)

A connection request containing a database name that begins with “-” could be crafted to damage or destroy files within the server’s data directory, even if the request is eventually rejected. (CVE-2013-1899)

• Reset OpenSSL randomness state in each postmaster child process (Marko Kreen)

This avoids a scenario wherein random numbers generated by contrib/pgcrypto functions might be relatively easy for another database user to guess. The risk is only significant when the postmaster is configured with ssl = on but most connections don’t use SSL encryption. (CVE-2013-1900)

• Make REPLICATION privilege checks test current user not authenticated user (Noah Misch)

An unprivileged database user could exploit this mistake to call pg_start_backup() or pg_stop_backup(), thus possibly interfering with creation of routine backups. (CVE-2013-1901)

• Fix GiST indexes to not use “fuzzy” geometric comparisons when it’s not appropriate to do so (Alexander Korotkov)

The core geometric types perform comparisons using “fuzzy” equality, but gist_box_same must do exact comparisons, else GiST indexes using it might become inconsistent. After installing this update, users should REINDEX any GiST indexes on box, polygon, circle, or point columns, since all of these use gist_box_same.

• Fix erroneous range-union and penalty logic in GiST indexes that use contrib/btree_gist for variable-width data types, that is text, bytea, bit, and numeric columns (Tom Lane)
These errors could result in inconsistent indexes in which some keys that are present would not be found by searches, and also in useless index bloat. Users are advised to `REINDEX` such indexes after installing this update.

- **Fix bugs in GiST page splitting code for multi-column indexes (Tom Lane)**
  These errors could result in inconsistent indexes in which some keys that are present would not be found by searches, and also in indexes that are unnecessarily inefficient to search. Users are advised to `REINDEX` multi-column GiST indexes after installing this update.

- **Fix `gist_point_consistent` to handle fuzziness consistently (Alexander Korotkov)**
  Index scans on GiST indexes on `point` columns would sometimes yield results different from a sequential scan, because `gist_point_consistent` disagreed with the underlying operator code about whether to do comparisons exactly or fuzzily.

- **Fix buffer leak in WAL replay (Heikki Linnakangas)**
  This bug could result in “incorrect local pin count” errors during replay, making recovery impossible.

- **Ensure we do crash recovery before entering archive recovery, if the database was not stopped cleanly and a `recovery.conf` file is present (Heikki Linnakangas, Kyotaro Horiguchi, Mitsumasa Kondo)**
  This is needed to ensure that the database is consistent in certain scenarios, such as initializing a standby server with a filesystem snapshot from a running server.

- **Avoid deleting not-yet-archived WAL files during crash recovery (Heikki Linnakangas, Fujii Masao)**

- **Fix race condition in `DELETE RETURNING` (Tom Lane)**
  Under the right circumstances, `DELETE RETURNING` could attempt to fetch data from a shared buffer that the current process no longer has any pin on. If some other process changed the buffer meanwhile, this would lead to garbage `RETURNING` output, or even a crash.

- **Fix infinite-loop risk in regular expression compilation (Tom Lane, Don Porter)**

- **Fix potential null-pointer dereference in regular expression compilation (Tom Lane)**

- **Fix `to_char()` to use ASCII-only case-folding rules where appropriate (Tom Lane)**
  This fixes misbehavior of some template patterns that should be locale-independent, but mishandled “ı” and “İ” in Turkish locales.

- **Fix unwanted rejection of timestamp `1999-12-31 24:00:00` (Tom Lane)**

- **Fix SQL-language functions to be safely usable as support functions for range types (Tom Lane)**

- **Fix logic error when a single transaction does `UNLISTEN` then `LISTEN` (Tom Lane)**
  The session wound up not listening for notify events at all, though it surely should listen in this case.

- **Fix possible planner crash after columns have been added to a view that’s depended on by another view (Tom Lane)**

- **Fix performance issue in `EXPLAIN (ANALYZE, TIMING OFF)` (Pavel Stehule)**

- **Remove useless “picksplit doesn’t support secondary split” log messages (Josh Hansen, Tom Lane)**
  This message seems to have been added in expectation of code that was never written, and probably never will be, since GiST’s default handling of secondary splits is actually pretty good. So stop nagging end users about it.
Appendix E. Release Notes

- Remove vestigial secondary-split support in `gist_box_picksplit()` (Tom Lane)
  Not only was this implementation of secondary-split not better than the default implementation, it’s actually worse. So remove it and let the default code path handle the case.
- Fix possible failure to send a session’s last few transaction commit/abort counts to the statistics collector (Tom Lane)
- Eliminate memory leaks in PL/Perl’s `spi_prepare()` function (Alex Hunsaker, Tom Lane)
- Fix `pg_dumpall` to handle database names containing “=” correctly (Heikki Linnakangas)
- Avoid crash in `pg_dump` when an incorrect connection string is given (Heikki Linnakangas)
- Ignore invalid indexes in `pg_dump` and `pg_upgrade` (Michael Paquier, Bruce Momjian)
  Dumping invalid indexes can cause problems at restore time, for example if the reason the index creation failed was because it tried to enforce a uniqueness condition not satisfied by the table’s data. Also, if the index creation is in fact still in progress, it seems reasonable to consider it to be an uncommitted DDL change, which `pg_dump` wouldn’t be expected to dump anyway. `pg_upgrade` now also skips invalid indexes rather than failing.
- In `pg_basebackup`, include only the current server version’s subdirectory when backing up a tablespace (Heikki Linnakangas)
- Add a server version check in `pg_basebackup` and `pg_receivexlog`, so they fail cleanly with version combinations that won’t work (Heikki Linnakangas)
- Fix `contrib/dblink` to handle inconsistent settings of `DateStyle` or `IntervalStyle` safely (Daniel Farina, Tom Lane)
  Previously, if the remote server had different settings of these parameters, ambiguous dates might be read incorrectly. This fix ensures that datetime and interval columns fetched by a `dblink` query will be interpreted correctly. Note however that inconsistent settings are still risky, since literal values appearing in SQL commands sent to the remote server might be interpreted differently than they would be locally.
- Fix `contrib/pg_trgm`’s `similarity()` function to return zero for trigram-less strings (Tom Lane)
  Previously it returned `NaN` due to internal division by zero.
- Enable building PostgreSQL with Microsoft Visual Studio 2012 (Brar Piening, Noah Misch)
- Update time zone data files to `tzdata` release 2013b for DST law changes in Chile, Haiti, Morocco, Paraguay, and some Russian areas. Also, historical zone data corrections for numerous places.
  Also, update the time zone abbreviation files for recent changes in Russia and elsewhere: `CHOT, GET, IRKT, KGT, Kvat, MAGT, MAWT, MSK, NOVT, OMST, TKT, VLAT, WST, YAKT, YEKT` now follow their current meanings, and `VOLT` (Europe/Volgograd) and `MIST` (Antarctica/Macquarie) are added to the default abbreviations list.

E.82. Release 9.2.3

Release date: 2013-02-07

This release contains a variety of fixes from 9.2.2. For information about new features in the 9.2 major release, see Section E.85.
E.82.1. Migration to Version 9.2.3

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.2, see Section E.83.

E.82.2. Changes

- Prevent execution of `enum_recv` from SQL (Tom Lane)
  The function was misdeclared, allowing a simple SQL command to crash the server. In principle an attacker might be able to use it to examine the contents of server memory. Our thanks to Sumit Soni (via Secunia SVCRP) for reporting this issue. (CVE-2013-0255)
- Fix multiple problems in detection of when a consistent database state has been reached during WAL replay (Fujii Masao, Heikki Linnakangas, Simon Riggs, Andres Freund)
- Fix detection of end-of-backup point when no actual redo work is required (Heikki Linnakangas)
  This mistake could result in incorrect “WAL ends before end of online backup” errors.
- Update minimum recovery point when truncating a relation file (Heikki Linnakangas)
  Once data has been discarded, it’s no longer safe to stop recovery at an earlier point in the timeline.
- Fix recycling of WAL segments after changing recovery target timeline (Heikki Linnakangas)
- Properly restore timeline history files from archive on cascading standby servers (Heikki Linnakangas)
- Fix lock conflict detection on hot-standby servers (Andres Freund, Robert Haas)
- Fix missing cancellations in hot standby mode (Noah Misch, Simon Riggs)
  The need to cancel conflicting hot-standby queries would sometimes be missed, allowing those queries to see inconsistent data.
- Prevent recovery pause feature from pausing before users can connect (Tom Lane)
- Fix SQL grammar to allow subscripting or field selection from a sub-SELECT result (Tom Lane)
- Fix performance problems with autovacuum truncation in busy workloads (Jan Wieck)
  Truncation of empty pages at the end of a table requires exclusive lock, but autovacuum was coded to fail (and release the table lock) when there are conflicting lock requests. Under load, it is easily possible that truncation would never occur, resulting in table bloat. Fix by performing a partial truncation, releasing the lock, then attempting to re-acquire the lock and continue. This fix also greatly reduces the average time before autovacuum releases the lock after a conflicting request arrives.
- Improve performance of `SPI_execute` and related functions, thereby improving PL/pgSQL’s `EXECUTE` (Heikki Linnakangas, Tom Lane)
  Remove some data-copying overhead that was added in 9.2 as a consequence of revisions in the plan caching mechanism. This eliminates a performance regression compared to 9.1, and also saves memory, especially when the query string to be executed contains many SQL statements.
  A side benefit is that multi-statement query strings are now processed fully serially, that is we complete execution of earlier statements before running parse analysis and planning on the following ones. This eliminates a long-standing issue, in that DDL that should affect the behavior of a later statement will now behave as expected.
• Restore pre-9.2 cost estimates for index usage (Tom Lane)
  An ill-considered change of a fudge factor led to undesirably high cost estimates for use of very large indexes.
• Fix intermittent crash in \texttt{DROP INDEX CONCURRENTLY} (Tom Lane)
• Fix potential corruption of shared-memory lock table during \texttt{CREATE/DROP INDEX CONCURRENTLY} (Tom Lane)
• Fix \texttt{COPY}'s multiple-tuple-insertion code for the case of a tuple larger than page size minus fillfactor (Heikki Linnakangas)
  The previous coding could get into an infinite loop.
• Protect against race conditions when scanning \texttt{pg_tablespace} (Stephen Frost, Tom Lane)
  \texttt{CREATE DATABASE} and \texttt{DROP DATABASE} could misbehave if there were concurrent updates of \texttt{pg_tablespace} entries.
• Prevent \texttt{DROP OWNED} from trying to drop whole databases or tablespaces (Álvaro Herrera)
  For safety, ownership of these objects must be reassigned, not dropped.
• Fix error in \texttt{vacuum_freeze_table_age} implementation (Andres Freund)
  In installations that have existed for more than \texttt{vacuum_freeze_min_age} transactions, this mistake prevented autovacuum from using partial-table scans, so that a full-table scan would always happen instead.
• Prevent misbehavior when a \texttt{RowExpr} or \texttt{XmlExpr} is parse-analyzed twice (Andres Freund, Tom Lane)
  This mistake could be user-visible in contexts such as \texttt{CREATE TABLE LIKE INCLUDING INDEXES}.
• Improve defenses against integer overflow in hashtable sizing calculations (Jeff Davis)
• Fix some bugs associated with privileges on datatypes (Tom Lane)
  There were some issues with default privileges for types, and \texttt{pg_dump} failed to dump such privileges at all.
• Fix failure to ignore leftover temporary tables after a server crash (Tom Lane)
• Fix failure to rotate postmaster log files for size reasons on Windows (Jeff Janes, Heikki Linnakangas)
• Reject out-of-range dates in \texttt{to_date()} (Hitoshi Harada)
• Fix \texttt{pg_extension_config_dump()} to handle extension-update cases properly (Tom Lane)
  This function will now replace any existing entry for the target table, making it usable in extension update scripts.
• Fix PL/pgSQL’s reporting of plan-time errors in possibly-simple expressions (Tom Lane)
  The previous coding resulted in sometimes omitting the first line in the \texttt{CONTEXT} traceback for the error.
• Fix PL/Python’s handling of functions used as triggers on multiple tables (Andres Freund)
• Ensure that non-ASCII prompt strings are translated to the correct code page on Windows (Alexander Law, Noah Misch)
  This bug affected \texttt{psql} and some other client programs.
• Fix possible crash in \texttt{psql’s \\?} command when not connected to a database (Meng Qingzhong)
Appendix E. Release Notes

- Fix possible error if a relation file is removed while pg_basebackup is running (Heikki Linnakan-gas)
- Tolerate timeline switches while pg_basebackup -X fetch is backing up a standby server (Heikki Linnakangas)
- Make pg_dump exclude data of unlogged tables when running on a hot-standby server (Magnus Hagander)
  This would fail anyway because the data is not available on the standby server, so it seems most convenient to assume --no-unlogged-table-data automatically.
- Fix pg_upgrade to deal with invalid indexes safely (Bruce Momjian)
- Fix pg_upgrade's -O/-o options (Marti Raudsepp)
- Fix one-byte buffer overrun in libpq's PQprintTuples (Xi Wang)
  This ancient function is not used anywhere by PostgreSQL itself, but it might still be used by some client code.
- Make ecpglib use translated messages properly (Chen Huajun)
- Properly install ecpg_compat and pgtypes libraries on MSVC (Jiang Guiqing)
- Include our version of isinf() in libecpg if it’s not provided by the system (Jiang Guiqing)
- Rearrange configure’s tests for supplied functions so it is not fooled by bogus exports from libedit/libreadline (Christoph Berg)
- Ensure Windows build number increases over time (Magnus Hagander)
- Make pgxs build executables with the right .exe suffix when cross-compiling for Windows (Zoltan Boszormenyi)
- Add new timezone abbreviation FET (Tom Lane)
  This is now used in some eastern-European time zones.

E.83. Release 9.2.2

Release date: 2012-12-06

This release contains a variety of fixes from 9.2.1. For information about new features in the 9.2 major release, see Section E.85.

E.83.1. Migration to Version 9.2.2

A dump/restore is not required for those running 9.2.X.

However, you may need to perform REINDEX operations to correct problems in concurrently-built indexes, as described in the first changelog item below.

Also, if you are upgrading from version 9.2.0, see Section E.84.
E.83.2. Changes

- Fix multiple bugs associated with CREATE/DROP INDEX CONCURRENTLY (Andres Freund, Tom Lane, Simon Riggs, Pavan Deolasee)

  An error introduced while adding DROP INDEX CONCURRENTLY allowed incorrect indexing decisions to be made during the initial phase of CREATE INDEX CONCURRENTLY; so that indexes built by that command could be corrupt. It is recommended that indexes built in 9.2.X with CREATE INDEX CONCURRENTLY be rebuilt after applying this update.

  In addition, fix CREATE/DROP INDEX CONCURRENTLY to use in-place updates when changing the state of an index’s pg_index row. This prevents race conditions that could cause concurrent sessions to miss updating the target index, thus again resulting in corrupt concurrently-created indexes.

  Also, fix various other operations to ensure that they ignore invalid indexes resulting from a failed CREATE INDEX CONCURRENTLY command. The most important of these is VACUUM, because an auto-vacuum could easily be launched on the table before corrective action can be taken to fix or remove the invalid index.

  Also fix DROP INDEX CONCURRENTLY to not disable insertions into the target index until all queries using it are done.

  Also fix misbehavior if DROP INDEX CONCURRENTLY is canceled: the previous coding could leave an un-droppable index behind.

- Correct predicate locking for DROP INDEX CONCURRENTLY (Kevin Grittner)

  Previously, SSI predicate locks were processed at the wrong time, possibly leading to incorrect behavior of serializable transactions executing in parallel with the DROP.

- Fix buffer locking during WAL replay (Tom Lane)

  The WAL replay code was insufficiently careful about locking buffers when replaying WAL records that affect more than one page. This could result in hot standby queries transiently seeing inconsistent states, resulting in wrong answers or unexpected failures.

- Fix an error in WAL generation logic for GIN indexes (Tom Lane)

  This could result in index corruption, if a torn-page failure occurred.

- Fix an error in WAL replay logic for SP-GiST indexes (Tom Lane)

  This could result in index corruption after a crash, or on a standby server.

- Fix incorrect detection of end-of-base-backup location during WAL recovery (Heikki Linnakangas)

  This mistake allowed hot standby mode to start up before the database reaches a consistent state.

- Properly remove startup process’s virtual XID lock when promoting a hot standby server to normal running (Simon Riggs)

  This oversight could prevent subsequent execution of certain operations such as CREATE INDEX CONCURRENTLY.

- Avoid bogus “out-of-sequence timeline ID” errors in standby mode (Heikki Linnakangas)

- Prevent the postmaster from launching new child processes after it’s received a shutdown signal (Tom Lane)

  This mistake could result in shutdown taking longer than it should, or even never completing at all without additional user action.
Appendix E. Release Notes

- Fix the syslogger process to not fail when `log_rotation_age` exceeds $2^{31}$ milliseconds (about 25 days) (Tom Lane)

- Fix `WaitLatch()` to return promptly when the requested timeout expires (Jeff Janes, Tom Lane)

  With the previous coding, a steady stream of non-wait-terminating interrupts could delay return from `WaitLatch()` indefinitely. This has been shown to be a problem for the autovacuum launcher process, and might cause trouble elsewhere as well.

- Avoid corruption of internal hash tables when out of memory (Hitoshi Harada)

- Prevent file descriptors for dropped tables from being held open past transaction end (Tom Lane)

  This should reduce problems with long-since-dropped tables continuing to occupy disk space.

- Prevent database-wide crash and restart when a new child process is unable to create a pipe for its latch (Tom Lane)

  Although the new process must fail, there is no good reason to force a database-wide restart, so avoid that. This improves robustness when the kernel is nearly out of file descriptors.

- Avoid planner crash with joins to unflattened subqueries (Tom Lane)

- Fix planning of non-strict equivalence clauses above outer joins (Tom Lane)

  The planner could derive incorrect constraints from a clause equating a non-strict construct to something else, for example `WHERE COALESCE(foo, 0) = 0` when `foo` is coming from the nullable side of an outer join. 9.2 showed this type of error in more cases than previous releases, but the basic bug has been there for a long time.

- Fix `SELECT DISTINCT` with index-optimized `MIN`/`MAX` on an inheritance tree (Tom Lane)

  The planner would fail with “failed to re-find MinMaxAggInfo record” given this combination of factors.

- Make sure the planner sees implicit and explicit casts as equivalent for all purposes, except in the minority of cases where there’s actually a semantic difference (Tom Lane)

- Include join clauses when considering whether partial indexes can be used for a query (Tom Lane)

  A strict join clause can be sufficient to establish an $x$ IS NOT NULL predicate, for example. This fixes a planner regression in 9.2, since previous versions could make comparable deductions.

- Limit growth of planning time when there are many indexable join clauses for the same index (Tom Lane)

- Improve planner’s ability to prove exclusion constraints from equivalence classes (Tom Lane)

- Fix partial-row matching in hashed subplans to handle cross-type cases correctly (Tom Lane)

  This affects multicolum NOT IN subplans, such as `WHERE (a, b) NOT IN (SELECT x, y FROM ...)` when for instance $b$ and $y$ are `int4` and `int8` respectively. This mistake led to wrong answers or crashes depending on the specific datatypes involved.

- Fix btree mark/restore functions to handle array keys (Tom Lane)

  This oversight could result in wrong answers from merge joins whose inner side is an index scan using an `indexed_column = ANY(array)` condition.

- Revert patch for taking fewer snapshots (Tom Lane)

  The 9.2 change to reduce the number of snapshots taken during query execution led to some anomalous behaviors not seen in previous releases, because execution would proceed with a snapshot acquired before locking the tables used by the query. Thus, for example, a query would not be guaranteed to see updates committed by a preceding transaction even if that transaction had exclu-
Appendix E. Release Notes

delete

Acquire buffer lock when re-fetching the old tuple for an AFTER ROW UPDATE/DELETE trigger (Andres Freund)

In very unusual circumstances, this oversight could result in passing incorrect data to a trigger WHEN condition, or to the precheck logic for a foreign-key enforcement trigger. That could result in a crash, or in an incorrect decision about whether to fire the trigger.

Fix ALTER COLUMN TYPE to handle inherited check constraints properly (Pavan Deolasee)

This worked correctly in pre-8.4 releases, and now works correctly in 8.4 and later.

Fix ALTER EXTENSION SET SCHEMA’s failure to move some subsidiary objects into the new schema (Álvaro Herrera, Dimitri Fontaine)

Handle CREATE TABLE AS EXECUTE correctly in extended query protocol (Tom Lane)

Don’t modify the input parse tree in DROP RULE IF NOT EXISTS and DROP TRIGGER IF NOT EXISTS (Tom Lane)

This mistake would cause errors if a cached statement of one of these types was re-executed.

Fix REASSIGN OWNED to handle grants on tablespaces (Álvaro Herrera)

Ignore incorrect pg_attribute entries for system columns for views (Tom Lane)

Views do not have any system columns. However, we forgot to remove such entries when converting a table to a view. That’s fixed properly for 9.3 and later, but in previous branches we need to defend against existing mis-converted views.

Fix rule printing to dump INSERT INTO table DEFAULT VALUES correctly (Tom Lane)

Guard against stack overflow when there are too many UNION/INTERSECT/EXCEPT clauses in a query (Tom Lane)

Prevent platform-dependent failures when dividing the minimum possible integer value by -1 (Xi Wang, Tom Lane)

Fix possible access past end of string in date parsing (Hitoshi Harada)

Fix failure to advance XID epoch if XID wraparound happens during a checkpoint and wal_level is hot_standby (Tom Lane, Andres Freund)

While this mistake had no particular impact on PostgreSQL itself, it was bad for applications that rely on txid_current() and related functions: the TXID value would appear to go backwards.

Fix pg_terminate_backend() and pg_cancel_backend() to not throw error for a non-existent target process (Josh Kupershmidt)

This case already worked as intended when called by a superuser, but not so much when called by ordinary users.

Fix display of pg_stat_replication.sync_state at a page boundary (Kyotaro Horiguchi)

Produce an understandable error message if the length of the path name for a Unix-domain socket exceeds the platform-specific limit (Tom Lane, Andrew Dunstan)

Formerly, this would result in something quite unhelpful, such as “Non-recoverable failure in name resolution”.

Fix memory leaks when sending composite column values to the client (Tom Lane)

Save some cycles by not searching for subtransaction locks at commit (Simon Riggs)

In a transaction holding many exclusive locks, this useless activity could be quite costly.
Appendix E. Release Notes

- Make pg_ctl more robust about reading the postmaster.pid file (Heikki Linnakangas)
  This fixes race conditions and possible file descriptor leakage.
- Fix possible crash in psql if incorrectly-encoded data is presented and the client_encoding setting is a client-only encoding, such as SJIS (Jiang Guiqing)
- Make pg_dump dump SEQUENCE SET items in the data not pre-data section of the archive (Tom Lane)
  This fixes an undesirable inconsistency between the meanings of --data-only and --section=data, and also fixes dumping of sequences that are marked as extension configuration tables.
- Fix pg_dump’s handling of DROP DATABASE commands in --clean mode (Guillaume Lelarge)
  Beginning in 9.2.0, pg_dump --clean would issue a DROP DATABASE command, which was either useless or dangerous depending on the usage scenario. It no longer does that. This change also fixes the combination of --clean and --create to work sensibly, i.e., emit DROP DATABASE then CREATE DATABASE before reconnecting to the target database.
- Fix pg_dump for views with circular dependencies and no relation options (Tom Lane)
  The previous fix to dump relation options when a view is involved in a circular dependency didn’t work right for the case that the view has no options; it emitted ALTER VIEW foo SET () which is invalid syntax.
- Fix bugs in the restore.sql script emitted by pg_dump in tar output format (Tom Lane)
  The script would fail outright on tables whose names include upper-case characters. Also, make the script capable of restoring data in --inserts mode as well as the regular COPY mode.
- Fix pg_restore to accept POSIX-conformant tar files (Brian Weaver, Tom Lane)
  The original coding of pg_dump’s tar output mode produced files that are not fully conformant with the POSIX standard. This has been corrected for version 9.3. This patch updates previous branches so that they will accept both the incorrect and the corrected formats, in hopes of avoiding compatibility problems when 9.3 comes out.
- Fix tar files emitted by pg_basebackup to be POSIX conformant (Brian Weaver, Tom Lane)
- Fix pg_resetxlog to locate postmaster.pid correctly when given a relative path to the data directory (Tom Lane)
  This mistake could lead to pg_resetxlog not noticing that there is an active postmaster using the data directory.
- Fix libpq’s lo_import() and lo_export() functions to report file I/O errors properly (Tom Lane)
- Fix ecpg’s processing of nested structure pointer variables (Muhammad Usama)
- Fix ecpg’s ecpg_get_data function to handle arrays properly (Michael Meskes)
- Prevent pg_upgrade from trying to process TOAST tables for system catalogs (Bruce Momjian)
  This fixes an error seen when the information_schema has been dropped and recreated. Other failures were also possible.
- Improve pg_upgrade performance by setting synchronous_commit to off in the new cluster (Bruce Momjian)
- Make contrib/pageinspect’s btree page inspection functions take buffer locks while examining pages (Tom Lane)
- Work around unportable behavior of malloc(0) and realloc(NULL, 0) (Tom Lane)
On platforms where these calls return `NULL`, some code mistakenly thought that meant out-of-memory. This is known to have broken `pg_dump` for databases containing no user-defined aggregates. There might be other cases as well.

- Ensure that `make install` for an extension creates the `extension` installation directory (Cédric Villemain)
  
  Previously, this step was missed if `MODULEDIR` was set in the extension’s Makefile.

- Fix `pgxs` support for building loadable modules on AIX (Tom Lane)
  
  Building modules outside the original source tree didn’t work on AIX.

- Update time zone data files to `tzdata` release 2012j for DST law changes in Cuba, Israel, Jordan, Libya, Palestine, Western Samoa, and portions of Brazil.

### E.84. Release 9.2.1

**Release date:** 2012-09-24

This release contains a variety of fixes from 9.2.0. For information about new features in the 9.2 major release, see Section E.85.

#### E.84.1. Migration to Version 9.2.1

A dump/restore is not required for those running 9.2.X. However, you may need to perform `REINDEX` and/or `VACUUM` operations to recover from the effects of the data corruption bug described in the first changelog item below.

#### E.84.2. Changes

- Fix persistence marking of shared buffers during WAL replay (Jeff Davis)
  
  This mistake can result in buffers not being written out during checkpoints, resulting in data corruption if the server later crashes without ever having written those buffers. Corruption can occur on any server following crash recovery, but it is significantly more likely to occur on standby slave servers since those perform much more WAL replay. There is a low probability of corruption of btree and GIN indexes. There is a much higher probability of corruption of table “visibility maps”, which might lead to wrong answers from index-only scans. Table data proper cannot be corrupted by this bug.

  While no index corruption due to this bug is known to have occurred in the field, as a precautionary measure it is recommended that production installations `REINDEX` all btree and GIN indexes at a convenient time after upgrading to 9.2.1.

  Also, it is recommended to perform a `VACUUM` of all tables while having `vacuum_freeze_table_age` set to zero. This will fix any incorrect visibility map data. `vacuum_cost_delay` can be adjusted to reduce the performance impact of vacuuming, while causing it to take longer to finish.

- Fix possible incorrect sorting of output from queries involving `WHERE indexed_column IN (list_of_values)` (Tom Lane)
Appendix E. Release Notes

• Fix planner failure for queries involving GROUP BY expressions along with window functions and aggregates (Tom Lane)

• Fix planner’s assignment of executor parameters (Tom Lane)

  This error could result in wrong answers from queries that scan the same WITH subquery multiple times.

• Improve planner’s handling of join conditions in index scans (Tom Lane)

• Improve selectivity estimation for text search queries involving prefixes, i.e. word:* patterns (Tom Lane)

• Fix delayed recognition of permissions changes (Tom Lane)

  A command that needed no locks other than ones its transaction already had might fail to notice a concurrent GRANT or REVOKE that committed since the start of its transaction.

• Fix ANALYZE to not fail when a column is a domain over an array type (Tom Lane)

• Prevent PL/Perl from crashing if a recursive PL/Perl function is redefined while being executed (Tom Lane)

• Work around possible misoptimization in PL/Perl (Tom Lane)

  Some Linux distributions contain an incorrect version of pthread.h that results in incorrect compiled code in PL/Perl, leading to crashes if a PL/Perl function calls another one that throws an error.

• Remove unnecessary dependency on pg_config from pg_upgrade (Peter Eisentraut)

• Update time zone data files to tzdata release 2012f for DST law changes in Fiji

E.85. Release 9.2

Release date: 2012-09-10

E.85.1. Overview

This release has been largely focused on performance improvements, though new SQL features are not lacking. Work also continues in the area of replication support. Major enhancements include:

• Allow queries to retrieve data only from indexes, avoiding heap access (index-only scans)

• Allow the planner to generate custom plans for specific parameter values even when using prepared statements

• Improve the planner’s ability to use nested loops with inner index scans

• Allow streaming replication slaves to forward data to other slaves (cascading replication)

• Allow pg_basebackup to make base backups from standby servers

• Add a pg_receivexlog tool to archive WAL file changes as they are written

• Add the SP-GiST (Space-Partitioned GiST) index access method

• Add support for range data types

• Add a JSON data type
Appendix E. Release Notes

- Add a security_barrier option for views
- Allow libpq connection strings to have the format of a URI
- Add a single-row processing mode to libpq for better handling of large result sets

The above items are explained in more detail in the sections below.

E.85.2. Migration to Version 9.2

A dump/restore using pg_dump, or use of pg_upgrade, is required for those wishing to migrate data from any previous release.

Version 9.2 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

E.85.2.1. System Catalogs

- Remove the spclocation field from pg_tablespace (Magnus Hagander)
  This field was duplicative of the symbolic links that actually define tablespace locations, and thus risked errors of omission when moving a tablespace. This change allows tablespace directories to be moved while the server is down, by manually adjusting the symbolic links. To replace this field, we have added pg_tablespace_location() to allow querying of the symbolic links.

- Move tsvector most-common-element statistics to new pg_stats columns (Alexander Ko-rotkov)
  Consult most_common_elems and most_common_elem_freqs for the data formerly available in most_common_vals and most_common_freqs for a tsvector column.

E.85.2.2. Functions

- Remove hstore’s |> operator (Robert Haas)
  Users should now use hstore(text, text). Since PostgreSQL 9.0, a warning message has been emitted when an operator named |> is created because the SQL standard reserves that token for another use.

- Ensure that xpath() escapes special characters in string values (Florian Pflug)
  Without this it is possible for the result not to be valid XML.

- Make pg_relation_size() and friends return NULL if the object does not exist (Phil Sorber)
  This prevents queries that call these functions from returning errors immediately after a concurrent DROP.

- Make EXTRACT(EPOCH FROM timestamp without time zone) measure the epoch from local midnight, not UTC midnight (Tom Lane)
  This change reverts an ill-considered change made in release 7.3. Measuring from UTC midnight was inconsistent because it made the result dependent on the timezone setting, which computations for timestamp without time zone should not be. The previous behavior remains available by casting the input value to timestamp with time zone.

- Properly parse time strings with trailing yesterday, today, and tomorrow (Dean Rasheed)
Previously, `SELECT '04:00:00 yesterday'::timestamp` returned yesterday’s date at midnight.

- Fix `to_date()` and `to_timestamp()` to wrap incomplete dates toward 2020 (Bruce Momjian)
  Previously, supplied years and year masks of less than four digits wrapped inconsistently.

### E.85.2.3. Object Modification

- Prevent `ALTER DOMAIN` from working on non-domain types (Peter Eisentraut)
  Owner and schema changes were previously possible on non-domain types.
- No longer forcibly lowercase procedural language names in `CREATE FUNCTION` (Robert Haas)
  While unquoted language identifiers are still lowercased, strings and quoted identifiers are no longer forcibly down-cased. Thus for example `CREATE FUNCTION ... LANGUAGE 'C'` will no longer work; it must be spelled `c'`, or better omit the quotes.
- Change system-generated names of foreign key enforcement triggers (Tom Lane)
  This change ensures that the triggers fire in the correct order in some corner cases involving self-referential foreign key constraints.

### E.85.2.4. Command-Line Tools

- Provide consistent backquote, variable expansion, and quoted substring behavior in `psql` meta-command arguments (Tom Lane)
  Previously, such references were treated oddly when not separated by whitespace from adjacent text. For example `‘FOO’BAR` was output as `FOO BAR` (unexpected insertion of a space) and `FOO’BAR’BAZ` was output unchanged (not removing the quotes as most would expect).
- No longer treat clusterdb table names as double-quoted; no longer treat reindexdb table and index names as double-quoted (Bruce Momjian)
  Users must now include double-quotes in the command arguments if quoting is wanted.
- `createuser` no longer prompts for option settings by default (Peter Eisentraut)
  Use `--interactive` to obtain the old behavior.
- Disable prompting for the user name in `dropuser` unless `--interactive` is specified (Peter Eisentraut)

### E.85.2.5. Server Settings

- Add server parameters for specifying the locations of server-side SSL files (Peter Eisentraut)
  This allows changing the names and locations of the files that were previously hard-coded as `server.crt`, `server.key`, `root.crt`, and `root.crl` in the data directory. The server will no longer examine `root.crt` or `root.crl` by default; to load these files, the associated parameters must be set to non-default values.
- Remove the `silent_mode` parameter (Heikki Linnakangas)
  Similar behavior can be obtained with `pg_ctl start -l postmaster.log`. 
Appendix E. Release Notes

- Remove the `wal_sender_delay` parameter, as it is no longer needed (Tom Lane)
- Remove the `custom_variable_classes` parameter (Tom Lane)

  The checking provided by this setting was dubious. Now any setting can be prefixed by any class name.

E.85.2.6. Monitoring

- Rename `pg_stat_activity.procpid` to `pid`, to match other system tables (Magnus Hagander)
- Create a separate `pg_stat_activity` column to report process state (Scott Mead, Magnus Hagander)

  The previous `query` and `query_start` values now remain available for an idle session, allowing enhanced analysis.
- Rename `pg_stat_activity.current_query` to `query` because it is not cleared when the query completes (Magnus Hagander)
- Change all SQL-level statistics timing values to be `float8` columns measured in milliseconds (Tom Lane)

  This change eliminates the designed-in assumption that the values are accurate to microseconds and no more (since the `float8` values can be fractional). The columns affected are `pg_stat_user_functions.total_time`, `pg_stat_user_functions.self_time`, `pg_stat_xact_user_functions.total_time`, and `pg_stat_xact_user_functions.self_time`. The statistics functions underlying these columns now also return `float8` milliseconds, rather than `bigint` microseconds. `contrib/pg_stat_statements`' `total_time` column is now also measured in milliseconds.

E.85.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 9.2 and the previous major release.

E.85.3.1. Server

E.85.3.1.1. Performance

- Allow queries to retrieve data only from indexes, avoiding heap access (Robert Haas, Ibrar Ahmed, Heikki Linnakangas, Tom Lane)

  This feature is often called index-only scans. Heap access can be skipped for heap pages containing only tuples that are visible to all sessions, as reported by the visibility map; so the benefit applies mainly to mostly-static data. The visibility map was made crash-safe as a necessary part of implementing this feature.
- Add the SP-GiST (Space-Partitioned GiST) index access method (Teodor Sigaev, Oleg Bartunov, Tom Lane)
SP-GiST is comparable to GiST in flexibility, but supports unbalanced partitioned search structures rather than balanced trees. For suitable problems, SP-GiST can be faster than GiST in both index build time and search time.

- Allow group commit to work effectively under heavy load (Peter Geoghegan, Simon Riggs, Heikki Linnakangas)

Previously, batching of commits became ineffective as the write workload increased, because of internal lock contention.

- Allow uncontended locks to be managed using a new fast-path lock mechanism (Robert Haas)
- Reduce overhead of creating virtual transaction ID locks (Robert Haas)
- Reduce the overhead of serializable isolation level locks (Dan Ports)
- Improve PowerPC and Itanium spinlock performance (Manabu Ori, Robert Haas, Tom Lane)
- Reduce overhead for shared invalidation cache messages (Robert Haas)
- Move the frequently accessed members of the PGPROC shared memory array to a separate array (Pavan Deolasee, Heikki Linnakangas, Robert Haas)
- Improve COPY performance by adding tuples to the heap in batches (Heikki Linnakangas)
- Improve GiST index performance for geometric data types by producing better trees with less memory allocation overhead (Alexander Korotkov)
- Improve GiST index build times (Alexander Korotkov, Heikki Linnakangas)
- Allow hint bits to be set sooner for temporary and unlogged tables (Robert Haas)
- Allow sorting to be performed by inlined, non-SQL-callable comparison functions (Peter Geoghegan, Robert Haas, Tom Lane)
- Make the number of CLOG buffers scale based on shared_buffers (Robert Haas, Simon Riggs, Tom Lane)
- Improve performance of buffer pool scans that occur when tables or databases are dropped (Jeff Janes, Simon Riggs)
- Improve performance of checkpointer’s fsync-request queue when many tables are being dropped or truncated (Tom Lane)
- Pass the safe number of file descriptors to child processes on Windows (Heikki Linnakangas)

This allows Windows sessions to use more open file descriptors than before.

E.85.3.1.2. Process Management

- Create a dedicated background process to perform checkpoints (Simon Riggs)

Formerly the background writer did both dirty-page writing and checkpointing. Separating this into two processes allows each goal to be accomplished more predictably.

- Improve asynchronous commit behavior by waking the walwriter sooner (Simon Riggs)

Previously, only wal_writer_delay triggered WAL flushing to disk; now filling a WAL buffer also triggers WAL writes.

- Allow the bgwriter, walwriter, checkpointer, statistics collector, log collector, and archiver background processes to sleep more efficiently during periods of inactivity (Peter Geoghegan, Tom Lane)
This series of changes reduces the frequency of process wake-ups when there is nothing to do, dramatically reducing power consumption on idle servers.

**E.85.3.1.3. Optimizer**

- Allow the planner to generate custom plans for specific parameter values even when using prepared statements (Tom Lane)
  
  In the past, a prepared statement always had a single “generic” plan that was used for all parameter values, which was frequently much inferior to the plans used for non-prepared statements containing explicit constant values. Now, the planner attempts to generate custom plans for specific parameter values. A generic plan will only be used after custom plans have repeatedly proven to provide no benefit. This change should eliminate the performance penalties formerly seen from use of prepared statements (including non-dynamic statements in PL/pgSQL).

- Improve the planner’s ability to use nested loops with inner index scans (Tom Lane)
  
  The new “parameterized path” mechanism allows inner index scans to use values from relations that are more than one join level up from the scan. This can greatly improve performance in situations where semantic restrictions (such as outer joins) limit the allowed join orderings.

- Improve the planning API for foreign data wrappers (Etsuro Fujita, Shigeru Hanada, Tom Lane)
  
  Wrappers can now provide multiple access “paths” for their tables, allowing more flexibility in join planning.

- Recognize self-contradictory restriction clauses for non-table relations (Tom Lane)
  
  This check is only performed when constraint_exclusion is on.

- Allow indexed_col op ANY(ARRAY[…]) conditions to be used in plain index scans and index-only scans (Tom Lane)
  
  Formerly such conditions could only be used in bitmap index scans.

- Support MIN/MAX index optimizations on boolean columns (Marti Raudsepp)

- Account for set-returning functions in SELECT target lists when setting row count estimates (Tom Lane)

- Fix planner to handle indexes with duplicated columns more reliably (Tom Lane)

- Collect and use element-frequency statistics for arrays (Alexander Korotkov, Tom Lane)
  
  This change improves selectivity estimation for the array <@, &&, and @> operators (array containment and overlaps).

- Allow statistics to be collected for foreign tables (Etsuro Fujita)

- Improve cost estimates for use of partial indexes (Tom Lane)

- Improve the planner’s ability to use statistics for columns referenced in subqueries (Tom Lane)

- Improve statistical estimates for subqueries using DISTINCT (Tom Lane)

**E.85.3.1.4. Authentication**

- Do not treat role names and samerole specified in pg_hba.conf as automatically including superusers (Andrew Dunstan)
  
  This makes it easier to use reject lines with group roles.
• Adjust pg_hba.conf processing to handle token parsing more consistently (Brendan Jurd, Álvaro Herrera)

• Disallow empty pg_hba.conf files (Tom Lane)
  This was done to more quickly detect misconfiguration.

• Make superuser privilege imply replication privilege (Noah Misch)
  This avoids the need to explicitly assign such privileges.

**E.85.3.1.5. Monitoring**

• Attempt to log the current query string during a backend crash (Marti Raudsepp)
• Make logging of autovacuum I/O activity more verbose (Greg Smith, Noah Misch)
  This logging is triggered by log_autovacuum_min_duration.
• Make WAL replay report failures sooner (Fujii Masao)
  There were some cases where failures were only reported once the server went into master mode.
• Add pg_xlog_location_diff() to simplify WAL location comparisons (Euler Taveira de Oliveira)
  This is useful for computing replication lag.
• Support configurable event log application names on Windows (MauMau, Magnus Hagander)
  This allows different instances to use the event log with different identifiers, by setting the event_source server parameter, which is similar to how syslog_ident works.
• Change “unexpected EOF” messages to DEBUG1 level, except when there is an open transaction (Magnus Hagander)
  This change reduces log chatter caused by applications that close database connections ungracefully.

**E.85.3.1.6. Statistical Views**

• Track temporary file sizes and file counts in the pg_stat_database system view (Tomas Vondra)
• Add a deadlock counter to the pg_stat_database system view (Magnus Hagander)
• Add a server parameter track_io_timing to track I/O timings (Ants Asmaa, Robert Haas)
• Report checkpoint timing information in pg_stat_bgwriter (Greg Smith, Peter Geoghegan)

**E.85.3.1.7. Server Settings**

• Silently ignore nonexistent schemas specified in search_path (Tom Lane)
  This makes it more convenient to use generic path settings, which might include some schemas that don’t exist in all databases.
• Allow superusers to set deadlock_timeout per-session, not just per-cluster (Noah Misch)
  This allows deadlock_timeout to be reduced for transactions that are likely to be involved in a deadlock, thus detecting the failure more quickly. Alternatively, increasing the value can be used to reduce the chances of a session being chosen for cancellation due to a deadlock.
Appendix E. Release Notes

• Add a server parameter `temp_file_limit` to constrain temporary file space usage per session (Mark Kirkwood)

• Allow a superuser to `SET` an extension’s superuser-only custom variable before loading the associated extension (Tom Lane)
  
  The system now remembers whether a `SET` was performed by a superuser, so that proper privilege checking can be done when the extension is loaded.

• Add `postmaster -C` option to query configuration parameters (Bruce Momjian)
  
  This allows `pg_ctl` to better handle cases where `PGDATA` or `-D` points to a configuration-only directory.

• Replace an empty locale name with the implied value in `CREATE DATABASE` (Tom Lane)
  
  This prevents cases where `pg_database`.datcollate or `datctype` could be interpreted differently after a server restart.

E.85.3.1.7.1. `postgresql.conf`

• Allow multiple errors in `postgresql.conf` to be reported, rather than just the first one (Alexey Klyukin, Tom Lane)

• Allow a reload of `postgresql.conf` to be processed by all sessions, even if there are some settings that are invalid for particular sessions (Alexey Klyukin)
  
  Previously, such not-valid-within-session values would cause all setting changes to be ignored by that session.

• Add an `include_if_exists` facility for configuration files (Greg Smith)
  
  This works the same as `include`, except that an error is not thrown if the file is missing.

• Identify the server time zone during `initdb`, and set `postgresql.conf` entries `timezone` and `log_timezone` accordingly (Tom Lane)
  
  This avoids expensive time zone probes during server start.

• Fix `pg_settings` to report `postgresql.conf` line numbers on Windows (Tom Lane)

E.85.3.2. Replication and Recovery

• Allow streaming replication slaves to forward data to other slaves (`cascading replication`) (Fujii Masao)
  
  Previously, only the master server could supply streaming replication log files to standby servers.

• Add new `synchronous_commit` mode `remote_write` (Fujii Masao, Simon Riggs)
  
  This mode waits for the standby server to write transaction data to its own operating system, but does not wait for the data to be flushed to the standby’s disk.

• Add a `pg接收xlog` tool to archive WAL file changes as they are written, rather than waiting for completed WAL files (Magnus Hagander)

• Allow `pg_basebackup` to make base backups from standby servers (Jun Ishizuka, Fujii Masao)
  
  This feature lets the work of making new base backups be off-loaded from the primary server.
• Allow streaming of WAL files while pg_basebackup is performing a backup (Magnus Hagander)
  This allows passing of WAL files to the standby before they are discarded on the primary.

E.85.3.3. Queries

• Cancel the running query if the client gets disconnected (Florian Pflug)
  If the backend detects loss of client connection during a query, it will now cancel the query rather
  than attempting to finish it.
• Retain column names at run time for row expressions (Andrew Dunstan, Tom Lane)
  This change allows better results when a row value is converted to \texttt{hstore} or \texttt{json} type: the fields
  of the resulting value will now have the expected names.
• Improve column labels used for \texttt{sub-SELECT} results (Marti Raudsepp)
  Previously, the generic label \texttt{?column?} was used.
• Improve heuristics for determining the types of unknown values (Tom Lane)
  The longstanding rule that an unknown constant might have the same type as the value on the other
  side of the operator using it is now applied when considering polymorphic operators, not only for
  simple operator matches.
• Warn about creating casts to or from domain types (Robert Haas)
  Such casts have no effect.
• When a row fails a \texttt{CHECK} or \texttt{NOT NULL} constraint, show the row’s contents as error detail (Jan
  Kundrát)
  This should make it easier to identify which row is problematic when an insert or update is pro-
  cessing many rows.

E.85.3.4. Object Manipulation

• Provide more reliable operation during concurrent DDL (Robert Haas, Noah Misch)
  This change adds locking that should eliminate “cache lookup failed” errors in many scenarios.
  Also, it is no longer possible to add relations to a schema that is being concurrently dropped, a
  scenario that formerly led to inconsistent system catalog contents.
• Add \texttt{CONCURRENTLY} option to \texttt{DROP INDEX} (Simon Riggs)
  This allows index removal without blocking other sessions.
• Allow foreign data wrappers to have per-column options (Shigeru Hanada)
• Improve pretty-printing of view definitions (Andrew Dunstan)

E.85.3.4.1. Constraints

• Allow \texttt{CHECK} constraints to be declared \texttt{NOT VALID} (Álvaro Herrera)
  Adding a \texttt{NOT VALID} constraint does not cause the table to be scanned to verify that existing rows
  meet the constraint. Subsequently, newly added or updated rows are checked. Such constraints are
ignored by the planner when considering constraint exclusion, since it is not certain that all rows meet the constraint.

The new ALTER TABLE VALIDATE command allows NOT VALID constraints to be checked for existing rows, after which they are converted into ordinary constraints.

- Allow CHECK constraints to be declared NO INHERIT (Nikhil Sontakke, Alex Hunsaker, Álvaro Herrera)

  This makes them enforceable only on the parent table, not on child tables.

- Add the ability to rename constraints (Peter Eisentraut)

### E.85.3.4.2. ALTER

- Reduce need to rebuild tables and indexes for certain ALTER TABLE ... ALTER COLUMN TYPE operations (Noah Misch)

  Increasing the length limit for a varchar or varbit column, or removing the limit altogether, no longer requires a table rewrite. Similarly, increasing the allowable precision of a numeric column, or changing a column from constrained numeric to unconstrained numeric, no longer requires a table rewrite. Table rewrites are also avoided in similar cases involving the interval, timestamp, and timestamptz types.

- Avoid having ALTER TABLE revalidate foreign key constraints in some cases where it is not necessary (Noah Misch)

- Add IF EXISTS options to some ALTER commands (Pavel Stehule)

  For example, ALTER FOREIGN TABLE IF EXISTS foo RENAME TO bar.

- Add ALTER FOREIGN DATA WRAPPER ... RENAME and ALTER SERVER ... RENAME (Peter Eisentraut)

- Add ALTER DOMAIN ... RENAME (Peter Eisentraut)

  You could already rename domains using ALTER TYPE.

- Throw an error for ALTER DOMAIN ... DROP CONSTRAINT on a nonexistent constraint (Peter Eisentraut)

  An IF EXISTS option has been added to provide the previous behavior.

### E.85.3.4.3. CREATE TABLE

- Allow CREATE TABLE (LIKE ...) from foreign tables, views, and composite types (Peter Eisentraut)

  For example, this allows a table to be created whose schema matches a view.

- Fix CREATE TABLE (LIKE ...) to avoid index name conflicts when copying index comments (Tom Lane)

- Fix CREATE TABLE ... AS EXECUTE to handle WITH NO DATA and column name specifications (Tom Lane)
Appendix E. Release Notes

E.85.3.4.4. Object Permissions

- Add a `security_barrier` option for views (KaiGai Kohei, Robert Haas)
  This option prevents optimizations that might allow view-protected data to be exposed to users, for example pushing a clause involving an insecure function into the `WHERE` clause of the view. Such views can be expected to perform more poorly than ordinary views.

- Add a new `LEAKPROOF` function attribute to mark functions that can safely be pushed down into `security_barrier` views (KaiGai Kohei)

- Add support for privileges on data types (Peter Eisentraut)
  This adds support for the SQL-conforming `USAGE` privilege on types and domains. The intent is to be able to restrict which users can create dependencies on types, since such dependencies limit the owner’s ability to alter the type.

- Check for `INSERT` privileges in `SELECT INTO` or `CREATE TABLE AS` (KaiGai Kohei)
  Because the object is being created by `SELECT INTO` or `CREATE TABLE AS`, the creator would ordinarily have insert permissions; but there are corner cases where this is not true, such as when `ALTER DEFAULT PRIVILEGES` has removed such permissions.

E.85.3.5. Utility Operations

- Allow `VACUUM` to more easily skip pages that cannot be locked (Simon Riggs, Robert Haas)
  This change should greatly reduce the incidence of `VACUUM` getting “stuck” waiting for other sessions.

- Make `EXPLAIN (BUFFERS)` count blocks dirtied and written (Robert Haas)

- Make `EXPLAIN ANALYZE` report the number of rows rejected by filter steps (Marko Tiikkaja)

- Allow `EXPLAIN ANALYZE` to avoid timing overhead when time values are not wanted (Tomas Vondra)
  This is accomplished by setting the new `TIMING` option to `FALSE`.

E.85.3.6. Data Types

- Add support for range data types (Jeff Davis, Tom Lane, Alexander Korotkov)
  A range data type stores a lower and upper bound belonging to its base data type. It supports operations like contains, overlaps, and intersection.

- Add a `JSON` data type (Robert Haas)
  This type stores JSON (JavaScript Object Notation) data with proper validation.

- Add `array_to_json()` and `row_to_json()` (Andrew Dunstan)

- Add a `SMALLSERIAL` data type (Mike Pultz)
  This is like `SERIAL`, except it stores the sequence in a two-byte integer column (`int2`).

- Allow domains to be declared `NOT VALID` (Álvaro Herrera)
Appendix E. Release Notes

This option can be set at domain creation time, or via ALTER DOMAIN ... ADD CONSTRAINT ... NOT VALID. ALTER DOMAIN ... VALIDATE CONSTRAINT fully validates the constraint.

- Support more locale-specific formatting options for the money data type (Tom Lane)
  Specifically, honor all the POSIX options for ordering of the value, sign, and currency symbol in monetary output. Also, make sure that the thousands separator is only inserted to the left of the decimal point, as required by POSIX.

- Add bitwise “and”, “or”, and “not” operators for the macaddr data type (Brendan Jurd)

- Allow xpath() to return a single-element XML array when supplied a scalar value (Florian Pflug)
  Previously, it returned an empty array. This change will also cause xpath_exists() to return true, not false, for such expressions.

- Improve XML error handling to be more robust (Florian Pflug)

E.85.3.7. Functions

- Allow non-superusers to use pg_cancel_backend() and pg_terminate_backend() on other sessions belonging to the same user (Magnus Hagander, Josh Kupershmidt, Dan Farina)
  Previously only superusers were allowed to use these functions.

- Allow importing and exporting of transaction snapshots (Joachim Wieland, Tom Lane)
  This allows multiple transactions to share identical views of the database state. Snapshots are exported via pg_export_snapshot() and imported via SET TRANSACTION SNAPSHOT. Only snapshots from currently-running transactions can be imported.

- Support COLLATION FOR on expressions (Peter Eisentraut)
  This returns a string representing the collation of the expression.

- Add pg_opfamily_is_visible() (Josh Kupershmidt)

- Add a numeric variant of pg_size_pretty() for use with pg_xlog_location_diff() (Fujii Masao)

- Add a pg_trigger_depth() function (Kevin Grittner)
  This reports the current trigger call depth.

- Allow string_agg() to process bytea values (Pavel Stehule)

- Fix regular expressions in which a back-reference occurs within a larger quantified subexpression (Tom Lane)
  For example, ^\w+( \1)+$. Previous releases did not check that the back-reference actually matched the first occurrence.

E.85.3.8. Information Schema

- Add information schema views role_udt_grants, udt_privileges, and user_defined_types (Peter Eisentraut)

- Add composite-type attributes to the information schema element_types view (Peter Eisentraut)

- Implement interval_type columns in the information schema (Peter Eisentraut)
Formerly these columns read as nulls.

- Implement collation-related columns in the information schema attributes, columns, domains, and element_types views (Peter Eisentraut)
- Implement the with_hierarchy column in the information schema table_privileges view (Peter Eisentraut)
- Add display of sequence usage privileges to information schema (Peter Eisentraut)
- Make the information schema show default privileges (Peter Eisentraut)
  Previously, non-empty default permissions were not represented in the views.

**E.85.3.9. Server-Side Languages**

**E.85.3.9.1. PL/pgSQL Server-Side Language**

- Allow the PL/pgSQL open cursor command to supply parameters by name (Yeb Havinga)
- Add a GET STACKED DIAGNOSTICS PL/pgSQL command to retrieve exception info (Pavel Stehule)
- Speed up PL/pgSQL array assignment by caching type information (Pavel Stehule)
- Improve performance and memory consumption for long chains of elsif clauses (Tom Lane)
- Output the function signature, not just the name, in PL/pgSQL error messages (Pavel Stehule)

**E.85.3.9.2. PL/Python Server-Side Language**

- Add PL/Python SPI cursor support (Jan Urbanski)
  This allows PL/Python to read partial result sets.
- Add result metadata functions to PL/Python (Peter Eisentraut)
  Specifically, this adds result object functions .colnames, .coltypes, and .coltypmods.
- Remove support for Python 2.2 (Peter Eisentraut)

**E.85.3.9.3. SQL Server-Side Language**

- Allow SQL-language functions to reference parameters by name (Matthew Draper)
  To use this, simply name the function arguments and then reference the argument names in the SQL function body.

**E.85.3.10. Client Applications**

- Add initdb options --auth-local and --auth-host (Peter Eisentraut)
  This allows separate control of local and host pg_hba.conf authentication settings. --auth still controls both.
• Add \--replication\--no-replication flags to createuser to control replication permission (Fujii Masao)

• Add the \--if-exists option to dropdb and dropuser (Josh Kupershmidt)

• Give command-line tools the ability to specify the name of the database to connect to, and fall back to template1 if a postgres database connection fails (Robert Haas)

**E.85.3.10.1. psql**

• Add a display mode to auto-expand output based on the display width (Peter Eisentraut)
   
   This adds the auto option to the \x command, which switches to the expanded mode when the normal output would be wider than the screen.

• Allow inclusion of a script file that is named relative to the directory of the file from which it was invoked (Gurjeet Singh)
   
   This is done with a new command \ir.

• Add support for non-ASCII characters in psql variable names (Tom Lane)

• Add support for major-version-specific .psqlrc files (Bruce Momjian)
   
   psql already supported minor-version-specific .psqlrc files.

• Provide environment variable overrides for psql history and startup file locations (Andrew Dunstan)
   
   PSQL_HISTORY and PSQLRC now determine these file names if set.

• Add a \setenv command to modify the environment variables passed to child processes (Andrew Dunstan)

• Name psql’s temporary editor files with a .sql extension (Peter Eisentraut)
   
   This allows extension-sensitive editors to select the right mode.

• Allow psql to use zero-byte field and record separators (Peter Eisentraut)
   
   Various shell tools use zero-byte (NUL) separators, e.g. find.

• Make the \timing option report times for failed queries (Magnus Hagander)
   
   Previously times were reported only for successful queries.

• Unify and tighten psql’s treatment of \copy and SQL COPY (Noah Misch)
   
   This fix makes failure behavior more predictable and honors \set ON_ERROR_ROLLBACK.

**E.85.3.10.2. Informational Commands**

• Make \d on a sequence show the table/column name owning it (Magnus Hagander)

• Show statistics target for columns in \d+ (Magnus Hagander)

• Show role password expiration dates in \du (Fabrízio de Royes Mello)

• Display comments for casts, conversions, domains, and languages (Josh Kupershmidt)
   
   These are included in the output of \dc+, \dc+, \dD+, and \dL respectively.

• Display comments for SQL/MED objects (Josh Kupershmidt)
   
   These are included in the output of \des+, \det+, and \dew+ for foreign servers, foreign tables, and foreign data wrappers respectively.
• Change `\dd` to display comments only for object types without their own backslash command (Josh Kupershmidt)

**E.85.3.10.3. Tab Completion**

• In psql tab completion, complete SQL keywords in either upper or lower case according to the new `COMP_KEYWORD_CASE` setting (Peter Eisentraut)
• Add tab completion support for `EXECUTE` (Andreas Karlsson)
• Allow tab completion of role references in `GRANT/REVOKE` (Peter Eisentraut)
• Allow tab completion of file names to supply quotes, when necessary (Noah Misch)
• Change tab completion support for `TABLE` to also include views (Magnus Hagander)

**E.85.3.10.4. pg_dump**

• Add an `--exclude-table-data` option to `pg_dump` (Andrew Dunstan)
  This allows dumping of a table’s definition but not its data, on a per-table basis.
• Add a `--section` option to `pg_dump` and `pg_restore` (Andrew Dunstan)
  Valid values are `pre-data`, `data`, and `post-data`. The option can be given more than once to select two or more sections.
• Make `pg_dumpall` dump all roles first, then all configuration settings on roles (Phil Sorber)
  This allows a role’s configuration settings to mention other roles without generating an error.
• Allow `pg_dumpall` to avoid errors if the `postgres` database is missing in the new cluster (Robert Haas)
• Dump foreign server user mappings in user name order (Peter Eisentraut)
  This helps produce deterministic dump files.
• Dump operators in a predictable order (Peter Eisentraut)
• Tighten rules for when extension configuration tables are dumped by `pg_dump` (Tom Lane)
• Make `pg_dump` emit more useful dependency information (Tom Lane)
  The dependency links included in archive-format dumps were formerly of very limited use, because they frequently referenced objects that appeared nowhere in the dump. Now they represent actual dependencies (possibly indirect) among the dumped objects.
• Improve `pg_dump`’s performance when dumping many database objects (Tom Lane)

**E.85.3.11. libpq**

• Allow `libpq` connection strings to have the format of a URI (Alexander Shulgin)
  The syntax begins with `postgres://`. This can allow applications to avoid implementing their own parser for URIs representing database connections.
• Add a connection option to disable SSL compression (Laurenz Albe)
This can be used to remove the overhead of SSL compression on fast networks.

- Add a single-row processing mode for better handling of large result sets (Kyotaro Horiguchi, Marko Kreen)
  Previously, libpq always collected the entire query result in memory before passing it back to the application.

- Add `const` qualifiers to the declarations of the functions `PQconnectdbParams`, `PQconnectStartParams`, and `PQpingParams` (Lionel Elie Mamane)

- Allow the `.pgpass` file to include escaped characters in the password field (Robert Haas)

- Make library functions use `abort()` instead of `exit()` when it is necessary to terminate the process (Peter Eisentraut)
  This choice does not interfere with the normal exit codes used by the program, and generates a signal that can be caught by the caller.

### E.85.3.12. Source Code

- Remove dead ports (Peter Eisentraut)
  The following platforms are no longer supported: dgux, nextstep, sunos4, svr4, ultrix4, univel, bsdi.
- Add support for building with MS Visual Studio 2010 (Brar Piening)
- Enable compiling with the MinGW-w64 32-bit compiler (Lars Kanis)
- Install `plpgsql.h` into `include/server` during installation (Heikki Linnakangas)
- Improve the latch facility to include detection of postmaster death (Peter Geoghegan, Heikki Linnakangas, Tom Lane)
  This eliminates one of the main reasons that background processes formerly had to wake up to poll for events.
- Use C flexible array members, where supported (Peter Eisentraut)
- Improve the concurrent transaction regression tests (isolationtester) (Noah Misch)
- Modify `thread_test` to create its test files in the current directory, rather than `/tmp` (Bruce Momjian)
- Improve flex and bison warning and error reporting (Tom Lane)
- Add memory barrier support (Robert Haas)
  This is currently unused.
- Modify `pgindent` to use a typedef file (Bruce Momjian)
- Add a hook for processing messages due to be sent to the server log (Martin Pihlak)
- Add object access hooks for `DROP` commands (KaiGai Kohei)
- Centralize `DROP` handling for some object types (KaiGai Kohei)
- Add a `pg_upgrade` test suite (Peter Eisentraut)
- Sync regular expression code with TCL 8.5.11 and improve internal processing (Tom Lane)
- Move CRC tables to `libpqport`, and provide them in a separate include file (Daniel Farina)
- Add options to `git_changelog` for use in major release note creation (Bruce Momjian)
- Support Linux’s `/proc/self/oom_score_adj` API (Tom Lane)
Appendix E. Release Notes

E.85.3.13. Additional Modules

- Improve efficiency of dblink by using libpq’s new single-row processing mode (Kyotaro Horiguchi, Marko Kreen)
  This improvement does not apply to `dblink_send_query()`/`dblink_get_result()`.
- Support `force_not_null` option in `file_fdw` (Shigeru Hanada)
- Implement dry-run mode for `pg_archivecleanup` (Gabriele Bartolini)
  This only outputs the names of files to be deleted.
- Add new `pgbench` switches `--unlogged-tables`, `--tablespace`, and `--index-tablespace` (Robert Haas)
- Change `pg_test_fsync` to test for a fixed amount of time, rather than a fixed number of cycles (Bruce Momjian)
  The `-o/cycles` option was removed, and `-s/seconds` added.
- Add a `pg_test_timing` utility to measure clock monotonicity and timing overhead (Ants Aasma, Greg Smith)
- Add a tcn (triggered change notification) module to generate `NOTIFY` events on table changes (Kevin Grittner)

E.85.3.13.1. `pg_upgrade`

- Adjust `pg_upgrade` environment variables (Bruce Momjian)
  Rename data, bin, and port environment variables to begin with `PG`, and support `PGPORTOLD/PGPORTNEW`, to replace `PGPORT`.
- Overhaul `pg_upgrade` logging and failure reporting (Bruce Momjian)
  Create four append-only log files, and delete them on success. Add `-r/--retain` option to unconditionally retain these files. Also remove `pg_upgrade` options `-g/-G/-l` options as unnecessary, and tighten log file permissions.
- Make `pg_upgrade` create a script to incrementally generate more accurate optimizer statistics (Bruce Momjian)
  This reduces the time needed to generate minimal cluster statistics after an upgrade.
- Allow `pg_upgrade` to upgrade an old cluster that does not have a `postgres` database (Bruce Momjian)
- Allow `pg_upgrade` to handle cases where some old or new databases are missing, as long as they are empty (Bruce Momjian)
- Allow `pg_upgrade` to handle configuration-only directory installations (Bruce Momjian)
- In `pg_upgrade`, add `-o/-O` options to pass parameters to the servers (Bruce Momjian)
  This is useful for configuration-only directory installs.
- Change `pg_upgrade` to use port 50432 by default (Bruce Momjian)
  This helps avoid unintended client connections during the upgrade.
- Reduce cluster locking in `pg_upgrade` (Bruce Momjian)
  Specifically, only lock the old cluster if link mode is used, and do it right after the schema is restored.
Appendix E. Release Notes

E.85.3.13.2. pg_stat_statements

- Allow pg_stat_statements to aggregate similar queries via SQL text normalization (Peter Geoghegan, Tom Lane)
  Users with applications that use non-parameterized SQL will now be able to monitor query performance without detailed log analysis.
- Add dirtied and written block counts and read/write times to pg_stat_statements (Robert Haas, Ants Aasma)
- Prevent pg_stat_statements from double-counting PREPARE and EXECUTE commands (Tom Lane)

E.85.3.13.3. sepgsql

- Support SECURITY LABEL on global objects (KaiGai Kohei, Robert Haas)
  Specifically, add security labels to databases, tablespaces, and roles.
- Allow sepgsql to honor database labels (KaiGai Kohei)
- Perform sepgsql permission checks during the creation of various objects (KaiGai Kohei)
- Add sepgsql_setcon() and related functions to control the sepgsql security domain (KaiGai Kohei)
- Add a user space access cache to sepgsql to improve performance (KaiGai Kohei)

E.85.3.14. Documentation

- Add a rule to optionally build HTML documentation using the stylesheet from the website (Magnus Hagander)
  Use `gmake STYLE=website draft`.
- Improve EXPLAIN documentation (Tom Lane)
- Document that user/database names are preserved with double-quoting by command-line tools like vacuumdb (Bruce Momjian)
- Document the actual string returned by the client for MD5 authentication (Cyan Ogilvie)
- Deprecate use of GLOBAL and LOCAL in CREATE TEMP TABLE (Noah Misch)
  PostgreSQL has long treated these keyword as no-ops, and continues to do so; but in future they might mean what the SQL standard says they mean, so applications should avoid using them.

E.86. Release 9.1.24

Release date: 2016-10-27

This release contains a variety of fixes from 9.1.23. For information about new features in the 9.1 major release, see Section E.110.
This is expected to be the last PostgreSQL release in the 9.1.X series. Users are encouraged to update to a newer release branch soon.

### E.86.1. Migration to Version 9.1.24

A dump/restore is not required for those running 9.1.X. However, if you are upgrading from a version earlier than 9.1.16, see Section E.94.

### E.86.2. Changes

- **Fix EvalPlanQual rechecks involving CTE scans (Tom Lane)**
  
  The recheck would always see the CTE as returning no rows, typically leading to failure to update rows that were recently updated.

- **Fix improper repetition of previous results from hashed aggregation in a subquery (Andrew Gierth)**
  
  The test to see if we can reuse a previously-computed hash table of the aggregate state values neglected the possibility of an outer query reference appearing in an aggregate argument expression. A change in the value of such a reference should lead to recalculating the hash table, but did not.

- **Fix timeout length when VACUUM is waiting for exclusive table lock so that it can truncate the table (Simon Riggs)**
  
  The timeout was meant to be 50 milliseconds, but it was actually only 50 microseconds, causing VACUUM to give up on truncation much more easily than intended. Set it to the intended value.

- **Remove artificial restrictions on the values accepted by numeric_in() and numeric_recv() (Tom Lane)**
  
  We allow numeric values up to the limit of the storage format (more than 1e100000), so it seems fairly pointless that numeric_in() rejected scientific-notation exponents above 1000. Likewise, it was silly for numeric_recv() to reject more than 1000 digits in an input value.

- **Fix timeout length when VACUUM is waiting for exclusive table lock so that it can truncate the table (Simon Riggs)**

  The timeout was meant to be 50 milliseconds, but it was actually only 50 microseconds, causing VACUUM to give up on truncation much more easily than intended. Set it to the intended value.

- **Fix file descriptor leakage when truncating a temporary relation of more than 1GB (Andres Freund)**

- **Disallow starting a standalone backend with standby_mode turned on (Michael Paquier)**
  
  This can’t do anything useful, since there will be no WAL receiver process to fetch more WAL data; and it could result in misbehavior in code that wasn’t designed with this situation in mind.

- **Pay attention to��るSSL contexts across multiple connections in libpq (Heikki Linnakangas)**
  
  This led to assorted corner-case bugs, particularly when trying to use different SSL parameters for different connections.

- **Avoid corner-case memory leak in libpq (Tom Lane)**

  The reported problem involved leaking an error report during PQreset(), but there might be related cases.

- **Make ecpg’s --help and --version options work consistently with our other executables (Haribabu Kommi)**

- **Fix contrib/intarray/bench/bench.pl to print the results of the EXPLAIN it does when given the -e option (Daniel Gustafsson)**
• Prevent failure of obsolete dynamic time zone abbreviations (Tom Lane)

If a dynamic time zone abbreviation does not match any entry in the referenced time zone, treat it as equivalent to the time zone name. This avoids unexpected failures when IANA removes abbreviations from their time zone database, as they did in tzdata release 2016f and seem likely to do again in the future. The consequences were not limited to not recognizing the individual abbreviation; any mismatch caused the \texttt{pg\_timezone\_abbrevs} view to fail altogether.

• Update time zone data files to tzdata release 2016h for DST law changes in Palestine and Turkey, plus historical corrections for Turkey and some regions of Russia. Switch to numeric abbreviations for some time zones in Antarctica, the former Soviet Union, and Sri Lanka.

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the \texttt{pg\_timezone\_names} view nor used for output.

In this update, \textit{AMT} is no longer shown as being in use to mean Armenia Time. Therefore, we have changed the \texttt{Default} abbreviation set to interpret it as Amazon Time, thus UTC-4 not UTC+4.

\section*{E.87. Release 9.1.23}

\textbf{Release date:} 2016-08-11

This release contains a variety of fixes from 9.1.22. For information about new features in the 9.1 major release, see Section E.110.

The PostgreSQL community will stop releasing updates for the 9.1.X release series in September 2016. Users are encouraged to update to a newer release branch soon.

\section*{E.87.1. Migration to Version 9.1.23}

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.16, see Section E.94.

\section*{E.87.2. Changes}

• Fix possible mis-evaluation of nested \texttt{CASE-WHEN} expressions (Heikki Linnakangas, Michael Paquier, Tom Lane)

A \texttt{CASE} expression appearing within the test value subexpression of another \texttt{CASE} could become confused about whether its own test value was null or not. Also, inlining of a SQL function implementing the equality operator used by a \texttt{CASE} expression could result in passing the wrong test value to functions called within a \texttt{CASE} expression in the SQL function’s body. If the test values were of different data types, a crash might result; moreover such situations could be abused to allow disclosure of portions of server memory. (CVE-2016-5423)

• Fix client programs’ handling of special characters in database and role names (Noah Misch, Nathan Bossart, Michael Paquier)
Numerous places in vacuumdb and other client programs could become confused by database and role names containing double quotes or backslashes. Tighten up quoting rules to make that safe. Also, ensure that when a conninfo string is used as a database name parameter to these programs, it is correctly treated as such throughout.

Fix handling of paired double quotes in psql's `\connect` and `\password` commands to match the documentation.

Introduce a new `-reuse-previous` option in psql's `\connect` command to allow explicit control of whether to re-use connection parameters from a previous connection. (Without this, the choice is based on whether the database name looks like a conninfo string, as before.) This allows secure handling of database names containing special characters in `pg_dumpall` scripts.

`pg_dumpall` now refuses to deal with database and role names containing carriage returns or newlines, as it seems impractical to quote those characters safely on Windows. In future we may reject such names on the server side, but that step has not been taken yet.

These are considered security fixes because crafted object names containing special characters could have been used to execute commands with superuser privileges the next time a superuser executes `pg_dumpall` or other routine maintenance operations. (CVE-2016-5424)

- Fix corner-case misbehaviors for `IS NULL/IS NOT NULL` applied to nested composite values (Andrew Gierth, Tom Lane)

  The SQL standard specifies that `IS NULL` should return TRUE for a row of all null values (thus `ROW(NULL,NULL) IS NULL` yields TRUE), but this is not meant to apply recursively (thus `ROW(NULL, ROW(NULL,NULL)) IS NULL` yields FALSE). The core executor got this right, but certain planner optimizations treated the test as recursive (thus producing TRUE in both cases), and contrib/postgres_fdw could produce remote queries that misbehaved similarly.

- Make the `inet` and `cidr` data types properly reject IPv6 addresses with too many colon-separated fields (Tom Lane)

- Prevent crash in `close_ps()` (the point `## lseg` operator) for NaN input coordinates (Tom Lane)

  Make it return NULL instead of crashing.

- Fix several one-byte buffer over-reads in `to_number()` (Peter Eisentraut)

  In several cases the `to_number()` function would read one more character than it should from the input string. There is a small chance of a crash, if the input happens to be adjacent to the end of memory.

- Avoid unsafe intermediate state during expensive paths through `heap_update()` (Masahiko Sawada, Andres Freund)

  Previously, these cases locked the target tuple (by setting its XMAX) but did not WAL-log that action, thus risking data integrity problems if the page were spilled to disk and then a database crash occurred before the tuple update could be completed.

- Avoid consuming a transaction ID during `VACUUM` (Alexander Korotkov)

  Some cases in `VACUUM` unnecessarily caused an XID to be assigned to the current transaction. Normally this is negligible, but if one is up against the XID wraparound limit, consuming more XIDs during anti-wraparound vacuums is a very bad thing.

- Avoid canceling hot-standby queries during `VACUUM FREEZE` (Simon Riggs, Álvaro Herrera)

  `VACUUM FREEZE` on an otherwise-idle master server could result in unnecessary cancellations of queries on its standby servers.
• When a manual \texttt{ANALYZE} specifies a column list, don’t reset the table’s \texttt{changes\_since\_analyze} counter (Tom Lane)

If we’re only analyzing some columns, we should not prevent routine auto-analyze from happening for the other columns.

• Fix \texttt{ANALYZE}'s overestimation of \texttt{n\_distinct} for a unique or nearly-unique column with many null entries (Tom Lane)

The nulls could get counted as though they were themselves distinct values, leading to serious planner misestimates in some types of queries.

• Prevent autovacuum from starting multiple workers for the same shared catalog (Álvaro Herrera)

Normally this isn’t much of a problem because the vacuum doesn’t take long anyway; but in the case of a severely bloated catalog, it could result in all but one worker uselessly waiting instead of doing useful work on other tables.

• Fix \texttt{contrib/btree\_gin} to handle the smallest possible \texttt{bigint} value correctly (Peter Eisentraut)

• Teach \texttt{libpq} to correctly decode server version from future servers (Peter Eisentraut)

It’s planned to switch to two-part instead of three-part server version numbers for releases after 9.6. Make sure that \texttt{PQserverVersion()} returns the correct value for such cases.

• Fix \texttt{ecpg}'s code for \texttt{unsigned long long} array elements (Michael Meskes)

• Make \texttt{pg\_basebackup} accept \texttt{-Z 0} as specifying no compression (Fujii Masao)

• Revert to the old heuristic timeout for \texttt{pg\_ctl start \_w} (Tom Lane)

The new method adopted as of release 9.1.20 does not work when \texttt{silent\_mode} is enabled, so go back to the old way.

• Fix makefiles’ rule for building AIX shared libraries to be safe for parallel make (Noah Misch)

• Fix TAP tests and MSVC scripts to work when build directory’s path name contains spaces (Michael Paquier, Kyotaro Horiguchi)

• Make \texttt{pg\_basebackup} accept \texttt{-Z 0} as specifying no compression (Fujii Masao)

• Revert to the old heuristic timeout for \texttt{pg\_ctl start \_w} (Tom Lane)

The new method adopted as of release 9.1.20 does not work when \texttt{silent\_mode} is enabled, so go back to the old way.

• Fix makefiles’ rule for building AIX shared libraries to be safe for parallel make (Noah Misch)

• Fix TAP tests and MSVC scripts to work when build directory’s path name contains spaces (Michael Paquier, Kyotaro Horiguchi)

• Make \texttt{pg\_basebackup} accept \texttt{-Z 0} as specifying no compression (Fujii Masao)

• Revert to the old heuristic timeout for \texttt{pg\_ctl start \_w} (Tom Lane)

The new method adopted as of release 9.1.20 does not work when \texttt{silent\_mode} is enabled, so go back to the old way.

• Fix makefiles’ rule for building AIX shared libraries to be safe for parallel make (Noah Misch)

• Fix TAP tests and MSVC scripts to work when build directory’s path name contains spaces (Michael Paquier, Kyotaro Horiguchi)

• Make \texttt{pg\_basebackup} accept \texttt{-Z 0} as specifying no compression (Fujii Masao)

• Revert to the old heuristic timeout for \texttt{pg\_ctl start \_w} (Tom Lane)

The new method adopted as of release 9.1.20 does not work when \texttt{silent\_mode} is enabled, so go back to the old way.

• Fix makefiles’ rule for building AIX shared libraries to be safe for parallel make (Noah Misch)

• Fix TAP tests and MSVC scripts to work when build directory’s path name contains spaces (Michael Paquier, Kyotaro Horiguchi)

• Make \texttt{pg\_basebackup} accept \texttt{-Z 0} as specifying no compression (Fujii Masao)

• Revert to the old heuristic timeout for \texttt{pg\_ctl start \_w} (Tom Lane)

The new method adopted as of release 9.1.20 does not work when \texttt{silent\_mode} is enabled, so go back to the old way.

• Fix makefiles’ rule for building AIX shared libraries to be safe for parallel make (Noah Misch)

• Fix TAP tests and MSVC scripts to work when build directory’s path name contains spaces (Michael Paquier, Kyotaro Horiguchi)

• Make \texttt{pg\_basebackup} accept \texttt{-Z 0} as specifying no compression (Fujii Masao)

• Revert to the old heuristic timeout for \texttt{pg\_ctl start \_w} (Tom Lane)

The new method adopted as of release 9.1.20 does not work when \texttt{silent\_mode} is enabled, so go back to the old way.

• Fix makefiles’ rule for building AIX shared libraries to be safe for parallel make (Noah Misch)

• Fix TAP tests and MSVC scripts to work when build directory’s path name contains spaces (Michael Paquier, Kyotaro Horiguchi)

• Make \texttt{pg\_basebackup} accept \texttt{-Z 0} as specifying no compression (Fujii Masao)
Appendix E. Release Notes

E.88.1. Migration to Version 9.1.22

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.16, see Section E.94.

E.88.2. Changes

- Clear the OpenSSL error queue before OpenSSL calls, rather than assuming it’s clear already; and make sure we leave it clear afterwards (Peter Geoghegan, Dave Vitek, Peter Eisentraut)
  This change prevents problems when there are multiple connections using OpenSSL within a single process and not all the code involved follows the same rules for when to clear the error queue. Failures have been reported specifically when a client application uses SSL connections in libpq concurrently with SSL connections using the PHP, Python, or Ruby wrappers for OpenSSL. It’s possible for similar problems to arise within the server as well, if an extension module establishes an outgoing SSL connection.
- Fix “failed to build any $n$-way joins” planner error with a full join enclosed in the right-hand side of a left join (Tom Lane)
- Fix possible misbehavior of TH, th, and YYYY format codes in \texttt{to\_timestamp()} (Tom Lane)
  These could advance off the end of the input string, causing subsequent format codes to read garbage.
- Fix dumping of rules and views in which the \texttt{array} argument of a \texttt{value operator ANY (array)} construct is a sub-SELECT (Tom Lane)
- Make \texttt{pg\_regress} use a startup timeout from the \texttt{PGCTLTIMEOUT} environment variable, if that’s set (Tom Lane)
  This is for consistency with a behavior recently added to \texttt{pg\_ctl}; it eases automated testing on slow machines.
- Fix \texttt{pg\_upgrade} to correctly restore extension membership for operator families containing only one operator class (Tom Lane)
  In such a case, the operator family was restored into the new database, but it was no longer marked as part of the extension. This had no immediate ill effects, but would cause later \texttt{pg\_dump} runs to emit output that would cause (harmless) errors on restore.
- Rename internal function \texttt{strtoi()} to \texttt{strtoint()} to avoid conflict with a NetBSD library function (Thomas Munro)
- Fix reporting of errors from \texttt{bind()} and \texttt{listen()} system calls on Windows (Tom Lane)
- Reduce verbosity of compiler output when building with Microsoft Visual Studio (Christian Ullrich)
- Avoid possibly-unsafe use of Windows’ \texttt{FormatMessage()} function (Christian Ullrich)
  Use the \texttt{FORMAT\_MESSAGE\_IGNORE\_INSERTS} flag where appropriate. No live bug is known to exist here, but it seems like a good idea to be careful.
- Update time zone data files to \texttt{tzdata} release 2016d for DST law changes in Russia and Venezuela.
  There are new zone names \texttt{Europe/Kirov} and \texttt{Asia/Tomsk} to reflect the fact that these regions now have different time zone histories from adjacent regions.
E.89. Release 9.1.21

Release date: 2016-03-31

This release contains a variety of fixes from 9.1.20. For information about new features in the 9.1 major release, see Section E.110.

E.89.1. Migration to Version 9.1.21

A dump/restore is not required for those running 9.1.X. However, if you are upgrading from a version earlier than 9.1.16, see Section E.94.

E.89.2. Changes

- Fix incorrect handling of NULL index entries in indexed `ROW()` comparisons (Tom Lane)
  An index search using a row comparison such as `ROW(a, b) > ROW(’x’, ’y’)` would stop upon reaching a NULL entry in the `b` column, ignoring the fact that there might be non-NULL `b` values associated with later values of `a`.
- Avoid unlikely data-loss scenarios due to renaming files without adequate `fsync()` calls before and after (Michael Paquier, Tomas Vondra, Andres Freund)
- Correctly handle cases where `pg_subtrans` is close to XID wraparound during server startup (Jeff Janes)
- Fix corner-case crash due to trying to free `localeconv()` output strings more than once (Tom Lane)
- Fix parsing of affix files for `ispell` dictionaries (Tom Lane)
  The code could go wrong if the affix file contained any characters whose byte length changes during case-folding, for example `ı` in Turkish UTF8 locales.
- Avoid use of `sscanf()` to parse `ispell` dictionary files (Artur Zakirov)
  This dodges a portability problem on FreeBSD-derived platforms (including macOS).
- Avoid a crash on old Windows versions (before 7SP1/2008R2SP1) with an AVX2-capable CPU and a Postgres build done with Visual Studio 2013 (Christian Ullrich)
  This is a workaround for a bug in Visual Studio 2013’s runtime library, which Microsoft have stated they will not fix in that version.
- Fix `psql`’s tab completion logic to handle multibyte characters properly (Kyotaro Horiguchi, Robert Haas)
- Fix `psql`’s tab completion for `SECURITY LABEL` (Tom Lane)
  Pressing `TAB` after `SECURITY LABEL` might cause a crash or offering of inappropriate keywords.
- Make `pg_ctl` accept a wait timeout from the `PGCTLTIMEOUT` environment variable, if none is specified on the command line (Noah Misch)
  This eases testing of slower buildfarm members by allowing them to globally specify a longer-than-normal timeout for postmaster startup and shutdown.
- Fix incorrect test for Windows service status in `pg_ctl` (Manuel Mathar)
Appendix E. Release Notes

The previous set of minor releases attempted to fix pg_ctl to properly determine whether to send log messages to Window’s Event Log, but got the test backwards.

- Fix pgbench to correctly handle the combination of \(-C\) and \(-M\) prepared options (Tom Lane)
- In PL/Perl, properly translate empty Postgres arrays into empty Perl arrays (Alex Hunsaker)
- Make PL/Python cope with function names that aren’t valid Python identifiers (Jim Nasby)
- Fix multiple mistakes in the statistics returned by contrib/pgstattuple’s pgstatindex() function (Tom Lane)
- Remove dependency on psed in MSVC builds, since it’s no longer provided by core Perl (Michael Paquier, Andrew Dunstan)
- Update time zone data files to tzdata release 2016c for DST law changes in Azerbaijan, Chile, Haiti, Palestine, and Russia (Altai, Astrakhan, Kirov, Sakhalin, Ulyanovsk regions), plus historical corrections for Lithuania, Moldova, and Russia (Kaliningrad, Samara, Volgograd).

E.90. Release 9.1.20

Release date: 2016-02-11

This release contains a variety of fixes from 9.1.19. For information about new features in the 9.1 major release, see Section E.110.

E.90.1. Migration to Version 9.1.20

A dump/restore is not required for those running 9.1.X. However, if you are upgrading from a version earlier than 9.1.16, see Section E.94.

E.90.2. Changes

- Fix infinite loops and buffer-overrun problems in regular expressions (Tom Lane)
  Very large character ranges in bracket expressions could cause infinite loops in some cases, and memory overwrites in other cases. (CVE-2016-0773)
- Perform an immediate shutdown if the postmaster.pid file is removed (Tom Lane)
  The postmaster now checks every minute or so that postmaster.pid is still there and still contains its own PID. If not, it performs an immediate shutdown, as though it had received SIGQUIT. The main motivation for this change is to ensure that failed buildfarm runs will get cleaned up without manual intervention; but it also serves to limit the bad effects if a DBA forcibly removes postmaster.pid and then starts a new postmaster.
- In SERIALIZABLE transaction isolation mode, serialization anomalies could be missed due to race conditions during insertions (Kevin Grittner, Thomas Munro)
- Fix failure to emit appropriate WAL records when doing ALTER TABLE ... SET TABLESPACE for unlogged relations (Michael Paquier, Andres Freund)
  Even though the relation’s data is unlogged, the move must be logged or the relation will be inaccessible after a standby is promoted to master.
Appendix E. Release Notes

- Fix possible misinitialization of unlogged relations at the end of crash recovery (Andres Freund, Michael Paquier)
- Fix ALTER COLUMN TYPE to reconstruct inherited check constraints properly (Tom Lane)
- Fix REASSIGN OWNED to change ownership of composite types properly (Álvaro Herrera)
- Fix REASSIGN OWNED and ALTER OWNER to correctly update granted-permissions lists when changing owners of data types, foreign data wrappers, or foreign servers (Bruce Momjian, Álvaro Herrera)
- Fix REASSIGN OWNED to ignore foreign user mappings, rather than fail (Álvaro Herrera)
- Add more defenses against bad planner cost estimates for GIN index scans when the index’s internal statistics are very out-of-date (Tom Lane)
- Make planner cope with hypothetical GIN indexes suggested by an index advisor plug-in (Julien Rouhaud)
- Fix dumping of whole-row Vars in ROW() and VALUES() lists (Tom Lane)
- Fix possible internal overflow in numeric division (Dean Rasheed)
- Fix enforcement of restrictions inside parentheses within regular expression lookahead constraints (Tom Lane)
  Lookahead constraints aren’t allowed to contain backrefs, and parentheses within them are always considered non-capturing, according to the manual. However, the code failed to handle these cases properly inside a parenthesized subexpression, and would give unexpected results.
- Conversion of regular expressions to indexscan bounds could produce incorrect bounds from reg-exps containing lookahead constraints (Tom Lane)
- Fix regular-expression compiler to handle loops of constraint arcs (Tom Lane)
  The code added for CVE-2007-4772 was both incomplete, in that it didn’t handle loops involving more than one state, and incorrect, in that it could cause assertion failures (though there seem to be no bad consequences of that in a non-assert build). Multi-state loops would cause the compiler to run until the query was canceled or it reached the too-many-states error condition.
- Improve memory-usage accounting in regular-expression compiler (Tom Lane)
  This causes the code to emit “regular expression is too complex” errors in some cases that previously used unreasonable amounts of time and memory.
- Improve performance of regular-expression compiler (Tom Lane)
- Make %h and %r escapes in log_line_prefix work for messages emitted due to log_connections (Tom Lane)
  Previously, %h/%r started to work just after a new session had emitted the “connection received” log message; now they work for that message too.
- On Windows, ensure the shared-memory mapping handle gets closed in child processes that don’t need it (Tom Lane, Amit Kapila)
  This oversight resulted in failure to recover from crashes whenever logging_collector is turned on.
- Fix possible failure to detect socket EOF in non-blocking mode on Windows (Tom Lane)
  It’s not entirely clear whether this problem can happen in pre-9.5 branches, but if it did, the symptom would be that a walsender process would wait indefinitely rather than noticing a loss of connection.
- Avoid leaking a token handle during SSPI authentication (Christian Ullrich)
• In psql, ensure that libreadline’s idea of the screen size is updated when the terminal window size changes (Merlin Moncure)

Previously, libreadline did not notice if the window was resized during query output, leading to strange behavior during later input of multiline queries.

• Fix psql’s \det command to interpret its pattern argument the same way as other \d commands with potentially schema-qualified patterns do (Reece Hart)

• Avoid possible crash in psql’s \c command when previous connection was via Unix socket and command specifies a new hostname and same username (Tom Lane)

• In pg_ctl start -w, test child process status directly rather than relying on heuristics (Tom Lane, Michael Paquier)

Previously, pg_ctl relied on an assumption that the new postmaster would always create postmaster.pid within five seconds. But that can fail on heavily-loaded systems, causing pg_ctl to report incorrectly that the postmaster failed to start.

Except on Windows, this change also means that a pg_ctl start -w done immediately after another such command will now reliably fail, whereas previously it would report success if done within two seconds of the first command.

• In pg_ctl start -w, don’t attempt to use a wildcard listen address to connect to the postmaster (Kondo Yuta)

On Windows, pg_ctl would fail to detect postmaster startup if listen_addresses is set to 0.0.0.0 or ::, because it would try to use that value verbatim as the address to connect to, which doesn’t work. Instead assume that 127.0.0.1 or ::1, respectively, is the right thing to use.

• In pg_ctl on Windows, check service status to decide where to send output, rather than checking if standard output is a terminal (Michael Paquier)

• In pg_dump and pg_basebackup, adopt the GNU convention for handling tar-archive members exceeding 8GB (Tom Lane)

The POSIX standard for tar file format does not allow archive member files to exceed 8GB, but most modern implementations of tar support an extension that fixes that. Adopt this extension so that pg_dump with -Ft no longer fails on tables with more than 8GB of data, and so that pg_basebackup can handle files larger than 8GB. In addition, fix some portability issues that could cause failures for members between 4GB and 8GB on some platforms. Potentially these problems could cause unrecoverable data loss due to unreadable backup files.

• Fix assorted corner-case bugs in pg_dump’s processing of extension member objects (Tom Lane)

• Make pg_dump mark a view’s triggers as needing to be processed after its rule, to prevent possible failure during parallel pg_restore (Tom Lane)

• Ensure that relation option values are properly quoted in pg_dump (Kouhei Sutou, Tom Lane)

A reloption value that isn’t a simple identifier or number could lead to dump/reload failures due to syntax errors in CREATE statements issued by pg_dump. This is not an issue with any reloption currently supported by core PostgreSQL, but extensions could allow reloptions that cause the problem.

• Fix pg_upgrade’s file-copying code to handle errors properly on Windows (Bruce Momjian)

• Install guards in pgbench against corner-case overflow conditions during evaluation of script-specified division or modulo operators (Fabien Coelho, Michael Paquier)

• Prevent certain PL/Java parameters from being set by non-superusers (Noah Misch)
This change mitigates a PL/Java security bug (CVE-2016-0766), which was fixed in PL/Java by marking these parameters as superuser-only. To fix the security hazard for sites that update PostgreSQL more frequently than PL/Java, make the core code aware of them also.

- Improve libpq’s handling of out-of-memory situations (Michael Paquier, Amit Kapila, Heikki Linnakangas)
- Fix order of arguments in ecpg-generated typedef statements (Michael Meskes)
- Use %g not %f format in ecpg’s PGYPESnumeric_from_double() (Tom Lane)
- Fix ecpg-supplied header files to not contain comments continued from a preprocessor directive line onto the next line (Michael Meskes)

Such a comment is rejected by ecpg. It’s not yet clear whether ecpg itself should be changed.

- Ensure that contrib/pgcrypto’s crypt() function can be interrupted by query cancel (Andreas Karlsson)
- Accept flex versions later than 2.5.x (Tom Lane, Michael Paquier)

Now that flex 2.6.0 has been released, the version checks in our build scripts needed to be adjusted.

- Install our missing script where PGXS builds can find it (Jim Nasby)

This allows sane behavior in a PGXS build done on a machine where build tools such as bison are missing.

- Ensure that dynloader.h is included in the installed header files in MSVC builds (Bruce Momjian, Michael Paquier)
- Add variant regression test expected-output file to match behavior of current libxml2 (Tom Lane)

The fix for libxml2’s CVE-2015-7499 causes it not to output error context reports in some cases where it used to do so. This seems to be a bug, but we’ll probably have to live with it for some time, so work around it.

- Update time zone data files to tzdata release 2016a for DST law changes in Cayman Islands, Metlakatla, and Trans-Baikal Territory (Zabaykalsky Krai), plus historical corrections for Pakistan.

---

### E.91. Release 9.1.19

**Release date:** 2015-10-08

This release contains a variety of fixes from 9.1.18. For information about new features in the 9.1 major release, see Section E.110.

#### E.91.1. Migration to Version 9.1.19

A dump/restore is not required for those running 9.1.X. However, if you are upgrading from a version earlier than 9.1.16, see Section E.94.

#### E.91.2. Changes

- Fix contrib/pgcrypto to detect and report too-short crypt() salts (Josh Kupershmidt)
Appendix E. Release Notes

Certain invalid salt arguments crashed the server or disclosed a few bytes of server memory. We have not ruled out the viability of attacks that arrange for presence of confidential information in the disclosed bytes, but they seem unlikely. (CVE-2015-5288)

- Fix subtransaction cleanup after a portal (cursor) belonging to an outer subtransaction fails (Tom Lane, Michael Paquier)

A function executed in an outer-subtransaction cursor could cause an assertion failure or crash by referencing a relation created within an inner subtransaction.

- Fix insertion of relations into the relation cache “init file” (Tom Lane)

An oversight in a patch in the most recent minor releases caused pg_trigger_tgrelid_tgname_index to be omitted from the init file. Subsequent sessions detected this, then deemed the init file to be broken and silently ignored it, resulting in a significant degradation in session startup time. In addition to fixing the bug, install some guards so that any similar future mistake will be more obvious.

- Avoid O(N^2) behavior when inserting many tuples into a SPI query result (Neil Conway)

- Improve LISTEN startup time when there are many unread notifications (Matt Newell)

- Back-patch 9.3-era addition of per-resource-owner lock caches (Jeff Janes)

This substantially improves performance when pg_dump tries to dump a large number of tables.

- Disable SSL renegotiation by default (Michael Paquier, Andres Freund)

While use of SSL renegotiation is a good idea in theory, we have seen too many bugs in practice, both in the underlying OpenSSL library and in our usage of it. Renegotiation will be removed entirely in 9.5 and later. In the older branches, just change the default value of ssl_renegotiation_limit to zero (disabled).

- Lower the minimum values of the *_freeze_max_age parameters (Andres Freund)

This is mainly to make tests of related behavior less time-consuming, but it may also be of value for installations with limited disk space.

- Limit the maximum value of wal_buffers to 2GB to avoid server crashes (Josh Berkus)

- Fix rare internal overflow in multiplication of numeric values (Dean Rasheed)

- Guard against hard-to-reach stack overflows involving record types, range types, json, jsonb, tsquery, ltxquery and query_int (Noah Misch)

- Fix handling of DOW and DOY in datetime input (Greg Stark)

These tokens aren’t meant to be used in datetime values, but previously they resulted in opaque internal error messages rather than “invalid input syntax”.

- Add more query-cancel checks to regular expression matching (Tom Lane)

- Add recursion depth protections to regular expression, SIMILAR TO, and LIKE matching (Tom Lane)

Suitable search patterns and a low stack depth limit could lead to stack-overflow crashes.

- Fix potential infinite loop in regular expression execution (Tom Lane)

A search pattern that can apparently match a zero-length string, but actually doesn’t match because of a back reference, could lead to an infinite loop.

- Fix low-memory failures in regular expression compilation (Andreas Seltenreich)

- Fix low-probability memory leak during regular expression execution (Tom Lane)

- Fix rare low-memory failure in lock cleanup during transaction abort (Tom Lane)
Appendix E. Release Notes

- Fix “unexpected out-of-memory situation during sort” errors when using tuplestores with small `work_mem` settings (Tom Lane)
- Fix very-low-probability stack overrun in `qsort` (Tom Lane)
- Fix “invalid memory alloc request size” failure in hash joins with large `work_mem` settings (Tomas Vondra, Tom Lane)
- Fix assorted planner bugs (Tom Lane)

These mistakes could lead to incorrect query plans that would give wrong answers, or to assertion failures in assert-enabled builds, or to odd planner errors such as “could not devise a query plan for the given query”, “could not find pathkey item to sort”, “plan should not reference subplan’s variable”, or “failed to assign all NestLoopParams to plan nodes”. Thanks are due to Andreas Seltenreich and Piotr Stefaniak for fuzz testing that exposed these problems.
- Use fuzzy path cost tiebreaking rule in all supported branches (Tom Lane)

This change is meant to avoid platform-specific behavior when alternative plan choices have effectively-identical estimated costs.
- Ensure standby promotion trigger files are removed at postmaster startup (Michael Paquier, Fujii Masao)

This prevents unwanted promotion from occurring if these files appear in a database backup that is used to initialize a new standby server.
- During postmaster shutdown, ensure that per-socket lock files are removed and listen sockets are closed before we remove the `postmaster.pid` file (Tom Lane)

This avoids race-condition failures if an external script attempts to start a new postmaster as soon as `pg_ctl stop` returns.
- Fix postmaster’s handling of a startup-process crash during crash recovery (Tom Lane)

If, during a crash recovery cycle, the startup process crashes without having restored database consistency, we’d try to launch a new startup process, which typically would just crash again, leading to an infinite loop.
- Do not print a `WARNING` when an autovacuum worker is already gone when we attempt to signal it, and reduce log verbosity for such signals (Tom Lane)
- Prevent autovacuum launcher from sleeping unduly long if the server clock is moved backwards a large amount (Álvaro Herrera)
- Ensure that cleanup of a GIN index’s pending-insertions list is interruptable by cancel requests (Jeff Janes)
- Allow all-zeroes pages in GIN indexes to be reused (Heikki Linnakangas)

Such a page might be left behind after a crash.
- Fix off-by-one error that led to otherwise-harmless warnings about “apparent wraparound” in sub-trans/multixact truncation (Thomas Munro)
- Fix misreporting of `CONTINUE` and `MOVE` statement types in PL/pgSQL’s error context messages (Pavel Stehule, Tom Lane)
- Fix PL/Perl to handle non-ASCII error message texts correctly (Alex Hunsaker)
- Fix PL/Python crash when returning the string representation of a record result (Tom Lane)
- Fix some places in PL/Tcl that neglected to check for failure of `malloc()` calls (Michael Paquier, Álvaro Herrera)
- In `contrib/isn`, fix output of ISBN-13 numbers that begin with 979 (Fabien Coelho)
EANs beginning with 979 (but not 9790) are considered ISBNs, but they must be printed in the new 13-digit format, not the 10-digit format.

- Improve libpq’s handling of out-of-memory conditions (Michael Paquier, Heikki Linnakangas)
- Fix memory leaks and missing out-of-memory checks in ecpg (Michael Paquier)
- Fix psql’s code for locale-aware formatting of numeric output (Tom Lane)
  The formatting code invoked by \pset numericlocale on did the wrong thing for some uncommon cases such as numbers with an exponent but no decimal point. It could also mangle already-localized output from the money data type.
- Prevent crash in psql’s \c command when there is no current connection (Noah Misch)
- Fix selection of default zlib compression level in pg_dump’s directory output format (Andrew Dunstan)
- Ensure that temporary files created during a pg_dump run with tar-format output are not world-readable (Michael Paquier)
- Fix pg_dump and pg_upgrade to support cases where the postgres or template1 database is in a non-default tablespace (Marti Raudsepp, Bruce Momjian)
- Fix pg_dump to handle object privileges sanely when dumping from a server too old to have a particular privilege type (Tom Lane)
  When dumping functions or procedural languages from pre-7.3 servers, pg_dump would produce GRANT/REVOKE commands that revoked the owner’s grantable privileges and instead granted all privileges to PUBLIC. Since the privileges involved are just USAGE and EXECUTE, this isn’t a security problem, but it’s certainly a surprising representation of the older systems’ behavior. Fix it to leave the default privilege state alone in these cases.
- Fix pg_dump to dump shell types (Tom Lane)
  Shell types (that is, not-yet-fully-defined types) aren’t useful for much, but nonetheless pg_dump should dump them.
- Fix assorted minor memory leaks in pg_dump and other client-side programs (Michael Paquier)
- Fix spinlock assembly code for PPC hardware to be compatible with AIX’s native assembler (Tom Lane)
  Building with gcc didn’t work if gcc had been configured to use the native assembler, which is becoming more common.
- On AIX, test the -qlonglong compiler option rather than just assuming it’s safe to use (Noah Misch)
- On AIX, use -Wl,-brtllib link option to allow symbols to be resolved at runtime (Noah Misch)
  Perl relies on this ability in 5.8.0 and later.
- Avoid use of inline functions when compiling with 32-bit xlc, due to compiler bugs (Noah Misch)
- Use librt for sched_yield() when necessary, which it is on some Solaris versions (Oskari Saarenmaa)
- Fix Windows install.bat script to handle target directory names that contain spaces (Heikki Linnakangas)
- Make the numeric form of the PostgreSQL version number (e.g., 90405) readily available to extension Makefiles, as a variable named VERSION_NUM (Michael Paquier)
Appendix E. Release Notes

- Update time zone data files to tzdata release 2015g for DST law changes in Cayman Islands, Fiji, Moldova, Morocco, Norfolk Island, North Korea, Turkey, and Uruguay. There is a new zone name America/Fort_Nelson for the Canadian Northern Rockies.

E.92. Release 9.1.18

Release date: 2015-06-12

This release contains a small number of fixes from 9.1.17. For information about new features in the 9.1 major release, see Section E.110.

E.92.1. Migration to Version 9.1.18

A dump/restore is not required for those running 9.1.X. However, if you are upgrading from a version earlier than 9.1.16, see Section E.94.

E.92.2. Changes

- Fix rare failure to invalidate relation cache init file (Tom Lane)

  With just the wrong timing of concurrent activity, a VACUUM FULL on a system catalog might fail to update the “init file” that’s used to avoid cache-loading work for new sessions. This would result in later sessions being unable to access that catalog at all. This is a very ancient bug, but it’s so hard to trigger that no reproducible case had been seen until recently.

- Avoid deadlock between incoming sessions and CREATE/DROP DATABASE (Tom Lane)

  A new session starting in a database that is the target of a DROP DATABASE command, or is the template for a CREATE DATABASE command, could cause the command to wait for five seconds and then fail, even if the new session would have exited before that.

E.93. Release 9.1.17

Release date: 2015-06-04

This release contains a small number of fixes from 9.1.16. For information about new features in the 9.1 major release, see Section E.110.

E.93.1. Migration to Version 9.1.17

A dump/restore is not required for those running 9.1.X. However, if you are upgrading from a version earlier than 9.1.16, see Section E.94.
Appendix E. Release Notes

E.93.2. Changes

- Avoid failures while fsync’ing data directory during crash restart (Abhijit Menon-Sen, Tom Lane)
  In the previous minor releases we added a patch to fsync everything in the data directory after a crash. Unfortunately its response to any error condition was to fail, thereby preventing the server from starting up, even when the problem was quite harmless. An example is that an unwritable file in the data directory would prevent restart on some platforms; but it is common to make SSL certificate files unwritable by the server. Revise this behavior so that permissions failures are ignored altogether, and other types of failures are logged but do not prevent continuing.

- Remove configure’s check prohibiting linking to a threaded libpython on OpenBSD (Tom Lane)
  The failure this restriction was meant to prevent seems to not be a problem anymore on current OpenBSD versions.

- Allow libpq to use TLS protocol versions beyond v1 (Noah Misch)
  For a long time, libpq was coded so that the only SSL protocol it would allow was TLS v1. Now that newer TLS versions are becoming popular, allow it to negotiate the highest commonly-supported TLS version with the server. (PostgreSQL servers were already capable of such negotiation, so no change is needed on the server side.) This is a back-patch of a change already released in 9.4.0.

E.94. Release 9.1.16

Release date: 2015-05-22

This release contains a variety of fixes from 9.1.15. For information about new features in the 9.1 major release, see Section E.110.

E.94.1. Migration to Version 9.1.16

A dump/restore is not required for those running 9.1.X.

However, if you use contrib/citext’s regexp_matches() functions, see the changelog entry below about that.

Also, if you are upgrading from a version earlier than 9.1.14, see Section E.96.

E.94.2. Changes

- Avoid possible crash when client disconnects just before the authentication timeout expires (Benkocs Norbert Attila)
  If the timeout interrupt fired partway through the session shutdown sequence, SSL-related state would be freed twice, typically causing a crash and hence denial of service to other sessions. Experimentation shows that an unauthenticated remote attacker could trigger the bug somewhat consistently, hence treat as security issue. (CVE-2015-3165)

- Improve detection of system-call failures (Noah Misch)
  Our replacement implementation of snprintf() failed to check for errors reported by the underlying system library calls; the main case that might be missed is out-of-memory situations. In the
Appendix E. Release Notes

In the worst case this might lead to information exposure, due to our code assuming that a buffer had been overwritten when it hadn’t been. Also, there were a few places in which security-relevant calls of other system library functions did not check for failure.

It remains possible that some calls of the `printf()` family of functions are vulnerable to information disclosure if an out-of-memory error occurs at just the wrong time. We judge the risk to not be large, but will continue analysis in this area. (CVE-2015-3166)

- In `contrib/pgcrypto`, uniformly report decryption failures as “Wrong key or corrupt data” (Noah Misch)

  Previously, some cases of decryption with an incorrect key could report other error message texts. It has been shown that such variance in error reports can aid attackers in recovering keys from other systems. While it’s unknown whether `pgcrypto`’s specific behaviors are likewise exploitable, it seems better to avoid the risk by using a one-size-fits-all message. (CVE-2015-3167)

- Fix incorrect declaration of `contrib/citext`’s `regexp_matches()` functions (Tom Lane)

  These functions should return `setof text[]`, like the core functions they are wrappers for; but they were incorrectly declared as returning just `text[]`. This mistake had two results: first, if there was no match you got a scalar null result, whereas what you should get is an empty set (zero rows). Second, the `g` flag was effectively ignored, since you would get only one result array even if there were multiple matches.

  While the latter behavior is clearly a bug, there might be applications depending on the former behavior; therefore the function declarations will not be changed by default until PostgreSQL 9.5. In pre-9.5 branches, the old behavior exists in version 1.0 of the `citext` extension, while we have provided corrected declarations in version 1.1 (which is not installed by default). To adopt the fix in pre-9.5 branches, execute `ALTER EXTENSION citext UPDATE TO '1.1'` in each database in which `citext` is installed. (You can also “update” back to 1.0 if you need to undo that.) Be aware that either update direction will require dropping and recreating any views or rules that use `citext`’s `regexp_matches()` functions.

- Fix incorrect checking of deferred exclusion constraints after a HOT update (Tom Lane)

  If a new row that potentially violates a deferred exclusion constraint is HOT-updated (that is, no indexed columns change and the row can be stored back onto the same table page) later in the same transaction, the exclusion constraint would be reported as violated when the check finally occurred, even if the row(s) the new row originally conflicted with had been deleted.

- Prevent improper reordering of antijoins (NOT EXISTS joins) versus other outer joins (Tom Lane)

  This oversight in the planner has been observed to cause “could not find RelOptInfo for given relids” errors, but it seems possible that sometimes an incorrect query plan might get past that consistency check and result in silently-wrong query output.

- Fix incorrect matching of subexpressions in outer-join plan nodes (Tom Lane)

  Previously, if textually identical non-strict subexpressions were used both above and below an outer join, the planner might try to re-use the value computed below the join, which would be incorrect because the executor would force the value to NULL in case of an unmatched outer row.

- Fix GEQO planner to cope with failure of its join order heuristic (Tom Lane)

  This oversight has been seen to lead to “failed to join all relations together” errors in queries involving `LATERAL`, and that might happen in other cases as well.

- Fix possible deadlock at startup when `max_prepared_transactions` is too small (Heikki Linnakangas)

- Don’t archive useless preallocated WAL files after a timeline switch (Heikki Linnakangas)
Appendix E. Release Notes

• Avoid “cannot GetMultiXactIdMembers() during recovery” error (Álvaro Herrera)

• Recursively \texttt{fsync()} the data directory after a crash (Abhijit Menon-Sen, Robert Haas)
  This ensures consistency if another crash occurs shortly later. (The second crash would have to be a system-level crash, not just a database crash, for there to be a problem.)

• Fix autovacuum launcher’s possible failure to shut down, if an error occurs after it receives SIGTERM (Álvaro Herrera)

• Cope with unexpected signals in \texttt{LockBufferForCleanup()} (Andres Freund)
  This oversight could result in spurious errors about “multiple backends attempting to wait for pin-count 1”.

• Avoid waiting for WAL flush or synchronous replication during commit of a transaction that was read-only so far as the user is concerned (Andres Freund)
  Previously, a delay could occur at commit in transactions that had written WAL due to HOT page pruning, leading to undesirable effects such as sessions getting stuck at startup if all synchronous replicas are down. Sessions have also been observed to get stuck in catchup interrupt processing when using synchronous replication; this will fix that problem as well.

• Fix crash when manipulating hash indexes on temporary tables (Heikki Linnakangas)

• Fix possible failure during hash index bucket split, if other processes are modifying the index concurrently (Tom Lane)

• Check for interrupts while analyzing index expressions (Jeff Janes)
  \texttt{ANALYZE} executes index expressions many times; if there are slow functions in such an expression, it’s desirable to be able to cancel the \texttt{ANALYZE} before that loop finishes.

• Ensure \texttt{tableoid} of a foreign table is reported correctly when a \texttt{READ COMMITTED} recheck occurs after locking rows in \texttt{SELECT FOR UPDATE}, \texttt{UPDATE}, or \texttt{DELETE} (Etsuro Fujita)

• Add the name of the target server to object description strings for foreign-server user mappings (Álvaro Herrera)

• Recommend setting \texttt{include_realm} to 1 when using Kerberos/GSSAPI/SSPI authentication (Stephen Frost)
  Without this, identically-named users from different realms cannot be distinguished. For the moment this is only a documentation change, but it will become the default setting in PostgreSQL 9.5.

• Remove code for matching IPv4 \texttt{pg_hba.conf} entries to IPv4-in-IPv6 addresses (Tom Lane)
  This hack was added in 2003 in response to a report that some Linux kernels of the time would report IPv4 connections as having IPv4-in-IPv6 addresses. However, the logic was accidentally broken in 9.0. The lack of any field complaints since then shows that it’s not needed anymore. Now we have reports that the broken code causes crashes on some systems, so let’s just remove it rather than fix it. (Had we chosen to fix it, that would make for a subtle and potentially security-sensitive change in the effective meaning of IPv4 \texttt{pg_hba.conf} entries, which does not seem like a good thing to do in minor releases.)

• Report WAL flush, not insert, position in \texttt{IDENTIFY_SYSTEM} replication command (Heikki Linnakangas)
  This avoids a possible startup failure in \texttt{pg_receivexlog}.

• While shutting down service on Windows, periodically send status updates to the Service Control Manager to prevent it from killing the service too soon; and ensure that \texttt{pg_ctl} will wait for shutdown (Krystian Bigaj)
• Reduce risk of network deadlock when using libpq’s non-blocking mode (Heikki Linnakangas)

When sending large volumes of data, it’s important to drain the input buffer every so often, in case the server has sent enough response data to cause it to block on output. (A typical scenario is that the server is sending a stream of NOTICE messages during COPY FROM STDIN.) This worked properly in the normal blocking mode, but not so much in non-blocking mode. We’ve modified libpq to opportunistically drain input when it can, but a full defense against this problem requires application cooperation: the application should watch for socket read-ready as well as write-ready conditions, and be sure to call PQconsumeInput() upon read-ready.

• Fix array handling in ecpg (Michael Meskes)

• Fix psql to sanely handle URIs and conninfo strings as the first parameter to \connect (David Fetter, Andrew Dunstan, Álvaro Herrera)

This syntax has been accepted (but undocumented) for a long time, but previously some parameters might be taken from the old connection instead of the given string, which was agreed to be undesirable.

• Suppress incorrect complaints from psql on some platforms that it failed to write ~/.psql_history at exit (Tom Lane)

This misbehavior was caused by a workaround for a bug in very old (pre-2006) versions of libedit. We fixed it by removing the workaround, which will cause a similar failure to appear for anyone still using such versions of libedit. Recommendation: upgrade that library, or use libreadline.

• Fix pg_dump’s rule for deciding which casts are system-provided casts that should not be dumped (Tom Lane)

• In pg_dump, fix failure to honor -Z compression level option together with -Fd (Michael Paquier)

• Make pg_dump consider foreign key relationships between extension configuration tables while choosing dump order (Gilles Darold, Michael Paquier, Stephen Frost)

This oversight could result in producing dumps that fail to reload because foreign key constraints are transiently violated.

• Fix dumping of views that are just VALUES(...) but have column aliases (Tom Lane)

• In pg_upgrade, force timeline 1 in the new cluster (Bruce Momjian)

This change prevents upgrade failures caused by bogus complaints about missing WAL history files.

• In pg_upgrade, check for improperly non-connectable databases before proceeding (Bruce Momjian)

• In pg_upgrade, quote directory paths properly in the generated delete_old_cluster script (Bruce Momjian)

• In pg_upgrade, preserve database-level freezing info properly (Bruce Momjian)

This oversight could cause missing-clog-file errors for tables within the postgres and template1 databases.

• Run pg_upgrade and pg_resetxlog with restricted privileges on Windows, so that they don’t fail when run by an administrator (Muhammad Asif Naeem)

• Improve handling of readdir() failures when scanning directories in initdb and pg_basebackup (Marco Nenciarini)

• Fix slow sorting algorithm in contrib/intarray (Tom Lane)

• Fix compile failure on Sparc V8 machines (Rob Rowan)
Appendix E. Release Notes

- Update time zone data files to tzdata release 2015d for DST law changes in Egypt, Mongolia, and Palestine, plus historical changes in Canada and Chile. Also adopt revised zone abbreviations for the America/Adak zone (HST/HDT not HAST/HADT).

E.95. Release 9.1.15

Release date: 2015-02-05

This release contains a variety of fixes from 9.1.14. For information about new features in the 9.1 major release, see Section E.110.

E.95.1. Migration to Version 9.1.15

A dump/restore is not required for those running 9.1.X. However, if you are upgrading from a version earlier than 9.1.14, see Section E.96.

E.95.2. Changes

- Fix buffer overruns in to_char() (Bruce Momjian)
  When to_char() processes a numeric formatting template calling for a large number of digits, PostgreSQL would read past the end of a buffer. When processing a crafted timestamp formatting template, PostgreSQL would write past the end of a buffer. Either case could crash the server. We have not ruled out the possibility of attacks that lead to privilege escalation, though they seem unlikely. (CVE-2015-0241)

- Fix buffer overrun in replacement *printf() functions (Tom Lane)
  PostgreSQL includes a replacement implementation of printf and related functions. This code will overrun a stack buffer when formatting a floating point number (conversion specifiers e, E, f, F, g or G) with requested precision greater than about 500. This will crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. A database user can trigger such a buffer overrun through the to_char() SQL function. While that is the only affected core PostgreSQL functionality, extension modules that use printf-family functions may be at risk as well.
  This issue primarily affects PostgreSQL on Windows. PostgreSQL uses the system implementation of these functions where adequate, which it is on other modern platforms. (CVE-2015-0242)

- Fix buffer overruns in contrib/pgcrypto (Marko Tiikkaja, Noah Misch)
  Errors in memory size tracking within the pgcrypto module permitted stack buffer overruns and improper dependence on the contents of uninitialized memory. The buffer overrun cases can crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. (CVE-2015-0243)

- Fix possible loss of frontend/backend protocol synchronization after an error (Heikki Linnakangas)
  If any error occurred while the server was in the middle of reading a protocol message from the client, it could lose synchronization and incorrectly try to interpret part of the message’s data as a new protocol message. An attacker able to submit crafted binary data within a command parameter
might succeed in injecting his own SQL commands this way. Statement timeout and query cancellation are the most likely sources of errors triggering this scenario. Particularly vulnerable are applications that use a timeout and also submit arbitrary user-crafted data as binary query parameters. Disabling statement timeout will reduce, but not eliminate, the risk of exploit. Our thanks to Emil Lenngren for reporting this issue. (CVE-2015-0244)

• Fix information leak via constraint-violation error messages (Stephen Frost)
Some server error messages show the values of columns that violate a constraint, such as a unique constraint. If the user does not have SELECT privilege on all columns of the table, this could mean exposing values that the user should not be able to see. Adjust the code so that values are displayed only when they came from the SQL command or could be selected by the user. (CVE-2014-8161)

• Lock down regression testing’s temporary installations on Windows (Noah Misch)
Use SSPI authentication to allow connections only from the OS user who launched the test suite. This closes on Windows the same vulnerability previously closed on other platforms, namely that other users might be able to connect to the test postmaster. (CVE-2014-0067)

• Avoid possible data corruption if ALTER DATABASE SET TABLESPACE is used to move a database to a new tablespace and then shortly later move it back to its original tablespace (Tom Lane)

• Avoid corrupting tables when ANALYZE inside a transaction is rolled back (Andres Freund, Tom Lane, Michael Paquier)
If the failing transaction had earlier removed the last index, rule, or trigger from the table, the table would be left in a corrupted state with the relevant pg_class flags not set though they should be.

• Ensure that unlogged tables are copied correctly during CREATE DATABASE or ALTER DATABASE SET TABLESPACE (Pavan Deolasee, Andres Freund)

• Fix DROP’s dependency searching to correctly handle the case where a table column is recursively visited before its table (Petr Jelinek, Tom Lane)
This case is only known to arise when an extension creates both a datatype and a table using that datatype. The faulty code might refuse a DROP EXTENSION unless CASCADE is specified, which should not be required.

• Fix use-of-already-freed-memory problem in EvalPlanQual processing (Tom Lane)
In READ COMMITTED mode, queries that lock or update recently-updated rows could crash as a result of this bug.

• Fix planning of SELECT FOR UPDATE when using a partial index on a child table (Kyotaro Horiguchi)
In READ COMMITTED mode, SELECT FOR UPDATE must also recheck the partial index’s WHERE condition when rechecking a recently-updated row to see if it still satisfies the query’s WHERE condition. This requirement was missed if the index belonged to an inheritance child table, so that it was possible to incorrectly return rows that no longer satisfy the query condition.

• Fix corner case wherein SELECT FOR UPDATE could return a row twice, and possibly miss returning other rows (Tom Lane)
In READ COMMITTED mode, a SELECT FOR UPDATE that is scanning an inheritance tree could incorrectly return a row from a prior child table instead of the one it should return from a later child table.

• Reject duplicate column names in the referenced-columns list of a FOREIGN KEY declaration (David Rowley)
This restriction is per SQL standard. Previously we did not reject the case explicitly, but later on the code would fail with bizarre-looking errors.
• Fix bugs in raising a numeric value to a large integral power (Tom Lane)

The previous code could get a wrong answer, or consume excessive amounts of time and memory before realizing that the answer must overflow.

• In numeric_recv(), truncate away any fractional digits that would be hidden according to the value's dscale field (Tom Lane)

A numeric value's display scale (dscale) should never be less than the number of nonzero fractional digits; but apparently there's at least one broken client application that transmits binary numeric values in which that's true. This leads to strange behavior since the extra digits are taken into account by arithmetic operations even though they aren't printed. The least risky fix seems to be to truncate away such “hidden” digits on receipt, so that the value is indeed what it prints as.

• Reject out-of-range numeric timezone specifications (Tom Lane)

Simple numeric timezone specifications exceeding +/- 168 hours (one week) would be accepted, but could then cause null-pointer dereference crashes in certain operations. There’s no use-case for such large UTC offsets, so reject them.

• Fix bugs in tsquery @@ tsquery operator (Heikki Linnakangas)

Two different terms would be considered to match if they had the same CRC. Also, if the second operand had more terms than the first, it would be assumed not to be contained in the first; which is wrong since it might contain duplicate terms.

• Improve ispell dictionary’s defenses against bad affix files (Tom Lane)

• Allow more than 64K phrases in a thesaurus dictionary (David Boutin)

The previous coding could crash on an oversize dictionary, so this was deemed a back-patchable bug fix rather than a feature addition.

• Fix namespace handling in xpath() (Ali Akbar)

Previously, the xml value resulting from an xpath() call would not have namespace declarations if the namespace declarations were attached to an ancestor element in the input xml value, rather than to the specific element being returned. Propagate the ancestral declaration so that the result is correct when considered in isolation.

• Fix planner problems with nested append relations, such as inherited tables within UNION ALL subqueries (Tom Lane)

• Fail cleanly when a GiST index tuple doesn’t fit on a page, rather than going into infinite recursion (Andrew Gierth)

• Exempt tables that have per-table cost_limit and/or cost_delay settings from autovacuum’s global cost balancing rules (Álvaro Herrera)

The previous behavior resulted in basically ignoring these per-table settings, which was unintended. Now, a table having such settings will be vacuumed using those settings, independently of what is going on in other autovacuum workers. This may result in heavier total I/O load than before, so such settings should be re-examined for sanity.

• Avoid wholesale autovacuuming when autovacuum is nominally off (Tom Lane)

Even when autovacuum is nominally off, we will still launch autovacuum worker processes to vacuum tables that are at risk of XID wraparound. However, such a worker process then proceeded to vacuum all tables in the target database, if they met the usual thresholds for autovacuuming. This is at best pretty unexpected; at worst it delays response to the wraparound threat. Fix it so that if autovacuum is turned off, workers only do anti-wraparound vacuums and not any other work.
Appendix E. Release Notes

- During crash recovery, ensure that unlogged relations are rewritten as empty and are synced to disk before recovery is considered complete (Abhijit Menon-Sen, Andres Freund)
  This prevents scenarios in which unlogged relations might contain garbage data following database crash recovery.
- Fix race condition between hot standby queries and replaying a full-page image (Heikki Linnakan-gas)
  This mistake could result in transient errors in queries being executed in hot standby.
- Fix several cases where recovery logic improperly ignored WAL records for COMMIT/ABORT PREPARED (Heikki Linnakangas)
  The most notable oversight was that recovery_target_xid could not be used to stop at a two-phase commit.
- Avoid creating unnecessary .ready marker files for timeline history files (Fujii Masao)
- Fix possible null pointer dereference when an empty prepared statement is used and the log_statement setting is mod or ddl (Fujii Masao)
- Change “pgstat wait timeout” warning message to be LOG level, and rephrase it to be more under-standable (Tom Lane)
  This message was originally thought to be essentially a can’t-happen case, but it occurs often enough on our slower buildfarm members to be a nuisance. Reduce it to LOG level, and expend a bit more effort on the wording: it now reads “using stale statistics instead of current ones because stats collector is not responding”.
- Fix SPARC spinlock implementation to ensure correctness if the CPU is being run in a non-TSO coherency mode, as some non-Solaris kernels do (Andres Freund)
- Warn if macOS’s setlocale() starts an unwanted extra thread inside the postmaster (Noah Misch)
- Fix processing of repeated dbname parameters in PQconnectdbParams() (Alex Shulgin)
  Unexpected behavior ensued if the first occurrence of dbname contained a connection string or URI to be expanded.
- Ensure that libpq reports a suitable error message on unexpected socket EOF (Marko Tiikkaja, Tom Lane)
  Depending on kernel behavior, libpq might return an empty error string rather than something useful when the server unexpectedly closed the socket.
- Clear any old error message during PQreset() (Heikki Linnakangas)
  If PQreset() is called repeatedly, and the connection cannot be re-established, error messages from the failed connection attempts kept accumulating in the PGconn’s error string.
- Properly handle out-of-memory conditions while parsing connection options in libpq (Alex Shulgin, Heikki Linnakangas)
- Fix array overrun in ecpg’s version of ParseDateTime() (Michael Paquier)
- In initdb, give a clearer error message if a password file is specified but is empty (Mats Erik And-ersson)
- Fix psql’s \s command to work nicely with libedit, and add pager support (Stepan Rutz, Tom Lane)
  When using libedit rather than readline, \s printed the command history in a fairly unreadable encoded format, and on recent libedit versions might fail altogether. Fix that by printing the history
ourselves rather than having the library do it. A pleasant side-effect is that the pager is used if appropriate.

This patch also fixes a bug that caused newline encoding to be applied inconsistently when saving the command history with libedit. Multiline history entries written by older psql versions will be read cleanly with this patch, but perhaps not vice versa, depending on the exact libedit versions involved.

- Improve consistency of parsing of psql’s special variables (Tom Lane)
  Allow variant spellings of `on` and `off` (such as `1/0`) for `ECHO_HIDDEN` and `ON_ERROR_ROLLBACK`. Report a warning for unrecognized values for `COMP_KEYWORD_CASE`, `ECHO`, `ECHO_HIDDEN`, `HISTCONTROL`, `ON_ERROR_ROLLBACK`, and `VERBOSITY`. Recognize all values for all these variables case-insensitively; previously there was a mishmash of case-sensitive and case-insensitive behaviors.

- Fix psql’s expanded-mode display to work consistently when using `border = 3` and `linestyle = ascii` or `unicode` (Stephen Frost)

- Improve performance of `pg_dump` when the database contains many instances of multiple dependency paths between the same two objects (Tom Lane)

- Fix possible deadlock during parallel restore of a schema-only dump (Robert Haas, Tom Lane)

- Fix core dump in `pg_dump --binary-upgrade` on zero-column composite type (Rushabh Lathia)

- Prevent WAL files created by `pg_basebackup -x/-X` from being archived again when the standby is promoted (Andres Freund)

- Fix upgrade-from-unpackaged script for `contrib/citext` (Tom Lane)

- Fix block number checking in `contrib/pageinspect`’s `get_raw_page()` (Tom Lane)
  The incorrect checking logic could prevent access to some pages in non-main relation forks.

- Fix `contrib/pgcrypto`’s `pgp_sym_decrypt()` to not fail on messages whose length is 6 less than a power of 2 (Marko Tiikkaja)

- Fix file descriptor leak in `contrib/pg_test_fsync` (Jeff Janes)
  This could cause failure to remove temporary files on Windows.

- Handle unexpected query results, especially NULLs, safely in `contrib/tablefunc`’s `connectby()` (Michael Paquier)

- Avoid a possible crash in `contrib/xml2`’s `xs1t_process()` (Mark Simonetti)

- Mark some `contrib` I/O functions with correct volatility properties (Tom Lane)

- Numerous cleanups of warnings from Coverity static code analyzer (Andres Freund, Tatsuo Ishii, Marko Kreen, Tom Lane, Michael Paquier)
These changes are mostly cosmetic but in some cases fix corner-case bugs, for example a crash
rather than a proper error report after an out-of-memory failure. None are believed to represent
security issues.

- Detect incompatible OpenLDAP versions during build (Noah Misch)
  With OpenLDAP versions 2.4.24 through 2.4.31, inclusive, PostgreSQL backends can crash at exit.
  Raise a warning during configure based on the compile-time OpenLDAP version number, and test
  the crashing scenario in the contrib/dblink regression test.

- In non-MSVC Windows builds, ensure libpq.dll is installed with execute permissions (Noah
  Misch)

- Make pg_regress remove any temporary installation it created upon successful exit (Tom Lane)
  This results in a very substantial reduction in disk space usage during make check-world, since
  that sequence involves creation of numerous temporary installations.

- Support time zone abbreviations that change UTC offset from time to time (Tom Lane)
  Previously, PostgreSQL assumed that the UTC offset associated with a time zone abbreviation
  (such as EST) never changes in the usage of any particular locale. However this assumption fails
  in the real world, so introduce the ability for a zone abbreviation to represent a UTC offset that
  sometimes changes. Update the zone abbreviation definition files to make use of this feature in
  timezone locales that have changed the UTC offset of their abbreviations since 1970 (according to
  the IANA timezone database). In such timezones, PostgreSQL will now associate the correct UTC
  offset with the abbreviation depending on the given date.

- Update time zone abbreviations lists (Tom Lane)
  Add CST (China Standard Time) to our lists. Remove references to ADT as “Arabia Daylight
  Time”, an abbreviation that’s been out of use since 2007; therefore, claiming there is a conflict with
  “Atlantic Daylight Time” doesn’t seem especially helpful. Fix entirely incorrect GMT offsets for
  CKT (Cook Islands), FJT, and FJST (Fiji); we didn’t even have them on the proper side of the date
  line.

- Update time zone data files to tzdata release 2015a.
  The IANA timezone database has adopted abbreviations of the form A\text{ST}/A\text{DT} for all Australian
  time zones, reflecting what they believe to be current majority practice Down Under. These names
do not conflict with usage elsewhere (other than ACST for Acre Summer Time, which has been in
disuse since 1994). Accordingly, adopt these names into our “Default” timezone abbreviation set.
  The “Australia” abbreviation set now contains only CST, EAST, EST, SAST, SAT, and WST, all of
  which are thought to be mostly historical usage. Note that SAST has also been changed to be South

  Also, add zone abbreviations SRET (Asia/Srednekolymsk) and XJT (Asia/Urumqi), and use
  WSST/WSDT for western Samoa. Also, there were DST law changes in Chile, Mexico, the Turks
  & Caicos Islands (America/Grand_Turk), and Fiji. There is a new zone Pacific/Bougainville for
  portions of Papua New Guinea. Also, numerous corrections for historical (pre-1970) time zone
  data.

E.96. Release 9.1.14

Release date: 2014-07-24
Appendix E. Release Notes

This release contains a variety of fixes from 9.1.13. For information about new features in the 9.1 major release, see Section E.110.

E.96.1. Migration to Version 9.1.14

A dump/restore is not required for those running 9.1.X.

However, this release corrects an index corruption problem in some GiST indexes. See the first changelog entry below to find out whether your installation has been affected and what steps you should take if so.

Also, if you are upgrading from a version earlier than 9.1.11, see Section E.99.

E.96.2. Changes

- Correctly initialize padding bytes in `contrib/btree_gist` indexes on `bit` columns (Heikki Linnakangas)
  
  This error could result in incorrect query results due to values that should compare equal not being seen as equal. Users with GiST indexes on `bit` or `bit varying` columns should REINDEX those indexes after installing this update.

- Protect against torn pages when deleting GIN list pages (Heikki Linnakangas)
  
  This fix prevents possible index corruption if a system crash occurs while the page update is being written to disk.

- Don’t clear the right-link of a GiST index page while replaying updates from WAL (Heikki Linnakangas)
  
  This error could lead to transiently wrong answers from GiST index scans performed in Hot Standby.

- Fix feedback status when `hot_standby_feedback` is turned off on-the-fly (Simon Riggs)

- Fix possibly-incorrect cache invalidation during nested calls to `ReceiveSharedInvalidMessages` (Andres Freund)

- Fix “could not find pathkey item to sort” planner failures with `UNION ALL` over subqueries reading from tables with inheritance children (Tom Lane)

- Don’t assume a subquery’s output is unique if there’s a set-returning function in its targetlist (David Rowley)
  
  This oversight could lead to misoptimization of constructs like `WHERE x IN (SELECT y, generate_series(1,10) FROM t GROUP BY y)`.

- Fix failure to detoast fields in composite elements of structured types (Tom Lane)
  
  This corrects cases where TOAST pointers could be copied into other tables without being dereferenced. If the original data is later deleted, it would lead to errors like “missing chunk number 0 for toast value ...” when the now-dangling pointer is used.

- Fix “record type has not been registered” failures with whole-row references to the output of Append plan nodes (Tom Lane)

- Fix possible crash when invoking a user-defined function while rewinding a cursor (Tom Lane)

- Fix query-lifespan memory leak while evaluating the arguments for a function in `FROM` (Tom Lane)
Appendix E. Release Notes

- Fix session-lifespan memory leaks in regular-expression processing (Tom Lane, Arthur O’Dwyer, Greg Stark)

- Fix data encoding error in `hungarian.stop` (Tom Lane)

- Prevent foreign tables from being created with OIDS when `default_with_oids` is true (Etsuro Fujita)

- Fix liveness checks for rows that were inserted in the current transaction and then deleted by a now-rolled-back subtransaction (Andres Freund)

  This could cause problems (at least spurious warnings, and at worst an infinite loop) if `CREATE INDEX` or `CLUSTER` were done later in the same transaction.

- Clear `pg_stat_activity.xact_start` during `PREPARE TRANSACTION` (Andres Freund)

  After the `PREPARE`, the originating session is no longer in a transaction, so it should not continue to display a transaction start time.

- Fix `REASSIGN OWNED` to not fail for text search objects (Álvaro Herrera)

- Block signals during postmaster startup (Tom Lane)

  This ensures that the postmaster will properly clean up after itself if, for example, it receives SIG-INT while still starting up.

- Fix client host name lookup when processing `pg_hba.conf` entries that specify host names instead of IP addresses (Tom Lane)

  Ensure that reverse-DNS lookup failures are reported, instead of just silently not matching such entries. Also ensure that we make only one reverse-DNS lookup attempt per connection, not one per host name entry, which is what previously happened if the lookup attempts failed.

- Secure Unix-domain sockets of temporary postmasters started during `make check` (Noah Misch)

  Any local user able to access the socket file could connect as the server’s bootstrap superuser, then proceed to execute arbitrary code as the operating-system user running the test, as we previously noted in CVE-2014-0067. This change defends against that risk by placing the server’s socket in a temporary, mode 0700 subdirectory of `/tmp`. The hazard remains however on platforms where Unix sockets are not supported, notably Windows, because then the temporary postmaster must accept local TCP connections.

  A useful side effect of this change is to simplify `make check` testing in builds that override `DEFAULT_PGSOCKET_DIR`. Popular non-default values like `/var/run/postgresql` are often not writable by the build user, requiring workarounds that will no longer be necessary.

- Fix tablespace creation WAL replay to work on Windows (MauMau)

- Fix detection of socket creation failures on Windows (Bruce Momjian)

- On Windows, allow new sessions to absorb values of PGC_BACKEND parameters (such as `log_connections`) from the configuration file (Amit Kapila)

  Previously, if such a parameter were changed in the file post-startup, the change would have no effect.

- Properly quote executable path names on Windows (Nikhil Deshpande)

  This oversight could cause `initdb` and `pg_upgrade` to fail on Windows, if the installation path contained both spaces and `@` signs.

- Fix linking of `libpython` on macOS (Tom Lane)

  The method we previously used can fail with the Python library supplied by Xcode 5.0 and later.

- Avoid buffer bloat in `libpq` when the server consistently sends data faster than the client can absorb it (Shin-ichi Morita, Tom Lane)
Appendix E. Release Notes

libpq could be coerced into enlarging its input buffer until it runs out of memory (which would be reported misleadingly as “lost synchronization with server”). Under ordinary circumstances it’s quite far-fetched that data could be continuously transmitted more quickly than the recv() loop can absorb it, but this has been observed when the client is artificially slowed by scheduler constraints.

- Ensure that LDAP lookup attempts in libpq time out as intended (Laurenz Albe)
- Fix ecpg to do the right thing when an array of char * is the target for a FETCH statement returning more than one row, as well as some other array-handling fixes (Ashutosh Bapat)
- Fix pg_restore’s processing of old-style large object comments (Tom Lane)
  A direct-to-database restore from an archive file generated by a pre-9.0 version of pg_dump would usually fail if the archive contained more than a few comments for large objects.
- In contrib/pgcrypto functions, ensure sensitive information is cleared from stack variables before returning (Marko Kreen)
- In contrib/uuid-ossp, cache the state of the OSSP UUID library across calls (Tom Lane)
  This improves the efficiency of UUID generation and reduces the amount of entropy drawn from /dev/urandom, on platforms that have that.
- Update time zone data files to tzdata release 2014e for DST law changes in Crimea, Egypt, and Morocco.

Release date: 2014-03-20

This release contains a variety of fixes from 9.1.12. For information about new features in the 9.1 major release, see Section E.110.

E.97.1. Migration to Version 9.1.13

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.11, see Section E.99.

E.97.2. Changes

- Restore GIN metapages unconditionally to avoid torn-page risk (Heikki Linnakangas)
  Although this oversight could theoretically result in a corrupted index, it is unlikely to have caused any problems in practice, since the active part of a GIN metapage is smaller than a standard 512-byte disk sector.
- Avoid race condition in checking transaction commit status during receipt of a NOTIFY message (Marko Tiikkaja)
  This prevents a scenario wherein a sufficiently fast client might respond to a notification before database updates made by the notifier have become visible to the recipient.
- Allow regular-expression operators to be terminated early by query cancel requests (Tom Lane)
Appendix E. Release Notes

This prevents scenarios wherein a pathological regular expression could lock up a server process uninterruptibly for a long time.

- Remove incorrect code that tried to allow `OVERLAPS` with single-element row arguments (Joshua Yanovski)
  This code never worked correctly, and since the case is neither specified by the SQL standard nor documented, it seemed better to remove it than fix it.

- Avoid getting more than `AccessShareLock` when de-parsing a rule or view (Dean Rasheed)
  This oversight resulted in `pg_dump` unexpectedly acquiring `RowExclusiveLock` locks on tables mentioned as the targets of `INSERT/UPDATE/DELETE` commands in rules. While usually harmless, that could interfere with concurrent transactions that tried to acquire, for example, `ShareLock` on those tables.

- Improve performance of index endpoint probes during planning (Tom Lane)
  This change fixes a significant performance problem that occurred when there were many not-yet-committed rows at the end of the index, which is a common situation for indexes on sequentially-assigned values such as timestamps or sequence-generated identifiers.

- Fix walsender’s failure to shut down cleanly when client is `pg_receivexlog` (Fujii Masao)

- Fix test to see if hot standby connections can be allowed immediately after a crash (Heikki Linnakangas)

- Prevent interrupts while reporting non-`ERROR` messages (Tom Lane)
  This guards against rare server-process freezeups due to recursive entry to `syslog()`, and perhaps other related problems.

- Fix memory leak in PL/Perl when returning a composite result, including multiple-OUT-parameter cases (Alex Hunsaker)

- Prevent intermittent “could not reserve shared memory region” failures on recent Windows versions (MauMau)

- Update time zone data files to `tzdata` release 2014a for DST law changes in Fiji and Turkey, plus historical changes in Israel and Ukraine.

E.98. Release 9.1.12

Release date: 2014-02-20

This release contains a variety of fixes from 9.1.11. For information about new features in the 9.1 major release, see Section E.110.

E.98.1. Migration to Version 9.1.12

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.11, see Section E.99.
Appendix E. Release Notes

E.98.2. Changes

• Shore up GRANT . . . WITH ADMIN OPTION restrictions (Noah Misch)

  Granting a role without ADMIN OPTION is supposed to prevent the grantee from adding or removing members from the granted role, but this restriction was easily bypassed by doing SET ROLE first. The security impact is mostly that a role member can revoke the access of others, contrary to the wishes of his grantor. Unapproved role member additions are a lesser concern, since an uncooperative role member could provide most of his rights to others anyway by creating views or SECURITY DEFINER functions. (CVE-2014-0060)

• Prevent privilege escalation via manual calls to PL validator functions (Andres Freund)

  The primary role of PL validator functions is to be called implicitly during CREATE FUNCTION, but they are also normal SQL functions that a user can call explicitly. Calling a validator on a function actually written in some other language was not checked for and could be exploited for privilege-escalation purposes. The fix involves adding a call to a privilege-checking function in each validator function. Non-core procedural languages will also need to make this change to their own validator functions, if any. (CVE-2014-0061)

• Avoid multiple name lookups during table and index DDL (Robert Haas, Andres Freund)

  If the name lookups come to different conclusions due to concurrent activity, we might perform some parts of the DDL on a different table than other parts. At least in the case of CREATE INDEX, this can be used to cause the permissions checks to be performed against a different table than the index creation, allowing for a privilege escalation attack. (CVE-2014-0062)

• Prevent buffer overrun with long datetime strings (Noah Misch)

  The MAXDATELEN constant was too small for the longest possible value of type interval, allowing a buffer overrun in interval_out(). Although the datetime input functions were more careful about avoiding buffer overrun, the limit was short enough to cause them to reject some valid inputs, such as input containing a very long timezone name. The ecpg library contained these vulnerabilities along with some of its own. (CVE-2014-0063)

• Prevent buffer overrun due to integer overflow in size calculations (Noah Misch, Heikki Linnakangas)

  Several functions, mostly type input functions, calculated an allocation size without checking for overflow. If overflow did occur, a too-small buffer would be allocated and then written past. (CVE-2014-0064)

• Prevent overruns of fixed-size buffers (Peter Eisentraut, Jozef Mlich)

  Use strlcpy() and related functions to provide a clear guarantee that fixed-size buffers are not overrun. Unlike the preceding items, it is unclear whether these cases really represent live issues, since in most cases there appear to be previous constraints on the size of the input string. Nonetheless it seems prudent to silence all Coverity warnings of this type. (CVE-2014-0065)

• Avoid crashing if crypt() returns NULL (Honza Horak, Bruce Momjian)

  There are relatively few scenarios in which crypt() could return NULL, but contrib/chkpass would crash if it did. One practical case in which this could be an issue is if libc is configured to refuse to execute unapproved hashing algorithms (e.g., “FIPS mode”). (CVE-2014-0066)

• Document risks of make check in the regression testing instructions (Noah Misch, Tom Lane)

  Since the temporary server started by make check uses “trust” authentication, another user on the same machine could connect to it as database superuser, and then potentially exploit the privileges of the operating-system user who started the tests. A future release will probably incorporate
changes in the testing procedure to prevent this risk, but some public discussion is needed first. So for the moment, just warn people against using `make check` when there are untrusted users on the same machine. (CVE-2014-0067)

- Fix possible mis-replay of WAL records when some segments of a relation aren’t full size (Greg Stark, Tom Lane)

  The WAL update could be applied to the wrong page, potentially many pages past where it should have been. Aside from corrupting data, this error has been observed to result in significant “bloat” of standby servers compared to their masters, due to updates being applied far beyond where the end-of-file should have been. This failure mode does not appear to be a significant risk during crash recovery, only when initially synchronizing a standby created from a base backup taken from a quickly-changing master.

- Fix bug in determining when recovery has reached consistency (Tomonari Katsumata, Heikki Linnakangas)

  In some cases WAL replay would mistakenly conclude that the database was already consistent at the start of replay, thus possibly allowing hot-standby queries before the database was really consistent. Other symptoms such as “PANIC: WAL contains references to invalid pages” were also possible.

- Fix improper locking of btree index pages while replaying a `VACUUM` operation in hot-standby mode (Andres Freund, Heikki Linnakangas, Tom Lane)

  This error could result in “PANIC: WAL contains references to invalid pages” failures.

- Ensure that insertions into non-leaf GIN index pages write a full-page WAL record when appropriate (Heikki Linnakangas)

  The previous coding risked index corruption in the event of a partial-page write during a system crash.

- When `pause_at_recovery_target` and `recovery_target_inclusive` are both set, ensure the target record is applied before pausing, not after (Heikki Linnakangas)

- Fix race conditions during server process exit (Robert Haas)

  Ensure that signal handlers don’t attempt to use the process’s `MyProc` pointer after it’s no longer valid.

- Fix race conditions in walsender shutdown logic and walreceiver SIGHUP signal handler (Tom Lane)

- Fix unsafe references to `errno` within error reporting logic (Christian Kruse)

  This would typically lead to odd behaviors such as missing or inappropriate `HINT` fields.

- Fix possible crashes from using `ereport()` too early during server startup (Tom Lane)

  The principal case we’ve seen in the field is a crash if the server is started in a directory it doesn’t have permission to read.

- Clear retry flags properly in OpenSSL socket write function (Alexander Kukushkin)

  This omission could result in a server lockup after unexpected loss of an SSL-encrypted connection.

- Fix length checking for Unicode identifiers (\u\"...\" syntax) containing escapes (Tom Lane)

  A spurious truncation warning would be printed for such identifiers if the escaped form of the identifier was too long, but the identifier actually didn’t need truncation after de-escaping.

- Allow keywords that are type names to be used in lists of roles (Stephen Frost)
Appendix E. Release Notes

A previous patch allowed such keywords to be used without quoting in places such as role identifiers; but it missed cases where a list of role identifiers was permitted, such as DROP ROLE.

• Fix parser crash for EXISTS(SELECT * FROM zero_column_table) (Tom Lane)
• Fix possible crash due to invalid plan for nested sub-selects, such as WHERE (... x IN (SELECT ...) ...) IN (SELECT ...) (Tom Lane)
• Ensure that ANALYZE creates statistics for a table column even when all the values in it are “too wide” (Tom Lane)

ANALYZE intentionally omits very wide values from its histogram and most-common-values calculations, but it neglected to do something sane in the case that all the sampled entries are too wide.

• In ALTER TABLE ... SET TABLESPACE, allow the database’s default tablespace to be used without a permissions check (Stephen Frost)

CREATE TABLE has always allowed such usage, but ALTER TABLE didn’t get the memo.

• Fix “cannot accept a set” error when some arms of a CASE return a set and others don’t (Tom Lane)
• Fix checks for all-zero client addresses in pgstat functions (Kevin Grittner)
• Fix possible misclassification of multibyte characters by the text search parser (Tom Lane)

Non-ASCII characters could be misclassified when using C locale with a multibyte encoding. On Cygwin, non-C locales could fail as well.

• Fix possible misbehavior in plantino_tsquery() (Heikki Linnakangas)

Use memmove() not memcpy() for copying overlapping memory regions. There have been no field reports of this actually causing trouble, but it’s certainly risky.

• Fix placement of permissions checks in pg_start_backup() and pg_stop_backup() (Andres Freund, Magnus Hagander)

The previous coding might attempt to do catalog access when it shouldn’t.

• Accept SHIFT_JIS as an encoding name for locale checking purposes (Tatsuo Ishii)
• Fix misbehavior of PQhost() on Windows (Fujii Masao)

It should return localhost if no host has been specified.

• Improve error handling in libpq and psql for failures during COPY TO STDOUT/FROM STDIN (Tom Lane)

In particular this fixes an infinite loop that could occur in 9.2 and up if the server connection was lost during COPY FROM STDIN. Variants of that scenario might be possible in older versions, or with other client applications.

• Fix possible incorrect printing of filenames in pg_basebackup’s verbose mode (Magnus Hagander)
• Avoid including tablespaces inside PGDATA twice in base backups (Dimitri Fontaine, Magnus Hagander)
• Fix misaligned descriptors in ecpg (MauMau)
• In ecpg, handle lack of a hostname in the connection parameters properly (Michael Meskes)

• Fix performance regression in contrib/dblink connection startup (Joe Conway)

Avoid an unnecessary round trip when client and server encodings match.

• In contrib/isn, fix incorrect calculation of the check digit for ISMN values (Fabien Coelho)
• Ensure client-code-only installation procedure works as documented (Peter Eisentraut)
• In Mingw and Cygwin builds, install the libpq DLL in the `bin` directory (Andrew Dunstan)

  This duplicates what the MSVC build has long done. It should fix problems with programs like `psql` failing to start because they can’t find the DLL.

• Avoid using the deprecated `dllwrap` tool in Cygwin builds (Marco Atzeri)

• Don’t generate plain-text `HISTORY` and `src/test/regress/README` files anymore (Tom Lane)

  These text files duplicated the main HTML and PDF documentation formats. The trouble involved in maintaining them greatly outweighs the likely audience for plain-text format. Distribution tar-balls will still contain files by these names, but they’ll just be stubs directing the reader to consult the main documentation. The plain-text `INSTALL` file will still be maintained, as there is arguably a use-case for that.

• Update time zone data files to tzdata release 2013i for DST law changes in Jordan and historical changes in Cuba.

  In addition, the zones `Asia/Riyadh87`, `Asia/Riyadh88`, and `Asia/Riyadh89` have been removed, as they are no longer maintained by IANA, and never represented actual civil timekeeping practice.

---

**E.99. Release 9.1.11**

**Release date:** 2013-12-05

This release contains a variety of fixes from 9.1.10. For information about new features in the 9.1 major release, see Section E.110.

**E.99.1. Migration to Version 9.1.11**

A dump/restore is not required for those running 9.1.X.

However, this release corrects a number of potential data corruption issues. See the first two changelog entries below to find out whether your installation has been affected and what steps you can take if so.

Also, if you are upgrading from a version earlier than 9.1.9, see Section E.101.

**E.99.2. Changes**

• Fix `VACUUM`’s tests to see whether it can update `relfrozenxid` (Andres Freund)

  In some cases `VACUUM` (either manual or autovacuum) could incorrectly advance a table’s `relfrozenxid` value, allowing tuples to escape freezing, causing those rows to become invisible once `2^31` transactions have elapsed. The probability of data loss is fairly low since multiple incorrect advancements would need to happen before actual loss occurs, but it’s not zero. Users upgrading from releases 9.0.4 or 8.4.8 or earlier are not affected, but all later versions contain the bug.

  The issue can be ameliorated by, after upgrading, vacuuming all tables in all databases while having `vacuum_freeze_table_age` set to zero. This will fix any latent corruption but will not be able to fix all pre-existing data errors. However, an installation can be presumed safe after performing this...
Appendix E. Release Notes

vacuuming if it has executed fewer than $2^{31}$ update transactions in its lifetime (check this with `SELECT txid_current() < 2^{31}`).

- **Fix initialization of `pg_clog` and `pg_subtrans` during hot standby startup** (Andres Freund, Heikki Linnakangas)

  This bug can cause data loss on standby servers at the moment they start to accept hot-standby queries, by marking committed transactions as uncommitted. The likelihood of such corruption is small unless, at the time of standby startup, the primary server has executed many updating transactions since its last checkpoint. Symptoms include missing rows, rows that should have been deleted being still visible, and obsolete versions of updated rows being still visible alongside their newer versions.

  This bug was introduced in versions 9.3.0, 9.2.5, 9.1.10, and 9.0.14. Standby servers that have only been running earlier releases are not at risk. It’s recommended that standby servers that have ever run any of the buggy releases be re-cloned from the primary (e.g., with a new base backup) after upgrading.

- **Truncate `pg_multixact` contents during WAL replay** (Andres Freund)

  This avoids ever-increasing disk space consumption in standby servers.

- **Fix race condition in GIN index posting tree page deletion** (Heikki Linnakangas)

  This could lead to transient wrong answers or query failures.

- **Avoid flattening a subquery whose `SELECT` list contains a volatile function wrapped inside a sub-`SELECT`** (Tom Lane)

  This avoids unexpected results due to extra evaluations of the volatile function.

- **Fix planner’s processing of non-simple-variable subquery outputs nested within outer joins** (Tom Lane)

  This error could lead to incorrect plans for queries involving multiple levels of subqueries within `JOIN` syntax.

- **Fix incorrect generation of optimized MIN()/MAX() plans for inheritance trees** (Tom Lane)

  The planner could fail in cases where the MIN()/MAX() argument was an expression rather than a simple variable.

- **Fix premature deletion of temporary files** (Andres Freund)

- **Fix possible read past end of memory in rule printing** (Peter Eisentraut)

- **Fix array slicing of `int2vector` and `oidvector` values** (Tom Lane)

  Expressions of this kind are now implicitly promoted to regular `int2` or `oid` arrays.

- **Fix incorrect behaviors when using a SQL-standard, simple GMT offset timezone** (Tom Lane)

  In some cases, the system would use the simple GMT offset value when it should have used the regular timezone setting that had prevailed before the simple offset was selected. This change also causes the `timeofday` function to honor the simple GMT offset zone.

- **Prevent possible misbehavior when logging translations of Windows error codes** (Tom Lane)

- **Properly quote generated command lines in `pg_ctl`** (Naoya Anzai and Tom Lane)

  This fix applies only to Windows.

- **Fix `pg_dumpall` to work when a source database sets `default_transaction_read_only` via `ALTER DATABASE SET`** (Kevin Grittner)

  Previously, the generated script would fail during restore.
Appendix E. Release Notes

- Make ecpg search for quoted cursor names case-sensitively (Zoltán Bőszörényi)
- Fix ecpg’s processing of lists of variables declared varchar (Zoltán Bőszörényi)
- Make contrib/lo defend against incorrect trigger definitions (Marc Cousin)
- Update time zone data files to tzdata release 2013h for DST law changes in Argentina, Brazil, Jordan, Libya, Liechtenstein, Morocco, and Palestine. Also, new timezone abbreviations WIB, WIT, WITA for Indonesia.

E.100. Release 9.1.10

Release date: 2013-10-10

This release contains a variety of fixes from 9.1.9. For information about new features in the 9.1 major release, see Section E.110.

E.100.1. Migration to Version 9.1.10

A dump/restore is not required for those running 9.1.X.
However, if you are upgrading from a version earlier than 9.1.9, see Section E.101.

E.100.2. Changes

- Prevent corruption of multi-byte characters when attempting to case-fold identifiers (Andrew Dunstan)
  PostgreSQL case-folds non-ASCII characters only when using a single-byte server encoding.
- Fix checkpoint memory leak in background writer when wal_level = hot_standby (Naoya Anzai)
- Fix memory leak caused by lo_open() failure (Heikki Linnakangas)
- Fix memory overcommit bug when work_mem is using more than 24GB of memory (Stephen Frost)
- Serializable snapshot fixes (Kevin Grittner, Heikki Linnakangas)
- Fix deadlock bug in libpq when using SSL (Stephen Frost)
- Fix possible SSL state corruption in threaded libpq applications (Nick Phillips, Stephen Frost)
- Properly compute row estimates for boolean columns containing many NULL values (Andrew Gierth)
  Previously tests like col IS NOT TRUE and col IS NOT FALSE did not properly factor in NULL values when estimating plan costs.
- Prevent pushing down WHERE clauses into unsafe UNION/INTERSECT subqueries (Tom Lane)
  Subqueries of a UNION or INTERSECT that contain set-returning functions or volatile functions in their SELECT lists could be improperly optimized, leading to run-time errors or incorrect query results.
- Fix rare case of “failed to locate grouping columns” planner failure (Tom Lane)
- Fix pg_dump of foreign tables with dropped columns (Andrew Dunstan)
Previously such cases could cause a pg_upgrade error.

- Reorder pg_dump processing of extension-related rules and event triggers (Joe Conway)
- Force dumping of extension tables if specified by \texttt{pg_dump -t} or \texttt{-n} (Joe Conway)
- Improve view dumping code's handling of dropped columns in referenced tables (Tom Lane)
- Fix \texttt{pg_restore -l} with the directory archive to display the correct format name (Fujii Masao)
- Properly record index comments created using \texttt{UNIQUE} and \texttt{PRIMARY} \texttt{KEY} syntax (Andres Freund)
  This fixes a parallel pg_restore failure.
- Properly guarantee transmission of WAL files before clean switchover (Fujii Masao)
  Previously, the streaming replication connection might close before all WAL files had been replayed
  on the standby.
- Fix WAL segment timeline handling during recovery (Mitsumasa Kondo, Heikki Linnakangas)
  WAL file recycling during standby recovery could lead to premature recovery completion, resulting
  in data loss.
- Fix \texttt{REINDEX} \texttt{TABLE} and \texttt{REINDEX} \texttt{DATABASE} to properly revalidate constraints and mark invalid
  dated indexes as valid (Noah Misch)
  \texttt{REINDEX} \texttt{INDEX} has always worked properly.
- Fix possible deadlock during concurrent \texttt{CREATE} \texttt{INDEX} \texttt{CONCURRENTLY} operations (Tom Lane)
- Fix \texttt{regexp_matches()} handling of zero-length matches (Jeevan Chalke)
  Previously, zero-length matches like \texttt{'^'} could return too many matches.
- Fix crash for overly-complex regular expressions (Heikki Linnakangas)
- Fix regular expression match failures for back references combined with non-greedy quantifiers
  (Jeevan Chalke)
- Prevent \texttt{CREATE FUNCTION} from checking \texttt{SET} variables unless function body checking is enabled
  (Tom Lane)
- Allow \texttt{ALTER DEFAULT PRIVILEGES} to operate on schemas without requiring \texttt{CREATE} permission
  (Tom Lane)
- Loosen restriction on keywords used in queries (Tom Lane)
  Specifically, lessen keyword restrictions for role names, language names, \texttt{EXPLAIN} and \texttt{COPY}
  options, and \texttt{SET} values. This allows \texttt{COPY ... (FORMAT BINARY)} to work as expected; previously
  \texttt{BINARY} needed to be quoted.
- Fix \texttt{pgp_pub_decrypt()} so it works for secret keys with passwords (Marko Kreen)
- Make \texttt{pg_upgrade} use \texttt{pg_dump --quote-all-identifiers} to avoid problems with keyword
  changes between releases (Tom Lane)
- Remove rare inaccurate warning during vacuum of index-less tables (Heikki Linnakangas)
- Ensure that \texttt{VACUUM ANALYZE} still runs the \texttt{ANALYZE} phase if its attempt to truncate the file is
  cancelled due to lock conflicts (Kevin Grittner)
- Avoid possible failure when performing transaction control commands (e.g \texttt{ROLLBACK}) in prepared
  queries (Tom Lane)
- Ensure that floating-point data input accepts standard spellings of “infinity” on all platforms (Tom
  Lane)
The C99 standard says that allowable spellings are `inf`, `+inf`, `-inf`, `infinity`, `+infinity`, and `-infinity`. Make sure we recognize these even if the platform’s `strtod` function doesn’t.

- Expand ability to compare rows to records and arrays (Rafal Rzepecki, Tom Lane)
- Update time zone data files to tzdata release 2013d for DST law changes in Israel, Morocco, Palestine, and Paraguay. Also, historical zone data corrections for Macquarie Island.

### E.101. Release 9.1.9

**Release date:** 2013-04-04

This release contains a variety of fixes from 9.1.8. For information about new features in the 9.1 major release, see Section E.110.

#### E.101.1. Migration to Version 9.1.9

A dump/restore is not required for those running 9.1.X. However, this release corrects several errors in management of GiST indexes. After installing this update, it is advisable to `REINDEX` any GiST indexes that meet one or more of the conditions described below.

Also, if you are upgrading from a version earlier than 9.1.6, see Section E.104.

#### E.101.2. Changes

- Fix insecure parsing of server command-line switches (Mitsumasa Kondo, Kyotaro Horiguchi)
  A connection request containing a database name that begins with “-” could be crafted to damage or destroy files within the server’s data directory, even if the request is eventually rejected. (CVE-2013-1899)

- Reset OpenSSL randomness state in each postmaster child process (Marko Kreen)
  This avoids a scenario wherein random numbers generated by `contrib/pgcrypto` functions might be relatively easy for another database user to guess. The risk is only significant when the postmaster is configured with `ssl = on` but most connections don’t use SSL encryption. (CVE-2013-1900)

- Make `REPLICATION` privilege checks test current user not authenticated user (Noah Misch)
  An unprivileged database user could exploit this mistake to call `pg_start_backup()` or `pg_stop_backup()`, thus possibly interfering with creation of routine backups. (CVE-2013-1901)

- Fix GiST indexes to not use “fuzzy” geometric comparisons when it’s not appropriate to do so (Alexander Korotkov)
  The core geometric types perform comparisons using “fuzzy” equality, but `gist_box_same` must do exact comparisons, else GiST indexes using it might become inconsistent. After installing this update, users should `REINDEX` any GiST indexes on `box`, `polygon`, `circle`, or `point` columns, since all of these use `gist_box_same`. 

2507
Appendix E. Release Notes

- Fix erroneous range-union and penalty logic in GiST indexes that use contrib/btree_gist for variable-width data types, that is text, bytea, bit, and numeric columns (Tom Lane)
  These errors could result in inconsistent indexes in which some keys that are present would not be found by searches, and also in useless index bloat. Users are advised to \texttt{REINDEX} such indexes after installing this update.

- Fix bugs in GiST page splitting code for multi-column indexes (Tom Lane)
  These errors could result in inconsistent indexes in which some keys that are present would not be found by searches, and also in indexes that are unnecessarily inefficient to search. Users are advised to \texttt{REINDEX} multi-column GiST indexes after installing this update.

- Fix \texttt{gist\_point\_consistent} to handle fuzziness consistently (Alexander Korotkov)
  Index scans on GiST indexes on \texttt{point} columns would sometimes yield results different from a sequential scan, because \texttt{gist\_point\_consistent} disagreed with the underlying operator code about whether to do comparisons exactly or fuzzily.

- Fix buffer leak in WAL replay (Heikki Linnakangas)
  This bug could result in “incorrect local pin count” errors during replay, making recovery impossible.

- Fix infinite-loop risk in regular expression compilation (Tom Lane, Don Porter)

- Fix potential null-pointer dereference in regular expression compilation (Tom Lane)

- Fix \texttt{to\_char()} to use ASCII-only case-folding rules where appropriate (Tom Lane)
  This fixes misbehavior of some template patterns that should be locale-independent, but mishandled “i” and “ı” in Turkish locales.

- Fix unwanted rejection of timestamp 1999-12-31 24:00:00 (Tom Lane)

- Fix logic error when a single transaction does \texttt{UNLISTEN} then \texttt{LISTEN} (Tom Lane)
  The session wound up not listening for notify events at all, though it surely should listen in this case.

- Fix possible planner crash after columns have been added to a view that’s depended on by another view (Tom Lane)

- Remove useless “picksplit doesn’t support secondary split” log messages (Josh Hansen, Tom Lane)
  This message seems to have been added in expectation of code that was never written, and probably never will be, since GiST’s default handling of secondary splits is actually pretty good. So stop nagging end users about it.

- Fix possible failure to send a session’s last few transaction commit/abort counts to the statistics collector (Tom Lane)

- Eliminate memory leaks in PL/Perl’s \texttt{spi\_prepare()} function (Alex Hunsaker, Tom Lane)

- Fix \texttt{pg\_dumpall} to handle database names containing “=” correctly (Heikki Linnakangas)

- Avoid crash in \texttt{pg\_dump} when an incorrect connection string is given (Heikki Linnakangas)

- Ignore invalid indexes in \texttt{pg\_dump} and \texttt{pg\_upgrade} (Michael Paquier, Bruce Momjian)
Dumping invalid indexes can cause problems at restore time, for example if the reason the index creation failed was because it tried to enforce a uniqueness condition not satisfied by the table’s data. Also, if the index creation is in fact still in progress, it seems reasonable to consider it to be an uncommitted DDL change, which pg_dump wouldn’t be expected to dump anyway. pg_upgrade now also skips invalid indexes rather than failing.

- In pg_basebackup, include only the current server version’s subdirectory when backing up a tablespace (Heikki Linnakangas)
- Add a server version check in pg_basebackup and pg_receivexlog, so they fail cleanly with version combinations that won’t work (Heikki Linnakangas)
- Fix contrib/pg_trgm’s similarity() function to return zero for trigram-less strings (Tom Lane)
  
  Previously it returned NaN due to internal division by zero.
- Update time zone data files to tzdata release 2013b for DST law changes in Chile, Haiti, Morocco, Paraguay, and some Russian areas. Also, historical zone data corrections for numerous places.
  
  Also, update the time zone abbreviation files for recent changes in Russia and elsewhere: CHOT, GET, IRKT, KGT, KRAT, MAST, MAWT, MSK, NOVT, TKT, VLAT, WST, YAKT, YEKT now follow their current meanings, and VOLT (Europe/Volgograd) and MIST (Antarctica/Macquarie) are added to the default abbreviations list.

### E.102. Release 9.1.8

**Release date:** 2013-02-07

This release contains a variety of fixes from 9.1.7. For information about new features in the 9.1 major release, see Section E.110.

### E.102.1. Migration to Version 9.1.8

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.6, see Section E.104.

### E.102.2. Changes

- Prevent execution of `enum_recv` from SQL (Tom Lane)

  The function was misdeclared, allowing a simple SQL command to crash the server. In principle an attacker might be able to use it to examine the contents of server memory. Our thanks to Sumit Soni (via Secunia SVCRP) for reporting this issue. (CVE-2013-0255)

- Fix multiple problems in detection of when a consistent database state has been reached during WAL replay (Fujii Masao, Heikki Linnakangas, Simon Riggs, Andres Freund)

- Update minimum recovery point when truncating a relation file (Heikki Linnakangas)

  Once data has been discarded, it’s no longer safe to stop recovery at an earlier point in the timeline.

- Fix recycling of WAL segments after changing recovery target timeline (Heikki Linnakangas)
Appendix E. Release Notes

- Fix missing cancellations in hot standby mode (Noah Misch, Simon Riggs)
  The need to cancel conflicting hot-standby queries would sometimes be missed, allowing those queries to see inconsistent data.
- Prevent recovery pause feature from pausing before users can connect (Tom Lane)
- Fix SQL grammar to allow subcribing or field selection from a sub-SELECT result (Tom Lane)
- Fix performance problems with autovacuum truncation in busy workloads (Jan Wieck)
  Truncation of empty pages at the end of a table requires exclusive lock, but autovacuum was coded to fail (and release the table lock) when there are conflicting lock requests. Under load, it is easily possible that truncation would never occur, resulting in table bloat. Fix by performing a partial truncation, releasing the lock, then attempting to re-acquire the lock and continue. This fix also greatly reduces the average time before autovacuum releases the lock after a conflicting request arrives.
- Protect against race conditions when scanning pg_tablespace (Stephen Frost, Tom Lane)
- Prevent DROP OWNED from trying to drop whole databases or tablespaces (Álvaro Herrera)
  For safety, ownership of these objects must be reassigned, not dropped.
- Fix error in vacuum_freeze_table_age implementation (Andres Freund)
  In installations that have existed for more than vacuum_freeze_min_age transactions, this mistake prevented autovacuum from using partial-table scans, so that a full-table scan would always happen instead.
- Prevent misbehavior when a RowExpr or XmlExpr is parse-analyzed twice (Andres Freund, Tom Lane)
  This mistake could be user-visible in contexts such as CREATE TABLE LIKE INCLUDING INDEXES.
- Improve defenses against integer overflow in hashtable sizing calculations (Jeff Davis)
- Fix failure to ignore leftover temporary tables after a server crash (Tom Lane)
- Reject out-of-range dates in to_date() (Hitoshi Harada)
- Fix pg_extension_config_dump() to handle extension-update cases properly (Tom Lane)
  This function will now replace any existing entry for the target table, making it usable in extension update scripts.
- Fix PL/Python’s handling of functions used as triggers on multiple tables (Andres Freund)
- Ensure that non-ASCII prompt strings are translated to the correct code page on Windows (Alexander Law, Noah Misch)
  This bug affected psql and some other client programs.
- Fix possible crash in psql’s \? command when not connected to a database (Meng Qingzhong)
- Fix possible error if a relation file is removed while pg_basebackup is running (Heikki Linnakan-gas)
- Make pg_dump exclude data of unlogged tables when running on a hot-standby server (Magnus Hagander)
  This would fail anyway because the data is not available on the standby server, so it seems most convenient to assume --no-unlogged-table-data automatically.
Appendix E. Release Notes

• Fix pg_upgrade to deal with invalid indexes safely (Bruce Momjian)
• Fix one-byte buffer overrun in libpq's PQprintTuples (Xi Wang)
  This ancient function is not used anywhere by PostgreSQL itself, but it might still be used by some
  client code.
• Make ecpglib use translated messages properly (Chen Huajun)
• Properly install ecpg_compat and pgtypes libraries on MSVC (Jiang Guiqing)
• Include our version of isninf() in libecpg if it's not provided by the system (Jiang Guiqing)
• Rearrange configure's tests for supplied functions so it is not fooled by bogus exports from
  libedit/libreadline (Christoph Berg)
• Ensure Windows build number increases over time (Magnus Hagander)
• Make pgxs build executables with the right .exe suffix when cross-compiling for Windows (Zoltan
  Boszormenyi)
• Add new timezone abbreviation FET (Tom Lane)
  This is now used in some eastern-European time zones.

E.103. Release 9.1.7

Release date: 2012-12-06

This release contains a variety of fixes from 9.1.6. For information about new features in the 9.1 major
release, see Section E.110.

E.103.1. Migration to Version 9.1.7

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.6, see Section E.104.

E.103.2. Changes

• Fix multiple bugs associated with CREATE INDEX CONCURRENTLY (Andres Freund, Tom Lane)

  Fix CREATE INDEX CONCURRENTLY to use in-place updates when changing the state of an index’s
  pg_index row. This prevents race conditions that could cause concurrent sessions to miss updating
  the target index, thus resulting in corrupt concurrently-created indexes.

  Also, fix various other operations to ensure that they ignore invalid indexes resulting from a failed
  CREATE INDEX CONCURRENTLY command. The most important of these is VACUUM, because an
  auto-vacuum could easily be launched on the table before corrective action can be taken to fix or
  remove the invalid index.

• Fix buffer locking during WAL replay (Tom Lane)

  The WAL replay code was insufficiently careful about locking buffers when replaying WAL records
  that affect more than one page. This could result in hot standby queries transiently seeing inconsis-
  tent states, resulting in wrong answers or unexpected failures.
Appendix E. Release Notes

- Fix an error in WAL generation logic for GIN indexes (Tom Lane)
  This could result in index corruption, if a torn-page failure occurred.

- Properly remove startup process’s virtual XID lock when promoting a hot standby server to normal running (Simon Riggs)
  This oversight could prevent subsequent execution of certain operations such as `CREATE INDEX CONCURRENTLY`.

- Avoid bogus “out-of-sequence timeline ID” errors in standby mode (Heikki Linnakangas)

- Prevent the postmaster from launching new child processes after it’s received a shutdown signal (Tom Lane)
  This mistake could result in shutdown taking longer than it should, or even never completing at all without additional user action.

- Avoid corruption of internal hash tables when out of memory (Hitoshi Harada)

- Prevent file descriptors for dropped tables from being held open past transaction end (Tom Lane)
  This should reduce problems with long-since-dropped tables continuing to occupy disk space.

- Prevent database-wide crash and restart when a new child process is unable to create a pipe for its latch (Tom Lane)
  Although the new process must fail, there is no good reason to force a database-wide restart, so avoid that. This improves robustness when the kernel is nearly out of file descriptors.

- Fix planning of non-strict equivalence clauses above outer joins (Tom Lane)
  The planner could derive incorrect constraints from a clause equating a non-strict construct to something else, for example `WHERE COALESCE(foo, 0) = 0` when `foo` is coming from the nullable side of an outer join.

- Fix `SELECT DISTINCT with index-optimized MIN/MAX` on an inheritance tree (Tom Lane)
  The planner would fail with “failed to re-find MinMaxAggInfo record” given this combination of factors.

- Improve planner’s ability to prove exclusion constraints from equivalence classes (Tom Lane)

- Fix partial-row matching in hashed subplans to handle cross-type cases correctly (Tom Lane)
  This affects multicolumn NOT IN subplans, such as `WHERE (a, b) NOT IN (SELECT x, y FROM ...)` when for instance `b` and `y` are `int4` and `int8` respectively. This mistake led to wrong answers or crashes depending on the specific datatypes involved.

- Acquire buffer lock when re-fetching the old tuple for an AFTER ROW UPDATE/DELETE trigger (Andres Freund)
  In very unusual circumstances, this oversight could result in passing incorrect data to a trigger `WHEN` condition, or to the precheck logic for a foreign-key enforcement trigger. That could result in a crash, or in an incorrect decision about whether to fire the trigger.

- Fix `ALTER COLUMN TYPE` to handle inherited check constraints properly (Pavan Deolasee)
  This worked correctly in pre-8.4 releases, and now works correctly in 8.4 and later.

- Fix `ALTER EXTENSION SET SCHEMA`’s failure to move some subsidiary objects into the new schema (Álvaro Herrera, Dimitri Fontaine)

- Fix `REASSIGN OWNED` to handle grants on tablespaces (Álvaro Herrera)

- Ignore incorrect `pg_attribute` entries for system columns for views (Tom Lane)
Views do not have any system columns. However, we forgot to remove such entries when converting a table to a view. That’s fixed properly for 9.3 and later, but in previous branches we need to defend against existing mis-converted views.

- Fix rule printing to dump `INSERT INTO table DEFAULT VALUES` correctly (Tom Lane)
- Guard against stack overflow when there are too many `UNION/INTERSECT/EXCEPT` clauses in a query (Tom Lane)
- Prevent platform-dependent failures when dividing the minimum possible integer value by -1 (Xi Wang, Tom Lane)
- Fix possible access past end of string in date parsing (Hitoshi Harada)
- Fix failure to advance XID epoch if XID wraparound happens during a checkpoint and `wal_level` is `hot_standby` (Tom Lane, Andres Freund)
  
  While this mistake had no particular impact on PostgreSQL itself, it was bad for applications that rely on `txid_current()` and related functions: the TXID value would appear to go backwards.

- Fix display of `pg_stat_replication.sync_state` at a page boundary (Kyotaro Horiguchi)
- Produce an understandable error message if the length of the path name for a Unix-domain socket exceeds the platform-specific limit (Tom Lane, Andrew Dunstan)
  
  Formerly, this would result in something quite unhelpful, such as “Non-recoverable failure in name resolution”.

- Fix memory leaks when sending composite column values to the client (Tom Lane)
- Make `pg_ctl` more robust about reading the `postmaster.pid` file (Heikki Linnakangas)
  Fix race conditions and possible file descriptor leakage.
- Fix possible crash in `psql` if incorrectly-encoded data is presented and the `client_encoding` setting is a client-only encoding, such as SJIS (Jiang Guiqing)
- Make `pg_dump` dump `SEQUENCE SET` items in the data not pre-data section of the archive (Tom Lane)
  
  This change fixes dumping of sequences that are marked as extension configuration tables.

- Fix bugs in the `restore.sql` script emitted by `pg_dump` in `tar` output format (Tom Lane)
  
  The script would fail outright on tables whose names include upper-case characters. Also, make the script capable of restoring data in `--inserts` mode as well as the regular COPY mode.

- Fix `pg_restore` to accept POSIX-conformant `tar` files (Brian Weaver, Tom Lane)
  
  The original coding of `pg_dump`'s `tar` output mode produced files that are not fully conformant with the POSIX standard. This has been corrected for version 9.3. This patch updates previous branches so that they will accept both the incorrect and the corrected formats, in hopes of avoiding compatibility problems when 9.3 comes out.

- Fix `tar` files emitted by `pg_basebackup` to be POSIX conformant (Brian Weaver, Tom Lane)
- Fix `pg_resetxlog` to locate `postmaster.pid` correctly when given a relative path to the data directory (Tom Lane)
  
  This mistake could lead to `pg_resetxlog` not noticing that there is an active postmaster using the data directory.

- Fix `libpq`’s `lo_import()` and `lo_export()` functions to report file I/O errors properly (Tom Lane)

- Fix `ecpg`’s processing of nested structure pointer variables (Muhammad Usama)
Appendix E. Release Notes

- Fix ecpg's ecpg_get_data function to handle arrays properly (Michael Meskes)
- Make contrib/pageinspect's btree page inspection functions take buffer locks while examining pages (Tom Lane)
- Ensure that make install for an extension creates the extension installation directory (Cédric Villemain)
  Previously, this step was missed if MODULEDIR was set in the extension’s Makefile.
- Fix pgxs support for building loadable modules on AIX (Tom Lane)
  Building modules outside the original source tree didn’t work on AIX.
- Update time zone data files to tzdata release 2012j for DST law changes in Cuba, Israel, Jordan, Libya, Palestine, Western Samoa, and portions of Brazil.

E.104. Release 9.1.6

Release date: 2012-09-24
This release contains a variety of fixes from 9.1.5. For information about new features in the 9.1 major release, see Section E.110.

E.104.1. Migration to Version 9.1.6

A dump/restore is not required for those running 9.1.X.
However, you may need to perform REINDEX operations to recover from the effects of the data corruption bug described in the first changelog item below.
Also, if you are upgrading from a version earlier than 9.1.4, see Section E.106.

E.104.2. Changes

- Fix persistence marking of shared buffers during WAL replay (Jeff Davis)
  This mistake can result in buffers not being written out during checkpoints, resulting in data corruption if the server later crashes without ever having written those buffers. Corruption can occur on any server following crash recovery, but it is significantly more likely to occur on standby slave servers since those perform much more WAL replay. There is a low probability of corruption of btree and GIN indexes. There is a much higher probability of corruption of table “visibility maps”. Fortunately, visibility maps are non-critical data in 9.1, so the worst consequence of such corruption in 9.1 installations is transient inefficiency of vacuuming. Table data proper cannot be corrupted by this bug.

  While no index corruption due to this bug is known to have occurred in the field, as a precautionary measure it is recommended that production installations REINDEX all btree and GIN indexes at a convenient time after upgrading to 9.1.6.

  Also, if you intend to do an in-place upgrade to 9.2.X, before doing so it is recommended to perform a VACUUM of all tables while having vacuum_freeze_table_age set to zero. This will ensure that any lingering wrong data in the visibility maps is corrected before 9.2.X can depend on
it, vacuum_cost_delay can be adjusted to reduce the performance impact of vacuuming, while causing it to take longer to finish.

- Fix planner’s assignment of executor parameters, and fix executor’s rescan logic for CTE plan nodes (Tom Lane)

  These errors could result in wrong answers from queries that scan the same WITH subquery multiple times.

- Fix misbehavior when default_transaction_isolation is set to serializable (Kevin Grittner, Tom Lane, Heikki Linnakangas)

  Symptoms include crashes at process start on Windows, and crashes in hot standby operation.

- Improve selectivity estimation for text search queries involving prefixes, i.e. word:* patterns (Tom Lane)

- Improve page-splitting decisions in GiST indexes (Alexander Korotkov, Robert Haas, Tom Lane)

  Multi-column GiST indexes might suffer unexpected bloat due to this error.

- Fix cascading privilege revoke to stop if privileges are still held (Tom Lane)

  If we revoke a grant option from some role $X$, but $X$ still holds that option via a grant from someone else, we should not recursively revoke the corresponding privilege from role(s) $Y$ that $X$ had granted it to.

- Disallow extensions from containing the schema they are assigned to (Thom Brown)

  This situation creates circular dependencies that confuse pg_dump and probably other things. It’s confusing for humans too, so disallow it.

- Improve error messages for Hot Standby misconfiguration errors (Gurjeet Singh)

- Make configure probe for mbstowcs_l (Tom Lane)

  This fixes build failures on some versions of AIX.

- Fix handling of SIGFPE when PL/Perl is in use (Andres Freund)

  Perl resets the process’s SIGFPE handler to SIG_IGN, which could result in crashes later on. Restore the normal Postgres signal handler after initializing PL/Perl.

- Prevent PL/Perl from crashing if a recursive PL/Perl function is redefined while being executed (Tom Lane)

- Work around possible misoptimization in PL/Perl (Tom Lane)

  Some Linux distributions contain an incorrect version of pthread.h that results in incorrect compiled code in PL/Perl, leading to crashes if a PL/Perl function calls another one that throws an error.

- Fix bugs in contrib/pg_trgm’s LIKE pattern analysis code (Fujii Masao)

  LIKE queries using a trigram index could produce wrong results if the pattern contained LIKE escape characters.

- Fix pg_upgrade’s handling of line endings on Windows (Andrew Dunstan)

  Previously, pg_upgrade might add or remove carriage returns in places such as function bodies.

- On Windows, make pg_upgrade use backslash path separators in the scripts it emits (Andrew Dunstan)

- Remove unnecessary dependency on pg_config from pg_upgrade (Peter Eisentraut)

- Update time zone data files to tzdata release 2012f for DST law changes in Fiji
E.105. Release 9.1.5

Release date: 2012-08-17

This release contains a variety of fixes from 9.1.4. For information about new features in the 9.1 major release, see Section E.110.

E.105.1. Migration to Version 9.1.5

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.4, see Section E.106.

E.105.2. Changes

- Prevent access to external files/URLs via XML entity references (Noah Misch, Tom Lane)
  
  `xml_parse()` would attempt to fetch external files or URLs as needed to resolve DTD and entity references in an XML value, thus allowing unprivileged database users to attempt to fetch data with the privileges of the database server. While the external data wouldn’t get returned directly to the user, portions of it could be exposed in error messages if the data didn’t parse as valid XML; and in any case the mere ability to check existence of a file might be useful to an attacker. (CVE-2012-3489)

- Prevent access to external files/URLs via `contrib/xml2′s `xslt_process()` (Peter Eisentraut)
  
  `libxslt` offers the ability to read and write both files and URLs through stylesheet commands, thus allowing unprivileged database users to both read and write data with the privileges of the database server. Disable that through proper use of `libxslt`'s security options. (CVE-2012-3488)

  Also, remove `xslt_process()`’s ability to fetch documents and stylesheets from external files/URLs. While this was a documented “feature”, it was long regarded as a bad idea. The fix for CVE-2012-3489 broke that capability, and rather than expend effort on trying to fix it, we’re just going to summarily remove it.

- Prevent too-early recycling of btree index pages (Noah Misch)
  
  When we allowed read-only transactions to skip assigning XIDs, we introduced the possibility that a deleted btree page could be recycled while a read-only transaction was still in flight to it. This would result in incorrect index search results. The probability of such an error occurring in the field seems very low because of the timing requirements, but nonetheless it should be fixed.

- Fix crash-safety bug with newly-created-or-reset sequences (Tom Lane)
  
  If `ALTER SEQUENCE` was executed on a freshly created or reset sequence, and then precisely one `nextval()` call was made on it, and then the server crashed, WAL replay would restore the sequence to a state in which it appeared that no `nextval()` had been done, thus allowing the first sequence value to be returned again by the next `nextval()` call. In particular this could manifest for serial columns, since creation of a serial column’s sequence includes an `ALTER SEQUENCE` OWNED BY step.

- Fix race condition in `enum`-type value comparisons (Robert Haas, Tom Lane)
  
  Comparisons could fail when encountering an enum value added since the current query started.

- Fix `txid_current()` to report the correct epoch when not in hot standby (Heikki Linnakangas)
  
  This fixes a regression introduced in the previous minor release.
Appendix E. Release Notes

• Prevent selection of unsuitable replication connections as the synchronous standby (Fujii Masao)
  The master might improperly choose pseudo-servers such as pg_receivexlog or pg_basebackup as
  the synchronous standby, and then wait indefinitely for them.
• Fix bug in startup of Hot Standby when a master transaction has many subtransactions (Andres
  Freund)
  This mistake led to failures reported as “out-of-order XID insertion in KnownAssignedXids”.
• Ensure the backup_label file is fsync’d after pg_start_backup() (Dave Kerr)
• Fix timeout handling in walsender processes (Tom Lane)
  WAL sender background processes neglected to establish a SIGALRM handler, meaning they
  would wait forever in some corner cases where a timeout ought to happen.
• Wake walsenders after each background flush by walwriter (Andres Freund, Simon Riggs)
  This greatly reduces replication delay when the workload contains only asynchronously-committed
  transactions.
• Fix LISTEN/NOTIFY to cope better with I/O problems, such as out of disk space (Tom Lane)
  After a write failure, all subsequent attempts to send more NOTIFY messages would fail with mes-
  sages like “Could not read from file "pg_notify/nnnn" at offset nnnnn: Success”.
• Only allow autovacuum to be auto-canceled by a directly blocked process (Tom Lane)
  The original coding could allow inconsistent behavior in some cases; in particular, an autovacuum
  could get canceled after less than deadlock_timeout grace period.
• Improve logging of autovacuum cancels (Robert Haas)
• Fix log collector so that log_truncate_on_rotation works during the very first log rotation
  after server start (Tom Lane)
• Fix WITH attached to a nested set operation (UNION/INTERSECT/EXCEPT) (Tom Lane)
• Ensure that a whole-row reference to a subquery doesn’t include any extra GROUP BY or ORDER
  BY columns (Tom Lane)
• Fix dependencies generated during ALTER TABLE ... ADD CONSTRAINT USING INDEX (Tom
  Lane)
  This command left behind a redundant pg_depend entry for the index, which could confuse later
  operations, notably ALTER TABLE ... ALTER COLUMN TYPE on one of the indexed columns.
• Fix REASSIGN OWNED to work on extensions (Alvaro Herrera)
•Disallow copying whole-row references in CHECK constraints and index definitions during CREATE
  TABLE (Tom Lane)
  This situation can arise in CREATE TABLE with LIKE or INHERITS. The copied whole-row variable
  was incorrectly labeled with the row type of the original table not the new one. Rejecting the case
  seems reasonable for LIKE, since the row types might well diverge later. For INHERITS we should
  ideally allow it, with an implicit coercion to the parent table’s row type; but that will require more
  work than seems safe to back-patch.
• Fix memory leak in ARRAY(SELECT ...) subqueries (Heikki Linnakangas, Tom Lane)
• Fix planner to pass correct collation to operator selectivity estimators (Tom Lane)
  This was not previously required by any core selectivity estimation function, but third-party code
  might need it.
• Fix extraction of common prefixes from regular expressions (Tom Lane)
The code could get confused by quantified parenthesized subexpressions, such as `^(foo)?bar`. This would lead to incorrect index optimization of searches for such patterns.

- Fix bugs with parsing signed `hh:mm` and `hh:mm:ss` fields in `interval` constants (Amit Kapila, Tom Lane)
- Fix `pg_dump` to better handle views containing partial `GROUP BY` lists (Tom Lane)
  A view that lists only a primary key column in `GROUP BY`, but uses other table columns as if they were grouped, gets marked as depending on the primary key. Improper handling of such primary key dependencies in `pg_dump` resulted in poorly-ordered dumps, which at best would be inefficient to restore and at worst could result in outright failure of a parallel `pg_restore` run.
- In PL/Perl, avoid setting UTF8 flag when in `SQL_ASCII` encoding (Alex Hunsaker, Kyotaro Horiguchi, Alvaro Herrera)
- Use Postgres’ encoding conversion functions, not Python’s, when converting a Python Unicode string to the server encoding in PL/Python (Jan Urbanski)
  This avoids some corner-case problems, notably that Python doesn’t support all the encodings Postgres does. A notable functional change is that if the server encoding is `SQL_ASCII`, you will get the UTF-8 representation of the string; formerly, any non-ASCII characters in the string would result in an error.
- Fix mapping of PostgreSQL encodings to Python encodings in PL/Python (Jan Urbanski)
- Report errors properly in `contrib/xml2`'s `xslt_process()` (Tom Lane)
- Update time zone data files to tzdata release 2012e for DST law changes in Morocco and Tokelau

---

**E.106. Release 9.1.4**

**Release date:** 2012-06-04

This release contains a variety of fixes from 9.1.3. For information about new features in the 9.1 major release, see Section E.110.

**E.106.1. Migration to Version 9.1.4**

A dump/restore is not required for those running 9.1.X.

However, if you use the `citext` data type, and you upgraded from a previous major release by running `pg_upgrade`, you should run `CREATE EXTENSION citext FROM unpackaged` to avoid collation-related failures in `citext` operations. The same is necessary if you restore a dump from a pre-9.1 database that contains an instance of the `citext` data type. If you’ve already run the `CREATE EXTENSION` command before upgrading to 9.1.4, you will instead need to do manual catalog updates as explained in the third changelog item below.

Also, if you are upgrading from a version earlier than 9.1.2, see Section E.108.

**E.106.2. Changes**

- Fix incorrect password transformation in `contrib/pgcrypto`'s `DES crypt()` function (Solar Designer)
Appendix E. Release Notes

If a password string contained the byte value \(0x80\), the remainder of the password was ignored, causing the password to be much weaker than it appeared. With this fix, the rest of the string is properly included in the DES hash. Any stored password values that are affected by this bug will thus no longer match, so the stored values may need to be updated. (CVE-2012-2143)

- Ignore `SECURITY DEFINER` and `SET` attributes for a procedural language’s call handler (Tom Lane)

  Applying such attributes to a call handler could crash the server. (CVE-2012-2655)

- Make contrib/citext’s upgrade script fix collations of `citext` arrays and domains over `citext` (Tom Lane)

  Release 9.1.2 provided a fix for collations of `citext` columns and indexes in databases upgraded or reloaded from pre-9.1 installations, but that fix was incomplete: it neglected to handle arrays and domains over `citext`. This release extends the module’s upgrade script to handle these cases. As before, if you have already run the upgrade script, you’ll need to run the collation update commands by hand instead. See the 9.1.2 release notes for more information about doing this.

- Allow numeric timezone offsets in `timestamp` input to be up to 16 hours away from UTC (Tom Lane)

  Some historical time zones have offsets larger than 15 hours, the previous limit. This could result in dumped data values being rejected during reload.

- Fix timestamp conversion to cope when the given time is exactly the last DST transition time for the current timezone (Tom Lane)

  This oversight has been there a long time, but was not noticed previously because most DST-using zones are presumed to have an indefinite sequence of future DST transitions.

- Fix `text` to `name` and `char` to `name` casts to perform string truncation correctly in multibyte encodings (Karl Schnaitter)

- Fix memory copying bug in `to_tsquery()` (Heikki Linnakangas)

- Ensure `txid_current()` reports the correct epoch when executed in hot standby (Simon Riggs)

- Fix planner’s handling of outer `PlaceHolderVars` within subqueries (Tom Lane)

  This bug concerns sub-SELECTs that reference variables coming from the nullable side of an outer join of the surrounding query. In 9.1, queries affected by this bug would fail with “ERROR: Upper-level PlaceHolderVar found where not expected”. But in 9.0 and 8.4, you’d silently get possibly-wrong answers, since the value transmitted into the subquery wouldn’t go to null when it should.

- Fix planning of `UNION ALL` subqueries with output columns that are not simple variables (Tom Lane)

  Planning of such cases got noticeably worse in 9.1 as a result of a misguided fix for “MergeAppend child’s targetlist doesn’t match MergeAppend” errors. Revert that fix and do it another way.

- Fix slow session startup when `pg_attribute` is very large (Tom Lane)

  If `pg_attribute` exceeds one-fourth of `shared_buffers`, cache rebuilding code that is sometimes needed during session start would trigger the synchronized-scan logic, causing it to take many times longer than normal. The problem was particularly acute if many new sessions were starting at once.

- Ensure sequential scans check for query cancel reasonably often (Merlin Moncure)

  A scan encountering many consecutive pages that contain no live tuples would not respond to interrupts meanwhile.
• Ensure the Windows implementation of PGSemaphoreLock() clears ImmediateInterruptOK before returning (Tom Lane)

This oversight meant that a query-cancel interrupt received later in the same query could be accepted at an unsafe time, with unpredictable but not good consequences.

• Show whole-row variables safely when printing views or rules (Abbas Butt, Tom Lane)

Corner cases involving ambiguous names (that is, the name could be either a table or column name of the query) were printed in an ambiguous way, risking that the view or rule would be interpreted differently after dump and reload. Avoid the ambiguous case by attaching a no-op cast.

• Fix COPY FROM to properly handle null marker strings that correspond to invalid encoding (Tom Lane)

A null marker string such as E’\0’ should work, and did work in the past, but the case got broken in 8.4.

• Fix EXPLAIN VERBOSE for writable CTEs containing RETURNING clauses (Tom Lane)

• Fix PREPARE TRANSACTION to work correctly in the presence of advisory locks (Tom Lane)

Historically, PREPARE TRANSACTION has simply ignored any session-level advisory locks the session holds, but this case was accidentally broken in 9.1.

• Fix truncation of unlogged tables (Robert Haas)

• Ignore missing schemas during non-interactive assignments of search_path (Tom Lane)

This re-aligns 9.1’s behavior with that of older branches. Previously 9.1 would throw an error for nonexistent schemas mentioned in search_path settings obtained from places such as ALTER DATABASE SET.

• Fix bugs with temporary or transient tables used in extension scripts (Tom Lane)

This includes cases such as a rewriting ALTER TABLE within an extension update script, since that uses a transient table behind the scenes.

• Ensure autovacuum worker processes perform stack depth checking properly (Heikki Linnakangas)

Previously, infinite recursion in a function invoked by auto-Analyze could crash worker processes.

• Fix logging collector to not lose log coherency under high load (Andrew Dunstan)

The collector previously could fail to reassemble large messages if it got too busy.

• Fix logging collector to ensure it will restart file rotation after receiving SIGHUP (Tom Lane)

• Fix “too many LWLocks taken” failure in GiST indexes (Heikki Linnakangas)

• Fix WAL replay logic for GIN indexes to not fail if the index was subsequently dropped (Tom Lane)

• Correctly detect SSI conflicts of prepared transactions after a crash (Dan Ports)

• Avoid synchronous replication delay when committing a transaction that only modified temporary tables (Heikki Linnakangas)

In such a case the transaction’s commit record need not be flushed to standby servers, but some of the code didn’t know that and waited for it to happen anyway.

• Fix error handling in pg_basebackup (Thomas Ogrisegg, Fujii Masao)

• Fix walsender to not go into a busy loop if connection is terminated (Fujii Masao)

• Fix memory leak in PL/pgSQL’s RETURN NEXT command (Joe Conway)
• Fix PL/pgSQL’s GET DIAGNOSTICS command when the target is the function’s first variable (Tom Lane)

• Ensure that PL/Perl package-qualifies the _TD variable (Alex Hunsaker)

  This bug caused trigger invocations to fail when they are nested within a function invocation that changes the current package.

• Fix PL/Python functions returning composite types to accept a string for their result value (Jan Urbanski)

  This case was accidentally broken by the 9.1 additions to allow a composite result value to be supplied in other formats, such as dictionaries.

• Fix potential access off the end of memory in psql’s expanded display (\x) mode (Peter Eisentraut)

• Fix several performance problems in pg_dump when the database contains many objects (Jeff Janes, Tom Lane)

  pg_dump could get very slow if the database contained many schemas, or if many objects are in dependency loops, or if there are many owned sequences.

• Fix memory and file descriptor leaks in pg_restore when reading a directory-format archive (Peter Eisentraut)

• Fix pg_upgrade for the case that a database stored in a non-default tablespace contains a table in the cluster’s default tablespace (Bruce Momjian)

• In ecpg, fix rare memory leaks and possible overwrite of one byte after the sqlca_t structure (Peter Eisentraut)

• Fix contrib/dblink’s dblink_exec() to not leak temporary database connections upon error (Tom Lane)

• Fix contrib/dblink to report the correct connection name in error messages (Kyotaro Horiguchi)

• Fix contrib/vacuumlo to use multiple transactions when dropping many large objects (Tim Lewis, Robert Haas, Tom Lane)

  This change avoids exceeding max_locks_per_transaction when many objects need to be dropped. The behavior can be adjusted with the new -l (limit) option.

• Update time zone data files to tzdata release 2012c for DST law changes in Antarctica, Armenia, Chile, Cuba, Falkland Islands, Gaza, Haiti, Hebron, Morocco, Syria, and Tokelau Islands; also historical corrections for Canada.

---

**E.107. Release 9.1.3**

**Release date:** 2012-02-27

This release contains a variety of fixes from 9.1.2. For information about new features in the 9.1 major release, see Section E.110.

**E.107.1. Migration to Version 9.1.3**

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.2, see Section E.108.
E.107.2. Changes

- **Require execute permission on the trigger function for CREATE TRIGGER (Robert Haas)**
  
  This missing check could allow another user to execute a trigger function with forged input data, by installing it on a table he owns. This is only of significance for trigger functions marked SECURITY DEFINER, since otherwise trigger functions run as the table owner anyway. (CVE-2012-0866)

- **Remove arbitrary limitation on length of common name in SSL certificates (Heikki Linnakangas)**
  
  Both libpq and the server truncated the common name extracted from an SSL certificate at 32 bytes. Normally this would cause nothing worse than an unexpected verification failure, but there are some rather-implausible scenarios in which it might allow one certificate holder to impersonate another. The victim would have to have a common name exactly 32 bytes long, and the attacker would have to persuade a trusted CA to issue a certificate in which the common name has that string as a prefix. Impersonating a server would also require some additional exploit to redirect client connections. (CVE-2012-0867)

- **Convert newlines to spaces in names written in pg_dump comments (Robert Haas)**
  
  pg_dump was incautious about sanitizing object names that are emitted within SQL comments in its output script. A name containing a newline would at least render the script syntactically incorrect. Maliciously crafted object names could present a SQL injection risk when the script is reloaded. (CVE-2012-0868)

- **Fix btree index corruption from insertions concurrent with vacuuming (Tom Lane)**
  
  An index page split caused by an insertion could sometimes cause a concurrently-running VACUUM to miss removing index entries that it should remove. After the corresponding table rows are removed, the dangling index entries would cause errors (such as “could not read block N in file ...”) or worse, silently wrong query results after unrelated rows are re-inserted at the now-free table locations. This bug has been present since release 8.2, but occurs so infrequently that it was not diagnosed until now. If you have reason to suspect that it has happened in your database, reindexing the affected index will fix things.

- **Fix transient zeroing of shared buffers during WAL replay (Tom Lane)**
  
  The replay logic would sometimes zero and refill a shared buffer, so that the contents were transiently invalid. In hot standby mode this can result in a query that’s executing in parallel seeing garbage data. Various symptoms could result from that, but the most common one seems to be “invalid memory alloc request size”.

- **Fix handling of data-modifying WITH subplans in READ COMMITTED rechecking (Tom Lane)**
  
  A WITH clause containing INSERT/UPDATE/DELETE would crash if the parent UPDATE or DELETE command needed to be re-evaluated at one or more rows due to concurrent updates in READ COMMITTED mode.

- **Fix corner case in SSI transaction cleanup (Dan Ports)**
  
  When finishing up a read-write serializable transaction, a crash could occur if all remaining active serializable transactions are read-only.

- **Fix postmaster to attempt restart after a hot-standby crash (Tom Lane)**
  
  A logic error caused the postmaster to terminate, rather than attempt to restart the cluster, if any backend process crashed while operating in hot standby mode.

- **Fix CLUSTER/VACUUM FULL handling of toast values owned by recently-updated rows (Tom Lane)**
Appendix E. Release Notes

This oversight could lead to “duplicate key value violates unique constraint” errors being reported against the toast table’s index during one of these commands.

- Update per-column permissions, not only per-table permissions, when changing table owner (Tom Lane)
  Failure to do this meant that any previously granted column permissions were still shown as having been granted by the old owner. This meant that neither the new owner nor a superuser could revoke the now-untraceable-to-table-owner permissions.

- Support foreign data wrappers and foreign servers in `REASSIGN OWNED` (Alvaro Herrera)
  This command failed with “unexpected classid” errors if it needed to change the ownership of any such objects.

- Allow non-existent values for some settings in `ALTER USER/DATABASE SET` (Heikki Linnakangas)
  Allow `default_text_search_config`, `default_tablespace`, and `temp_tablespaces` to be set to names that are not known. This is because they might be known in another database where the setting is intended to be used, or for the tablespace cases because the tablespace might not be created yet. The same issue was previously recognized for `search_path`, and these settings now act like that one.

- Fix “unsupported node type” error caused by `COLLATE` in an `INSERT` expression (Tom Lane)

- Avoid crashing when we have problems deleting table files post-commit (Tom Lane)
  Dropping a table should lead to deleting the underlying disk files only after the transaction commits. In event of failure then (for instance, because of wrong file permissions) the code is supposed to just emit a warning message and go on, since it’s too late to abort the transaction. This logic got broken as of release 8.4, causing such situations to result in a PANIC and an unrestartable database.

- Recover from errors occurring during WAL replay of `DROP TABLESPACE` (Tom Lane)
  Replay will attempt to remove the tablespace’s directories, but there are various reasons why this might fail (for example, incorrect ownership or permissions on those directories). Formerly the replay code would panic, rendering the database unrestartable without manual intervention. It seems better to log the problem and continue, since the only consequence of failure to remove the directories is some wasted disk space.

- Fix race condition in logging `AccessExclusiveLocks` for hot standby (Simon Riggs)

- Track the OID counter correctly during WAL replay, even when it wraps around (Tom Lane)
  Previously the OID counter would remain stuck at a high value until the system exited replay mode. The practical consequences of that are usually nil, but there are scenarios wherein a standby server that’s been promoted to master might take a long time to advance the OID counter to a reasonable value once values are needed.

- Prevent emitting misleading “consistent recovery state reached” log message at the beginning of crash recovery (Heikki Linnakangas)

- Fix initial value of `pg_stat_replication.replay_location` (Fujii Masao)
  Previously, the value shown would be wrong until at least one WAL record had been replayed.

- Fix regular expression back-references with `*` attached (Tom Lane)
  Rather than enforcing an exact string match, the code would effectively accept any string that satisfies the pattern sub-expression referenced by the back-reference symbol.
A similar problem still afflicts back-references that are embedded in a larger quantified expression, rather than being the immediate subject of the quantifier. This will be addressed in a future PostgreSQL release.

- Fix recently-introduced memory leak in processing of `inet/cidr` values (Heikki Linnakangas)

- Fix planner’s ability to push down index-expression restrictions through `UNION ALL` (Tom Lane)

- Fix planning of `WITH` clauses referenced in `UPDATE/DELETE` on an inherited table (Tom Lane)

- Fix GIN cost estimation to handle `column IN (...)` index conditions (Marti Raudsepp)

- Prevent assertion failure when exiting a session with an open, failed transaction (Tom Lane)

- Avoid double close of file handle in `syslogger` on Windows (MauMau)

- Fix I/O-conversion-related memory leaks in plpgsql (Andres Freund, Jan Urbanski, Tom Lane)

- Improve `pg_dump`’s handling of inherited table columns (Tom Lane)

- Fix `pg_restore`’s direct-to-database mode for INSERT-style table data (Tom Lane)

- Teach `pg_upgrade` to handle renaming of `plpython`’s shared library (Bruce Momjian)
Since `pg_upgrade` now takes care to preserve `pg_class` OIDs, there was no longer any reason for this restriction.

- Make `libpq` ignore `ENOTDIR` errors when looking for an SSL client certificate file (Magnus Hagander)
  This allows SSL connections to be established, though without a certificate, even when the user’s home directory is set to something like `/dev/null`.
- Fix some more field alignment issues in `ecpg`’s SQLDA area (Zoltan Boszormenyi)
- Allow `AT` option in `ecpg` `DEALLOCATE` statements (Michael Meskes)
  The infrastructure to support this has been there for awhile, but through an oversight there was still an error check rejecting the case.
- Do not use the variable name when defining a varchar structure in `ecpg` (Michael Meskes)
- Fix `contrib/auto_explain`’s JSON output mode to produce valid JSON (Andrew Dunstan)
  The output used brackets at the top level, when it should have used braces.
- Fix error in `contrib/intarray`’s `int[] & int[]` operator (Guillaume Lelarge)
  If the smallest integer the two input arrays have in common is 1, and there are smaller values in either array, then 1 would be incorrectly omitted from the result.
- Fix error detection in `contrib/pgcrypto`’s `encrypt_iv()` and `decrypt_iv()` (Marko Kreen)
  These functions failed to report certain types of invalid-input errors, and would instead return random garbage values for incorrect input.
- Fix one-byte buffer overrun in `contrib/test_parser` (Paul Guyot)
  The code would try to read one more byte than it should, which would crash in corner cases. Since `contrib/test_parser` is only example code, this is not a security issue in itself, but bad example code is still bad.
- Use `__sync_lock_test_and_set()` for spinlocks on ARM, if available (Martin Pitt)
  This function replaces our previous use of the `SWPB` instruction, which is deprecated and not available on ARMv6 and later. Reports suggest that the old code doesn’t fail in an obvious way on recent ARM boards, but simply doesn’t interlock concurrent accesses, leading to bizarre failures in multiprocess operation.
- Use `--fexcess-precision=standard` option when building with gcc versions that accept it (Andrew Dunstan)
  This prevents assorted scenarios wherein recent versions of gcc will produce creative results.
- Allow use of threaded Python on FreeBSD (Chris Rees)
  Our configure script previously believed that this combination wouldn’t work; but FreeBSD fixed the problem, so remove that error check.
- Allow MinGW builds to use standardly-named OpenSSL libraries (Tomasz Ostrowski)

### E.108. Release 9.1.2

**Release date:** 2011-12-05

This release contains a variety of fixes from 9.1.1. For information about new features in the 9.1 major release, see Section E.110.
Appendix E. Release Notes

E.108.1. Migration to Version 9.1.2

A dump/restore is not required for those running 9.1.X.

However, a longstanding error was discovered in the definition of the `information_schema.referential_constraints` view. If you rely on correct results from that view, you should replace its definition as explained in the first changelog item below.

Also, if you use the `citext` data type, and you upgraded from a previous major release by running `pg_upgrade`, you should run `CREATE EXTENSION citext FROM unpackaged` to avoid collation-related failures in `citext` operations. The same is necessary if you restore a dump from a pre-9.1 database that contains an instance of the `citext` data type. If you’ve already run the `CREATE EXTENSION` command before upgrading to 9.1.2, you will instead need to do manual catalog updates as explained in the second changelog item.

E.108.2. Changes

- Fix bugs in `information_schema.referential_constraints` view (Tom Lane)

This view was being insufficiently careful about matching the foreign-key constraint to the depended-on primary or unique key constraint. That could result in failure to show a foreign key constraint at all, or showing it multiple times, or claiming that it depends on a different constraint than the one it really does.

Since the view definition is installed by initdb, merely upgrading will not fix the problem. If you need to fix this in an existing installation, you can (as a superuser) drop the `information_schema` schema then re-create it by sourcing `SHAREDIR/information_schema.sql`. (Run `pg_config --sharedir` if you're uncertain where `SHAREDIR` is.) This must be repeated in each database to be fixed.

- Make `contrib/citext`'s upgrade script fix collations of `citext` columns and indexes (Tom Lane)

Existing `citext` columns and indexes aren’t correctly marked as being of a collatable data type during `pg_upgrade` from a pre-9.1 server, or when a pre-9.1 dump containing the `citext` type is loaded into a 9.1 server. That leads to operations on these columns failing with errors such as “could not determine which collation to use for string comparison”. This change allows them to be fixed by the same script that upgrades the `citext` module into a proper 9.1 extension during `CREATE EXTENSION citext FROM unpackaged`.

If you have a previously-upgraded database that is suffering from this problem, and you already ran the `CREATE EXTENSION` command, you can manually run (as superuser) the `UPDATE` commands found at the end of `SHAREDIR/extension/citext--unpackaged--1.0.sql`. (Run `pg_config --sharedir` if you’re uncertain where `SHAREDIR` is.) There is no harm in doing this again if unsure.

- Fix possible crash during `UPDATE` or `DELETE` that joins to the output of a scalar-returning function (Tom Lane)

A crash could only occur if the target row had been concurrently updated, so this problem surfaced only intermittently.

- Fix incorrect replay of WAL records for GIN index updates (Tom Lane)

This could result in transiently failing to find index entries after a crash, or on a hot-standby server. The problem would be repaired by the next `VACUUM` of the index, however.
• Fix TOAST-related data corruption during `CREATE TABLE dest AS SELECT * FROM src` or `INSERT INTO dest SELECT * FROM src` (Tom Lane)

If a table has been modified by `ALTER TABLE ADD COLUMN`, attempts to copy its data verbatim to another table could produce corrupt results in certain corner cases. The problem can only manifest in this precise form in 8.4 and later, but we patched earlier versions as well in case there are other code paths that could trigger the same bug.

• Fix possible failures during hot standby startup (Simon Riggs)

• Start hot standby faster when initial snapshot is incomplete (Simon Riggs)

• Fix race condition during toast table access from stale syscache entries (Tom Lane)

The typical symptom was transient errors like "missing chunk number 0 for toast value NNNNN in pg_toast_2619", where the cited toast table would always belong to a system catalog.

• Track dependencies of functions on items used in parameter default expressions (Tom Lane)

Previously, a referenced object could be dropped without having dropped or modified the function, leading to misbehavior when the function was used. Note that merely installing this update will not fix the missing dependency entries; to do that, you’d need to `CREATE OR REPLACE` each such function afterwards. If you have functions whose defaults depend on non-built-in objects, doing so is recommended.

• Fix incorrect management of placeholder variables in nestloop joins (Tom Lane)

This bug is known to lead to “variable not found in subplan target list” planner errors, and could possibly result in wrong query output when outer joins are involved.

• Fix window functions that sort by expressions involving aggregates (Tom Lane)

Previously these could fail with “could not find pathkey item to sort” planner errors.

• Fix "MergeAppend child’s targetlist doesn’t match MergeAppend" planner errors (Tom Lane)

• Fix index matching for operators with both collatable and noncollatable inputs (Tom Lane)

In 9.1.0, an indexable operator that has a non-collatable left-hand input type and a collatable right-hand input type would not be recognized as matching the left-hand column’s index. An example is the `hstore ? text` operator.

• Allow inlining of set-returning SQL functions with multiple OUT parameters (Tom Lane)

• Don’t trust deferred-unique indexes for join removal (Tom Lane and Marti Raudsepp)

A deferred uniqueness constraint might not hold intra-transaction, so assuming that it does could give incorrect query results.

• Make `DatumGetInetP()` unpack inet datums that have a 1-byte header, and add a new macro, `DatumGetInetPP()`, that does not (Heikki Linnakangas)

This change affects no core code, but might prevent crashes in add-on code that expects `DatumGetInetP()` to produce an unpacked datum as per usual convention.

• Improve locale support in `money` type’s input and output (Tom Lane)

Aside from not supporting all standard `lc_monetary` formatting options, the input and output functions were inconsistent, meaning there were locales in which dumped `money` values could not be re-read.

• Don’t let `transform_null_equals` affect `CASE foo WHEN NULL` ... constructs (Heikki Linnakangas)

`transform_null_equals` is only supposed to affect `foo = NULL` expressions written directly by the user, not equality checks generated internally by this form of `CASE`. 

2527
• Change foreign-key trigger creation order to better support self-referential foreign keys (Tom Lane)

For a cascading foreign key that references its own table, a row update will fire both the \texttt{ON UPDATE} trigger and the \texttt{CHECK} trigger as one event. The \texttt{ON UPDATE} trigger must execute first, else the \texttt{CHECK} will check a non-final state of the row and possibly throw an inappropriate error. However, the firing order of these triggers is determined by their names, which generally sort in creation order since the triggers have auto-generated names following the convention “RI_ConstraintTrigger_NNNN”. A proper fix would require modifying that convention, which we will do in 9.2, but it seems risky to change it in existing releases. So this patch just changes the creation order of the triggers. Users encountering this type of error should drop and re-create the foreign key constraint to get its triggers into the right order.

• Fix \texttt{IF EXISTS} to work correctly in \texttt{DROP OPERATOR FAMILY} (Robert Haas)

• Disallow dropping of an extension from within its own script (Tom Lane)

This prevents odd behavior in case of incorrect management of extension dependencies.

• Don’t mark auto-generated types as extension members (Robert Haas)

Relation rowtypes and automatically-generated array types do not need to have their own extension membership entries in \texttt{pg_depend}, and creating such entries complicates matters for extension upgrades.

• Cope with invalid pre-existing search_path settings during \texttt{CREATE EXTENSION} (Tom Lane)

• Avoid floating-point underflow while tracking buffer allocation rate (Greg Matthews)

While harmless in itself, on certain platforms this would result in annoying kernel log messages.

• Prevent autovacuum transactions from running in serializable mode (Tom Lane)

Autovacuum formerly used the cluster-wide default transaction isolation level, but there is no need for it to use anything higher than \texttt{READ COMMITTED}, and using \texttt{SERIALIZABLE} could result in unnecessary delays for other processes.

• Ensure walsender processes respond promptly to SIGTERM (Magnus Hagander)

• Exclude \texttt{postmaster.opts} from base backups (Magnus Hagander)

• Preserve configuration file name and line number values when starting child processes under Windows (Tom Lane)

Formerly, these would not be displayed correctly in the \texttt{pg_settings} view.

• Fix incorrect field alignment in ecpg’s SQLDA area (Zoltan Boszormenyi)

• Preserve blank lines within commands in psql’s command history (Robert Haas)

The former behavior could cause problems if an empty line was removed from within a string literal, for example.

• Avoid platform-specific infinite loop in \texttt{pg_dump} (Steve Singer)

• Fix compression of plain-text output format in \texttt{pg_dump} (Adrian Klaver and Tom Lane)

\texttt{pg_dump} has historically understood \texttt{-Z} with no \texttt{-F} switch to mean that it should emit a gzip-compressed version of its plain text output. Restore that behavior.

• Fix \texttt{pg_dump} to dump user-defined casts between auto-generated types, such as table rowtypes (Tom Lane)

• Fix missed quoting of foreign server names in \texttt{pg_dump} (Tom Lane)

• Assorted fixes for \texttt{pg_upgrade} (Bruce Momjian)
Appendix E. Release Notes

Handle exclusion constraints correctly, avoid failures on Windows, don’t complain about mismatched toast table names in 8.4 databases.

- In PL/pgSQL, allow foreign tables to define row types (Alexander Soudakov)
- Fix up conversions of PL/Perl functions’ results (Alex Hunsaker and Tom Lane)
  
  Restore the pre-9.1 behavior that PL/Perl functions returning `void` ignore the result value of their last Perl statement; 9.1.0 would throw an error if that statement returned a reference. Also, make sure it works to return a string value for a composite type, so long as the string meets the type’s input format. In addition, throw errors for attempts to return Perl arrays or hashes when the function’s declared result type is not an array or composite type, respectively. (Pre-9.1 versions rather uselessly returned strings like `ARRAY(0x221a9a0)` or `HASH(0x221aa90)` in such cases.)
- Ensure PL/Perl strings are always correctly UTF8-encoded (Amit Khandekar and Alex Hunsaker)
- Use the preferred version of xsubpp to build PL/Perl, not necessarily the operating system’s main copy (David Wheeler and Alex Hunsaker)
- Correctly propagate SQLSTATE in PL/Python exceptions (Mika Eloranta and Jan Urbanski)
- Do not install PL/Python extension files for Python major versions other than the one built against (Peter Eisentraut)
- Change all the contrib extension script files to report a useful error message if they are fed to psql (Andrew Dunstan and Tom Lane)
  
  This should help teach people about the new method of using `CREATE EXTENSION` to load these files. In most cases, sourcing the scripts directly would fail anyway, but with harder-to-interpret messages.
- Fix incorrect coding in contrib/dict_int and contrib/dict_xsyn (Tom Lane)
  
  Some functions incorrectly assumed that memory returned by `palloc()` is guaranteed zeroed.
- Remove contrib/sepgsql tests from the regular regression test mechanism (Tom Lane)
  
  Since these tests require root privileges for setup, they’re impractical to run automatically. Switch over to a manual approach instead, and provide a testing script to help with that.
- Fix assorted errors in contrib/unaccent’s configuration file parsing (Tom Lane)
- Honor query cancel interrupts promptly in `pgstatindex()` (Robert Haas)
- Fix incorrect quoting of log file name in macOS start script (Sidar Lopez)
- Revert unintentional enabling of `WAL_DEBUG` (Robert Haas)
  
  Fortunately, as debugging tools go, this one is pretty cheap; but it’s not intended to be enabled by default, so revert.
- Ensure VPATH builds properly install all server header files (Peter Eisentraut)
- Shorten file names reported in verbose error messages (Peter Eisentraut)
  
  Regular builds have always reported just the name of the C file containing the error message call, but VPATH builds formerly reported an absolute path name.
- Fix interpretation of Windows timezone names for Central America (Tom Lane)
  
  Map “Central America Standard Time” to `CST6`, not `CST6CDT`, because DST is generally not observed anywhere in Central America.
- Update time zone data files to tzdata release 2011n for DST law changes in Brazil, Cuba, Fiji, Palestine, Russia, and Samoa; also historical corrections for Alaska and British East Africa.
E.109. Release 9.1.1

Release date: 2011-09-26

This release contains a small number of fixes from 9.1.0. For information about new features in the 9.1 major release, see Section E.110.

E.109.1. Migration to Version 9.1.1

A dump/restore is not required for those running 9.1.X.

E.109.2. Changes

- Make `pg_options_to_table` return NULL for an option with no value (Tom Lane)
  Previously such cases would result in a server crash.
- Fix memory leak at end of a GiST index scan (Tom Lane)
  Commands that perform many separate GiST index scans, such as verification of a new GiST-based exclusion constraint on a table already containing many rows, could transiently require large amounts of memory due to this leak.
- Fix explicit reference to `pg_temp` schema in `CREATE TEMPORARY TABLE` (Robert Haas)
  This used to be allowed, but failed in 9.1.0.

E.110. Release 9.1

Release date: 2011-09-12

E.110.1. Overview

This release shows PostgreSQL moving beyond the traditional relational-database feature set with new, ground-breaking functionality that is unique to PostgreSQL. The streaming replication feature introduced in release 9.0 is significantly enhanced by adding a synchronous-replication option, streaming backups, and monitoring improvements. Major enhancements include:

- Allow synchronous replication
- Add support for foreign tables
- Add per-column collation support
- Add extensions which simplify packaging of additions to PostgreSQL
- Add a true serializable isolation level
- Support unlogged tables using the `UNLOGGED` option in `CREATE TABLE`
- Allow data-modification commands (`INSERT/UPDATE/DELETE`) in `WITH` clauses
- Add nearest-neighbor (order-by-operator) searching to GiST indexes
- Add a `SECURITY LABEL` command and support for SELinux permissions control
• Update the PL/Python server-side language
The above items are explained in more detail in the sections below.

E.110.2. Migration to Version 9.1
A dump/restore using pg_dump, or use of pg_upgrade, is required for those wishing to migrate data from any previous release.

Version 9.1 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

E.110.2.1. Strings

• Change the default value of standard_conforming_strings to on (Robert Haas)

By default, backslashes are now ordinary characters in string literals, not escape characters. This change removes a long-standing incompatibility with the SQL standard. escape_string_warning has produced warnings about this usage for years. E" strings are the proper way to embed backslash escapes in strings and are unaffected by this change.

Warning
This change can break applications that are not expecting it and do their own string escaping according to the old rules. The consequences could be as severe as introducing SQL-injection security holes. Be sure to test applications that are exposed to untrusted input, to ensure that they correctly handle single quotes and backslashes in text strings.

E.110.2.2. Casting

• Disallow function-style and attribute-style data type casts for composite types (Tom Lane)

For example, disallow composite_value.text and text(composite_value). Unintentional uses of this syntax have frequently resulted in bug reports; although it was not a bug, it seems better to go back to rejecting such expressions. The CAST and :: syntaxes are still available for use when a cast of an entire composite value is actually intended.

• Tighten casting checks for domains based on arrays (Tom Lane)

When a domain is based on an array type, it is allowed to “look through” the domain type to access the array elements, including subcripting the domain value to fetch or assign an element. Assignment to an element of such a domain value, for instance via UPDATE ... SET domaincol[5] = ..., will now result in rechecking the domain type’s constraints, whereas before the checks were skipped.

E.110.2.3. Arrays

• Change string_to_array() to return an empty array for a zero-length string (Pavel Stehule)
Previously this returned a null value.

- Change `string_to_array()` so a NULL separator splits the string into characters (Pavel Stehule)

Previously this returned a null value.

### E.110.2.4. Object Modification

- Fix improper checks for before/after triggers (Tom Lane)

Triggers can now be fired in three cases: BEFORE, AFTER, or INSTEAD OF some action. Trigger function authors should verify that their logic behaves sanely in all three cases.

- Require superuser or `CREATEROLE` permissions in order to set comments on roles (Tom Lane)

### E.110.2.5. Server Settings

- Change `pg_last_xlog_receive_location()` so it never moves backwards (Fujii Masao)

Previously, the value of `pg_last_xlog_receive_location()` could move backward when streaming replication is restarted.

- Have logging of replication connections honor `log_connections` (Magnus Hagander)

Previously, replication connections were always logged.

### E.110.2.6. PL/pgSQL Server-Side Language

- Change PL/pgSQL’s `RAISE` command without parameters to be catchable by the attached exception block (Piyush Newe)

Previously `RAISE` in a code block was always scoped to an attached exception block, so it was uncatchable at the same scope.

- Adjust PL/pgSQL’s error line numbering code to be consistent with other PLs (Pavel Stehule)

Previously, PL/pgSQL would ignore (not count) an empty line at the start of the function body. Since this was inconsistent with all other languages, the special case was removed.

- Make PL/pgSQL complain about conflicting IN and OUT parameter names (Tom Lane)

Formerly, the collision was not detected, and the name would just silently refer to only the OUT parameter.

- Type modifiers of PL/pgSQL variables are now visible to the SQL parser (Tom Lane)

A type modifier (such as a varchar length limit) attached to a PL/pgSQL variable was formerly enforced during assignments, but was ignored for all other purposes. Such variables will now behave more like table columns declared with the same modifier. This is not expected to make any visible difference in most cases, but it could result in subtle changes for some SQL commands issued by PL/pgSQL functions.
E.110.2.7. Contrib

- All contrib modules are now installed with `CREATE EXTENSION` rather than by manually invoking their SQL scripts (Dimitri Fontaine, Tom Lane)
  
  To update an existing database containing the 9.0 version of a contrib module, use `CREATE EXTENSION ... FROM unpackaged` to wrap the existing contrib module’s objects into an extension. When updating from a pre-9.0 version, drop the contrib module’s objects using its old uninstall script, then use `CREATE EXTENSION`.

E.110.2.8. Other Incompatibilities

- Make `pg_stat_reset()` reset all database-level statistics (Tomas Vondra)
  
  Some `pg_stat_database` counters were not being reset.
- Fix some `information_schema.triggers` column names to match the new SQL-standard names (Dean Rasheed)
- Treat ECPG cursor names as case-insensitive (Zoltan Boszormenyi)

E.110.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 9.1 and the previous major release.

E.110.3.1. Server

E.110.3.1.1. Performance

- Support unlogged tables using the `UNLOGGED` option in `CREATE TABLE` (Robert Haas)
  
  Such tables provide better update performance than regular tables, but are not crash-safe: their contents are automatically cleared in case of a server crash. Their contents do not propagate to replication slaves, either.
- Allow `FULL OUTER JOIN` to be implemented as a hash join, and allow either side of a `LEFT OUTER JOIN` or `RIGHT OUTER JOIN` to be hashed (Tom Lane)
  
  Previously `FULL OUTER JOIN` could only be implemented as a merge join, and `LEFT OUTER JOIN` and `RIGHT OUTER JOIN` could hash only the nullable side of the join. These changes provide additional query optimization possibilities.
- Merge duplicate fsync requests (Robert Haas, Greg Smith)
  
  This greatly improves performance under heavy write loads.
- Improve performance of `commit_siblings` (Greg Smith)
  
  This allows the use of `commit_siblings` with less overhead.
- Reduce the memory requirement for large ispell dictionaries (Pavel Stehule, Tom Lane)
- Avoid leaving data files open after “blind writes” (Alvaro Herrera)
This fixes scenarios in which backends might hold files open long after they were deleted, preventing the kernel from reclaiming disk space.

**E.110.3.1.2. Optimizer**

- Allow inheritance table scans to return meaningfully-sorted results (Greg Stark, Hans-Jurgen Schonig, Robert Haas, Tom Lane)
  
  This allows better optimization of queries that use `ORDER BY`, `LIMIT`, or `MIN/MAX` with inherited tables.

- Improve GIN index scan cost estimation (Teodor Sigaev)

- Improve cost estimation for aggregates and window functions (Tom Lane)

**E.110.3.1.3. Authentication**

- Support host names and host suffixes (e.g. `.example.com`) in `pg_hba.conf` (Peter Eisentraut)
  
  Previously only host IP addresses and CIDR values were supported.

- Support the key word `all` in the host column of `pg_hba.conf` (Peter Eisentraut)
  
  Previously people used `0.0.0.0/0` or `::/0` for this.

- Reject local lines in `pg_hba.conf` on platforms that don’t support Unix-socket connections (Magnus Hagander)
  
  Formerly, such lines were silently ignored, which could be surprising. This makes the behavior more like other unsupported cases.

- Allow GSSAPI to be used to authenticate to servers via SSPI (Christian Ullrich)

  Specifically this allows Unix-based GSSAPI clients to do SSPI authentication with Windows servers.

- Ident authentication over local sockets is now known as `peer` (Magnus Hagander)

  The old term is still accepted for backward compatibility, but since the two methods are fundamentally different, it seemed better to adopt different names for them.

- Rewrite peer authentication to avoid use of credential control messages (Tom Lane)

  This change makes the peer authentication code simpler and better-performing. However, it requires the platform to provide the `getpeereid` function or an equivalent socket operation. So far as is known, the only platform for which peer authentication worked before and now will not is pre-5.0 NetBSD.

**E.110.3.1.4. Monitoring**

- Add details to the logging of restartpoints and checkpoints, which is controlled by `log_checkpoints` (Fujii Masao, Greg Smith)

  New details include WAL file and sync activity.

- Add `log_file_mode` which controls the permissions on log files created by the logging collector (Martin Pihlak)

- Reduce the default maximum line length for syslog logging to 900 bytes plus prefixes (Noah Misch)
Appendix E. Release Notes

This avoids truncation of long log lines on syslog implementations that have a 1KB length limit, rather than the more common 2KB.

E.110.3.1.5. Statistical Views

- Add client_hostname column to pg_stat_activity (Peter Eisentraut)
  Previously only the client address was reported.
- Add pg_stat_xact_* statistics functions and views (Joel Jacobson)
  These are like the database-wide statistics counter views, but reflect counts for only the current transaction.
- Add time of last reset in database-level and background writer statistics views (Tomas Vondra)
- Add columns showing the number of vacuum and analyze operations in pg_stat_*_tables views (Magnus Hagander)
- Add buffers_backend_fsync column to pg_stat_bgwriter (Greg Smith)
  This new column counts the number of times a backend fsyncs a buffer.

E.110.3.1.6. Server Settings

- Provide auto-tuning of wal_buffers (Greg Smith)
  By default, the value of wal_buffers is now chosen automatically based on the value of shared_buffers.
- Increase the maximum values for deadlock_timeout, log_min_duration_statement, and log_autovacuum_min_duration (Peter Eisentraut)
  The maximum value for each of these parameters was previously only about 35 minutes. Much larger values are now allowed.

E.110.3.2. Replication and Recovery

E.110.3.2.1. Streaming Replication and Continuous Archiving

- Allow synchronous replication (Simon Riggs, Fujii Masao)
  This allows the primary server to wait for a standby to write a transaction’s information to disk before acknowledging the commit. One standby at a time can take the role of the synchronous standby, as controlled by the synchronous_standby_names setting. Synchronous replication can be enabled or disabled on a per-transaction basis using the synchronous_commit setting.
- Add protocol support for sending file system backups to standby servers using the streaming replication network connection (Magnus Hagander, Heikki Linnakangas)
  This avoids the requirement of manually transferring a file system backup when setting up a standby server.
- Add replication_timeout setting (Fujii Masao, Heikki Linnakangas)
Replication connections that are idle for more than the `replication_timeout` interval will be terminated automatically. Formerly, a failed connection was typically not detected until the TCP timeout elapsed, which is inconveniently long in many situations.

- Add command-line tool `pg_basebackup` for creating a new standby server or database backup (Magnus Hagander)
- Add a replication permission for roles (Magnus Hagander)
  This is a read-only permission used for streaming replication. It allows a non-superuser role to be used for replication connections. Previously only superusers could initiate replication connections; superusers still have this permission by default.

### E.110.3.2.2. Replication Monitoring

- Add system view `pg_stat_replication` which displays activity of WAL sender processes (Itagaki Takahiro, Simon Riggs)
  This reports the status of all connected standby servers.
- Add monitoring function `pg_last_xact_replay_timestamp()` (Fujii Masao)
  This returns the time at which the primary generated the most recent commit or abort record applied on the standby.

### E.110.3.2.3. Hot Standby

- Add configuration parameter `hot_standby_feedback` to enable standbys to postpone cleanup of old row versions on the primary (Simon Riggs)
  This helps avoid canceling long-running queries on the standby.
- Add the `pg_stat_database_conflicts` system view to show queries that have been canceled and the reason (Magnus Hagander)
  Cancellations can occur because of dropped tables, lock timeouts, old snapshots, pinned buffers, and deadlocks.
- Add a `conflicts` count to `pg_stat_database` (Magnus Hagander)
  This is the number of conflicts that occurred in the database.
- Increase the maximum values for `max_standby_archive_delay` and `max_standby_streaming_delay`
  The maximum value for each of these parameters was previously only about 35 minutes. Much larger values are now allowed.
- Add `ERRCODE_T_R_DATABASE_DROPPED` error code to report recovery conflicts due to dropped databases (Tatsuo Ishii)
  This is useful for connection pooling software.

### E.110.3.2.4. Recovery Control

- Add functions to control streaming replication replay (Simon Riggs)
Appendix E. Release Notes

The new functions are `pg_xlog_replay_pause()`, `pg_xlog_replay_resume()`, and the status function `pg_is_xlog_replay_paused()`.

- Add `recovery.conf` setting `pause_at_recovery_target` to pause recovery at target (Simon Riggs)
  
  This allows a recovery server to be queried to check whether the recovery point is the one desired.

- Add the ability to create named restore points using `pg_create_restore_point()` (Jaime Casanova)
  
  These named restore points can be specified as recovery targets using the new `recovery.conf` setting `recovery_target_name`.

- Allow standby recovery to switch to a new timeline automatically (Heikki Linnakangas)
  
  Now standby servers scan the archive directory for new timelines periodically.

- Add `restart_after_crash` setting which disables automatic server restart after a backend crash (Robert Haas)
  
  This allows external cluster management software to control whether the database server restarts or not.

- Allow `recovery.conf` to use the same quoting behavior as `postgresql.conf` (Dimitri Fontaine)
  
  Previously all values had to be quoted.

### E.110.3.3. Queries

- Add a true serializable isolation level (Kevin Grittner, Dan Ports)
  
  Previously, asking for serializable isolation guaranteed only that a single MVCC snapshot would be used for the entire transaction, which allowed certain documented anomalies. The old snapshot isolation behavior is still available by requesting the `REPEATABLE READ` isolation level.

- Allow data-modification commands (`INSERT/UPDATE/DELETE`) in `WITH` clauses (Marko Tiikkaja, Hitoshi Harada)
  
  These commands can use `RETURNING` to pass data up to the containing query.

- Allow `WITH` clauses to be attached to `INSERT, UPDATE, DELETE` statements (Marko Tiikkaja, Hitoshi Harada)

- Allow non-`GROUP BY` columns in the query target list when the primary key is specified in the `GROUP BY` clause (Peter Eisentraut)
  
  The SQL standard allows this behavior, and because of the primary key, the result is unambiguous.

- Allow use of the key word `DISTINCT` in `UNION/INTERSECT/EXCEPT` clauses (Tom Lane)
  
  `DISTINCT` is the default behavior so use of this key word is redundant, but the SQL standard allows it.

- Fix ordinary queries with rules to use the same snapshot behavior as `EXPLAIN ANALYZE` (Marko Tiikkaja)
  
  Previously `EXPLAIN ANALYZE` used slightly different snapshot timing for queries involving rules. The `EXPLAIN ANALYZE` behavior was judged to be more logical.
E.110.3.3.1. Strings

- Add per-column collation support (Peter Eisentraut, Tom Lane)

  Previously collation (the sort ordering of text strings) could only be chosen at database creation. Collation can now be set per column, domain, index, or expression, via the SQL-standard \texttt{COLLATE} clause.

E.110.3.4. Object Manipulation

- Add extensions which simplify packaging of additions to PostgreSQL (Dimitri Fontaine, Tom Lane)

  Extensions are controlled by the new \texttt{CREATE/ALTER/DROP EXTENSION} commands. This replaces ad-hoc methods of grouping objects that are added to a PostgreSQL installation.

- Add support for foreign tables (Shigeru Hanada, Robert Haas, Jan Urbanski, Heikki Linnakangas)

  This allows data stored outside the database to be used like native PostgreSQL-stored data. Foreign tables are currently read-only, however.

- Allow new values to be added to an existing enum type via \texttt{ALTER TYPE} (Andrew Dunstan)

- Add \texttt{ALTER TYPE ... ADD/DROP/ALTER/RENAME ATTRIBUTE} (Peter Eisentraut)

  This allows modification of composite types.

E.110.3.4.1. \texttt{ALTER} Object

- Add \texttt{RESTRICT/CASCADE} to \texttt{ALTER TYPE} operations on typed tables (Peter Eisentraut)

  This controls \texttt{ADD/DROP/ALTER/RENAME ATTRIBUTE} cascading behavior.

- Support \texttt{ALTER TABLE name \{OF | NOT OF\} type} (Noah Misch)

  This syntax allows a standalone table to be made into a typed table, or a typed table to be made standalone.

- Add support for more object types in \texttt{ALTER ... SET SCHEMA} commands (Dimitri Fontaine)

  This command is now supported for conversions, operators, operator classes, operator families, text search configurations, text search dictionaries, text search parsers, and text search templates.

E.110.3.4.2. \texttt{CREATE/ALTER TABLE}

- Add \texttt{ALTER TABLE ... ADD UNIQUE/PRIMARY KEY USING INDEX} (Gurjeet Singh)

  This allows a primary key or unique constraint to be defined using an existing unique index, including a concurrently created unique index.

- Allow \texttt{ALTER TABLE} to add foreign keys without validation (Simon Riggs)

  The new option is called \texttt{NOT VALID}. The constraint’s state can later be modified to \texttt{VALIDATED} and validation checks performed. Together these allow you to add a foreign key with minimal impact on read and write operations.
• Allow `ALTER TABLE ... SET DATA TYPE` to avoid table rewrites in appropriate cases (Noah Misch, Robert Haas)

For example, converting a `varchar` column to `text` no longer requires a rewrite of the table. However, increasing the length constraint on a `varchar` column still requires a table rewrite.

• Add `CREATE TABLE IF NOT EXISTS` syntax (Robert Haas)

This allows table creation without causing an error if the table already exists.

• Fix possible “tuple concurrently updated” error when two backends attempt to add an inheritance child to the same table at the same time (Robert Haas)

`ALTER TABLE` now takes a stronger lock on the parent table, so that the sessions cannot try to update it simultaneously.

### E.110.3.4.3. Object Permissions

• Add a `SECURITY LABEL` command (KaiGai Kohei)

This allows security labels to be assigned to objects.

### E.110.3.5. Utility Operations

• Add transaction-level advisory locks (Marko Tiikkaja)

These are similar to the existing session-level advisory locks, but such locks are automatically released at transaction end.

• Make `TRUNCATE ... RESTART IDENTITY` restart sequences transactionally (Steve Singer)

Previously the counter could have been left out of sync if a backend crashed between the on-commit truncation activity and commit completion.

#### E.110.3.5.1. COPY

• Add `ENCODING` option to `COPY TO/FROM` (Hitoshi Harada, Itagaki Takahiro)

This allows the encoding of the `COPY` file to be specified separately from client encoding.

• Add bidirectional `COPY` protocol support (Fujii Masao)

This is currently only used by streaming replication.

#### E.110.3.5.2. EXPLAIN

• Make `EXPLAIN VERBOSE` show the function call expression in a `FunctionScan` node (Tom Lane)

#### E.110.3.5.3. VACUUM

• Add additional details to the output of `VACUUM FULL VERBOSE` and `CLUSTER VERBOSE` (Itagaki Takahiro)
New information includes the live and dead tuple count and whether `CLUSTER` is using an index to rebuild.

- Prevent autovacuum from waiting if it cannot acquire a table lock (Robert Haas)
  It will try to vacuum that table later.

**E.110.3.5.4. CLUSTER**

- Allow `CLUSTER` to sort the table rather than scanning the index when it seems likely to be cheaper (Leonardo Francalanci)

**E.110.3.5.5. Indexes**

- Add nearest-neighbor (order-by-operator) searching to GiST indexes (Teodor Sigaev, Tom Lane)
  This allows GiST indexes to quickly return the $N$ closest values in a query with `LIMIT`. For example,
  ```sql
  SELECT * FROM places ORDER BY location <-> point '(101,456)' LIMIT 10;
  ```
  finds the ten places closest to a given target point.
- Allow GIN indexes to index null and empty values (Tom Lane)
  This allows full GIN index scans, and fixes various corner cases in which GIN scans would fail.
- Allow GIN indexes to better recognize duplicate search entries (Tom Lane)
  This reduces the cost of index scans, especially in cases where it avoids unnecessary full index scans.
- Fix GiST indexes to be fully crash-safe (Heikki Linnakangas)
  Previously there were rare cases where a `REINDEX` would be required (you would be informed).

**E.110.3.6. Data Types**

- Allow `numeric` to use a more compact, two-byte header in common cases (Robert Haas)
  Previously all `numeric` values had four-byte headers; this change saves on disk storage.
- Add support for dividing `money` by `money` (Andy Balholm)
- Allow binary I/O on type `void` (Radoslaw Smogura)
- Improve hypotenuse calculations for geometric operators (Paul Matthews)
  This avoids unnecessary overflows, and may also be more accurate.
- Support hashing array values (Tom Lane)
  This provides additional query optimization possibilities.
- Don’t treat a composite type as sortable unless all its column types are sortable (Tom Lane)
  This avoids possible “could not identify a comparison function” failures at runtime, if it is possible to implement the query without sorting. Also, `ANALYZE` won’t try to use inappropriate statistics-gathering methods for columns of such composite types.
Appendix E. Release Notes

E.110.3.6.1. Casting

- Add support for casting between money and numeric (Andy Balholm)
- Add support for casting from int4 and int8 to money (Joey Adams)
- Allow casting a table’s row type to the table’s supertype if it’s a typed table (Peter Eisentraut)

This is analogous to the existing facility that allows casting a row type to a supertable’s row type.

E.110.3.6.2. XML

- Add XML function XMLEXISTS and xpath_exists() functions (Mike Fowler)
  These are used for XPath matching.
- Add XML functions xml_is_well_formed(), xml_is_well_formed_document(), xml_is_well_formed_content() (Mike Fowler)
  These check whether the input is properly-formed XML. They provide functionality that was previously available only in the deprecated contrib/xml2 module.

E.110.3.7. Functions

- Add SQL function format(text, ...), which behaves analogously to C’s printf() (Pavel Stehule, Robert Haas)
  It currently supports formats for strings, SQL literals, and SQL identifiers.
- Add string functions concat(), concat_ws(), left(), right(), and reverse() (Pavel Stehule)
  These improve compatibility with other database products.
- Add function pg_read_binary_file() to read binary files (Dimitri Fontaine, Itagaki Takahiro)
- Add a single-parameter version of function pg_read_file() to read an entire file (Dimitri Fontaine, Itagaki Takahiro)
- Add three-parameter forms of array_to_string() and string_to_array() for null value processing control (Pavel Stehule)

E.110.3.7.1. Object Information Functions

- Add the pg_describe_object() function (Alvaro Herrera)
  This function is used to obtain a human-readable string describing an object, based on the pg_class OID, object OID, and sub-object ID. It can be used to help interpret the contents of pg_depend.
- Update comments for built-in operators and their underlying functions (Tom Lane)
  Functions that are meant to be used via an associated operator are now commented as such.
- Add variable quote_all_identifiers to force the quoting of all identifiers in EXPLAIN and in system catalog functions like pg_get_viewdef() (Robert Haas)
  This makes exporting schemas to tools and other databases with different quoting rules easier.
Appendix E. Release Notes

- Add columns to the `information_schema.sequences` system view (Peter Eisentraut)
  Previously, though the view existed, the columns about the sequence parameters were unimplemented.
- Allow `public` as a pseudo-role name in `has_table_privilege()` and related functions (Alvaro Herrera)
  This allows checking for public permissions.

E.110.3.7.2. Function and Trigger Creation

- Support `INSTEAD OF` triggers on views (Dean Rasheed)
  This feature can be used to implement fully updatable views.

E.110.3.8. Server-Side Languages

E.110.3.8.1. PL/pgSQL Server-Side Language

- Add `FOREACH IN ARRAY` to PL/pgSQL (Pavel Stehule)
  This is more efficient and readable than previous methods of iterating through the elements of an array value.
- Allow `RAISE` without parameters to be caught in the same places that could catch a `RAISE ERROR` from the same location (Piyush Newe)
  The previous coding threw the error from the block containing the active exception handler. The new behavior is more consistent with other DBMS products.

E.110.3.8.2. PL/Perl Server-Side Language

- Allow generic record arguments to PL/Perl functions (Andrew Dunstan)
  PL/Perl functions can now be declared to accept type `record`. The behavior is the same as for any named composite type.
- Convert PL/Perl array arguments to Perl arrays (Alexey Klyukin, Alex Hunsaker)
  String representations are still available.
- Convert PL/Perl composite-type arguments to Perl hashes (Alexey Klyukin, Alex Hunsaker)
  String representations are still available.

E.110.3.8.3. PL/Python Server-Side Language

- Add table function support for PL/Python (Jan Urbanski)
  PL/Python can now return multiple `OUT` parameters and record sets.
- Add a validator to PL/Python (Jan Urbanski)
  This allows PL/Python functions to be syntax-checked at function creation time.
Appendix E. Release Notes

• Allow exceptions for SQL queries in PL/Python (Jan Urbanski)
  This allows access to SQL-generated exception error codes from PL/Python exception blocks.
• Add explicit subtransactions to PL/Python (Jan Urbanski)
• Add PL/Python functions for quoting strings (Jan Urbanski)
  These functions are `plpy.quote_ident`, `plpy.quote_literal`, and `plpy.quote_nullable`.
• Add traceback information to PL/Python errors (Jan Urbanski)
• Report PL/Python errors from iterators with `PLy_elog` (Jan Urbanski)
• Fix exception handling with Python 3 (Jan Urbanski)
  Exception classes were previously not available in `plpy` under Python 3.

E.110.3.9. Client Applications

• Mark createlang and droplang as deprecated now that they just invoke extension commands (Tom Lane)

E.110.3.9.1. psql

• Add psql command `\conninfo` to show current connection information (David Christensen)
• Add psql command `\sf` to show a function’s definition (Pavel Stehule)
• Add psql command `\dL` to list languages (Fernando Ike)
• Add the `S` ("system") option to psql’s `\dn` (list schemas) command (Tom Lane)
  `\dn` without `S` now suppresses system schemas.
• Allow psql’s `\e` and `\ef` commands to accept a line number to be used to position the cursor in the editor (Pavel Stehule)
  This is passed to the editor according to the `PSQL_EDITOR_LINENUMBER_ARG` environment variable.
• Have psql set the client encoding from the operating system locale by default (Heikki Linnakangas)
  This only happens if the `PGCLIENTENCODING` environment variable is not set.
• Make `\d` distinguish between unique indexes and unique constraints (Josh Kupershmidt)
• Make `\dt+` report `pg_table_size` instead of `pg_relation_size` when talking to 9.0 or later servers (Bernd Helmle)
  This is a more useful measure of table size, but note that it is not identical to what was previously reported in the same display.
• Additional tab completion support (Itagaki Takahiro, Pavel Stehule, Andrey Popp, Christoph Berg, David Fetter, Josh Kupershmidt)

E.110.3.9.2. pg_dump

• Add `pg_dump` and `pg_dumpall` option `--quote-all-identifiers` to force quoting of all identifiers (Robert Haas)
Appendix E. Release Notes

• Add directory format to pg_dump (Joachim Wieland, Heikki Linnakangas)
  This is internally similar to the tar pg_dump format.

E.110.3.9.3. pg_ctl

• Fix pg_ctl so it no longer incorrectly reports that the server is not running (Bruce Momjian)
  Previously this could happen if the server was running but pg_ctl could not authenticate.
• Improve pg_ctl start’s “wait” (-w) option (Bruce Momjian, Tom Lane)
  The wait mode is now significantly more robust. It will not get confused by non-default postmaster port numbers, non-default Unix-domain socket locations, permission problems, or stale postmaster lock files.
• Add promote option to pg_ctl to switch a standby server to primary (Fujii Masao)

E.110.3.10. Development Tools

E.110.3.10.1. libpq

• Add a libpq connection option client_encoding which behaves like the PGCLIENTENCODING environment variable (Heikki Linnakangas)
  The value auto sets the client encoding based on the operating system locale.
• Add PQlibVersion() function which returns the libpq library version (Magnus Hagander)
  libpq already had PQserverVersion() which returns the server version.
• Allow libpq-using clients to check the user name of the server process when connecting via Unix-domain sockets, with the new requirepeer connection option (Peter Eisentraut)
  PostgreSQL already allowed servers to check the client user name when connecting via Unix-domain sockets.
• Add PQping() and PQpingParams() to libpq (Bruce Momjian, Tom Lane)
  These functions allow detection of the server’s status without trying to open a new session.

E.110.3.10.2. ECPG

• Allow ECPG to accept dynamic cursor names even in WHERE CURRENT OF clauses (Zoltan Boszormenyi)
• Make ecpglib write double values with a precision of 15 digits, not 14 as formerly (Akira Kurosawa)

E.110.3.11. Build Options

• Use +Olibmerrno compile flag with HP-UX C compilers that accept it (Ibrar Ahmed)
Appendix E. Release Notes

This avoids possible misbehavior of math library calls on recent HP platforms.

E.110.3.11.1. Makefiles

- Improved parallel make support (Peter Eisentraut)
  This allows for faster compiles. Also, `make -k` now works more consistently.
- Require GNU make 3.80 or newer (Peter Eisentraut)
  This is necessary because of the parallel-make improvements.
- Add `make maintainer-check` target (Peter Eisentraut)
  This target performs various source code checks that are not appropriate for either the build or the regression tests. Currently: duplicate_oids, SGML syntax and tabs check, NLS syntax check.
- Support `make check` in `contrib` (Peter Eisentraut)
  Formerly only `make installcheck` worked, but now there is support for testing in a temporary installation. The top-level `make check-world` target now includes testing `contrib` this way.

E.110.3.11.2. Windows

- On Windows, allow `pg_ctl` to register the service as auto-start or start-on-demand (Quan Zongliang)
- Add support for collecting crash dumps on Windows (Craig Ringer, Magnus Hagander)
  Minidumps can now be generated by non-debug Windows binaries and analyzed by standard debugging tools.
- Enable building with the MinGW64 compiler (Andrew Dunstan)
  This allows building 64-bit Windows binaries even on non-Windows platforms via cross-compiling.

E.110.3.12. Source Code

- Revise the API for GUC variable assign hooks (Tom Lane)
  The previous functions of assign hooks are now split between check hooks and assign hooks, where the former can fail but the latter shouldn’t. This change will impact add-on modules that define custom GUC parameters.
- Add latches to the source code to support waiting for events (Heikki Linnakangas)
- Centralize data modification permissions-checking logic (KaiGai Kohei)
- Add missing `get_object_oid()` functions, for consistency (Robert Haas)
- Improve ability to use C++ compilers for compiling add-on modules by removing conflicting key words (Tom Lane)
- Add support for DragonFly BSD (Rumko)
- Expose `quote_literal_cstr()` for backend use (Robert Haas)
- Run regression tests in the default encoding (Peter Eisentraut)
  Regression tests were previously always run with `SQL_ASCII` encoding.
- Add `src/tools/git_changelog` to replace `cvs2cl` and `pgcvslog` (Robert Haas, Tom Lane)
Appendix E. Release Notes

• Add git-external-diff script to src/tools (Bruce Momjian)
  This is used to generate context diffs from git.
• Improve support for building with Clang (Peter Eisentraut)

E.110.3.12.1. Server Hooks

• Add source code hooks to check permissions (Robert Haas, Stephen Frost)
• Add post-object-creation function hooks for use by security frameworks (KaiGai Kohei)
• Add a client authentication hook (KaiGai Kohei)

E.110.3.13. Contrib

• Modify contrib modules and procedural languages to install via the new extension mechanism (Tom Lane, Dimitri Fontaine)
• Add contrib/file_fdw foreign-data wrapper (Shigeru Hanada)
  Foreign tables using this foreign data wrapper can read flat files in a manner very similar to COPY.
• Add nearest-neighbor search support to contrib/pg_trgm and contrib/btree_gist (Teodor Sigaev)
• Add contrib/btree_gist support for searching on not-equals (Jeff Davis)
• Fix contrib/fuzzystrmatch’s levenshtein() function to handle multibyte characters (Alexander Korotkov)
• Add ssl_cipher() and ssl_version() functions to contrib/sslinfo (Robert Haas)
• Fix contrib/intarray and contrib/hstore to give consistent results with indexed empty arrays (Tom Lane)
  Previously an empty-array query that used an index might return different results from one that used a sequential scan.
• Allow contrib/intarray to work properly on multidimensional arrays (Tom Lane)
• In contrib/intarray, avoid errors complaining about the presence of nulls in cases where no nulls are actually present (Tom Lane)
• In contrib/intarray, fix behavior of containment operators with respect to empty arrays (Tom Lane)
  Empty arrays are now correctly considered to be contained in any other array.
• Remove contrib/xml2’s arbitrary limit on the number of parameter=value pairs that can be handled by xslt_process() (Pavel Stehule)
  The previous limit was 10.
• In contrib/pageinspect, fix heap_page_item to return infomasks as 32-bit values (Alvaro Herrera)
  This avoids returning negative values, which was confusing. The underlying value is a 16-bit unsigned integer.
Appendix E. Release Notes

E.110.3.13.1. Security

- Add contrib/sepgsql to interface permission checks with SELinux (KaiGai Kohei)
  This uses the new SECURITY LABEL facility.
- Add contrib module auth_delay (KaiGai Kohei)
  This causes the server to pause before returning authentication failure; it is designed to make brute force password attacks more difficult.
- Add dummy_seclabel contrib module (KaiGai Kohei)
  This is used for permission regression testing.

E.110.3.13.2. Performance

- Add support for LIKE and ILIKE index searches to contrib/pg_trgm (Alexander Korotkov)
- Add levenshtein_less_equal() function to contrib/fuzzystrmatch, which is optimized for small distances (Alexander Korotkov)
- Improve performance of index lookups on contrib/seg columns (Alexander Korotkov)
- Improve performance of pg_upgrade for databases with many relations (Bruce Momjian)
- Add flag to contrib/pgbench to report per-statement latencies (Florian Pflug)

E.110.3.13.3. Fsync Testing

- Move src/tools/test_fsync to contrib/pg_test_fsync (Bruce Momjian, Tom Lane)
- Add O_DIRECT support to contrib/pg_test_fsync (Bruce Momjian)
  This matches the use of O_DIRECT by wal_sync_method.
- Add new tests to contrib/pg_test_fsync (Bruce Momjian)

E.110.3.14. Documentation

- Extensive ECPG documentation improvements (Satoshi Nagayasu)
- Extensive proofreading and documentation improvements (Thom Brown, Josh Kupershmidt, Susanne Ebrecht)
- Add documentation for exit_on_error (Robert Haas)
  This parameter causes sessions to exit on any error.
- Add documentation for pg_options_to_table() (Josh Berkus)
  This function shows table storage options in a readable form.
- Document that it is possible to access all composite type fields using (compositeval).* syntax (Peter Eisentraut)
- Document that translate() removes characters in from that don’t have a corresponding to character (Josh Kupershmidt)
Appendix E. Release Notes

- Merge documentation for `CREATE CONSTRAINT TRIGGER` and `CREATE TRIGGER` (Alvaro Herrera)
- Centralize permission and upgrade documentation (Bruce Momjian)
- Add kernel tuning documentation for Solaris 10 (Josh Berkus)
  Previously only Solaris 9 kernel tuning was documented.
- Handle non-ASCII characters consistently in `HISTORY` file (Peter Eisentraut)
  While the `HISTORY` file is in English, we do have to deal with non-ASCII letters in contributor names. These are now transliterated so that they are reasonably legible without assumptions about character set.

E.111. Release 9.0.23

**Release date:** 2015-10-08

This release contains a variety of fixes from 9.0.22. For information about new features in the 9.0 major release, see Section E.134.

This is expected to be the last PostgreSQL release in the 9.0.X series. Users are encouraged to update to a newer release branch soon.

E.111.1. Migration to Version 9.0.23

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.18, see Section E.116.

E.111.2. Changes

- Fix `contrib/pgcrypto` to detect and report too-short `crypt()` salts (Josh Kupershmidt)
  Certain invalid salt arguments crashed the server or disclosed a few bytes of server memory. We have not ruled out the viability of attacks that arrange for presence of confidential information in the disclosed bytes, but they seem unlikely. (CVE-2015-5288)
- Fix subtransaction cleanup after a portal (cursor) belonging to an outer subtransaction fails (Tom Lane, Michael Paquier)
  A function executed in an outer-subtransaction cursor could cause an assertion failure or crash by referencing a relation created within an inner subtransaction.
- Fix insertion of relations into the relation cache “init file” (Tom Lane)
  An oversight in a patch in the most recent minor releases caused `pg_trigger_tgrelid_tgname_index` to be omitted from the init file. Subsequent sessions detected this, then deemed the init file to be broken and silently ignored it, resulting in a significant degradation in session startup time. In addition to fixing the bug, install some guards so that any similar future mistake will be more obvious.
- Avoid O(N^2) behavior when inserting many tuples into a SPI query result (Neil Conway)
• Improve `LISTEN` startup time when there are many unread notifications (Matt Newell)

• Disable SSL renegotiation by default (Michael Paquier, Andres Freund)

  While use of SSL renegotiation is a good idea in theory, we have seen too many bugs in practice, both in the underlying OpenSSL library and in our usage of it. Renegotiation will be removed entirely in 9.5 and later. In the older branches, just change the default value of `ssl_renegotiation_limit` to zero (disabled).

• Lower the minimum values of the `*_freeze_max_age` parameters (Andres Freund)

  This is mainly to make tests of related behavior less time-consuming, but it may also be of value for installations with limited disk space.

• Limit the maximum value of `wal_buffers` to 2GB to avoid server crashes (Josh Berkus)

• Fix rare internal overflow in multiplication of numeric values (Dean Rasheed)

• Guard against hard-to-reach stack overflows involving record types, range types, `json`, `jsonb`, `tsquery`, `ltxtquery` and `query_int` (Noah Misch)

• Fix handling of `DOW` and `DOY` in datetime input (Greg Stark)

  These tokens aren’t meant to be used in datetime values, but previously they resulted in opaque internal error messages rather than “invalid input syntax”.

• Add more query-cancel checks to regular expression matching (Tom Lane)

• Add recursion depth protections to regular expression, `SIMILAR TO`, and `LIKE` matching (Tom Lane)

  Suitable search patterns and a low stack depth limit could lead to stack-overrun crashes.

• Fix potential infinite loop in regular expression execution (Tom Lane)

  A search pattern that can apparently match a zero-length string, but actually doesn’t match because of a back reference, could lead to an infinite loop.

• Fix low-memory failures in regular expression compilation (Andreas Seltenreich)

• Fix low-probability memory leak during regular expression execution (Tom Lane)

• Fix rare low-memory failure in lock cleanup during transaction abort (Tom Lane)

• Fix “unexpected out-of-memory situation during sort” errors when using tuplestores with small `work_mem` settings (Tom Lane)

• Fix very-low-probability stack overrun in `qsort` (Tom Lane)

• Fix “invalid memory alloc request size” failure in hash joins with large `work_mem` settings (Tomas Vondra, Tom Lane)

• Fix assorted planner bugs (Tom Lane)

  These mistakes could lead to incorrect query plans that would give wrong answers, or to assertion failures in assert-enabled builds, or to odd planner errors such as “could not devise a query plan for the given query”, “could not find pathkey item to sort”, “plan should not reference subplan’s variable”, or “failed to assign all NestLoopParams to plan nodes”. Thanks are due to Andreas Seltenreich and Piotr Stefaniak for fuzz testing that exposed these problems.

• Use fuzzy path cost tiebreaking rule in all supported branches (Tom Lane)

  This change is meant to avoid platform-specific behavior when alternative plan choices have effectively-identical estimated costs.

• During postmaster shutdown, ensure that per-socket lock files are removed and listen sockets are closed before we remove the `postmaster.pid` file (Tom Lane)
Appendix E. Release Notes

This avoids race-condition failures if an external script attempts to start a new postmaster as soon as `pg_ctl stop` returns.

- Fix postmaster’s handling of a startup-process crash during crash recovery (Tom Lane)
  If, during a crash recovery cycle, the startup process crashes without having restored database consistency, we’d try to launch a new startup process, which typically would just crash again, leading to an infinite loop.

- Do not print a WARNING when an autovacuum worker is already gone when we attempt to signal it, and reduce log verbosity for such signals (Tom Lane)

- Prevent autovacuum launcher from sleeping unduly long if the server clock is moved backwards a large amount (Álvaro Herrera)

- Ensure that cleanup of a GIN index’s pending-insertions list is interruptable by cancel requests (Jeff Janes)

- Allow all-zeros pages in GIN indexes to be reused (Heikki Linnakangas)
  Such a page might be left behind after a crash.

- Fix off-by-one error that led to otherwise-harmless warnings about “apparent wraparound” in subtrans/multixact truncation (Thomas Munro)

- Fix misreporting of CONTINUE and MOVE statement types in PL/pgSQL’s error context messages (Pavel Stehule, Tom Lane)

- Fix some places in PL/Tcl that neglected to check for failure of `malloc()` calls (Michael Paquier, Álvaro Herrera)

- Improve libpq’s handling of out-of-memory conditions (Michael Paquier, Heikki Linnakangas)

- Fix memory leaks and missing out-of-memory checks in ecpg (Michael Paquier)

- Fix psq1’s code for locale-aware formatting of numeric output (Tom Lane)
  The formatting code invoked by `\pset numericlocale` on did the wrong thing for some uncommon cases such as numbers with an exponent but no decimal point. It could also mangle already-localized output from the `money` data type.

- Prevent crash in psql’s `\c` command when there is no current connection (Noah Misch)

- Ensure that temporary files created during a `pg_dump` run with tar-format output are not world-readable (Michael Paquier)

- Fix `pg_dump` and `pg_upgrade` to support cases where the `postgres` or `template1` database is in a non-default tablespace (Marti Raudsepp, Bruce Momjian)

- Fix `pg_dump` to handle object privileges sanely when dumping from a server too old to have a particular privilege type (Tom Lane)
  When dumping functions or procedural languages from pre-7.3 servers, `pg_dump` would produce `GRANT/REVOKE` commands that revoked the owner’s grantable privileges and instead granted all privileges to `PUBLIC`. Since the privileges involved are just `USAGE` and `EXECUTE`, this isn’t a security problem, but it’s certainly a surprising representation of the older systems’ behavior. Fix it to leave the default privilege state alone in these cases.

- Fix `pg_dump` to dump shell types (Tom Lane)
  Shell types (that is, not-yet-fully-defined types) aren’t useful for much, but nonetheless `pg_dump` should dump them.

- Fix spinlock assembly code for PPC hardware to be compatible with AIX’s native assembler (Tom Lane)
Building with gcc didn’t work if gcc had been configured to use the native assembler, which is becoming more common.

- On AIX, test the `–qlonglong` compiler option rather than just assuming it’s safe to use (Noah Misch)
- On AIX, use `–Wl,-brtllib` link option to allow symbols to be resolved at runtime (Noah Misch)
  Perl relies on this ability in 5.8.0 and later.
- Avoid use of inline functions when compiling with 32-bit xlc, due to compiler bugs (Noah Misch)
- Use `librt` for `sched_yield()` when necessary, which it is on some Solaris versions (Oskari Saarenmaa)
- Fix Windows `install.bat` script to handle target directory names that contain spaces (Heikki Linnakangas)
- Make the numeric form of the PostgreSQL version number (e.g., 90405) readily available to extension Makefiles, as a variable named `VERSION_NUM` (Michael Paquier)
- Update time zone data files to `tzdata` release 2015g for DST law changes in Cayman Islands, Fiji, Moldova, Morocco, Norfolk Island, North Korea, Turkey, and Uruguay. There is a new zone name `America/Fort_Nelson` for the Canadian Northern Rockies.

E.112. Release 9.0.22

Release date: 2015-06-12

This release contains a small number of fixes from 9.0.21. For information about new features in the 9.0 major release, see Section E.134.

The PostgreSQL community will stop releasing updates for the 9.0.X release series in September 2015. Users are encouraged to update to a newer release branch soon.

E.112.1. Migration to Version 9.0.22

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.18, see Section E.116.

E.112.2. Changes

- Fix rare failure to invalidate relation cache init file (Tom Lane)
  With just the wrong timing of concurrent activity, a `VACUUM FULL` on a system catalog might fail to update the “init file” that’s used to avoid cache-loading work for new sessions. This would result in later sessions being unable to access that catalog at all. This is a very ancient bug, but it’s so hard to trigger that no reproducible case had been seen until recently.
- Avoid deadlock between incoming sessions and `CREATE/DROP DATABASE` (Tom Lane)
  A new session starting in a database that is the target of a `DROP DATABASE` command, or is the template for a `CREATE DATABASE` command, could cause the command to wait for five seconds and then fail, even if the new session would have exited before that.
E.113. Release 9.0.21

Release date: 2015-06-04

This release contains a small number of fixes from 9.0.20. For information about new features in the 9.0 major release, see Section E.134.

The PostgreSQL community will stop releasing updates for the 9.0.X release series in September 2015. Users are encouraged to update to a newer release branch soon.

E.113.1. Migration to Version 9.0.21

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.18, see Section E.116.

E.113.2. Changes

- Avoid failures while fsync'ing data directory during crash restart (Abhijit Menon-Sen, Tom Lane)
  In the previous minor releases we added a patch to fsync everything in the data directory after a crash. Unfortunately its response to any error condition was to fail, thereby preventing the server from starting up, even when the problem was quite harmless. An example is that an unwritable file in the data directory would prevent restart on some platforms; but it is common to make SSL certificate files unwritable by the server. Revise this behavior so that permissions failures are ignored altogether, and other types of failures are logged but do not prevent continuing.

- Remove configure's check prohibiting linking to a threaded libpython on OpenBSD (Tom Lane)
  The failure this restriction was meant to prevent seems to not be a problem anymore on current OpenBSD versions.

- Allow libpq to use TLS protocol versions beyond v1 (Noah Misch)
  For a long time, libpq was coded so that the only SSL protocol it would allow was TLS v1. Now that newer TLS versions are becoming popular, allow it to negotiate the highest commonly-supported TLS version with the server. (PostgreSQL servers were already capable of such negotiation, so no change is needed on the server side.) This is a back-patch of a change already released in 9.4.0.

E.114. Release 9.0.20

Release date: 2015-05-22

This release contains a variety of fixes from 9.0.19. For information about new features in the 9.0 major release, see Section E.134.

The PostgreSQL community will stop releasing updates for the 9.0.X release series in September 2015. Users are encouraged to update to a newer release branch soon.

E.114.1. Migration to Version 9.0.20

A dump/restore is not required for those running 9.0.X.
However, if you are upgrading from a version earlier than 9.0.18, see Section E.116.

E.114.2. Changes

- Avoid possible crash when client disconnects just before the authentication timeout expires (Benkocs Norbert Attila)

  If the timeout interrupt fired partway through the session shutdown sequence, SSL-related state
  would be freed twice, typically causing a crash and hence denial of service to other sessions.
  Experimentation shows that an unauthenticated remote attacker could trigger the bug somewhat
  consistently, hence treat as security issue. (CVE-2015-3165)

- Improve detection of system-call failures (Noah Misch)

  Our replacement implementation of `snprintf()` failed to check for errors reported by the under-
  lying system library calls; the main case that might be missed is out-of-memory situations. In the
  worst case this might lead to information exposure, due to our code assuming that a buffer had been
  overwritten when it hadn’t been. Also, there were a few places in which security-relevant calls of
  other system library functions did not check for failure.

  It remains possible that some calls of the `*printf()` family of functions are vulnerable to infor-
  mation disclosure if an out-of-memory error occurs at just the wrong time. We judge the risk to not
  be large, but will continue analysis in this area. (CVE-2015-3166)

- In `contrib/pgcrypto`, uniformly report decryption failures as “Wrong key or corrupt data”
  (Noah Misch)

  Previously, some cases of decryption with an incorrect key could report other error message texts. It
  has been shown that such variance in error reports can aid attackers in recovering keys from other
  systems. While it’s unknown whether `pgcrypto`’s specific behaviors are likewise exploitable, it
  seems better to avoid the risk by using a one-size-fits-all message. (CVE-2015-3167)

- Fix incorrect checking of deferred exclusion constraints after a HOT update (Tom Lane)

  If a new row that potentially violates a deferred exclusion constraint is HOT-updated (that is, no
  indexed columns change and the row can be stored back onto the same table page) later in the same
  transaction, the exclusion constraint would be reported as violated when the check finally occurred,
  even if the row(s) the new row originally conflicted with had been deleted.

- Prevent improper reordering of antijoins (NOT EXISTS joins) versus other outer joins (Tom Lane)

  This oversight in the planner has been observed to cause “could not find RelOptInfo for given
  relids” errors, but it seems possible that sometimes an incorrect query plan might get past that
  consistency check and result in silently-wrong query output.

- Fix incorrect matching of subexpressions in outer-join plan nodes (Tom Lane)

  Previously, if textually identical non-strict subexpressions were used both above and below an outer
  join, the planner might try to re-use the value computed below the join, which would be incorrect
  because the executor would force the value to NULL in case of an unmatched outer row.

- Fix GEQO planner to cope with failure of its join order heuristic (Tom Lane)

  This oversight has been seen to lead to “failed to join all relations together” errors in queries in-
  volving `LATERAL`, and that might happen in other cases as well.

- Fix possible deadlock at startup when `max_prepared_transactions` is too small (Heikki Lin-
nakangas)
• Don’t archive useless preallocated WAL files after a timeline switch (Heikki Linnakangas)

• Avoid “cannot GetMultiXactIdMembers() during recovery” error (Álvaro Herrera)

• Recursively fsync() the data directory after a crash (Abhijit Menon-Sen, Robert Haas)
  This ensures consistency if another crash occurs shortly later. (The second crash would have to be a system-level crash, not just a database crash, for there to be a problem.)

• Fix autovacuum launcher’s possible failure to shut down, if an error occurs after it receives SIGTERM (Álvaro Herrera)

• Cope with unexpected signals in LockBufferForCleanup() (Andres Freund)
  This oversight could result in spurious errors about “multiple backends attempting to wait for pin-count 1”.

• Avoid waiting for WAL flush or synchronous replication during commit of a transaction that was read-only so far as the user is concerned (Andres Freund)
  Previously, a delay could occur at commit in transactions that had written WAL due to HOT page pruning, leading to undesirable effects such as sessions getting stuck at startup if all synchronous replicas are down. Sessions have also been observed to get stuck in catchup interrupt processing when using synchronous replication; this will fix that problem as well.

• Fix crash when manipulating hash indexes on temporary tables (Heikki Linnakangas)

• Fix possible failure during hash index bucket split, if other processes are modifying the index concurrently (Tom Lane)

• Check for interrupts while analyzing index expressions (Jeff Janes)
  ANALYZE executes index expressions many times; if there are slow functions in such an expression, it’s desirable to be able to cancel the ANALYZE before that loop finishes.

• Add the name of the target server to object description strings for foreign-server user mappings (Álvaro Herrera)

• Recommend setting include_realm to 1 when using Kerberos/GSSAPI/SSPI authentication (Stephen Frost)
  Without this, identically-named users from different realms cannot be distinguished. For the moment this is only a documentation change, but it will become the default setting in PostgreSQL 9.5.

• Remove code for matching IPv4 pg_hba.conf entries to IPv4-in-IPv6 addresses (Tom Lane)
  This hack was added in 2003 in response to a report that some Linux kernels of the time would report IPv4 connections as having IPv4-in-IPv6 addresses. However, the logic was accidentally broken in 9.0. The lack of any field complaints since then shows that it’s not needed anymore. Now we have reports that the broken code causes crashes on some systems, so let’s just remove it rather than fix it. (Had we chosen to fix it, that would make for a subtle and potentially security-sensitive change in the effective meaning of IPv4 pg_hba.conf entries, which does not seem like a good thing to do in minor releases.)

• While shutting down service on Windows, periodically send status updates to the Service Control Manager to prevent it from killing the service too soon; and ensure that pg_ctl will wait for shutdown (Krystian Bigaj)

• Reduce risk of network deadlock when using libpq’s non-blocking mode (Heikki Linnakangas)
  When sending large volumes of data, it’s important to drain the input buffer every so often, in case the server has sent enough response data to cause it to block on output. (A typical scenario is that the server is sending a stream of NOTICE messages during COPY FROM STDIN.) This worked
properly in the normal blocking mode, but not so much in non-blocking mode. We’ve modified libpq to opportunistically drain input when it can, but a full defense against this problem requires application cooperation: the application should watch for socket read-ready as well as write-ready conditions, and be sure to call PQconsumeInput() upon read-ready.

• Fix array handling in ecpg (Michael Meskes)
• Fix psql to sanely handle URIs and conninfo strings as the first parameter to \connect (David Fetter, Andrew Dunstan, Álvaro Herrera)

This syntax has been accepted (but undocumented) for a long time, but previously some parameters might be taken from the old connection instead of the given string, which was agreed to be undesirable.

• Suppress incorrect complaints from psql on some platforms that it failed to write ~/.psql_history at exit (Tom Lane)

This misbehavior was caused by a workaround for a bug in very old (pre-2006) versions of libedit. We fixed it by removing the workaround, which will cause a similar failure to appear for anyone still using such versions of libedit. Recommendation: upgrade that library, or use libreadline.

• Fix pg_dump’s rule for deciding which casts are system-provided casts that should not be dumped (Tom Lane)
• Fix dumping of views that are just VALUES(...) but have column aliases (Tom Lane)
• In pg_upgrade, force timeline 1 in the new cluster (Bruce Momjian)

This change prevents upgrade failures caused by bogus complaints about missing WAL history files.

• In pg_upgrade, check for improperly non-connectable databases before proceeding (Bruce Momjian)
• In pg_upgrade, quote directory paths properly in the generated delete_old_cluster script (Bruce Momjian)
• In pg_upgrade, preserve database-level freezing info properly (Bruce Momjian)

This oversight could cause missing-clog-file errors for tables within the postgres and template1 databases.

• Run pg_upgrade and pg_resetxlog with restricted privileges on Windows, so that they don’t fail when run by an administrator (Muhammad Asif Naeem)
• Fix slow sorting algorithm in contrib/intarray (Tom Lane)
• Fix compile failure on Sparc V8 machines (Rob Rowan)
• Update time zone data files to tzdata release 2015d for DST law changes in Egypt, Mongolia, and Palestine, plus historical changes in Canada and Chile. Also adopt revised zone abbreviations for the America/Adak zone (HST/HDT not HAST/HADT).

E.115. Release 9.0.19

Release date: 2015-02-05

This release contains a variety of fixes from 9.0.18. For information about new features in the 9.0 major release, see Section E.134.
Appendix E. Release Notes

E.115.1. Migration to Version 9.0.19

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.18, see Section E.116.

E.115.2. Changes

- **Fix buffer overruns in to_char()** (Bruce Momjian)

  When to_char() processes a numeric formatting template calling for a large number of digits, PostgreSQL would read past the end of a buffer. When processing a crafted timestamp formatting template, PostgreSQL would write past the end of a buffer. Either case could crash the server. We have not ruled out the possibility of attacks that lead to privilege escalation, though they seem unlikely. (CVE-2015-0241)

- **Fix buffer overrun in replacement *printf() functions** (Tom Lane)

  PostgreSQL includes a replacement implementation of printf and related functions. This code will overrun a stack buffer when formatting a floating point number (conversion specifiers e, E, f, F, g or G) with requested precision greater than about 500. This will crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. A database user can trigger such a buffer overrun through the to_char() SQL function. While that is the only affected core PostgreSQL functionality, extension modules that use printf-family functions may be at risk as well.

  This issue primarily affects PostgreSQL on Windows. PostgreSQL uses the system implementation of these functions where adequate, which it is on other modern platforms. (CVE-2015-0242)

- **Fix buffer overruns in contrib/pgcrypto** (Marko Tiikkaja, Noah Misch)

  Errors in memory size tracking within the pgcrypto module permitted stack buffer overruns and improper dependence on the contents of uninitialized memory. The buffer overrun cases can crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. (CVE-2015-0243)

- **Fix possible loss of frontend/backend protocol synchronization after an error** (Heikki Linnakangas)

  If any error occurred while the server was in the middle of reading a protocol message from the client, it could lose synchronization and incorrectly try to interpret part of the message’s data as a new protocol message. An attacker able to submit crafted binary data within a command parameter might succeed in injecting his own SQL commands this way. Statement timeout and query cancellation are the most likely sources of errors triggering this scenario. Particularly vulnerable are applications that use a timeout and also submit arbitrary user-crafted data as binary query parameters. Disabling statement timeout will reduce, but not eliminate, the risk of exploit. Our thanks to Emil Lenngren for reporting this issue. (CVE-2015-0244)

- **Fix information leak via constraint-violation error messages** (Stephen Frost)

  Some server error messages show the values of columns that violate a constraint, such as a unique constraint. If the user does not have SELECT privilege on all columns of the table, this could mean exposing values that the user should not be able to see. Adjust the code so that values are displayed only when they came from the SQL command or could be selected by the user. (CVE-2014-8161)

- **Lock down regression testing’s temporary installations on Windows** (Noah Misch)
Appendix E. Release Notes

Use SSPI authentication to allow connections only from the OS user who launched the test suite. This closes on Windows the same vulnerability previously closed on other platforms, namely that other users might be able to connect to the test postmaster. (CVE-2014-0067)

• Avoid possible data corruption if \texttt{ALTER DATABASE SET TABLESPACE} is used to move a database to a new tablespace and then shortly later move it back to its original tablespace (Tom Lane)

• Avoid corrupting tables when \texttt{ANALYZE} inside a transaction is rolled back (Andres Freund, Tom Lane, Michael Paquier)

If the failing transaction had earlier removed the last index, rule, or trigger from the table, the table would be left in a corrupted state with the relevant \texttt{pg_class} flags not set though they should be.

• Fix use-of-already-freed-memory problem in EvalPlanQual processing (Tom Lane)

In \texttt{READ COMMITTED} mode, queries that lock or update recently-updated rows could crash as a result of this bug.

• Fix planning of \texttt{SELECT FOR UPDATE} when using a partial index on a child table (Kyotaro Horiguchi)

In \texttt{READ COMMITTED} mode, \texttt{SELECT FOR UPDATE} must also recheck the partial index’s \texttt{WHERE} condition when rechecking a recently-updated row to see if it still satisfies the query’s \texttt{WHERE} condition. This requirement was missed if the index belonged to an inheritance child table, so that it was possible to incorrectly return rows that no longer satisfy the query condition.

• Fix corner case wherein \texttt{SELECT FOR UPDATE} could return a row twice, and possibly miss returning other rows (Tom Lane)

In \texttt{READ COMMITTED} mode, a \texttt{SELECT FOR UPDATE} that is scanning an inheritance tree could incorrectly return a row from a prior child table instead of the one it should return from a later child table.

• Reject duplicate column names in the referenced-columns list of a \texttt{FOREIGN KEY} declaration (David Rowley)

This restriction is per SQL standard. Previously we did not reject the case explicitly, but later on the code would fail with bizarre-looking errors.

• Fix bugs in raising a \texttt{numeric} value to a large integral power (Tom Lane)

The previous code could get a wrong answer, or consume excessive amounts of time and memory before realizing that the answer must overflow.

• In \texttt{numeric_recv()}, truncate away any fractional digits that would be hidden according to the value’s \texttt{dscale} field (Tom Lane)

A \texttt{numeric} value’s display scale (\texttt{dscale}) should never be less than the number of nonzero fractional digits; but apparently there’s at least one broken client application that transmits binary \texttt{numeric} values in which that’s true. This leads to strange behavior since the extra digits are taken into account by arithmetic operations even though they aren’t printed. The least risky fix seems to be to truncate away such “hidden” digits on receipt, so that the value is indeed what it prints as.

• Reject out-of-range numeric timezone specifications (Tom Lane)

Simple numeric timezone specifications exceeding +/- 168 hours (one week) would be accepted, but could then cause null-pointer dereference crashes in certain operations. There’s no use-case for such large UTC offsets, so reject them.

• Fix bugs in \texttt{tsquery @> tsquery} operator (Heikki Linnakangas)
Two different terms would be considered to match if they had the same CRC. Also, if the second operand had more terms than the first, it would be assumed not to be contained in the first; which is wrong since it might contain duplicate terms.

- Improve ispell dictionary’s defenses against bad affix files (Tom Lane)
- Allow more than 64K phrases in a thesaurus dictionary (David Boutin)
  The previous coding could crash on an oversize dictionary, so this was deemed a back-patchable bug fix rather than a feature addition.
- Fix namespace handling in xpath() (Ali Akbar)
  Previously, the xml value resulting from an xpath() call would not have namespace declarations if the namespace declarations were attached to an ancestor element in the input xml value, rather than to the specific element being returned. Propagate the ancestral declaration so that the result is correct when considered in isolation.
- Fix planner problems with nested append relations, such as inherited tables within UNION ALL subqueries (Tom Lane)
- Fail cleanly when a GiST index tuple doesn’t fit on a page, rather than going into infinite recursion (Andrew Gierth)
- Exempt tables that have per-table cost_limit and/or cost_delay settings from autovacuum’s global cost balancing rules (Álvaro Herrera)
  The previous behavior resulted in basically ignoring these per-table settings, which was unintended. Now, a table having such settings will be vacuumed using those settings, independently of what is going on in other autovacuum workers. This may result in heavier total I/O load than before, so such settings should be re-examined for sanity.
- Avoid wholesale autovacuuming when autovacuum is nominally off (Tom Lane)
  Even when autovacuum is nominally off, we will still launch autovacuum worker processes to vacuum tables that are at risk of XID wraparound. However, such a worker process then proceeded to vacuum all tables in the target database, if they met the usual thresholds for autovacuuming. This is at best pretty unexpected; at worst it delays response to the wraparound threat. Fix it so that if autovacuum is turned off, workers only do anti-wraparound vacuums and not any other work.
- Fix race condition between hot standby queries and replaying a full-page image (Heikki Linnakangas)
  This mistake could result in transient errors in queries being executed in hot standby.
- Fix several cases where recovery logic improperly ignored WAL records for COMMIT/ABORT PREPARED (Heikki Linnakangas)
  The most notable oversight was that recovery_target_xid could not be used to stop at a two-phase commit.
- Avoid creating unnecessary .ready marker files for timeline history files (Fujii Masao)
- Fix possible null pointer dereference when an empty prepared statement is used and the log_statement setting is mod or ddl (Fujii Masao)
- Change “pgstat wait timeout” warning message to be LOG level, and rephrase it to be more understandable (Tom Lane)
  This message was originally thought to be essentially a can’t-happen case, but it occurs often enough on our slower buildfarm members to be a nuisance. Reduce it to LOG level, and expend a bit more effort on the wording: it now reads “using stale statistics instead of current ones because stats collector is not responding”.

2558
Appendix E. Release Notes

- Fix SPARC spinlock implementation to ensure correctness if the CPU is being run in a non-TSO coherency mode, as some non-Solaris kernels do (Andres Freund)
- Warn if OS X’s `setlocale()` starts an unwanted extra thread inside the postmaster (Noah Misch)
- Fix processing of repeated `dbname` parameters in `PQconnectdbParams()` (Alex Shulgin)
  Unexpected behavior ensued if the first occurrence of `dbname` contained a connection string or URI to be expanded.
- Ensure that libpq reports a suitable error message on unexpected socket EOF (Marko Tiikkaja, Tom Lane)
  Depending on kernel behavior, libpq might return an empty error string rather than something useful when the server unexpectedly closed the socket.
- Clear any old error message during `PQreset()` (Heikki Linnakangas)
  If `PQreset()` is called repeatedly, and the connection cannot be re-established, error messages from the failed connection attempts kept accumulating in the `PGconn`'s error string.
- Properly handle out-of-memory conditions while parsing connection options in libpq (Alex Shulgin, Heikki Linnakangas)
- Fix array overrun in ecpg’s version of `ParseDateTime()` (Michael Paquier)
- In initdb, give a clearer error message if a password file is specified but is empty (Mats Erik Andersson)
- Fix psql’s `\s` command to work nicely with libedit, and add pager support (Stepan Rutz, Tom Lane)
  When using libedit rather than readline, `\s` printed the command history in a fairly unreadable encoded format, and on recent libedit versions might fail altogether. Fix that by printing the history ourselves rather than having the library do it. A pleasant side-effect is that the pager is used if appropriate.
  This patch also fixes a bug that caused newline encoding to be applied inconsistently when saving the command history with libedit. Multiline history entries written by older psql versions will be read cleanly with this patch, but perhaps not vice versa, depending on the exact libedit versions involved.
- Improve consistency of parsing of psql’s special variables (Tom Lane)
  Allow variant spellings of `on` and `off` (such as `1/0`) for `ECHO_HIDDEN` and `ON_ERROR_ROLLBACK`. Report a warning for unrecognized values for `COMP_KEYWORD_CASE`, `ECHO`, `ECHO_HIDDEN`, `HISTCONTROL`, `ON_ERROR_ROLLBACK`, and `VERBOSITY`. Recognize all values for all these variables case-insensitively; previously there was a mishmash of case-sensitive and case-insensitive behaviors.
- Fix psql’s expanded-mode display to work consistently when using `border = 3` and `linestyle = ascii` or `unicode` (Stephen Frost)
- Fix possible deadlock during parallel restore of a schema-only dump (Robert Haas, Tom Lane)
- Fix core dump in `pg_dump --binary-upgrade` on zero-column composite type (Rushabh Lathia)
- Fix block number checking in `contrib/pageinspect`’s `get_raw_page()` (Tom Lane)
  The incorrect checking logic could prevent access to some pages in non-main relation forks.
- Fix `contrib/pgcrypto`’s `pgp_sym_decrypt()` to not fail on messages whose length is 6 less than a power of 2 (Marko Tiikkaja)
Appendix E. Release Notes

- Handle unexpected query results, especially NULLs, safely in contrib/tablefunc's connectby() (Michael Paquier)
  connectby() previously crashed if it encountered a NULL key value. It now prints that row but doesn’t recurse further.

- Avoid a possible crash in contrib/xml2's xslt_process() (Mark Simonetti)
  libxslt seems to have an undocumented dependency on the order in which resources are freed; reorder our calls to avoid a crash.

- Numerous cleanups of warnings from Coverity static code analyzer (Andres Freund, Tatsuo Ishii, Marko Kreen, Tom Lane, Michael Paquier)
  These changes are mostly cosmetic but in some cases fix corner-case bugs, for example a crash rather than a proper error report after an out-of-memory failure. None are believed to represent security issues.

- Detect incompatible OpenLDAP versions during build (Noah Misch)
  With OpenLDAP versions 2.4.24 through 2.4.31, inclusive, PostgreSQL backends can crash at exit. Raise a warning during configure based on the compile-time OpenLDAP version number, and test the crashing scenario in the contrib/dblink regression test.

- In non-MSVC Windows builds, ensure libpq.dll is installed with execute permissions (Noah Misch)

- Make pg_regress remove any temporary installation it created upon successful exit (Tom Lane)
  This results in a very substantial reduction in disk space usage during make check-world, since that sequence involves creation of numerous temporary installations.

- Support time zone abbreviations that change UTC offset from time to time (Tom Lane)
  Previously, PostgreSQL assumed that the UTC offset associated with a time zone abbreviation (such as EST) never changes in the usage of any particular locale. However this assumption fails in the real world, so introduce the ability for a zone abbreviation to represent a UTC offset that sometimes changes. Update the zone abbreviation definition files to make use of this feature in timezone locales that have changed the UTC offset of their abbreviations since 1970 (according to the IANA timezone database). In such timezones, PostgreSQL will now associate the correct UTC offset with the abbreviation depending on the given date.

- Update time zone abbreviations lists (Tom Lane)
  Add CST (China Standard Time) to our lists. Remove references to ADT as “Arabia Daylight Time”, an abbreviation that’s been out of use since 2007; therefore, claiming there is a conflict with “Atlantic Daylight Time” doesn’t seem especially helpful. Fix entirely incorrect GMT offsets for CKT (Cook Islands), FJT, and FJST (Fiji); we didn’t even have them on the proper side of the date line.

- Update time zone data files to tzdata release 2015a.
  The IANA timezone database has adopted abbreviations of the form A_xST/A_xDT for all Australian time zones, reflecting what they believe to be current majority practice Down Under. These names do not conflict with usage elsewhere (other than ACST for Acre Summer Time, which has been in disuse since 1994). Accordingly, adopt these names into our “Default” timezone abbreviation set. The “Australia” abbreviation set now contains only CST, EAST, EST, SAST, SAT, and WST, all of which are thought to be mostly historical usage. Note that SAST has also been changed to be South Africa Standard Time in the “Default” abbreviation set.
  Also, add zone abbreviations SRET (Asia/Srednekolymsk) and XJT (Asia/Urumqi), and use WSST/WSDT for western Samoa. Also, there were DST law changes in Chile, Mexico, the Turks...
& Caicos Islands (America/Grand_Turk), and Fiji. There is a new zone Pacific/Bougainville for portions of Papua New Guinea. Also, numerous corrections for historical (pre-1970) time zone data.

### E.116. Release 9.0.18

**Release date:** 2014-07-24

This release contains a variety of fixes from 9.0.17. For information about new features in the 9.0 major release, see Section E.134.

### E.116.1. Migration to Version 9.0.18

A dump/restore is not required for those running 9.0.X.

However, this release corrects an index corruption problem in some GiST indexes. See the first changelog entry below to find out whether your installation has been affected and what steps you should take if so.

Also, if you are upgrading from a version earlier than 9.0.15, see Section E.119.

### E.116.2. Changes

- Correctly initialize padding bytes in `contrib/btree_gist` indexes on `bit` columns (Heikki Linnakangas)
  
  This error could result in incorrect query results due to values that should compare equal not being seen as equal. Users with GiST indexes on `bit` or `bit varying` columns should `REINDEX` those indexes after installing this update.

- Protect against torn pages when deleting GIN list pages (Heikki Linnakangas)
  
  This fix prevents possible index corruption if a system crash occurs while the page update is being written to disk.

- Don’t clear the right-link of a GiST index page while replaying updates from WAL (Heikki Linnakangas)
  
  This error could lead to transiently wrong answers from GiST index scans performed in Hot Standby.

- Fix possibly-incorrect cache invalidation during nested calls to `ReceiveSharedInvalidMessages` (Andres Freund)

- Don’t assume a subquery’s output is unique if there’s a set-returning function in its targetlist (David Rowley)
  
  This oversight could lead to misoptimization of constructs like `WHERE x IN (SELECT y, generate_series(1,10) FROM t GROUP BY y)`.

- Fix failure to detoast fields in composite elements of structured types (Tom Lane)
  
  This corrects cases where TOAST pointers could be copied into other tables without being dereferenced. If the original data is later deleted, it would lead to errors like “missing chunk number 0 for toast value ...” when the now-dangling pointer is used.
Appendix E. Release Notes

- Fix “record type has not been registered” failures with whole-row references to the output of Append plan nodes (Tom Lane)
- Fix possible crash when invoking a user-defined function while rewinding a cursor (Tom Lane)
- Fix query-lifespan memory leak while evaluating the arguments for a function in FROM (Tom Lane)
- Fix session-lifespan memory leaks in regular-expression processing (Tom Lane, Arthur O’Dwyer, Greg Stark)
- Fix data encoding error in hungarian.stop (Tom Lane)
- Fix liveness checks for rows that were inserted in the current transaction and then deleted by a now-rolled-back subtransaction (Andres Freund)
  This could cause problems (at least spurious warnings, and at worst an infinite loop) if CREATE INDEX or CLUSTER were done later in the same transaction.
- Clear pg_stat_activity.xact_start during PREPARE TRANSACTION (Andres Freund)
  After the PREPARE, the originating session is no longer in a transaction, so it should not continue to display a transaction start time.
- Fix REASSIGN OWNED to not fail for text search objects (Álvaro Herrera)
- Block signals during postmaster startup (Tom Lane)
  This ensures that the postmaster will properly clean up after itself if, for example, it receives SIGINT while still starting up.
- Secure Unix-domain sockets of temporary postmasters started during make check (Noah Misch)
  Any local user able to access the socket file could connect as the server’s bootstrap superuser, then proceed to execute arbitrary code as the operating-system user running the test, as we previously noted in CVE-2014-0067. This change defends against that risk by placing the server’s socket in a temporary, mode 0700 subdirectory of /tmp. The hazard remains however on platforms where Unix sockets are not supported, notably Windows, because then the temporary postmaster must accept local TCP connections.
  A useful side effect of this change is to simplify make check testing in builds that override DEFAULT_PGSOCKET_DIR. Popular non-default values like /var/run/postgresql are often not writable by the build user, requiring workarounds that will no longer be necessary.
- Fix tablespace creation WAL replay to work on Windows (MauMau)
- Fix detection of socket creation failures on Windows (Bruce Momjian)
- On Windows, allow new sessions to absorb values of PGC_BACKEND parameters (such as log_connections) from the configuration file (Amit Kapila)
  Previously, if such a parameter were changed in the file post-startup, the change would have no effect.
- Properly quote executable path names on Windows (Nikhil Deshpande)
  This oversight could cause initdb and pg_upgrade to fail on Windows, if the installation path contained both spaces and @ signs.
- Fix linking of libpython on OS X (Tom Lane)
  The method we previously used can fail with the Python library supplied by Xcode 5.0 and later.
- Avoid buffer bloat in libpq when the server consistently sends data faster than the client can absorb it (Shin-ichi Morita, Tom Lane)
Appendix E. Release Notes

libpq could be coerced into enlarging its input buffer until it runs out of memory (which would be reported misleadingly as “lost synchronization with server”). Under ordinary circumstances it’s quite far-fetched that data could be continuously transmitted more quickly than the recv() loop can absorb it, but this has been observed when the client is artificially slowed by scheduler constraints.

- Ensure that LDAP lookup attempts in libpq time out as intended (Laurenz Albe)
- Fix ecpg to do the right thing when an array of char * is the target for a FETCH statement returning more than one row, as well as some other array-handling fixes (Ashutosh Bapat)
- Fix pg_restore’s processing of old-style large object comments (Tom Lane)
  A direct-to-database restore from an archive file generated by a pre-9.0 version of pg_dump would usually fail if the archive contained more than a few comments for large objects.
- In contrib/pgcrypto functions, ensure sensitive information is cleared from stack variables before returning (Marko Kreen)
- In contrib/uuid-ossp, cache the state of the OSSP UUID library across calls (Tom Lane)
  This improves the efficiency of UUID generation and reduces the amount of entropy drawn from /dev/urandom, on platforms that have that.
- Update time zone data files to tzdata release 2014e for DST law changes in Crimea, Egypt, and Morocco.

E.117. Release 9.0.17

Release date: 2014-03-20

This release contains a variety of fixes from 9.0.16. For information about new features in the 9.0 major release, see Section E.134.

E.117.1. Migration to Version 9.0.17

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.15, see Section E.119.

E.117.2. Changes

- Restore GIN metapages unconditionally to avoid torn-page risk (Heikki Linnakangas)
  Although this oversight could theoretically result in a corrupted index, it is unlikely to have caused any problems in practice, since the active part of a GIN metapage is smaller than a standard 512-byte disk sector.
- Avoid race condition in checking transaction commit status during receipt of a NOTIFY message (Marko Tiikkaja)
  This prevents a scenario wherein a sufficiently fast client might respond to a notification before database updates made by the notifier have become visible to the recipient.
- Allow regular-expression operators to be terminated early by query cancel requests (Tom Lane)
Appendix E. Release Notes

This prevents scenarios wherein a pathological regular expression could lock up a server process uninterruptibly for a long time.

- Remove incorrect code that tried to allow overlaps with single-element row arguments (Joshua Yanovsky)
  This code never worked correctly, and since the case is neither specified by the SQL standard nor documented, it seemed better to remove it than fix it.
- Avoid getting more than AccessShareLock when de-parsing a rule or view (Dean Rasheed)
  This oversight resulted in pg_dump unexpectedly acquiring RowExclusiveLock locks on tables mentioned as the targets of INSERT/UPDATE/DELETE commands in rules. While usually harmless, that could interfere with concurrent transactions that tried to acquire, for example, ShareLock on those tables.
- Improve performance of index endpoint probes during planning (Tom Lane)
  This change fixes a significant performance problem that occurred when there were many not-yet-committed rows at the end of the index, which is a common situation for indexes on sequentially-assigned values such as timestamps or sequence-generated identifiers.
- Fix test to see if hot standby connections can be allowed immediately after a crash (Heikki Linnakangas)
- Prevent interrupts while reporting non-ERROR messages (Tom Lane)
  This guards against rare server-process freezeups due to recursive entry to syslog(), and perhaps other related problems.
- Prevent intermittent “could not reserve shared memory region” failures on recent Windows versions (MauMau)
- Update time zone data files to tzdata release 2014a for DST law changes in Fiji and Turkey, plus historical changes in Israel and Ukraine.

E.118. Release 9.0.16

Release date: 2014-02-20

This release contains a variety of fixes from 9.0.15. For information about new features in the 9.0 major release, see Section E.134.

E.118.1. Migration to Version 9.0.16

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.15, see Section E.119.

E.118.2. Changes

- Shore up Grant ... WITH ADMIN OPTION restrictions (Noah Misch)
  Granting a role without ADMIN OPTION is supposed to prevent the grantee from adding or removing members from the granted role, but this restriction was easily bypassed by doing SET ROLE
first. The security impact is mostly that a role member can revoke the access of others, contrary to the wishes of his grantor. Unapproved role member additions are a lesser concern, since an uncooperative role member could provide most of his rights to others anyway by creating views or SECURITY DEFINER functions. (CVE-2014-0060)

- Prevent privilege escalation via manual calls to PL validator functions (Andres Freund)
  
The primary role of PL validator functions is to be called implicitly during CREATE FUNCTION, but they are also normal SQL functions that a user can call explicitly. Calling a validator on a function actually written in some other language was not checked for and could be exploited for privilege-escalation purposes. The fix involves adding a call to a privilege-checking function in each validator function. Non-core procedural languages will also need to make this change to their own validator functions, if any. (CVE-2014-0061)

- Avoid multiple name lookups during table and index DDL (Robert Haas, Andres Freund)
  
  If the name lookups come to different conclusions due to concurrent activity, we might perform some parts of the DDL on a different table than other parts. At least in the case of CREATE INDEX, this can be used to cause the permissions checks to be performed against a different table than the index creation, allowing for a privilege escalation attack. (CVE-2014-0062)

- Prevent buffer overrun with long datetime strings (Noah Misch)
  
  The MAXDATELEN constant was too small for the longest possible value of type interval, allowing a buffer overrun in interval_out(). Although the datetime input functions were more careful about avoiding buffer overrun, the limit was short enough to cause them to reject some valid inputs, such as input containing a very long timezone name. The ecpg library contained these vulnerabilities along with some of its own. (CVE-2014-0063)

- Prevent buffer overrun due to integer overflow in size calculations (Noah Misch, Heikki Linnakan-gas)
  
  Several functions, mostly type input functions, calculated an allocation size without checking for overflow. If overflow did occur, a too-small buffer would be allocated and then written past. (CVE-2014-0064)

- Prevent overruns of fixed-size buffers (Peter Eisentraut, Jozef Mlich)
  
  Use strlcpy() and related functions to provide a clear guarantee that fixed-size buffers are not overrun. Unlike the preceding items, it is unclear whether these cases really represent live issues, since in most cases there appear to be previous constraints on the size of the input string. Nonetheless it seems prudent to silence all Coverity warnings of this type. (CVE-2014-0065)

- Avoid crashing if crypt() returns NULL (Honza Horak, Bruce Momjian)
  
  There are relatively few scenarios in which crypt() could return NULL, but contrib/chkpass would crash if it did. One practical case in which this could be an issue is if libc is configured to refuse to execute unapproved hashing algorithms (e.g., “FIPS mode”). (CVE-2014-0066)

- Document risks of make check in the regression testing instructions (Noah Misch, Tom Lane)
  
  Since the temporary server started by make check uses “trust” authentication, another user on the same machine could connect to it as database superuser, and then potentially exploit the privileges of the operating-system user who started the tests. A future release will probably incorporate changes in the testing procedure to prevent this risk, but some public discussion is needed first. So for the moment, just warn people against using make check when there are untrusted users on the same machine. (CVE-2014-0067)

- Fix possible mis-replay of WAL records when some segments of a relation aren’t full size (Greg Stark, Tom Lane)
The WAL update could be applied to the wrong page, potentially many pages past where it should have been. Aside from corrupting data, this error has been observed to result in significant “bloat” of standby servers compared to their masters, due to updates being applied far beyond where the end-of-file should have been. This failure mode does not appear to be a significant risk during crash recovery, only when initially synchronizing a standby created from a base backup taken from a quickly-changing master.

- Fix bug in determining when recovery has reached consistency (Tomonari Katsumata, Heikki Linnakangas)
  In some cases WAL replay would mistakenly conclude that the database was already consistent at the start of replay, thus possibly allowing hot-standby queries before the database was really consistent. Other symptoms such as “PANIC: WAL contains references to invalid pages” were also possible.

- Fix improper locking of btree index pages while replaying a VACUUM operation in hot-standby mode (Andres Freund, Heikki Linnakangas, Tom Lane)
  This error could result in “PANIC: WAL contains references to invalid pages” failures.

- Ensure that insertions into non-leaf GIN index pages write a full-page WAL record when appropriate (Heikki Linnakangas)
  The previous coding risked index corruption in the event of a partial-page write during a system crash.

- Fix race conditions during server process exit (Robert Haas)
  Ensure that signal handlers don’t attempt to use the process’s MyProc pointer after it’s no longer valid.

- Fix unsafe references to errno within error reporting logic (Christian Kruse)
  This would typically lead to odd behaviors such as missing or inappropriate HINT fields.

- Fix possible crashes from using ereport() too early during server startup (Tom Lane)
  The principal case we’ve seen in the field is a crash if the server is started in a directory it doesn’t have permission to read.

- Clear retry flags properly in OpenSSL socket write function (Alexander Kukushkin)
  This omission could result in a server lockup after unexpected loss of an SSL-encrypted connection.

- Fix length checking for Unicode identifiers (U"..." syntax) containing escapes (Tom Lane)
  A spurious truncation warning would be printed for such identifiers if the escaped form of the identifier was too long, but the identifier actually didn’t need truncation after de-escaping.

- Allow keywords that are type names to be used in lists of roles (Stephen Frost)
  A previous patch allowed such keywords to be used without quoting in places such as role identifiers; but it missed cases where a list of role identifiers was permitted, such as DROP ROLE.

- Fix possible crash due to invalid plan for nested sub-selects, such as WHERE (... x IN (SELECT ...) ...) IN (SELECT ...)(Tom Lane)

- Ensure that ANALYZE creates statistics for a table column even when all the values in it are “too wide” (Tom Lane)
  ANALYZE intentionally omits very wide values from its histogram and most-common-values calculations, but it neglected to do something sane in the case that all the sampled entries are too wide.
Appendix E. Release Notes

- In `ALTER TABLE ... SET TABLESPACE`, allow the database’s default tablespace to be used without a permissions check (Stephen Frost)
  
  `CREATE TABLE` has always allowed such usage, but `ALTER TABLE` didn’t get the memo.

- Fix “cannot accept a set” error when some arms of a `CASE` return a set and others don’t (Tom Lane)

- Fix checks for all-zero client addresses in pgstat functions (Kevin Grittner)

- Fix possible misclassification of multibyte characters by the text search parser (Tom Lane)
  
  Non-ASCII characters could be misclassified when using C locale with a multibyte encoding. On Cygwin, non-C locales could fail as well.

- Fix possible misbehavior in `plainto_tsquery()` (Heikki Linnakangas)
  
  Use `memmove()` not `memcpy()` for copying overlapping memory regions. There have been no field reports of this actually causing trouble, but it’s certainly risky.

- Accept `SHIFT_JIS` as an encoding name for locale checking purposes (Tatsuo Ishii)

- Fix misbehavior of `PQhost()` on Windows (Fujii Masao)
  
  It should return `localhost` if no host has been specified.

- Improve error handling in `libpq` and `psql` for failures during `COPY TO STDOUT/FROM STDIN` (Tom Lane)
  
  In particular this fixes an infinite loop that could occur in 9.2 and up if the server connection was lost during `COPY FROM STDIN`. Variants of that scenario might be possible in older versions, or with other client applications.

- Fix misaligned descriptors in `ecpg` (MauMau)

- In `ecpg`, handle lack of a hostname in the connection parameters properly (Michael Meskes)

- Fix performance regression in `contrib/dblink` connection startup (Joe Conway)
  
  Avoid an unnecessary round trip when client and server encodings match.

- In `contrib/isn`, fix incorrect calculation of the check digit for ISMN values (Fabien Coelho)

- Ensure client-code-only installation procedure works as documented (Peter Eisentraut)

- In Mingw and Cygwin builds, install the `libpq` DLL in the `bin` directory (Andrew Dunstan)
  
  This duplicates what the MSVC build has long done. It should fix problems with programs like `psql` failing to start because they can’t find the DLL.

- Avoid using the deprecated `dllwrap` tool in Cygwin builds (Marco Atzeri)

- Don’t generate plain-text `HISTORY` and `src/test/regress/README` files anymore (Tom Lane)
  
  These text files duplicated the main HTML and PDF documentation formats. The trouble involved in maintaining them greatly outweighs the likely audience for plain-text format. Distribution tarballs will still contain files by these names, but they’ll just be stubs directing the reader to consult the main documentation. The plain-text `INSTALL` file will still be maintained, as there is arguably a use-case for that.

- Update time zone data files to `tzdata` release 2013i for DST law changes in Jordan and historical changes in Cuba.
  
  In addition, the zones `Asia/Riyadh87`, `Asia/Riyadh88`, and `Asia/Riyadh89` have been removed, as they are no longer maintained by IANA, and never represented actual civil timekeeping practice.
E.119. Release 9.0.15

Release date: 2013-12-05

This release contains a variety of fixes from 9.0.14. For information about new features in the 9.0 major release, see Section E.134.

E.119.1. Migration to Version 9.0.15

A dump/restore is not required for those running 9.0.X.

However, this release corrects a number of potential data corruption issues. See the first two changelog entries below to find out whether your installation has been affected and what steps you can take if so.

Also, if you are upgrading from a version earlier than 9.0.13, see Section E.121.

E.119.2. Changes

- **Fix** VACUUM's tests to see whether it can update relfrozenxid (Andres Freund)

  In some cases VACUUM (either manual or autovacuum) could incorrectly advance a table’s relfrozenxid value, allowing tuples to escape freezing, causing those rows to become invisible once $2^{31}$ transactions have elapsed. The probability of data loss is fairly low since multiple incorrect advancements would need to happen before actual loss occurs, but it’s not zero. Users upgrading from releases 9.0.4 or 8.4.8 or earlier are not affected, but all later versions contain the bug.

  The issue can be ameliorated by, after upgrading, vacuuming all tables in all databases while having vacuum_freeze_table_age set to zero. This will fix any latent corruption but will not be able to fix all pre-existing data errors. However, an installation can be presumed safe after performing this vacuuming if it has executed fewer than $2^{31}$ update transactions in its lifetime (check this with SELECT txid_current() < $2^{31}$).

- **Fix** initialization of pg_clog and pg_subtrans during hot standby startup (Andres Freund, Heikki Linnakangas)

  This bug can cause data loss on standby servers at the moment they start to accept hot-standby queries, by marking committed transactions as uncommitted. The likelihood of such corruption is small unless, at the time of standby startup, the primary server has executed many updating transactions since its last checkpoint. Symptoms include missing rows, rows that should have been deleted being still visible, and obsolete versions of updated rows being still visible alongside their newer versions.

  This bug was introduced in versions 9.3.0, 9.2.5, 9.1.10, and 9.0.14. Standby servers that have only been running earlier releases are not at risk. It’s recommended that standby servers that have ever run any of the buggy releases be re-cloned from the primary (e.g., with a new base backup) after upgrading.

- **Truncate** pg_multixact contents during WAL replay (Andres Freund)

  This avoids ever-increasing disk space consumption in standby servers.

- **Fix** race condition in GIN index posting tree page deletion (Heikki Linnakangas)

  This could lead to transient wrong answers or query failures.
Appendix E. Release Notes

- Avoid flattening a subquery whose `SELECT` list contains a volatile function wrapped inside a sub-
  `SELECT` (Tom Lane)
  This avoids unexpected results due to extra evaluations of the volatile function.
- Fix planner’s processing of non-simple-variable subquery outputs nested within outer joins (Tom Lane)
  This error could lead to incorrect plans for queries involving multiple levels of subqueries within
  `JOIN` syntax.
- Fix premature deletion of temporary files (Andres Freund)
- Fix possible read past end of memory in rule printing (Peter Eisentraut)
- Fix array slicing of `int2vector` and `oidvector` values (Tom Lane)
  Expressions of this kind are now implicitly promoted to regular `int2` or `oid` arrays.
- Fix incorrect behaviors when using a SQL-standard, simple GMT offset timezone (Tom Lane)
  In some cases, the system would use the simple GMT offset value when it should have used the
  regular timezone setting that had prevailed before the simple offset was selected. This change also
  causes the `timeofday` function to honor the simple GMT offset zone.
- Prevent possible misbehavior when logging translations of Windows error codes (Tom Lane)
- Properly quote generated command lines in `pg_ctl` (Naoya Anzai and Tom Lane)
  This fix applies only to Windows.
- Fix `pg_dumpall` to work when a source database sets `default_transaction_read_only` via
  `ALTER DATABASE SET` (Kevin Grittner)
  Previously, the generated script would fail during restore.
- Fix `ecpg`’s processing of lists of variables declared `varchar` (Zoltán Böszörményi)
- Make `contrib/lo` defend against incorrect trigger definitions (Marc Cousin)
- Update time zone data files to tzdata release 2013h for DST law changes in Argentina, Brazil, Jor-
  dan, Libya, Liechtenstein, Morocco, and Palestine. Also, new timezone abbreviations WIB, WIT,
  WITA for Indonesia.

E.120. Release 9.0.14

Release date: 2013-10-10
This release contains a variety of fixes from 9.0.13. For information about new features in the 9.0
major release, see Section E.134.

E.120.1. Migration to Version 9.0.14

A dump/restore is not required for those running 9.0.X.
However, if you are upgrading from a version earlier than 9.0.13, see Section E.121.
E.120.2. Changes

- Prevent corruption of multi-byte characters when attempting to case-fold identifiers (Andrew Dunstan)
  PostgreSQL case-folds non-ASCII characters only when using a single-byte server encoding.
- Fix checkpoint memory leak in background writer when wal_level = hot_standby (Naoya Anzai)
- Fix memory leak caused by lo_open() failure (Heikki Linnakangas)
- Fix memory overcommit bug when work_mem is using more than 24GB of memory (Stephen Frost)
- Fix deadlock bug in libpq when using SSL (Stephen Frost)
- Fix possible SSL state corruption in threaded libpq applications (Nick Phillips, Stephen Frost)
- Properly compute row estimates for boolean columns containing many NULL values (Andrew Gierth)
  Previously tests like col IS NOT TRUE and col IS NOT FALSE did not properly factor in NULL values when estimating plan costs.
- Prevent pushing down WHERE clauses into unsafe UNION/INTERSECT subqueries (Tom Lane)
  Subqueries of a UNION or INTERSECT that contain set-returning functions or volatile functions in their SELECT lists could be improperly optimized, leading to run-time errors or incorrect query results.
- Fix rare case of “failed to locate grouping columns” planner failure (Tom Lane)
- Improve view dumping code’s handling of dropped columns in referenced tables (Tom Lane)
- Properly record index comments created using UNIQUE and PRIMARY KEY syntax (Andres Freund)
  This fixes a parallel pg_restore failure.
- Fix REINDEX TABLE and REINDEX DATABASE to properly revalidate constraints and mark invalidated indexes as valid (Noah Misch)
  REINDEX INDEX has always worked properly.
- Fix possible deadlock during concurrent CREATE INDEX CONCURRENTLY operations (Tom Lane)
- Fix regexp_matches() handling of zero-length matches (Jeevan Chalke)
  Previously, zero-length matches like '^' could return too many matches.
- Fix crash for overly-complex regular expressions (Heikki Linnakangas)
- Fix regular expression match failures for back references combined with non-greedy quantifiers (Jeevan Chalke)
- Prevent CREATE FUNCTION from checking SET variables unless function body checking is enabled (Tom Lane)
- Allow ALTER DEFAULT PRIVILEGES to operate on schemas without requiring CREATE permission (Tom Lane)
- Loosen restriction on keywords used in queries (Tom Lane)
  Specifically, lessen keyword restrictions for role names, language names, EXPLAIN and COPY options, and SET values. This allows COPY ... (FORMAT BINARY) to work as expected; previously BINARY needed to be quoted.
- Fix pgp_pub_decrypt() so it works for secret keys with passwords (Marko Kreen)
- Remove rare inaccurate warning during vacuum of index-less tables (Heikki Linnakangas)
- Ensure that VACUUM ANALYZE still runs the ANALYZE phase if its attempt to truncate the file is cancelled due to lock conflicts (Kevin Grittner)
- Avoid possible failure when performing transaction control commands (e.g. ROLLBACK) in prepared queries (Tom Lane)
- Ensure that floating-point data input accepts standard spellings of “infinity” on all platforms (Tom Lane)
  The C99 standard says that allowable spellings are \(\text{inf, +inf, -inf, infinity, +infinity, and -infinity. Make sure we recognize these even if the platform’s \text{strtol} function doesn’t.}\)
- Expand ability to compare rows to records and arrays (Rafal Rzepecki, Tom Lane)
- Update time zone data files to tzdata release 2013d for DST law changes in Israel, Morocco, Palestine, and Paraguay. Also, historical zone data corrections for Macquarie Island.

E.121. Release 9.0.13

Release date: 2013-04-04

This release contains a variety of fixes from 9.0.12. For information about new features in the 9.0 major release, see Section E.134.

E.121.1. Migration to Version 9.0.13

A dump/restore is not required for those running 9.0.X. However, this release corrects several errors in management of GiST indexes. After installing this update, it is advisable to REINDEX any GiST indexes that meet one or more of the conditions described below.

Also, if you are upgrading from a version earlier than 9.0.6, see Section E.128.

E.121.2. Changes

- Fix insecure parsing of server command-line switches (Mitsumasa Kondo, Kyotaro Horiguchi)
  A connection request containing a database name that begins with “-” could be crafted to damage or destroy files within the server’s data directory, even if the request is eventually rejected. (CVE-2013-1899)
- Reset OpenSSL randomness state in each postmaster child process (Marko Kreen)
  This avoids a scenario wherein random numbers generated by contrib/pgcrypto functions might be relatively easy for another database user to guess. The risk is only significant when the postmaster is configured with \text{ssl = on} but most connections don’t use SSL encryption. (CVE-2013-1900)
- Fix GiST indexes to not use “fuzzy” geometric comparisons when it’s not appropriate to do so (Alexander Korotkov)
The core geometric types perform comparisons using “fuzzy” equality, but `gist_box_same` must do exact comparisons, else GiST indexes using it might become inconsistent. After installing this update, users should `REINDEX` any GiST indexes on `box`, `polygon`, `circle`, or `point` columns, since all of these use `gist_box_same`.

- Fix erroneous range-union and penalty logic in GiST indexes that use `contrib/btree_gist` for variable-width data types, that is `text`, `bytea`, `bit`, and `numeric` columns (Tom Lane)
  These errors could result in inconsistent indexes in which some keys that are present would not be found by searches, and also in useless index bloat. Users are advised to `REINDEX` such indexes after installing this update.

- Fix bugs in GiST page splitting code for multi-column indexes (Tom Lane)
  These errors could result in inconsistent indexes in which some keys that are present would not be found by searches, and also in indexes that are unnecessarily inefficient to search. Users are advised to `REINDEX` multi-column GiST indexes after installing this update.

- Fix `gist_point_consistent` to handle fuzziness consistently (Alexander Korotkov)
  Index scans on GiST indexes on `point` columns would sometimes yield results different from a sequential scan, because `gist_point_consistent` disagreed with the underlying operator code about whether to do comparisons exactly or fuzzily.

- Fix buffer leak in WAL replay (Heikki Linnakangas)
  This bug could result in “incorrect local pin count” errors during replay, making recovery impossible.

- Fix race condition in `DELETE RETURNING` (Tom Lane)
  Under the right circumstances, `DELETE RETURNING` could attempt to fetch data from a shared buffer that the current process no longer has any pin on. If some other process changed the buffer meanwhile, this would lead to garbage `RETURNING` output, or even a crash.

- Fix infinite-loop risk in regular expression compilation (Tom Lane, Don Porter)
- Fix potential null-pointer dereference in regular expression compilation (Tom Lane)
- Fix `to_char()` to use ASCII-only case-folding rules where appropriate (Tom Lane)
  This fixes misbehavior of some template patterns that should be locale-independent, but mishandled “i” and “I” in Turkish locales.
- Fix unwanted rejection of timestamp `1999-12-31 24:00:00` (Tom Lane)
- Fix logic error when a single transaction does `UNLISTEN` then `LISTEN` (Tom Lane)
  The session wound up not listening for notify events at all, though it surely should listen in this case.
- Remove useless “picksplit doesn’t support secondary split” log messages (Josh Hansen, Tom Lane)
  This message seems to have been added in expectation of code that was never written, and probably never will be, since GiST’s default handling of secondary splits is actually pretty good. So stop nagging end users about it.
- Fix possible failure to send a session’s last few transaction commit/abort counts to the statistics collector (Tom Lane)
- Eliminate memory leaks in PL/Perl’s `spi_prepare()` function (Alex Hunsaker, Tom Lane)
- Fix `pg_dumpall` to handle database names containing “=” correctly (Heikki Linnakangas)
- Avoid crash in `pg_dump` when an incorrect connection string is given (Heikki Linnakangas)
• Ignore invalid indexes in pg_dump and pg_upgrade (Michael Paquier, Bruce Momjian)

Dumping invalid indexes can cause problems at restore time, for example if the reason the index creation failed was because it tried to enforce a uniqueness condition not satisfied by the table’s data. Also, if the index creation is in fact still in progress, it seems reasonable to consider it to be an uncommitted DDL change, which pg_dump wouldn’t be expected to dump anyway. pg_upgrade now also skips invalid indexes rather than failing.

• Fix contrib/pg_trgm’s similarity() function to return zero for trigram-less strings (Tom Lane)

Previously it returned NaN due to internal division by zero.

• Update time zone data files to tzdata release 2013b for DST law changes in Chile, Haiti, Morocco, Paraguay, and some Russian areas. Also, historical zone data corrections for numerous places. Also, update the time zone abbreviation files for recent changes in Russia and elsewhere: CHOT, GET, IRKT, KGT, KRAT, MAGT, MAWT, MSK, NOVT, OMST, TKT, VLAT, WST, YAKT, YEKT now follow their current meanings, and VOLT (Europe/Volgograd) and MIST (Antarctica/Macquarie) are added to the default abbreviations list.

E.122. Release 9.0.12

Release date: 2013-02-07

This release contains a variety of fixes from 9.0.11. For information about new features in the 9.0 major release, see Section E.134.

E.122.1. Migration to Version 9.0.12

A dump/restore is not required for those running 9.0.X. However, if you are upgrading from a version earlier than 9.0.6, see Section E.128.

E.122.2. Changes

• Prevent execution of enum_recv from SQL (Tom Lane)

The function was misdeclared, allowing a simple SQL command to crash the server. In principle an attacker might be able to use it to examine the contents of server memory. Our thanks to Sumit Soni (via Secunia SVCRP) for reporting this issue. (CVE-2013-0255)

• Fix multiple problems in detection of when a consistent database state has been reached during WAL replay (Fujii Masao, Heikki Linnakangas, Simon Riggs, Andres Freund)

• Update minimum recovery point when truncating a relation file (Heikki Linnakangas)

Once data has been discarded, it’s no longer safe to stop recovery at an earlier point in the timeline.

• Fix missing cancellations in hot standby mode (Noah Misch, Simon Riggs)

The need to cancel conflicting hot-standby queries would sometimes be missed, allowing those queries to see inconsistent data.

• Fix SQL grammar to allow subscripting or field selection from a sub-SELECT result (Tom Lane)
Appendix E. Release Notes

- Fix performance problems with autovacuum truncation in busy workloads (Jan Wieck)
  Truncation of empty pages at the end of a table requires exclusive lock, but autovacuum was coded
to fail (and release the table lock) when there are conflicting lock requests. Under load, it is easily
possible that truncation would never occur, resulting in table bloat. Fix by performing a partial
truncation, releasing the lock, then attempting to re-acquire the lock and continue. This fix also
greatly reduces the average time before autovacuum releases the lock after a conflicting request
arrives.

- Protect against race conditions when scanning `pg_tablespace` (Stephen Frost, Tom Lane)
  `CREATE DATABASE` and `DROP DATABASE` could misbehave if there were concurrent updates of
  `pg_tablespace` entries.

- Prevent `DROP OWNED` from trying to drop whole databases or tablespaces (Álvaro Herrera)
  For safety, ownership of these objects must be reassigned, not dropped.

- Fix error in `vacuum_freeze_table_age` implementation (Andres Freund)
  In installations that have existed for more than `vacuum_freeze_min_age` transactions, this mis-
  take prevented autovacuum from using partial-table scans, so that a full-table scan would always
  happen instead.

- Prevent misbehavior when a `RowExpr` or `XmlExpr` is parse-analyzed twice (Andres Freund, Tom
  Lane)
  This mistake could be user-visible in contexts such as `CREATE TABLE LIKE INCLUDING
  INDEXES`.

- Improve defenses against integer overflow in hashtable sizing calculations (Jeff Davis)

- Reject out-of-range dates in `to_date()` (Hitoshi Harada)

- Ensure that non-ASCII prompt strings are translated to the correct code page on Windows (Alexan-
  der Law, Noah Misch)
  This bug affected psql and some other client programs.

- Fix possible crash in psql’s `\?` command when not connected to a database (Meng Qingzhong)

- Fix `pg_upgrade` to deal with invalid indexes safely (Bruce Momjian)

- Fix one-byte buffer overrun in `libpq`'s `PQprintTuples` (Xi Wang)
  This ancient function is not used anywhere by PostgreSQL itself, but it might still be used by some
  client code.

- Make ecpglib use translated messages properly (Chen Huajun)

- Properly install ecpg_compat and pgtypes libraries on MSVC (Jiang Guiqing)

- Include our version of `isinf()` in libecpg if it’s not provided by the system (Jiang Guiqing)

- Rearrange configure’s tests for supplied functions so it is not fooled by bogus exports from
  libedit/libreadline (Christoph Berg)

- Ensure Windows build number increases over time (Magnus Hagander)

- Make `pgxs` build executables with the right `.exe` suffix when cross-compiling for Windows (Zoltan
  Boszormenyi)

- Add new timezone abbreviation `FET` (Tom Lane)
  This is now used in some eastern-European time zones.
E.123. Release 9.0.11

Release date: 2012-12-06

This release contains a variety of fixes from 9.0.10. For information about new features in the 9.0 major release, see Section E.134.

E.123.1. Migration to Version 9.0.11

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.6, see Section E.128.

E.123.2. Changes

- Fix multiple bugs associated with CREATE INDEX CONCURRENTLY (Andres Freund, Tom Lane)
  Fix CREATE INDEX CONCURRENTLY to use in-place updates when changing the state of an index’s pg_index row. This prevents race conditions that could cause concurrent sessions to miss updating the target index, thus resulting in corrupt concurrently-created indexes.
  Also, fix various other operations to ensure that they ignore invalid indexes resulting from a failed CREATE INDEX CONCURRENTLY command. The most important of these is VACUUM, because an auto-vacuum could easily be launched on the table before corrective action can be taken to fix or remove the invalid index.

- Fix buffer locking during WAL replay (Tom Lane)
  The WAL replay code was insufficiently careful about locking buffers when replaying WAL records that affect more than one page. This could result in hot standby queries transiently seeing inconsistent states, resulting in wrong answers or unexpected failures.

- Fix an error in WAL generation logic for GIN indexes (Tom Lane)
  This could result in index corruption, if a torn-page failure occurred.

- Properly remove startup process’s virtual XID lock when promoting a hot standby server to normal running (Simon Riggs)
  This oversight could prevent subsequent execution of certain operations such as CREATE INDEX CONCURRENTLY.

- Avoid bogus “out-of-sequence timeline ID” errors in standby mode (Heikki Linnakangas)

- Prevent the postmaster from launching new child processes after it’s received a shutdown signal (Tom Lane)
  This mistake could result in shutdown taking longer than it should, or even never completing at all without additional user action.

- Avoid corruption of internal hash tables when out of memory (Hitoshi Harada)

- Fix planning of non-strict equivalence clauses above outer joins (Tom Lane)
  The planner could derive incorrect constraints from a clause equating a non-strict construct to something else, for example WHERE COALESCE(foo, 0) = 0 when foo is coming from the nullable side of an outer join.

- Improve planner’s ability to prove exclusion constraints from equivalence classes (Tom Lane)
Appendix E. Release Notes

• Fix partial-row matching in hashed subplans to handle cross-type cases correctly (Tom Lane)
  This affects multicolumn NOT IN subplans, such as WHERE (a, b) NOT IN (SELECT x, y FROM ...) when for instance b and y are int4 and int8 respectively. This mistake led to wrong answers or crashes depending on the specific datatypes involved.

• Acquire buffer lock when re-fetching the old tuple for an AFTER ROW UPDATE/DELETE trigger (Andres Freund)
  In very unusual circumstances, this oversight could result in passing incorrect data to the precheck logic for a foreign-key enforcement trigger. That could result in a crash, or in an incorrect decision about whether to fire the trigger.

• Fix ALTER COLUMN TYPE to handle inherited check constraints properly (Pavan Deolasee)
  This worked correctly in pre-8.4 releases, and now works correctly in 8.4 and later.

• Fix REASSIGN OWNED to handle grants on tablespaces (Álvaro Herrera)

• Ignore incorrect pg_attribute entries for system columns for views (Tom Lane)
  Views do not have any system columns. However, we forgot to remove such entries when converting a table to a view. That’s fixed properly for 9.3 and later, but in previous branches we need to defend against existing mis-converted views.

• Fix rule printing to dump INSERT INTO table DEFAULT VALUES correctly (Tom Lane)

• Guard against stack overflow when there are too many UNION/INTERSECT/EXCEPT clauses in a query (Tom Lane)

• Prevent platform-dependent failures when dividing the minimum possible integer value by -1 (Xi Wang, Tom Lane)

• Fix possible access past end of string in date parsing (Hitoshi Harada)

• Fix failure to advance XID epoch if XID wraparound happens during a checkpoint and wal_level is hot_standby (Tom Lane, Andres Freund)
  While this mistake had no particular impact on PostgreSQL itself, it was bad for applications that rely on txid_current() and related functions: the TXID value would appear to go backwards.

• Produce an understandable error message if the length of the path name for a Unix-domain socket exceeds the platform-specific limit (Tom Lane, Andrew Dunstan)
  Formerly, this would result in something quite unhelpful, such as “Non-recoverable failure in name resolution”.

• Fix memory leaks when sending composite column values to the client (Tom Lane)

• Make pg_ctl more robust about reading the postmaster.pid file (Heikki Linnakangas)
  Fix race conditions and possible file descriptor leakage.

• Fix possible crash in psql if incorrectly-encoded data is presented and the client_encoding setting is a client-only encoding, such as SJIS (Jiang Guiqing)

• Fix bugs in the restore.sql script emitted by pg_dump in tar output format (Tom Lane)
  The script would fail outright on tables whose names include upper-case characters. Also, make the script capable of restoring data in --inserts mode as well as the regular COPY mode.

• Fix pg_restore to accept POSIX-conformant tar files (Brian Weaver, Tom Lane)
  The original coding of pg_dump’s tar output mode produced files that are not fully conformant with the POSIX standard. This has been corrected for version 9.3. This patch updates previous
branches so that they will accept both the incorrect and the corrected formats, in hopes of avoiding compatibility problems when 9.3 comes out.

- Fix pg_resetxlog to locate `postmaster.pid` correctly when given a relative path to the data directory (Tom Lane)
  This mistake could lead to pg_resetxlog not noticing that there is an active postmaster using the data directory.
- Fix libpq's `lo_import()` and `lo_export()` functions to report file I/O errors properly (Tom Lane)
- Fix ecpg’s processing of nested structure pointer variables (Muhammad Usama)
- Fix ecpg’s `ecpg_get_data` function to handle arrays properly (Michael Meskes)
- Make contrib/pageinspect’s btree page inspection functions take buffer locks while examining pages (Tom Lane)
- Fix pgxs support for building loadable modules on AIX (Tom Lane)
  Building modules outside the original source tree didn’t work on AIX.
- Update time zone data files to tzdata release 2012j for DST law changes in Cuba, Israel, Jordan, Libya, Palestine, Western Samoa, and portions of Brazil.

### E.124. Release 9.0.10

**Release date:** 2012-09-24

This release contains a variety of fixes from 9.0.9. For information about new features in the 9.0 major release, see Section E.134.

### E.124.1. Migration to Version 9.0.10

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.6, see Section E.128.

### E.124.2. Changes

- Fix planner’s assignment of executor parameters, and fix executor’s rescan logic for CTE plan nodes (Tom Lane)
  These errors could result in wrong answers from queries that scan the same WITH subquery multiple times.
- Improve page-splitting decisions in GiST indexes (Alexander Korotkov, Robert Haas, Tom Lane)
  Multi-column GiST indexes might suffer unexpected bloat due to this error.
- Fix cascading privilege revoke to stop if privileges are still held (Tom Lane)
  If we revoke a grant option from some role \( x \), but \( x \) still holds that option via a grant from someone else, we should not recursively revoke the corresponding privilege from role(s) \( y \) that \( x \) had granted it to.
• Improve error messages for Hot Standby misconfiguration errors (Gurjeet Singh)

• Fix handling of SIGFPE when PL/Perl is in use (Andres Freund)
  Perl resets the process’s SIGFPE handler to SIG_IGN, which could result in crashes later on. Re-
  store the normal Postgres signal handler after initializing PL/Perl.

• Prevent PL/Perl from crashing if a recursive PL/Perl function is redefined while being executed
  (Tom Lane)

• Work around possible misoptimization in PL/Perl (Tom Lane)
  Some Linux distributions contain an incorrect version of pthread.h that results in incorrect com-
  piled code in PL/Perl, leading to crashes if a PL/Perl function calls another one that throws an
  error.

• Fix pg_upgrade’s handling of line endings on Windows (Andrew Dunstan)
  Previously, pg_upgrade might add or remove carriage returns in places such as function bodies.

• On Windows, make pg_upgrade use backslash path separators in the scripts it emits (Andrew Dun-
  stan)

• Update time zone data files to tzdata release 2012f for DST law changes in Fiji

E.125. Release 9.0.9

Release date: 2012-08-17

This release contains a variety of fixes from 9.0.8. For information about new features in the 9.0 major
release, see Section E.134.

E.125.1. Migration to Version 9.0.9

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.6, see Section E.128.

E.125.2. Changes

• Prevent access to external files/URLs via XML entity references (Noah Misch, Tom Lane)
  xml_parse() would attempt to fetch external files or URLs as needed to resolve DTD and entity
  references in an XML value, thus allowing unprivileged database users to attempt to fetch data with
  the privileges of the database server. While the external data wouldn’t get returned directly to the
  user, portions of it could be exposed in error messages if the data didn’t parse as valid XML; and
  in any case the mere ability to check existence of a file might be useful to an attacker. (CVE-2012-
  3489)

• Prevent access to external files/URLs via contrib/xml2’s xslt_process() (Peter Eisentraut)
  libxml offers the ability to read and write both files and URLs through stylesheet commands, thus
  allowing unprivileged database users to both read and write data within the privileges of the database
  server. Disable that through proper use of libxml’s security options. (CVE-2012-3488)
Appendix E. Release Notes

Also, remove xslt_process()’s ability to fetch documents and stylesheets from external files/URLs. While this was a documented “feature”, it was long regarded as a bad idea. The fix for CVE-2012-3489 broke that capability, and rather than expend effort on trying to fix it, we’re just going to summarily remove it.

- Prevent too-early recycling of btree index pages (Noah Misch)
  When we allowed read-only transactions to skip assigning XIDs, we introduced the possibility that a deleted btree page could be recycled while a read-only transaction was still in flight to it. This would result in incorrect index search results. The probability of such an error occurring in the field seems very low because of the timing requirements, but nonetheless it should be fixed.

- Fix crash-safety bug with newly-created-or-reset sequences (Tom Lane)
  If ALTER SEQUENCE was executed on a freshly created or reset sequence, and then precisely one nextval() call was made on it, and then the server crashed, WAL replay would restore the sequence to a state in which it appeared that no nextval() had been done, thus allowing the first sequence value to be returned again by the next nextval() call. In particular this could manifest for serial columns, since creation of a serial column’s sequence includes an ALTER SEQUENCE OWNED BY step.

- Fix txid_current() to report the correct epoch when not in hot standby (Heikki Linnakangas)
  This fixes a regression introduced in the previous minor release.

- Fix bug in startup of Hot Standby when a master transaction has many subtransactions (Andres Freund)
  This mistake led to failures reported as “out-of-order XID insertion in KnownAssignedXids”.

- Ensure the backup_label file is fsync’d after pg_start_backup() (Dave Kerr)

- Fix timeout handling in walsender processes (Tom Lane)
  WAL sender background processes neglected to establish a SIGALRM handler, meaning they would wait forever in some corner cases where a timeout ought to happen.

- Back-patch 9.1 improvement to compress the fsync request queue (Robert Haas)
  This improves performance during checkpoints. The 9.1 change has now seen enough field testing to seem safe to back-patch.

- Fix LISTEN/NOTIFY to cope better with I/O problems, such as out of disk space (Tom Lane)
  After a write failure, all subsequent attempts to send more NOTIFY messages would fail with messages like “Could not read from file "pg_notify/nnnn" at offset nnnnn: Success”.

- Only allow autovacuum to be auto-canceled by a directly blocked process (Tom Lane)
  The original coding could allow inconsistent behavior in some cases; in particular, an autovacuum could get canceled after less than deadlock_timeout grace period.

- Improve logging of autovacuum cancels (Robert Haas)

- Fix log collector so that log_truncate_on_rotation works during the very first log rotation after server start (Tom Lane)

- Fix WITH attached to a nested set operation (UNION/INTERSECT/EXCEPT) (Tom Lane)

- Ensure that a whole-row reference to a subquery doesn’t include any extra GROUP BY or ORDER BY columns (Tom Lane)

- Disallow copying whole-row references in CHECK constraints and index definitions during CREATE TABLE (Tom Lane)
This situation can arise in `CREATE TABLE` with `LIKE` or `INHERITS`. The copied whole-row variable was incorrectly labeled with the row type of the original table not the new one. Rejecting the case seems reasonable for `LIKE`, since the row types might well diverge later. For `INHERITS` we should ideally allow it, with an implicit coercion to the parent table’s row type; but that will require more work than seems safe to back-patch.

- Fix memory leak in `ARRAY(SELECT ...)` subqueries (Heikki Linnakangas, Tom Lane)
- Fix extraction of common prefixes from regular expressions (Tom Lane)

The code could get confused by quantified parenthesized subexpressions, such as `^((foo)?bar`. This would lead to incorrect index optimization of searches for such patterns.

- Fix bugs with parsing signed `hh:mm` and `hh:mm:ss` fields in `interval` constants (Amit Kapila, Tom Lane)

Use Postgres’ encoding conversion functions, not Python’s, when converting a Python Unicode string to the server encoding in PL/Python (Jan Urbanski)

This avoids some corner-case problems, notably that Python doesn’t support all the encodings Postgres does. A notable functional change is that if the server encoding is SQL_ASCII, you will get the UTF-8 representation of the string; formerly, any non-ASCII characters in the string would result in an error.

- Fix mapping of PostgreSQL encodings to Python encodings in PL/Python (Jan Urbanski)
- Report errors properly in `contrib/xml2`’s `xmlt_process()` (Tom Lane)
- Update time zone data files to tzdata release 2012e for DST law changes in Morocco and Tokelau

---

**E.126. Release 9.0.8**

**Release date:** 2012-06-04

This release contains a variety of fixes from 9.0.7. For information about new features in the 9.0 major release, see Section E.134.

**E.126.1. Migration to Version 9.0.8**

A dump/restore is not required for those running 9.0.X.

However, if you are upgrading from a version earlier than 9.0.6, see Section E.128.

**E.126.2. Changes**

- Fix incorrect password transformation in `contrib/pgcrypto`’s `DES crypt()` function (Solar Designer)

  If a password string contained the byte value 0x80, the remainder of the password was ignored, causing the password to be much weaker than it appeared. With this fix, the rest of the string is properly included in the DES hash. Any stored password values that are affected by this bug will thus no longer match, so the stored values may need to be updated. (CVE-2012-2143)

- Ignore `SECURITY DEFINER` and `SET` attributes for a procedural language’s call handler (Tom Lane)
Applying such attributes to a call handler could crash the server. (CVE-2012-2655)

- Allow numeric timezone offsets in timestamp input to be up to 16 hours away from UTC (Tom Lane)
  Some historical time zones have offsets larger than 15 hours, the previous limit. This could result in dumped data values being rejected during reload.
- Fix timestamp conversion to cope when the given time is exactly the last DST transition time for the current timezone (Tom Lane)
  This oversight has been there a long time, but was not noticed previously because most DST-using zones are presumed to have an indefinite sequence of future DST transitions.
- Fix text to name and char to name casts to perform string truncation correctly in multibyte encodings (Karl Schnaitter)
- Fix memory copying bug in to_tsquery() (Heikki Linnakangas)
- Ensure txid_current() reports the correct epoch when executed in hot standby (Simon Riggs)
- Fix planner’s handling of outer PlaceHolderVars within subqueries (Tom Lane)
  This bug concerns sub-SELECTs that reference variables coming from the nullable side of an outer join of the surrounding query. In 9.1, queries affected by this bug would fail with “ERROR: Upper-level PlaceHolderVar found where not expected”. But in 9.0 and 8.4, you’d silently get possibly-wrong answers, since the value transmitted into the subquery wouldn’t go to null when it should.
- Fix slow session startup when pg_attribute is very large (Tom Lane)
  If pg_attribute exceeds one-fourth of shared_buffers, cache rebuilding code that is sometimes needed during session start would trigger the synchronized-scan logic, causing it to take many times longer than normal. The problem was particularly acute if many new sessions were starting at once.
- Ensure sequential scans check for query cancel reasonably often (Merlin Moncure)
  A scan encountering many consecutive pages that contain no live tuples would not respond to interrupts meanwhile.
- Ensure the Windows implementation of PGSemaphoreLock() clears ImmediateInterruptOK before returning (Tom Lane)
  This oversight meant that a query-cancel interrupt received later in the same query could be accepted at an unsafe time, with unpredictable but not good consequences.
- Show whole-row variables safely when printing views or rules (Abbas Butt, Tom Lane)
  Corner cases involving ambiguous names (that is, the name could be either a table or column name of the query) were printed in an ambiguous way, risking that the view or rule would be interpreted differently after dump and reload. Avoid the ambiguous case by attaching a no-op cast.
- Fix COPY FROM to properly handle null marker strings that correspond to invalid encoding (Tom Lane)
